***7.3.2 Transportation.*** It consists of two interrelated models. The first model encompasses urban transportation, that is, it renders the annual flow (vehicle·km/year) for each transportation mode (train, electric train, light vehicle, bus, and heavy duty vehicle) in any centroid (conurbation in a province).

Most methodologies of calculating urban transportation emissions are based on emissions factors and operational parameters that represent real-world traffic conditions [15–18]. The emissions factors represent emissions of each pollutant as a function of vehicle speed under normal traffic conditions. These factors are obtained experimentally with transient tests conducted on chassis dynamometers with a representative sample of technologies, vehicle types, and driving patterns [19–20]. Operational parameters are a function of link flow densities, average speed, and activity levels measured in kilometer per year per vehicle. These operational parameters are normally obtained from strategic transportation models, traffic surveys, and vehicle fleet databases [20]. However, for long-term and large-scale strategic studies, the data collection and parameter calibration components of these emission estimation methodologies are highly time consuming.

The second model represents the interurban transportation, which estimates the total flow between centroids for each transportation mode. This is a synthetic model that combines generation, distribution, and modal partition in one single stage. Mathematically, it corresponds to an econometric polynomial model.

The total vehicular activity associated with passengers is estimated through a two-stage sequential model that should reach a system-wide equilibrium: generation-attraction (G-A: stage 1) and joint distribution-modal split (D-M: stage 2). Separately, the freight movement is modeled with a direct demand model that simultaneously calculates the trip

generation, distribution, and mode choice. The assignment stage in both cases is carried out by a shortest path algorithm on the interurban network.

Because data from Chile is available at the province level, the models are specified at the province level. A province is a subdivision of a larger area called a *region*, and Chile is made up of 15 regions

***7.3.3 Fuel Network.*** Fuel consumption is determined by using existing historical data, which is used to adjust a logarithmic model to the activity indices.

## 7.4 Results

A scenario with an electric growth rate of 7%, for years 2003 and 2004, and 8% from year 2005 to 2011, considering hydro and thermal technologies in generation is presented in Figure 11. The scenario of Figure 11 is built under the assumption that no new hydro projects are carried out. Accordingly, the increase in demand is satisfied mainly by NG generating units.

Simultaneously, the fuel network activity model detects the expected capacity requirements for the pipeline infrastructure. As a consequence of this development, expected emissions increase in the system as shown for the NO$x$ case in Figure 12.

A summary of the urban transportation activity for the main provinces of the Chilean territory in the year 2002 is shown in Figure 13 to show the geographical capability of the model.

The corresponding emissions (ton/year) of the transportation activity for MP, NO$x$, HC, and CO are shown in Figure 14.

From Figure 14 it can be seen that Cachapoal, Iquique, and San Antonio provinces have high degrees of CO emissions, which can be related with public transportation (Fig. 13). This suggests that CO and NO$x$ mitigation could be achieved by converting the public transportation technology, for instance, to electric vehicles for the whole public

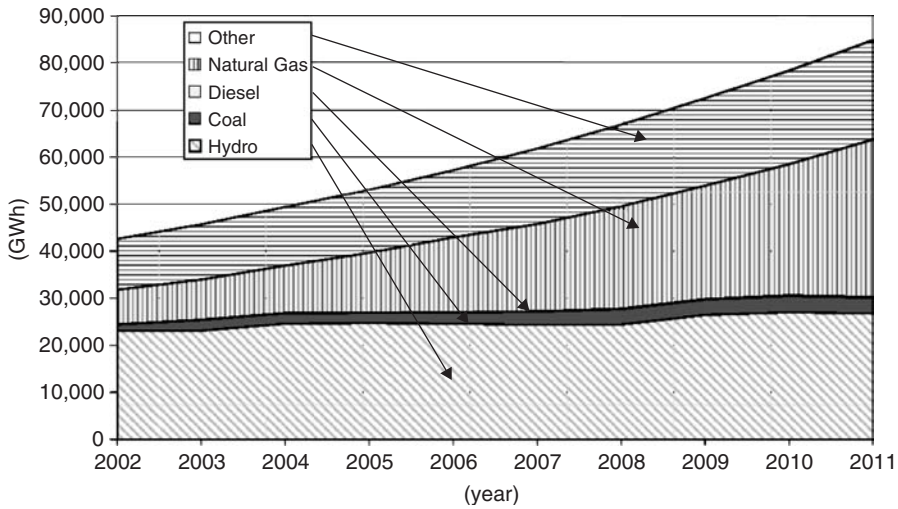

**FIGURE 11** Annual energy by technology [GWh].

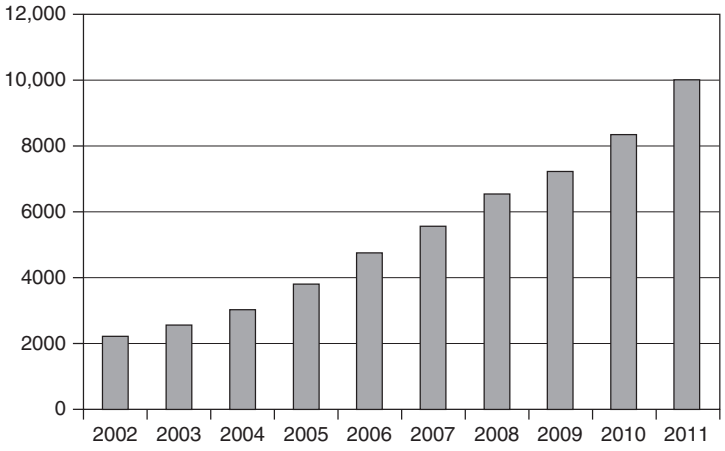

**FIGURE 12** Annual NO*x* emission in power network [ton/year].

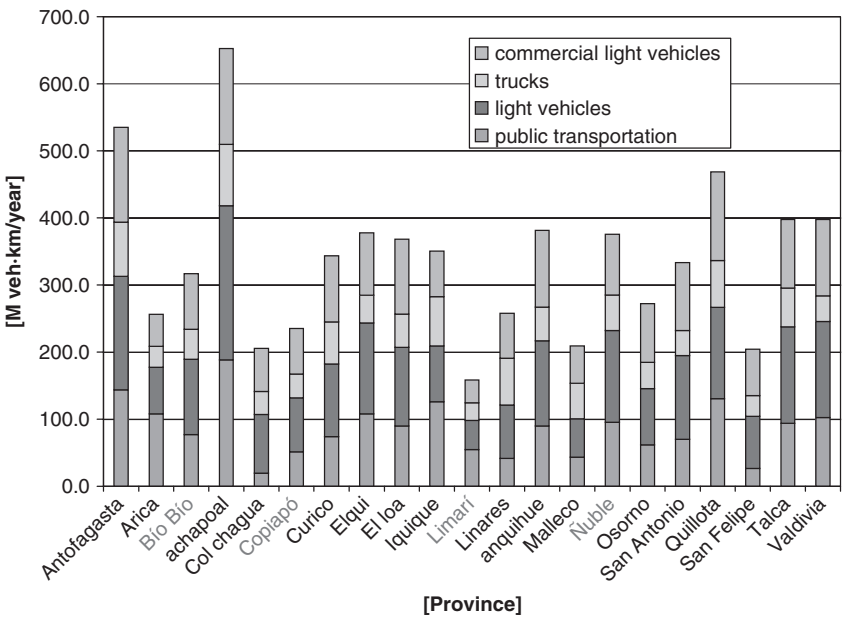

**FIGURE 13** Transportation activity in year 2002 by technology [M vehicle·km/year].

transportation system. The impact of these changes in the electric and fuel networks is summarized in Table 2.

Rows 1–3 of Table 2 show the base case information for provinces Cachapoal, Iquique, and San Antonio in year 2002. In these provinces, the public transportation activity is entirely diesel based (39 $\times$ 106 ga/year). After the proposed change, diesel consumption is replaced by electric energy, which means an important increase in NG consumption in combined cycle units. In fact, a new combined cycle unit is necessary (400 MW). The conversion scenario achieved a dramatic reduction in CO emission of 89%. In addition,

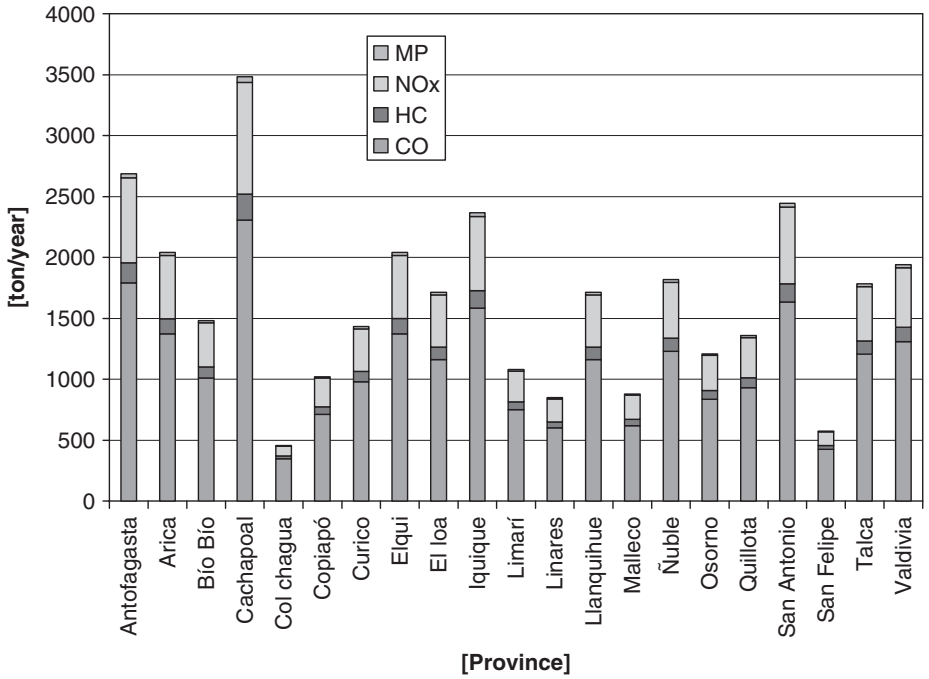

**FIGURE 14** Transportation emissions in year 2002 [ton/year].

**TABLE 2 Public Transportation Technology Conversion**

| | |
|---|---|
| **Provinces information (base case 2002)** | |
| Public transportation activity | $446 \times 10^6$ vehicle km/year |
| Diesel consumption | $39 \times 10^6$ ga/year |
| **Energy balance after conversion** | |
| Natural gas consumption | $+1716 \times 10^6$ $m^3$/year |
| Electric energy generation | +6460 GWh/year |
| **CO and NO*x* balance after conversion** | |
| CO emissions | −4529 ton/year (−89%) |
| NO*x* emissions | −107 ton/year (−5%) |

PIET shows that existing NG pipeline system supports the new requirements without new investments.

## 8 CONCLUSION

The OOP approach is useful to perform analysis of energy and transportation networks in the context of strategic planning. OOP and Java technology allow both flexible scenario definitions and a friendly GUI. Thus, a platform like PIET is flexibly adapted as a server

structure for the development of several analysis tools. Ongoing research is focused on identifying critical requirements for the energy and transportation infrastructure, and the improvement on activity models for each network and their relationships.

# GEOSPATIAL DATA SUPPORT FOR INFRASTRUCTURE INTERDEPENDENCIES ANALYSIS

ANTHONY F. ADDUCI, SCOTT D. BAILEY, AND RONALD E. FISHER
*Argonne National Laboratory, Argonne, Illinois*

## 1 INTRODUCTION

Geospatial data provide a unique and rich source of information on the distribution of both environmental and man-made assets and reveal specific themes of the earth's surface. Such data are an element in almost all public decision-making processes [1]. Nonspatial data provide key attributes, such as the facility owner, size, and operational information, that augment geospatial data and provide additional insight for analysts. Geographic information system (GIS) and other visualization technologies are optimal solutions for displaying geospatial and nonspatial data. By providing a user-friendly, yet powerful, framework to quickly display data in varying layers at a variety of zoom levels, GIS presents a wide range of unique capabilities, such as thematic mapping, data overlay and synthesis, network analysis, geospatial modeling, and visual data exploration. Thus,

the use of geospatial data and GIS are essential to the analysis of the many components that make up critical infrastructures and key resources (CIKR).

## 2 TECHNOLOGY OVERVIEW

Infrastructure interdependencies are complex to identify and analyze because of the vast infrastructure components that are involved and the complex interactions among them. (GISs) and other visualization technologies provide innovative ways to identify and analyze infrastructure interdependencies because they give analysts the ability to overlay, zoom, pan, query, and manipulate geospatial and nonspatial data sets. These techniques also allow analysts to view infrastructure for any selected area, to determine its criticality to other infrastructures, and to identify and quantify interdependencies, such as proximity, connectivity, common corridor sharing, etc.

Computer and software advancements have greatly enhanced the area of geospatial visualization technology used in infrastructure interdependency analysis. Several types of tools are available to analysts, including stand-alone GIS, shared GIS, Web-based GIS, open source GIS, three-dimensional (3D) visualization, aerial imagery, and aerial flyover. Each of these tools offers unique advantages in the analysis of infrastructure interdependencies. They are described below.

- *Stand-alone GIS.* Although GIS capabilities have been available for many years, it has been only since the mid-1990s that GIS has been part of the mainstream. In the past, GISs were predominantly housed on Unix workstations, and data were limiting and expensive. However, rapid advancements have made GIS available on the personal computer (PC). As software capabilities have increased, data sets have become more readily available and less expensive. Furthermore, GIS has become much more user-friendly. Once, only trained geographers were able to apply GIS technologies, but now, nontechnical users can use GIS software. Today's GIS market includes several vendors, such as Environmental Systems Research Institute (ESRI), MapInfo, Intergraph, and Autodesk. Additionally, Microsoft has a GIS product called *Microsoft Streets and Trips*, and several global positioning system (GPS) units come with GIS software (i.e. DeLorme).
- *Shared GIS.* As the quantity of GIS data has increased so has its user base. Shared GIS applications became available that allowed for shared licensing among users and shared systems to house software and data. This development opened the door to an expanded group of users, especially those who do not use GIS enough to acquire their own licenses or who do not have the PC requirements to support these systems. Subsequently, this development led to the expansion of Web-based GIS, which will be addressed in the next section. Information about three examples of shared GIS products is provided in the following paragraphs.

  ArcIMS is a server-based GIS developed by ESRI that allows users to create, publish, and share maps over the Internet or within an organization. This product provides GIS access to users that do not have stand-alone GIS. Once the final product is published, it is available on the Internet and is accessible to numerous users. With ArcIMS, the end user can interactively view a map and have the ability to zoom, pan, identify layer attributes, and find and turn layers on and off. ArcIMS can be useful, particularly for infrastructure analysts who are knowledgeable in a

particular field, but do not have an extensive background in GIS that is required to operate most GIS software.

ArcGIS server is a more advanced server-based ESRI product. Like ArcIMS, the primary function of this tool is to deliver GIS data and maps to customers or clients using a browser-based environment. ArcGIS server is more advanced than ArcIMS because it provides users with not only the ability to publish interactive maps, but also the ability to publish more functionality, such as advanced geoprocessing, 3D visualization, and more enhanced analysis options. Users do not need to have expensive stand-alone GIS to perform analysis or previous experience with GIS to use this product. With ArcGIS server, users can create user-friendly and self-explanatory maps and tools, which are especially useful in the field of infrastructure analysis because they allow infrastructure analysts to have access to GIS functionality without possessing the software or extensive GIS knowledge.

GeoPDF by TerraGo is another example of a shared GIS product. GeoPDF provides GIS capabilities to anyone with access to Adobe Reader. Users can view GIS-produced maps and coordinates, pan, zoom, identify features, obtain attribute information, measure distances, and turn data layers on and off. The functionality of this product is not as advanced as ArcGIS server, but it is the easiest to use of the three examples of shared GIS products. The GeoPDF file is originally created in a GIS environment and there is a fee for the software license, but viewing a GeoPDF document is of no cost to the end user. The main advantage of this tool is that users can create interactive maps for other infrastructure analysts who do not have access to costly GIS software but can readily access widely used Adobe products.

- *Web-based GIS.* As web site capabilities expanded, GIS became a mainstream application for web site developers. Many sites, such as Geography Network, GeoComm, iMAP, Mapserver, United States Geological Survey (USGS) seamless site, and Google Earth, now offer key services that use Web-based GIS technologies as their backbone. Google Earth, for example, is a free service that offers a limited but useful range of GIS capabilities that are not as powerful as stand-alone GIS end products, but are still powerful and highly useful. The capabilities of Web-based GIS are combining various infrastructure layers with high resolution aerial imagery, terrain, 3D buildings, the ability to search for locations using GPS coordinates or keywords, and Keyhole Markup Language (KML) capabilities. KML is an XML language that allows users to view geographic data on Google Earth and web browsers. Other sites also include GIS capabilities that have become commonplace. For instance, numerous web sites, such as Mapquest, Google Maps, and Yahoo! Maps, use geocoding to allow users to find site locations or to obtain driving directions to specific locations. Such Web-based GIS tools have greatly increased the number of developers and users of GIS technologies. The main advantages to these tools are the same as those listed above for stand-alone and shared GIS: infrastructure analysts do not have to purchase expensive GIS software to analyze geospatial data. Instead, interactive GIS web sites and applications allow users to perform limited GIS analysis and data manipulation at a lower cost.
- *Open source GIS.* In addition to the proliferation of GIS technology as a whole, there has been recent growth in the development and use of open source GIS tools, libraries, and standards. Many common GIS tasks can now be accomplished with free or open source software. The biggest advantage of open source GIS is that these tools are typically free to users and provide a source code that can be customized

and integrated with other tools. Additionally, nonproprietary and open data formats, such as the shapefile format for vector data and the GeoTIFF format for raster data, have been widely adopted. The Open Geospatial Consortium (OGC) protocols, such as web mapping service (WMS) and web feature service (WFS), provide protocols that further encourage the continued development of open source software, especially for Web and Web service oriented applications. Examples of open source GIS tools are BASINS, Demeter, Geocoder, GRASS, ImageMagick, libGRASS, MP2KML, and VGMap. These products contain various GIS capabilities, including image processing, 3D analysis, interpolation, and access to geospatial libraries. As open source GIS technology continues to mature, users will be afforded greater flexibility in analyzing infrastructure interdependencies and in linking GIS tools to other crucial analysis capabilities, such as modeling and simulation, visualization, and data mining.

- *3D visualization.* In the past, geographers were bound by the limits of technology and confined to two-dimensional (2D) views for analyzing geographic data. Three-dimensional modeling enables a real-world representation of geospatial data to interact with physical land feature data in terms of terrain and surrounding environment. A leading product in this area is ArcGIS 3D Analyst developed by ESRI [2]. Three-dimensional applications change the way analysts view geospatial data and allow users to view and analyze data in new dimensions, which greatly benefits the infrastructure interdependency analysis. Traditionally, users have been limited to static maps and forced to use their imaginations to visualize what a landscape, city, or terrain look like. With 3D tools users can view elevation, depth, buildings, terrain, and bathymetry, which are not easily discernible on static maps. Three-dimensional applications are powerful tools for interdependency analysis because they allow users to portray enhanced depictions of how relationships exist between various infrastructure assets.
- *Aerial imagery.* Aerial imagery is a key data source to GIS applications and visualization. Integrating relevant imagery with GIS technologies allows for additional visualization options previously available through only high-resolution maps, photographs, or site visits. Infrastructure analysts commonly use aerial imagery to validate and verify facility locations in relation to other infrastructure assets. Aerial imagery also increases the reliability of GIS data by allowing users to verify geospatial and nonspatial data.
- *Aerial flyover.* Aerial flyover, which provides users a bird's-eye view of the region of analysis, is available in applications, such as ArcGIS 3D Analyst and ArcView 3D Analyst. Such tools are useful in the presentation and representation of geospatial analysis as viewed from a perspective that was previously unavailable to analysts. Prior to the availability of aerial flyover, photographers were limited to using 2D maps and were forced to use their imaginations to visualize GIS work. Aerial flyover technology combines 3D capabilities with an aerial perspective similar to that from an airplane or helicopter. Recent advancements in the GIS field have brought this new tool to the forefront.

From an interdependencies perspective, the wide array of GIS tools available provides methods to

1. accurately locate facilities within a geographic region;

2. identify the critical infrastructure within that region;
3. visualize and quantify relationships between critical infrastructures; and
4. support infrastructure interdependencies analysis.

Table 1 summarizes the GIS tool types identified in this section; identifies the strengths and weaknesses associated with each tool type; and addresses the applications of each tool type to interdependency analysis.

## 3 GEOSPATIAL AND NONSPATIAL GAPS

As noted in the preceding section, many modeling and visualization tools are available to analysts, but without complete and accurate data, these tools are limited in their application. This problem became evident within the US Department of Energy's Visualization Working Group, which discovered the limiting factor to the visualization of the energy infrastructure was the lack of available geospatial and nonspatial data [3]. Although much geospatial data currently is available (e.g. highways, streets, waterways, rail lines), limited geospatial data exists on the energy infrastructure (e.g. oil and gas pipelines, electric substations). In some cases, geospatial data exists but lacks attributes, completeness, or sufficient accuracy for interdependency analysts.

Infrastructure interdependency analysis requires vast amounts of data across CIKR, as well as a high level of data fidelity. Data accuracy and precision are critical to problem solving and decision making in this field. Limitations include lack of required data (data gaps) and erroneous data, which include existing but misleading data. Geospatial data used for interdependency analysis often contain errors that are not always obvious to users, and some examples of geospatial data pitfalls are provided below.

Erroneous data are more difficult to identify than data gaps. Such data are not always misleading upon examination, because the specific limitations to the data set may not be clear. For example, a map reader may not be aware that newer streets are not included on a map and that some of the streets may be slightly off in their placement. The producer of the map may be aware of the flaws, but they are not obvious to the map reader. Errors in geospatial data are well documented in the geospatial community but are not well known to external users of the data. Goodchild states, "The process by which a geospatial database is created from a source map is complex, and error of various types is introduced at each step [4]." The larger the area involved, the more important the mapping errors due to projection become [5]. Many of the sources of error are due to the method and process of geocoding, which is the key component in processing geospatial data.

Many researchers have stressed the need to deal with issues of geospatial data quality, as the risk of misuse of geospatial data has greatly increased [6]. Significant causes of the enhanced risk of misuse include the increased availability of geospatial data, the greater possibility that the data have been manipulated, and a growing group of inexperienced users [7]. Furthermore, producers of geospatial data sets provide little information regarding the quality of their data [8]. Understanding errors and their propagation during data manipulation and processing is becoming one of the major issues in geospatial analysis [9]. If uncorrected, these errors can lead to erroneous interdependency analyses. For example, an infrastructure analyst studying shared right-of-way corridors may not correctly identify collocated infrastructures if the geospatial layers display infrastructure

**TABLE 1 GIS Tool Types for Interdependency Analysis**

| GIS Tool Type | Strengths | Weaknesses | Interdependency Applications |
|---|---|---|---|
| Stand-alone | Full GIS functionality | Software cost | Offers robust GIS capabilities for interdependencies analysis by GIS trained staff |
| | | Learning curve (GIS/data) | |
| | Extensive analytical geospatial tools and extensions | | |
| | | Requires significant digital storage space and high-performance computers | |
| Shared | Low cost | Limited functionality for end user | Provides basic GIS capabilities for use in interdependencies analysis with little or no background in GIS |
| | Ability to control end user functionality | | |
| | | Limited integration with other programs | |
| | Published products | | |
| Web-based | Ease of use | Limited geoprocessing functionality | Quickly provides data for critical facilities and surrounding areas for interdependencies analysis |
| | Low cost | | |
| | Readily available | | |
| | | Lack of metadata | |
| | Interactive | | |
| Open source | Low cost | Steep learning curve | Provides a solution for extending legacy interdependencies tools to include GIS capabilities |
| | Ease of customizing and integrating | | |
| | | Programming skills required | |
| 3D visualization | Specialized functionality | Increased computational requirements | Allows for correlating interdependencies attributes and gives users an improved perspective of infrastructure interdependencies |
| | Improved visual perspective | | |
| | | Access and ability to create 3D data | |
| Aerial imagery | Provides excellent insights and reference points | Large files and datasets | Allows users to quickly zoom to areas of interest and determine first-order interpretation |
| | | Availability and cost | |
| | Real-world perspective | Quality/resolution | |
| Aerial flyover | Interactive | Limited data coverage | Offers an excellent tool for viewing infrastructure dependencies and interdependencies |
| | Combines raster and vector data in a virtual environment | Increased computational requirements | |

assets miles apart due to data errors. The same can be true if infrastructure assets on a map show they are collocated when in reality they are miles apart. Thus, accuracy is critical to GIS interdependency applications.

Table 2 provides a list of five common errors made in geospatial data processing, including a description of each error and potential corrections. A sample map of each of the five errors is provided to illustrate its significance.

Figure 1 shows a typical error caused by the difference in the number of decimal places used in representing a facility's absolute location. An accurate absolute location (latitude/longitude) should include four to eight decimal places. Figure 1 shows two different locations for what should be the same site. One shapefile is built by using five decimal places and accurately represents the location of the Advanced Photon Source building at Argonne National Laboratory. Although the other point is supposed to represent the same facility, it is actually located one-half mile southeast of the correct location because the latitude/longitude fields were truncated from five decimal places to two. This type of error is quite common to GIS users because of either manipulation or lack of knowledge in the construction of the database.

GIS data inherently contain errors due to the wide range of variables involved in the data collection process. Infrastructure analysts should be knowledgeable about the source of the data they use and about how the data were obtained. A commonly used practice in the creation of geospatial data is the use of geocoding or address matching. This method assigns geographic coordinates to a data table based on nonspatial information, such as addresses or ZIP codes. In the GIS field, this is a quick, primitive, and simple method of designating a geographic point to a data set. This method is useful because a user can take a large amount of nonspatial information, for example, a Microsoft Office Excel spreadsheet, and produce a geospatially registered dataset. The GIS tool will quickly assign geographic coordinates $(x,y)$ to a data set based solely on the relationship between the address and the street or reference layer. Rather than placing a feature point directly on the actual facility, the GIS tool will place the feature point on the point of reference, which is, in most cases, a street segment. Thus, the geographic coordinates will always be located on a street adjacent to a facility or site if the reference data is a street layer, rather than on the site of interest. Although this method of site location is adequate for some purposes (e.g. driving directions), it could produce misleading results for infrastructure analysts.

For example, Figure 2 displays the Argonne complex and a red star produced by using street-referenced geocoding. The address provided by Argonne is the business office, which is typically used by large facilities. In this case, the business address is beyond the physical parcel boundary of Argonne's property and does not provide the most accurate location of the facility. A more useful absolute location for an infrastructure analyst would be the centroid of the facility, which is represented in Figure 2 by a green star. Furthermore, since the complex is comprised of many facilities located across several acres, the complex would be better represented by a polygon rather than a point. The yellow lines demonstrate the best way to represent the complex, that is, by outlining the boundaries. This process consumes more time because the boundary of the site needs to be determined, but for positional purposes, it is a superior method for representing location. However, geocoding points is easier than creating polygons; while geocoding provides an effective way to initiate the process of representing absolute location, it should not be the final method of site location if user of the data.

**TABLE 2 Five Common Errors Made in Spatial Data Processing**

| Figure | Common Error | Description | Correction |
|---|---|---|---|
| 1 | Numerical spatial data decimal places truncated | Original created data contained latitude and longitude values with a higher number of decimal places than the data used in map production. In this example, the original spatial information (latitude/longitude values) contained five decimal places, which were reduced to two. | Use the number of original decimal values derived from the original data collection to obtain the most accurate location of facility. |
| 2 | Exact site location identified with geocoding method | Street addresses are used to locate facility in geocoding. However, this method does not provide accurate site location due to its emphasis on address ranges rather than physical locations. | Use methods such as GPS, which use satellites for coordinate accuracy. Other methods include verification using imagery and Web-based programs. |
| 3 | Outdated imagery used in cartographic production | Outdated imagery is used to represent current geographic features within an area. In this example, a 1999 aerial photograph of the Millennium Park area in Chicago is used. In Figure 3a notice the evidence of construction taking place within the boundary of the site. | Use updated imagery, as shown in Figure 3b in cartographic production. In this imagery produced in 2005, signs of construction are no longer visible. Updated imagery allows for a better representation of the area under analysis. |
| 4 | Incorrect map projection applied to data for display | The incorrect map projection that renders a geographic region into its true shape was applied to the data in Figure 4. Using a projection that was not used in creating the data causes location inaccuracies that can be either severe or more locally distorted, depending on the spatial difference between the projections. | Investigate metadata associated with the dataset to verify and apply correct map projection. The green circle in Figure 4 represents data with correct map projection. |
| 5 | Data digitized at scale not optimal for region of analysis | A 1 : 50,000 scale of digitization was used to create road infrastructure in Fig. 5a. This scale produced inaccurate and distorted results, because the scale of the area being drawn (1 : 5,000, large scale) did not match the scale of digitization (1 : 50,000, small scale). | Match the scale of the area being analyzed with the scale of digitization to produce more accurate and precise results, as shown in Figure 5b. |

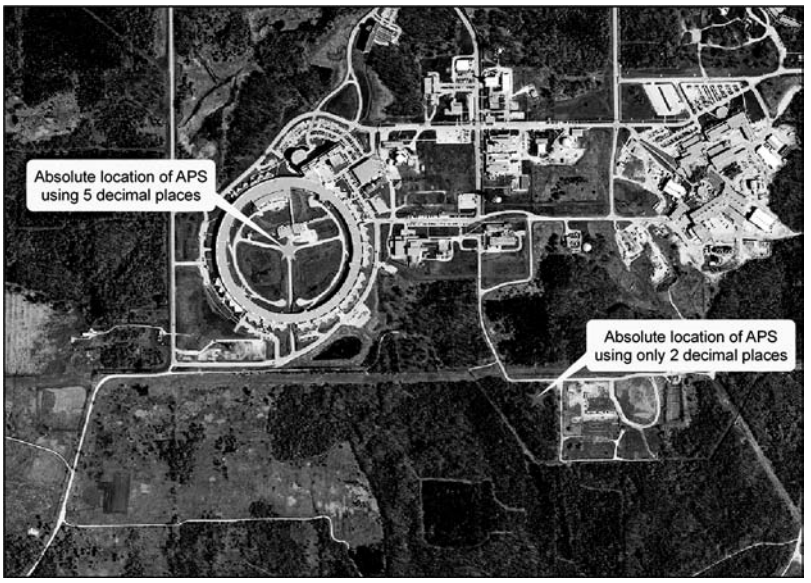

**FIGURE 1** Map example of error from truncating decimal places from five places to two places.

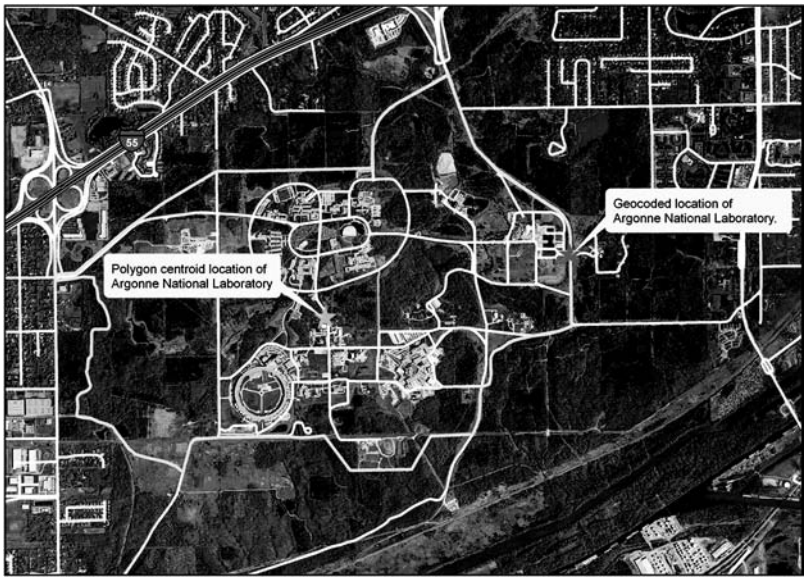

**FIGURE 2** Map example of error from geocoding.

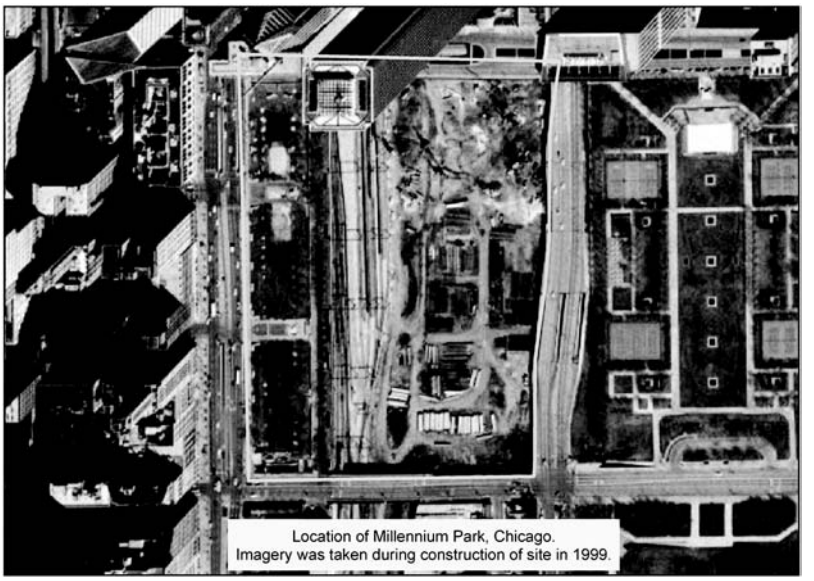
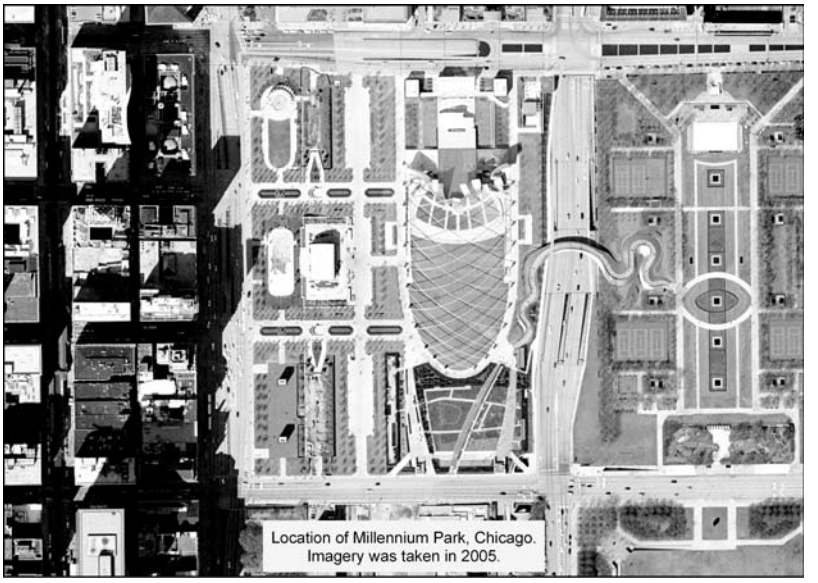
Figure 3 represents a third pitfall shared by GIS users. Knowledge of the most recent available data is of utmost importance when it comes to visually displaying the location of a facility by using aerial imagery. Figure 3 shows two aerial photographs taken 6 years apart. Figure 3a represents the location from aerial photography taken in 1999, whereas Figure 3b represents the same location taken in 2005. The location is Millennium Park



(a)



(b)

**FIGURE 3** Map example of error from using outdated imagery.

in Chicago, IL, which was completed in 2004. The 1999 imagery does not accurately represent the current land use. Figure 3b, which is from the USGS seamless site, is a more appropriate choice of imagery for GIS purposes. This imagery allows for a more accurate site portrayal that will aid in a higher quality GIS analysis and cartographic production.

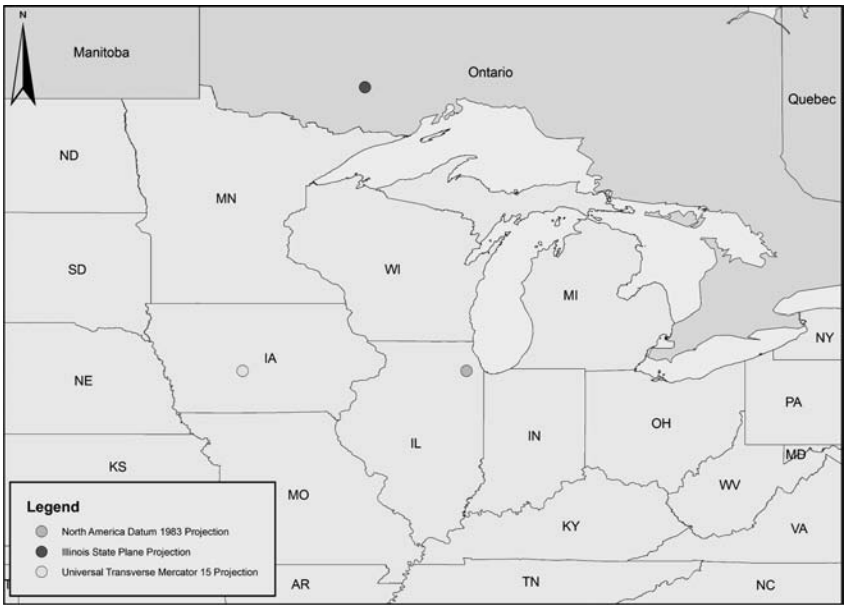


**FIGURE 4** Map example of error from incorrect map projection usage.

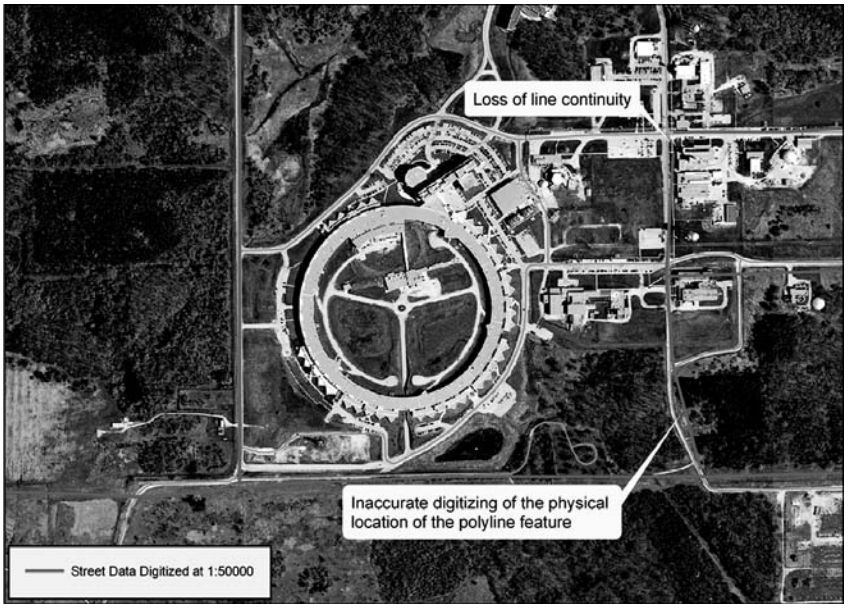
As previously discussed, differing map projections can lead to geospatial data errors. Figure 4 shows the same point represented by three different projections: the North American Datum 1983 projection, the Illinois State Plane Projection, and the Universal Transverse Mercator 15 Projection. If the projections are not converted to a common map projection, the same point and address place the point in Illinois, Iowa, and Canada. In this case, the inaccuracy results in a point hundreds of miles away, due to map projection error. As illustrated, differing projections, if not corrected, can lead to errors in facility identification and GIS analysis.

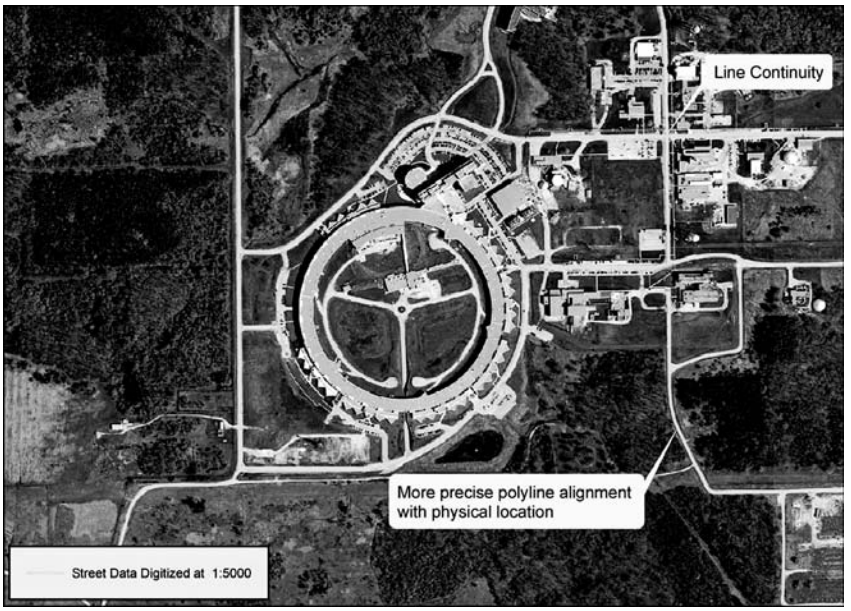
Figure 5 represents the final common error term—differing data scales. Figure 5a shows imagery at a 1 : 24,000 scale; the streets (represented in red) were digitized at a higher scale (1 : 500,000). The result is that the red lines do not correctly match the actual road locations. The red lines are coarse and do not capture all the curves in the road; and they are not continuous. Figure 5b shows imagery at a 1 : 24,000 scale; the streets (represented in yellow) were digitized at the same scale. The result is accurately placed and continuous lines. Thus, it is important to use consistently scaled data for the level of analysis being conducted.

## 4 METADATA GAPS

A major issue in GIS data consideration is the lack of or completeness of metadata. The term "metadata record" is defined by the Federal Geographic Data Committee (FGDC) as "a file of information, usually presented as an XML document, which captures the basic characteristics of a data or information resource [10]." The FGDC has developed a set of standards and guidelines for metadata, but these tools are often neglected during the production of GIS data. The objective of these standards is to provide users with a



(a)



(b)

**FIGURE 5** Map example of error from using differing levels of scale.

general set of terms and definitions for the documentation of digital geospatial data [10]. They were developed to be used by all levels of government and the private sector.

Data containing proper FGDC metadata are more legitimate in infrastructure interdependencies analyses than data that contain limited or no metadata at all, but having access to FGDC metadata does not guarantee that infrastructure GIS analysis is going to be of high quality. All GIS data have some type of error. The goal of the GIS or infrastructure analyst should be to use data with a minimized room for error and maximized accuracy. Available metadata give users the ability to assess data based on imperative information such as source, date, resolution, and method of collection. Properly created metadata guide the analysts in choosing data that will produce quality results and in turn, could lead to more effective decision making. Missing metadata may include the following:

- unknown organization/source/author of data;
- unknown method of data collection;
- unknown scale of data creation;
- unknown date of production;
- unknown projection and geospatial extent of data;
- unknown supporting data or web sites affiliated with data;
- unknown copyright and distribution restrictions;
- absence of definitions describing attribute table associated with data;
- unknown data classification; or
- unknown contact information for questions pertaining to data.

Other metadata initiatives have been developed by the USGS, ESRI, National Oceanic & Atmospheric Administration, US Department of Agriculture Forest Service North Central Research Station, and countless other agencies [10]. Two of the more common tools used for creating metadata are ESRI's ArcCatalog and Tkme or Tk metadata editor [11]. ESRI's ArcCatalog is a commercial data management tool that performs a number of functions, one of which is the creation and editing of metadata [10]. Although ArcCatalog is a highly useful and effective tool in metadata creation and editing, it is not a free software. However, most of the software is available at no cost, and one such is Tkme. This common, user-friendly tool is used to create metadata in a Windows-based environment and follows the guidelines set forth by the FGDC [11]. Numerous metadata tools are available to GIS users, and the choice of the tool depends on available resources, as well as on the nature of the data and the purpose of the project.

The essential objective of metadata is to provide GIS users with information that legitimizes the quality of the data being used and assures users that their data are sound. The use and creation of metadata are imperative entities of GIS data management, but the lack of its creation and misuse have resulted in data inaccuracies. Thus, interdependency analysts should convey their need for proper metadata to geospatial vendors and give preference to those geospatial datasets with complete metadata.

## 5 NEXT STEPS

Three recommendations are offered to increase the usefulness and accuracy of geospatial and nonspatial data to interdependency analysis: data investment, data documentation,

and data validation. Continued geospatial and nonspatial data investments are needed to alleviate data gaps by both public and private stakeholders. Some infrastructure layers such as roadways have sizable investments, regular updates, and high levels of accessibility. Other infrastructure layers, such as agriculture, energy, and telecommunications, lack investment and data stewardship.

Data investments lead to more accurate and updated geospatial data. As the geospatial features of the world change rapidly because of population growth, advancements in technology, and evolving political and cultural boundaries, the geospatial data attributed with these features must also change rapidly. Proper data investment ensures reliable, up-to-date data that create optimal standardization and awareness when distributed to the proper agencies.

Data documentation helps to inform the user of data limitations. The absence of GIS metadata creates risks that could influence decision makers in making poor choices that depend on potentially inaccurate data [12]. Analysts may use inaccurate data if they misunderstand the data limitations. Data uncertainty leads to erroneous assumptions that data are correct. Key documentation factors, such as data collection methods, date of creation, and attribute definitions, are crucial to the usage and accuracy of the data. For example, knowledge of the type of data collection used provides insights into the potential accuracy of the data. If a GPS receiver has been used in the data collection process, the user can expect a high degree of data accuracy because the data were collected by using highly accurate satellite systems. However, if the method of data collection has been geocoding, the user can expect a greater variance in the range of errors.

The lack of proper data documentation erodes users' confidence in the data implemented in their research. Data documentation includes widespread adoption of metadata standards. All data providers, public and private, should be required to include appropriate metadata. Geospatial data users, in particular, should require GIS data vendors to provide sufficient documentation. A strong front by GIS users will send a message to vendors that documentation is mandatory to conducting business. When none or limited documentation exists, users cannot be sure of the completeness and accuracy of their data.

Data validation involves understanding common errors, identifying them, and fixing them. Data validation may require a great deal of time and significant cost; it may also require manipulating the data to fix errors. When sufficient metadata are not available, users can take several steps to better understand the quality of the data they are using and to validate these data. These steps include the following actions:

- overlay high-resolution imagery to verify that geospatial data matches the accessible imagery. Public software is available from web sites such as Google Earth;
- use Web-based GIS applications that display land/parcel information to verify geospatial data. City and county web sites may provide such information;
- use GPS equipment to verify specific site locations. Low-cost GPS units are available for less than $500;
- verify sample data by visits or phone calls to facility owners;
- overlay duplicate geospatial data layers and analyze differences when duplicate sources are available; and
- geocode addresses and compare the addresses to provided geospatial data. Most GIS software includes user-friendly geocoding capabilities for nontechnical GIS users.

GIS tools (stand-alone, shared, Web-based, open source, 3D visualization, aerial imagery, and aerial flyover) provide infrastructure analysts with tremendous capabilities for interdependencies analyses. As discussed in this article, data investment, documentation, and validation are crucial to the quality of geospatial and nonspatial data. A high level of data fidelity is required to support the GIS and visualization tools needed for analyzing infrastructure interdependencies. Improvements in data investment, documentation, and validation will increase the value of GIS and visualization tools to infrastructure interdependencies analyses.

Several GIS forums continue to support data development and maintenance. An example of such a forum is Homeland Infrastructure Foundation-Level Data Working Group. This group is "a coalition of federal, state, and local government organizations, federally funded research and development centers (FFRDC), and supporting private industry partners who are involved with geospatial issues related to Homeland Security (HLS), Homeland Defense (HD), Civil Support (CS), and Emergency Preparedness and Response (EP&R)" [13]. This working group meets on a bimonthly basis and has a primary focus on geospatial information and its standards and presentation, as well as its accuracy. Such working groups promote a better understanding of data development and maintenance. They also create data uniformity among government agencies due to extensive collaboration, data sharing, and cooperative agreements on how to more accurately create and standardize data. Other GIS forums include vendor- specific, industry-specific, and state-level GIS forums. These forums are useful to all users of GIS tools and geospatial data.

# THE MILITARY ROOTS OF CRITICAL INFRASTRUCTURE ANALYSIS AND ATTACK

STEVEN M. RINALDI
*Sandia National Laboratories, Albuquerque, New Mexico*

## 1 INTRODUCTION

Critical infrastructures underpin the political, military, economic, and social fabrics of societies. In recent years, it has become widely recognized that infrastructure disruptions could disproportionately affect the normal functioning of a nation. Disruptions from natural disasters, major strikes, attacks, and other mechanisms have amply demonstrated that critical infrastructures are highly interdependent, complex adaptive systems. Of import is the intricate, highly interdependent character of today's infrastructures. A disruption in one infrastructure, such as the electric power grid, can spread to other infrastructures such as communications networks and the Internet, thereby creating cascading disturbances and magnifying the effects far beyond those of the original disruption [1].

Since the mid-1990s, the US government has placed increasing emphasis on protecting the nation's critical infrastructures and associated key resources as matters of national and economic security. In 1996, President William J. Clinton issued Executive Order 13010, *Critical Infrastructure Protection* [2].[1] This order recognized that "(c)ertain national infrastructures are so vital that their incapacity or destruction would have a debilitating impact on the defense or economic security of the United States." The order directed the establishment of the President's Commission on Critical Infrastructure Protection (PCCIP), with the mission of examining vulnerabilities of and threats to critical infrastructures, determining legal and policy issues associated with protecting critical infrastructures, recommending a comprehensive national policy and implementation strategy to protect critical infrastructures, and proposing statutory or regulatory changes required to enable its recommendations. The PCCIP submitted its report [3] to the President in October 1997. In particular, the PCCIP stated that infrastructures are interdependent, that the destruction of key nodes and linkages in one infrastructure could ripple over and affect other infrastructures, and that coordinated attacks upon critical infrastructures could severely impact national and economic security [4].

[1]Executive Order 13010, *Critical Infrastructure Protection*, The White House, 15 July 1996. This executive order recognized eight critical infrastructures: telecommunications, electrical power systems, gas and oil storage and transportation, banking and finance, transportation, water supply systems, emergency services (including medical, police, fire, and rescue), and continuity of government. Today, the Department of Homeland Security recognizes 17 critical infrastructures and key resources (agriculture, food, defense industrial base, energy, public health and healthcare, national monuments and icons, banking and finance, drinking water and water treatment systems, chemical facilities, commercial facilities, dams, emergency services, commercial nuclear reactors, information technology, telecommunications, postal and shipping, transportation systems, and government facilities).

Yet the understanding that the destruction of certain key nodes and linkages could disproportionately affect national and economic security is not new. In fact, the roots of this insight can be traced to the early 1900s. As early as 1911, the French Lieutenant Poutrin wrote in the *Revue Générale de l'Aéronautique Militaire* that German aerial attacks on key ministries, transportation networks, and communication centers in Paris would shut down essential public services, thereby preventing France from mobilizing [5]. During World War I, British, French, and American air planners clearly recognized that attacks upon certain sectors of the German war industry could disrupt the manufacture and flow of war materiel to the Front, thereby affecting the ability of the German military to operate. American air warfare doctrine developed in the 1920s and 1930s by the Air Corps Tactical School (ACTS) significantly extended this line of thinking with the development of the "industrial web" theory of economic attack. This doctrine was put to test in World War II in the Allied bomber offensives against the Axis powers. Fifty years later, the air war waged against Iraq during Operation Desert Storm demonstrated refinements of the theory and the understanding and employment of critical infrastructure attack. Subsequent detailed academic studies of critical infrastructures and their interdependencies at the US Air Force's Air University in the 1990s indicate the emphasis placed by that Service on infrastructure attack to obtain specific strategic and operational effects and objectives.

This article traces the development of the theory and application of infrastructure attack in the 1900s. By and large, this development has occurred in air forces. Freed of the necessity to penetrate opposing surface forces, airmen realized early on that aircraft could range far beyond the terrestrial, tactical battle lines and directly attack strategic targets, including critical infrastructure. The objective of war was no longer engaging and destroying the enemy surface forces; rather, the air forces had an independent strategic mission of carrying the war to the enemy nation itself. The ability of airmen to identify, target, attack, and destroy key nodes and linkages is largely a story of the complex interplay of military doctrine and theory, wartime experience, and technological advancement. Initially, the ability to attack key nodes and linkages was limited by crude bombsights and small, dumb bombs. Operational considerations, such as the inability to bomb in adverse weather, decreased nighttime bombing precision, and primitive navigation capabilities, severely hampered and limited the effectiveness of counter-infrastructure operations in World War I. These issues were overcome by the end of the century with precision-guided weapons and all-weather, day–night attack capabilities. Furthermore, engineering and mathematical advancements, such as modeling, simulation, and analysis of critical infrastructures and operations research, enabled planners to better identify key nodes and linkages, all while driving the need for precision intelligence on adversary systems.

The sections below do not examine nuclear targeting doctrine and issues. Further, the analysis will focus predominantly on the development of American theory and doctrine of critical infrastructure attack.

## 2 INITIAL DEVELOPMENTS: WORLD WAR I

With the advent of military aviation in the first decades of the 1900s, nations at war had the ability to directly attack targets throughout their adversaries' homelands. World War I saw the first major operational analysis and application of this capability. Although the initial application of airpower during World War I was primarily limited to tactical

reconnaissance for the land forces, by the end of the conflict, strategic bombardment and targeting theories were coming into being.

British, French, and American airmen believed that airpower could be employed against both moral and material objectives. With respect to moral objectives, the British Admiralty theorized that bombing targets in Germany would force the recall of German aircraft from the front to defend the homeland. Further, the Admiralty hoped that bombardment would undermine the will of the German populace, and "optimistically attributed" an immense moral effect to every bomb that fell on Germany [6]. For General Hugh M. Trenchard, the first Chief of Staff of the British Air Ministry, the moral effect of bombing was critical. In a 26 November 1917 memo to the War Cabinet, he noted that bombardment had both a direct (material) and indirect (moral) effect:

> That purpose is to weaken the power of the enemy both directly and indirectly—directly by interrupting his production, transport and organization through infliction of damage to his industrial, railway and military centres, and by compelling him to draw back his fighting machines to deal with the menace—indirectly by producing discontent and alarm amongst the industrial population. In other words, it aims at achieving both a material and a moral effect [7].

The French had a different view of the moral effect of bombardment. Official policy held that the French would bomb German towns as reprisals for German bombardment of French towns. In one specific case of a reprisal, the French raided Freiberg on 14 April 1917 in retaliation for German submarine attacks on the hospital ships *Asturias* and *Gloucester Castle* the previous month. Interestingly, the French dropped leaflets upon Freiberg explaining the purpose of the raid [8].

With respect to the material effects of bombardment, the three allied nations sought to disrupt the ability of the German war industries to supply that nation's military forces. The British and French target sets can roughly be categorized as economic/industrial, infrastructural, and military:

- *Economic/industrial.* These targets would be termed the *defense industrial base* in today's parlance. They included iron and steel works, blast furnaces, gasworks, chemical works, benzene stores, and munitions factories. At the most fundamental level, these targets represent two primary commodities supporting the military—iron and explosives [9].
- *Infrastructural.* The primary targets in this set were rail assets, including rail yards, stations, lines, and rolling stock. These targets affected not only the ability of the German economy to produce war materiel but also that nation's ability to move finished goods to the front. In the last year of the war, the British also attacked at least three German electrical power grid targets [10].[2]
- *Military.* Targets included not only the lines of communication to the front but also aerodromes, fielded forces, and the German naval bases along the Belgian coast.

Beyond reprisals, the French developed bombardment plans that solely focused upon material objectives, primarily the factories and stations of the Saar Valley [11]. The

[2]The appendix of this source provides a detailed listing of raids by the British long-range bombing units (41st Wing, Eighth Brigade, Independent Forces) from 17 October 1917 to 11 November 1918. Information includes raid dates, target locations and descriptions, and bomb loads dropped. The target descriptions provide excellent insight into the types of targets considered important to crippling the German war industry.

French aimed at isolating the raw material producing regions, particularly iron ore, from the German factories. In a detailed analysis in January 1918, French planners determined that the Germans had altered rail traffic patterns for two primary reasons: "(1) to strip the area without using and consequently without burdening the main arteries of supply to the front and (2) to use the shortest possible route, in view of the shortage of rolling stock (locomotives and wagons), and in order to economize pit coal" [12]. The analysts concluding that attacking only four rail targets would isolate the iron ore regions, a significant aid to French operational planning.

American thinking was similar. A key goal of the US Air Service was to develop a bomber force capable of striking strategic targets in Germany. Targeting efforts concentrated on determining those assets without which Germany could not carry on its war effort [13]. Then-Major William "Billy" Mitchell believed that aviation could be divided into two types: tactical (observation for friendly artillery fire and control) and strategic (attacks on enemy materiel of all types behind the lines). He believed that the strategic attacks, if properly applied, would have the greatest effect upon the war effort [14].[3] Major Frank Parker, the US Liaison Officer to the French General Headquarters, reported to the US Board of Officers in July 1917 that the Air Service had a strategic function, acting independently of the ground forces to attack sources supplying the German military. This function included a military component (destroying aircraft, air depots, and the defensive air organization) and an economic component (destroying enemy depots, factories, lines of communications, and personnel) [15]. Major Edgar S. Gorrell, Chief of the Technical Section, Air Service, American Expeditionary Forces, developed a bombardment plan for the Air Service, dated 28 November 1917 [16]. He noted,

> The object of strategical bombing is to drop aerial bombs upon the commercial centers and the lines of communications in such quantities as will wreck the points aimed at and cut off the necessary supplies without which the armies in the field cannot exist... When we come to analyze the targets, we find that there are a few certain indispensable targets without which Germany cannot carry on the war.

Gorrell stated that a few "specific, well-known factories" were crucial to the manufacture of munitions. He noted that the destruction of the Mercedes engine and Bosch magneto plants in Stuttgart would cause the output of aircraft to drop in proportion to the damage done. He also called out rail, ammunition, and steel works for attack in the plan.

Following the end of the war, British and American intelligence services assessed the effects of bombardment from German records and interviews [17]. The Germans kept detailed records of the raids, including the resultant physical damages and estimates of their costs. Allied aircrew reports after raids were generally optimistic and overstated. One survey, which entailed extensive interviews with German plant directors, noted that the directors did not consider the bombardments effective, having created insignificant material damage and not affecting the war outcome. The effects of bombing munitions and chemical works did not meet the British expectations. The attacks upon the rail system were more of an annoyance, without ever producing a long-term isolation of rail stations or major dislocation of traffic.

[3]Memorandum for the Chief of Staff, US Expeditionary Forces, from Major Wm Mitchell, Aviation Section, Signal Corps.

A number of factors, driven in large part by the state of technology, contributed to the limited strategic results of bombardment. These factors included the following:

- limited bomb loads per aircraft;
- the generally small sizes of the bombs (anything under 112 pounds was ineffective, according to Germans interviewed after the war);
- failures of the bombs to detonate (e.g. 25% of the bombs dropped on the Saarbrücken region did not explode);
- poor radial blast effects of the bombs;
- limited combat radius of the aircraft;
- open cockpits, which exposed the pilots to environmental conditions;
- primitive bombsights and the inability to bomb accurately, particularly during night raids;
- navigation difficulties, particularly at night;
- mechanical difficulties and maintenance issues with the aircraft; and
- inexperienced and insufficiently trained aircrews [18].

Nevertheless, the stage had been set for strategic bombardment of the sources of war materiel, including supporting critical infrastructures such as transportation networks. Air planners clearly recognized the importance of attacking the adversary's defense industrial base. And, importantly, the first steps were taken toward analyzing that industry to determine chokepoints, bottlenecks, and key nodes for attack.

## 3 THE INTERWAR YEARS: THEORY AND DOCTRINE

The interwar period saw an intensive development of strategic bombardment theory and doctrine. Two early pioneers of airpower theory and vocal advocates for independent air forces with decisive strategic missions were the Italian General Giulio Douhet and the American Brigadier General William Mitchell. Both officers wrote extensively following World War I, arguing for independent air forces with their own respective strategic missions. Each discussed strategic target sets for bombardment, given that aircraft could fly over armies and navies and directly attack the interiors of adversarial nations.

Douhet argued that obtaining "command of the air"—essentially air supremacy—was a prerequisite and vital to victory. Once an air force had command of the air, it was free to range over the adversary and attack military, economic, and civil targets as well as the population itself at will:

> To have command of the air means to be in a position to wield offensive power so great it defies human imagination. It means to be able to cut an enemy's army and navy off from their bases of operation and nullify their chances of winning the war. It means complete protection of one's own country, the efficient operation of one's army and navy, and peace of mind to live and work in safety. In short, it means to be in a position *to win. To be defeated* in the air, on the other hand, is finally to be defeated and to be at the mercy of the enemy, with no chance at all of defending oneself, compelled to accept whatever terms he sees fit to dictate [19].

Douhet believed that the moral and material effects of bombardment would be tremendous, once command of the air was established. Receiving a relentless "pounding from the air", a nation's social structure would break down. The populace would rise up and demand an end to war, potentially even before the army and navy could mobilize [20].

Douhet clearly saw military utility in attacking critical infrastructure, both for its material and moral value. He wrote,

> In general, aerial offensives will be directed against such targets as peacetime industrial and commercial establishments; important buildings, private and public; transportation arteries and centers; and certain designated areas of civilian population as well. To destroy these targets three kinds of bombs are needed—explosive, incendiary, and poison gas—apportioned as the situation may require. The explosives will demolish the target, the incendiaries set fire to it, and the poison-gas bombs prevent fire fighters from extinguishing the fires [21].

Targeting civil infrastructure would spread confusion and panic among the populace. Douhet called for the rapid and complete destruction of rail, communications (including telegraph, telephone and radio), banks, public services, and government targets [22]. To hamper the ability of the army to mobilize, the air force should attack "railroad junctions and depots, population centers at road junctions, military depots, and other vital objectives". Naval operations would be degraded by "bombing naval bases, arsenals, oil stores, battleships at anchor, and mercantile ports " [23]. To Douhet, critical infrastructure was tightly intertwined with the ability of a nation to mobilize for and prosecute a war, and airpower provided the means to directly attack it.

Nonetheless, Douhet recognized that determining the specific targets to attack was not an easy task. He noted,

> The choice of enemy targets, as I have already pointed out, is the most delicate operation of aerial warfare, especially when both sides are armed with Independent Air Forces. . .The truth of the matter is that no hard and fast rules can be laid down on this aspect of aerial warfare. It is impossible even to outline general standards, because the choice of enemy targets will depend upon a number of circumstances, material, moral, and psychological, the importance of which, though real, is not easily estimated [24].

To Douhet, the selection of enemy targets would show the true abilities of the future air commanders.

From his experience in World War I, Mitchell was convinced that an air force should have an independent mission that would carry the war directly to the heartland of the enemy [25]. In his 1925 book *Winged Defense*, he argued that airpower should destroy the ability and will of the adversary to make war:

> To gain a lasting victory in war, the hostile nation's power to make war must be destroyed—this means the manufactories, the means of communication, the food products, even the farms, the fuel and oil and the places where people live and carry on their daily lives. Not only must these things be rendered incapable of supplying armed forces but the people's desire to renew the combat at a later date must be discouraged [26].

Sites manufacturing war material would be particularly inviting targets, as they took "months" to build and "if destroyed, cannot be replaced in the usual length of a modern war" [27]. While acknowledging that air forces would attack centers of production, he

did not believe that they should target the personnel *per se*. However, bombing could so terrorize a population that "the mere threat of bombing a town by an air force will cause it to be evacuated, and all work in munitions and supply factories to be stopped." In short, Mitchell proposed that war industries—and supporting systems such as the food and rail infrastructures—could be shut down by direct bombardment as well as worker absenteeism due to the threat of attack [28]. In contrast to Douhet, Mitchell almost always came out against directly attacking civilians, preferring to break the morale of the adversary indirectly by destruction of its vital centers [29].

Mitchell argued against the traditional view that destroying the enemy military forces constituted the main objective of war. "Vital centers" within the adversary nation were the true objective of a conflict:

> The advent of air power which can go to the vital centers and entirely neutralize or destroy them has put a completely new complexion on the old system of war. It is now realized that the hostile main army in the field is a false objective and the real objectives are the vital centers. The old theory that victory meant the destruction of the hostile main army, is untenable. Armies themselves can be disregarded by air power if a rapid strike is made against the opposing centers [30].

Mitchell believed that with airpower, it was no longer necessary to destroy an enemy's army in order to render the enemy incapable of waging war and induce him to sue for peace. Rather, by eliminating a nation's ability to manufacture and supply its forces with materiel, the nation would be unable to sustain a war—particularly a protracted conflict. Mitchell's views would strongly influence the next generation of air strategists and planners at the US Army's ACTS.

Economic attack and the concomitant destruction of critical infrastructures rose to an entirely new level at ACTS in the 1930s. Established as the Air Service Tactical School at Langley Field, VA, in November 1922, the school originally covered the tactics and techniques of the Air Service and other branches of the army and navy. In 1926, the school was renamed the Air Corps Tactical School. During the summer of 1931, the school relocated to Maxwell Field, AL, where it became the center of development of American airpower doctrine [31].

The doctrine of economic attack, along with a detailed methodology for target selection, developed at ACTS in the 1920s and 1930s. The fundamental precept of economic attack was that modern nations relied upon their economic and industrial systems for military weapons and supplies as well as the products and services required by a highly industrialized society. Destruction or paralysis of the economic and industrial systems would lead to a collapse of the enemy's military capability to fight and its social and political will to resist [32].

The 1926 ACTS text *Employment of Combined Air Force* argued that airpower could strike directly at vital centers in an enemy nation, thereby avoiding exhaustive wars of attrition and obtaining military victory at the minimum cost. If the enemy morale could not be destroyed, at least the enemy's military strength could be. The most suitable objectives for this purpose were the hostile air force; troops, supplies, and lines of communications in the combat zone; and industrial and transportation centers in the interior zone of the adversary [33].

By 1933, bombardment was firmly established as the primary means of employment of airpower at ACTS. At this junction, however, suitable surface targets were still vaguely designated. Instructor Major Donald Wilson undertook a more detailed approach to target

selection. Targets should be selected such that they would disrupt the adversary's *entire* economic fabric (supporting both the military and civilian sectors), thereby affecting normal civilian life to the point where faith in the military was lost and public outrage would force the government to sue for peace. The key was to locate those targets whose destruction could unravel this fabric—in other words, those key nodes or links that were vital to the functioning of the economy. That such targets existed was not doubted by the instructors: a prime example was a highly specialized spring used in controlled-pitch propellers. The spring was manufactured by only one firm, whose destruction would have meant the loss of the majority of production of aircraft in the United States. Determination and selection of such targets became central to ACTS theory [12].

During the period 1934–1940, the ACTS faculty refined its theory of economic warfare and target selection, known as the *industrial web theory*. As they were strictly forbidden to analyze foreign nations, the faculty surveyed American industry to locate those bottlenecks or nodes that would cause the destruction of the social, economic, political, and military fabric—or web—of a modern nation [34]. The 1934–1935 ACTS lecture *Air Force Objectives* stated that the ultimate objective in warfare was the destruction of national courage or morale [35]. Although the military arms of the nation might lose morale, the lecture noted that "loss of morale in the civil population is decisive. . .Morale is the pivotal factor. Its disintegration is the ultimate objective of all war." The resources to wage war were locked up in social, economic, political, and military spheres of a nation, so that pressure against these systems would lead to the destruction of morale and the defeat of the nation. Furthermore, the lecture noted that these spheres obtained an absolute interdependence during war, so disturbances in one sphere would affect all others. Those elements of an economy that supported the production of military goods were intricately intertwined with those elements supporting civilian life; pressure on one would affect the other.

The lecture then laid out in detail target sets in each of the spheres. The course provided a sophisticated analysis of the target sets including the interdependencies among them.

- *The social sphere.* Noting that "(t)he object here is the dislocation of normal life to the extent that the people are willing to surrender in the hope that they can at least regain a normal mode of living," the lecture discussed attacks against:
  - food supplies (which in turn relied upon lines of communication, transportation, and storage);
  - public utilities, including water-supply systems (linked to sanitation, public health, and firefighting), electric power (linked to modern conveniences and electric transportation modes), illuminating gas, and gasoline refining (linked to transportation); and
  - industry and transportation, which in turn would affect finances through loss of income, increase psychological pressure though worker idleness, and disrupt lines of communications.
- *The economic sphere.* The lecture stated that modern warfare placed an enormous load on an economy, which if it were to break down would "seriously influence the conduct of war by that nation, and greatly interfere with the social welfare of its nationals". The lecture examined in detail six primary target sets:
  - bottlenecks of specific commodities that entered into the production of many goods;

  - energy, including electricity (linked to manufacturing) [36], petroleum (linked to civil and military transportation and lubricants needed by industry), and coal (required for steel production and electric power generation);
  - raw materials, such as food, steel, fuel, nitrates, sulfuric acid, rubber, nonferrous metals, and cotton;
  - transportation, including rail, highways, and inland waterways;
  - manufacturing facilities; and
  - financial systems underpinning the economy.
- *The political sphere.* The lecture described government departments as the nervous system of the adversary, which if attacked would add confusion to the war effort. The lecture called for balance in attacking this sphere, as the political establishment would need to sense and react to the sentiments of the population.
- *The military sphere.* The lecture considered bombing military targets as strategically defensive, other than direct attacks against enemy airpower. Attacks against armies should be designed to prevent mobilization or strategic concentration; naval objectives included aircraft carriers, battleships, naval bases, docks, dry docks, shops, naval stores, and fuel oil reserves.

Other lectures that year amplified the themes of paralyzing the interdependent economic structures of a nation.[4] Bottlenecks received particular emphasis; the instructors sought those points that could unravel multiple sectors supporting both the war effort and civilian society. One lecture on the principles of war as applied to airpower postulated that the results of bombardment were sufficiently permanent that they would accumulate. It stressed that missions should have sufficient rapidity that the enemy could not repair and recover between attacks. Finally, and critically, the theory assumed that during a war, an economy would be stressed to its maximum point as it supported both civil and military needs. Without slack, the economy would be highly vulnerable to attack.

Although the destruction of morale was considered crucial, the faculty was opposed to direct attacks on civilians [37]. This presented a problem in that population centers frequently held industrial concentrations. The faculty believed that if certain systems supporting civil society were destroyed, then the cities would be rendered untenable and have to be evacuated. This could force the unraveling of the social sphere and morale of the nation, without the need to directly attack civilians. To this end, a 1939 lecture provided a detailed analysis of New York City, with specific target systems including the financial markets, transportation system, water supply, foodstuffs, and electric power [38].

In conjunction with its detailed analysis of targets, timing, mechanisms and objectives, the ACTS faculty also spent considerable effort considering the operational aspects of bombardment. By 1935, the preferred method of attack was high altitude, daylight precision bombardment of pinpoint targets. To carry out such missions, several technological innovations were required. Most notable were the development of long-range bombers with sufficiently heavy payload capacities. The B-17 bomber, successfully tested in 1935, provided this capability and profoundly affected the thinking of the ACTS faculty. Bombsights required marked improvements from the primitive devices of World War I. An

[4]These ACTS lectures included *Lecture—Air Force, General*, Lecture AF-2; *General Air Force Principles*, Lecture AF-6; *Lecture—Principles of War Applied to Air Force Action*, Lecture AF-7. These lectures were part of the 1934-35 *Air Force* course and were likely written by either Lieutenant Colonel Harold L. George or Captain Robert M. Webster.

improved Sperry bombsight appeared in 1933 and was followed by the more advanced Norden Mark XV bombsight. The Air Corps now had the ability to range widely over an enemy and attack individual targets [39].

ACTS came to its end in the summer of 1941. By this time, the faculty had developed a detailed airpower and targeting theory that focused on attacking the social, economic, political, and military spheres of an adversary, in which critical infrastructure attack played the central role. Locating and attacking bottlenecks would lead to an unraveling of this highly interconnected and stressed web, with an attendant loss of morale. The dislocation of civilian life under wartime conditions would be sufficient to cause the enemy to sue for peace. Although highly developed, the doctrine was theoretical with little basis in actual warfare. It awaited its test in the cauldron of World War II.

## 4 TRIAL BY FIRE: WORLD WAR II AND ECONOMIC TARGET SELECTION

In the years immediately before World War II, the British government began serious war planning, including collecting data on and analyzing the German economy. The Air Ministry developed a series of war plans, called the *Western Air Plans*, that focused on specific elements of the Germany economy [40]. WA-4 called for the destruction of the German railroad system, which by 1939 was deemed too dense for the existing British forces to make much of an impact. WA-5 planned the destruction of the Ruhr industrial region by primarily attacking power plants and coking plants. Subsequent analyses showed that it would be perhaps easier to shut down the Ruhr region by bombing the Möhne and Sorpe dams, which supplied water to industry. Unfortunately, the British did not possess sufficiently large bombs to destroy the dams. WA-6 focused on the German fuel supply, with 28 synthetic oil plants and refineries comprising the target list.

Some target systems such as the German fuel supply contained too many targets to be practical for the available British forces. Consequently, the British Ministry of Economic Warfare (MEW) sought out bottlenecks, particularly those critical items that were made only in a few isolated plants. Two such targets identified in 1941 were ball bearings and synthetic rubber. By late November 1942, the MEW identified other bottlenecks included alkalis, fuel injection pumps and electrical equipment for aircraft, and optical and laboratory glasses and instruments [41].

However, the British were hampered by several problems. Bomber range and payloads limited those targets that could be attacked. British bombers were not sufficiently armed and armored for daylight bombing of precision targets; the force had difficulty penetrating German fighters. The British switched to night bombing, which presented its own difficulties with navigation and accurate target identification. As a result, the British focused on area bombing as opposed to the destruction of precision targets until late in the war [42].

In 1940, the US Army Air Corps' Strategic Air Intelligence Section was also analyzing the industrial-economic structure of Germany. The Section initially focused on the following:

- electric power, including sources of fuel and the distribution system;
- steel, including raw materials;
- petroleum products, including the synthetic processes;

- the aircraft industry, including aluminum production and engine plants; and
- transportation networks, including railways, canals, and highways.

The section also examined the nonferrous metals supplies, machine tool production, and food processing and distribution [22].

In July 1941, then-Major Haywood Hansell visited the British as an observer. The express purpose of his visit was to explore British intelligence and bring home what material he could. Hansell, a former instructor at ACTS and member of the Strategic Air Intelligence Service, was impressed with the similarity of British and American targeting philosophies. Like the Americans, the British sought the collapse of German industry by destroying carefully selected targets. Hansell brought with him digests of American intelligence and found that he had much to offer. He noted that the Americans were better informed on the German electric power system and petroleum and synthetic products; the British had better information on the German aircraft industry including engine production, transportation, and the German Air Force. The British shared a considerable amount of information with Hansell, and he returned to the United States "loaded down" with targeting information [43].

In July 1941, the US Army Air Corps established its Air War Plans Division (AWPD). Lieutenant Colonel Harold L. George led the small staff, comprised of Lieutenant Colonel Kenneth N. Walker, Major Laurence S. Kuter, and Major Hansell. Each of these officers had been an ACTS faculty member. On 9 July 1941, President Franklin D. Roosevelt tasked the Secretaries of War and Navy to provide an estimate of "the overall production requirements required to defeat our potential enemies" [44]. In turn, General Henry H. "Hap" Arnold, Chief of the Army Air Force, tasked AWPD to develop the Air Annex for the requirements estimate. The guidance for the plan was quite broad and included four principal tasks:

> (1) (T)he provision of air forces in the defense of the Western Hemisphere; (2) the prosecution of an unremitting air offensive against Germany and lands occupied by German forces, including air preparation for a final invasion of the continent if that should be necessary; (3) the provision of strategic and close support air operations for such a land invasion; and (4) the provision of air defense and air support for strategic defensive operations elsewhere [45].

George's approach to developing the Air Annex was to plan a strategic offensive to debilitate the German war industry, defeat Germany if possible, and if necessary support an eventual invasion of the continent and Germany itself. Further, the planning effort assumed that the main burden for the strategic defensive in the Pacific region would lie on the Navy and that there would be no strategic offensive against Japan until Germany was defeated. Using the methods developed at ACTS, the officers examined in detail the German economy and military for vital links. As Hansell later recounted, several questions formed the basis of their analysis:

- What were the vital links?
- Among those links, which were the most vulnerable to air attack?
- Among those vulnerable to air attack, which would be the most difficult to replace or harden by dispersal or by going underground? [46].

The German economy was assumed to be highly stressed and drawn taut by the war effort. In the end, the plan focused on electric power, transportation (railways, canals, and highway networks), and the petroleum system (particularly synthetic oil production processes and the oil sources in Ploesti, Romania). An "intermediate objective" of overcoming the German fighter aircraft forces was established in order to permit the optimum effectiveness of the strategic attack against the German homeland. This could be accomplished by destroying the aircraft and engine manufacturing facilities, by elimination or curtailment of fuel supplies, or by attrition in air-to-air combat. The Germans were resourceful and their responses to the attacks would need to be anticipated. Further, the Germans would repair damaged targets so that revisiting targets would be necessary. The plan designated 154 targets in several systems, listed in Table 1 [47].

The resultant plan, AWPD-1, was accepted by the Combined Chiefs of Staff at the Acadia Conference in December 1941–January 1942. Of critical note is that AWPD-1 was essentially an aircraft production requirements plan and schedule, based upon a strategic campaign against Germany and Japan. The acceptance of the plan by the Combined Chiefs of Staff was interpreted as an acceptance of the strategic air campaign as well: Major General Carl Spaatz, Commanding General of Eighth Air Force, and Brigadier General Ira Eaker, Commanding General of VIIIth Bomber Command, accepted AWPD-1 (and its successor plan, AWPD-42) as the authoritative strategic guidance for the air campaign in the European theater [48].

A year after its delivery, AWPD-1 underwent the first of two modifications. In August 1942, the American air planning group modified it based on changes in the strategic situation and lessons learned to date. The new plan, AWPD-42, was delivered to the President on 24 August 1942. Like its predecessor, it was a requirements plan for aircraft

**TABLE 1 Targeting Priorities in World War II**

production. Its fundamental strategic philosophy called for a strategic offensive against Germany and a strategic defensive against Japan. As with AWPD-1, the primary strategic purpose was to undermine and destroy the capability and will of Germany to prosecute the war by destroying those industries supporting the war effort and associated structures that supported both the war industries and the civilian economy. The secondary purpose of the plan was to provide air support to forces operating in Mediterranean and the Pacific. It was a combined US–British air plan, with the US Army Air Forces focused on daylight bombing of precision targets, and the Royal Air Force taking on nighttime bombing of area objectives associated with munitions manufacturing. The targeting systems were similar to those of AWPD-1 and are detailed in Table 1 [49].

In December 1942, General Arnold issued a directive establishing the Committee of Operations Analysts (COA), an organization of respected American businessmen, economists, and military air planners. Unfortunately, the memo did not make clear the purpose of the COA and the objective of the air campaign. Subsequently, the Casablanca Directive clarified the COA's mission by calling for an air offensive against Germany to "bring about the progressive destruction and dislocation of the German military, industrial and economic system and the undermining of the morale of the German people to a point where their capacity for armed resistance is fatally weakened" [50].[5] The COA analyzed potential target sets, applying available intelligence information. It submitted its initial report in March 1943. The report, endorsed and slightly modified by MEW, contained the following list of priority target sets:

- German aircraft industry, with first priority on fighter aircraft, including assembly plants and engine factories;
- ball bearings;
- petroleum;
- grinding wheels and crude abrasives;
- nonferrous metals—copper, aluminum, zinc;
- synthetic rubber and tires;
- submarine construction yards and bases;
- military motor transport vehicles;
- transportation systems in general;
- coking plants;
- steel;
- machines tools;
- electric power;
- electrical equipment;
- optical precision instruments;
- chemicals;
- food production;
- nitrogen and the chemical industry; and
- antitank machinery and antiaircraft machinery.

[5]This directive was amended in late April/early May 1943 to include a final sentence that read, "This is construed as meaning so weakened as to permit initiation of final combined operations on the Continent."

This list was similar in target selection and philosophy to the targeting lists compiled for AWPD-1 and AWPD-42 [51].

The inputs of the COA were used by an American–British joint planning team headed by Brigadier General Hansell in VIII Bomber Command. This team developed its final list of targets based upon operational considerations that it believed would create the most damage to Germany given the existing and planned bomber force. This plan, which formed the basis of the US–British Combined Bomber Offensive (CBO), differed from AWPD-1 and AWPD-42, in that it was primarily a capabilities plan based on existing aircraft and those in the production pipeline as opposed to an aircraft requirements plan. The target sets of the CBO Plan are listed in Table 1. This plan was briefed to and accepted by the Eighth Air Force Commander, the European Theater Commander, and the Joint Chiefs of Staff, as well as their British counterparts [52]. The CBO, code-named POINTBLANK, got underway in May 1943.

The strategic concept for the air war against Japan paralleled the approach with Germany: defeat the Japanese air force and so weaken Japan's capability and will to fight that it would either capitulate or permit occupation against disorganized resistance, or, failing this, would enable an invasion at minimal cost [53]. The experiences in Europe heavily influenced the selection of target systems in Japan. In late 1943, General Arnold asked the COA for its recommended list of targets for a final offensive in Japan. The COA recommended seven target systems, although not in priority order:

- merchant shipping in harbors and at sea;
- iron and steel production, via the coke ovens;
- urban industrial areas vulnerable to incendiary attack;
- aircraft plants;
- antifriction bearing plants;
- the electronics industry; and
- the petroleum industry [54].

The following year, the Air Staff and ultimately the Joint Chiefs of Staff gave the overriding priority to the destruction or neutralization of the Japanese air force. Aircraft and engine plants were designated as the top priority targets for the newly formed XXI Bomber Command, led by Hansell.

Targets in Japan fell into two broad categories: select targets to be attacked with precision bombardment and urban area targets slated for incendiary attack. Hansell preferred precision attack. However, much of the Japanese industry was dispersed in small shops in the highly flammable urban areas, which made incendiary attacks attractive. In fact, in late 1944, the COA raised urban attacks to a higher priority than economic and industrial systems [55]. Given the critical importance of shipping, the XXI Bomber Command also executed aerial mining operations [56].

The selection of targets for attack in the two theaters followed a rigorous, scientific approach. Colonel Guido R. Perera, a member of the COA, described the process followed by that group in selecting targets in a 1943 memorandum to General Arnold:

> The Committee has arrived at certain conclusions in regard to target selection. It is better to cause a high degree of destruction in a few really essential industries or services than to cause a small degree of destruction in many industries. Results are cumulative and the plan once

> adopted should be adhered to with relentless determination. In the determination of target priorities, there should be considered (a) the indispensability of the product to the enemy war economy; (b) the enemy position as to current production, capacity for production and stocks on hand; (c) the enemy requirements for the product for various degrees of activity; (d) the possibilities of substitution for the product; (e) the number, distribution and vulnerability of vital installations; (f) the recuperative possibilities of the industry; (g) the time lag between the destruction of installations and the desired effect upon the enemy war effort [57].

Similarly, a RAND memorandum written shortly after the war provides insights into the analyses behind the selection of military and economic targets for bombardment by the Enemy Objectives Unit (EOU). The London-based EOU was comprised of US Army Air Corps officers and members of several intelligence units, including the Office of Special Studies and the Board of Economic Warfare. It assisted the 8th and 15th Air Forces with target selection and target intelligence. For each item or service considered for targeting, the EOU examined the following:

- the military importance of the item (e.g. frictionless bearings were essential for military vehicles);
- the percentage of direct military usage of the item;
- the depth, defined as the time elapsed between the end of production of an item and the occurrence of its shortage in tactical units;
- the economic vulnerability of an item or service, including the following:
  - the ratio of capacity to output (excess capacity, slack in the system, etc.);
  - substitutability for processes and equipment;
  - substitutability for the product (or service);
  - vulnerability of process and plant layout to attack; and
  - recuperability following attack;
- the physical vulnerability of the targets; and
- the location and size of the target sets.

The EOU gave preference to those targets with relatively small depth, that is, those items whose effects would show up rapidly. The relative size of the target set to the capabilities of the available air forces also influenced target selection [58]. Clearly, such analyses required insights from military planners, industrialists, and economists, all supported by the most detailed intelligence available.

How effective was the economic targeting of Germany and Japan? In November 1944, the Secretary of War established the United States Strategic Bombing Survey (USSBS), based on a directive from President Roosevelt. The Survey comprised civilians, officers, and enlisted personnel. The Survey was tasked to enter Germany and Japan as soon as possible and to assess the effectiveness of bombardment and its contribution to the victory over the Axis powers. Teams made close inspections of plants, cities, and areas; amassed statistical data and documentation; and interviewed and interrogated thousands of persons, including political, military, and industrial leaders in Germany and Japan. The Survey wrote several hundred highly detailed reports on the effectiveness of the bombardment campaigns [58].

In the conclusion section of its summary report on the war against Germany, the USSBS made a number of key observations about the effectiveness of bombing. In the words of the Survey,

- "A first-class military power—rugged and resilient as Germany was—cannot live long under full-scale and free exploitation of air weapons over the heart of its territory."
- "As the air offensive gained in tempo, the Germans were unable to prevent the decline and eventual collapse of their economy. Nevertheless the recuperative and defensive powers of Germany were immense; the speed and ingenuity with which they rebuilt and maintained essential war industries in operation clearly surpassed Allied expectations. . ." The German economy was undermobilized throughout much of the war, allowing it to recover and rebuild facilities to some levels of pre-attack production between raids, particularly in the early days of the war. The Germans employed numerous means to support their industrial operations, including camouflage, smoke screens, shadow plants, dispersal, and underground factories. The Germans were also able to make strategic substitutions for critical products [59], and employed means to increase industrial efficiencies. Dispersal, however, increased the importance of transportation networks, and thus multiplied the problems created by Allied air attacks against those networks.
- "The importance of careful selection of targets for air attack is emphasized by the German experience. The Germans were far more concerned over attacks on one or more of their basic industries and services—their oil, chemical, or steel industries or their power or transportation networks—than they were over attacks on their armament industry or the city areas. The most serious attacks were those which destroyed the industry or service which most indispensably served other industries."
- "The Germany experience showed that, whatever the target system, no indispensable industry was permanently put out of commission by a single attack. Persistent re-attack was necessary." Between attacks, the Germans worked to recover those destroyed facilities. For example, following the attacks on the ball bearing facilities at Schweinfurt, the Germans dispersed facilities, redesigned equipment where possible, and drew down existing stocks of frictionless bearings. An important lesson was that frequent reattack to ensure destruction of the industry was necessary.
- "In the field of strategic intelligence, there was an important need for further and more accurate information, especially before and during the early phases of the war." Much critical intelligence and analytic capability came from civilian experts not associated with the military before the war [60].

The USSBS examined the impacts of bombardment on specific target systems. With respect to the German transportation networks, the railroad system was unable to meet its transportation requirements after October 1944. This disorganized the flows of raw materials, components, and finished goods. Dispersal of industry only complicated the situation [61]. Coal was a particularly crucial commodity, as it was used for the manufacture of steel, electric power generation, and by the locomotives of rail system itself. One detailed analysis of the collapse of the German war economy concluded that the coal-rail nexus was the foundation of all economic activity in Germany, and its destruction created dire short-term effects on the economy, led to the disintegration of Germany's division of labor, created serious declines in armaments production, and caused a major decrease in supplies to the Wehrmacht [62].

Grinding wheels and abrasives were critical commodities in the German economy. During interrogations after the war, Albert Speer, the German Minister of Armaments

Production, stated that the entire armaments industry would have come to a standstill in 6 months if the production of abrasives had been destroyed. Furthermore, the complete loss of the ball bearing industry would have halted armaments production in 4 months [63].[6]

Speer was likewise concerned about the potential loss of electricity. Noting that "electricity alone could not be stockpiled," Speer stated that the destruction of the electric power grid would have been "the most radical measure, as it would at once lead to a breakdown of all industry and support of public life". The chief engineer in charge of the electric power grid observed that "the war would have been finished two years sooner if you concentrated on the bombing of our power plants" [64].

The destruction of the petroleum infrastructure had critical implications for the German economy and war effort. Significant declines in 1945 of petroleum stocks affected the ability of German ground and air forces to operate. From an infrastructure interdependencies perspective, loss of the synthetic petroleum industry killed nitrogen production, which itself was required for synthetic rubber and ammunition production [65].

In the Pacific theater, the Japanese economy was strangled by the destruction of its shipping industry by submarine and air attack as well as mining operations. Shipping logistically supported the fielded Japanese military forces and was vital to Japanese industry. Japan was critically dependent upon imports, which were cut off by the antishipping campaign. Steel production, for example, was directly affected by the destruction of shipping. Oil imports began declining in mid-1943 and were eliminated by April 1945. The USSBS report stated that even without air attacks on industry, the overall level of Japanese production in August 1945 would have been 40–50% below the peak levels of 1944 [66].

To paraphrase the USSBS, the air campaign against Japan destroyed its economy a second time over. The precision attacks against the aircraft and engine plants forced dispersal of those industries, including moving some manufacturing underground. The dispersal coupled with the destruction wrought by the bombing campaign crippled the Japanese aircraft industry. The electric power distribution system, though not explicitly targeted, and its associated load were largely destroyed by the urban incendiary attacks. The urban incendiary attacks severely damaged smaller urban industrial plants. Attacks against the rail system were beginning at the end of the war; consequently, the rail system was in reasonably good condition at the war's end. The labor force declined inefficiency due to malnutrition, fatigue, destruction of urban housing areas, and local transportation problems. Approximately 30% of the entire urban population of Japan lost their homes and possessions. The targeting of industry, both through area bombing and precision attacks, reduced prewar production by the following amounts:

- oil refineries: 83%;
- aircraft engine plants: 75%;
- airframe plants: 60%;
- electronics and communications equipment: 70%;
- army ordnance plants: 30%;
- naval ordnance plants: 28%;

[6]Some have questioned Speer's motivation behind his statements—was he stating what he honestly believed, or was he providing inputs that the USSBS and airpower advocates wanted to hear?

- merchant and naval shipyards: 15%;
- light metals: 35%;
- ingot steel: 15%; and
- chemicals: 10%. [67].

The Survey concluded that "heavy, sustained and accurate attack against carefully selected targets is required to produce decisive results when attacking an enemy's sustaining resources. . .no nation can long survive the free exploitation of air weapons over its homeland. For the future it is important fully to grasp the fact that enemy planes enjoying control of the sky over one's head can be as disastrous to one's country as its occupation by physical invasion" [68].

Technology was a major enabling factor in air campaigns of World War II. Long-range bombers able to deliver heavy bomb loads, the turbosupercharger, the Norden bombsight, radar bombing, and improved navigation all contributed to the ability to attack and destroy precision targets. Nonetheless, "precision" was limited during the war: the average miss distance for a 2000-lb bomb in the European campaign was 3300 feet. An Eighth Air Force assessment concluded that only 7% of the bombs dropped from September through December of 1944 fell within 1000 feet of their aimpoints. Numerous factors contributed to bombing problems, including inherent limitations in the bombsights, poor weather, dispersion of bomber formations when attacked by fighters, training, and poor aerodynamic designs of the bombs themselves [69]. By the end of the century, however, advanced technologies would largely resolve these issues, enabling truly precision attack.

## 5 MODERN THEORY AND PRACTICE

By the late 1980s to early 1990s, the confluence of technical developments, theory, and the Iraqi invasion of Kuwait drove a new test of critical infrastructure attack. The first driver, technology, had advanced to the point where the early promise of attacking precision targets on a global scale could finally be achieved. Bombing accuracies for unguided weapons had significantly improved, due to improved navigation, better aerodynamic designs of the bombs, improved weapons-release technologies, and better cockpit displays. Table 2 illustrates the improvement in bombing accuracy, for the case of hitting with a 90% probability a 60 $\times$ 100 feet target with an unguided 2000-lb bomb from medium altitude. CEP is the circular error probable, defined as the radius of a circle inscribed around a target inside of which 50% of the bombs fall [70]. Precision-guided weapons, introduced during the Vietnam War, completely redefined the military principle of mass. At the end of the century, laser- and global positioning system (GPS) guided weapons had advanced to the point where CEPs were measured in feet [71].[7] With this level of precision, the size of the weapon required to destroy a target could potentially be smaller. Reduced weapon sizes in principle meant that a single aircraft could carry more weapons, accurately attack multiple targets per sortie, and potentially reduce collateral damage. In fact, by the Gulf War of 1991, planners talked of "targets per sortie"

[7]As an example, F-117 fighters dropped 2041 tons of bombs during Operation DESERT STORM in 1991. One thousand six hundred and sixteen tons, or 79%, hit their targets, implying that they landed within 10 feet of the desired aimpoints. One well-publicized video showed a smart bomb flying down the ventilation shaft of the Iraqi Air Force headquarters building near Al Muthenna airfield.

**TABLE 2 Bombing Accuracy in the 1900s**

| War | Number of Bombs | Number of Aircraft | CEP (feet) |
|---|---|---|---|
| World War II | 9070 | 3024 | 3300 |
| Korean War | 1100 | 550 | 1000 |
| Vietnam War | 176 | 44 | 400 |
| Fall 1990 | 30 | 8 | 200 |

rather than "sorties per target" [72]. With aerial refueling, aircraft such as the B-1 and B-52 bombers had by this time achieved truly global range. Technologies such as GPS eliminated the navigation problems that had plagued bomber crews during the two world wars. The combination of accurate navigation and precision weaponry opened the night to precision attack operations, which during World War II had been used primarily for area attacks. Stealth technology enabled attacks against heavily defended targets. Finally, computer modeling of critical infrastructures and sophisticated engineering and operations research techniques opened the door to understanding the effects of destroying individual elements in a critical infrastructure—as well as potentially planning attacks to create very specific operational or strategic level effects [73].[8]

Airpower doctrine and theory had likewise advanced by the end of the 1900s, in large part due to the significant contributions of US Air Force Colonels John Boyd and John A. Warden III. Both men shared a common theme of defeating an adversary through strategic paralysis, or the incapacitation of the enemy, although from distinctly different perspectives and approaches. Further, both colonels emphasized a shift from the economic warfare of ACTS and World War II to forms of control warfare. Boyd emphasized the mental, moral, and temporal aspects of war, arguing that one could induce strategic paralysis in an adversary by operating inside the adversary's observe-orient-decide-act (OODA) loop. Warden developed a detailed airpower theory that focused on the physical aspects of warfare and considered in detail the question of targeting. His "Five Rings" model included critical infrastructure attacks and their influence upon the overarching objective of forcing strategic paralysis [74]. As Boyd did not consider in depth critical infrastructure targeting, we do not explore his theories below.

While a student at the National Defense University, Warden published his theories of air warfare at the strategic and operational levels in his book *The Air Campaign: Planning for Combat* [75]. In the 1990s, he published a series of articles that concisely described his theories [76]. Warden argued that the ultimate aim of all military operations was to control the civil and military command structures of the adversary. This could be accomplished by causing changes in one or more parts of the enemy's physical systems in such a manner as to force the adversary to adopt one's objectives as his own or by making it physically impossible for the adversary to offer opposition. To Warden,

[8]At the end of the century, Sandia National Laboratories and Los Alamos National Laboratory jointly established the National Infrastructure Simulation and Analysis Center (NISAC), with the mission of modeling, simulating, and analyzing critical infrastructures, key assets, and infrastructure interdependencies. NISAC employs highly sophisticated engineering and computer models to simulate infrastructures and the effects of disturbances, including high-order and cascading effects. In 2003, NISAC became a formal program of the Department of Homeland Security. NISAC has a homeland security mission focused on critical infrastructure protection and defense, as opposed to offensive military mission. See http://www.sandia.gov/mission/homeland/programs/critical/nisac.html.

making the adversary incapable of offering opposition was the essence of imposing strategic paralysis. Warden recognized that warfare had both a physical and morale side and suggested that war could be visualized in terms of the equation:

$$(\text{Physical}) \times (\text{Morale}) = \text{Outcome}$$

The physical side of war was, in principle, completely knowable and predictable, whereas the morale side involved humans and their reactions and therefore was not predictable. Consequently, Warden argued that one's efforts in war should be directed at the physical side.

Warden viewed an adversary from a systems engineering perspective with his "Five Rings" model. This model postulated that any strategic entity—whether a state, business, or terrorist organization—could be represented by five concentric rings (Fig. 1). The rings, from the innermost outward, and in order of importance, are as follows:

- Leadership, containing the enemy command structure and command communications.
- Organic essentials (or key production), comprised of more than just war-related industry. The electric power and petroleum industries are organic essentials; Warden noted that these systems had relatively few targets and were generally fragile.
- Infrastructure, with a focus on the adversary's transportation networks, including key nodes, railroads, and bridges. He noted that the targets in these systems were more numerous and redundant than the organic essentials and would likely take more effort to effectively damage.
- Population, including its food sources. Warden did not advocate directly targeting people, given that there were too many to effectively target, moral objections notwithstanding. However, he believed that indirectly attacking populations, such as the North Vietnamese did to the American populace during the Vietnam War, could be effective under certain circumstances.
- Field military forces. Warden emphasized that the fielded military forces were just means to an end and not the proper objective in war. He noted that fielded forces were often the "hardest" of all targets, given that they were designed for combat.

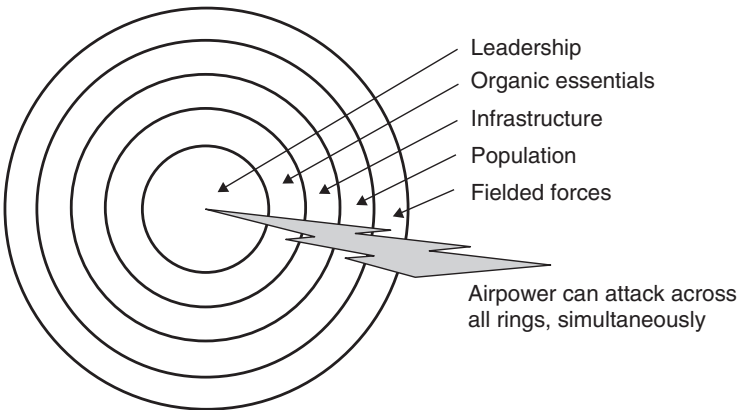

**FIGURE 1** Warden's Five Rings model.

Warden noted that the rings are not independent entities; rather, they are interdependent with one another. Like his predecessors, Warden was clear that an air force could attack targets within and throughout any of the rings. Nonetheless, he stressed that all actions must be aimed at the mind of the enemy command and that the essence of war was to apply pressure to the central ring—the enemy's command structure. Targeting this ring alone would generally not be sufficient, but all actions against targets in other rings must be focused on affecting the command structure. To Warden, this was "inside-out warfare", in that the traditional concept of attacking fielding forces was replaced with an emphasis on directly affecting and influencing the innermost leadership ring.

Warden also maintained that attacks should be compressed in time. Given that an air force could attack across an entire strategic entity, parallel attacks against many target sets were preferred to a serial attack stepping sequentially through target sets. He likened this to "death by a thousand cuts", which would only hasten strategic paralysis (and in the sense of Boyd, would enable one to get inside the adversary's OODA loop). With stealth and precision weaponry, many targets could be attacked simultaneously, thus enabling parallel warfare throughout the entire depth of an adversary. Given the time-compressed nature of parallel war and his experience in the Gulf War of 1991, Warden termed this form of conflict *hyperwar*.

The Gulf War put Warden's theories to the test. In August 1990, as Iraq invaded Kuwait, Colonel Warden led CHECKMATE, an office under the Air Force Deputy Chief of Staff for Plans and Operations. CHECKMATE was primarily tasked with long-range planning. Following the invasion, General Norman Schwarzkopf, the Commander in Chief (CINC) of Central Command, sent Lieutenant General Charles Horner, Commander of Ninth Air Force, to the theater as the onsight commander and the Joint Force Air Component Commander (JFACC). The JFACC was responsible for developing and executing the air campaign. However, in the days immediately following the Iraqi invasion, General Horner's staff was consumed with logistics and aircraft deployment and beddown issues. On August 8th, General Schwarzkopf consequently called upon the Air Force Chief of Staff for assistance in developing the air campaign. This tasking flowed down to Colonel Warden and his CHECKMATE staff. The staff developed the concept for a strategic air war within 2 days and on August 10th, briefed the plan to General Schwarzkopf at MacDill AFB in Florida. The air campaign, named INSTANT THUNDER, was accepted with some changes by US officials, General Horner, and General Schwarzkopf. In the theater, General Horner placed Brigadier General Buster C. Glosson in charge of planning and directed him to turn INSTANT THUNDER into an operational plan [77].

Warden's Five Rings provided the framework for the CHECKMATE planners. Their initial target breakout by ring is given in Table 3. The initial breakout, which changed little during the planning, provided a framework for determining individual targets. The planners considered interdependencies among target sets. Generally, they did not search for bottlenecks as did the World War II planners, as they were not constrained to serial attacks. Instead, the planners sought to attack simultaneously across the entirety of Iraq, aiming to impose strategic paralysis. For individual targets such as refineries, the planners took advantage of precision-guided weapons by seeking those specific aimpoints that would debilitate the target [78]. The objectives of the strategic campaign were to isolate

**TABLE 3 Breakout of the Five Rings in the Gulf War**

| Leadership | Organic Essentials | Infrastructure | Population | Fielded Forces |
|---|---|---|---|---|
| Communications | Electricity | Railroad bridges | Psychological operations | Strategic air defense system |
| Internal control mechanisms | Oil refining | Civilian airfields | | Strategic offensive forces |
| | Nuclear technology<br>Weapons production facilities | | | Republican Guard |

the Iraqi leadership, degrade key production, disrupt the infrastructure through transportation attacks, turn the population and the military forces against the Iraqi regime, and destroy Iraq's offense and defensive capabilities [79].

Airpower during the Gulf War had a decisive effect. By striking several dozen targets in the Baghdad area, the regime lost its ability to command and control its forces. In effect, the regime was rapidly rendered blind to the ongoing war. Air strikes against 27 selected electric power targets across the nation shut down the grid in the Baghdad area. Because electricity cannot be stockpiled, and given that other infrastructures depend upon electricity, the loss of power affected many Iraqi military facilities. The oil campaign reduced Iraq's production to near zero, with slightly more than 500 sorties against 28 targets. In 3 days of attacks against the oil infrastructure, Iraq's refined oil production was halved; after 13 days, production was reduced to zero. The transportation campaign reduced the flow of supplies to Basra, a major transshipment point, to a level well below that required to sustain Iraqi combat operations. The combination of stealth, precision, and parallel warfare reduced the Iraqi regime's ability to command its forces to near zero and rendered the Iraqi military ineffective before the commencement of ground operations [80].

Following the Gulf War, Colonel Warden was appointed as Commandant of Air Command and Staff College (ACSC) and the School of Advanced Airpower Studies (SAAS), the US Air Force's professional military schools for midgrade officers. His influence on the curriculum was profound; he oriented it toward the operational level of war with a heavy emphasis on air campaign planning. He instituted student research projects, again at the operational level of war [81]. A number of student papers and SAAS theses during his tenure examined critical infrastructure analysis and attack. These papers included analyses of telecommunications systems [82], the petroleum sector [83], electric power [84], and social networks [85]. One thesis provided a detailed examination of infrastructure interdependencies, postulating that modern economies are complex adaptive systems and must be targeted as such [86]. Chaos theory was applied to critical infrastructures, social systems, and campaign-level planning in an ACSC student research project [87]. Another detailed analysis of electric power grids included computer software that demonstrated effects-based targeting of that infrastructure [88]. Although these papers included detailed information on the functioning, structure, and architectures of their respective infrastructures, they were primarily studies of the strategic and operational utility of critical infrastructure attacks in the age of modern warfare.

By the end of the twentieth century, a new technology of warfare was emerging on the horizon: information or cyber warfare. Many have speculated in the open literature

about the possibility of cyber attacks against the computerized control systems that manage and operate the nation's critical infrastructures [89].[9] If disrupted, these supervisory control and data acquisition (SCADA) systems could directly affect the infrastructures they control. Adversarial control or attack of SCADA systems and the subsequent infrastructure disruptions could have important economic and national security ramifications. Today, the Departments of Homeland Security and Energy both have programs with the objectives of increasing the security of SCADA and other process control systems to reduce the risks and consequences of such attacks.

## 6 OBSERVATIONS

The above-mentioned historical survey demonstrates that airpower theory and practice in the 1900s leaned heavily upon critical infrastructure attacks to obtain national and military objectives. Analyzing the air campaigns and theories, we can make the following observations on military thought concerning specific critical infrastructures:

- *Defense industrial base.* Attacks against this infrastructure were employed primarily to deny an adversary the physical means to sustain a war. ACTS theorized that many industries were actual dual use; hence, their destruction would also undermine the social fabric of a nation.
- *Electricity.* Electric power is vital to the normal operation of a nation, including the functioning of its defense industrial base. Planners believed that disrupting electric power would affect the ability of the adversary government to carry out its essential functions and prosecute the war, degrade the military's ability to operate, and disrupt normal civilian life.
- *Petroleum.* Loss of refined petroleum products would preclude the operation of military vehicles, disrupt transportation networks, and deny raw materials used in many manufacturing processes vital to the production of war materiel.
- *Communications.* Disruption of communications would directly affect the ability of the national and military leadership to command and control military operations, add confusion to the war effort, and potentially panic and confuse the population.
- *Transportation.* Loss of transportation networks would hamper the ability to mobilize and concentrate forces, affect the ability to move raw materials to the defense industrial base, degrade the ability of dispersed industries to produce war materiel, and potentially affect the ability of the labor force to get to work.
- *Food.* Destruction of food supplies, including agricultural areas, would lead to malnutrition, with a particular target of the labor force of the defense industrial base.

Although this list is not exhaustive, particularly with respect to cascading and higher order effects, it is representative of the thought that went into targeting infrastructures throughout the 1900s.

[9]The massive cyber attacks on Estonia in April–May 2007 illustrate a means of attacking critical infrastructures that do not use SCADA systems yet rely upon the Internet to function. Targets included banks, newspapers, and the government—representative elements of several critical infrastructures. For example, the attacks forced Estonia's largest two financial institutes to severely restrict online access. Of note is that Estonia is one of the most wired European nations.

Despite the detailed development of economic and infrastructure attack theories and plans, the ability to carry out such attacks was tightly linked to the state of technology. Attacks in World War I were largely viewed by the Germans as ineffective; technology and operational considerations precluded the air services from obtaining their desired operational and strategic effects. Improvements in technology were a critical enabling factor for aerial bombardment in World War II; infrastructure attacks yielded decisive effects against the German and Japanese economies and warmaking abilities. Nevertheless, technological limitations were apparent in that war, such as the degree of precision that could be obtained by bombing. By the end of the century, these limitations had largely been overcome, thereby opening up new operational possibilities for infrastructure attack as demonstrated in the Gulf War.

## 7 CONCLUSIONS

While protection of critical infrastructures has risen to the level of a national priority only during the past 15 years, attacking critical infrastructures during conflicts is hardly new. With the advent of the airplane, air forces were able to fly over fielded surface forces and directly attack strategic objectives throughout an adversary's homeland. Target sets originally concentrated on the defense industrial base and transportation networks. By World War II, with improved aircraft, bombs, and bombsights, the Allied forces attacked "precision" targets throughout the Axis nations, including many critical infrastructures. By the end of the century, precision weapons had come to the forefront, enabling surgical attacks on critical infrastructure targets. Indeed, during the Gulf War of 1991, Coalition forces conducted rapid, parallel attacks against infrastructure targets throughout Iraq. Theory and technology contributed heavily to the use of critical infrastructure attack during conflicts in the twentieth century.

## 1 INTRODUCTION

The American way of life relies on the operations and interactions of a complex set of infrastructure networks. These networks include transportation, electric power, gas and liquid fuels, telecommunications, wastewater facilities, and water supplies. This set of civil infrastructures has also been included in the broader set of critical infrastructures defined by the USA Patriot Act of 2001 [1]. In the Patriot Act, critical infrastructures are those

> "systems and assets, whether physical or virtual, so vital to the United States that the incapacity or destruction of such would have a debilitating impact on security, national economic security, national public health or safety or any combination of these matters [1]."

Each of these infrastructure systems evolved independently. However as technology advanced, the systems became interconnected. The reliance of any of these systems

on electric power is obvious. Failures, by whatever cause, within the communications networks in one locale may have far-reaching effects across many systems.

Infrastructure management systems did not allow a manager of one system to "see" the operations and conditions of another system. Therefore, emergency managers would fail to recognize this "interconnectedness" or interdependence of infrastructures in responding to an incident, a fact recognized by *The National Strategy for the Physical Protection of Critical Infrastructures and Key Assets* [2]. This research provides a model of this "system of systems." Each system is explicitly modeled and the manager could be provided with a familiar view of their system. Additionally, the model captures how these systems rely on each other. The model and its associated decision support system becomes a tool for emergency and system managers to improve post-disruption response and better understand vulnerability due to this interconnectedness. In the sections to follow, this article provides a brief discussion of the policy documents and past studies in system modeling; a description of the model and its associated decision support system; and an overview of how the model can be used for post-disruption system restoration and vulnerability analysis.

## 2 BACKGROUND/PAST STUDIES

This literature and past studies relevant to this research fall into one of the three categories. These are the policy documents, the past research on single system modeling, and the work involving modeling multiple systems or a system of systems. In the interest of brevity, a lengthy discussion of this past study is not being presented in this article. An extensive review of the literature relating to this study can be found in [3] and [4].

The policy documents [1, , 5–12] have framed the discussion, recognizing the need for models to aid in decision making and discussing how models can provide better understanding of the behavior of these complex, interconnected systems.

Single system research [13–25] has focused on mitigating disruptions due to willful act or natural events. In general, this work has not included detailed discussions on how these systems are vulnerable due to their reliance on other networks.

Past research [26–30] has also studied vulnerability and reliability as they relate to interconnected systems. Some of these have been at the macroscopic levels of detail that are suitable for analyses relating to system vulnerability, but would not easily translate to restoration activities following a disruptive event. Other work has focused on just two specific systems and are not easily extendable across the system of systems. Again, a more detailed discussion of this work is found in [4]. Models of national scale are being developed by the national laboratories and within Department of Homeland Security-sponsored research. These models are useful in assessing impacts to quality of life, the economy, and national security. They can also aid in developing national response strategies. However, they lack the detail to be useful in guiding system restoration or identifying system vulnerabilities within smaller regions, a gap which is filled by this research, which is discussed in the next section.

## 3 THE INTERDEPENDENT LAYERED NETWORK MODEL

This research has developed a formal, mathematical representation of the set of civil infrastructure systems that explicitly incorporates the interdependencies among them and

is called the *Interdependent Layered Network model* (ILN). The ILN is a mixed-integer, network-flow-based model, which is implemented in a software that enables the resulting model to be exercised. The detailed mathematical formulation of the model can be found in [3] and [4]. The ILN is embedded in a prototype decision support system, that is, Multi-Network Interdependent Critical Infrastructure Program for Analysis of Lifelines (MUNICIPAL). MUNICIPAL consists of a geographic information system (GIS) interface for the user, a database with the attributes of the set of infrastructures, the ILN module, and a vulnerability and system design module.

The model provides the capability to understand how a disruptive event affects the interdependent set of civil infrastructures. This capability improves a society's ability to withstand the impact of and respond to events that can disrupt the provision of services that are required for the health, safety, and economic well being of its citizens. Managers of infrastructure systems are able to assess the vulnerability of their own system due to its reliance on other systems. Organizations responsible for coordinating emergency response efforts will also be able to model different event scenarios and assess their impact across the full set of systems and the services they provide. With this broader perspective of impact, mitigation, and preparedness strategies can be formulated and evaluated for their ability to reduce their effects on society.

MUNICIPAL is not based upon a unique configuration of infrastructures, but is generic and therefore, applicable to more than one location. It is also not specific to a particular type of event, such as an earthquake or hurricane. The only requirements are that the event is of sudden onset and the event causes damage to the physical components of the infrastructure system.

The intended use of MUNICIPAL was for response and restoration efforts following a disruptive event and as a training tool for personnel who would be guiding response and restoration efforts. As the research progressed, MUNICIPAL was found to be useful in supporting system design, assessing the vulnerability of a system, measuring the benefits of pre-staging resources, or installing backup power systems, and even changing the physical design of the existing systems. This research has developed a network flow formulation of interdependent networks, which clearly identifies effects of a disruptive event across the set of infrastructure systems.

### 3.1 The General Construction of the Model

Interdependent infrastructures are viewed as networks, with movement of commodities (i.e. material) corresponding to flows and with services corresponding to a desired level of these flows. For ease of representation, each network, or infrastructure system, is defined as a collection of nodes and arcs with commodities flowing from node to node along paths in the network. Fundamentals of network flow problems are fairly uniform within the literature and texts on the subject [31].

For each commodity, each node is either a supply node which is a source for the commodity; a demand node which is a point that requires some amount of the commodity; or a transshipment node which is a point that neither produces nor requires the commodity but serve as a point through which the commodity passes. Arcs may, of course, have limited capacities. Infrastructure systems operate in an environment subject to disruptions. These disruptions could be caused by a natural phenomenon, human error or willful act. Based upon performance criteria, an infrastructure system can be designed to minimize possible service degradation following a disruption. In addition, once a disruption occurs,

alternative ways of restoring service can be determined. Included in the model are *flow conservation constraints* that (i) for supply nodes ensure that total flow out of the node is no greater than the available supply, (ii) for demand nodes ensure that demand is met, and (iii) for transshipment nodes ensure that flow into the node equals flow out of the node. The structural requirements are modeled by constraints on the capacities of arcs and transshipment nodes.

Network flow models can also be characterized as single-commodity or multi-commodity systems. Infrastructures such as water, power, gas, and sewer would be single-commodity systems, where material moves from one or more supply points, through a set of arcs and nodes, subject to constraints on capacity, and reaches one of more demand points in an optimal fashion. However, systems like transportation and telecommunications have additional requirements. In these cases, commodities moving across the system have specific origin and destination requirements. For example, passengers arriving at a subway station may each have unique destinations and the needs of each passenger must be met. However, these multiple commodities are not moving independently of each other. Associated with each origin–destination (O–D) pair is a market, the amount of a commodity which must flow between that O–D pair. Between each O–D pair is a set of possible paths. Each path is comprised of a subset of the arcs. The flows across all the paths for a particular O–D pair must equal the market. If the flow is less than the market, then there is an unmet demand for service. The flow on an arc is determined by summing the flows on all paths which contain the arc and is constrained by the arc's capacity.

One common formulation of a network flow model is the minimization of service delivery (minimum cost incurred to move the material across the arcs) while minimizing the unmet demands for service. Following a disruption, the flow into demand nodes may be insufficient. This unmet demand is commonly referred to as slack. At points of interdependency, this unmet demand occurs at the parent node. In the case of a pump and motor combination, the motor would be the parent node and the pump would be the child node (the node in the dependent system which is relying on the parent node in order to be able to deliver service). All demand nodes in every system would be provided a weighting factor, indicating their relative importance. These weights could be decided on well in advance of a disruptive event and would let system and emergency managers decide the relative importance of various demands for service. These weights would tend to push service toward those with higher importance. The weights would also guide restoration (discussed later in this article) by focusing priority on these high importance nodes. How managers would decide on the importance of one facility or area over another, considering social factors and critical service needs, is a topic for future study and is not included in this article.

### 3.2 Types of Interdependence

Rinaldi et al. [9] formalized the definitions of interdependence within this ongoing discussion of critical infrastructure and defined four classes of interdependency. Due to the number of different types of dependencies and interdependencies, these authors classified the entire family of interrelationships among systems as interdependencies, an approach retained in this article. This research identified five types of interrelationships between infrastructure systems—input, mutual, shared, exclusive-or, and co-located. A discussion of these is provided below. The mathematical details of each can be found in [3] and [4].

### 3.3 Input

An infrastructure is input interdependent when it requires as input one or more services from another infrastructure in order to provide some other service. In the case of a telephone switching station, the switching station itself is a transshipment node within the telecommunications network. However, this same switching station, from the perspective of the electrical network, is seen as a demand node since it needs an adequate source of electricity to operate. If insufficient power is available for the switching center, then it will be unable to operate and this change of capacity will affect the telecommunications system. The effect on any set of systems can be analyzed in a similar manner.

The existence of slack at a parent node of interdependent systems acts as a control switch for a connector variable. This binary connector variable works to turn the child node on or off, altering its capacity, depending on the conditions at the parent. When a parent node has unmet demand, the corresponding capacity of its child node in the dependent system is reduced. (Note that some interdependent infrastructure system failures may result in reducing the system's capacity to some value other than zero. For example, loss of supervisory control systems in a subway system may result in operators exercising greater care and slowing trains. So the post-disruption capacity may be lower than normal.)

### 3.4 Mutual

A collection of infrastructures is said to be mutually interdependent if at least one of the activities of one infrastructure system is dependent upon any other infrastructure system and at least one of the activities of this other infrastructure system is dependent upon the first infrastructure system. Consider a natural gas system compressor and a gas-fired electric power generator. From the perspective of the natural gas system, the compressor is a transshipment node and the generator is a demand node. From the perspective of the electrical network, the generator is a supply node and the compressor is a demand node. The generator needs gas to produce electricity; the compressor needs electric power to deliver gas through the system to the generator. If the compressor were to fail, supply of gas to the generator would be inadequate. If the capacity of the generator is set to zero, all flows on the arcs (i.e., the power lines) leaving the generator would be zero. Alternately, a lack of power at the compressor's demand node in the electrical generating network causes its capacity to be set to zero. To correct his situation, either an alternate source of gas must be found for the generator or an alternate source of power must be found for the compressor.

### 3.5 Shared

Shared interdependence occurs when some physical components and/or activities of the infrastructure used in providing the services are shared. Phone lines could be considered in the shared interdependence. Each phone line carries two types of calls, incoming and outgoing. Therefore, if a cable section contains 50 lines, they could be 50 incoming calls or 50 outgoing calls or some combination totaling 50. This type of interdependence is common in modeling of multicommodity systems. This is modeled mathematically by limiting the sum of the flows of the various commodities across the component to not exceed the total capacity.

### 3.6 Exclusive-Or

Exclusive-or interdependence occurs when multiple services share infrastructure component(s), but the component can only be used by one service at a time. In the first few days following the World Trade Center (WTC) attacks, streets (i.e., shared components) could not be used by both the emergency response personnel and financial district workers. This conflict had to be resolved prior to reopening the New York Stock Exchange [32]. Exclusive-or interdependencies are modeled by selecting additional constraints to restrict flow to one commodity or the other.

### 3.7 Co-Located

The co-located interdependency occurs when any of the physical components or activities of the civil infrastructure systems are situated within a prescribed geographical region. It was previously noted that managers of individual infrastructure systems would identify the components of their respective system at or near the site of the incident that may have been affected by the event. Based on further investigation, the status of these components will be adjusted. However, since only those emergency response agencies who are responsible for coordinating activities across multiple agencies maintain the complete view of all civil infrastructure systems, it is ultimately their responsibility to ensure that all co-located interdependencies have been considered and the models of the affected infrastructures revised as appropriate.

## 4 THE COMPONENTS OF MUNICIPAL

### 4.1 The User Interface and Database

A GIS was selected as the user interface as this seemed to be the most natural method of displaying systems and determining affected areas. The interface allows the operator to update the conditions of the modeled systems' components and to add temporary systems during restoration and when the display areas are affected by inabilities to meet demands.

The database contains the component attributes such as name, their capacity and their priority, as well as spatial attributes such as location and length. These spatial characteristics are generated automatically by the GIS software, ESRI's ArcGIS [33] in this case. The remaining attributes are added by the modeler. Changes to attributes, caused by disruption, can easily be made.

### 4.2 The Manhattan Dataset

In Manhattan, the goal was to develop highly detailed models in the area south of 60th Street of the power, telecommunications and subway systems, three major infrastructure systems impacted by the September 11 attacks. While unable to obtain details on specific components and their locations, Consolidated Edison, Verizon, and the Metropolitan Transit Authority were very open in discussing the general construction and operation of their respective systems and have provided a feedback during the model's construction. The subway system includes 115 stations and 338 local and express track sections. The phone system includes 18 switching centers and their associated service areas, 72 controlled environmental vaults where distribution cables are joined into larger feeder

cables and all the associated wiring. Below Canal St, approximately 500 blocks of phone service were modeled in detail. The power system as modeled includes 16 substations and 32 service areas. Each substation distributes power along 8–24 feeders to 18 phone switching centers, 178 AC/DC rectifiers for the subways, and service to all residences and businesses in the area.

## 5 USING MUNICIPAL DURING SYSTEM DISRUPTIONS

When an event occurs which disrupts any of the infrastructure systems included in MUNICIPAL, the operators would first use the GIS interface to identify components in and around the area of the disruption that may have been affected. Crews could then be dispatched to determine the actual condition of these possibly affected components. Outage reports from customers could also be entered in a separate database and linked to the GIS. On-scene reports would ascertain the actual condition of these components and the GIS would be used to update the component database. The operator would update the capacity of links and nodes based upon these reports.

With the direct impact of the disruption entered, MUNICIPAL can be run to determine where demands for service are not being met. In the case of the Manhattan data set, these unmet demands could include the number and location of electric power outages, number of telephone system calls that cannot be completed, and the number of subway system passengers who cannot reach their destinations. These outages would be due to failures of components in a system as well as outages caused by failure between interdependent systems.

With the full extent of the disruption modeled, the operators can use MUNICIPAL to begin restoration planning. Priorities can be set for each customer outage and plans can be developed in a collaborative environment. A complete example of the use of MUNICIPAL for a disruption is found in [3] and [4]. When a restoration plan is decided upon, MUNICIPAL can then develop work schedules based upon available resources, cost, and priorities.

## 6 USING MUNICIPAL FOR VULNERABILITY ANALYSIS

System managers are limited in their ability to evaluate the resilience of the systems they control because they cannot take into account the interdependencies of their systems with other infrastructures. In Lee et al. [34] and in [3], a procedure was introduced to evaluate the vulnerability of current or proposed designs of infrastructures that considers their interdependence to other systems. This procedure allows a system engineer to evaluate existing paths which are considered to provide redundancy for example, two existing paths in a telecommunications network between two important government or corporate offices. Since these two paths do not share any telecommunications components, they would appear to be redundant. However, using MUNICIPAL and its interconnected system model, the system engineer can conduct a backward trace into each system that telecommunications relies on. If these backward traces find single components in other systems whose failure causes both telecommunications paths to fail, then no redundancy has been provided. Examples could include single points in a power system that could lead to failure of redundant paths in telecommunications or single

components in a gas system that provide fuel to both the normal and backup generators for a facility or region.

MUNICIPAL can also aid in designing redundant paths. By conducting its backward trace along any path considered vital into all systems the path relies on, MUNICIPAL can be used to determine if a new, redundant path can be provided, utilizing the components not used by the current path and new connections or components, when appropriate.

## 7 CONCLUSIONS

This article has provided an overview of the ILN and MUNICIPAL and the capabilities of each. Our research continues and includes alternative formulations and solvers, extension of the study from the civil infrastructure systems to service systems such as supply chains and public safety. There is also an intent to improve the method by which priorities are established during system restoration, based upon methods found in the social sciences and economic impacts. Future research will also include the improvement of the decision support system and user interfaces.

## ACKNOWLEDGMENT

The authors wish to acknowledge the valuable assistance of the Manhattan offices of Consolidated Edison and Verizon, as well as the New York City Office of Emergency Management and the New York State Emergency Management Office. This study was supported by the National Science Foundation under Grant CMS 0139306, Impact of the World Trade Center Attack on Critical Infrastructure Interdependencies; Grant DMII 0228402, Disruptions in Interdependent Infrastructures: A Network Flows Approach; and Grant CMS 0301661, Decision Technologies for Managing Critical Infrastructure Interdependencies.

# SOCIAL AND BEHAVIORAL RESEARCH

# SOCIAL AND PSYCHOLOGICAL ASPECTS OF TERRORISM

FATHALI M. MOGHADDAM AND NAOMI LEE
*Georgetown University, Washington, D.C.*

## 1 INTRODUCTION

Claims that "one person's terrorist is another person's freedom fighter" have made it notoriously difficult to define terrorism [1]. From a social psychological perspective, terrorism can be defined as *politically motivated violence, perpetrated by individuals, groups, or state-sponsored agents, intended to bring about feelings of terror and helplessness in a population in order to influence decision making and to change behavior* [Reference 2, p. 161]. Social and psychological processes are at the heart of terrorism, because it is through bringing about particular feelings and perceptions (terror and helplessness) that terrorists attempt to change actual behavior of victim individuals and societies.

## 2 SOCIAL ROOTS OF TERRORISM

In order to explain why people commit terrorist acts, a variety of socio-psychological explanations have been put forward [3, 4]. These include irrationalist explanations influenced by Freud, as well as rationalist, materialist explanations. An overlooked factor is functionality: terrorism is adopted as a tactic because it sometimes works effectively. For example, it is generally agreed that the March 11, 2004, terrorist attacks in Madrid, resulting in close to 200 deaths and over 1000 serious injuries, led to the ruling party in Spain being voted out of power because of their close alliance with the Iraq policies of the Bush administration. Of course, this kind of political impact tends to be short term and limited in scope.

In this discussion, our focus is on terrorism carried out by fanatical Muslims, particularly violent Salafists, because at the dawn of the twenty-first century this type of terrorism poses the greatest threat at the global level, as reflected by the focus of research [5–12]. On the other hand, other types of terrorism, such as by members of Euskadi ta Askatasuna, Basque Homeland and Freedom (ETA) in Spain or the Tamil Tigers in Sri

Lanka, have not ended, but tend to be confined to particular regions and separatist causes, and are a less serious threat globally.

We outline the social and psychological aspects of terrorism in two main parts. First, we examine the roots of terrorism; second, we explore the consequences of terrorism. In order to better understand the roots of terrorism, it is useful to adopt a staircase metaphor [3]: imagine a narrowing staircase winding up a multistory building. Everyone begins on the ground floor, and it may be that people are sufficiently satisfied with conditions to remain on the ground floor. However, under certain conditions, people will feel they are being treated unjustly and some individuals will start climbing up the staircase, searching for ways to change the social–economic–political situation.

The climb up the staircase to terrorism involves radicalization. The challenge is to transform the conditions, to facilitate deradicalization, so that people are not motivated to climb up, and those who have climbed up become motivated to climb back down.

The weight of evidence suggests that contextual rather than dispositional factors best explain movement up and down the staircase to terrorism (e.g. see 13–15). Terrorism is not explained by psychopathology, illiteracy, or poverty [3, 16, 17]. Under certain conditions, individuals with "normal" psychological profiles will do harm to others [18]. The staircase metaphor helps to highlight the role of context, as well as the psychological processes that characterize thought and action on each floor of the staircase to terrorism.

### 2.1 Radicalization: Moving Up the Staircase

Radicalization typically involves a step-by-step process, well documented in almost a century of research on conformity and obedience (see Reference 19, Articles 15 and 16). As individuals move up the staircase, step-by-step, they gradually adopt those attitudes, beliefs and morality that condone terrorism, and some of them eventually become recruited to carry out terrorist attacks. This process begins with the radicalization of entire communities on the ground floor.

*Ground floor*. The ground floor is occupied by about 1.2 billion Muslims. Psychological processes central to thought and action on this floor are relative deprivation and identity.

In the Near and Middle East, as well as in North Africa—including other important Islamic countries such as Egypt, Saudi Arabia, and Pakistan—Muslims are ruled by governments that cannot be voted out by popular will, yet they are supported by Western powers (e.g. United States). This support comes in the form of political and military interventions (as in the case of Kuwait and Saudi Arabia) and economic aid (as in the case of Egypt and Pakistan). Oil producing countries have suffered from an "oil paradox" [Reference 3, pp. 74–76): instead of improving the lives of the masses, oil revenue has allowed despotic ruling groups, such as the Saudis, to pay for a stronger security apparatus and to win the support of Western powers through enormous arms purchases and promises of reliable, cheaper oil supplies.

Two factors have helped to raise expectations and to create fraternal (collective) relative deprivation among the populations on the ground floor. First, the global mass media has presented the impoverished Islamic masses with images of an opulent life that is available to people in some countries. Secondly, Western politicians have promised

democratization and reform. Consequently, the expectation has been raised among the Islamic masses for great choice and greater participation.

In practice, most people in the Near and Middle East lack choices both in economic and political spheres. In the economic arena, wealth disparities are enormous and the standard of educational and social services have remained poor. In the political sphere, little actual progress has been made toward giving people a voice in government, although there has been considerable publicity about "democratic changes" in places such as Egypt and Saudi Arabia.

Globalization has also helped to create an identity crisis in Islamic communities [3]. In the midst of social–economic–technological global changes, one set of extremists in Islamic societies are urging the abandonment of traditional life-styles and the copying of the West; other extremists push for a return to "pure Islam" as it was (supposedly) practiced in its original form 1400 years ago. The "become copies of the West" strategy has led to the "good copy problem" [3] because following this option means Muslims will lack an authentic identity, and at best can only become "good copies" of a Western ideal. The "return to pure Islam" option is also associated with enormous problems because it is being used by fundamentalists to implement regressive interpretations of Islam.

An alternative, secular "middle ground" needs to be constructed, but for this to happen the governments of Islamic societies must allow greater political freedom. At present, procedures to allow people to participate in decision making about the cultural, social, economic, and political future of their societies are still not in place. Social psychological research suggests that procedural justice is vitally important, and influences how fair people believe a system is, independent of the actual outcome of decision making.

*First floor*. Individuals climb to the first floor particularly motivated to achieve individual mobility, and central to their experiences is procedural justice. The importance of openness and circulation has been emphasized by thinkers from Plato to modern theorists: closed systems lead to corruption, a sense of injustice, and eventual collapse [2]. Individuals who feel that paths for progress are not available, now move further up the staircase.

*Second floor*. Those who arrive on the second floor are experiencing tremendous frustration because the paths to change and improvement seem blocked to them. They become vulnerable to the influence of radical preachers as well as government propaganda, displacing aggression onto Westerns, the United States and Israel in particular, as the "cause of all problems". Research demonstrates that displacement of aggression is a powerful factor in redirecting frustrations onto external targets [20].

*Third floor*. Individuals who climb to the third floor already perceive their own societies to be unjust, and perceive external targets (particularly the United States) as the root cause of injustice. On the third floor, these individuals gradually "disengage" from moderate policies and morality, and engage with a morality supportive of terrorism, often seeing terrorist tactics as the only weapon at the disposal of Muslims fighting for justice.

*Fourth floor*. Recruitment takes place on the fourth floor, where individuals become integrated into the culture of small, secretive terrorist cells. The new recruits are trained to view the world in a rigidly categorical, us versus them, good versus evil manner, and to see the terrorist organization as legitimate. Unfortunately, the categorical thinking of extremist Islamic groups tends to mirror, and be reinforced by, the categorical "us versus them" thinking of extremists in the West.

*Fifth floor*. In the animal kingdom, intraspecies aggression is limited by inhibitory mechanisms brought on by one animal's display of submission to another. Inhibitory mechanisms prevent serious injury and death. In order to carry out terrorist acts, often resulting in multiple deaths and injuries, individuals must learn to sidestep the inhibitory mechanisms that function to prevent human aggression under normal circumstances. This "learning" takes place on the fifth floor, and in part involves further distancing and dehumanizing of targets. Having to live in isolation, separated from the rest of society by secrecy and fear, results in even tighter bonds within terrorist cells.

### 2.2 Deradicalization: Moving Down the Staircase

Using the staircase metaphor, as well as insights from earlier research on deradicalization [16, 21, 22], we arrive at important general guidelines for deradicalization programs.

First, research suggests that for any given individual, the path to deradicalization is not necessarily the opposite of the path that person took to radicalization; the path down is not always the same as the path up.

Secondly, deradicalization programs need to be designed for each set of individuals depending on the floor they have reached on the staircase to terrorism. For example, individuals on the top floor are ready to carry out terrorist attacks, and deradicalization can be most effective after the terrorist has been captured. However, individuals who reach the third floor are in the process of adopting terrorist morality, and they can be influenced by deradicalization programs without necessarily first being captured.

Thirdly, resources should be focused particularly on the ground floor, where the vast majority of people reside. International surveys reveal that the populations of many important Islamic societies have become radicalized on the ground floor [23]. This is associated with a rise in conspiratorial thinking. For example, in 2006 the percentages of people who believed that Arabs *did not* carry out the 9/11 attacks were: Indonesia 65%, Egypt 59%, Jordan 53%, and Pakistan 41%. In the traditionally "pro-Western" society of Turkey, the percentage of Muslims who expressed disbelief that Arabs carried out the 9/11 attacks went up from 43% in 2002 to 59% in 2006. In Egypt 28% and in Jordan 29% of Muslims believe that violence against civilian targets in order to defend Islam is sometimes justified [23]. These findings reflect a broad radicalization processes associated with some support for terrorism and generally higher anti-Western sentiment.

## 3 SOCIAL PSYCHOLOGICAL CONSEQUENCES OF TERRORISM

Research attention to the effects of terrorism on civil society and psychological well-being was ignited after the attacks of September 11, 2001. This research can be organized into three general topics: political attitudes, prejudice, and mental health.

### 3.1 Political Attitudes

Terrorism is associated with demonstrable changes in political attitudes, as both experimental studies and surveys have shown. Research linking terrorist attacks in support of more authoritarian political policies and abdication of civil liberties, is discussed.

Authoritarianism is a personality trait popularized by Adorno [24] and subsequently refined by Altemeyer [25] as consisting of submissiveness to authority, aggressiveness toward outgroups, and conventionalism. This personality trait appears to both predict people's responses to aggression and increase in response to aggression.

In a quasi-experimental study of the effects of Islamic terrorist attacks in Madrid (March 11, 2004), right-wing authoritarianism and conservatism were measured in Spanish citizens both before and after the attacks [26]. Right-wing authoritarianism increased, and Spanish citizens reported a stronger attachment to traditional conservative values. Since the study was quasi-experimental, a causal link between the attacks and changes in political beliefs could not be established. In a controlled laboratory experiment [27], the presence of a terrorist threat was manipulated. Results showed that the more authoritarian participants were prior to the threat, the less they supported democratic values, the more they supported military aggression. It was concluded that threats increase the activation of an authoritarian response.

Repeated attacks (whether terrorist or military) appear to elicit support for escalating retaliatory actions among young, voting-age US citizens in controlled experiments [28]. Retaliatory responses were stronger when the attacks were perpetrated by terrorists rather than a militia. The signing of a peace treaty prior to attacks led males to retaliate more than females, supporting the thesis that men act with vengeance after a transgression while women pursue conciliation. In all permutations of their experiment (terrorist vs. military attack, peace treaty vs. no peace treaty, democratic vs. nondemocratic adversary), repeated attacks corresponded with responses that eventually matched or surpassed the conflict level of the initial attack. These studies have important implications for policies designed to contain conflicts.

The issue of civil liberties in the context of the US "War on Terror" has received extensive media coverage. The scholarly literature on this topic, however, is limited to correlational analyses based on public polling. Although these analyses do not permit causal inferences, they are highly informative. In a review of all the major political polls conducted pre- and post-September 11th, 2001, US respondents expressed increased willingness to abdicate civil liberties, increased confidence in the government's ability to protect the United States from terrorist threats, and increased support for the use of ground troops in combating terrorism [29]. In the months following the attacks, however, perceived threat declined, as did support for surveillance of Americans' communications and respondents' confidence in the US government's ability to prevent future attacks.

### 3.2 Prejudice and Social Cohesion

Well-established social psychological research on intergroup relations demonstrates that people placed into groups will discriminate against outgroup members and favor ingroup members [30]. When placed into groups, people also exaggerate the homogeneity of their ingroup and its distinctiveness from outgroups. These effects are even present when groups are formed on the basis of such trivial dimensions as one's estimation of how many dots appear on a piece of paper. These well-established research findings provide a backdrop to reports of rising anti-Arab and anti-Muslim prejudice in the United States since September 11th, 2001.

Nearly all studies of prejudice in the United States concern White prejudice toward Blacks. This focus warrants broadening, particularly in the light of evidence suggesting that prejudice directed more toward Arabs than Blacks [31]. Both immediately after 9/11 and one year later, American college students reported higher levels of prejudice toward Arabs than Blacks. Those students with higher levels of media exposure displayed higher levels of overall minority prejudice, whether toward Arabs or Blacks. Anti-Arab prejudice was also higher among those who more strongly endorsed social hierarchies, more strongly identified as "American", and believed future terrorist attacks are likely [32].

Terrorism is also linked to increased social cohesion, as international research demonstrates. Akhahena [33] documented how the terrorist bombing in Kenya (August 1998) helped Kenyans forge a new national identity that united previously fractured social identities. A negative aspect of increased social cohesion, however, is decreased intergroup contact. Persistent violence between Catholics and Protestants in Northern Ireland over the past 30 years has led to segregation in the areas of education, residence, and personal life. This segregation limits contact between Catholic and Protestant communities and arguably plays a major role in maintaining intergroup conflict [34].

### 3.3 Mental Health

Mental health has been the most intensively researched aspect of terrorism's psychological consequences, with posttraumatic stress disorder (PTSD) comprising the majority of studies. The most common psychological effects of a traumatic event such as a terrorist attack are acute stress disorder (in the short term) and PTSD (in the longer term), with depression, anxiety disorders, and substance abuse as the next most frequent effects [35].

Which factors determine who will suffer psychologically after a terrorist attack? This matter has been disputed. Silver et al. [36] conducted a nationally representative longitudinal study of US residents' psychological response to the attacks of September 11th, 2001. They found that proximity or degree of exposure was not a necessary precondition for high levels of acute and posttraumatic stress symptoms at 2 weeks and 12 months post-9/11. These results indicate the need to study the effects of indirect exposure to terrorism. In contrast, Schlenger's [37] review of the major studies of psychological distress post-9/11 concluded that PTSD following the attack was concentrated in the New York City metropolitan area. Furthermore, PTSD prevalence was strongly associated with direct connection to the attacks. Though many adults across the United States were distressed by the attacks, Schlenger [37] concludes that much of this distress resolved over time without professional treatment.

It is important to recognize that the vast majority of mental health literature follows a Euro-American academic traditional and adopts a Western medical perspective. It follows that important cross-cultural differences in response to terrorism may exist that are not captured by predominant methods. De Jong [38], for instance, has asserted that the predominant diagnostic criteria (DSM-IV and ICD-10) are not always appropriate for non-Western cultures.

Research on the effects of terrorism is little, but growing. The more expansive literature on traumatic events such as war and natural disasters can complement and further enrich our understanding of terrorism's social psychological consequences.

## 1 INTRODUCTION

Sträter begins his book *Cognition and Safety* with the statement "Human society has become an information processing society" [1, p. 3]. This statement is as true for homeland security tasks as for any other tasks that require people to interact with machines and other people in complex systems. Homeland security involves people interacting with information technology, and use of this technology to communicate effectively is an important aspect of security [2]. For communication to be effective, human–machine interactions must conform to users perceptual, cognitive, and motoric capabilities. In particular, because all information that a person processes enters by way of the senses, sensory and perceptual processes are going to be critical factors. These processes are relevant to detecting a weapon in luggage during screening, identifying vulnerable targets for which risk is high, and communicating warnings to individuals. Given the masses of data extracted from intelligence gathering activities of various types, these data need to be integrated and displayed to appropriate security personnel in an easy to perceive form at the proper time. These and other aspects of homeland security systems require an understanding of fundamental concepts of sensation and perception.

## 2 BACKGROUND

Much is known about the methods for studying perception, the structure and function of the sensory systems, and specific aspects of perception such as the role of attention [3]. Understanding how people sense, perceive, and act on the information they receive is essential for homeland security because many of the surveillance tasks involve monitoring, detecting, and reporting events.

This article provides an overview of sensation and perception, with emphasis on topics that seem relevant to homeland security. Five sensory modalities are typically distinguished: vision, hearing, touch, smell, and taste—all of which are relevant to certain aspects of homeland security. For the sake of brevity, we cover vision and hearing in most detail, describing the other senses only briefly. The reader is referred to longer and more specialized review chapters [4], as well as to textbooks on sensation and perception [3].

All sensory systems have receptors that convert physical stimulus energy into electrochemical energy in the nervous system. The sensory information is coded in the activity of neurons and travels to the brain via structured pathways consisting of interconnected

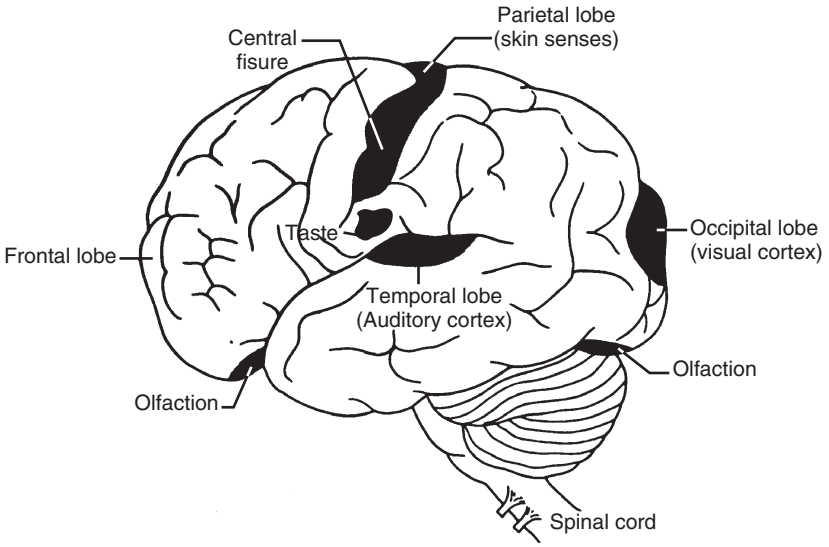

**FIGURE 1** Illustration of the primary sensory receiving areas in the cerebral cortex.

networks of neurons. For most senses, two or more pathways operate in parallel to analyze and convey different kinds of information from the sensory signal. The pathways project to primary receiving areas in the cerebral cortex (Fig. 1) and then to many other areas within the brain.

The study of sensation and perception involves not only the anatomy and physiology of the sensory systems, but also behavioral measures of perception. Psychophysical data obtained from tasks in which observers detect, discriminate, rate, or recognize stimuli provide information about how the properties of the sensory systems relate to what is perceived. They also provide information about the functions of higher-level brain processes that interpret the sensory input through mental representation, decision-making, and inference. Thus, perceptual experiments provide evidence about how the sensory input is organized into a coherent percept on which actions are based.

## 3 METHODS FOR INVESTIGATING SENSATION AND PERCEPTION

Many methods for studying sensation and perception exist. We emphasize behavioral and psychophysiological methods because of their relevance to homeland security.

### 3.1 Threshold Methods and Scaling

Classical psychophysical methods for measuring detectability and discriminability of stimuli are based on the concept of a threshold, the minimum amount of stimulation necessary for an observer to detect a stimulus (absolute threshold) or distinguish a stimulus from another one (difference threshold). Examining how thresholds change in different settings can tell us much about perception and whether specific stimuli such as alarms

may be effective. Many techniques have been developed for measuring thresholds in basic and applied settings [5].

Classical psychophysics also provides methods for building scales of perceived magnitude [6]. Indirect methods construct scales from an observer's accuracy at discriminating stimuli, whereas direct methods construct scales from an observer's magnitude estimates. Scaling methods can be used to quantify perceptual experience on any dimension that varies in magnitude, such as perception of risk. They can be used as design tools in development of new methods for displaying information, for example, data sonifications (representations of data by sound; [7]).

### 3.2 Signal Detection Methods

An observer's judgments, when stimuli are difficult to detect or discriminate, are influenced by the willingness to give one response or another. Signal detection methods allow measurement of this response criterion, or bias, separately from detectability or discriminatiblity [8]. Situations for which signal detection is applicable involve a "signal" (e.g. a weapon in luggage) that an observer must discriminate from "noise" (e.g. other items in luggage). If the observer is to respond "yes" when a signal is present and "no" when it is not, the outcome can be classified as a hit ("yes" to signal), false alarm ("yes" to noise), miss ("no" to signal), or correct rejection ("no" to noise). Measures of detectability (how accurately a weapon can be discriminated from other items) can be calculated based on the difference between hit and false alarm rates, and measures of response bias (the tendency to open the luggage regardless of whether a weapon is present) on overall rate of responding "yes" versus "no".

For a given level of detectability, the possible combinations of hit and false-alarm rates vary as a function of the observer's response criterion. For example, immediately after a terrorist attempt, screeners may adopt a liberal criterion and open any luggage that they think might possibly contain a weapon, yielding a high hit rate coupled with a high false alarm rate. Detectability can be improved by providing better screening equipment and operator training, whereas a desired response bias can be induced by an appropriate reward system. Signal detection methods and theory provide powerful tools for investigating and conceptualizing performance of other security-related tasks such as maintaining vigilance [9].

### 3.3 Psychophysiological Methods and Brain Imaging

Methods for measuring physiological reactions to stimuli are useful in studying perception [10]. Measures of electrical brain activity, electroencephalograms, can be recorded from the scalp. Event-related potentials, which measure brain activity locked to an event such as stimulus onset, provide detailed information about the timecourse of brain activation. Functional neuroimaging techniques, which measure brain activity indirectly through bloodflow, provide insight into the spatial organization of brain functions. These methods can be used to determine whether a particular behavioral phenomenon has its locus in processes associated with sensation and perception or with subsequent response-selection and execution. Their use for applied purposes is being explored in the areas of neuroergonomics [11] and augmented cognition [12], which have the goals of implementing

and adapting high-technology interfaces to facilitate communication of large amounts of information.

## 4 VISION

Vision is arguably the most vital sense for interacting with the world. It provides detailed information about objects in the surrounding environment, and their locations and movements. Complex information can be depicted in high fidelity displays that mimic the external environment, more abstract graphical formats that represent data or interactions among system components, and alphanumerically to convey verbal messages and numerical values.

### 4.1 Visual Sensory System

The stimulus for vision is light energy generated by, or reflected from, objects in the environment. Light travels in waves, with the wavelengths of the visual spectrum varying from 400 to 700 nm. Light enters the eye through the cornea and passes through the pupil and lens (Figure 2). The pupil adjusts between 8 and 2 mm diameter in dim and bright light, respectively, allowing a larger percentage of light to enter when it is scarce. The cornea and lens focus images on the photoreceptors, located on the retina at the back of the eye. The cornea provides a fixed focusing power, and the lens changes its shape through a process of accommodation to provide increased focusing power as the distance of a fixated object changes from far to near. The amount of rotation of the eyes inward, the vergence angle, also increases as the distance of a fixated object is reduced. Because accommodation and vergence require muscular activity, tasks that necessitate rapid and numerous changes in them will cause visual fatigue.

The retina contains two types of photoreceptors, rods and cones, which have photopigments that begin a process of converting light into neural signals. Rods are responsible for night vision and do not support color perception. Cones are responsible for daylight vision and for perception of color and detail. The image of a fixated object will fall on the fovea, a small retinal region containing only cones. The retina also contains another region, the blind spot, where the optic nerve leaves the eye and there are no photoreceptors.

The nerve fibers leaving the eye form two pathways. One is devoted to rapid transmission of global information across the retina. It carries high temporal frequency information

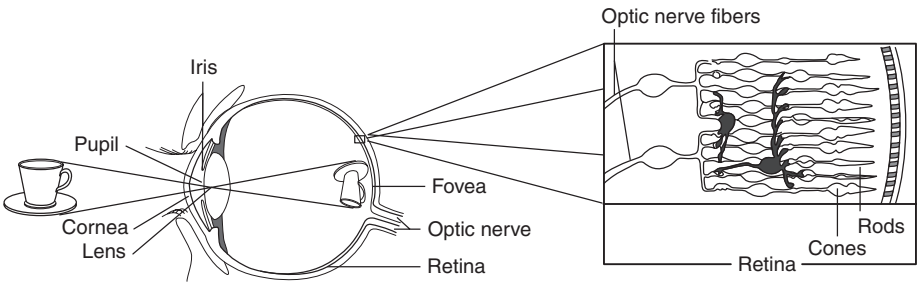

**FIGURE 2** Illustration of the primary structures of the eye, with an object's image focused on the retina. (Adapted from E. B. Goldstein (2002). /Sensation and Perception/ (6th ed.). Pacific Grove, CA: Wadsworth.)

needed for motion perception and detection of abrupt changes. The other is devoted to slower transmission of detailed features from the fovea and plays a role in color and pattern perception.

The optic nerve projects into the lateral geniculate nucleus and then into the primary visual cortex, located at the back of the brain. More than 30 cortical areas subsequent to the primary visual cortex are involved in the processing of visual information [13]. Two different pathways play distinct roles in perception. The ventral pathway, which goes to a region in the temporal lobe, is involved in identifying objects. The dorsal pathway, which goes to a region in the parietal lobe, is involved in determining where objects are located. This dissociation of what and where processing affects performance as well; for example, navigational tasks that rely on "where" information are performed well under low lighting levels at which pattern recognition is impaired [14].

### 4.2 Visual Perception

Sensitivity to light increases for a period after entering the dark (see Figure 3). Several factors contribute to this dark-adaptation process: larger pupil size, photopigments returning to a light sensitive state, and shift from cones to rods. Because cones have a spectral sensitivity function that peaks at higher wavelengths than that for rods, short wavelength stimuli appear relatively brighter when dark adapted. Displays intended for use in the field need to be designed with the different sensitivities of day and night vision taken into account.

Acuity is high in the fovea and decreases as stimulus location becomes more peripheral. The acuity function is due to the density of cones being greatest in the fovea (see Figure 4) and to less convergence of foveal than peripheral photoreceptors in the sensory pathway. Acuity can be measured in several ways, including with a standard Snellen eye chart, that are not perfectly correlated. Resolution acuity can be specified by a spatial

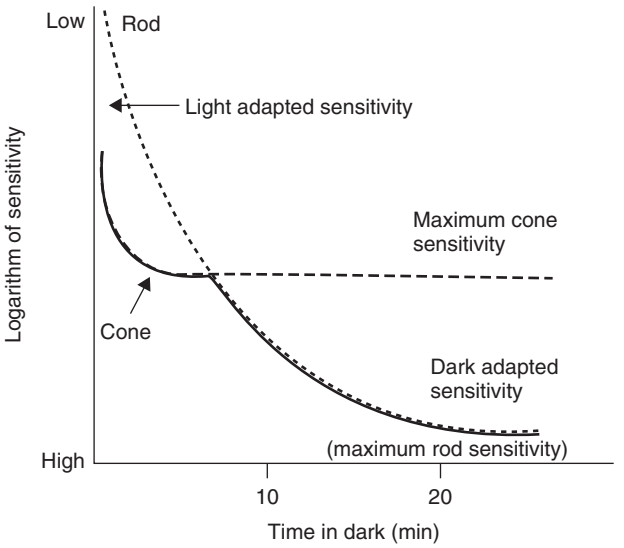

**FIGURE 3** Dark adaptation function illustrating sensitivity to visual stimuli as a function of time in the dark for cone and rods.

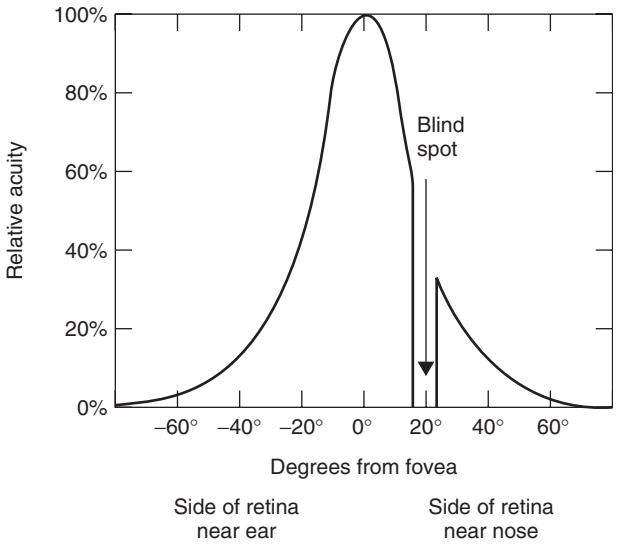

**FIGURE 4** Visual acuity as a function of retinal location.

contrast sensitivity function, which for an adult shows maximum sensitivity at a spatial frequency of 3–5 cycles/degree of visual angle. Because high spatial frequencies convey detail and low frequencies the global properties of stimuli, acuity tests based on contrast sensitivity provide a more detailed analysis than standard acuity tests about aspects of vision necessary for performing various tasks. For example, contrast sensitivity at intermediate and low spatial frequencies predicts detectability of signs at night [15].

An abrupt change in a display to signal a change in system mode may go undetected. The change is more likely to attract attention if it is signaled by a flickering stimulus. Conversely, stimuli such as displays on cathode ray tube (CRT) screens may flicker but with the intent of being seen as continuous. The highest rate at which flicker can be perceived is called the *critical flicker frequency*. A display intended to be seen as flickering should be well below the critical flicker frequency, whereas a display intended to be seen as continuous should be well above that frequency.

People show good lightness constancy, which is that a stimulus appears to be constant on a white-to-black dimension under different amounts of illumination. However, *lightness contrast*, for which an object looks darker when a surrounding or adjacent object is white rather than black, may occur when the intensity of local regions is changed, as in displays or signs.

Because color perception is a function of the output of the three cone types, color vision is trichromatic: Any spectral color can be matched by a combination of three primary colors from the short, middle, and long wavelength regions of the spectrum. This fact is used in the design of color televisions and computer monitors, for which all colors are generated from combinations of pixels of three different colors. For many perceptual phenomena, blue and yellow are paired in opposing manners, as are red and green: One color of the pair may produce an afterimage of the other; a background of one color may induce the other in a figure that would otherwise be seen as a neutral color; combinations of the two colors are not perceived. These complimentary color relations are based in the visual sensory pathways. That is, output from the cones is rewired

into opponent-process neural coding in the optic nerve. A given neuron can signal, for example, blue or yellow, but not both at the same time. Finally, 8% of males are color blind and cannot distinguish all colors that a person with trichromatic vision can, which may cause objects in those colors to be less conspicuous [16]. The use of color to convey information, thus, must be done with care.

### 4.3 Higher-Level Properties of Visual Perception

The patches of light stimulating the photoreceptors must be organized into a perceptual world of meaningful objects. This is done effortlessly in everyday life, with little confusion. However, organization can be critical for constructed displays. A symbol on a sign that is incorrectly grouped may not be recognized as intended. Similarly, if a warning signal is grouped perceptually with other displays, then its message may be lost. The investigation of perceptual organization was begun by Gestalt psychologists.

According to the Gestalt psychologists, perceptual organization follows the *principle of präagnanz*: The organizational processes will produce the simplest possible organization allowed by the conditions [17]. The first step in perceiving a figure requires separating it from the background. The importance of *figure-ground* organization is seen in figures with ambiguous figure-ground organizations, as the well-known Ruben's vase (see Figure 5). When a region is seen as figure, the contour appears to be part of it, the region seems to be in front of the background, and it takes on a distinct form.

Several factors influence figure-ground organization: Symmetric rather than asymmetric patterns tend to be seen as figure; a region surrounded completely by another tends to be seen as figure and the surround as background; the smaller of two regions tends to be seen as figure and the larger as ground. Figure-ground principles can be used to camouflage targets in the field.

The way that the figure is grouped is also important to perception. *Grouping principles* include: proximity—display elements that are located close together will tend to be grouped together; similarity—display elements that are similar in appearance, for example, orientation or color, will tend to be grouped together; continuity—figures will tend to be organized along continuous contours; closure—display elements that make up a closed figure will tend to be grouped together; and common fate—elements with a common motion will tend to be grouped together; connectedness—elements can be grouped

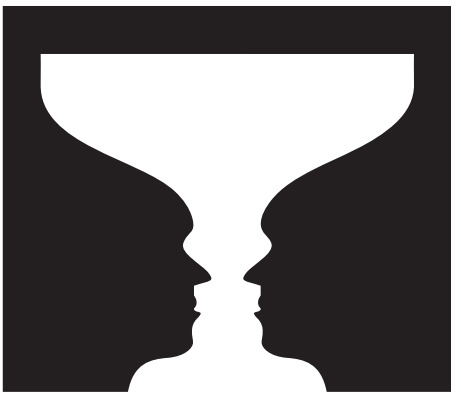

**FIGURE 5** Ruben's vase: An illustration of reversible figure-ground relations.

by lines connecting them; and common region—a contour drawn around elements will cause those elements to be grouped together.

Another distinction is between *integral* and *separable* stimulus dimensions [18]: Stimuli composed from integral dimensions are perceived as wholes, whereas those composed from separable dimensions are perceived in terms of their component dimensions. Speed of classification on one dimension is unaffected by the relation to the other if the dimensions are separable. However, for integral dimensions, classifications are slowed when the value of the irrelevant dimension is uncorrelated with that of the relevant dimension but speeded when the two dimensions are correlated. Combinations of hue, saturation, and lightness, and of pitch and loudness have been classified as integral, and size with lightness or angle as separable.

The distinction between integral and separable dimensions is incorporated in the proximity compatibility principle [19]: If a task requires information to be integrated mentally (i.e. processing proximity is high), then that information should be presented in an integral display (i.e. one with high display proximity). High display proximity can be accomplished by increasing the spatial proximity of the display elements so that the elements are integrated and appear as a distinct object. The idea is to replace the cognitive computations that someone must perform to combine the pieces of information with a less mentally demanding pattern-recognition process.

To survive, a person must be able to perceive locations of objects accurately. Moreover, representational displays should provide the information necessary for accurate spatial perception. Many cues play roles in the perception of distance and spatial relations [20, see Figure 6], and the perceptual system constructs the three-dimensional percept using these cues. Among the possible depth cues are accommodation and vergence angle, which, at relatively close distances, vary systematically as a function of the distance of the fixated object from the observer. Binocular disparity is a cue that is a consequence of the two eyes viewing objects from different positions. A fixated object falls on corresponding points of the two retinas. For objects in front of or behind a curved region passing through the fixated object, the images fall on disparate locations. The direction and amount of disparity indicate how near or far the object is from fixation. Binocular disparity is a strong cue to depth that can enhance the perception of depth relations in displays of naturalistic scenes and may be of value to scientists and

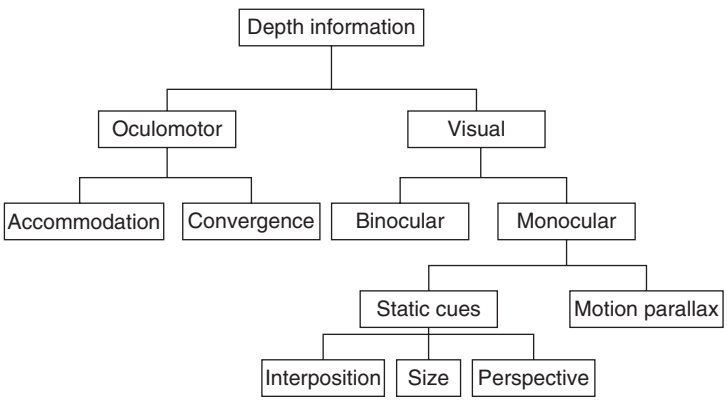

**FIGURE 6** Diagram of oculomotor and visual depth cues. (Adapted from R. Sekuler and R. Blake (1994). /Perception/ (3rd ed.). New York: McGraw Hill.)

others in evaluating multidimensional data sets (e.g. a three-dimensional data set could be processed faster and more accurately to answer questions that required integration of the information if the display was stereoptic than if it was not [21]).

There are many static, or pictorial, monocular cues to depth. These include retinal size—larger images appear to be closer—and familiar size—for example, a small image of a car provides a cue that the car is far away. The cue of interposition is that an object that appears to block part of the image of another object located in front of it. Other cues come from shading, aerial perspective, and linear perspective. Texture gradient, which is a combination of linear perspective and relative size, is important in depth perception [22].

Depth cues become dynamic when an observer moves. If fixation is maintained on an object and as location changes, as when looking out a train window, objects in the background will move in the same direction in the image as you are moving, whereas objects in the foreground will move in the opposite direction. This cue is called *motion parallax*. When you move straight ahead, the optical flow pattern conveys information about how fast your position is changing with respect to objects in the environment [23].

The size of the retinal image of an object varies as a function of the object's distance from the observer. When accurate depth cues are present, size constancy results: Perceived object size does not vary as a function of changes in retinal image size that accompany changes in depth. Size constancy breaks down and illusions of size appear when depth cues are misleading. Misperceptions of size and distance also can occur when depth cues are minimal, as when navigating at night.

For displayed information to be transmitted accurately, the objects and words must be recognized. Pattern recognition is typically presumed to begin with feature analysis. Alphanumeric characters are analyzed in terms of features such as vertical or horizontal line segments (see Figure 7). Confusion matrices obtained when letters are misidentified indicate that an incorrect identification is most likely to be a letter whose features overlap with the one that was displayed. Letters are components of syllables and words. Numerous studies have provided evidence for the need to distinguish several different levels of reading units [24].

Pattern recognition is also influenced by "top-down" information of several types [25]: regularities in mapping between spelling and spoken sounds and orthographic, syntactic, semantic, and pragmatic constraints. For accurate pattern recognition, the possible alternatives need to be physically distinct and consistent with expectancies created by the context.

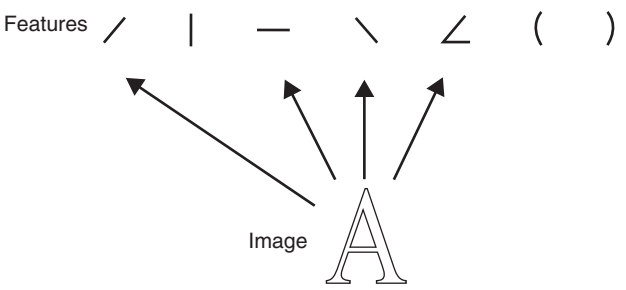

**FIGURE 7** Pattern (letter) recognition through analysis of features.

For a skilled reader, the pattern recognition involved in reading occurs almost instantaneously and relatively automatically. This is true for other pattern recognition skills as well (e.g. identifying enemy tanks or intrusion detection patterns). The important point is that, with experience, people can come to recognize very complex patterns that would seem meaningless to a novice. In fact, it is generally that efficient pattern recognition underlies expertise in most domains [26]. Some stimuli, such as faces, are special in that they are processed by different areas of the brain from other objects and their recognition is more sensitive to global configuration and orientation [27].

## 5 HEARING

The sense of hearing is also used extensively to convey information [2]. It is an effective modality for warnings, due to sound being able to be heard from any direction and because rapid onsets tend to attract attention.

### 5.1 Auditory Sensory System

Sound waves are fluctuations in air pressure produced by mechanical disturbances; the frequency of oscillations correlates with the sound's pitch and the amplitude with its loudness. A sound wave moves outward from its source at 344 m $s^{-1}$, with the amplitude being a decreasing function of distance. When sound reaches the outer ear, it is funneled into the middle ear (see Figure 8). The eardrum, which separates the outer and middle ears, vibrates in response to the fluctuations in air pressure produced by the sound wave. The middle ear contains a system of three bones that move when the eardrum vibrates, and this movement gets transferred to the fluid-filled inner ear. A flexible membrane, the basilar membrane, runs the length of the inner ear. Movement of this membrane bends hair cells, which are the sensory receptors that initiate neural signals.

The pathways from the auditory nerve project to the primary auditory cortex in the temporal lobe after first passing through several neuroanatomical structures. The auditory cortex contains neurons that extract complex features of auditory stimulation.

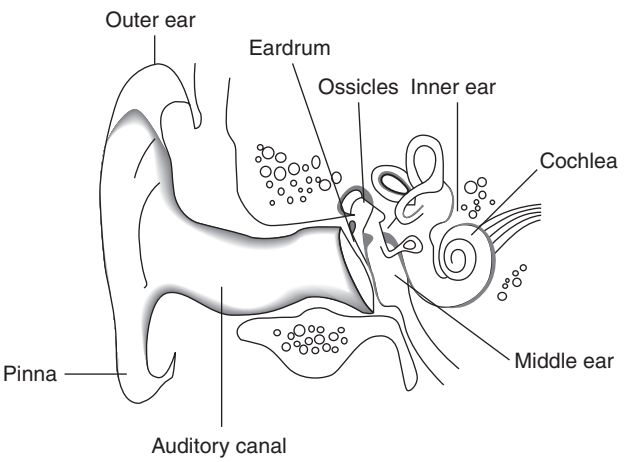

**FIGURE 8** Illustration of the major structures of the ear.

## 5.2 Auditory Perception

Loudness is affected by many factors in addition to amplitude. Humans are insensitive to tones below 200 Hz and, to a lesser extent, to tones exceeding 6 kHz. This is illustrated by equal loudness contours, which show that low and high frequency sounds must be of higher amplitude to be of equal loudness to tones of intermediate frequency (see Figure 9).

Extraneous sounds can mask targeted sounds. This is important for work environments, in which audibility of auditory input must be evaluated with respect to the level of background noise. The amount of masking depends on the spectral composition of the target and noise stimuli. Masking only occurs from frequencies within a critical bandwidth. A masking noise will exert a much greater effect on sounds of higher frequency than on sounds of lower frequency, with this asymmetry due to properties of the basilar membrane.

## 5.3 Higher-Level Properties of Auditory Perception

The principles of perceptual organization apply to auditory stimuli. Grouping can occur on the basis of similarity (e.g. frequency) and spatial and temporal properties (see Figure 10). Tones can be grouped into distinct streams based on similarities on various dimensions [28].

Being able to identify where a threat is coming from is important to survival. Two different sources of information, interaural intensity and time differences, are relied on to

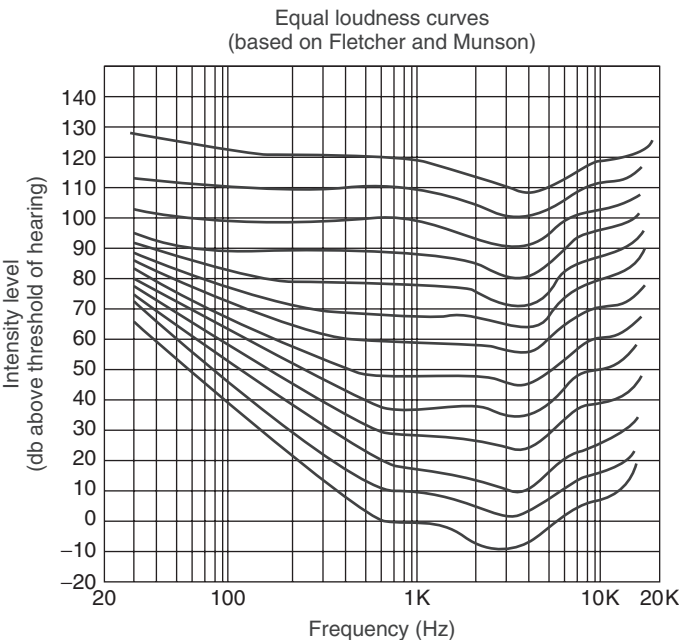

**FIGURE 9** Equal loudness contour curves. Each curve indicates the intensity for tones of different frequencies required for the tones to sound equally loud as a 1KHz tone at the indicated intensity level.

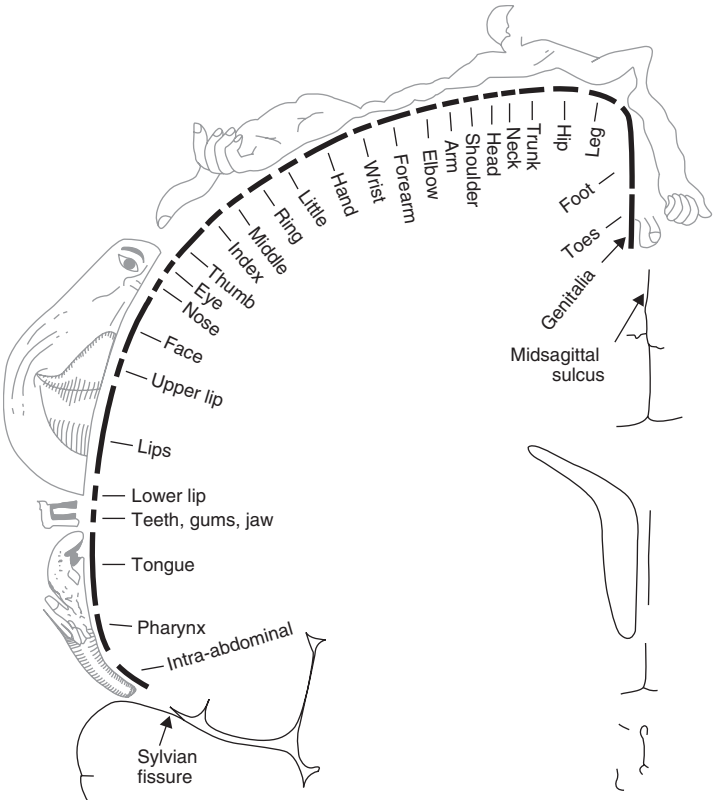

**FIGURE 10** Somatotopic map of the cerebral cortex. (Based on one from W. Penfield & T. Rasmussen (1950). "The cerebral cortex of man." New York: Macmillan.)

perceive the location of sound around us. At the front and back of the listener, the intensity of the sound and the time at which it reaches the ears is equal. As the sound moves progressively toward one side or the other of the listener's head, the sound becomes increasingly more intense at the closer ear than at the farther one, and it also reaches the ipsilateral ear first. The interaural intensity cue is most effective for high frequency tones, and the interaural time cue for low frequency sounds. Localization accuracy is poorest for tones between 2 and 4 kHz, where neither cue is effective. Because both cues are ambiguous at the front and back, front-back confusions of the location of brief sounds often occur.

## 6 BODY SENSES, SMELL, AND TASTE

Though we cannot go into detail on the remaining sensory modalities, they have important implications for homeland security as well.

### 6.1 Touch, Proprioception, Pain, and Temperature

The body senses are composed of four distinct modalities [29]—touch, proprioception, pain, and thermal sensations—that are elicited respectively by mechanical stimulation

of the skin, mechanical displacements of the muscles and joints, stimuli of sufficient intensity to damage tissue, and cool and warm stimuli. The receptors for these senses are the endings of neurons located in the back side of the spinal cord. The fibers follow two major pathways, dorsal and anterolateral. The former pathway conveys information about touch and proprioception, and the latter information about pain and temperature.

The fibers project to the somatosensory cortex, which is organized as a homunculus representing the opposite side of the body. Areas of the body for which sensitivity is greater have larger areas devoted to them than areas with lesser sensitivity (see Figure 10). Some of the cells respond to complex features of stimulation, such as movement of an object across the skin.

*Vibrotaction* is an effective way for transmitting complex information [30]. When mechanical vibrations are applied to a region of skin, the frequency and location of the stimulation can be varied. For frequencies of less than 40 Hz, the size of the contactor area does not influence the absolute threshold for detecting vibration. For higher frequencies, the threshold decreases with increasing size of the contactor, indicating spatial summation of the energy within the stimulated region. For multicontactor devices, which can present complex spatial patterns of stimulation, masking stimuli presented in close temporal proximity to the target stimulus can degrade identification. However, with practice, pattern recognition capabilities with these types of devices can become quite good. As a result, they can be used as reading aids for the blind and to a lesser extent as hearing aids for the hearing impaired [30].

A distinction is commonly made between active and passive touch [31]. Passive touch refers to situations in which the individual does not move her hand, and the touch stimulus is applied passively, as in vibrotaction. Active touch refers to situations in which the individual intentionally moves the hand to manipulate and explore an object. Pattern recognition with active touch is superior to that with passive touch. However, the success of passive vibrotactile displays for the blind indicates that much information can also be conveyed passively.

### 6.2 Smell and Taste

Smell and taste can communicate information about potential danger. The smell of a toxic substance or taste of rancid potato chips may be noxious and convey that they should not be consumed. Contaminated water also may have a noxious smell and taste, and a chemical attack may produce a burning sensation in the throat and nose. Both sensory modalities can be used for warning signals. For example, ethylmercaptan is added to natural gas to warn of gas leaks because humans are sensitive to its odor.

The sensory receptors for taste are groups of cells called *taste buds* located on the tongue, throat, roof of the mouth, and inside the cheeks. Sensory transduction occurs when a taste solution comes in contact with the taste buds. The nerve fibers from the taste receptors project to several nuclei in the brain and then to the insular cortex, located between the temporal and parietal lobes, and the limbic system. Four basic tastes can be distinguished: sweet, sour, salty, and bitter, though many sensations fall outside of their range [32].

For smell, molecules in the air that are inhaled affect receptor cells located in a region of the nasal cavity. Different receptor types have different proteins that bind the odorant molecules to the receptor. The fibers from the smell receptors project to the olfactory

bulb, located in the front of the brain. From there, the fibers project to a cluster of neural structures called the *olfactory brain*. Although odors are useful as warnings, they are not very effective at waking someone from sleep, which is why smoke detectors that emit a loud sound are needed. The sense of smell shows considerable plasticity, with associations of odors to events readily learned and habituation occurring to odors of little consequence [33].

## 7 MULTIMODAL SENSORY INTERACTIONS AND ROLE OF ACTION

In everyday life, we receive input constantly through the various senses. This input must be integrated into a coherent percept. It is important, therefore, to understand how the information from different senses is weighted and combined in perception, and how processing of input from one modality is affected by processing of input from another [34].

Many systems tend to overload the visual system with displays. As a result, there is an increased interest in using multimodal display technologies, which uses other modalities to augment visual perception. For example, auditory and tactile displays have been used to direct an observer's attention to certain areas of a visual display that require further analysis [35]. Multimodal displays also allow information to be presented to users in virtual worlds that represent real-world interactions of the senses [36].

The use of multiple display and control modalities enables different ways of presenting and responding to information, the incorporation of redundancy into displays, and emulation of real-life environments. Multimodal interfaces can reduce mental workload and make human-computer interactions more naturalistic. However, designing effective multimodal interfaces is a challenge because many interactive effects between different modalities may arise. These effects must be taken into account if the full benefits of multimodal interfaces are to be realized.

There is a tendency to think of perception independent from action because "input precedes output." However, a close relation between perception and action exists. For example, it is natural to orient attention to the location of a sound, making auditory displays a good choice for actions that require users to respond to the location of the sound (e.g. fire alarms should be place close to the exit). As a result, the decisions and actions that need to be made in response to a signal or display must be taken into account when designing to optimize perception [37].

## 8 CONCLUSION

Many of the technical devices that have been, and are being, developed to aid in homeland security depend on successful human-system interactions. Human perception is an important aspect of such interactions. Operators must be able to sense and perceive the displayed information accurately and efficiently, and in a way that maps compatibly onto the tasks and actions that they must perform, for the system to achieve its goals. Regardless of the exact forms that future security technologies take, as long as humans are in the system the basic principles and concepts of sensation and perception must be taken into account.

## 1 INTRODUCTION

Terrorism at its core is a human endeavor. Human beings cultivate what they hate, plan, and then execute terrorist attacks. Thus, any information that can aid the intelligence or security officer to weigh the veracity of the information he or she obtains from suspected terrorists or those harboring them would help prevent attacks. This would then not only add another layer to force protection but would facilitate future intelligence gathering. Yet the face-to-face gathering of information through suspected terrorists, informants, or witnesses is replete with obstacles that affect its accuracy such as the well-documented shortcomings of human memory, honest differences of opinion, as well as what is the focus of this article—outright deception [1].

The evidence suggests that in day-to-day life most lies are betrayed by factors or circumstances surrounding the lie, and not by behavior [2]. However, there are times when demeanor is all a Homeland security agent has at his or her disposal to detect someone who is lying about his or her current actions or future intent. Because a lie involves a deliberate, conscious behavior, we can speculate that this effort may leave some trace, sign, or signal that may betray that lie. What interests the scientist, as well as society at large, is (i) are there clues perceptible to the unaided eye that can reliably discriminate between liars and truth tellers; (ii) do these clues consistently predict deception across time, types of lies, different situations, and cultures?; and if (i) and (ii) are true, then (iii) How well can our counter-terrorism professionals make these judgments, and can they do this in real time, with or without technological assistance?

## 2 SCIENTIFIC OVERVIEW—BEHAVIORAL SIGNS OF DECEPTION

To date no researcher has documented a "Pinocchio response"; that is, a behavior or pattern of behaviors that in all people, across all situations, is specific to deception (e.g. [3]). All the behaviors identified and examined by researchers to date can occur for reasons unrelated to deception. Generally speaking, the research on detecting lies from behavior suggests that two broad families of behavioral clues are likely to occur when someone is lying—clues related to liar's memory and thinking about what they are saying (cognitive clues), and clues related to liar's feelings and feelings about deception (emotional clues) [3–8].

### 2.1 Cognitive Clues

A lie conceals, fabricates, or distorts information; this involves additional mental effort. The liar must think harder than a truth teller to cover up, create events that have not happened, or to describe events in a way to allow multiple interpretations. Additional mental effort is not solely the domain of the outright liar; however, a person who must tell an uncomfortable truth to another will also engage in additional mental effort to come up with the proper phrasing while simultaneously reducing the potential negative emotional reaction of the other. This extra effort tends to manifest itself with longer speech latencies, increased speech disturbances, less plausible content, less verbal and vocal involvement, less talking time, more repeated words and phrases, and so forth [9]. Research has also shown that some nonverbal behaviors change as a result of this mental effort. For example, illustrators—hand or head movements that accompany speech, and are considered by many to be a part of speech (e.g. [10])—will decrease when lying compared to telling the truth [11, 12].

Another way in which cognition is involved in telling a lie is through identification of naturalistic memory characteristics. This means that experienced events have memory qualities that are apparent upon description that are different from events that have not been experienced (the "Undeutsch hypothesis" [13]). Events that were not actually experienced feature more ambivalence, have fewer details, a poorer logical structure, less plausibility, more negative statements, and are less embedded in context. Liars are also less likely to admit lack of memory and have less spontaneous corrections (reviewed by [8, 9]), and may use more negative emotion words and fewer self and other references [14]. Mental effort clues seem to occur more in the delivery of the lie, whereas memory recall clues tend to rest more in the content of the lie.

We note that not all lies will tax mental effort; for example, it is much less mentally taxing to answer a close ended question like "Did you pack your own bags?" with a yes or no than to answer an open ended "What do you intend to do on your trip?" Moreover, a clever liar can appear more persuasive if he or she substitutes an actual experienced event as their alibi rather than creating an entirely new event. This may be why a recent general review paper [9] found consistent nonhomogeneous effect sizes for these mental effort and memory-based cues across the studies they reviewed, as the particular paradigms used by researchers varied greatly in the extent to which the lies that were studied mentally taxed the liars.

### 2.2 Emotional Clues

Lies can also generate emotions, ranging from the excitement and pleasure of "pulling the wool over someone's eyes" to fear of getting caught to feelings of guilt [4]. Darwin [15] first suggested that emotions tend to manifest themselves in the facial expressions, as well as in the voice tones, and that these could be reliable enough to accurately identify emotional states. Research has since shown that for some expressions—e.g. anger, contempt, disgust, fear, happiness, sadness/distress, or surprise—cultures throughout the planet recognize and express these emotions in both the face and voice similarly [16]. To the extent that a lie features higher stakes for getting caught, we would expect to see more of these signs of emotion in liars compared to truth tellers. If the lie is a polite lie that people tell often and effortlessly, there would be less emotion involved (e.g. [17]). Meta-analytic studies suggest that liars do appear more nervous than truth tellers, with

less facial pleasantness, higher vocal tension, higher vocal pitch, greater pupil dilation, and fidgeting [9]. If the lie itself is about emotions—e.g. telling someone that one feels calm, when in fact one is nervous—the research shows that signs of the truly felt emotion appear in the face and voice despite attempts to conceal, although these signs are often subtle and brief [18, 19].

### 2.3 Measurement Issues

One issue in measuring lie signs is to make clear what is meant by the terms cognition and emotion. For example, in deception research, the term arousal is used interchangeably with emotion, but often refers to many different phenomena: an orienting response [20], an expression of fear [21], a more indeterminate affect somewhere between arousal and emotion ([22]; see also discussion by Waid and Orne [23]), as well as physiological states as different as stress, anxiety, embarrassment, and even anger [24].

A second issue in measuring lie signs is to clarify the level of detail of measurement as well as to specify why that level of detail may or may not correlate with lying [25]. Many meta-analyses of behavioral deception clues report insignificant effect sizes, but the variance among effect is not homogeneous (e.g. [3, 9, 26–28]). For example, some studies investigated behavior at the most elemental *physical* units of measurement such as counting the movements in the hands, feet, arms, legs, torso, eye movements, eye blinks, pupil dilation, lip pressing, brow lowering or raising, lip corner puller (smiling), fundamental frequency, amplitude, pauses, filled pauses, response latency, speech rate, length of response, connector words, unique words, self-references, and so forth. Other studies investigated behavior at the most elemental *psychological meaning* units of measurement. Some of these included manipulators—which involve touching, rubbing, etc., of various body parts—which could be composed of a number of hand, finger, and arm movements, but which were scored for theoretical rather than merely descriptive reasons. Other psychologically meaningful units of measurement include illustrators, which accompany speech to help keep the rhythm of the speech, emphasize a word, show direction of thought, etc. or emblems, which are gestures that have a speech equivalent, such as a head nod meaning "yes", or a shrug meaning "I am not sure", or facial emblems such as winking. The psychological meaning units might also include vocal tension, speech disturbances, negative statements, contextual embedding, unusual details, logical structure, unexpected complications, superfluous details, self-doubt, and so forth. Finally, other studies investigated behavior at the most *interpretative/impressionistic* unit level, which are further unarticulated composites of the physical and the psychological meaning units described earlier. Some of these impressionistic variables of the behaviors include fidgeting, involvement, body animation, posture, facial pleasantness, expressiveness, vocal immediacy and involvement; and spoken uncertainty; plausibility; and cognitive complexity (see review by [9]). The problem of course is that as one moves from physical to impressionistic measures, it would seem to become harder to make those judgments reliably. This is not always the case though, for example, the term "smile" has rarely been defined in research reports, yet independent coders are typically above 0.90 reliability when coding smiles (see [29] for a review). Although research works suggest that people can be more accurate when they employ indirect inferences to deception (e.g. does the person have to think hard? [30]), "gut" impressions tend to be uncorrelated with accuracy [26]. This suggests that we must be cautious about clues at the impressionistic level, and

that it may be more productive to study them at their psychological level where they might be more meaningful to understanding deception.

### 2.4 Prognosis on Generalizability of Deception Findings Across Time, Lies, Situations, and Cultures

It is safe to conclude that although there are some clues that betray a lie at rates greater than chance, none of them are exclusive to deception. This conclusion applies to machine based physiological approaches as well. However, the origins of these signs—mental effort, memory, and emotion—are universal. This suggests that if the context in which the information is gathered is controlled, and designed to differentially affect liars and truth tellers, it would increase greatly the chances of being able to distinguish people with deceptive intent from those with truthful intent. Polygraph examination has done this by controlling their question style to improve hit rates, but to date this has not been done systematically in behavioral studies. Thus its effects are unknown, but we can speculate based upon what we know about normal, truthful human behavior. If the lie is of no significance to the person, with no costs for getting caught, and involves a simple yes or no answer, odds are there will not be many clues to distinguish the liar from the truth teller. If the situation has significance to the person, there are consequences for getting caught, and the person is required to recount an event in an open ended question, then we would expect more clues to surface that would distinguish the liar from the truth teller. This may be a curvilinear relationship; a situation of extraordinary high mental effort and emotion—e.g. one in which a person is being beaten, screamed at, and threatened with execution—will generate all the "lie clues" described earlier, but equally in liar and truth teller. Nonetheless, information about mental effort, experienced memory, and emotion can be very useful clues to Homeland Security personnel to identify behavioral "hot spots" [4] that can provide information about issues of importance to the subject. A counter-terrorism Intelligence officer who knows when a subject is feeling an emotion or thinking hard can know what topics to pursue or avoid in an interview, whether the subject is fabricating, concealing information, or merely feeling uncomfortable with the topic, although truthful.

## 3 SCIENTIFIC OVERVIEW—ABILITIES TO SPOT LIARS

Research over the past 30 years suggests that the average person is slightly statistically better than chance at identifying deception, but not practically better. The most recent review of over 100 studies has shown that when chance accuracy is 50%, the average person is approximately 54% accurate [31]. There are a number of reasons for this poor ability; among them poor feedback in daily life (i.e. a person only knows about the lies they have caught); the general tendency among people to believe others until proven otherwise (i.e. a "truth bias"; [32]), and especially a faulty understanding of what liars actually look like (i.e. the difference between people's perceived clues to lying, compared to the actual clues; [26]).

### 3.1 General Abilities of Specialized Groups

Most of the studies reviewed were laboratory based and involved observers judging strangers. But similar results are found even when the liars and truth tellers are known

to the observers (also reviewed by [31]. If the lies being told are low stakes, so that little emotion is aroused and the lie can be told without much extra cognitive effort, there may be few clues available on which to base a judgment. But even studies of high stakes lies, in which both liars and truth tellers are highly motivated to be successful, suggest an accuracy level that is not much different from chance.

Researches that examined unselected professionals involved in security settings—police, federal agents, and so forth—have typically found that they too are not any more accurate in their abilities to spot deception than laypeople (e.g., [27, 33–36]). However, within these studies there have been a handful of groups that have performed better than 60% accurate on both lies and truths, and what these groups are doing might be informative for Homeland Security applications. The first group identified was a group of Secret Service agents who not only were superior, as a group, in detecting lies about one's emotions, but those who were more accurate were more likely to report using nonverbal clues than those who were less accurate. The authors [33] speculated that the Secret Service agents were more accurate than the other groups because they were trained in scanning crowds for nonverbal behaviors that did not fit, and they also dealt with assassination threats, many of which were made by mentally ill individuals. Unlike most police officers whose assumption of guilt in suspects is high [37], reflecting the experience of their daily work, Secret Service agents interviewed suspects where they knew the base rate of true death threats was low. The second set of groups identified included forensic psychologists, federal judges, selected federal law enforcement officers, and a group of sheriffs [34]. A commonality among these groups seemed to be their very high motivation to improve their lie detecting skills. A third set of groups identified were police officers examining real-life lies, who showed 65% overall accuracy in detecting lies and truths [38].

### 3.2 Individual Differences

As with any ability, research suggests that some people are better able to detect deception than others in high-stake lies (e.g. [39]); this skill does not seem to translate to lower-stake lies [32]. One element of better skill in higher-stake settings is the ability to judge micromomentary displays of emotion [33, 39]. Other groups who showed better than 60% accuracy included people with left hemisphere brain lesions that prevented them from comprehending speech [40], and those subjects who scored higher on a test of knowledge of clues to deceit were also more accurate than those who did not [41]. A different approach has been to identify individuals who obtain high scores on lie detection tests and studying them in detail [42]. After testing more than 12,000 people using a sequential testing protocol involving three different lie detection accuracy measures, O'Sullivan and Ekman identified 29 highly accurate individuals. These individuals had a kind of genius with respect to the observation of verbal and nonverbal clues, but since genius often connotes academic intelligence, the expert lie detectors were labeled "truth wizards" to suggest their special talent. Although this term is unfortunate in mistakenly suggesting that their abilities are due to magic rather than talent and practice, the term does reflect the rarity of their abilities. One of the first findings of the Wizard Project was a profession-specific sensitivity to certain kinds of lies. About one-third of the wizards were highly accurate on all three of the tests used. Another third did very well on two of the tests, but not on the third, in which people lied or told the truth about whether they had stolen money. Nearly all of these wizards were therapists who had little, if

any, experience with lies about crime. On the other hand, the remaining third of the wizards were law enforcement personnel—police and lawyers—who did very well on the crime lie detection test, but not on a test in which people lied or told the truth about their feelings. Compared with a matched control group, expert lie detectors are more likely than controls to attend to a wide array of nonverbal behaviors and to be more consciously aware of inconsistencies between verbal and nonverbal behaviors. Although expert lie detectors make almost instantaneous judgments about the kind of person they are observing, they are also more cautious than controls about reaching a final decision about truthfulness.

## 4 CRITICAL NEEDS ANALYSIS

Research on human behavior and deception detection can make a useful contribution to Homeland Security needs as long as scientists and practitioners understand what it is they are observing—signs of thinking or signs of feeling. This rule applies to automated approaches that measure physiology as well. Even with this limitation, training in behavioral hot spot recognition may make security personnel better at spotting those with malfeasant intent. Other critical needs are discussed below.

### 4.1 More Relevant Laboratory Paradigms and Subjects

We must recognize that general meta-analyses of the research literature, although useful, are limited in their applicability to security contexts, since such analyses tend to combine studies that feature lies told with few stakes and cognitive demands with those with higher stakes and stronger cognitive demands. Thus, we should be more selective about which studies to examine for clues that may be useful or relevant to security contexts. This also means it is important for scientists to develop research paradigms that more closely mirror the real-life contexts in which security personnel work. Although laboratory settings are not as powerful as real-world settings, high-stake laboratory deception situations can provide insights with the best chance of applicability. Consistent with this approach, two current airport security techniques capitalize on behaviors identified by research studies on stress, with anecdotal success (i.e. Transportation Security Administration (TSA)'s Screening Passengers by Observation Techniques and the MA State Police Behavioral Assessment System). One way to facilitate this type of progress is to have Homeland Security personnel advise laboratory research, as well as allow researchers to spend on-the-job time with them. We believe that pairing the researchers and practitioners would eventually result in calls for laboratory studies featuring higher stakes to the liars, different subject populations beyond US/Europeans (as research suggests that people can detect deception in other cultures at rates greater than chance; [43, 44]), and differing interview lengths such as examining shorter interviews (i.e. a 30–90 s security screening) and longer interviews (i.e. a 1–4 h intelligence interview).

### 4.2 Examination and Creation of Real-World Databases

There have been very few studies of real-world deception (e.g. [38]), yet the technological capability exists to create many more. The biggest problem with real-world data is determining the ground truth (was the person really lying, or did he or she truly

believe what he or she just stated?). Estimating ground truth—as compared to knowing ground truth—will slow down the identification of any patterns or systems. Clear criteria must be established *a priori* to determine this ground truth. For example, confessions of malfeasance are a good criterion, but false confessions do happen. Catching someone with contraband (i.e. a "hit") is also a good criterion, but occasionally the person may be truthful when he or she states that someone must have snuck it into his or her luggage. Moreover, academics should advise on the capture and recording of these databases, to ensure that the materials are able to be examined by the widest number of researchers and research approaches. For example, most of the police interview video we have seen is of such poor quality that we cannot analyze facial expressions in any detail. It is only when these databases are combined with the laboratory work that we can more sharply identify behaviors or behavioral patterns that will increase the chances of catching those with malfeasant intent. To optimally use this information though, we must also examine in detail known cases of false negatives and false positives as well as correct hits to determine why mistakes were made in these judgments.

### 4.3 Ground Truth Base Rates

Security personnel do not know the base rates for malfeasance in their settings. Although it may be logistically impossible to hand-search every piece of hand luggage in a busy airport, or follow every investigative lead, it would be essential to know this base rate in order to ascertain the effectiveness of any new behavioral observational technique. This would also permit more useful cost–benefit analyses of various levels of security and training. A less satisfying but still useful way to ascertain effectiveness is to compare hit rates for contraband for those using various behavioral observation techniques with those who are stopped randomly (as long as the day of the week and time of the day/year are scientifically controlled).

### 4.4 Optimizing Training

The most recent meta-analysis of the research literature on training people to improve deception detection from behavior has shown that across over 2000 subjects, there was a modest effect for training, despite the use of substandard training techniques [45]. This obviously suggests that better training techniques will yield larger improvements in people's abilities to sort out truth from lie. One training change would be to train on behavioral clues that are derived from similar situations and supported by research. For example, one study trained research subjects to recognize a set of behavioral clues that are believed to be indicative of deception, and are often taught to law enforcement personnel as signs of deception, although many of these signs are not supported by the scientific literature [46]. This study reported a 10% decrease in accuracy for the groups receiving such training. Therefore, the first step in adequate training is to identify what information is useful for training (see above). The second step is to determine the most effective way to deliver that information. For example, what is the training duration that maximizes comprehension—one full day, three full days, or more? Should it be done in a group or self-study? Does it need simple repetition, or more creative approaches, and how many training items are needed? Does it need to be reinforced at particular intervals? How many clues should be taught—i.e. at what point do you overwhelm trainees? How do you train in such a way as to improve accuracy without overinflating confidence? These are just a few of the questions with unknown answers.

### 4.5 Identifying Excellence

Another critical need is to identify who within relevant organizations shows signs of excellence, through their higher hit rates or whatever other clear criteria can be applied. This strategy is similar to the strategy of the "wizards" study [42]. One caution is that to date, most testing material will be laboratory experiment based, and the generalizability of that information to real-world contexts is not perfect. An examination of the convergent validity of laboratory tests of deception detection and other more naturalistic approach measures (peer ratings, field observations in airports, or other points of entry with accuracy determined by the rate of contraband "hits" by individuals compared to random selection) would be a great start.

## 5 FUTURE RESEARCH DIRECTIONS

The aforementioned critical needs suggest several research questions, but by no means is that section comprehensive. As we peer into the future, there is much work to do. A partial list of future directions shown below suggests what we should do.

- Examine the role of technology in facilitating behavioral observation. A number of computer vision algorithms are now available that can aid observation, such as recognizing emotional expressions in the face (e.g. [47]). What is unknown is how robust these algorithms are in real-world contexts. What is also unknown is how best to combine technological observation of behavior with human judgment. Would there be a tendency for humans to overrely upon the technology over time?
- Identify the optimal environmental set up for surveillance, whether with technology or the unaided eye. This includes proxemic placement of tables, lines, stanchions, other individuals, and so forth. One goal would be to create an environment that would reduce the typical stress felt by the normal traveler, which would hopefully increase the salience of any sign of stress exhibited by the malfeasant to increase the chances of its being observed.
- Identify optimal interaction style between security agents and the public. One can aggressively question and threaten travelers, but that might render behavioral observation useless due to the overall stress engendered. A rapport-building approach (e.g. [48]) might be better, but this needs more research.
- Identify the optimal interview style. Phrasing of questions is important in obtaining information, but this has not been researched in the open literature. Small changes in phrasing—e.g. open versus close ended—might add to the additional cognitive burden of the liar and thus could be useful. The order of questions will also be important, as well as whether one should make a direct accusation. But only additional research will tell.
- Identify the optimal way to combine behavioral clues. Research tends to examine individual behavioral clues to ascertain their effectiveness, yet more modern neural network and machine learning approaches may be successful in identifying patterns and combinations of behaviors that better predict deception in particular contexts.
- Identify the presence of countermeasures. An inevitable side effect of the release of any information about what behaviors are being examined by security officers, to

identify riskier individuals in security settings, is that this information will find its way onto the Internet or other public forums. This means a potential terrorist can learn what to do and what not to do in order to escape further scrutiny. The problem is that we do not know yet whether one can conceal all their behaviors in these real-life contexts. Moreover, some of these behaviors, like emotional behavior, is more involuntary [16] and should be harder to conceal than more voluntary behavior like word choice. Thus it remains an open question as to whether a potential terrorist can countermeasure all of the critical behaviors.

Space limitations preclude an exhaustive list of needs, future directions, and research. In general, the research suggests that there are limited clues that are useful to sorting out liars and truth tellers, but most people cannot spot them. However, a closer examination of this literature suggests that some behavioral clues can be useful to security personnel, and some people can spot these clues well. We feel that it may be ultimately most productive to expand our thinking about behavioral clues to deceit to include thinking about behavioral clues to a person's reality—clues that someone is recounting a true memory, thinking hard, or having an emotion he or she wishes to hide. This would enable a security officer to make the most accurate inference about the inner state of the person they are observing, which, when combined with better interaction and interviewing techniques, would enable them to better infer the real reasons for this inner state, be it intending us harm, telling a lie, or telling the truth.

# SPEECH AND VIDEO PROCESSING FOR HOMELAND SECURITY

MARK MAYBURY
*Information Technology Center, The MITRE Corporation, Bedford, Massachusetts*

## 1 SPEECH AND VIDEO FOR HOMELAND SECURITY

As articulated in the National Strategy for Homeland Security (www.whitehouse.gov/homeland/book) [1], homeland security requires effective performance of a number of

primary missions such as border and transportation security and critical infrastructure protection. These activities are human intensive, both in terms of the objects of focus (e.g. citizens or foreigners crossing a border) as well as the government or contractor personnel performing these function (e.g. TSA at US airports). Automation is necessary to ensure effective, objective, and affordable operations. Speech and video processing are important technologies that promise to address some of the severe challenges of the homeland security mission. Furthermore, there is some hope that the detection of visual or acoustic anomalies (e.g. unnatural human motion and voice stress) could yield improved deception detection.

With thousands of miles of border with Mexico and Canada and 95,000 miles of shoreline, border and transportation security is a daunting challenge. Some important applications include the following:

- Video surveillance for anomalous and/or hostile behavior detection has important applications at border crossings as well as monitoring remote border areas.
- Identification and tracking of individuals using biometrics (e.g. speech, face, gait, and iris). For example, speaker identification can be used for authentication for both physical access control and computer account access. While details of biometrics are beyond the scope of this article, we refer the reader to an overview text [2] or a more detailed algorithmic approach [3].

Other critical homeland security applications are as follows:

- Critical infrastructure protection to include key site monitoring (e.g. transportation, energy, food, and commerce) or video surveillance of public areas. This could include automated video understanding, in particular the detection, classification, and tracking of objects such as cars, people, or animals in time and space in and around key sites. Beyond object detection and tracking, it would include recognition of relationships and events.
- Automated processing of audio and video to understand broadcast news and/or index video surveillance archives.
- Audio hot spotting for surveillance at a border crossing or large-scale public events.
- The use of audio or video analysis to detect deception (e.g. irregular physical behavior and/or speech patterns) but also audio and video cryptography to obscure message content or audio and video stenography to hide its very existence, and countermeasures thereof.

Some of the requirements for these applications are severe. These include

- broad area surveillance;
- long duration: $24 \times 7$ detection;
- real-time detection;
- high accuracy and consistency;
- completely autonomous operation;
- low or intermittent communications bandwidth (e.g. for storage and exfiltration);
- low acquisition and maintenance cost.

Some deployments may also require low power consumption (and/or long battery life), limited storage, and intermitted connectivity.

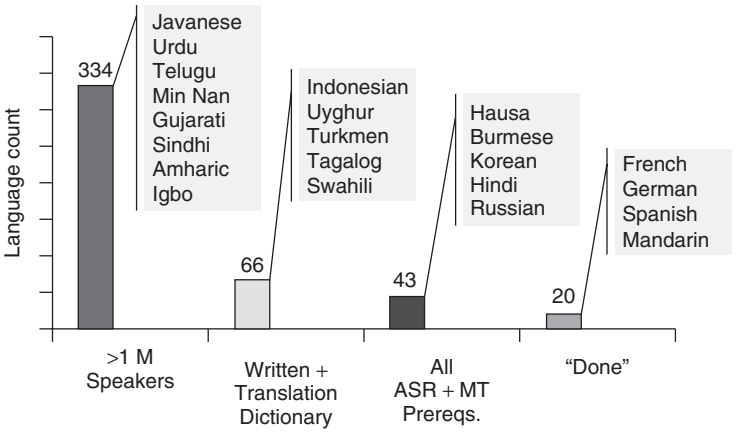
## 2 THE CHALLENGE OF SPEECH

The ability to detect and track criminal or adversary communications is essential to homeland security. Whether for law enforcement or intelligence, searching conversational speech is a grand challenge. Telephone conversations alone illustrate the scale of the challenge with over a billion fixed lines worldwide creating 3785 billion minutes (63B hours) of conversations annually, equivalent to about 15 exabytes of data (ITU 2002). Add to this rapidly growing mobile and wireless communication. In addition, 47,776 radio stations add 70 million hours of original radio programming per year. Further complicating this, approximately 6800 languages and as much as 10,000 dialects are spoken globally. In spite of this untapped audio gold mine, audio search requirements are only beginning to appear.

As Figure 1 illustrates, there are over 300 spoken languages with more than one million speakers, but only 66 of these are written and for which we have a translation dictionary. Of these, we have ASR and MT for only 44, and only 20 of these are considered "done" in the sense that systems exist for automated transcription and translation.

In addition to the challenge of lack of written materials, which we will return to subsequently, there are many challenges beyond scale. These include challenges with language in general, such as polysemy, ambiguity, imprecision, malformedness, intention, and emotion. And in addition to the traditional set of challenges with automated speech recognition such as noise, microphone variability, and speaker disfluencies, the kind of conversational speech that occurs in telephone calls, meetings, interviews has the following additional challenges:

- *Multiparty.* Multiple, interacting speakers.
- *Talkover.* Multiple simultaneous speakers talk over speaker turns.



(Source: Linguistic Data Consortum's DARPA Surprise Language Experiment assessment of FL resources, 2003)

**FIGURE 1** Spoken foreign language systems and needs.

- *Spontaneity.* Unpredictable shifts in speakers, topics, and acoustic environments.
- *Diverse settings.* Conversation is found in many venues including outdoor border crossings, indoor meetings, radio/TV talk shows, interviews, public debates, lectures or presentations that vary in degree of structure, roles of participants, lengths, degree of formality, as well as variable acoustic properties.
- *Acoustic challenges.* Spoken conversations often occur over cell phones or handheld radios which come in and out of range and have highly variable signal to noise ratios.
- *Nonacoustic conversational elements.* Speakers use clapping, laughing, booing, whistling, and other sounds and gestures to express agreement, disagreement, enjoyment, and other emotions, as well as outdoor noise (e.g. weather and animals) and indoor noise (e.g. machinery and music).
- *Real time and retrospective.* Access during the speech event (e.g. real-time stream processing) or after.
- *Tasks.* Speaker identification, word hot spotting, audio document routing (doc/passage/fact), retrieval or question/answering, tracking entities and events, and summarization (e.g. speakers and topics)
- *Multilingual.* Multiple languages, sometimes from the same speaker.
- *References.* Since conversations are often performed in a physical context, the language often contains references to items therein (exophora).

Compounding these challenges, expert translators, particularly for low density languages are expensive and scarce.

In addition to the challenges with speech, for large collections of audio, there exist many retrieval challenges such as triage, storage, query formulation, query expansion, query by example, results display, browsing, and so on.

## 3 AUTOMATED SPEECH PROCESSING

Figure 2 illustrates the significant progress made over the years in spoken language processing. The figure shows best systems each year in evaluations administered by NIST to objectively benchmark performance of speech recognition systems over time. The graph reports reduction of word error rate (WER) over time. The systems were assessed based on a wide range of increasingly complex and challenging tasks moving from read speech, to broadcast (e.g. TV and radio) speech, to conversational speech, to spontaneous speech, to foreign language speech (e.g. Chinese Mandarin and Arabic). Over time, tasks have ranged from understanding read Wall Street Journal text, to understanding foreign television broadcasts, to the so-called "switchboard" (fixed telephone and cellphone) conversations. Future plans include meeting room speech recognition (NIST; [4]).

As Figure 2 illustrates, while recognition, rates of word error for English (clean, well-formed, single speaker, speaking clearly to computer) are well below 10%. For example, computers can understand someone reading the Wall Street Journal with a 5% word error rate (WER) (1 word in 20 wrong). Conversations are harder, with broadcast news often achieving only a 15–20% WER and the CALLHOME data collection (phone calls) achieving 30–40% WER.

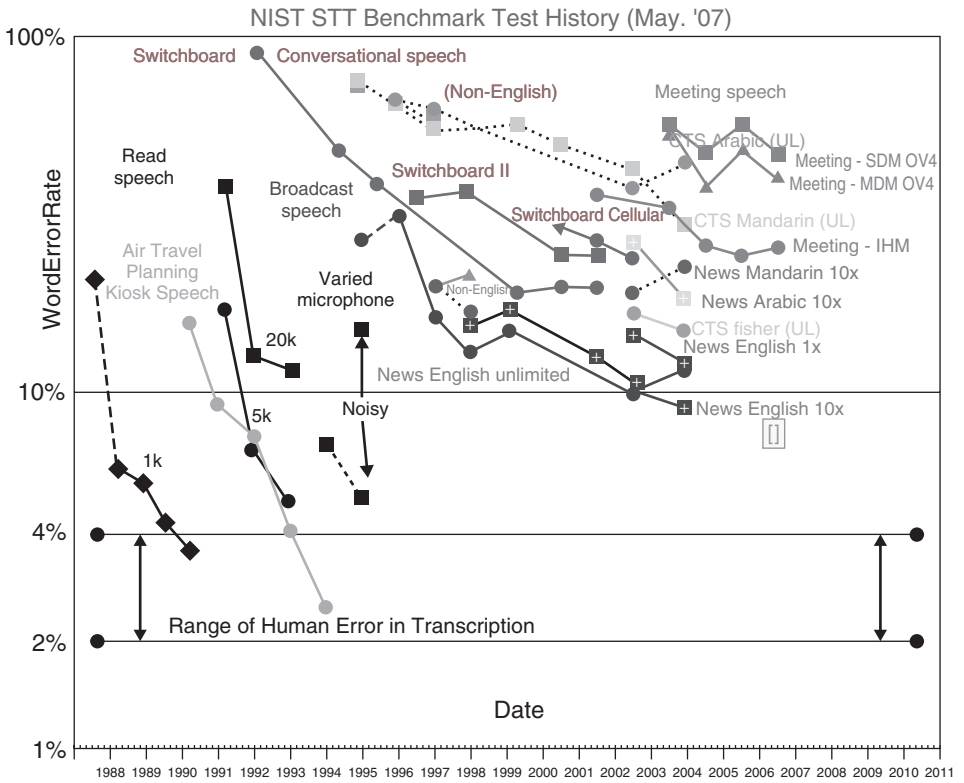


**FIGURE 2** NIST benchmarks over time. (http://www.nist.gov/speech/history.)

## 4 AUDIO HOT SPOTTING

As an illustration of the state of the art, the Audio Hot Spotting project [5–7] aims to support natural querying of audio and video, including meetings, news broadcasts, telephone conversations, and tactical communications/surveillance. As Figure 3 illustrates, the architecture of AHS integrates a variety of technologies including speaker ID, language ID, nonspeech audio detection, keyword spotting, transcription, prosodic feature and speech rate detection (e.g. for speaker emotional detection), and cross language search.

An important innovation of AHS is the combination of word-based speech recognition with phoneme-based audio retrieval for mutual compensation for keyword queries. Phoneme-based audio retrieval is fast, more robust to spelling variations and audio quality, and may have more false positives for short-word queries. In addition, phoneme-based engines can retrieve proper names or words not in the dictionary (e.g. "Shengzhen") but, unfortunately, produces no transcripts for downstream processes. In contrast, word-based retrieval is more precise for single-word queries in good quality audio and provides transcripts for automatic downstream processes. Of course it has its limitations too. For example, it may miss hits for phrasal queries, out-of-vocabulary words, and in noisy audio, and is slower in preprocessing.

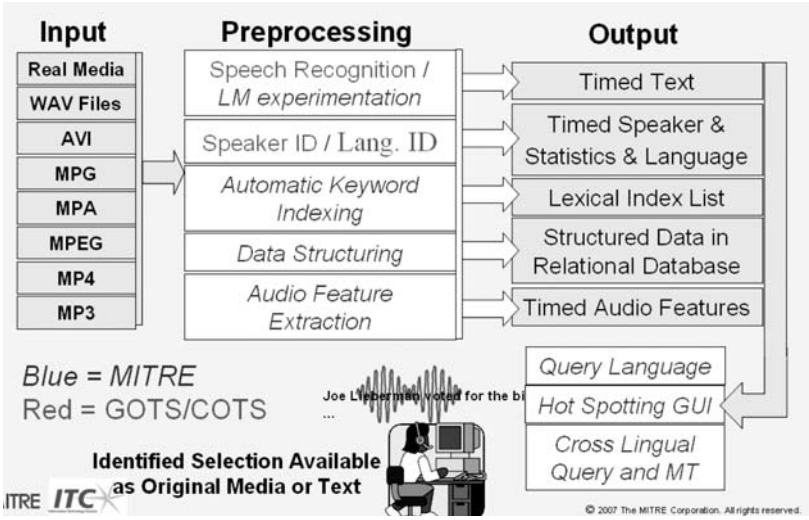

**FIGURE 3** AHS architecture.

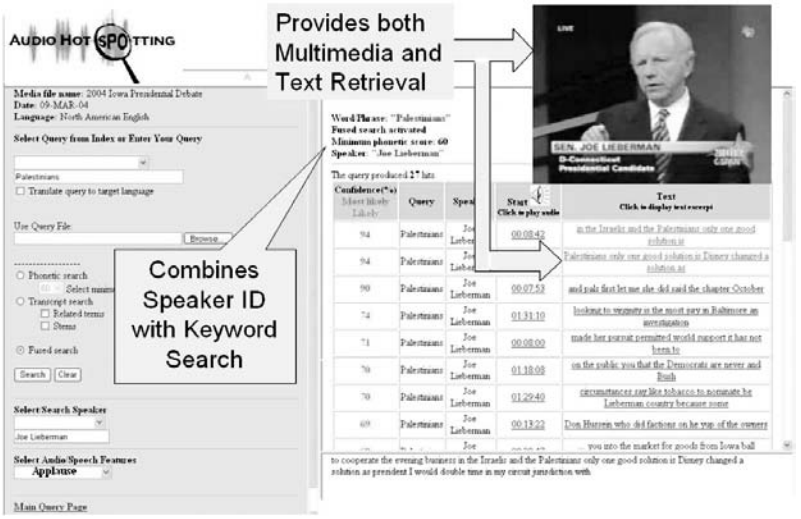

**FIGURE 4** AHS search interface.

Figure 4 illustrates the user interface for speech search, and includes a speaker and keyword search facility against both video and audio collections. The user can also search by nonspeech audio (e.g. clapping and laughter).

For crosslingual needs, a query in English is translated to a foreign language (e.g. Spanish and Arabic) and is used to retrieve hot spots in a transcription of the target media, which is then retrieved and translated into the query language. This process is illustrated in Figure 5. The user typed in word “crisis” is translated into Arabic query term and is used to search the target media, which is subsequently translated as shown.

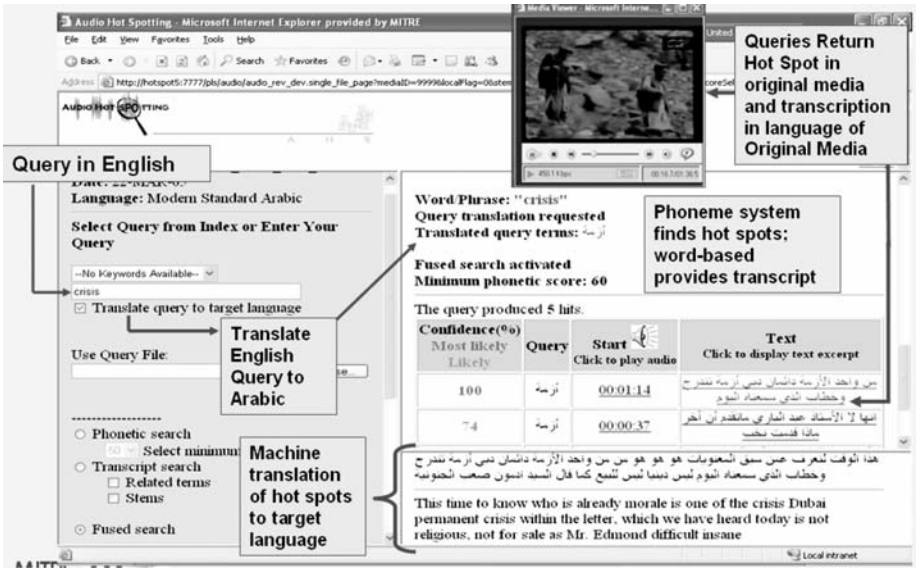

**FIGURE 5** AHS crosslingual audio hot spotting.

## 5 DECEPTION DETECTION

Detection of deception is important for assessing the value of informants, identifying deception at border crossing, and for antifraud, and can be revealed by face, voice, and body [8]. Evidence of increased pitch and vocal tension in deceptive subjects has been found from the literature survey [9]. The most widely cited sources of evidence of deception using speech include latency, filled pauses, discourse coherence, and the use of passive voice and contractions. However, most research on deceptive behavior has focused on visual cues such as body and facial gestures or on descriptive as opposed to empirical studies much less automated means of detection.

Hirschberg et al. [10] and Graciarena et al. [11] report on the use of a corpus-based machine learning approach to automated detection of deception in speech. Both leverage the Columbia-SRI-Colorado (CSC) corpus that consists of 22 native American English speakers who were motivated by financial reward to deceive an interviewer on two tasks out of six in sessions lasting between 25 and 50 min. Using a support vector machine based on prosodic/lexical features combined with a Gaussian mixture model based on acoustic features, Graciarena et al. [11] report 64.4% accuracy in automatically distinguishing deceptive from nondeceptive speech. Although these efforts are promising, one national study [12] argues for the need for significant interdisciplinary research in this important area.

## 6 THE CHALLENGE OF VIDEO

Just as acoustic information provides vital information for homeland security, so too visual information is a critical enabler. Although static images are commonly used to

identify suspects, characterize facilities, and/or describe weapons and threats, motion pictures have become increasing valuable because of their ability to capture not only static objects and their properties but also dynamic events. The following are the challenges faced by video processing:

- *Broad area coverage.* 24 × 7 video surveillance of a broad area poses challenges with processing, storage, power, and sustainability. For example,
  - thousands of cameras are deployed in the United Kingdom for tasks such as facility surveillance, traffic monitoring, and environmental observations (e.g. river levels).
- *Real-time processing.* Events (e.g. border crossing and crimes) occur in real time and frequently require immediate intervention. For example,
  - a new nationwide network of cameras at the National Automatic Number Plate Recognition Data Centre north of London will record up to 50 million license plates a day to detect duplicates and track criminals.
- *Massive volume.* Video requires roughly 10 times as much storage as audio therefore methods for compression should be efficient for storage and dissemination. Moreover, real-time or retrospective human review of material is tedious and an ideal opportunity for automation.
- *Accuracy and consistency of detection, identification, and tracking.* Object and event detection and recognition in a broad range of conditions (lighting, occlusion, and resolution) are severe challenges.
- *Privacy preservation.* The broad deployment of cameras raises challenges for privacy as well as cross boundary sharing identical systems.
- *Processing.* Effective understanding of video requires many subchallenges including format conversion, detection, segmentation, object/face recognition, gesture and gait recognition, and event understanding.
- *Nature.* Occlusion (e.g. fog and rain), lighting, object orientation, and motion require size, rotation, shape, and motion invariant detection that are robust to natural variation.
- *Noise.* Noise from lenses, cameras, the environment (e.g. lighting and smoke/fog/snow), storage, and transmission.
- *Variability.* The natural variability in foreground, background, objects, relationships, and behaviors as well as wide variations in illumination, pose, scale, motion, and appearance.

There are many benefits of automated video processing including the followin:

- Automated identification and tracking.
- Correlation. Storage and indexing can enable correlation of objects across time and space, pattern detection, forensics as well as trend analysis.
- Cross cuing. Initial detection of objects or events can cue more complete or higher quality tracking.
- Compression. Object ID and tracking can dramatically reduce storage and dissemination needs.

There are many important application areas of video processing, from interview deception detection to monitoring of border crossings or facilities (e.g. airport and military base entrances). For example, the Bordersafe project [13] automatically extracts license plate numbers from video as cars travel in and around Tucson, Arizona. The Tuscon Customs and Border Protection (CBP) has captured over 1 million records of license plate numbers, state, date, and time from over 225,000 distinct vehicles from both the United States and Mexico. Comparison revealed that plates from over 13,000 of those border crossing vehicles (involved in nearly 60,000 border crossings) were associated with criminal records from Tuscon and Pima County law enforcement.

## 7 AUTOMATED VIDEO PROCESSING

The key elements necessary for automated understanding of video have been explored since the early days of vision research in robotics in artificial intelligence. In addition to systems to process imagery from security surveillance cameras, algorithms are needed to analyze the 31 million hours of original television programming per year from over 20,000 broadcast stations around the world. For example, as illustrated in Figure 6, using an integration of text, audio, imagery, and video processing, the Broadcast News Navigator [14] enables a user to browse and perform content-based search on videos personalized to their interests. Users can find content two and one half times faster over sequential video search with no loss in accuracy by searching directly for specific content. The related Informedia system (www.informedia.cs.cmu.edu) has explored video privacy protection via methods such as face pixelizing, body scrambling, masking, and body replacement.

Homeland security users may need to monitor not only broadcast news, but other video sources such as security cameras. As illustrated in Figure 7, research at MIT has

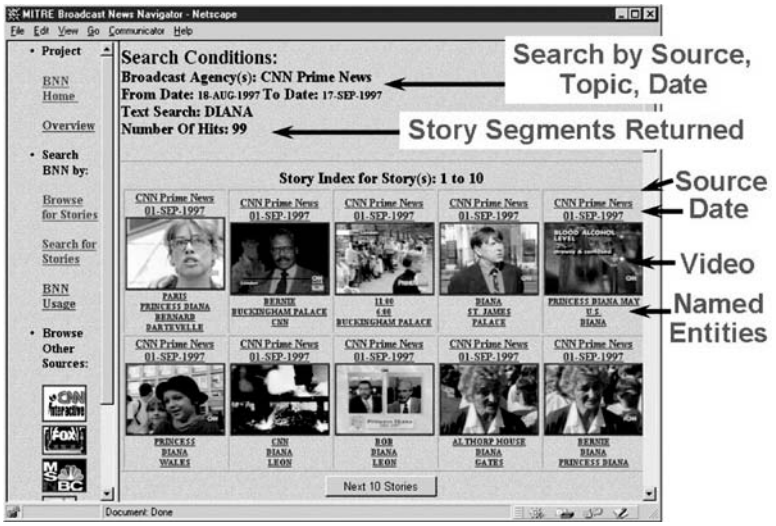

**FIGURE 6** Broadcast news navigation.

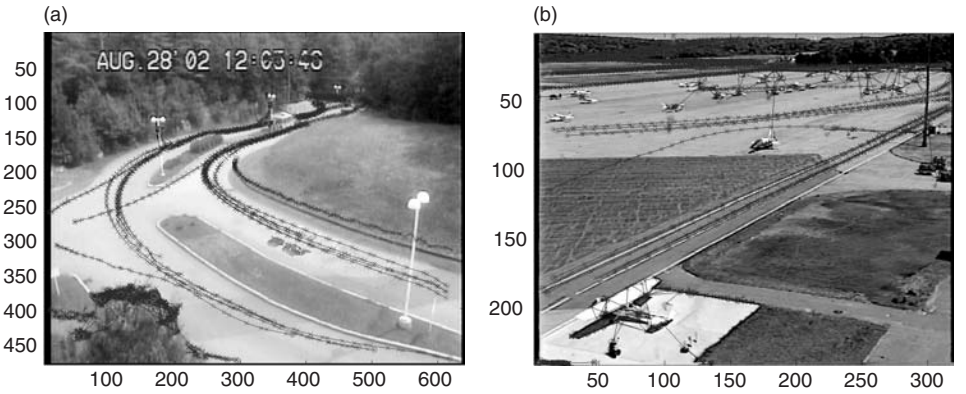

**FIGURE 7** Motion tracks detected on airport tarmac (a) and office park (b).

integrated question answering technology together with video understanding methods to create a video question answering system.

Figure 7 illustrates motion tracks detected in two different settings: an airport tarmac (a) and an entrance gate to an office park (b). This is used by Katz et al. [15] in a prototype information access system, called *Spot*, that combines a video understating system together with a question answering natural language front end to answer questions about video surveillance footage taken around the Technology Square area in Cambridge, Massachusetts. Spot can answer questions such as the following:

- "Show me all cars leaving the garage."
- "Show me cars dropping off people in front of the white building"
- "Did any cars leave the garage toward the north?"
- "How many cars pulled up in front of the office building?"
- "Show me cars entering Technology Square."
- "Give me all northbound traffic."

This kind of intuitive, query-based access to information can dramatically enhance both facility situational awareness and enable focused investigation.

## 8 MULTICAMERA VIDEO ANALYSIS

In addition to moving object detection, identification, and tracking, employment of active multicamera systems enables wide area surveillance, mitigates occlusion, and reveals 3D information [16]. However, multicamera systems require solutions for emplacement and use, selection of best views, cross camera handoff of tracked objects, and multisensor fusion. These have been successfully used for surveillance of people at the SuperBowl or for traffic monitoring. Active cameras—that support active pan, tilt, and zoom—allow automated focus attention on objects of interest in scenes. In addition to the visible spectrum, infrared sensors can help track humans, animals, and vehicles hidden in dense foliage. Multicamera environments can enable, for example, continuous monitoring of critical infrastructure (e.g. air or seaport, military facility, and power plant), detect

perimeter breaches, track moving people or vehicles, pan/tilt/zoom for identification, and issue alerts.

## 9 STATE OF THE ART

With all of the rapid advances in video processing, how well do these systems work? As illustrated in Figure 8, NIST organizes an annual benchmarking activity to compare the performance of video understanding systems. As can be seen, this annual event has grown from a few participants in 2001 processing about a dozen hours of video to dozens of participants processing hundreds of hours worth of video to support search for particular video segments.

For example, in the 2004 NIST TRECVID benchmarking activities [17], participants included IBM Research, Carnegie Mellon University, University of Amsterdam. They applied their systems to four tasks required to find relevant segments in video data sets: shot boundary, story boundary, and feature detection as well as search. The video data set contained over 184 h of digitized news episodes from ABC and CNN with the task of discovering 10 types of segment, in particular:

- *Boat/ship.* Segment contains video of at least one boat, canoe, kayak, or ship of any type.
- *Bill Clinton.* Segment contains video of Bill Clinton.
- *Madeleine Albright.* Segment contains video of Madeleine Albright.
- *Train.* Segment contains video of one or more trains or railroad cars that are part of a train.
- *Beach.* Segment contains video of a beach with the water and the shore visible.
- *Airplane takeoff.* Segment contains video of an airplane taking off, moving away from the viewer.
- *People walking/running.* Segment contains video of more than one person walking or running.

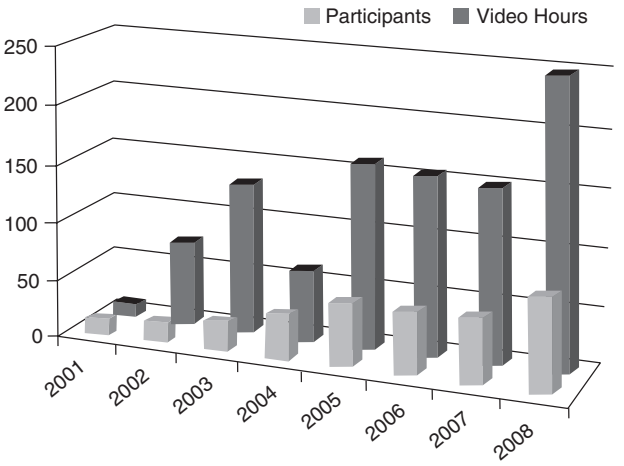

**FIGURE 8** TRECVID trends.

- *Physical violence.* Segment contains video of violent interaction between people and/or objects.
- *Road.* Segment contains video of part of a road, any size, paved or not.
- *Basket scored.* Segment contains video of a basketball passing down through the hoop and into the net to score a basket—as part of a game or not.

To address the diversity of potential video data and to continually challenge researchers, each year the data sets grow and the evaluation tasks are expanded. For example, the TRECVID 2005 data set added multilingual video (Chinese and Arabic in addition to English) and the topics were slightly different and ranged from finding video segments of people (e.g. prisoner), places (e.g. mountain, building exterior, and waterscape/waterfront), things (e.g. car, map, and US flag) to events (e.g. people walking/running, explosion or fire, and sports). In 2007, a video summary task was added to the existing shot boundary, search, and feature detection tasks and in 2008 surveillance event detection was added along with 100 h of airport surveillance video.

Effectiveness on video segment retrieval is measured primarily using mean average precision (the mean of the average precision of each query), which ranges widely by topic. Other measures include search processing time and precision at various depths. For interactive searches, participants are encouraged to collect data on usability as seen by each searcher. For example, in 2006, interactive retrieval of Tony Blair segments were achieved at nearly 90% mean average precision, whereas segments of people entering or leaving a building were recognized at only the 10% level.

## 10 FUTURE RESEARCH

The challenges of audio and video analysis are daunting but with the rapid growth of sources, the need is equally great. Spoken dialog retrieval is an exciting research area precisely because it contains all the traditional challenges of spoken language processing together with the challenges imposed by the retrieval task. Some important spoken conversation processing challenges include [18]

- dealing with multiple speakers;
- dealing with foreign language and associated accents;
- incorporating nonspeech audio dialog acts (e.g. clapping and laughter);
- conversational segmentation and summarization;
- discourse analysis, such as analyzing speaking rates, turn taking (frequency and durations), concurrence/disagreement, which often provides insights into speaker emotional state, attitudes toward topics and other speakers, and roles/relationships.

Some important speech retrieval challenges include the following:

- How can we provide a query by example for a speech or audio signal, for example, find speech that sounds (acoustically and perceptually) like this? (See Sound Fisher in Reference 19.)
- How can we provide (acoustic) relevancy feedback to enhance subsequent searchers?

- How do we manage whole story/long passage retrieval that exposes users to too much errorful ASR output or too much audio to scan?
- Because text-based keyword search alone is insufficient for audio data, how do we retain and expose valuable information embedded in the audio signal?
- Are nonlinguistic audio cues detectable and useful?
- Can we utilize speech and conversational gists (of sources or segments) to provide more efficient querying and browsing.

Some interesting application challenges are raised, such as dialog visualization, dialog comparison (e.g. call centers), or dialog summarization, simultaneously with the challenge of addressing speech and dialog.

Like audio analysis, video analysis has many remaining research challenges. These include

- scalable processing to address large-scale video collections;
- processing of heterogeneous video sources from cell phone cameras to handheld video cameras to high definition mobile cameras;
- robustness to noise, variability, and environmental conditions;
- bridging the "semantic gap" between low level features (e.g. color, shape, and texture) and high level objects and events.

The combination of both audio and video processing is an area of research that promises combined effects. These include

- cross modal analysis to support cross cuing for tasks such as segmentation and summarization;
- cross modal sentiment analysis for detection of bias and/or of deception;
- cross media analysis for biometrics for identity management to overcome the noise and errorful detection in single media (e.g. audio and video) identification;
- utilization of speech and conversational gists (of video sources or segments) to provide more efficient video querying and browsing.

In conclusion, speech and video processing promise significant enhancement to homeland security missions. Addressing challenges such as scalability, robustness, and privacy up front will improve the likelihood of success. Mission-oriented development and application promises to detect dangerous behavior, protect borders, and, overall, improve citizen security.

# TRAINING AND LEARNING DEVELOPMENT FOR HOMELAND SECURITY

EDUARDO SALAS AND ELIZABETH H. LAZZARA
*University of Central Florida, Orlando, Florida*

## 1 INTRODUCTION

On December 22, 2001, Richard Colvin Reid hid explosives in his shoes in an effort to destroy American Airlines Flight 63 bound to the United States from Paris (BBC News 2008) [1]. His attempt was ultimately unsuccessful because other passengers were able to resolve the situation; however, the world would come to know this man as the "shoe bomber". This incident marked a drastic change in the policies and procedures for commercial airlines in order to ensure the safety of all people onboard. Due to the high-risk nature of the situation and the consequences of possible outcomes, all employees responsible for screening passengers boarding aircrafts would be mandated to undergo intense training to be able to detect any clues to prevent another such occurrence happening in the future.

This example illustrates the importance of training and learning development in Homeland Security (HS). Recently, Salas and colleagues [2] define training as "the systematic acquisition of knowledge (i.e. what we need to know), skills (i.e. what we need to do), and attitudes (i.e. what we need to feel) (KSAs) that together lead to improved performance in a particular environment" (p. 473). Learning occurs when there is a permanent cognitive and behavioral change by acquiring the requisite competencies to perform the

job. We submit that learning is facilitated when the training design and delivery is guided by the findings from the science of learning (and training). The purpose of this article is to provide some insights about the science and offer some principles to help in designing, developing, implementing, and evaluating training.

## 2 THE PHASES OF TRAINING

The design of training is a process that consists of a set of interrelated phases that have to be effective; it must be applied systematically. In this article, we discuss four general training phases. These phases, and associated principles and guidelines, represent what we know from the science that works and must be done when designing and delivering training in any organization. We hope that these will guide those in the practice of designing and implementing training for HS purposes. As noted, effective training requires attention to four phases [3]. These are discussed below with specific principles to guide the focus and shape the actual elements in each phase.

### 2.1 Phase 1: Analyze the Organizational Training Needs

This is one of the most critical phases of training because many important decisions are made at this juncture. It is in this phase where skill deficiencies are determined and where the environment is prepared and set for learning and transfer to occur in the organization. Therefore, before training can be successfully designed and implemented, it is necessary to assess the needs of the organization. This is done in order to properly set up the learning environment to uncover the necessary KSAs and prepare the organization for the training.

***2.1.1 Uncover the Required KSAs.*** To determine what KSAs are needed, all of the required tasks to be performed must be analyzed. Ideally, the analysis focuses on the competencies that must be acquired and not on the actual tasks to be performed because competencies are common throughout a variety of tasks. To uncover the requisite KSAs, organizations should conduct a task analysis and/or cognitive task analysis. Task analyses are needed to determine what competencies are needed to perform a job successfully. Cognitive tasks analysis goes deeper and uncovers the knowledge or cognitions underneath job performance. These analyses set the foundation for designing a successful training program. It helps in establishing the training objectives, the learning outcomes, and provides the learning expectations for both trainers and trainees. Furthermore, the training objectives outline the conditions that will take place during job performance, and they provide the acceptable criterion to measure performance [4].

In addition to uncovering and analyzing the necessary competencies, it is also critical to determine who exactly needs to be trained and what they need to be trained on. Conducting a person analysis ensures that the right people get the appropriate training. Employees possess and need different KSAs; therefore, they do not necessarily require the same kind of training. More experienced employees would not need an extensive, intense training session compared to new, inexperienced employees.

***2.1.2 Prepare the Organization.*** Before a training system can be designed and implemented, the organization needs to be prepared. Goldstein and Ford [5] proposed that some aspects of the organization to be considered include "an examination of organizational goals, resources of the organization, transfer climate for training, and internal and external constraints present in the environment" (p. 41). In other words, do the goals of the organization and training program align? Does the training support the strategic goals of the organization? What are the available resources (e.g. finances, technology, and so on)? What are the possible limitations that the training might encounter based upon the existing resources? Lastly, is the organizational climate fostering learning and the importance of the training? That is, is the climate and culture conducive in transferring the newly acquired KSAs to the actual operating environment? Is the organization motivating the trainees to attend training? To set up the appropriate climate, organizations need to send out positive messages about training so that trainees will see the value of the training. Trainees will also be more supportive of the training system if it is voluntary rather than being mandatory. If training must be mandatory, make it with as few obstacles as possible. Overall, the organizational climate should support and encourage the training to ensure its success.

In total, determining the precise training needs is imperative. Knowing what, why, who, when, and how to train before designing training is a must. Organizations get the most out of training when the required KSAs are uncovered and the organizations prepare the training and set its climate to support learning.

## 2.2 Phase 2: Design and Develop Instruction

The second phase is about designing and developing the instructional content, storyboards, lesson plans, materials, curriculum, and preparing all the resources needed to deliver and implement the training. A number of factors are important here; most notably, the reliance of the science of training to drive the decision as much as possible. This science has produced many guidelines, tips and examples that can be applied [3, 6, 7].

***2.2.1 Rely on Scientifically Rooted Instructional Principles.*** Clearly, effective training is about applying pedagogically sound principles to the design of instruction. It is about using the science to create a learning environment that will engage, motivate, propel, and immerse the trainee in acquiring KSAs. Thus, it is critical when designing training to consider individual factors (e.g. cognitive ability, self efficacy, and motivation) as well as organizational factors (e.g. policies, procedures, prepractice conditions, and feedback) because they are extremely influential in the learning outcomes. For example, a trainee's motivation level can determine their ability to acquire, retain, and apply trained skills; therefore, training should be designed to enhance the motivation to learning of the trainees [8, 9].

***2.2.2 Set up Prepractice Conditions.*** In addition to establishing a positive organizational climate, organizations must set up prepractice conditions to enhance the effectiveness of the training system [10]. The efforts made prior to training will positively affect learning and ultimately performance; therefore, trainees should be prepared even before training begins. They should receive preparatory information about the training

(e.g. brochures and pamphlets) or advanced organizers to manage the information [11]. Furthermore, providing trainees with attentional advice can guide them in deciding what strategies will foster learning [3]. The benefit of setting up the prepractice conditions is that not only will it benefit trainees by optimizing learning but it is also a cost-effective way to facilitate the success of the training system.

***2.2.3 Create Opportunities to Practice and Receive Feedback.*** Any training seeks to give information about needed concepts, demonstrate required cognitions and behaviors, and creates opportunities to practice and receive feedback. The instructional delivery should be guided by training objectives; and the information, demonstration, and/or practice-based strategy demonstrations should target the wanted KSAs. The practice opportunities should be challenging and vary in difficulty because it is not the quantity of practice per se that is important but rather the quality of practice. Mere repetition does not necessarily enhance learning; therefore, as trainees learn and improve their KSAs, the scenarios should be more difficult and varied. To ease comparisons and ensure standardizations, scenarios should be designed a priori [12]. Moreover, developing the scenarios prior to training eases the burden on trainers by allowing them more control. In addition, instructors can focus on providing trainees with feedback because it will foster training by providing guidance on what areas are lacking and still need improvement [13].

***2.2.4 Seek to Diagnose KSAs' Deficiences.*** In order to establish whether trainees learned the requisite KSA, performance measures must be created to assess the trained competencies against the stated objectives. Ideally, performance measures evaluate processes as well as outcomes on both the individual and team level (if applicable; [3]). The effectiveness of the training lies heavily on the ability to assess and diagnose performance [14]. Therefore, organizations should take careful consideration when deciding what tool to use to evaluate performance against the trained objectives. One approach is to utilize a behavioral checklist (e.g. Targeted Acceptable Responses to Generated Events or Tasks (TARGETS)—), which evaluates trainees by recording the presence or absence of desired behaviors to scripted events [15]. Other approaches are available as well (see [16]).

## 2.3 Phase 3: Implement the Training

The third phase is the implementation or actual execution of the training program or system. This is the more "mechanical" part, but pay attention to the location, resources, instructor, and the delivery of the instructional system (e.g. information or practice based).

***2.3.1 Put Everything into Action.*** After the training has been designed, it is time to implement it. Now, it is time to identify the training site and ensure that it is prepared prior to training. The training site should be a comfortable setting and equipped with the proper resources. Instructors must also be trained and prepared to be able to address any issues/concerns that may arise during training. At this point, any instructional materials are finally carried out and the training is completely functional. Preferably, the fully

functioning training should be pilot tested to discover any potential problems and to be able to make the appropriate adjustments [17]. Because of the possibility that things will go wrong, relapse prevention procedures should be created in order to solve any dilemmas.

### 2.4 Phase 4: Evaluate the Training

The fourth phase is one that most organizations want to implement; however, most avoid it altogether or just simply do not go deep enough to truly determine the effectiveness of the training. Evaluations are designed to determine what worked and to assess the impact of the training system on the organization.

***2.4.1 Use a Multilevel Approach.*** Incorporating a training program into an organization does not stop once it has been implemented. The training must be evaluated to truly determine its effectiveness. Ideally, researchers suggest taking a multilevel approach to evaluation in order to obtain the complete picture. Kirkpatrick [18] devised a popular evaluation strategy measuring reactions, learning, behavioral change, and organizational impact. A multilevel approach will identify the successful aspects of the training program as well as the elements that are still lacking and need further adjustments in order to improve. When evaluations are based on only one dimension, it is easy to obtain an inaccurate assessment of the impact of the training intervention. For example, it is possible that trainee reactions are positive, yet learning did not take place [19]. Therefore, it is beneficial to examine at higher levels (e.g. learning and behavioral change; [20]). Assessments at the behavioral level will indicate whether the trained KSAs will be transferred to on the job performance [5]. Thus, it is not only crucial that trainees react positively and learn the material, but it is also important that they apply the trained KSAs to the job.

***2.4.2 Ensure Transfer of the Acquired KSAs.*** Training is only beneficial to the organization when the learned KSAs are not only learned during the training but also applied and maintained on the job [7, 21]. Hence, organizations must prepare the climate to facilitate using the KSAs learned during training [22]. For example, trainees need opportunities to perform [23] because a substantial delay between training and job performance can lead to significant skill decay [24]. Supervisors should also encourage trainees to use their trained skills on the job by providing positive reinforcement (e.g. verbal praise and monetary reward; [25]). Positive reinforcement when applied appropriately (i.e. immediately following behavior) will lead to repetition [26]. Having supervisory support and providing reinforcements sends out a positive message to trainees, which is imperative to the success and effectiveness of training.

## 3 LEARNING DEVELOPMENT

Now that we have an understanding of the science behind designing, developing, implementing, and evaluating a training program, we can discuss some of the possible training strategies. Because employees must implement a variety of information and skills on a

daily basis, it is necessary to possess a variety of training strategies in your arsenal to be able to customize and adapt to all of the different requisite competencies required to perform each task. As technology permeates throughout businesses, more complex skills are required to complete tasks in the work environment; therefore, it is necessary that our training strategies become more complex as well to adjust to the growing changes. Due to the popularity of technology and the growing demand of organizations to use teams to perform complex tasks, we will elaborate on simulation-based training (SBT) and games as a learning development strategy. Moreover, because organizations often lack the time to implement a formal training program, we will discuss an informal technique called *on-the-job training* (OJT).

### 3.1 Simulation-based Training

SBT is an interactive, practice-based instructional strategy which provides opportunities for trainees to develop the requisite competencies and enhance their expertise through scenarios and feedback [12]. The scenarios serve as the "curriculum". In other words, the learning objectives derived from the training needs analysis are embedded within the scenarios. The SBT "life cycle" consists of a number of interrelated and critical stages and each step is fundamental to the next [27]. The first step is to verify trainees' existing skills and their previous performance record. Next, determine the tasks and competencies that will be emphasized during training. As a result of the second step, the training/learning objectives can be established. Upon the completion of all of these steps, scenarios can be created. The scenarios are scripted and designed to elicit the requisite competencies by incorporating "trigger" events. Afterwards, performance measures must be developed to assess the effectiveness of the training. Then, the performance data is collected and compared to the existing, previous data. The collected data serves as the foundation and guide for providing feedback to the trainees. Lastly, all of the information can then be used to make any adjustments or modifications to the training program.

SBT can be an optimal instructional strategy because it has many benefits. First, SBT mimics the job environment; therefore, it is very realistic, which makes transferring skills to the job easier [28]. In addition, SBT allows an organization to explore training with a variety of scenarios, which facilitates and accelerates expertise [2]. Third, SBT is interactive and engaging. Being engrossed in training is influential to motivation, and researchers have shown that motivation enhances learning [29]. Last, SBT when utilizing carefully crafted scenarios and measures, can facilitate the diagnosis of performance.

### 3.2 Games

Recently, the military along with other organizations have started to use games as instructional tools to acquire knowledge, skills, and attitudes applicable in the work place as well as other settings. Games can be defined as "a set of activities involving one or more players. It has goals, constraints, payoffs, and consequences. A game is rule-guided and artificial in some respects. Finally, a game involves some aspect of competition, even if that competition is with oneself" [30], p. 159. Although the definition of what constitutes

a game is being debated by researchers because they are available in a wide array of formats (e.g. board games, console-based games PC-based games), there is agreement that games provide educational benefits to learning as a training tool. For example, Vogel and colleagues [31] conducted a meta-analysis and found that cognitive and attitudinal abilities were enhanced in participants when they used interactive games and simulations as opposed to traditional instruction methods.

Games have become a popular instructional tool because they not only benefit the learner but are also advantageous for the developers and instructors. Users benefit by "playing" because the skills necessary to accomplish the goals within the game are applicable to other situations. Furthermore, games elicit motivation in users because they are interactive, fun, and engaging [32]. Developers and instructors benefit from leveraging games as well because they are modifiable (i.e. instructional features can be added in some cases with ease) and a cost-effective approach to learning.

### 3.3 On-the-Job Training

Frequently, in HS and in other organizations there is not sufficient time or resources to implement a formal training because new policies and procedures must be integrated immediately; therefore, OJT is one possible solution. OJT is "job instruction occurring in the work setting and during the work" [33] p.3. Because it occurs on the job and does not require instructors or trainees to leave the job site, it is a very economical alternative. Moreover, occurring in the actual work environment has the added benefit of facilitating training transfer since trainees can see that the training is relevant and applicable to completing the job tasks. Therefore, the KSAs have more significance.

However, in order to reap the benefits of such an applicable, customizable, low cost alternative, OJT needs to be executed correctly. All OJT is not created equal. Practitioners need to abide by several learning principles in order to optimize the effectiveness of OJT. First, as with any other training, the top of the organization and its leaders needs to support the OJT. For example, as noted, earlier organizations can show support through rewards and incentive programs [34]. Second, OJT facilitators also need to be included throughout the process [35]. OJT facilitators need to be involved in designing and developing the program as well as being trained on instructional techniques (e.g. coaching and mentoring). Often, facilitators are knowledgeable in their field; however, they lack the expertise to effectively teach others. Once the organization and the training facilitators are supportive, the trainees must be prepared. Preparatory information about the content of the upcoming OJT will not only establish the appropriate expectations, it will also foster motivation [10]. Third, it is absolutely critical that the OJT be structured and guided to be optimally effective. A structured OJT ensures standardizations reducing discrepancies in the way training is delivered and executed. OJT is a useful strategy when guided by the science of learning as well.

## 4 CONCLUDING REMARKS

Regardless of the strategy (e.g. SBT, games, and OJT) being implemented, training must follow the basic principles to ensure its success [6]. It must be developed

systematically because all of the facets are interrelated, serving as the foundation for the next component—assessing the needs of the organization, identifying the necessary resources, developing the practice scenarios, evaluating the effectiveness, and providing feedback to make adjustments. But to ensure that trainees learn the requisite KSAs, the design, delivery, implementation, and evaluation of the training must be provided with the science of learning and training.

## 1 INTRODUCTION

Catching terrorists is a multilayered process. Although technological sensors are both rapid and reliable, as in the use of thermographic or facial and body analysis programs (see Human Behavior and Deception Detection), there are points in the process of assessing deception where only a human lie detector can be used. This may occur after the automated system shows a "hit" on an individual, which subjects him or her to further scrutiny, or in other security domains where access to technology is limited or nonexistent. Given these situations, it is important to determine who should interview such potential terrorists. Should we train all security personnel to improve their basic abilities? Or, should we select those most amenable to training, because of their motivation, skill, or other characteristics? Or, should we select already expert lie catchers; and if we do, how do we find them?

The literature on how to increase lie detection accuracy through training has been sparse, although an increasing number of scientists are addressing this issue. This overview will enumerate some of the factors involved in designing a good training study and examine the current state of knowledge concerning training for improved lie detection accuracy.

## 2 INDIVIDUAL DIFFERENCES IN LIE DETECTION ABILITY

Over the last 50 years, a general presumption has been that lie detection accuracy is a particular ability or cognitive skill [1] that might be an aspect of social-emotional intelligence [2]. This widely held belief implies something approximating a normal distribution of lie detection accuracy scores, with most scores in the average range and a few being very high or very low. However, a recent study questioned this assumption. A 2008 meta-analysis [3] of 247 lie detection accuracy samples concluded that although there was reliable evidence that people vary in the ease with which their lies can be detected,

there is no evidence of reliable variance in the ability to detect deception. This rather controversial conclusion was criticized on a variety of grounds [4, 5]: most of the studies used college students, not professional lie catchers; the statistical model did not satisfy the classical test theory on which it was based; the metric used was standard deviations without reference to means, a highly misleading unit of measurement; and the authors ignored a substantial literature demonstrating convergent validity between lie detection accuracy and various social and psychological variables. Furthermore, in the last several years, as researchers use lie scenarios more appropriate to security personnel in their research, the number of reports in which highly accurate groups have been identified has increased [6].

The study of highly accurate individual lie detectors has been less common [7–9]. These studies suggest, however, that practice and motivation to detect deception are important variables. Moreover, expert lie detectors are more accurate with lies relevant to their profession [5, 9, 10]. Frank and Hurley [10] found that among law enforcement personnel, accuracy was greater for those with more experience in different domains of law enforcement. Homicide investigators, for example, were more accurate than fraud investigators who were more accurate than patrolmen walking a beat. Similarly, O'Sullivan [11] found, as predicted, that college administrators were more accurate in detecting the lies of college students than other non-faculty college personnel. In addition to supporting the view that experience makes a difference in lie detection accuracy, some of these studies support the view that experience with a particular kind of lie is important in lie detection. By extension, training to enhance lie detection accuracy should emphasize the particular lie of interest. Evidence relating to this point is reviewed below.

## 3 HOW EFFECTIVE IS TRAINING TO INCREASE LIE DETECTION ACCURACY?

In a review of 11 lie detection training studies completed between 1987 and 1999, Frank and Feeley [12] reported a small, but significant, positive effect of training. Their methodological review suggested that the literature was hindered by several weaknesses in the research designs of most of the studies performed. They emphasized the importance of several variables in designing training programs and evaluating them: (i) the *relevance* of the lie to the lie detectors being trained. Training college students to detect lies about friends told by other college students may not generalize to training law enforcement personnel about lies about past or present crimes; (ii) whether the lie scenario uses *high stakes* lies—lies that involve strong rewards and punishments for successful and unsuccessful deceiving—may affect both lie detection accuracy, and training conducted with them. A recent meta-analysis [6] suggests that even professional lie catchers, such as police personnel, will not be accurate in detecting low stakes lies, lies that are not important to the liars' or the truth tellers' self-identity, or lies without significant rewards or punishments. Their meta-analysis found that the average lie detection accuracy of police tested with high stakes lies was significantly higher than that of police tested with low stakes lies; (iii) in many studies, *training* consists of a brief, written description of potential cues to deception with no actual examples of the behaviors, no feedback, and no practice with similar or related kinds of behavior. Adequate training needs practice, feedback, and exemplars similar to the materials; (iv) basic experimental protocol should be followed, ideally, through the use of randomly determined experimental (trained) and control (untrained) groups with pre- and post-*testing* of both the experimental and

the control groups. Different liars and truth tellers should be included in the pre- and post-testing measures. And, of course, the difficulty of the two measures should be calibrated for equivalence; (v) assuming that a *bona fide* training effect is found (based on a standard experimental protocol), and that training with one kind of lie has been shown to increase accuracy with that lie, another issue is whether the training is lie-specific or *generalizes* to increased accuracy with other kinds of lies; (vi) in addition to generalization to other kinds of lies (what Frank and Feeley [12] called Situational Generality), a related issue is *time generality*. How long does such increased accuracy last? Is it a permanent learning effect? Or one that dissipates outside of the training environment?

These six factors are *sine qua nons* for lie detection training research. In a more recent methodological review, Frank [13] expanded the discussion of these topics and included many suggestions about ways in which to improve lie detection accuracy studies. In the present overview, however, we use the Frank and Feeley [12] paradigm to examine the nine lie detection training studies that were completed from 2000 to 2007. Table 1 summarizes the strengths and defects of these studies in the light of the Frank and Feeley paradigm. In conclusion, we will discuss the importance of individual differences in designing training programs, over and above the variation in individual lie detection accuracy.

As Table 1 shows, of the nine training studies, three found no significant training effect; in one of these studies the lie scenario may have been irrelevant to the test takers [14]. In the others, the training may have been inadequate [18, 20]. Among 16 different groups tested, nine (Table 1, groups 4–8, 12,13, 15, 16) showed a significant lie detection accuracy increase, ranging from 2% to 37% (median increase = 20%).

## 4 RELEVANCE

Frank and Feeley [12] argued that training should be on lies relevant to the trainees. We agree, but in a recent publication [6] we refined this argument. It may be even more important that the lie scenario used for training contains the kinds of behaviors, both verbal and non-verbal, that provide clues to deception than that the lie superficially looks like a lie of interest. This distinction is what test psychologists call face validity versus construct validity and what experimental psychologists term mundane realism versus experimental realism. A lie scenario may seem relevant to a law enforcement lie detection situation because it shows a felon being interviewed by a police officer (face validity, mundane realism). But if the lie is about a topic of no importance to the felon, the emotional and cognitive aspects of a high stakes lie will not be present. Conversely, a college student discussing a strongly held belief, who will receive substantial rewards if he tells the truth successfully or lies successfully and who will be punished if he is unsuccessful, may better simulate the behaviors seen in a law enforcement interview (construct validity, experimental realism). So while the construct validity or experimental realism of a scenario is the more important variable, the relevance or interest of the lie to the lie catcher (its face validity or mundane realism) must also be considered. In screening expert lie detectors from several different professional groups including law enforcement personnel and therapists, O'Sullivan [5] found that about one-third of the experts were at least 80% accurate on each of three different lie detection tasks. The remaining two-thirds of the experts obtained 80% on two of the three tests. For this second group, their lowest score was either on a test in which young men lied about

**TABLE 1 Lie Detection Accuracy Training Studies, 2000–2007**

| Group | Study | n | Sample Trained | Accuracy Pre/Post | Relevance of Test | High Stakes of Test | Training Adequacy | Testing Adequacy | Situational Generality | Time Generality |

*Note*: College: college students; Accuracy: pretest accuracy/post-test accuracy scores for same individuals.
[a]Accuracy for post-test only design: untrained accuracy/trained accuracy scores.

stealing a significant amount of money or a test in which young women lied or told the truth about whether they were watching a gruesome surgical film or a pleasant nature film. Not surprisingly, the lowest of the three scores for therapists was on the crime test; for law enforcement personnel, their lowest score was on the emotion test. This finding was highly significant.

Among recently published lie detection accuracy studies, several meet the criterion of relevance, whether this term is used to refer to importance to the trainees (mundane realism, face validity) or actual validity for the lies that lie catchers need to be accurate on (experimental realism, construct validity). Hartwig [17] tested police officers using a mock theft scenario and allowed the trainees to interview the experimental suspects. Akehurst [14], on the other hand, used test stimuli in which children lied or told the truth about an adult taking a photograph. Since it is unlikely that much arousal happened, whether this scenario had either mundane or experimental realism for the subjects is doubtful. All of the other studies used college students as target liars and truth tellers. Insofar as the trainees were students or therapists, who work with clients in that age group, such materials are probably relevant to them.

## 5 HIGH STAKES LIES

Among the nine training studies published between 2000 and 2007, four used what we consider to be high stakes lies. Porter [20, 21] used a scenario in which targets lied or told the truth about highly emotional events in their personal lives. We consider lies with a strong self-identity aspect to be high stakes. O'Sullivan [19] used a scenario in which both personal identity and a large cash reward were involved. Although the Hartwig study [17] used a sanctioned mock theft scenario which reduces the stakes for the liars and truth tellers, the targets also received a lawyer's letter which may have "bumped up" the stress of the situation. (Three of these four studies achieved a significant learning effect.) The other studies included scenarios in which college students told social lies about friends or lied about whether they had headphones hidden in their pockets. (They had been directed to do so by the experimenter, so little emotional arousal could be expected.)

## 6 TRAINING

Outstanding expertise in lie detection is likely the result of a host of individual difference variables such as interest, extensive and varied life experience, motivation, practice, and feedback with professionally relevant lies that most expert lie detectors seem to share. In addition, there are probably particular kinds of skills such as visual or auditory acuity, pattern recognition and social or emotional memory that vary from expert to expert and that will cause them to be more or less expert on different kinds of lies, depending on their particular subset of skills. So while expert lie detection employs a host of skills, training for lie detection accuracy in a particular course or a particular study might more efficiently proceed by training in a focused skill or set of skills known to be related to lie detection. Many of the recent lie detection studies used this approach, narrowing their focus and evaluating the effectiveness of training with a particular kind of knowledge or subset of cues.

Santarcangelo [22] found that informing trainees about either (i) verbal content cues (plausibility, concreteness, consistency, and clarity which are included in the more extensive Criteria-Based Content Analysis (CBCA) protocol); (ii) nonverbal cues (adaptors, hand gestures, foot and leg movements, and postural shifts) or (iii) vocal cues (response duration, pauses, speech errors, and response latency) resulted in lie detection accuracy greater than a no-cues control group.

Levine [18] conducted a series of studies on how to increase lie detection accuracy that also used mere verbal description of cues. In three of the studies, a lecture describing general behavioral cues comprised one condition. A second condition was a bogus training group in which *incorrect* information about lie detection clues was given to the subjects. The control group received no information about lie detection clues. None of the three studies obtained significant results in the predicted direction. In the fourth study, behavioral cues actually occurring in the stimulus materials were used for the lecture condition. In this condition, a significant result was found between the training lecture (58%) and the control condition (50%). However, the bogus training also resulted in significantly increased training (56%) which was not significantly different from the authentic training condition. Interpretation of this study is complicated by the use of only two different stimulus persons as the target liars and truth tellers. Other researchers are also designing training studies which teach those behavioral cues actually existing in the training and testing materials [15, 23]. For studies using this training method, situational generality (testing on other lie detection tests as well) is particularly important.

Hartwig [17] took a novel approach by training police trainees to adjust the timing of their questions. Rather than assessing the nonverbal behaviors of the liars and truth tellers, actual evidence (eyewitness testimony, fingerprints, etc.) was available and the liars and truth tellers were informed of this during the interview. The Hartwig study found that if interviewers held back knowledge of the evidence until later in the interview, liars were more likely to make inconsistent statements which increased detection accuracy for the interviewers. This training is much more like the kind of interview situation in which law enforcement officers decide the honesty of suspects. Such training, however, may not generalize to interview situations in which no evidence is available.

An unusual feature of deception research, although certainly not new in other kinds of training, is the use of computer programs in lieu of instructor presentation or printed materials. Crews [15] and George [16] demonstrated that there was no difference between a computer-based training program and the same material presented by a human instructor. In both cases, significantly increased accuracy was achieved.

Although most of the studies provided examples of honest and deceptive behaviors for trainees, some did not. Subjects in the Levine [18] and Santarcangelo [22] studies, for example, only received a written sheet of cue information that could be read rather quickly. It is interesting that these studies found a significant, albeit small (4%) increase in accuracy, whereas studies using more lengthy training procedures [15, 17] reported gains in excess of 20%.

## 7 TESTING

(a) *Randomization.* Trainees were randomly assigned in all of the studies. Most of the studies used a pre—post design except those of Hartwig [17] and Levine [18] which utilized a random assignment, post-group comparison design. Random assignment in a post-group-only design assumes that all assigned interviewers or judges are

alike prior to training and that differences afterwards are due to the training alone. A post-test-only design does not completely rule out the possibility that trained and untrained interviewers or judges, even if randomly assigned, were different before the experiment.

(b) *Independence of items in the stimulus materials.* Although most of the lie detection materials used different liars or truth tellers for each "item" some did not. Levine [18], for example, used only two targets, who both lied and told the truth about items on a test. When "items" are not independent, the effect of biases, personal likes and dislikes with particular kinds of people, familiarity with particular kinds of people or particular kinds of behavioral styles can all affect the final scores. These biases may reflect factors other than lie detection accuracy.

(c) *Independence of targets in pre—post designs.* All of the pre- and post studies, except O'Sullivan's [19], used different liars and truth tellers for their pre- and post-tests. Although a control group ameliorates the effect of mere familiarity on increased lie detection accuracy, it is preferable to have different individuals as targets in the pre- and post-test measures and to ensure that the tests are of equivalent difficulty. The Crews study [15] did an especially careful job of determining that their pre- and post tests were equivalent in difficulty, establishing their norms in a pilot study. None of the other studies did this, or if they did, they did not mention it.

(d) *Numbers of targets.* Except for Levine [18] who used only two test subjects, most of the studies used 6 to 12 subjects for the pre-test and/or post-test measures.

## 8 SITUATIONAL GENERALITY

All of the studies used a single kind of lie so the generalizability of training for lie detection accuracy is unknown. Given that some of the studies with the greatest increase in accuracy taught and emphasized the cues that were actually contained in the materials [15, 16], the issue of situational or lie generality is an important one.

## 9 TIME GENERALITY

None of the studies reviewed examined the temporal stability of any gain in lie detection accuracy, so we have no way of knowing whether gains in lie detection accuracy survive the time span of the training course. Researchers are aware of this issue, however. Porter [21] spread the training over five weeks, and found a highly significant increase in detection accuracy. Whether this gain would last longer than five weeks, however, is unknown. Marett [24] was specifically interested in the effect of lie detection history (training over time) on final accuracy, but the small number of subjects and items did not allow them to reach any conclusions. (This study is not reviewed since no accuracy means were reported.)

## 10 INDIVIDUAL DIFFERENCES RELATED TO LIE DETECTION ACCURACY

In training to increase lie detection accuracy, a variety of individual difference abilities need to be considered. The already existing ability of the trainees is one that has

often been overlooked. It seems reasonable, however, that training which provides new information to mediocre lie detectors, may be superfluous to expert ones. And providing specialized training, in verbal content analysis or facial expression recognition or other nonverbal cues, might be more advantageous for those already at an average or above average lie detection accuracy level. No research exists which examines the role of pre-existing lie detection accuracy on the efficacy of different lie detection training paradigms.

In our work with expert lie detectors who have been trained in facial expression recognition, several of them have reported a disruption of their ability to assess truthfulness in the months immediately following the training. With practice, however, according to their self-reports, they were able to incorporate the new information into their skill set. Kohnken [25] and Akehurst [14] also described reports from police trainees that they needed more time to incorporate the new information provided. (In these studies it was verbal content training rather than facial expression recognition.) A difficulty in examining this hypothesis (that more expert lie detectors may have an initial disruption effect, resulting in a decrement in lie detection accuracy) may occur due to the ceiling effect or regression to the mean for the lucky guessers in the first testing. If trainees are already highly accurate prior to training (70% or better), there is little room for improvement as measured by most existing lie detection accuracy measures. Many lie detection accuracy tests are relatively brief; the median number of items is ten. Clearly, new tests containing more items of greater difficulty are necessary. The issue of item difficulty is also an important one. Many items in existing lie detection measures are difficult because the lies are trivial and there are no emotional and/or cognitive clues to discern. Item difficulty should be based on subtle cues that are present although, difficult to distinguish, or should reflect the kinds of personality types (outgoing, friendly) that are particularly difficult for American judges to perceive as liars.

Other individual difference variables that have been largely overlooked in studies of lie detection accuracy training are the intelligence and cognitive abilities of the lie detector. O'Sullivan [26] demonstrated that the fundamental attribution error was negatively related with accurate detection of liars. Whether such cognitive biases can be corrected through training has not been examined. Although many people seem to believe that lie detection is a natural ability unrelated to education or training, O'Sullivan noted [27] that more than half of her 50 expert lie detectors have advanced degrees and all have at least a two year associates degree. The interpretation of the many cognitive and emotional cues that occur while lying and telling the truth may take a superior baseline level of intelligence to decipher. This hypothesis has also not been examined. On the other hand, Ask and Granhag [28] found no relationship between cognitive or personality variables such as need for closure, attributional complexity, and absorption. The lie scenarios they used, however, may not have provided sufficient score variance to examine their hypotheses adequately.

Many expert lie detectors seem to have an ongoing life commitment to seeking the truth [5]. This kind of commitment and practice cannot be taught in a single training program, which suggests that selecting already accurate lie detectors might be a more sensible approach to use when staffing personnel to perform lie detection interviews. This option, however, may be difficult to implement given the relative rarity of expert lie detectors (from 1 per thousand in some professional groups to 20% in others [5]) and the personnel restrictions in some agencies.

In addition to individual differences in lie detection accuracy as a factor to be considered in designing and implementing lie detection accuracy training courses, the role of other individual difference factors needs to be considered. Deception researchers [9] have noted the extraordinary motivation of expert lie detectors to know the truth. Porter [29] attempted to examine motivation by randomly assigning subjects to one of two levels of motivation to succeed at a lie detection task. This motivation manipulation had no impact on consequent lie detection accuracy. An experimentally manipulated motivation to detect deception, however, may not be a sufficient analog for the life-long commitment to discern the truth in one's profession and one's life that some expert lie detectors show.

To date there is mounting evidence that certain law enforcement personnel groups [6, 30, 31] and individuals [5, 7] are accurate at least with certain kinds of lies. There is replicated evidence that groups of forensic specialists (psychologists and psychiatrists), federal judges [31], and dispute mediators [5] are also significantly above chance in their ability to discern the truth. In all of these studies, comparison groups, usually of college students, have average accuracies at the chance level on the tests used. This provides some support for the view that the lie detection tests are not easy, which rules out one explanation for their high accuracy.

While commitment to lie detection is an aspect of some expert lie catcher's professional lives, O'Sullivan [19] found that even among college students, concern for honesty was significantly related to lie detection accuracy. Students who reported rarely lying to friends obtained higher accuracy on a lie detection measure than students who lied to friends frequently. In this same study, a high rating for honesty as a value when compared with other values (such as a comfortable life) also distinguished more and less accurate lie detectors.

Given the importance of emotional clues in detecting deception, it is not surprising that a number of studies have reported significant correlations between emotional recognition ability and lie detection accuracy. Warren, Schertler, and Bull [32], for example, demonstrated that accuracy at recognizing subtle facial expressions using the SETT (Subtle Expression Training Tool [33]) was positively related to accuracy in detecting emotional lies, but not nonemotional ones. (This study underscores the need for situational generality of lie scenarios as discussed earlier.) Ekman and O'Sullivan [30], Frank and Ekman [34], and Frank and Hurley [10] all found a significant relationship between micro-expression detection accuracy and lie detection accuracy using precursors of the Micro-Expression Training Tool (METT) [35]. Frank [36] also found that being trained on micro-expressions significantly improved detecting emotions that occurred while lying.

Many IQ tests are highly saturated with verbal content, so it is likely that the ability to apply one type of verbal system (e.g., CBCA) in improving lie detection accuracy may be related to verbal intelligence. Vrij [37] found individual differences in the ability to learn CBCA in order to lie or tell the truth more effectively. While the ability to learn CBCA may have a cognitive component, the study also found that ability to use CBCA in truth and lie performance was related to social anxiety.

Porter's [29] report of a significant correlation between handedness and lie detection accuracy (left-handed lie catchers being superior) also suggests a biologically based individual difference that should be considered in lie detection accuracy programs. Etcoff and her colleagues [38] also reported a similar right brain advantage in lie detection.

Other individual difference variables of interest have included gender and personality variables such as social skill and Machiavellianism. For all of these variables, conclusions are difficult to draw because of the widely varying adequacy of the lie detection scenarios used, or the lack of variance in lie detection accuracy of some of the subjects. For example, in one study [39] which reported an interaction effect between gender and increased accuracy with training, the differing mean accuracies of the two genders at the start of the study compromises this conclusion. Before training, average accuracy for males was 47% which increased to 70% after training. For females, pretraining accuracy was 68% which decreased to 62% after training. Pretraining performance for females was significantly higher than for males, giving females less headroom for improvement. Even though the males' accuracy increased significantly while the females did not, the difference in their final accuracy levels was not significant. This effect might reflect a room-for-improvement phenomenon rather than a gender one. Some low-scoring females might have shown some improvement. The confounding of base accuracy level and gender would need to be clarified before conclusions can be drawn about gender effects. Over all, no consistent gender superiority in lie detection accuracy or in training effectiveness has been demonstrated.

Training studies with relevant tasks, focused training programs, and reliable test materials known to contain behavioral clues or other evidence relevant to lie detection, have resulted in a growing body of research demonstrating that lie detection is difficult for most people, but that improvement is possible with well-honed training programs.

Selecting the best detectors within an organization may be more cost-effective, but it too is fraught with problems. The tasks used to determine who goes forward need to mirror the structural features of the scenarios to which these personnel will apply their skills. And, ideally it would be useful to develop some metric as to how well they do in the real world, compared to those not selected. For example, we can consider criteria such as how much contraband is confiscated, or how many cases go to trial and result in a conviction, or other goals specific to the agency may be useful. This would require a new way of thinking about security, but it may violate assumptions about equal treatment for all agency personnel.

## 11 CONCLUSION

We end on an optimistic note. Increasingly, researchers are identifying highly accurate lie catchers. This increased range of lie detection accuracy can provide a proving ground for developing lie-specific training. Research on how expert lie detectors do what they do can suggest materials to be included in lie detection courses. Researchers have also become increasingly sophisticated about the need for experimental validity in their work. They have also become more sophisticated about the value of training on one particular skill or clue domain at a time (e.g., CBCA, METT). We believe the tools of the scientist can be successfully applied to real-world security settings. But more work is needed in order to calibrate the cost/benefit ratio because so much of the science is not directly relevant to security personnel. We see this as a call for increased cooperation between scientists who are sympathetic to the pressures on security personnel and practitioners who desire scientific help in their professions. Once we achieve that combination of forces, we can move this issue forward to identify the optimal way to deploy people in the lie detection process.

# DETERRENCE: AN EMPIRICAL PSYCHOLOGICAL MODEL

ROBERT W. ANTHONY

*Institute for Defense Analyses, Alexandria, Virginia*

## 1 INTRODUCTION

Although deterrence has not led to a strategic victory to date against the entire loosely knit network of cocaine traffickers. However, it has shut down nearly all direct smuggler flights into the United States [1, 2], eliminated Peru as a major cocaine producing country [2, 3], and recently closed down nearly all Caribbean go-fast boat traffic. Section 3 recounts how data obtained from these various success stories facilitated the derivation and calibration of an unexpectedly simple mathematical function representing the psychology of deterrence [1, 3]. It goes on to explain how these tactical victories teach several practical lessons and reveal operational dilemmas. To apply these results to terrorism, Section 4 summarizes an analysis of terrorist preparations for the 9/11 attacks. This analysis suggests that "deterrence" influences decision making for terrorists perpetrating complex plots. The section also explains the methods for estimating the deterrent effect of a mixture of several possible consequences and methods for estimating the deterrence contribution of multilayer defenses. Section 5 introduces several testable hypotheses concerning the generality of these findings and possible explanations for the willingness function. It also emphasizes the importance of interdisciplinary, integrated research to focus all available knowledge on understanding the risk judgments of criminals, insurgents, and terrorists.

## 2 DEFINITIONS AND SOURCES

A great deal of deterrence research addresses the prisoner's dilemma gaming of the cold war standoff, rate of loss models of military attrition, or guidance to law enforcement in various situations, often with the underlying assumption of a linear relationship between effort and effect. By contrast, this work focuses on the psychology of perpetrators represented as a fraction of a pool willing to act. Therefore, this approach does not discriminate between individual behavior and distributions across a perpetrator population.

The US military has formally defined both deterrence and strategic deterrence; the first applies to thwarting terrorists in general, while the second applies to complex plots that could damage the vital interests of the United States. Remarkably, these definitions include a psychological interpretation of deterrence.

Primary data sources in the public domain are cited at the end of this section. Unfortunately, many organizations applying deterrence in their operations cannot publicly release their classified data, and others with fewer restrictions are reluctant to do so. Moreover, these organizations also do not see their mission as one of justifying support for sustained applied research or any basic science.

### 2.1 Definition of Deterrence

The US Department of Defense (DoD) defines deterrence as "the prevention from action by fear of consequences—deterrence is a state of mind brought about by the existence of a credible threat of unacceptable counteraction" [4]. Even suicide terrorists must fear some consequences, especially risks that undermine their motives for taking such drastic action. For example, some terrorists might fear failure, arrest, or loss of life without completing their mission; dishonoring or bringing retribution upon their families; embarrassing their cause and supporters of their cause; or revealing a larger scheme or its supporting network.

### 2.2 Definition of Strategic Deterrence

Recently, the DoD introduced a related concept: "*strategic deterrence* is defined as the prevention of adversary aggression or coercion threatening vital interests of the United States and/or our national survival; strategic deterrence convinces adversaries not to take grievous courses of action by means of decisive influence over their decision making" [5]. This definition should exclude individuals who are mentally ill, act impulsively, or act alone. Strategic deterrence primarily applies to complex plots and networks with sufficient resources to threaten national vital interests. Although the empirical quantitative model reveals that deterrence will not thwart everyone, its cumulative and systemic impact on complex plots or networks should be capable of debilitating virtually all of them.

### 2.3 Information from Operational Sources

Operational organizations provided an interview report summarizing the responses of a very diverse population of 109 imprisoned drug smugglers. Analyses of these data led to the development of a simple mathematical expression representing the psychology of deterrence [1, 3]. Two reports provide more details on the interviews and operational data from major countercocaine operations [3, 6] used to verify and calibrate the deterrence model. Unfortunately, other data sets are not available for public release.

## 3 PRINCIPAL FINDINGS

Deterrence is essential for amplifying limited interdiction capabilities to thwart hostile activity. For example, lethal consequences can amplify interdiction effort by more than a factor of 10. The following quantitative representation of the psychology of deterrence and associated tactical lessons has been used to size forces, guide operations, and assess operational effectiveness in counterdrug and counterterrorism operations. Although the references provide more detail, one case is summarized: the air interdiction operations against smugglers flying cocaine from Peru to Colombia. This case illustrates the effectiveness of deterrence, verifies essential features of the mathematical form of the willingness function, and provides calibration for lethal consequences.

### 3.1 Willingness Function

The "willingness function" expresses the psychological aspects of deterrence in mathematical terms. It facilitates an estimate of the fraction of all would-be perpetrators willing to challenge the risks of interdiction. It has one independent variable, the probability of interdiction, $P_I$, and one constant parameter, the threshold of deterrence, $P_0$, calibrated to the specific perceived consequences of interdiction. Figure 1 plots the willingness functions for three different values of the deterrence threshold. The vertical axis represents the fraction of perpetrators and the horizontal axis represents the probability of interdiction.

To interpret a willingness function, consider the light curve. As the interdiction probability increases from zero, all would-be perpetrators remain willing to continue until their perception of the interdiction probability reaches the deterrence threshold at a probability of interdiction of 0.13. Beyond the deterrence threshold, the fraction of the perpetrators still willing to perpetrate, $W(P_I)$, declines in proportion to the inverse of the perceived

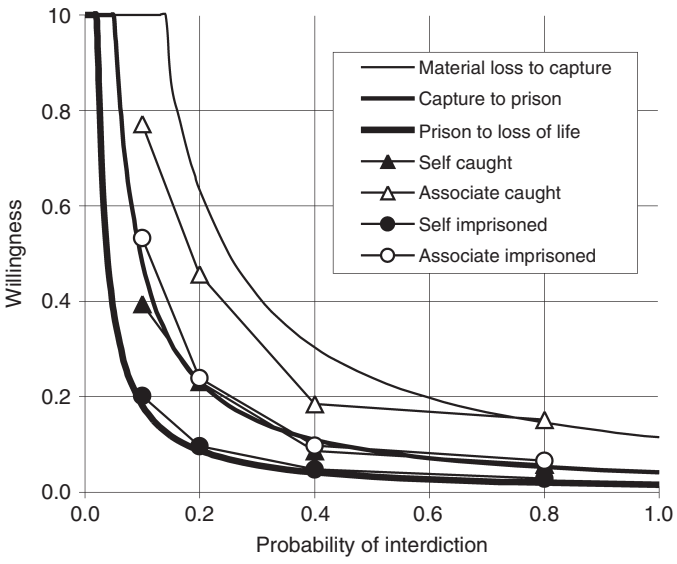

**FIGURE 1** The willingness function.

probability of interdiction:

$$W = \frac{P_0}{P_I}. \tag{1}$$

As the interdiction probability approaches 1.0, however, a small fraction, $P_0$, of the perpetrators persist, even expecting certain interdiction. In interviews with imprisoned drug smugglers, some commented that they would continue smuggling knowing they would be imprisoned since one fee, given in advance, would more than compensate for their prison time [3]. Scofflaw fishermen violating restrictions that protect living marine resources also behave according to the deterrence model and show no indication of quitting out to an 80% probability of interdiction [1].

Heavy, medium, and light curves in Figure 1 illustrate willingness functions bounding the ranges of four different types of consequences. The heavy curve represents the boundary between "lethal" consequences and "imprisonment" and is determined by a threshold of deterrence of 0.02. The medium weight curve separates "imprisonment" from "capture followed by release" and has a threshold of 0.05. The light curve separates "capture and release" from "loss of material assets" and has a threshold of 0.13.

Figure 1 also shows four sets of data obtained from voluntary interviews of imprisoned smugglers. Each was asked whether he or she would be willing to continue to smuggle if the chance of interdiction equaled successively higher values as indicated by data symbols along the trend lines. The same willingness questions were asked for different consequences, for example, being caught then released or being imprisoned, and for two different perceptual orientations, answering for themselves and answering as if they were a former associate smuggler. As the researchers anticipated, the interviewees estimated their associates would be more willing to continue smuggling than they would be now that they have experienced incarceration. These cumulative trends illustrate how well the willingness function boundaries parallel and bracket the interview responses.

In such very high-risk activities, perpetrators appear to decide whether the risks are acceptable before even considering the adequacy of the rewards. For example, all inmates stated their willingness to smuggle without any reference to wages. On separate questions exploring the sensitivity of willingness to wage levels, significantly higher wage offers did not increase the previously declared fraction of the smugglers willing to face the risks. However, if risks do increase, the wage necessary to sustain smuggler willingness at their previously declared levels increases quadratically relative to the increased risk.

### 3.2 Surge Operations

Surge operations typically consist of doubling or more the interdiction pressure and sustains it long enough to convince perpetrators that they cannot simply outwait the interdictors (typically 2–5 months for counterdrug operations). Surges have effectively communicated risks to perpetrators and caused lasting deterrence, even as interdiction efforts substantially relax from surge levels [1, 3].

A surge operation can provide valuable intelligence since it can induce perpetrators to react, thereby revealing their clandestine activity and the level of their deterrence threshold. Focusing surges on criminal hot spots should amplify the visibility of criminal reaction to deterrence, and has proven capable of doing so in urban areas [7]. However, if perpetrators can change their mode of operation or shift their location, the interview

data suggests they will change whenever interdiction risk reaches only approximately one-half of the deterrence threshold [1, 3]. Thus, operators must take this possibility into account in their subsequent planning.

### 3.3 Breakouts from Deterrence

A mathematical property of the willingness function shows that deterrence, once established, is at risk of instability. After deterrence has suppressed attempts, the estimated fraction of perpetrators actually interdicted tends to remain constant at a magnitude equal to the deterrence threshold:

$$W \cdot P_I = \left(\frac{P_0}{P_I}\right) \cdot P_I = P_0. \tag{2}$$

Under normal conditions, defenders need only interdict this constant fraction to deter. However, any diversion of interdiction effort elsewhere or additional recruitment expanding the pool of potential perpetrators, possibly as the result of an external event, could cause the fraction interdicted to drop below the deterrence threshold. This would most likely trigger a burst of perpetrator attempts, threatening a breakout from deterrence. Interdictors, therefore, need to maintain a reserve capacity, or other overwhelming threat of counteraction, to prevent breakout or reestablish deterrence.

### 3.4 Deterrence Model

The deterrence model estimates the fraction of all perpetrators thwarted by interdictors, $P_t$, that is, those who are either interdicted or deterred.

$$P_t = 1 - (1 - P_I) \cdot W(P_I^*) \tag{3}$$

where $P_I^*$ is the perceived probability of interdiction. Under steady conditions with well-informed perpetrators, the willingness function represents the subjective aspects of perceived risk, and $P_I^*$ equals $P_I$. During surges or other transition periods, however, there might be a diversity of perceptions with many misunderstandings of the real situation. Since the probability of thwarting an attempt equals the probability of unsuccessful attempts, it is one minus the probability of those willing and able to avoid interdiction.

### 3.5 Example—Peruvian Drug Flights

A series of operations to interdict and deter air traffickers flying cocaine base from Peru to Colombia provided an estimate of the deterrence threshold for lethal consequences [1, 3]. These operations also demonstrated the impact of an initial surge and proved that perpetrators will ignore even lethal consequences under some conditions.

The US detection and monitoring support to the Peruvians provided nearly perfect coverage of trafficker flights, and the combined capacities of those flights closely matched satellite estimates of the coca crop during periods without deterrence. This enabled an estimate of those willing, while complete and verified interdiction records gave probability of interdiction.

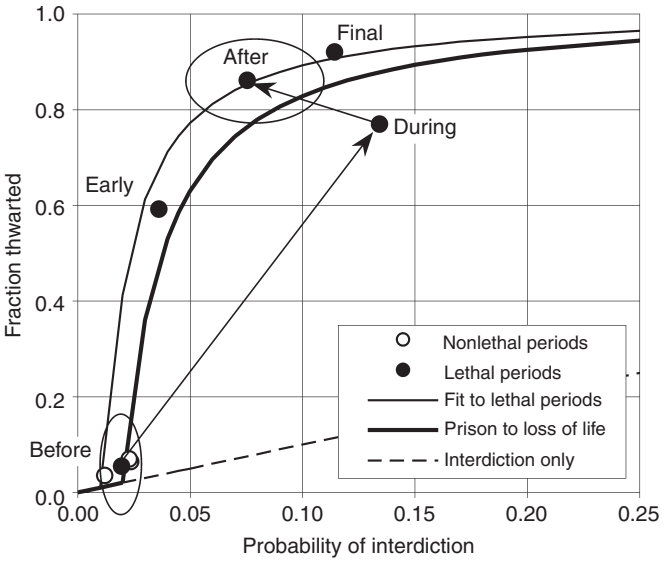

**FIGURE 2** Deterrence model for lethal interdiction showing operational periods intended to stop smuggler flights from Peru to Colombia.

Figure 2 shows the principal operational periods plotted over two deterrence model curves. The vertical axis is the fraction of flights thwarted and the horizontal axis shows the probability of interdiction. Each operational period lasted from 7 to 11 months, identified 100–500 smuggler flights, and involved 6–17 interdictions. Ovals represent conservative estimates of the asymmetric uncertainty ranges from both statistical and systematic sources. Open circles represent periods of nonlethal consequences during which air traffickers carried all cocaine base destined for Colombia. Filled circles represent periods with lethal consequences.

Three periods of lethal interdiction illustrate the transition from no deterrence to full deterrence, after passing through an intervening surge. Figure 2 labels these as "before," "during," and "after." In the 10-month "before" period, there is no evidence for deterrence; smugglers simply ignored lethal consequences. Since the Peruvians did not have US detection and monitoring support, they only shot down seven smugglers. This is well within the statistical uncertainty range of the deterrence threshold for lethal interdiction indicated by the heavy curve.

To aid the Peruvians in protecting their national security against an ongoing insurgency, the US Presidential Directive resumed intelligence support to their air force. This initiated the surge period "during" the transition. In the first month, Peruvian interceptors interdicted eight trafficker flights. Unusually high levels of lethal interdiction continued, and smuggling flights plummeted as trafficker pilots communicated and adjusted their perception of the risks. Full deterrence had set in by the period labeled "after." Since the probability of interdiction in the transition period exceeded the trafficker pilots' perceptions of that probability, the point labeled "during" is out of equilibrium and does not lie on the deterrence model curves.

In the first month of the "after" period, interdictors relaxed their pressure, and smuggler flights increased fourfold. Interdiction support resumed the next month, and once again,

traffickers were deterred. Thereafter, intelligence reports indicating depressed coca prices sustained the support for interdiction. Illicit Peruvian coca cultivation eventually declined to less than one-third of its previous levels.

The best-fit value for the deterrence threshold for lethal consequences, excluding the "during" period, is 1.2 ± 0.2%. Since the distribution of interdictions by month is a Poisson distribution, the operational variation about the threshold is comparable to the threshold itself. Consequently, operational planners adopt a conservative value of 2.0% for the lethal threshold to cover this variation.

### 3.6 Interdictor's Dilemma

The Peruvian experience illustrates the interdictor's dilemma: is deterrence working or are perpetrators avoiding detection? In the general case, the only resolution to this dilemma is convincing corroborating intelligence proving damage to the illicit activity. Often this is supplemented by intelligence indicating perpetrator intent, consequences perpetrators fear, and clandestine attempts.

### 3.7 Defender's Dilemma

Defense can be a thankless task. If there are no explicit hostile acts, why do we need to continue operations? If deterrence fails and there are attacks, who do we hold accountable? Defensive operations driven by concerns over accountability promote routine activities that become vulnerable to terrorist probes.

Two potential sources of information can transform passive and reactive defenses into dynamic ones taking the initiative. First, deterrence operations can be augmented with intelligence collection on perpetrator attempts to probe or defeat our defenses, and, second, red teams, exercises, and gaming can be employed to continually introduce new and adaptive elements into our defenses. These activities could also provide credible information for evaluating effectiveness and justifying resources.

## 4 IMPORTANT APPLICATIONS

Do lessons learned from criminals transfer to insurgents and terrorists? Analysis of the preparations for the 9/11 attacks indicates consistency between the drug smugglers' deterrence threshold for lethal consequences of 0.012 and the inferred subjective criterion used by Mohamed Atta to initiate the attack. Although factors other than psychological ones might also have applied, there was evidence of deterrence further up the leadership hierarchy. The 9/11 Commission Report stated on page 247, "According to [Ramzi] Binalshibh, had Bin Laden and [Khalid Sheikh Mohammed] KSM learned prior to 9/11 that Moussaoui had been detained, they might have canceled the operation." A second application of the willingness function extends it to estimate the deterrence effect of combinations of consequences. A third application extends the deterrence model to estimate the contribution of deterrence to multiple layers of defense.

### 4.1 Deterrence of 9/11 Terrorists

Although dedicated suicide terrorists perpetrated the 9/11 attacks, analysis reveals that they were probably deterred from hasty action until they developed confidence in their

plan [8]. Terrorists must exercise extreme caution day-to-day while preparing for a complex attack, and risk aversion provides a basis for deterrence. Their cautious preparations and practice flights were analyzed as a system reliability problem: for a plot consisting of *all four hijacked flights reaching their targets*, how many unchallenged "practice" flights would be necessary to reduce their perceived risk of failure to a level comparable to the deterrence threshold for lethal interdiction derived from studies of drug smugglers? By this criterion, in addition to the flights necessary to assemble the team in the United States, the 9/11 plot leaders would have had to practice 20–40 more times to be confident of the success of the attack. After this analysis was published, Chapter 7 of the 9/11 Commission Report mentions at least 80 flights, half of which are domestic, and 8 of those use the hijacking routes, box cutters and all. This analysis illustrates how our imperfect deterrence of individuals could have compounded to undermine their complex plot.

### 4.2 Deterrence through Combining Consequences

Interdictors need a means of estimating the deterrence effect of a combination of risks, especially for anticipating the effect of multiple layers of defense. A logically consistent method for doing this is obtained by drawing an analogy with expressions for expected utility and related models from the psychology of decision making under risk:

$$\sum_{i=1}^{N} \frac{P_{I,i}}{P_{0,i}} = P_I \cdot \sum_{i=1}^{N} \frac{(P_{I,i}/P_I)}{P_{0,i}} = \frac{P_I}{P_0} = \frac{1}{W} \text{ where } P_I = \sum_{i=1}^{N} P_{I,i}. \tag{4}$$

This represents a combination of $N$ risks, each with probability of interdiction, $P_{I,i}$, and deterrence threshold, $P_{0,i}$. The combination also recovers the mathematical form of an inverse willingness function by identifying the following expression as a deterrence threshold:

$$P_0 = \left[ \sum_{i=1}^{N} \frac{(P_{I,i}/P_I)}{P_{0,i}} \right]^{-1}. \tag{5}$$

Since $W \leq 1.0$ implies deterrence, the corresponding condition is $1/W \geq 1.0$. Note that the individual risks, $P_{I,i}/P_{0,i}$, all can be below their respective thresholds, yet their combination can deter.

Since the consequences represent losses, the inverse willingness, $1/W$, can be interpreted as a measure of risk. Those familiar with economics of choice among lotteries or the psychology of judgment under uncertainty will recognize the left-hand expression in Eq. (4) as similar to that for estimating risk, with $1/P_{0,i}$ corresponding to the utility function or more generally the subjective utility.

Other than the Peru–Colombia flights, all of the operations, for which there are data, involved a combination of consequences [1, 3], and these followed the willingness function. As an example of mixed consequences, consider the wide range of consequences faced by cocaine smugglers at each of the five transactional steps required to breakdown multiton loads from Colombia into gram-sized purchases by millions of users in the United States. Remarkably, traffickers at all levels share the risk since traffickers lose

on average 12% of their loads at each step [2]. The following equation illustrates how a plausible mixture of consequences could result in a 12% deterrence threshold:

$$\frac{P_I}{P_0} = \frac{0.12}{0.12} = 1.0 = \frac{P_{I,lethal}}{P_{0,lethal}} + \frac{P_{I,\mathrm{Pr}ison}}{P_{0,\mathrm{Pr}ison}} + \frac{P_{I,Drugs}}{P_{0,Drugs}} = \frac{0.004}{0.02} + \frac{0.022}{0.05} + \frac{0.094}{0.25} \quad (6)$$

Here, a 0.4% chance of death, a 2.2% chance of being imprisoned, and a 9.4% chance of losing the drugs and most likely the smuggling vehicle could combine to yield the 12% threshold. Note that each of the individual contributions is below its respective deterrence threshold.

Although the logical consistency and plausibility of this method for combining consequences can be verified, in general, one must exercise caution and plan to verify the estimated combination since the research on descriptive risk judgments describes many deviations from the simple prescriptive form of the expected utility [9–11]. Mathematical simplicity is an overriding practical consideration for counterterrorism operations, and the simplicity of the willingness function is remarkably relative to other models from the literature that require several parameters to represent subject responses. A fundamental difference, however, between the willingness function and expressions found in the literature is that acceptance or attractiveness of a gamble is generally interpreted as the *negative of risk* rather than its *reciprocal* [12]. Why the willingness function fits the available data so well remains a mystery. Possibly perpetrator preoccupation with extreme risk reduces the complex general case to a simpler asymptotic form.

### 4.3 Defense in Depth

Estimating the ability of several layers of defense to thwart terrorists requires an understanding of how terrorists might perceive those defenses. Some circumstances might cause terrorists to perceive all of the layers as one barrier (e.g. if penetrating the first layer required penetrating all layers, as with passengers on a ship, or if terrorist planners required several members of a cell to be able to penetrate all of the layers). By contrast, other situations would allow perpetrators to attempt penetrations one layer at a time.

If all layers are perceived as one barrier, each layer becomes a separate risk, and all layers a combination of those risks. Again, for such a combination, individual layers might not pose sufficient risk to exceed the deterrence threshold, yet together they could. This advantage of layers perceived as one barrier is offset by the high rate of undeterrables, numerically equivalent to the deterrence threshold for only one barrier.

If, however, the layers are viewed as independent risks, some or all must pose a risk above the deterrence threshold if deterrence is to contribute. Since the layers each thwart a fraction of the perpetrators, their effects compound multiplicatively to suppress residual leakage. This also assumes that undeterrables at one layer might be deterred by a risk at a subsequent layer. If it were otherwise, terrorist planners employing a team of less cautious undeterrables for a complex plot would risk revealing it before it could be executed.

Figure 3 shows the deterrence model for two-layer defenses plotted against the probability of interdiction for one layer that is assumed representative of both layers. A large deterrence threshold of 0.2 expands the graphic scale to ease visualization. With two layers perceived as one barrier, deterrence begins at approximately one-half the deterrence thresholds of the individual layers. (With very large thresholds at each layer, the

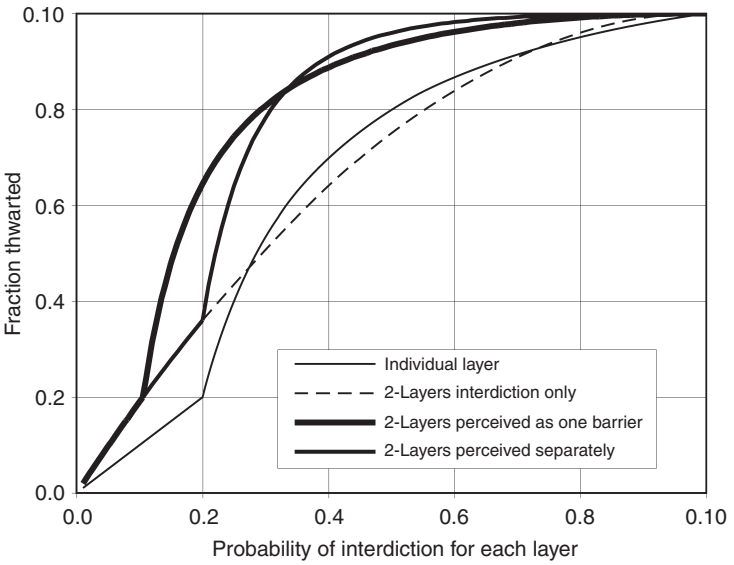

**FIGURE 3** Comparison of deterrence models for two-layered defenses.

probability of confronting deeper layers would be discounted by the chances of being interdicted at earlier ones.) Also, in Figure 3, the two layers acting separately compound to thwart relatively more perpetrators beyond an interdiction rate of approximately 0.33.

Correlations among layers could undermine or enhance deterrence relative to these baseline cases. Perpetrators might view both layers as equivalent—after crossing one, the other is an assured passage—hence undermining deterrence. Alternatively, the first layer could alert interdictors at subsequent layers to suspicious individuals for a more in-depth examination or perpetrators falsifying statements at one layer might increase the consequences if interdicted at a subsequent layer; both of these possibilities would enhance deterrence if they were known to would-be perpetrators.

## 5 RESEARCH DIRECTIONS

How broadly does the willingness function apply? How might the willingness function be knit into the body of established psychological and behavioral findings? Future research should integrate these findings and other work on deterrence into a unified area of study so that lessons transfer and deeper understanding informs our ongoing counterterrorism efforts.

### 5.1 General Result

Several testable hypotheses suggest that the understanding of deterrence presented here applies to those taking extreme risks, including drug traffickers, insurgents, and terrorists:

- People can judge risk directly [1, 3, 9–11], and with simple mathematical regularity in extreme situations.

- Underlying motives are more common than different. Even drug traffickers seek respect from their reference group, need to maintain a lifestyle, pursue the thrill of risk taking, and, in some cases, fund insurgencies and terrorism.
- The mathematical simplicity of the willingness function is difficult to explain without appealing to some overriding principle, given the intricacies of the psychological theories and models as well as the diversity of subjects and situations covered by the willingness function.

### 5.2 Explaining the Willingness Function

Future research might examine two alternative explanations of the willingness function and connect them with the study of decision under uncertainty:

- In the psychology of persuasion, the persuasiveness of a communication is a sum over salient novel arguments; thus, the constant fraction interdicted might represent a constant rate of persuasive argumentation against perpetrating acts [13].
- If the decline of those willing represents the distribution of those with greater needs than the likely consequences of deterrence, then the decline might parallel the Pareto distribution that extends toward lower incomes [14].

Extensive research into the psychology of judgment under risk should be applicable to deterrence, yet the models and methods address acceptance as the negative rather than the reciprocal of risk. Might there be a universal asymptotic distribution converging on an inverse power law?

### 5.3 Integrating the Research Community

Understanding the psychology of deterrence as it applies to terrorists requires information on, among other things, terrorist perspectives, intentions, perceptions of risk, and behavior. Results presented here indicate that it appears possible to relate deterrence of terrorists and insurgents to criminals and extreme risk takers. A national research effort to understand deterrence would have to integrate intelligence sources, operational experience, and various social science research communities. Today, the barriers between these three communities are formidable. Hopefully, this handbook will raise awareness of the value of, and need for, a synthesis across these institutional barriers, and catalyze efforts toward that end.

# DECISION SUPPORT SYSTEMS

# TECHNOLOGIES FOR REAL-TIME DATA ACQUISITION, INTEGRATION, AND TRANSMISSION

CHARLES K. HUYCK AND PAUL R. AMYX
*Imagecat, Inc., Long Beach, California*

## 1 INTRODUCTION

Real-time sources typically stream raw data for a given hazard tied to collection of specific locations. This data is useful not only for engineers and scientists studying natural phenomena, but when the data is processed correctly, it can aid in emergency management decisions. Real-time data can be used in a planning capacity to determine the likelihood of disaster striking a specific area, as with the monitoring of hurricanes tracks, or fault slip rates. Real-time data is essential in tracking events which are slow to evolve and provide ample time to respond, such as tracking hurricanes and flood stages. In some cases, real-time sensors provide immediate access to warning data, such as *in situ* hazardous material sensors or earthquake early warning systems. Immediately after an event, when the extent of damage is unclear, raw data from accelerometers and anemometers provide data to estimate the spatial extent of damage, and can be used to provide responders with a road map for response. During response, real-time data allows managers to monitor the public, asses traffic congestion, assess damage, and monitor progress. The following section provides a description of select real-time data sources in the United States.

## 2 AVAILABILITY OF REAL-TIME DATA

Real-time data acquisition should include data from the proliferation of mobile phone devices that can be used to record images, video, and send text, and data sent to a general repository from the general public. Increasingly, information and communication sources are becoming far more prevalent in the form of distributed GPS, video, mobile phones, and humans as sensors. This direction is sure to continue as wireless Internet devices and MEMS are integrated into commercial off-the-shelf (COTS) products. The communication and security equipment available on 11 September 2001 did not prevent United Airlines Flight 93 from being hijacked, but mobile phones played a crucial role in

preventing the ultimate goal of the hijacking. Successful real-time data integration should consider both *in situ* sensors sponsored by the government and informal multimodal real-time and near real-time data streams, including humans as sensors. This is particularly important in developing countries and when coordinating international response, where formal real-time data may not be available.

Real-time data can be critical in triggering decisions such as whether to evacuate, deploy personnel, and stage resources. With proper preparation, real-time data can be combined with modeling programs to estimate projected impact of a disaster in near real time. The next section explores how real-time data can be integrated into decision support systems (DSS) where they can effectively be used to make decisions.

## 3 UTILIZING REAL-TIME DATA FOR DECISION-MAKING

Typically it is not effective to stream raw hazard data directly to emergency managers. Although these data are critical to measuring the magnitude and spatial extent of an event, first responders and government officials generally lack the expertise to interpret raw numbers indicating contamination levels, wind speeds, and ground motions [1]. Raw data need to be interpreted by experts and converted into meaningful metrics, such as projected losses and casualties. In many cases, utilizing this data (Table 1 and Table 2) requires manually gleaning real-time data from web sites, FTP sites, or RSS feeds. The data must then be verified, processed, and massaged before it can be loaded into DSS. Real-time data is most effective when it is automatically processed, run through a DSS, and verified before dissemination. The knowledge required to massage raw data can be time-consuming, when timing is critical, and the expertise required to process data may be known by a limited number of people, who may not be available when disaster strikes. Table 3 presents several modeling platforms, highlighting the availability of real-time data.

The Federal Emergency Management Agency's (FEMA's) loss estimation tool, *haz*ards United States (HAZUS), does not incorporate real-time data feeds, but is capable of importing data derived from real-time sources [2]. Processing this data requires careful consideration, and can be problematic. HAZUS supported HurrEvac data in MR 1 and supports alerts in MR 3, but the functionality was not included in MR 2. Engineers adjusted the program in MR 3 to adjust wind speeds for the overly conservative assumptions from direct interpretation of broad maximum wind speeds, without interpolation. For the flood model real-time data must be heavily processed before it is suitable for analysis. The "Quick Look" feature enabling calculations from a polygon with a single depth of flooding is difficult to produce, and can generate highly inaccurate results. With the "Enhanced Quick Look" feature, a user is able to generate a depth of flooding grid from a DEM and an inundation boundary. However, this provides only a "quick look" and should not be mistaken for a full hydrologic analysis. Expert users, if not software developers, should be on call to assure real-time data is used correctly within HAZUS.

Prompt Assessment of Global Earthquakes for Response (PAGER) is an example of a system developed to work directly with real-time data and provides notification of population exposure to significant groundshaking directly after an event. PAGER does not provide loss estimates, largely because it is designed to work internationally where building exposure and vulnerability may be unknown, although this is the ultimate goal

**TABLE 1 Real-Time Data Feeds from US Government Sources**

| Real-Time Data Source | Agency | Description | Use | Web Site |
|---|---|---|---|---|
| Water Watch | United States Geological Survey | Stream gauge data providing water levels on major streams | Early warning for flooding | http://water.usgs.gov/ waterwatch/ |
| ShakeCast | United States Geological Survey | Accelerometer network | Real-time ground motion following an earthquake | http://earthquake.usgs.gov/ resources/software/shakecast/ |
| Deep-ocean Assessment and Reporting of Tsunamis (DART) | National Oceanic and Atmospheric Administration | Network of buoys | Early warning for tsunamis | http://www.ndbc.noaa.gov/ dart/dart.shtml |
| SeaWinds QuikSCAT | National Aeronautics and Space Administration | Scatterometer | Track hurricane wind speeds and direction | http://winds.jpl.nasa.gov/missions/ quikscat/index.cfm |
| National Climatic Data Center—extreme wind speed data sets | National Oceanic and Atmospheric Administration | Peak gust wind speeds from a network of anemometers | Hurricane advisories | http://www.ncdc.noaa.gov/oa/ land.html |
| National Weather Service—Doppler radar | National Oceanic and Atmospheric Administration | Weather radar | Probable weather for extreme weather hazards | http://radar.weather.gov/ |

of the program. The information provided by PAGER allows emergency managers to deduce whether they are facing a large event with significant exposure or a small event, which would not be possible based on earthquake magnitude alone.

INLET (INternet-based Loss Estimation Tool) is a technology testing tool developed for the National Science Foundation, based on exposure databases for Los Angeles and Orange counties [3, 4]. Damage and casualties are produced after ShakeCast pushes a ShakeMap onto the hard drive of the server. A ShakeMap is an array of ground motion data easily converted into a GIS file. ShakeCast supports automatic determination of ground motion levels for a collection of locations, and can be configured to trigger a Perl script when data arrives at the computer [5]. In Inlet, ShakeCast determines ground motion for a collection of census tract centroids. When completed, a Perl script feeds these data into the INLET database and triggers INLET loss estimation routines. Because the ground motion recordings are more accurate than the ground motions that would be calculated from the attenuation functions, INLET is able to produce better results. The estimated distribution of damaged structures and casualties allows emergency responders to immediately understand the potential ramifications of the event [6, 7].

When results from programs like HAZUS and INLET are ported to an on-line environment, they can be merged with disaster portals that integrate spatial data. Ideally, this data will be linked with technologies presented in Table 2, where the general public provides text, messages, photos, and videos that enable emergency managers to rapidly verify loss estimates. Table 2 provides a list of COTS products that can supplement sensor networks to monitor an event and coordinate response. Some, such as radio frequency identification (RFID), have not been extensively used for emergency response but hold great promise if the preparatory measures are taken to integrate the data into emergency response. Internet and cell phone use have provided tremendous amounts of information through Internet blogs, video posting on You Tube, and the media. The use of this data can be highly problematic due to verifiability and unstructured formats, but avoiding the use of these sources of data because they are problematic, is a mistake. These sources will continue to provide damage assessment data for events as they unfold, and devising clever strategies to harness humans as sensors can potentially yield much greater information than sensors alone. The United States Geological Survey (USGS) "Can you feel it" program allows the general public to provide feedback in the form of a short questionnaire. When combined with geo-referencing, observations from the general

**TABLE 2 Real-Time Data Feeds from Public and Private Sources**

| Source | Description | Potential Use |
|---|---|---|
| Mobile phones and wireless Internet devices | Voice, SMS text messages, photos, video, and location | Monitoring traffic flow, situational awareness, damage assessment |
| Closed-circuit television (CCTV) | Video stream for security and crowd control | Monitoring traffic flow, situational awareness, damage assessment |
| Internet | Webcams, blogs, chats, emails | Situational awareness at the local level |
| Radio frequency identification (RFID) | Product inventories | Emergency resource allocation |

**TABLE 3 Software Programs Utilizing Real-Time Data to Support Decision-Making**

| Tool | Description | Hazard | Real-Time Data Link |
|---|---|---|---|
| HAZUS-MH™ (HAZards United States, Multi-Hazard) | Multihazard loss estimation software developed for FEMA by National Institute of Building Sciences (NIBS) | Earthquake | No real-time link, USGS ShakeMap import |
| | | Hurricane | No real-time link, National Hurricane Center forecast/advisory data download from HurrEvac FTP site |
| | | Flood | No real-time link, inundation boundary import |
| INLET (INternet-based Loss Estimation Tool) | Earthquake loss estimation tool to test integration of technologies into emergency response. For NSF | Earthquake | ShakeCast |
| CATS (Consequence Assessment Toolkit) | Loss estimation program. Developed for FEMA. Currently supported by Defense Threat Reduction Agency (DTRA) | Multihazard | Global Disaster Alert and Coordination System (http://www.gdacs.org/), uses National Earthquake Information Center (NEIC) RSS for earthquakes |
| ShakeCast | USGS RSS extended to generates custom reports of ground shaking by facility in real time | Earthquake | ShakeCast RSS feed |
| PAGER (USGS Prompt Assessment of Global Earthquakes for Response) | GIS intersection between ground shaking and global population databases | Earthquake | NEIC |
| MIDAS (Metrological Information and Dose Assessment System) | Plume modeling software for commercial, military, and civil government applications | Plume modeling | Meteorological data, plant effluent monitor data, National Oceanic and Atmospheric Administration (NOAA) data, and other RSS feeds |
| HPAC (Hazard Prediction and Assessment Capability) | DTRA plume modeling software military, and civil government applications | Plume modeling | Wind speed from National Weather Service (NWS) |
| CWMS (Corps Water Management System) | United States Army Corps of Engineers (USACE) real-time data management system for the HEC-RAS hydrologic modeling platform | Reservoir management | Various NWS, USGS, and USACE readings of river stage, reservoir elevation, gauge precipitation, and other hydrological data sets |

public are used to adjust and verify ground motions where accelerograms are sparse. Real-time data feeds benefit substantially when merged spatially with real-time observed data utilizing humans as sensors. Although the estimates still need to be verified and accurate inventory data is critical, the availability of this data, directly after an event when no other information is available, has the potential to optimize the use of resources and reduce the likelihood that lack of information will lead to an inappropriate level of response [8].

Real-time data is routinely used in transportation, and this could possibly be extended to disasters. Before an event makes landfall, real-time data can be used to trigger evacuation and monitor evacuation routes [9]. Real-time data can be used to reverse the evacuation process. Before Hurricane Rita made landfall in 2005, the National Hurricane Center (NHC) posted data confirming that it was highly unlikely that Houston would be affected, but the evacuation continued. When there is advance notice to an impending disaster, such as an earthquake or tsunami, warnings could be disseminated through ITS and text messaging systems. Directly after an event, real-time data can be used to confirm the state of critical transportation infrastructure. Bridge-health monitoring can be used not only to monitor safety, but to prioritize restoration, such as through incentives programs rewarding the early completion of construction [10]. Given a widespread disaster, real-time data can be an essential component in data dissemination for situational awareness. Locations of roads that are obstructed or destroyed can be disseminated through a variety of handheld and Internet resources. Mobile phones and portable devices are routinely equipped with mapping applications. These applications could be modified to adapt instructions based on collapsed bridges and blocked roadways. These alternate routes would be available to first responders, many of which may be from out of town. Under rapidly evolving conditions, situation awareness could be disseminated to the public on the roadways through text messaging and reverse 911. Additionally, text messages from the public can be used to inform emergency responders about the extent of damage.

## 4 IMPLEMENTATION ROAD-BLOCKS

Even under normal driving conditions, integration of real-time data into transportation is problematic. Although ITS message boards placed on freeways provide estimated drive times so that drivers can plan for delays, drivers must rely on their own experience to determine alternate routes, and since information is not provided for local roadways, their decisions are not well-informed. The key to resolving this problem may be cell phones and wireless Internet devices. As these devices begin to track congestion on the roadways, they will be capable of relaying this information back to a centralized system that can combine information from other commuters to suggest alternative routes. It is not clear, however, that this information will reduce congestion. When drivers receive information, they attempt to assess: (i) the status of an event; (ii) the expected duration of disruption; and (iii) the best action to take. With more accurate information, drivers are expected to behave in a more predictable manner. However, a transportation system with no information may be more efficient than a transportation system which advises an inordinate number of users to take a specific alternate route. Transportation models suitable for routing traffic optimally in real time will be required to optimize the use of real-time traffic data. This basic research is required before the models can be extended to address homeland security, where the models will need to be informed by research

into how drivers will react to routing instructions in the face of conflicting priorities, such as their perceived safety and the safety of their children.

With the surge in wireless bandwidth and the advent of low-cost sensors, it is very likely that managers will face a torrent of data for making critical decisions. Transforming raw, multimodal data streams into meaningful information will require new tools for analyzing and finding patterns in information; it will require algorithms that not only fuse disparate data sources, but proactively seek patterns in the data. These patterns must be presented through intuitive visual interfaces with analytical capabilities so that urban planners and other decision-makers can monitor events as they unfold. Data mining and data fusion algorithms need to be brought into the emergency management arena to address the potential flood of real-time data available from the proliferation of wireless and embedded devices.

In many instances, there are legal implications complicating the application of real-time data [11]. Emergency responders are in new territory with advanced technologies that allow very rapid response, live tracking, or even prediction of events. Emergency managers need clear legal and legislative support to empower decisions to pursue or reject advanced technologies. Without this support, it is very difficult for emergency managers to integrate advanced technologies with confidence.

The risk of false alarms, missing alerts, and sensor error needs to be addressed thoroughly before systems are developed to work in conjunction with real-time data [11]. There should always be a backup method to verify records. This may be from *in situ* videos, security personnel, or volunteers from the public.

Technology is evolving rapidly and best practices have a short window of opportunity to arise, before the next innovation occurs. Open Internet mapping applications such as Virtual Earth and Google Earth greatly simplify the process of disseminating real-time information gleaned from a variety of web sites [12]. The Southern California fires of 2007 revealed a very high level of sophistication of the media in geocoding burnt structures and displaying them with on-line maps. But given the limited spatial accuracy and conservative approach of delineating burn areas, maps depicted many more burnt structures than detailed surveys could confirm. Given the amount of data verification and interpretation required to correctly use real-time data for loss estimation, the emergency response community needs to establish the best way to use these data sets so that they are not misinterpreted. This requires not only building the IT infrastructure to process real-time data, but funding development in areas such as transportation, where the optimal use of real-time data is not clear.

Real-time data combined with DSS and Internet support systems can give emergency managers the tools they need to make informed decisions if data are effectively collected, verified, processed, and disseminated. Automation of these tasks assures that the data are available when they are needed. If real-time data is processed using well-known standards it can disseminate results and DSS routines, allowing calculations to occur and maps to be produced in the first half hour following an event, when they are most useful. DSS results need to be combined with data supplied from the general public using mobile phones and other devices. These data sources will continue to provide damage assessment data for events as they unfold, and devise clever strategies to harness humans as sensors, since they can potentially yield much greater information than sensors alone. Further research into multimodal data collection and information dissemination is needed to guide the use of real-time data in emergency response, particularly in the field of transportation.

# MULTI-OBJECTIVE DECISION ANALYSIS

GREGORY S. PARNELL
*Department of Systems Engineering, United States Military Academy, West Point, New York*
*Innovative Decisions Inc., Vienna, Virginia*

## 1 INTRODUCTION

Multiobjective decision analysis (MODA) is an appropriate operations research technique to determine the best alternative when we have complex alternatives, multiple conflicting objectives, and significant uncertainties. Other names for this type of technique are multiple attribute utility theory, multiple attribute value theory, multiple attribute preference theory, and multiple criteria decision analysis. Keeney and Raiffa published the seminal

book in 1976 [1]. Kirkwood wrote an excellent contemporary textbook [2]. Value-focused thinking (VFT) is a philosophy to guide decision makers to create higher value alternatives [3]. It has three major ideas: start with values, use values to generate better alternatives, and use values to evaluate those alternatives. VFT is usually implemented using the mathematics of MODA. Since MODA requires an understanding of theory and the art of modeling, experienced decision analysts are required to effectively use the technique.

## 2 TYPES OF DECISION PROBLEMS

A decision is an irrevocable allocation of resources [4]. It is useful to distinguish two types of decision problems: a single decision and a portfolio of decisions. In a single-decision problem, we select the best alternative from a group of potential alternatives. An example is selecting the best vaccine for a bioagent that could be used by terrorists. In portfolio decision making, we select the best group of decisions. Examples include selecting the best set of vaccines to develop and protect the nation against the most likely bioagents that terrorists might use in the United States, selecting the best portfolio of research and development (R&D) projects to fund from a large set of projects, annually allocating an organization's budget to the best projects (or programs) from a large set of potential projects, and systems design using multiple subsystems and components.

In this article, we illustrate the first type of decision. Kirkwood [2] describes how to use MODA for resource allocation decision making and Parnell et al. [5] describe how to use MODA for systems design.

## 3 DEFINITIONS

Analysts should use precise technical language to define key MODA terms. Here are the terms used in this article in logical order.

- *Fundamental objective.* The most basic objective we are trying to achieve. Example: select the best vaccine for a bioagent.
- *Functions.* A function is a verb–object combination, for example, detect bioagents. When multiple decisions are involved, you may want to identify functions before identifying the objectives. An alternative term is missions or tasks.
- *Objective.* A preference statement that expands on the fundamental objective. Example: maximize effectiveness of the vaccine.
- *Value measure.* Scale to assess how well we attain an objective. For example, we may measure the time to detect the dispersal of a bioagent. Alternative terms are evaluation measures, measures of effectiveness, measure of performance, measures of merit, and metrics.
- *Range of a value measure.* The possible variation of the scores of a value measure, such as probability of detection in 24 h after dispersal may range from 0.0 to 1.0.
- *Score (level).* A specific numerical rating of the value measure, such as a time to detect a bioagent dispersal. A score may be on a natural or a constructed scale. (We avoid using the term value for scores because the value function uses that term.)

- *Qualitative value model.* The complete description of our qualitative values, including the fundamental objective, functions (if used), objectives, and value measures.
- *Value hierarchy (value tree).* Pictorial representation of the qualitative value model.
- *Tier (layer).* Levels in the value hierarchy.
- *Weights.* The weight assigns a value measure depending on the measure's importance and the range of the value measure. Weights are our relative preference for value measures. They must sum to one.
- *Value function.* A function that assigns value to a value measure's score. Quantitatively, value is defined as *returns to scale on the value measure* [2].
- *Quantitative value model.* The value functions, weights, and mathematical equation (such as the additive value model) to evaluate the alternatives.
- *Value model.* The qualitative and quantitative values models.
- *Utility.* Utility is different from value. It includes returns to scale and risk preference. Kirkwood [2] covers methods for assessing utility functions.
- *Utility function.* A function that assigns utility to a value-measure score. We assess utility functions using lotteries [2].

We should modify our lexicon to use terms that are familiar to our decision makers and stakeholders. For example, the problem domain may use criteria and performance measures instead of objectives and value measures.

## 4 QUALITATIVE VALUE MODELING

Qualitative value modeling is critical to the success of an analysis. If we do not get the decision makers' and stakeholders' values qualitatively right, they will not (and should not) care about our quantitative analysis. The key to successful value modeling is to determine whose values to model. In analyzing commercial decisions, the decision makers usually want to produce the highest shareholder value or net present value. When customers buy the product or service, future shareholder value will increase. Similarly, for many homeland security decisions, the values may be the future values of national, state, and local decision makers; private companies; and our citizens.

Value models usually include several key aspects of value:

- Why we are making this decision (fundamental objective)
- What we value (functions and objectives)
- Where we achieve an objective (location)
- When we achieve an objective (time preference)
- How well we attain an objective (value measures and value functions)
- How important is the objective (weights)

Notice that value models do not include *how* one does an activity. Instead, we care about how well the alternative works. For example, a vaccine could be a pill, a shot, or an aerosol. We do not score directly how it is used, but we might have a value measure that scores ease of use. Structured techniques based on clear criteria are the key to credible and defensible qualitative value modeling.

### 4.1 Criteria for Developing a Successful Value Model

Qualitative value models must satisfy four criteria by being collectively exhaustive, mutually exclusive, operable, and as small as possible—though Kirkwood describes the first two criteria differently [2]. By collectively exhaustive, it means that value models must consider all essential types of evaluation. Their criteria are mutually exclusive if they do not overlap. Further, the value measures must be operable, which means the data is available and everyone interprets them in the same way. Finally, we should use as few value measures as possible to limit the model's size. Only include those values that can be affected by the decision and those values that are essential to the decision.

Parnell [6] provides four structured techniques for value modeling. The amount of effort to develop a value model corresponds directly to the number of measures. Each value measure must have a defined scale and a value function. Thus, more value measures result in more time for model development and scoring.

### 4.2 Developing a Qualitative Value Model

It is useful to distinguish between models that use functions and objectives, and models that use only objectives. For portfolio decisions, it is useful to identify the functions first and then the objectives.

*Step 1: Identify the fundamental objective.* Identifying the fundamental objective is the essential first step that guides how we develop the value model. It must be a clear, concise statement of the most basic reason for the decision. In practice, we take time and apply thought to properly specify the fundamental objective. Once we understand it, we can determine if we have single or multiple functions. If we have a single function, we can skip step 2 and start to identify the objectives.

*Step 2: Identify functions that provide value.* We can get functions from documents or develop them using functional analysis [5]. Affinity diagramming is an excellent technique for identifying functions [7]. We use research and brainstorming to discover action verb–object combinations (e.g. detect attack and provide warning) that describe potential future functions. Then, we group verb–object combinations by affinity (similarity). Sometimes, it is useful to establish functions and subfunctions before identifying the objectives.

Affinity diagramming has two major benefits for value-model development. First, affinity groups are mutually exclusive (each function different) and collectively exhaustive (all necessary functions identified). Secondly, affinity diagramming usually identifies new functions required for our fundamental objective.

*Step 3: Identify the objectives that define value.* For each function, we need to identify the objectives that define value. Objectives can come from documents, interviews with senior leaders, or workshops with stakeholders (or stakeholders' representatives). Again, affinity diagrams are excellent for developing mutually exclusive and collectively exhaustive objectives.

*Step 4: Identify the value measures.* We can identify value measures by research and interviews with decision makers, stakeholders, and subject-matter experts. Access to stakeholders and subject-matter experts is the key to developing good value measures. Kirkwood [2] identifies two useful dimensions for value measures: alignment with the objective and type of measure. Alignment with the objective can be direct or by

**TABLE 1 Preference for Types of Value Measure**

| Type | Direct Alignment | Proxy Alignment |
|---|---|---|
| Natural | 1 | 3 |
| Constructed | 2 | 4 |

proxy. A direct measure focuses on attaining the objective, for example, efficacy of the vaccine against the bioagent. A proxy measure focuses on attaining an associated objective, for example, the number of casualties is a proxy for the consequences of a bioagent attack. The type of measure can be natural or constructed. A natural measure is in general use and commonly interpreted, such as cost in dollars. We develop a constructed measure (such as homeland security advisory system classifications [8]) when natural measures do not exist.

Table 1 reflects the author's preferences for types of value measures. Priorities 1 and 4 are obvious. Direct and constructed measures to proxy and natural for two reasons are preferred. First, alignment with the objective is more important than the type of scale. Secondly, one direct and constructed measure can replace many natural and proxy measures. Keeney and Raiffa [1], Kirkwood [2], and Keeney [3] provide useful information on how to develop value measures.

*Step 5: Vet the qualitative value model with key decision makers and stakeholders.* We must ensure that our model has captured the values of the decision makers and stakeholders. Vetting the qualitative value model and incorporating their comments is critical to ensuring that they will accept the analysis results.

Figure 1 provides a terrorist value hierarchy. The terrorist organization's fundamental objective is to remove US presence in the Middle East. The three objectives of a terrorist attack are to maximize economic impact (measured in dollars), maximize people killed (measured in number of deaths), and maximize citizen fear (measured in a constructed citizen fear scale).

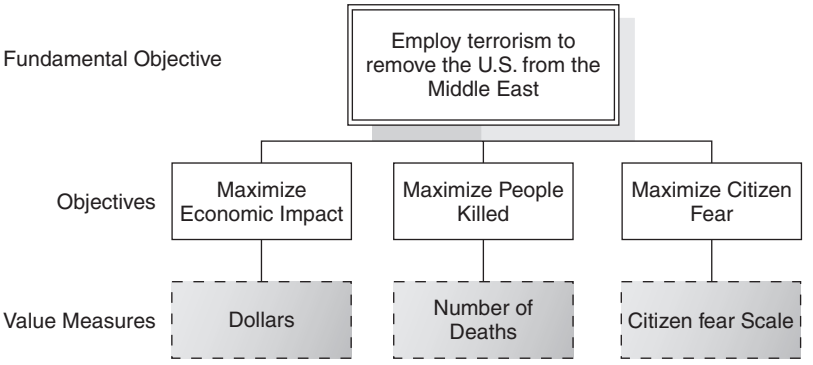

**FIGURE 1** Terrorist value hierarchy.

## 5 QUANTITATIVE VALUE MODELING

Once we have vetted the qualitative value model with our decision makers and key stakeholders, we are ready to develop the quantitative value model. It includes the mathematical model, value functions, and weights.

### 5.1 Mathematical Model

MODA uses many mathematical equations to evaluate alternatives [1]. The simplest and most commonly used model is the additive value model [2]. This model uses the following equation to calculate each alternative's value:

$$v(x) = \sum_{i=1}^{n} w_i v_i(x_i)$$

where $v(x)$ is the alternative's value, $i = 1$ to $n$ is the number of the value measure, $x_i$ is the alternative's score on the $i$th value measure, $v_i\ (x_i)$ is the single-dimensional value function that converts a score of $x_i$ to a normalized value, $w_i$ is the weight of the $i$th value measure, and $\sum_{i=1}^{n} w_i = 1$ (all weights sum to one).

The additive value model has no index for the alternatives because our values do not depend on the alternative since we do not put "how" in the model. We use the same equations to evaluate every alternative.

### 5.2 Value Functions Measure Returns to Scale

Value functions measure returns to scale on the value measures [2]. They have four basic shapes: linear, concave, convex, and an S curve (Fig. 2). The linear value function has constant returns to scale: each increment of the measure is equally valuable. The concave value function has decreasing returns to scale: each increment is worth less than the preceding increment. The convex value function has increasing returns to scale: each

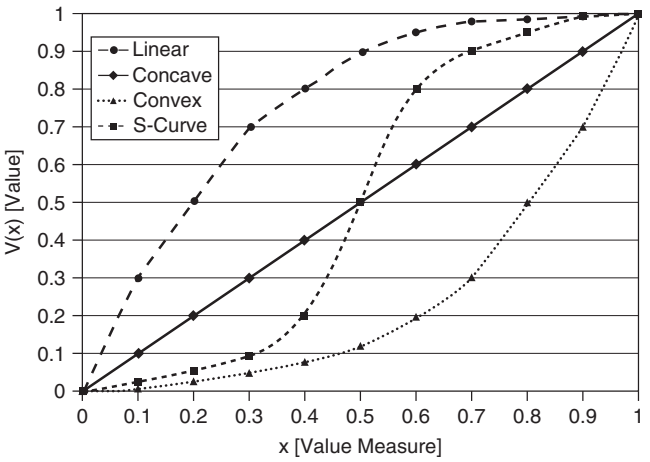

**FIGURE 2** Four types of value functions.

increment of the measure is worth more than the preceding increment. The S curve has increasing, then decreasing, returns to scale on the measure.

We have several techniques to develop value curves from subject-matter experts [2]. Our first step is to have the experts determine the shape of the value curve: linear, concave, convex, or S curve. Next, we use value increments to identify several points on the curve—asking experts the relative value of increments in the value-measure scale. Kirkwood [2] provides Excel macros that can be used to easily implement value functions.

### 5.3 Weights Depend on Importance and Range of the Value-Measure Scales

Weights play a key role in the additive value model. MODA quantitatively assesses the trade-offs between conflicting objectives by evaluating the alternative's contribution to the value measures (a score converted to value by single-dimensional value functions) and the importance of each value measure (weight). The weights depend on the measure scales' importance and range. If we hold constant all other measure ranges and reduce the range of one of the measure scales, the measure's relative weight decreases, and the weight assigned to the others increases since the weights add to 1.0. The only mathematically correct way to do weights is bottom-up using the variation of the value measures. A very effective weighting technique is the swing weight matrix [9].

## 6 ALTERNATIVE SCORING USING VALUE-FOCUSED THINKING

Once we have vetted the quantitative value model and developed alternatives, we must score the alternatives on the value measures. VFT [3] has three major ideas: start with your values, use your values to evaluate alternatives, and use your values to generate better alternatives. VFT is a tool to foster creativity. Since we use values to develop the value hierarchy, alternative scoring has two purposes: evaluating alternatives and generating better ones. The second purpose is most important. When we begin to score our alternatives, we will identify value gaps—chances to improve the alternatives (create better scores) to achieve higher value.

It is prudent to consider who will score the alternatives and how we will resolve scoring disagreements. Three scoring approaches have been successful: alternative champions, a scoring panel, and alternative champions reviewed by a scoring panel.

- *Scoring by alternative champions.* This approach is useful because it provides information about values from the value model directly to "champions" as they do the scoring. A disadvantage is the perception that a champion of an alternative may bias a score to unduly favor it or that scores from different champions will be inconsistent.
- *Scoring by a scoring panel.* To avoid the perception of scoring bias and potential scoring inconsistencies, subject-matter experts can convene as a panel to assign scores and improve the alternatives. Champions of alternatives can present scoring recommendations to the panel, but the panel assigns the score.
- *Scoring by alternative champions reviewed by a scoring panel.* Having the idea champion score the alternative and modify it to create more value is the essence of VFT. A scoring review panel can then ensure that the scores are unbiased and consistent.

Once we have the scores, we can start evaluating the alternatives—typically through deterministic analysis and probabilistic (or uncertainty) analysis.

## 7 ANALYSIS OF ALTERNATIVES

Analysis of alternatives using MODA involves deterministic and probabilistic analysis. In deterministic analysis, all the parameters are known for certain. In probabilistic analysis some of the parameters can be uncertain. Probabilistic analysis can provide insights about deterministic and stochastic domination [10].

### 7.1 Deterministic Analysis of Alternatives

In deterministic analysis, uncertainty is not a factor. We can determine the dominant alternatives and their values without probabilities. See Parnell [6] for deterministic analysis of portfolio decisions.

In addition to scoring our alternatives, we should always include the current (or baseline) alternative and the ideal (or perfect) alternative. Several types of analysis are useful to obtain insights about the alternatives, and many software packages have built-in features that "automate" do sensitivity analysis.

- *Stacked bar.* Stacked bar graphs are a useful way to compare alternatives. The "stacks" show the contribution for one level in the hierarchy. We can plot the stacked bar graphs for any level in the hierarchy. Analysis usually begins top down to identify insights.
- *Value gaps.* Value gaps are one of the key insights that we can extract from stacked bar graphs. Values gaps are the differences between the best alternative and the ideal alternative. We can examine them at all levels in the value hierarchy, so they "shine a light" on areas for VFT.
- *Value versus cost.* It is always find it useful to separate cost and benefits (value) typically by plotting the value versus the cost of the alternatives. This chart helps to quickly identify the dominant alternatives and enables decision makers to see the value added for the additional cost.
- *Sensitivity analysis.* Sensitivity analysis is useful for key parameters, including some weights and scores.

### 7.2 Probabilistic Analysis of Alternatives

The additive value model allows for three sources of uncertainty—alternative scores, value functions, and weights. Risk is the probability of a low value (utility). We can model our uncertainty about alternative scores using probability distributions. We can sequence the decisions and uncertainties using decision trees. Using distributions, the additive value model gives us the probability distribution of value (utility), from which decision makers can directly assess the alternative's risk. We also can do sensitivity analysis to weights or value functions that might change depending on the future scenario [6].

The usual approach to uncertainty analysis is to put probability distributions on the scores (or variables affecting the scores) that reflect our uncertainty about the alternative's future score on the value measures. The additive value model can then assess how uncertainty affects value (or utility). Two approaches are common: MODA with decision trees and Monte Carlo simulation.

- *MODA with decision trees.* We can add the uncertain variables (exogenous variables or alternative scores) as nodes in a decision tree. Then, we use the additive value model to assess value (utility) at the end of the tree. The best alternative comes from the decision tree's "average out/fold back" algorithm [10]. This method works equally well for independent and dependent uncertain variables.
- *Monte Carlo simulation.* Monte Carlo simulation is useful to assess how uncertainty affects alternative value (or utility). It has four main steps: develop probability distributions for uncertain variables, draw a random number for each uncertain variable and for each distribution, calculate the value (or utility) using all simulated scores, and do numerous runs and plot a value (utility) distribution to assess the alternative's risk. This method works for independent and dependent uncertain variables, but we must express the dependent variables as functions of the independent variables.

Parnell [6] provides additional techniques for probabilistic analysis.

## 8 USES OF MODA FOR HOMELAND SECURITY

Decision analysis using MODA/VFT has been used in many problem domains [11, 12]. Parnell et al. [5] describe a systems decision-making framework that can be applied to homeland security challenges. Recent applications include the following homeland security capabilities [13]: ports and harbors [14], information assurance [15–17], commercial airlines [18], and general terrorist attacks [19].

In this section, we briefly describe a probabilistic decision analysis application of an adversary threat scenario for bioterrorism to illustrate how MODA, using decision trees, can be applied to homeland security challenges. Usually, we are the decision makers and we use our assessment of our values and our uncertainties. However, since terrorists are intelligent adversaries, it may be useful to consider their values and uncertainties. The terrorist's influence diagram [20] is shown in Figure 3. Squares are decisions, circles are uncertain nodes, rounded squares are deterministic nodes, and terrorist value is the multiobjective value node used to solve the diagram. In this very simplified model, the terrorist has three decisions: the target, the agent, and the acquisition decisions. The terrorist has three major uncertainties: does he obtain the agent, is he detected before attack, and is the attack successful. The decision alternatives and the sequence of the decisions and events are shown in the decision tree in Figure 4. The probabilities are conditioned on the assumption that the terrorist has decided to attack. In addition, the probability of an event can depend on the terrorist's decisions and other uncertain events. For example, the probability that he obtains the agent depends on the type of agent and how he acquires the agent. In this simplified model, the migration effectiveness depends on the target and the agent. Finally, the terrorist has two objectives: maximize deaths and maximize economic impact. An additive value model with linear value functions and equal weights is assumed.

Using the DPL software [20], we can solve for the preferred terrorist decision. The highest value strategy for the terrorist is shown in Figure 5. On the basis of this (notional) data, the terrorist prefers to produce agent C to attack location Y. In addition to the decision, we can use decision analysis tools to learn significant additional information. For example, location Y is twice as good as location X; location Y stochastically dominates [10] locations X, and his probability of obtaining the agent is higher (0.42) than his probability of being detected before the attack (0.4).

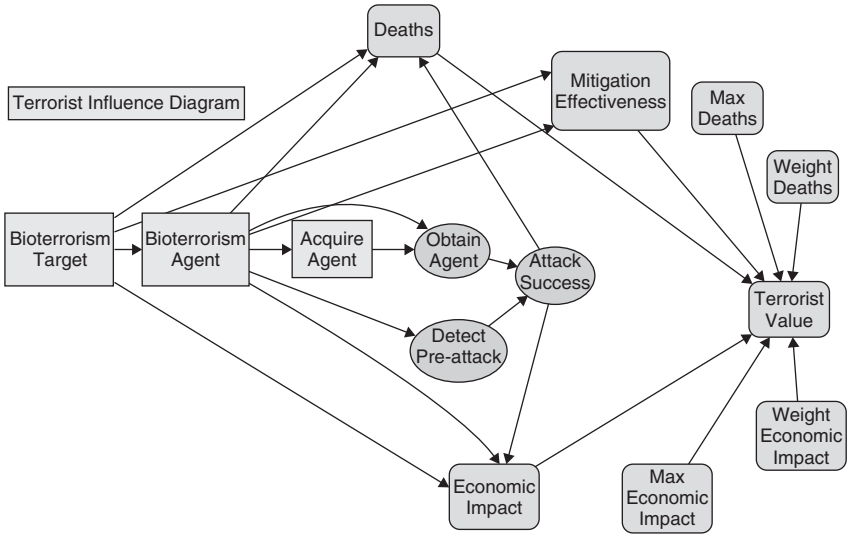

**FIGURE 3** Terrorist influence diagram.

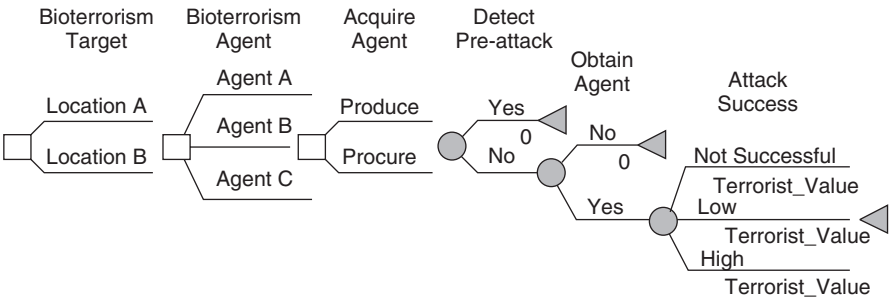

**FIGURE 4** Terrorist decision tree.

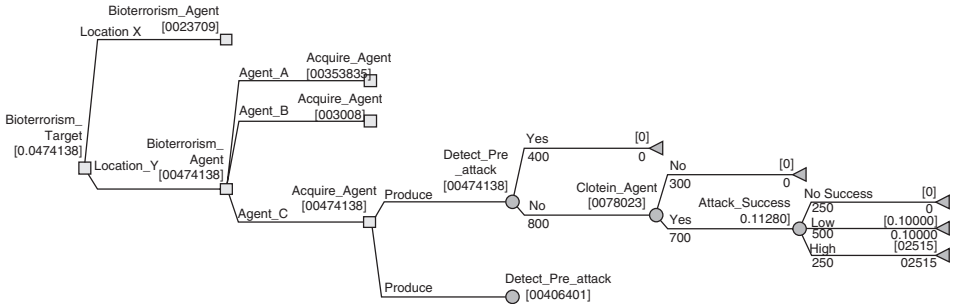

**FIGURE 5** Terrorist's highest value strategy.

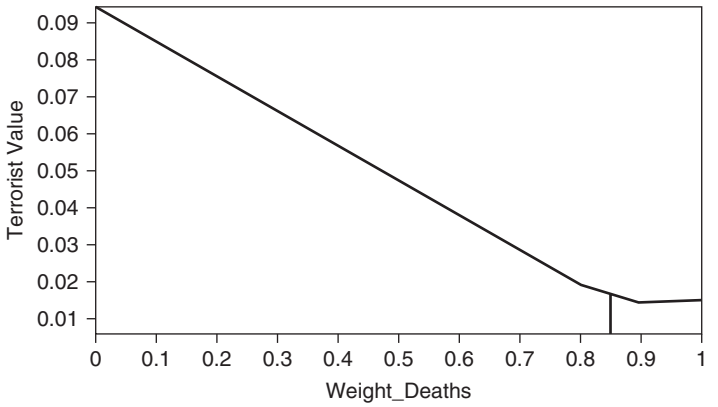

**FIGURE 6** Location sensitivity to weight assigned to deaths.

Decision analysis also provides useful tools for sensitivity analysis. Figure 6 shows the sensitivity of the target location decision to the assumption about weights. If the terrorist assigns a weight of less than 0.85 to deaths, he would prefer location Y. If the weight is greater than 0.85, he would prefer X. If we had considered multiple locations, some may never be preferred. In addition, two-way sensitivity plots and tornado diagrams can also be used to assess the sensitivity to assumptions.

## 9 SUMMARY

In this article, we have introduced and illustrated MODA. MODA is an appropriate operations research technique to determine the best alternative when we have complex alternatives, multiple conflicting objectives, and significant uncertainties. MODA asks the right questions: what we can value, what are the major uncertainties, and what can we do to achieve our values? We have seen that MODA can be used to analyze complex homeland security alternatives using value models (our values or our adversaries' values) of conflicting objectives, probability models of uncertainty, and decision trees to determine the best alternative. MODA provides a logically consistent, credible, and defensible methodology to provide analysis insights for decision makers.

## ACKNOWLEDGMENT

The anonymous reviewers provided useful suggestions to improve the clarity of this article.

# NATURALISTIC DECISION MAKING, EXPERTISE, AND HOMELAND SECURITY

EDUARDO SALAS AND MICHAEL A. ROSEN
*Department of Psychology, Institute for Simulation and Training, University of Central Florida, Orlando, Florida*

## 1 INTRODUCTION

Homeland Security (HS) is a "people business". It is fundamentally about the interaction of people with other people and understanding the intent of other people. It is about psychology, communication, deception, recognition, coordination, teamwork, situation assessment, and decision making. This is completely evident on the frontlines of HS where police officers, transportation security administration (TSA) agents, and border patrol agents come face to face with possible threats to security. However, it is equally the case in complex intelligence analysis where agents may be working behind several layers of sophisticated technology. No matter how elaborate a system of information collection, analysis, and representation may be, as long as there remains a human in the loop, the expertise of that human will play a role in HS. The decision-making effectiveness of people from the frontline law enforcers to intelligence analysts will impact these national goals. Therefore, understanding how people perceive, integrate, process, disseminate, communicate, and execute decision making in these types of complex environments is of critical importance. This knowledge can be used to train better decision makers and to design systems that support the way experts make decisions to further boost performance and safety.

So, if HS is about people, about interactions, decision making, and expertise, what are the means available to ensure the highest possible levels of safety and security? What should be the scientific basis of efforts to build and maintain safeguards against threats to the nation? This article is dedicated to reviewing the naturalistic decision making (NDM) approach and, more generally, the present understanding of the role of expertise in organizations. Also, we propose that the NDM approach and the scientific understanding of human expertise make valuable contributions to HS efforts. The substantial and continually growing scientific literature concerning how people develop, maintain, and leverage expertise in complex and stress-filled environments can provide information on the design and analysis of sociotechnical systems supporting HS. To this end, we pursue three main goals in this article: (i) provide a definition and general overview of NDM, (ii) review current methodological approaches and tools in NDM, and (iii) briefly highlight findings from the NDM literature that describe expert individual and team decision making. Before addressing these goals, we provide some illustrative examples of NDM applications to HS.

## 2 WHAT DO EXPERTISE AND NDM HAVE TO DO WITH HOMELAND SECURITY?

One of the defining features of NDM is a commitment to improving decision-making performance. This begs the question: how can NDM help HS efforts? In general, the NDM approach contributes to organizational effectiveness by providing an understanding of how expert decision makers perform effectively (i.e. What processes and knowledge does the expert use? What coordination strategies are used?). This understanding can be leveraged into better training programs [1] to create more expert decision makers at a faster rate as well as better system design [2] to facilitate the performance of experts. Specific applications of the NDM approach to HS are numerous. Two brief examples are provided below: information analysis and baggage screening.

The task of intelligence analysis is extremely complex. The analyst must "sort through enormous volumes of data and combine seemingly unrelated events to construct an accurate interpretation of a situation, and make predictions about complex dynamic events" [3, pp. 281–282]. During this process, a multitude of decisions must be made concerning the validity, reliability, and significance of various pieces of information, as well as how information may fit complex patterns extended over time [4]. To further complicate matters, this task is conducted in an environment where uncertainty and deception are pervasive, time is frequently scarce, and there are costly consequences for failing to detect (or misinterpreting) patterns in the data and draw faulty inferences and predictions [5]. All of these factors produce an "unfriendly" environment for decision making; however, human decision makers are robust and manage to do well in such circumstances. In fact, information analysts have developed numerous methods for accomplishing their task, and the process has been characterized as highly idiosyncratic [6]. No doubt, some analysts' processes are better than others, and the NDM approach can be used to identify methods that are more effective. This can serve as the foundation for the development of a set of formalized methods and processes (as called for by Johnston [6]). This would be a monumental contribution that would expedite the development of experts within the domain. Additionally, Hutchinson et al. [7] applied NDM methods to the information analysts' task and found that the use of analysis tools that forced analysts to make decisions without a context for information was a major source of poor performance. This finding, along with the specifications of the contextual information that is necessary, can be used to develop tools that facilitate rather than encumber decision-making processes.

Like information analysis, baggage screening is a vital component to defenses against terrorist attacks. Though in many senses, baggage screening does not involve the "cognitive complexity" of intelligence analysis, there is a great deal of perceptual expertise involved in effective baggage screening. Detecting a pattern indicating a threat, in a long sequence of patterns containing primarily innocuous items, requires not only sustained attention, but the capacity to detect subtle visual cues [8]. Understanding what cues are used by expert baggage screeners can facilitate tools (e.g. augmented displays that emphasize critical information) as well as training programs to build perceptual expertise.

The two types of tasks discussed above are different in many critical ways. However, they share a commonality in that success depends on the expertise of human decision makers. Consequently, the nature of expertise and decision making can serve as a valuable scientific knowledge base to build and maintain effective HS sociotechnical systems.

## 3 WHAT IS NATURALISTIC DECISION MAKING?

In 1988, the USS Vincennes, a US Navy-guided missile cruiser, mistook a commercial Iranian flight for an attacking military jet. The crew of the Vincennes fired two missiles at what they thought was an imminent threat to their safety. The immediate result of this decision by the Vincennes crew was the tragic death of the 290 innocent passengers and crew members aboard the Iranian flight. However, this event was to have an enormous impact on the study of human decision making as well. A major research project called the Tactical Decision Making Under Stress (TADMUS) program, was launched with the aim of better understanding how decisions are made in high-stress, high-stake military environments. This project [see Ref. 9], in conjunction with preexisting research efforts [10] helped to advance what has come to be known as the *NDM community*, a group of researchers working to understand decision making in contexts where traditional decision-making research is not applicable. In the following sections, we provide an overview of this field and related work in the study of expertise. There are many parallels between the situation experienced by the Vincennes crew and those encountered by HS personnel: intense time pressure, high stakes outcomes, and uncertain information. NDM seeks to understand and support decision making in these types of environments and is therefore well suited to contribute to the scientific basis of HS.

### 3.1 NDM and Traditional Decision-Making Research

Spurred by the practical implications of the topic, decision making has been an subject of scientific inquiry for centuries. The prolonged attention given to decision making has produced an extensive theoretical and empirical literature base, which can generally be understood through one of the three paradigms: the formal-empiricist, the rationalist, and the naturalistic [11]. The formal-empiricist paradigm is typified by the classical decision making (CDM) approach and the rationale paradigm by the judgment and decision making (JDM), and behavioral decision theory (BDT) threads of research. Although each of these research traditions have made unique contributions, they all share fatal flaws that have rendered them ineffectual at explaining "real-world" decision performance in high-stress, high-stake environments like the Vincennes incident and many others common to HS [12]. First, the rationalist and formal-empiricist traditions both viewed decision making as selection of an alternative from a set of concurrently available options, which were all evaluated by the decision maker. Essentially, this amounted to imposing an idealized structure (i.e. exhaustive search and evaluation of decision alternatives) on the decision-making process. Most people do not actually use this approach when given ample time, and it is impossible to use while making decisions under time pressure and other stressors. Second, the rationalist and formal-empiricist traditions do not account for the expertise of the decision maker nor do they address complex multicomponent decisions [13]. Decisions were viewed as isolated from one another, and the past experience of the decision maker was viewed as irrelevant. In contrast to these two prescriptive traditions, which are both based upon an unrealistic ideal decision-making process, the naturalistic paradigm seeks to describe how effective decisions are made by professionals working in complex situations, where time is scarce and information incomplete or uncertain. The naturalistic paradigm is typified by NDM and organizational decision making (ODM) traditions, both of which are based on observational and descriptive research,

focus on what real decision makers actually do (cf. artificial laboratory tasks), and reject a view of decision making as choice from an exhaustive set of decision alternatives [14].

### 3.2 Defining the NDM Approach

The NDM approach can be defined most succinctly as an investigation of "the way people use their experience to make decisions in field settings" Zsambok [15], p. 4. There are two important implications of this definition that form the basis of the NDM approach. First, the expertise of the decision maker is fundamental to the decision-making process. An understanding of how decisions are made within a particular domain cannot be divorced from an understanding of the expertise of the decision maker [16]. Second, the NDM approach emphasizes the real-world context of decision making. NDM research happens "in the field" because decision making and expertise are tightly bound to the context of work [17]. Providing guidance on how to improve HS effectiveness involves generating an understanding of how effective HS personnel do their jobs and make good decisions.

Because of this focus on the context of work, descriptions of environmental factors that define NDM research have been proposed. These include the presence of ill-structured problems, uncertain and dynamic environments, shifting and ill-defined or competing goals, action/feedback loops, time stress, high stakes for decision outcomes, multiple players, and the influence of organizational goals and norms [12]. Although not all of these factors are present in all NDM research, several usually play an important role. To further illustrate the nature of the NDM approach, Lipshitz et al. [18] provide five essential characteristics of NDM research: (i) an emphasis on proficient decision makers, (ii) an orientation toward the *process* of decision making (not just outcomes), (iii) the development of situation–action matching decision rules, (iv) context-bound informal modeling, and (v) empirical-based prescription. As previously noted, the expertise of the decision maker is at the center of inquiry [19]. NDM emphasizes the processes of decision making [20] and developing descriptions of these processes that are practically useful. As reflected in the recognition-primed decision (RPD) model described below, emphasizing expertise and describing the process leads to an understanding of decision making as a process of matching features of a situation to past experience to retrieve rules and possible courses of action. Similarly, the importance of context becomes salient; experts use features of a particular situation that are causally or correlationally related to the problem at hand. Ultimately, NDM is concerned with improving a decision-making performance. To this end, all prescriptions resulting from NDM research focus on realistic actions and strategies that are feasible to apply in the real world.

### 3.3 Defining Expertise

By this point, it should be clear that human expertise is the center of the NDM approach and the primary tool of decision makers in complex environments. But what is expertise? In general, expertise is thought of as high levels of skill or knowledge in a specific area. This conceptualization is apparently simple, but a scientific explanation of expertise has undergone a long evolution. Initially, expertise was considered to be the result of the application of superior general reasoning strategies [21]; however, this was found to be a flawed approach for reasons similar to those which rendered rationalist and formal-empiricist approaches ineffectual to decision making. Specific domain knowledge, and not general reasoning strategies, was found to play a major role in expert performance

[22]. This finding shifted expertise research into the knowledge-based phase; it is the novice's performance that is best characterized by the use of general reasoning strategies, not the expert's. However, it is not just the amount of knowledge (or even organization) that determines expert performance. Expertise has come to be viewed as the result of the many adaptations (e.g. skilled memory, automaticity, specialized reasoning strategies) to the constraints of a domain and set of tasks [23]. Consequently, experts use different performance processes from those of novices, and do not just reach higher levels of performance outcomes by being better at using the same processes.

### 3.4 Exemplar NDM Theoretical Models

Nothing is more practical than a good theory. This section provides a brief description of several theoretical models and approaches discussed in the NDM literature.

***3.4.1 Recognition-Primed Decision Making.*** The RPD model is grounded in the scientific understanding of expertise and developed through extensive field observations of fireground commanders [17]. This model was developed to explain these fireground commanders' ability to make effective and extremely rapid decisions without performing an exhaustive analysis of the situation. The RPD provides a two-process description of expert decision making: (i) pattern recognition and (ii) mental simulation. In the pattern matching process, decision makers scan the environment to build an understanding of the present situation. This situation representation is used to match cues in the environment to a past experience. When a match is found, the course of action associated with that past experience can be retrieved. This represents a course of action that was successful in the past and hence may be effective in the current situation. In addition to a course of action, the decision maker retrieves expectancies associated with the situation, information about cues that are most critical to attend to, and goals for the situation. If a successful match is not found, the decision maker searches for more information to build a better representation of the situation. Once a course of action has been retrieved through this pattern recognition process, the decision maker evaluates the likely effectiveness of the retrieved course of action considering the unique aspects of the present situation. This is accomplished through mental simulation wherein the decision maker does a "cognitive walkthrough" of the implementation of the course of action and considers how the unique features of the present situation will impact the effectiveness of the course of action. Mental simulation results in either the adoption of the retrieved course of action unchanged or modified to the new situation, or rejection of the course of action. If the option is rejected, the decision maker returns to pattern recognition activities.

***3.4.2 Heuristics and Bounded Rationality.*** A complimentary yet distinct line of research has produced an explanation of decision-making performance in terms of fast and frugal heuristics [24]. This approach is known as the *study of bounded rationality* [25] and is the analysis of heuristics used by people, the structure of the decision-making environment, and the fit between these two things (called *ecological rationality*; [24]). By using adaptive heuristics with high levels of "ecological rationality", decision makers can engage in satisficing (i.e. taking the first acceptable solution) in complex environments where optimization is unobtainable [26]. From this perspective, an expert decision maker is one who possesses an "adaptive toolbox" [27], a set of heuristics well suited to the information structure of the environment. NDM and the bounded rationality

approach share much in common [28]. However, whereas the RPD (and other NDM models) relies on informal and descriptive models, the bounded rationality approach focuses on the formal modeling of the rules that decision makers actually use [29].

***3.4.3 Shared Mental Models.*** The preceding two theoretical approaches deal with individual decision making. Shared mental model theory is a dominant explanation of how expert teams make decisions effectively [30]. A shared mental model is an organized knowledge structure that enables the coordination of interdependent teamwork processes [31]. On the individual level, mental models are knowledge structures involved in the integration and comprehension of information. On the team level, a shared mental model is a knowledge structure that is partially shared and partially distributed throughout a team. By sharing and distributing these knowledge structures, team members are able to interpret incoming information in a similar or compatible manner. This, in turn, facilitates effective coordination; team members develop similar causal explanations of information and inferences about possible future states of the environment. Additionally, shared mental models enable the implicit communication patterns characteristic of expert teams [32]. HS security operations frequently require the coordination of multiple individuals and possibly even multiple teams (e.g. maritime interdictions). Shared mental model theory is an important theoretical perspective to understanding and subsequently boosting the effectiveness of performance in these types of situations.

## 4 WHAT METHODS ARE USED IN NDM RESEARCH?

Methods in the NDM approach require tools and techniques for eliciting, analyzing, and representing the knowledge and cognitive processes involved in task performance. Fortunately, many methods rooted in the theory and methods of cognitive psychology and the other cognitive sciences have been developed to this end. Broadly, these methods have been grouped under the label cognitive task analysis (CTA). Table 1 provides a summary of the primary types of methods used in NDM research (for comprehensive reviews of these techniques, see Rosen et al. [33] and [2, 34]). CTA is a loose set of methods and tools and not a codified and unitary "one-size-fits-all" method. Any one specific CTA approach must be developed considering the purpose of the CTA, practical constraints (e.g. time and access to experts), and the relative strengths and weaknesses of each specific method and tool.

A comprehensive review of the methods used by NDM researchers is outside the scope of this article. However, these methods fall into one of the four general categories. First, *process tracing techniques* involve capturing the external processes of task performance in a way that enables inferences to be made about the internal cognitive processes of the person performing the task [36]. Protocol analysis, information monitoring (i.e. capturing keystroke data), and eye tracking are examples of process tracing techniques. These methods provide a very robust and rich data set, but frequently require substantial time and effort to analyze. Second, *interview and observation techniques* provide direct access to the full range of social, organizational, and physical factors influencing cognitive work; however, field observations can be difficult to arrange due to security, safety, or logistical reasons. Interview approaches include the critical decision method [37], and techniques from ethnography and cognitive anthropology have been adapted to facilitate field observations [38]. Third, there are several *indirect and conceptual methods* available that, in

**TABLE 1 Overview of Methods Used in NDM Research**

| Category of Methods | Examples | General Strengths | General Weaknesses |
|---|---|---|---|
| Process tracing techniques | Protocol analysis | Rich quantity and quality of information | Data collection and analysis can be time consuming for many of the methods |
| | Decision analysis | Readily applicable to "real-world" settings | Some methods used concurrently with task performance may alter performance processes (e.g. verbalizing aspects of performance not generally verbalized) |
| | Information sampling | Methods are process-oriented; they focus on the sequences of activity | |
| | Verbal reports | | |
| | Nonverbal reports | | |
| Interview and observation | Critical decision method | Rich data | Time consuming to analyze |
| | Critical incident technique | Techniques have face validity to experts; they are familiar with them | Retrospective techniques produce data with uncertain reliability due to memory degradation |
| | Structured/semistructured/ unstructured interviews | Techniques are highly flexible and applicable in most contexts | Gaining access to field observations can be difficult |
| | Field observations | Focusing on critical incidents is highly efficient | Access to time with experts is generally limited |
| | | Gives "real-world" perspective on work processes | Observation can be reactive |
| | | Effectively identifies individual differences in performance | |
| Indirect/Conceptual methods | Concept maps | Can be very efficient (especially when combined with interview techniques) | Methods do not have high "face validity" for most domain experts |

(*continued overleaf*)

**TABLE 1 (*Continued*)**

| Category of Methods | Examples | General Strengths | General Weaknesses |
|---|---|---|---|
| | Pairwise relatedness ratings | Helps experts make "tacit" knowledge explicit | |
| | Abstraction hierarchies | Knowledge elicitation and analysis are combined for concept mapping | |
| | Repertory grid technique | | |
| | Sorting techniques | | |
| | Multidimensional scaling, network scaling, and cluster analysis | | |
| Simulations and contrived tasks | Simulated task environment (ranging from high to low fidelity) | Allows for merger of experimental control and real-world task complexity | Risk of collecting data that is not valid in real context of performance |
| | Tasks that deviate from real-world task (hypotheticals) | Allows for observation of performance for tasks that occur at a low frequency on the job | Construction and validation of simulation takes time, effort, and money |
| | | Allows for observation of performance during events that would be unsafe in the real world | |

Adapted from Ref. 35.

general, attempt to assess the structure or organization of expert knowledge. Examples include concept mapping and paired comparison ratings [39]. These methods are very efficient and effective; however, they tend to lack face validity for domain experts. Fourth, the *simulations and contrived tasks* can be used to "bring the real world into the lab." Simulations offer a compromise between the complexity of the real world and experimental control and afford the ability to observe low-frequency events (e.g. observing how an expert flight crew handles a critical failure during a flight is not feasible in the real world but is possible and practical using simulations; [40]). However, simulations can be costly to develop and no matter how much effort is dedicated to replicating critical aspects of the real world, there will be some differences between the real world and the simulation that may influence a decision-making performance. Each of the types of methods has general strengths and weaknesses and any specific method will have its own trade-offs. Any one NDM investigation will likely use a combination of these methods in order to generate a robust understanding of the decision maker's expertise through triangulation while working within the practical constraints.

## 5 WHAT HAVE WE LEARNED FROM NDM AND EXPERTISE RESEARCH?

The NDM approach is solidly rooted in field research, and as such has been criticized for generating results with low levels of generalizability. The nature of expertise is domain specific; therefore, an understanding of one type of expert is not directly applicable to experts in other domains. However, a consistent pattern of findings has emerged from studies in many domains. These patterns represent a "prototype" of expert decision making; they are a set of mechanisms that individuals and teams use to make effective decisions. The importance of any one of the mechanisms will vary depending on the features of the decision-making task and environment. These mechanisms can be used as a framework for understanding expert decision making across domains, but must be contextualized to the specific task features of any one domain. We briefly review these patterns for expert individual and team decision making below. The mechanisms of expert individual and team decision making are listed in Tables 2 and 3, respectively.

**TABLE 2 Mechanisms of Expertise and Individual Decision Making**

| Expert Decision Makers . . . |
|---|
| Are tightly coupled to cues and contextual features of the environment . . . |
| They develop psychological and physiological adaptations to the task environment |
| They are sensitive to and leverage contextual patterns of cues in decision making |
| Have a larger knowledge base and organize it different than nonexperts . . . |
| They have a more conceptually organized knowledge base |
| They have more robust connections between aspects of their knowledge |
| They have a more abstracted and functional knowledge base |
| Engage in pattern recognition . . . |
| They perceive larger and more meaningful patterns in the environment |
| They are able to detect subtle cue configurations |
| They are able to retrieve courses of action based on situation/action matching rules |
| Have better situation assessment and problem representations . . . |
| They spend more time evaluating the situation |
| They create deeper, more conceptual, more functional, and more abstracted situation Representations |
| Have specialized memory skills . . . |
| They functionally increase their ability to handle large amounts of information |
| They anticipate what information will be needed in the decision making |
| Automate the small steps . . . |
| They quickly and effortlessly do what requires large amounts of attention for nonexperts |
| They have more cognitive resources available for dealing with more complex aspects of decision making |
| Self-regulate and monitor their processes . . . |
| They evaluate their own understanding of a situation |
| They judge the consistency, reliability and completeness of their information |
| They make good decisions about when to stop evaluating the situation |

Adapted from Ref. 33.

**TABLE 3 Prototypical Mechanisms of Expert Team Performance and Decision Making**

| Members of Expert Teams |
|---|
| They develop shared mental models |
| They anticipate each other's needs and actions |
| They can communicate implicitly |
| They interpret cues in a complimentary manner |
| Learn and adapt |
| They self-correct |
| They learn from past decision-making episodes |
| They adapt coordinating processes to dynamic environments |
| They compensate for each other |
| Maintain clear roles and responsibilities |
| They mange expectations. |
| They understand each others' roles and how they fit together |
| They maintain clarity of roles while maintaining flexibility |
| Possess clear, valued, and shared vision |
| They develop their goals with a shared sense of purpose |
| They guide their decisions with a common set of values |
| Develop a cycle of prebrief → performance → debrief |
| They regularly provide individual and team level feedback to one another |
| They establish and revise team goals and plans |
| They dynamically set priorities |
| They anticipate and review issues/problems of members |
| They periodically diagnose team decision making "effectiveness", including its results, and its processes |
| Are lead by strong team leaders |
| They are led by someone with good leadership skills and not just technical competence |
| They believe the leaders care about them |
| Leaders of expert teams provide situation updates |
| Leaders of expert teams foster teamwork, coordination and cooperation |
| Leaders of expert teams self-correct first |
| **Have a strong sense of "collective," trust, teamness, and confidence** |
| They manage conflict well; they confront each other effectively |
| They have a strong sense of team orientation |
| They trust other team members' "intentions" |
| They strongly believe in the team's collective ability to succeed |
| Cooperate and coordinate |
| They identify teamwork and task work requirements |
| They ensure that, through staffing and/or development, the team possesses the right mix of competencies |
| They consciously integrate new team members |
| They distribute and assign work thoughtfully |
| They examine and adjust the team's physical workplace to optimize communication and coordination |

Adapted from Ref. 41.

### 5.1 Individuals

With experience, decision makers adapt their psychological processes to fit the decision-making task and environmental constraints [42]. The ability to leverage contextual structure into decision-making processes [43] and a larger and more organized knowledge base [22] enables the expert decision maker's pattern recognition ability—the primary means of making effective decisions without exhaustive search and evaluation of options. As previously discussed, pattern recognition is critical in a broad range of HS tasks, including baggage screening and information analysis. The expert decision maker realizes the importance of having a good representation of the current situation and uses self-monitoring and metacognitive processes to ensure their representations are complete and accurate [44, 45]. For example, expert information analysts are able to assess their understanding of the situation and know the quality of the situation representation they are dealing with. This will prompt them to search for more information or know when they have an understanding that can be used to make a good decision. Expert decision makers manage overwhelming amounts of information by developing automaticity of low level task components as well as specialized memory skills [46, 47]. For a detailed review of the mechanisms of individual expert decision making, see Rosen et al. [33], Ross et al. [48], Phillips et al. [49], and Klein [17].

### 5.2 Teams

Having individual expertise is necessary, but frequently insufficient to ensure high levels of performance in modern organizations and HS. Few decisions are made in isolation from other individuals, and consequently decision making has become a team effort for most people. Just as there are general mechanisms that enable expert individual decision making, teams too develop a set of mechanisms to achieve high levels of effectiveness. Expert teams are defined as "a set of interdependent team members, each of whom possesses a unique and expert level knowledge, skills, and experience related to task performance, and who adapt, coordinate, and cooperate as a team, thereby producing sustainable and repeatable team functioning at superior or at least near-optimal levels of performance" [41, p. 440]. In order to achieve these high levels of performance, members of expert teams develop shared mental models [50]. Shared mental models allow team members to anticipate the needs of their fellow team members and interpret environmental cues in a compatible manner. Expert teams continuously learn from past experiences and adapt their coordination processes to meet changing task demands [51, 52]. To this end, they develop cycles of prebrief $\rightarrow$ performance $\rightarrow$ debrief, wherein team members establish and revise team goals and plans as well as provide developmental feedback to one another [53]. Expert teams have clear roles and responsibilities; everyone knows the part they play and how it fits together with their fellow team members' roles [54]. For example, TSA agents responding to an immediate and high-level threat in an airport terminal should all know what they are responsible for doing and what their fellow team members will be doing. This facilitates coordination of efforts and adaptation to unique situations. Definition of these roles and responsibilities is clear, but they are not rigid. They change, shift, and adapt as necessary; this process is guided by a shared vision and a sense of the team's purpose [55]. Leadership plays a major role in establishing this vision and other critical aspects of expert team decision making, such as providing situation updates, fostering coordination, and self-correcting and modeling a good decision-making performance [56].

## 6 CONCLUDING REMARKS

The NDM approach has already contributed to the understanding of the role of human expertise in HS; hopefully, this is just the beginning with more to come. From baggage screening, to maritime interdictions, to border patrol and intelligence analysis, human expertise and decision making drive the effectiveness of HS operations. The emergent science of NDM and expertise are poised to contribute scientifically based and practically relevant guidance for maximizing performance on HS tasks.

# CLASSIFICATION AND CLUSTERING FOR HOMELAND SECURITY APPLICATIONS

JIAWEI HAN AND XIAOLEI LI
*University of Illinois at Urbana-Champaign, Champaign, Illinois*

## 1 REPRESENTATION

Proper representation is the first step to utilize methods from classification and clustering [1]. To put it plainly, one has to take information from the real world, the analog world so-to-speak, and store them inside a computer, the digital world. Only after this, classification and clustering algorithms can operate on the real-world problem. This may seem like a simple step, but it can often be the most difficult part of the problem. A proper representation requires an accurate, concise, and static representation of something that can be dynamic and fluid in the real world. And without a good representation, the best algorithms will not be able to operate effectively.

| Color/type | Sedan | SUV | Truck | Motorcycle |
|---|---|---|---|---|
| Red | | | | |
| Green | | *x* | | |
| Blue | | | *y* | |
| Black | | | | |

**FIGURE 1** Feature space with "color" and "type".

To better explain, consider the example of a computer system observing vehicles at a border crossing. The goal of the system might be to automatically flag suspicious vehicles for the border agents to examine more closely. In order for this system to work, the first step is to *represent* the features of the vehicles inside the computer. This is not like how a border agent might describe a vehicle to his or her colleague. Some *features* he or she might use include the vehicle's brand, year, color, size, weight, and so on. The computer system uses a similar process.

Each vehicle is described by a set of features, which make up the so-called *feature space*. This space contains all possible vehicles that can be described by the set of associated features. Figure 1 shows a simple example where there are exactly two features: "color" and "type".

In this two-dimensional feature space shown in Figure 1, vehicles are distinguished only by color and type. Their combinations, which come up to 16, make up the feature space. Each vehicle in the real world can be described by a point in this feature space. A "green sport utility vehicle (SUV)" is point $x$ in Figure 1 and a "blue truck" is point $y$. Points in the feature space are sometimes called "feature vectors," because they can be written out as a vector. For example, $x$ can be written as <"green", "SUV">.

From this example, one might begin to get a sense of the importance of a proper feature space. The two-dimensional feature space in Figure 1 lacks much information valuable to border agents. The "year" and "make" are obvious misses. Without them, the agent will not be able to make an informed decision. At the same time, a feature space that includes everything under the sun is not a brilliant idea either. Suppose the feature space included information such as the fabric type of the seats or whether the vehicle has a CD player. These features are unlikely to have any impact on the decision-making process, but the inclusion of them in the feature might cause unnecessary confusion. To a computer algorithm, these extra features could reduce performance both in terms of accuracy and speed.

## 2 CLASSIFICATION

Classification or supervised learning is a problem from the field of machine learning that aims to learn a function (classifier) that maps a data point to a class label. For example, a data point could be a vehicle and the class label could either be "normal" or "suspicious." By using previously labeled data points, a classifier is able to tune its internal parameters such that in the future, it can correctly label previously unseen data points. Research in

classification mainly focuses on which classifiers to use and how to adjust the parameters inside the classifier.

### 2.1 Basic Concepts

Supervised learning entails the learning of a classifier from training data. The typical classification problem consists of the following components:

1. feature space
2. classification model
3. learning algorithm
4. training data
5. testing data.

The first item, feature space, has already been described in the previous section. To reiterate, it is the representation of the real-world data. The second item, the classification model, is described in detail later in this section. To put it bluntly, it is the brains in the computer that will automatically assign class labels to new objects. The third item, the learning algorithm, is in charge of "tuning" the classification model for optimal performance. Learning algorithms and classification models are often paired together. That is, each classification model has its own unique learning algorithm.

The fourth item, training data, is previously labeled data given to the learning algorithm. Training data consists of labeled data points in the given feature space. Each data point has assigned to it a class label. The set of class labels could either be binary (e.g. "normal" or "suspicious") or $n$-ary (e.g. "normal", "suspicious", "alarming", or "emergency"). With such data, the learning algorithm teaches the classification model how to recognize the features correlated with each different class label. Lastly, the testing data is a separate set of labeled data used to test the performance of the classification model after training. That is, after the classification model has been trained using the training data by the learning algorithm, it is tested using the testing data. The classification model will produce its own class labels for the data points in the testing data. These labels are compared with the true labels and the accuracy is reported back as the classification accuracy. Note that the training data and testing data are two different data sets. It is usually unwise to use the same data set for both training and testing. This leads to the undesirable result of the learning algorithm "over-fitting" the classification model just for the training data and not the general problem.

The training and testing process is similar to how human training occurs. Consider how a new border agent is trained to spot suspicious vehicles at a border crossing. The first few days on the job, he or she is probably trained by a more experienced agent, who teaches him or her the important skills in pinpointing suspicious vehicles. After a while, the new agent can proceed on his or her own after the supervisor is satisfied with his or her performance. The analogy to machine learning is something like the following. The new border agent is the classification model. Initially, it has a "blank" brain and does not really know how to identify suspicious behavior. The more experienced agent can be viewed as the learning algorithm since it teaches the new agent the knowledge required for the job. During the teaching process, the examples the experienced agent might use to teach the new agent are the training data. And finally, the supervisor might evaluate the new agent on some new cases, which are the testing data.

| Color/type | Sedan | SUV | Truck | Motorcycle |
|---|---|---|---|---|
| Red | | | | |
| Green | | *x* | | |
| Blue | | | *y* | |
| Black | | | | |

**FIGURE 2** Feature space with decision boundary for vehicles with four or more wheels versus vehicles with less than four wheels.

### 2.2 Classification Model

So far, the description of a classification model has largely been a black box. Somehow, it is able to put a class label on an object after some training. The exact method of how a model is able to do this depends on the classification model, but the general ideas are common across all models. A brief overview is given in this section.

At a high level, a classification model simply divides the feature space such that data points of different classes fall into separate regions. This division is sometimes called the *classification* or *decision boundary*. Figure 2 shows a classification boundary in the feature space of Figure 1 if the problems were to differentiate vehicles with four wheels or more versus vehicles with less than four wheels. The red decision boundary divides the feature space in a way such that all vehicles with four wheels or more are on the left-hand side of the boundary, while vehicles with less than four wheels are on the right-hand side. Points $x$ and $y$ fall on the left-hand side of the boundary. Given a decision boundary or possibly a set of them, classification on a new object is easy. One just has to find out which side of the boundary the object resides in and make the appropriate decision.

The role of the learning algorithm is to find the decision boundary for the given classification model and training data. Recall that points in the training data are labeled. Using these labels, the learning algorithm adjusts the decision boundary of the classification such that points of different class labels lie on different sides of the boundary. In practice, finding the perfect decision boundary is often impossible. There is usually no clear boundary that can clearly separate the data points of different classes. Because of noise or just the inherent difficulty of the problem, some training data will lie on the incorrect side. It is the duty of the learning algorithm to position the decision boundary such that this error is minimized.

### 2.3 Types of Classifiers

In the previous section, the classifier was discussed in general terms: it learns a decision boundary in the feature space. In practice, this could take shape in many forms. The "boundary" can be a line, a square, or any other shape. Different classifiers use different types of boundaries, and some boundaries might be more effective than others depending on the problem. There is no universal best. Furthermore, different classifiers use different learning algorithms to adjust its decision boundary. These algorithms have different characteristics as well. With respect to efficiency, some scale very nicely with the number of features and others scale very nicely with the number of points in the training data.

In the next few paragraphs, several popular classifiers are discussed.

***2.3.1 Decision Tree.*** Decision trees, one of the most basic and intuitive classifiers, are both accurate and easy to use. A decision tree's decision boundary is essentially a list of rules where each rule is a set of conditions. If a data object matches the conditions in the rule, then it is labeled according to the rule. For example, "Color = Black AND Type = SUV → Suspicious" could be a rule. In this case, all black SUVs would be labeled as suspicious. With these rules, the classifier can either make the decision automatically or the rules can be given to human agents for training [2].

Learning these rules is also relatively straightforward. The details are beyond the scope of this article but the intuitions are as follows. The classifier starts with a blank rule, that is, it applies to all data objects. Then, for every feature and its set of feature values, the classifier checks how useful it is with regard to classification. The measure of usefulness comes from information theory, and it essentially measures how discriminative it is alone at separating data points in the training set according to their class labels. The feature value that is most useful according to this measure is then added to the empty rule. At this point, this rule has split the training data, so the process continues recursively within each split.

There are many different decision tree algorithms but all of them basically work from the principles given above. Some of the more advanced techniques involve how to better measure the usefulness of a feature value and how to consolidate many rules together such that they are more accurate in the general case.

***2.3.2 Naïve Bayes.*** Bayes' rule is a basic equation from probability theory. Roughly speaking, it states that the probability of an event A conditional on another event B is related to event B conditional on A. If one lets A represent the event that an object is suspicious and B represent the event that feature $X$ is present, Bayes' rule would state the following: An object being suspicious conditional on feature $X$ is related to feature $X$ conditional on a suspicious object. From the training data, one can gather "evidence" on how often a suspicious object exhibits feature X. Then, through Bayes' rule, the same evidence can be used to guess how likely an object is suspicious given that it exhibits feature $X$ [2].

This describes how a single feature can be used to decide the class label. When there are multiple features, the same process is repeated independently and the final classification decision is a simple combination of them all. This independent feature assumption is often not true in the real world but it is used for the sake of simplifying the problem and making learning tractable.

***2.3.3 Support Vector Machine.*** In recent years, support vector machines (SVMs) have become the classifier of choice for many researchers. It has been shown to be more efficient and accurate when there are many features to consider (for example, text classification). It works by positioning its decision boundary in the feature space as close to the "middle" as possible. The intuition is that this boundary will work the best for future data points. In cases where a simple linear decision boundary cannot be found, SVMs can project the data points to a feature space with more dimensions such that it can be [3].

### 2.4 Applications of Classification in Homeland Security

The running example of labeling an object as being normal or suspicious is the most natural application of automated classification. The set of class labels does not have to be binary; there could be many classes. For instance, each class could be a different level of

alarm. Further, the object in question could be anything; the only question would be how to represent the object in a feature space. For example, if the object is a vehicle, some features would be the brand of the vehicle, the size of the vehicle, the license number, the year of the vehicle, the speed of travel, and so on. If the object is a person, some features would be age, height, hair color, and maybe other background information. If the object is a cargo container, some features would be the owner of the container, the source of the container, the destination, and so on.

The representation of a real-world problem as a classification problem is not difficult. Often, human beings already make these classification decisions; the only difference would be replacing a human by a classifier. However, there are two major issues that often prevent a classifier from being deployed. First and foremost, the exact representation and extraction of features of the object are difficult task. A person might look at a vehicle and say that it is a red truck; however, for an automated camera system to make that same decision is difficult. Any feature that requires the system to visually identify something is difficult. Although the most advanced vision algorithms can achieve a great degree of precision, 100% accuracy is still unreachable. Additionally, the "sixth sense" that humans have is simply impossible to represent in machine form.

Second, in order to train a classifier, training data must exist. A set of data points that have the correct class labels must be given to the classifier so that it can learn the right decision boundaries. In humans, this corresponds to experience one person might pass to another. In machines, this set of training data can be hard to obtain. Employee training programs might have case studies for training new hires, but they hardly cover the entire gambit of cases. Further, in many real-world "classification" problems, the answer is not always black-and-white. To translate such scenarios to a discrete world of machine learning is not always straightforward. All these problems make obtaining clean training data a tricky problem. And just like a new employee, without proper training, a classifier can never reach its full potential.

### 2.5 Semisupervised Learning

Supervised learning's paradigm is that there is a set of labeled data that is presented to the classifier for training. As mentioned, this is often difficult to achieve in practice. Labeled data might be very hard to obtain or simply may not exist. If there are too few training examples, the classifier will not be able to learn the correct decision boundary. However, there are many cases where unlabeled data exist in abundance. In these situations, semisupervised learning is more appropriate. In this new paradigm, the human user is involved in the training process of the classifier. For instance, the classifier might ask the user to classify a few data points that it finds difficult to process. The goal is for the classifier to maximize its learning while minimizing the number of interactions it must have with the human.

Semisupervised learning can often achieve better accuracy than supervised learning because it essentially has more training data. Further, these additional training data are selected based on their usefulness to the classifier. However, it does require more human intervention.

### 2.6 Incremental Learning

So far, the discussion has been focused on a classical learning system where all the training data are presented up front. Once the training is complete, the classifier is

"fixed." To borrow from the human learning analogy one more time, this learn-once paradigm is definitely untrue for humans. As new experiences and evidences become available, one would continuously readjust his or her thinking. For this paradigm, there are some classifiers that can do what is called *incremental learning* or *lifetime learning*. When new evidence becomes available, the classifier can consolidate it with its previous knowledge. This is more efficient than starting from scratch (that is, combine the new evidence with previous evidence and retrain from scratch).

## 3 CLUSTERING

Clustering or unsupervised learning is another problem from the field of machine learning. Compared to classification, the most obvious difference is that there are no longer training examples given. In other words, there is no supervision to guide the learning of parameters in the function. This is often the case in the real world where no labels are available. Clustering algorithms allow the user to see some natural groupings of data to gain some insight.

### 3.1 Basic Clustering Concepts

Much like classification, data points are first put into a feature space. Figure 3 shows a sample two-dimensional feature space with some points in it. The goal of clustering is to find natural groupings (clusters) of data points in this space. It is quite obvious in Figure 3 that there are two clusters. In fact, an automated clustering algorithm is likely to find them as well. In situations where the user knows very little about the data set, clustering can often reveal interesting information.

Just like classification, choosing of features is an important step. The same challenges there exist as here; however, there is one additional issue clustering has to consider. That is, how does one define similarity between two objects? This is known as the *similarity measure* in clustering. Theoretically, similar objects should be in the same cluster and dissimilar ones should be in different clusters. Therefore, the similarity measure is crucial in forming the right clustering. In Figure 3, the similarity function is the Euclidean distance between points. This is very natural in applications where data points represent physical locations. For example, if one wants to cluster all the gas stations in a city, Euclidean distance would be a good fit. However, in other situations, the similarity measure is tricky to choose. For example, suppose one is clustering the following three people: John, Jane, and Mary. If the similarity measure is the edit distance between the text string, John and Jane would likely be in one cluster and Mary be in another.

| Color/type | Sedan | SUV | Truck | Motorcycle |
|---|---|---|---|---|
| Red | $x_1$ | $x_2$ | | |
| Green | $x_3$ | $x_4$ | | |
| Blue | | | $y_1$ | $y_2$ |
| Black | | | $y_3$ | |

**FIGURE 3** Feature space with "color" and "type".

However, if the similarity measure is the gender of the person, Jane and Mary would be in one cluster (female) and John would be in his own cluster. Clearly, the similarity measure is highly application-specific and should be chosen with careful consideration.

With a similarity measure defined, one can then choose from a plethora of clustering algorithms. In other words, the choosing of the similarity measure and the clustering algorithm is somewhat independent. Both are important decisions and can affect the final outcome in many different ways.

### 3.2 Types of Clustering Algorithms

There are many types of clustering algorithms. Giving a single global taxonomy of all clustering algorithms would be impossible. There are, however, some properties that distinguish one from another.

Some of the basic clustering algorithms fall into the Partitioning group. The idea is to partition a data set into $k$ distinct groups. K-means and K-medoids are the classical examples in this. K-means is probably the most popular clustering algorithm [2]. It works as follows. Given a data set, it first randomly chooses $k$ points to be the centers of clusters, otherwise known as centroids. The value of $k$ is given in advance to the algorithm. Then, for all points in the data set, it is assigned to the closest centroid. This partitions the data into $k$ clusters, though it is rather random since the centroids are chosen randomly. Then, for each cluster, the algorithm recomputes a new centroid by taking the "average" or "mean" of all points that belong to that cluster. With these new centroids, all points in the data set are reassigned to their closest centroid. This process iterates until some stopping criterion, which could be when the recomputation of centroids does not alter their positions anymore. Though this process might seem rather random (the initial $k$ centroids are randomly chosen), it is guaranteed theoretically to converge.

The K-means algorithm and the similar K-medoids form the foundation of many clustering algorithms. It is relatively efficient and works quite well when the clusters are compact and isolated. It does, however, have several weaknesses. First and foremost, the value of $k$ is an input to the algorithm. The user must have some prior clue about the distribution of data. Although many works have focused on automatic selection of $k$, the results are still not perfect. Secondly, to compute the "average" of a cluster, numerical values are assumed. Many real-world data sets have categorical features that do not have an easy definition of average. Thirdly, outliers and noise can often confuse the algorithms to form unnatural clusters.

Another class of clustering algorithms is density-based clustering. As the name suggests, the density of data points at a local region dictate how clusters are formed. This has several advantages. First, clusters of arbitrary shapes can be formed. In partitioning algorithms, the distance metric or similarity measure often restricts the cluster shape. For example, using the Euclidean distance in K-means restricts cluster shapes to spheres. Secondly, density-based clustering is more robust with respect to noise. In it, the point in the upper-right corner is designated an outlier because its local region is sparse. A partitioning algorithm would either assign it to its own cluster or to a near-by cluster, thus stretching a cluster unnecessarily.

One of the first density-based clustering algorithms is DBSCAN [4]. It works as follows. Instead of defining the distance between two points in space as the Euclidean distance, it is defined as being "density-connected." Without going into the details, it roughly means that two points are either close to each other or connected via a sequence

of points that are also close to each other. While observing some other parameters, DBSCAN simply follows chains of density-connected points and mark each chain as being its own cluster. If a point is not density-connected to any other point, it is marked as an outlier.

Partitioning and density-based clustering algorithms produce "flat" clusters. That is, clusters are equal with respect to another. But in many real-world applications, a hierarchical structure to the clusters is more applicable. For example, shoes, socks, and boots might be clustered together in the "footwear" cluster, but the "footwear" cluster would belong to the apparel cluster, and so forth. This hierarchy makes organization easier and is often more natural. The very basic hierarchical clustering algorithm is called *hierarchical agglomerative clustering*. It starts by assigning each data point to its own cluster (or after some basic clustering). Then, the most similar pair of clusters is merged together. This process iterates until all original clusters are in the same cluster. The intermediate merge paths then form a binary hierarchy. One major issue in this algorithm is defining similarity between clusters. Two competing choices are single link and complete link. Single link uses the minimum of all similarity measures between a pairs of points between the two clusters and complete link uses the maximum. The choice between the two and possibly others is largely application dependent.

Lastly, we briefly examine one clustering algorithm that is particularly adept at dealing with large data sets. Algorithms like K-means or DBSCAN are only efficient up to a point. If there are millions or billions of data points, running K-means could require hours or days of computation. To this end, BIRCH was invented to handle very large data sets [4]. It works by the principle of "microclustering." That is, if a set of points is in a very tight cluster, they can essentially be treated as a single point or microcluster. The microclusters would then replace the original big data set and be presented to a clustering algorithm as input. The idea is that the number of microclusters is much smaller than the number of raw data points, and thus clustering can be completed in a reasonable time. Constructing microclusters is fairly straightforward. It relies basically on a user-defined maximum radius threshold. If the circle formed by a set of points has a radius smaller than the threshold, it is marked as a microcluster. Otherwise, points are redistributed to new microclusters such that the threshold value is not violated. After the microclusters are constructed, any other clustering algorithm can be run on top of it.

### 3.3 Outlier Detection

Related to clustering is outlier detection. One sometimes views it as a by-product of clustering. That is, if a cluster contains very few data points, it is regarded as an outlying cluster. This by-product can sometimes be gotten with no extra effort on the clustering algorithm; however, some assert that a dedicated outlier detection algorithm is better suited. One such algorithm is based on DBSCAN. Essentially, data points that are not density-connected to other points are marked as outliers.

### 3.4 Applications of Clustering to Homeland Security

Clustering is often applied to data about which little is known. It gives the user some preliminary ideas about some natural groupings in the data. The same case is true in homeland security. When there is so much data that one cannot make sense of it, clustering is helpful in shedding some light. For instance, clustering all vehicles at a busy border crossing can be helpful in dividing workload.

More applicable to homeland security is outlier detection. The majority of objects in question are normal and only a very subset is abnormal. In the border crossing example, the vast majority of vehicles are normal ones. The goal of the border agent is to seek out the small minority that is abnormal. This fits the model of outlier detection very well and is likely the common problem in homeland security.

## 4 FEATURE SELECTION

As mentioned previously, representation is just as important, if not more so, than the actual learning of the classifier. Consider the learning of a classifier for labeling the color of a vehicle. This is trivial if color is in the feature space; however, if it were not, the problem would be impossible regardless of the classifier. In this case, the feature space is not rich enough to capture the discriminating features. One might suggest to just throw all possible features to the classifier and might allow the classifier decide which ones are useful. This can also be problematic due to time constraints; a classifier could take an unrealistic amount of time to tune its parameters.

To this end, there is a field of research called *feature selection* that deals with this exact problem. Given a set of features, a feature selection algorithm chooses a subset, which can be just as good, if not better, than the full feature space with regard to classification accuracy. For instance, if the classifier is to label the color of a vehicle, the "number of wheels" feature can probably be dropped from the feature space. A properly pruned feature space can make the learning more efficient and also more accurate. A common approach is to rank the features according to some goodness measure and select the best features one-by-one until some stopping criteria is satisfied.

## 1 INTRODUCTION

The pros and cons of different weighting schemes remain a subject of research [1, 4]. The European Union (EU) contracted the TU Delft to review its applications both within EU projects, and elsewhere, in which experts assessed variables in their field of expertise for which the true values are known, in addition to variables of interest [3–6]. These are called *seed*, or *calibration*, variables. Since then, the TU Delft expert judgment database has nearly doubled. We now have studies involving over 67,000 experts' subjective probability distributions. The main sectors and summary information are given in Table 1.

The authors believe that this database represents a unique source from which much can be learned regarding the application of structured expert judgment in quantitative decision support. The entire data, appropriately anonymized, may be obtained from the

**TABLE 1 Summary of Applications per Sector**

| Sector | Number of Experts | Number of Variables | Number of Elicitations |
|---|---|---|---|
| Nuclear applications | 98 | 2,203 | 20,461 |
| Chemical and gas industry | 56 | 403 | 4,491 |
| Groundwater/water pollution/dike ring/barriers | 49 | 212 | 3,714 |
| Aerospace sector/space debris/aviation | 51 | 161 | 1,149 |
| Occupational sector: ladders/buildings (thermal physics) | 13 | 70 | 800 |
| Health: bovine/chicken (*Campylobacter*)/SARS | 46 | 240 | 2,979 |
| Banking: options/rent/operational risk | 24 | 119 | 4,328 |
| Volcanoes/dams | 231 | 673 | 29,079 |

first author. It is hoped that others will use this data to further develop methods for using structured expert judgment.

We assume that uncertainty is represented as subjective probability and concerns results of possible observations. For a discussion of foundational issues, the reader is referred to [7]. Section 2 discusses goals of a structured expert judgment study; Section 2 provides an explanation of the concepts and methods underlying the Delft expert judgment method. Section 3 gives an updated summary of the results, comparing equal weighting with performance-based weighting and with the best expert. Section 4 discusses seed variables and robustness, and Section 5 is devoted to lessons learned and anecdotal information, common pitfalls, and misconceptions. A concluding section identifies possible topics for future research.

## 2 STRUCTURED EXPERT JUDGMENT

Expert judgment is sought when substantial scientific uncertainty impacts a decision process. Because there is uncertainty, the experts themselves are not certain and hence will typically not agree. Informally soliciting expert's advice is not new. *Structured* expert judgment refers to an attempt to subject the decision process to transparent methodological rules, with the goal of treating expert judgments as scientific data in a formal decision process. The process by which experts come to agree is the scientific method itself. Structured expert judgment cannot preempt this role and therefore cannot have expert agreement as its goal. We may broadly distinguish three different goals to which a structured judgment method may aspire:

- Census
- Political consensus
- Rational consensus.

A study aiming at *census* will simply try to survey the distribution of views across an expert community. An illustration of this goal is found in the *Nuclear Regulatory Commission's Recommendations for Probabilistic Seismic Hazard Analysis: Guidance on Uncertainty and Use of Experts:*

> "To represent the overall community, if we wish to treat the outlier's opinion as equally credible to the other panelists, we might properly assign a weight (in a panel of 5 experts) of 1/100 to his or her position, not 1/5" (NUREG/CR-6372 [8], p. 36)

The goal of "representing the overall community" may in this view lead to a differential weighting of experts' views according to how representative they are of other experts. A similar goal is articulated in [9]. The philosophical underpinnings of this approach are elaborated in Budnitz et al. [10]. Expert agreement on the representation of the overall community is the weakest, and most accessible, type of consensus to which a study may aspire. Agreement on a "distribution to represent a group", agreement on a distribution, and agreement on a number are the other types of consensus, in decreasing accessibility.

*Political consensus* refers to a process in which experts are assigned weights according to the interests or stakeholders they represent. In practice, an equal number of experts

from different stakeholder groups would be placed and given equal weight in an expert panel. In this way the different groups are included equally in the resulting representation of uncertainty. This was the reasoning behind the selection of expert panels in the EU-USNRC accident consequence studies with equal weighting [11].

*Rational consensus* refers to a group decision process. The group agrees on a method according to which a representation of uncertainty will be generated for the purposes for which the panel was convened, without knowing the result of this method. It is not required that each individual member adopt this result as his/her personal degree of belief. This is a form of agreement on a distribution to represent a group. To be rational, this method must comply with necessary conditions devolving from the general scientific method. Cooke [1] formulated the necessary conditions or principles that any method warranting the predicate "science" should satisfy:

- *Scrutability/accountability.* All data, including experts' names and assessments, and all processing tools are open to peer review and results must be reproducible by competent reviewers.
- *Empirical control.* Quantitative expert assessments are subject to empirical quality controls.
- *Neutrality.* The method for combining/evaluating expert opinion should encourage experts to state their true opinions, and must not bias results.
- *Fairness.* Experts are not prejudged, before processing the results of their assessments.

Thus, a method which satisfies these conditions and to which the parties precommit is proposed. The method is applied and after the result of the method is obtained, parties wishing to withdraw from the consensus incur a burden of proof. They must demonstrate that some heretofore unmentioned necessary condition for rational consensus has been violated. If they fail to demonstrate, their dissent is "irrational". Of course any party may withdraw from the consensus because the result is hostile to his or her interests—this is not rational dissent and does not threaten rational consensus.

The requirement of empirical control will strike some as peculiar in this context. How can there be empirical control with regard to expert subjective probabilities? To answer this question, we must reflect on the question "when is a problem an expert judgment problem?" We would not have recourse to expert judgment to determine the speed of light in a vacuum. This is physically measurable and has been measured to everyone's satisfaction. Any experts we query would give the same answer. Nor do we consult expert judgment to determine the proclivities of a god. There are no experts in the operative sense of the word for this issue. A problem is susceptible for expert judgment only if there is relevant scientific expertise. This entails that there are theories *and* measurements relevant to the issues at hand, but that the quantities of interest themselves cannot be measured in practice. For example, toxicity of a substance for humans is measurable in principle, but is not measured for obvious reasons. However, there are toxicity measurements for other species, which might be relevant to the question of toxicity in humans. Other examples are given in Section 4. If a problem is an expert judgment problem, then necessarily there will be relevant experiments or measurements. Questions regarding such experiments can be used to implement empirical control. Studies indicate that performance on the so-called almanac questions does not predict performance on the variables in an expert's field of expertise [12]. The key question regarding seed variables is as follows: Is performance on

seed variables judged relevant to performance on the variables of interest? For example, should an expert who gave very overconfident off-mark assessments on the variables for which we know the true values be equally influential on the variables of interest as an expert who gave highly informative and statistically accurate assessments? That is indeed the choice that often confronts a problem owner after the results of an expert judgment study are in. If seed variables in this sense cannot be found, then rational consensus is not a feasible goal and the analyst should fall back on one of the other goals.

The above mentioned definition of "rational consensus" for group decision processes is evidently on a very high level of generality. Much work has gone into translating this into a workable procedure that gives good results in practice. This workable procedure is embodied in the "classical model" of Cooke [1] described in the following section.

Before going into details, it is appropriate to say something about Bayesian approaches. Since expert uncertainty concerns experts' subjective probabilities, many people believe that expert judgment should be approached from the Bayesian paradigm. This paradigm, recall, is based on the representation of preference of a rational individual in terms of maximal expected utility. If a Bayesian is given experts' assessments on variables of interest and on relevant seed variables, then (s)he may update themselves on the variables of interest by prior conditionalizing on the given information. This requires that the Bayesian formulates his/her joint distribution over

- the variables of interest;
- the seed variables;
- the experts' distributions over the seed variables and the variables of interest.

Issues that arise in building such a model are discussed in Cooke [1]. Suffice to say here that a group of rational individuals is not itself a rational individual, and group decision problems are notoriously resistant to the Bayesian paradigm.

## 3 THE CLASSICAL MODEL

The above principles have been operationalized in the so-called classical model, a performance-based linear pooling or weighted averaging model [1, 13]. The weights are derived from experts' calibration and information scores, as measured on seed variables. Seed variables serve a threefold purpose:

1. to quantify experts' performance as subjective probability assessors;
2. to enable performance-optimized combinations of expert distributions; and
3. to evaluate and hopefully validate the combination of expert judgments.

The name "classical model" is derived from an analogy between calibration measurement and classical statistical hypothesis testing. It contrasts with various Bayesian models.

The performance-based weights use two quantitative measures of performance, *calibration* and *information*. Loosely, calibration measures the statistical likelihood that a set of experimental results correspond, in a statistical sense, with the expert's assessments. Information measures the degree to which a distribution is concentrated.

These measures can be implemented for both discrete and quantile elicitation formats. In the discrete format, experts are presented with uncertain events and perform their elicitation by assigning each event to one of several predefined probability bins, typically 10, 20, . . . , 90%. In the quantile format, experts are presented with an uncertain quantity taking values in a continuous range, and they give predefined quantiles, or percentiles, of the subjective uncertainty distribution, typically 5, 50, and 95%. The quantile format has distinct advantages over the discrete format, and all the studies reported below use this format. In five studies, the 25 and 75% quantiles were also elicited. To simplify the exposition, we assume that the 5, 50, and 95% values were elicited.

### 3.1 Calibration

For each quantity, each expert divides the range into four interquantile intervals for which his/her probabilities are known, namely $p_1 = 0.05$: less than or equal to the 5% value, $p_2 = 0.45$: greater than the 5% value and less than or equal to the 50% value, and so on.

If $N$ quantities are assessed, each expert may be regarded as a statistical hypothesis, namely, that each realization falls in one of the four interquantile intervals with probability vector

$$p = (0.05, 0.45, 0.45, 0.05)$$

Suppose we have realizations $x_1, \ldots, x_N$ of these quantities. We may then form the sample distribution of the expert's interquantile intervals as

$$\begin{aligned} s_1(e) &= \#\{i | x_i \leq 5\% \text{ quantile}\}/N \\ s_2(e) &= \#\{i | 5\% \text{ quantile} < x_i \leq 50\% \text{ quantile}\}/N \\ s_3(e) &= \#\{i | 50\% \text{ quantile} < x_i \leq 95\% \text{ quantile}\}/N \\ s_4(e) &= \#\{i | 95\% \text{ quantile} < x_i\}/N \\ s(e) &= (s_1, \ldots, s_4) \end{aligned}$$

Note that the sample distribution depends on the expert $e$. If the realizations are indeed drawn independently from a distribution with quantiles as stated by the expert, then the quantity

$$2N I(s(e)|p) = 2N \Sigma_{i=1,\ldots,4}\ s_i \ln(s_i/p_i) \tag{1}$$

is asymptotically distributed as a chi-square variable with 3 degrees of freedom. This is the so-called likelihood ratio statistic and $I(s|p)$ is the relative information of distribution $s$ with respect to $p$. If we extract the leading term of the logarithm, we obtain the familiar chi-square test statistic for goodness of fit. There are advantages in using the form in Eq. (1) Cooke [1].

If after a few realizations the expert were to see that all realizations fell outside his 90% central confidence intervals, he/she might conclude that these intervals were too narrow and might broaden them on subsequent assessments. This means that for this expert the uncertainty distributions are not independent, and he/she learns from the realizations. Expert learning is not a goal of an expert judgment study and his/her joint distribution

is not elicited. Rather, the decision maker (DM) wants experts who do not need to learn from the elicitation. Hence, the DM scores expert $e$ as the statistical likelihood of the hypothesis. *$H_e$: the interquantile interval containing the true value for each variable is drawn independently from probability vector $p$.*

A simple test for this hypothesis uses the test statistic (Eq. (1)), and the likelihood, or $p$ value, or calibration score of this hypothesis, is

$$\text{Calibration score}(e) = p \text{ value} = \text{Prob}\{2NI(s(e)|p) \geq r|H_e\}$$

where $r$ is the value of Eq. (1) based on the observed values $x_1, \ldots, x_N$. It is the probability under hypothesis $H_e$ that a deviation at least as great as $r$ should be observed on $N$ realizations if $H_e$ were true. Calibration scores are absolute and can be compared across studies. However, before doing so, it is appropriate to equalize the power of the different hypothesis tests by equalizing the effective number of realizations. To compare scores on two data sets with $N$ and $N'$ *realizations*, we simply use the minimum of $N$ and $N'$ in Eq. (1), without changing the sample distribution $s$. In some cases involving multiple realizations of one and the same assessment, the effective number of seed variables is based on the number of assessments and not the number of realizations.

Although the calibration score uses the language of simple hypothesis testing, it must be emphasized that we are not rejecting expert hypotheses; rather we are using this language to measure the degree to which the data supports the hypothesis that the expert's probabilities are accurate. Low scores, near zero, mean that it is unlikely that the expert's probabilities are correct.

### 3.2 Information

The second scoring variable is information. Loosely, the information in a distribution is the degree to which the distribution is concentrated. Information cannot be measured absolutely, but only with respect to a background measure. Being concentrated or "spread out" is measured relative to some other distribution. Generally, the uniform and log-uniform background measures are used (other background measures are discussed in Yunusov et al. [14].

Measuring information requires associating a density with each quantile assessment of each expert. To do this, we use the unique density that complies with the experts' quantiles and is minimally informative with respect to the background measure. This density can easily be found with the method of Lagrange multipliers. For a uniform background measure, the density is constant between the assessed quantiles, and is such that the total mass between the quantiles agrees with $p$. The background measure is not elicited from experts as indeed it must be the same for all experts; instead it is chosen by the analyst.

The uniform and log-uniform background measures require an *intrinsic range* on which these measures are concentrated. The classical model implements the so-called $k\%$ overshoot rule: for each item we consider the smallest interval $I = [L, U]$ containing all the assessed quantiles of all experts and the realizations, if known. This interval is extended to

$$I^* = [L^*, U^*]; L^* = L - k(U - L)/100; U^* = U + k(U - L)/100$$

The value of $k$ is chosen by the analyst. A large value of $k$ tends to make all experts look quite informative, and tends to suppress the relative differences in information scores. The information score of expert $e$ on assessments for uncertain quantities $1, \ldots, N$ is

$$\text{Information Score}(e) = \text{Average relative information with respect to background}$$
$$= (1/N)\Sigma_{i=1,\ldots,N} I(f_{e,i}|g_i)$$

where $g_i$ is the background density for variable $i$ and $f_{e,i}$ is expert $e$'s density for item $i$. This is proportional to the relative information of the expert's joint distribution given the background, under the assumption that the variables are independent. As with calibration, the assumption of independence here reflects a desideratum of the DM and not an elicited feature of the expert's joint distribution. The information score does not depend on the realizations. An expert can give himself a high information score by choosing his quantiles very close together.

Evidently, the information score of $e$ depends on the intrinsic range and on the assessments of other experts. Hence, information scores cannot be compared across studies.

Of course, other measures of concentratedness could be contemplated. The above information score is chosen because it is

- familiar
- tail insensitive
- scale invariant
- slow.

The latter property means that relative information is a slow function; large changes in the expert assessments produce only modest changes in the information score. This contrasts with the likelihood function in the calibration score, which is a very fast function. This causes the product of calibration and information to be driven by the calibration score.

### 3.3 Decision Maker

A combination of expert assessments is called a *decision maker*. All DMs discussed here are examples of linear pooling. For a discussion of pros and cons of the linear pool, see Refs [1, 2, 15, 16]. The classical model is essentially a method for deriving weights in a linear pool. "Good expertise" corresponds to good calibration (high statistical likelihood, high $p$ value) and high information. We want weights that reward good expertise and that pass these virtues on to the DM.

The reward aspect of weights is very important. We could simply solve the following optimization problem: find a set of weights such that the linear pool under these weights maximizes the product of calibration and information. Solving this problem on real data, we have found that the weights do not generally reflect the performance of the individual experts. An example of this is given in Section 4.

As we do not want an expert's influence on the DM to appear haphazard, and we do not want to encourage experts to game the system by tilting their assessments to achieve a desired outcome, we must impose a strictly scoring rule constraint on the weighing

scheme. Roughly, this means that an expert achieves his/her maximal expected weight only by stating assessments in conformity with his/her true beliefs.

Consider the following score for expert $e$:

$$w_\alpha(e) = 1_\alpha(\text{calibration score}) \times \text{calibration score}(e) \times \text{information score}(e) \quad (2)$$

where $1_\alpha(x) = 0$ if $x < \alpha$ and $1_\alpha(x) = 1$ otherwise. Cooke [1] showed that Eq. (2) is asymptotically a strictly proper scoring rule for average probabilities. This means the following: suppose an expert has given his quantile assessments for a large number of variables and subsequently learns that his/her judgments will be scored and combined according to the classical model. If (s)he were then given the opportunity to change the quantile values (e.g. the numbers 5, 50, or 95%) in order to maximize the expected weight, the expert would choose values corresponding to his/her true beliefs. Note that this type of scoring rule scores a set of assessments on the basis of a set of realizations. Scoring rules for individual variables were found unsuitable for purposes of weighting, for more details the reader is referred to Cooke [1].

The scoring rule constraint requires the term $1_\alpha$*(calibration score)*, but does not say what value of $\alpha$ we should choose. Therefore, we choose $\alpha$ so as to maximize the combined score of the resulting DM. Let $\text{DM}_\alpha(i)$ be the result of linear pooling for item $i$ with weights proportional to Eq. (2):

$$\text{DM}_\alpha(i) = \Sigma_{e=1,\ldots,E}\ w_\alpha(e) f_{e,i} / \Sigma_{e=1,\ldots,E}\ w_\alpha(e) \quad (3)$$

The *global weight* DM is $\text{DM}_{\alpha^*}$ where $\alpha^*$ maximizes

$$\text{calibration score}(\text{DM}_a) \times \text{information score}(\text{DM}_\alpha) \quad (4)$$

This weight is termed global because the information score is based on all the assessed seed items.

A variation on this scheme allows a different set of weights to be used for each time. This is accomplished by using information scores for each item rather than the average information score:

$$w_\alpha(e, i) = 1_\alpha(\text{calibration score}) \times \text{calibration score}(e) \times I(f_{e,i} | g_i) \quad (5)$$

For each $\alpha$ we define the item weight $\text{DM}_\alpha$ for item $i$ as

$$\text{IDM}_\alpha(i) = \Sigma_{e=1,\ldots,E}\ w_\alpha(e, i) f_{e,i} / \Sigma_{e=1,\ldots,E}\ w_\alpha(e, i) \quad (6)$$

The *item weight* DM is $\text{IDM}_{\alpha^*}$ where $\alpha^*$ maximizes

$$\text{calibration score}(\text{IDM}_a) \times \text{information score}(\text{IDM}_\alpha) \quad (7)$$

Item weights are potentially more attractive as they allow an expert to up- or down weight himself/herself for individual items according to how much (s)he feels (s)he knows about that item. "Knowing less" means choosing quantiles further apart and lowering the information score for that item. Of course, good performance of item weights requires that experts can perform this up–down weighting successfully. Anecdotal evidence suggests

that item weights improve over global weights as the experts receive more training in probabilistic assessment. Both item and global weights can be pithily described as optimal weights under a strictly proper scoring rule constraint. In both global and item weights calibration dominates over information, information serves to modulate between more or less equally well-calibrated experts.

Since any combination of expert distributions yields assessments for the seed variables, any combination can be evaluated on the seed variables. In particular, we can compute the calibration and the information of any proposed DM. We should hope that the DM would perform better than the result of simple averaging, called the *equal weight decision maker* (*EWDM*), and we should also hope that the proposed DM is not worse than the best expert in the panel.

In the classical model, calibration and information are combined to yield an overall or combined score with the following properties:

1. Individual expert assessments, realizations, and scores are published. This enables any reviewer to check the application of the method, in compliance with the principle of *accountability/scrutability*.
2. Performance is measured and hopefully validated, in compliance with the principle of *empirical control*. An expert's weight is determined by performance.
3. The score is a long-run proper scoring rule for average probabilities, in compliance with the principle of *neutrality*.
4. Experts are treated equally, before the performance measurement, in compliance with the principle of *fairness*.

Expert names and qualifications are part of the published documentation of every expert judgment study in the database; however, they are not associated with assessments in the open literature. The experts reasoning is always recorded and sometimes published as expert rationales.

There is no mathematical theorem that either item weights or global weights outperform equal weighting or outperform the best expert. It is not difficult to construct artificial examples where this is not the case. Performance of these weighting schemes is a matter of experience. In practice, global weights are used unless item weights perform markedly better. Of course, there may be other ways of defining weights that perform better, and indeed there might be better performance measures. Good performance on one individual data set is not convincing. What is convincing is good performance on a large diverse data set, such as the TU Delft expert judgment database. In practice, a method should be easy to apply, easy to explain, should do better than equal weighting, and should never do something ridiculous.

## 4 APPLICATIONS OF THE CLASSICAL MODEL

Forty-five expert panels involving seed variables have been performed to date.[1] Because most of these studies were performed by or in collaboration with the TU Delft, it is

[1]These results are obtained with the EXCALIBUR software, available from http://delta.am.ewi.tudelft.nl/risk/. The windows version upgraded chi-square and information computational routines, and this may cause differences with the older DOS version, particularly with regard to very low calibration scores.

possible to retrieve relevant details of these studies, and to compare performance of performance-based and equal weight combination schemes. For studies by Ter Haar [17], the data has not been retrieved.

These are all studies performed under contract for a problem owner and reviewed and accepted by the contracting party. In most cases these have been published. Table 2 below lists these studies, references publications, and gives summary information. The number of variables and number of seed variables are shown, as is the number of effective seed variables. In general, the effective number of seeds is equal to the least number of seeds assessed by some expert. In this way each expert is scored with a test of the same power. In the Gas panel, the panel and the seed variables were split post hoc into corrosion and environmental panels.

The combined scores of EWDM, performance-based DM, and best expert are compared pairwise in Figure 1. Figure 2 compares the calibration ($p$ values) and information scores of the EWDM, the performance-based DM, and the best expert.

In 15 of 45 cases, the performance-based DM was the best expert, that is, one expert received weight one. In 27 cases, the combined score of the performance-based DM was strictly better than both the EWDM and the best expert. In one case [2], the EWDM performed best, and in two cases [16, 40] the best expert outperformed both equal weights and performance-based weights.

The EWDM is better calibrated than the best expert in 25 of the 45 cases, but in only two cases more informative. In 18 cases the combined score of the EWDM is better than that of the best expert. In 12 of the 45 cases the calibration of the best expert is less than or equal to 0.05; for the EWDM this happened in seven cases (15%).

The study on radiological transport in soil Genest and Zidek [16] was unusual in that all the experts and all DMs performed badly. Both the seed variables and the experts were identified by the National Radiological Protection Board, and reanalysis of the seed variables and expert data did not yield any satisfactory explanation for the poor performance. We concluded that this was simply due to the small number of experts and bad luck.

The motivation for performance-based weighting above equal weighting speaks for itself from this data. Most often the EWDM is slightly less well calibrated and significantly less informative, but sometimes the calibration of the EWDM is quite poor [41, 42]. Finally, we remark that the experts overwhelmingly have supported the idea of performance measurement. This sometimes comes as a surprise for people from the social sciences, but not for natural scientists. The essential point is that the performance measures are objective and fully transparent. It is impossible to tweak these measures for extrascientific expediency.

## 5 SEED VARIABLES, VARIABLES OF INTEREST, AND ROBUSTNESS

A recurring question is the degree to which performance on seed variables predicts performance on the variables of interest. Forecasting techniques always do better on data used to initialize the models than on fresh data. Might that not be the case here as well? Obviously, we have recourse to expert judgment *because* we cannot observe the variables of interest, so this question is likely to be with us for some time. Experts' information scores *can* be computed for the variables of interest and compared with the seed variables (see below). More difficult is the question whether calibration differences

**TABLE 2 Expert Judgment Studies**

| Case | Name/ Reference | Number of Experts | Number of Variables/ Seeds | Number of Effective Seeds | Performance Measure | Performance Weights | Equal Weights | Best Expert |
|---|---|---|---|---|---|---|---|---|

in experts and DMs "persist" outside the set of seed variables. Questions related to this are as follows

1. Are the differences in experts' calibration scores due to chance fluctuations?
2. Is an expert's ability to give informative and well-calibrated assessments persistent in time, dependent on training, seniority, or related to other psychosocial variables?

There has been much published and speculated on these questions, and the issue cannot be reviewed, let alone resolved here. If differences in experts' performance did

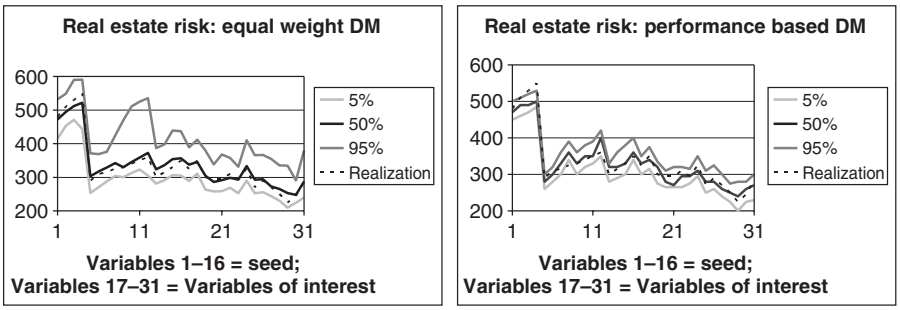

**FIGURE 3** Seed variables and variables of interest, Real Estate Risk.

*not* persist beyond the seed variables, then that would certainly cast a long shadow over performance-based combination. If, on the other hand, there are real and reasonably persistent differences in expert performance, then it is not implausible that a performance-based combination could systematically do "better than average". It is hoped that the TU Delft database can contribute to a further analysis of these issues.

Closely related is the question of robustness: to what extent would the results change if different experts or different seed variables had been used. This last question can be addressed, if not laid to rest, by removing seed variables and experts one at a time and recomputing the DM. We discuss a few studies to illustrate good and poor choices of seed variables and, where possible, compare with variables of interest.

### 5.1 Real Estate Risk

In this study, the seed variables were prime office rent indices for large Dutch cities, published quarterly (variables 1 through 16). The variables of interest were rents of the actual properties managed by the investment firm. After 1 year, the realized rents were retrieved and compared with the predictions. The results for the EWDM and performance DM are shown below.

The robustness analyses in this case are also revealing. First, we examine the five experts' (three portfolio managers and two risk analysts) and DM's scores, and the relative information of each of the experts to the equal weight combination of their distributions (Table 3). This gives a benchmark for how well the experts agree among themselves. The experts' densities are constructed relative to a background measure, so these comparisons also depend on the background measure. The relatively weak calibration performance of the EWDM is due to the fact that only 4 of the 16 seed variables were above the median assessment.[2] At the same time, the equal DM's medians are actually a bit closer to the realizations. Distance between median and realization is an example of a scoring variable, which is *not* taken into account by the performance-based DM.[3] Note also that the pattern of informativeness on seed variables is comparable to that on all variables; portfolio manager 3 is least informative and risk analyst 1 is most informative. Note also that low informativeness does not translate automatically into better calibration.

[2]The values cited in Table 3 are based on 31 seed variables, using also the variables of interest, which became available a year later.

[3]The reason is that distance is scale dependent. In this case, the scales of all variables are the same, so such a scoring variable could be used. Of course, such a rule may not be proper.

**TABLE 3 Real Estate Risk: Relative Information of the Five Experts to the Equal Weight Combination for All Variables and for Variables with Realizations**

| ID | Calibration | Mean Relative Information | | Number of Realization | Unnormalized Weight | Relative Information to Equal Weight DM | |
|---|---|---|---|---|---|---|---|
| | | All Variables | Seed Variables | | | All Variables | Seed Variables |
| Portfol1 | 0.3303 | 0.7932 | 0.8572 | 16 | 0.2832 | 0.5004 | 0.6241 |
| Portfol2 | 0.1473 | 1.02 | 0.9554 | 16 | 0 | 0.7764 | 0.6545 |
| Portfol3 | 0.02012 | 0.2492 | 0.1556 | 16 | 0 | 0.3633 | 0.2931 |
| Riskan1 | 6.06E−05 | 1.334 | 1.536 | 16 | 0 | 0.9575 | 1.21 |
| Riskan2 | 0.004167 | 0.5848 | 0.6126 | 16 | 0 | 0.4579 | 0.4402 |
| Performance DM | 0.3303 | 0.7932 | 0.8572 | 16 | 0.2832 | | |
| Equal DM | 0.05608 | 0.1853 | 0.179 | 16 | 0.01004 | | |

Next we remove the 16 seed variables one at a time and recompute the performance-based DM (Table 4).

The scores do not change much, but the relative information of the "perturbed DM" with respect to the original DM is rather large for eight of the variables, compared to the differences between the experts themselves. The explanation can be found by examining the robustness on experts (Table 5).

If we remove portfolio manager 1, the effect on the DM is large, compared to the largest relative information between a single expert and the equal weight combination. This is not surprising as portfolio manager 1 coincides with the performance-based DM. Interestingly, we get a significant change by removing portfolio manager 2. This is because the combination of portfolio managers 1 and 3 would give a higher score than portfolio manager 1 alone, or 1 and 2 alone. We should have to give portfolio manager 2 weight zero and portfolio manager 3 positive weight, even though the latter's calibration score is worse than that of the former. The proper scoring rule constraint prevents this from happening. This underscores the difference noted in Section 2 between optimization under the proper scoring rule constraint and unconstrained optimization. In the latter case, a better calibrated expert can have less weight than a poorly calibrated expert. The nonrobustness in Table 4 is caused by the fact that the removal of some seed variables cause the calibration of portfolio manager 2 to dip below that of portfolio manager 3.

### 5.2 AEX

In this case, the seed variables *were* the variables of interest, namely the opening price of the Amsterdam stock exchange, as estimated at closing the previous day. Note that some of the experts anticipated a large drop on the day corresponding to variable 20. This was reflected neither in the performance-based DM nor in the realization. Other than that, the pattern across seed variables does not look erratic. In spite of the excellent performance of the experts in this case, they were not able to predict the opening price better than the "historical average predictor". In other words, any information the experts might have had at closing time was already reflected in the closing price.

### 5.3 Dry Deposition

The seed variables were measured deposition velocities, though not configured according to the requirements of the study (per species, windspeed, particle diameter, and surface).

Here again, the poor statistical performance of the EWDM is due to the fact that all but one of the 14 seed variables fall above the median.

### 5.4 Dyke Ring

The seed variables were ratios of predicted versus measured water levels (at different water levels, around 2 m above the baseline). Variables of interest were the same, but at water levels above 3.5 m above the baseline. In this case, we had several realizations of this ratio from each of several measuring stations. This explains the step pattern of the quantiles; these are actually the same assessment with several realizations.

Although all 47 seed variables were used in the analysis, for purposes of comparing expert performance with that of other studies, the effective number of seeds was reduced to 10. This accounts for dependence in the experts' assessments and corresponds to the number most often used for such comparisons.

## 5.5 Space Debris

The seed variables were numbers of tracked space debris particles injected into orbit between the years 1961 and 1986. Variables of interest characterized the debris flux for 10 years into the future. It turned out that the experts did not possess year-by-year knowledge of the debris particles, and gave generic assessments assuming that the number was growing, where in fact the number appears to be quite random. This is a case in which the choice of seed variables was unsuccessful; the experts did not really have relevant knowledge to apply to the task.[4]

## 5.6 Out-of-Sample Validation?

In a review of the online version of this article, Clemen raised the important question: does the performance of the performance-weighted decision maker (PWDM) persist

[4]In this early study, the effective number of seed variables was chosen to optimize the DM's performance, a procedure which is no longer followed. The DOS version of the software used a table of the chi-square distribution and had problems with very low calibration scores. These problems will come to the fore, when the number of seed variables is high, as in this case.

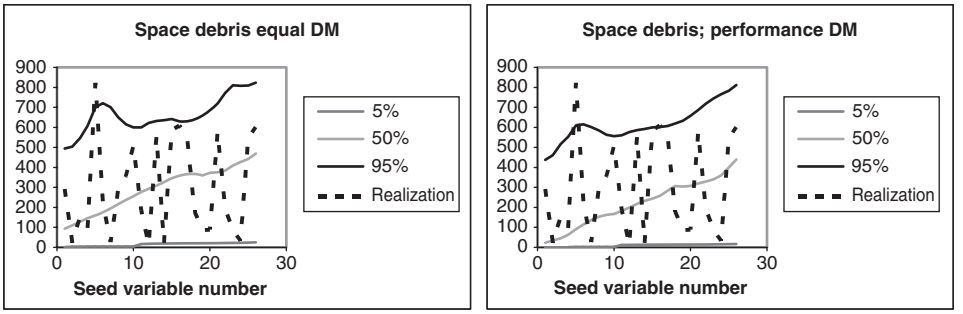

**FIGURE 7** Seed variables Space Debris.

beyond the set of seed variables. Clemen believes that there is no significant difference between the PWDM and the EWDM outside the variables on which PWDM has been constructed.

As noted above, PWDM does use optimization to remove a degree of freedom in the definition of the classical model. In every study, we routinely perform robustness analysis by removing seed variables (and experts) one at a time and recomputing PWDM. It is not uncommon to see the calibration scores of PWDM fluctuating by a factor 2 or 3 on 10 seed variables.

Out-of-sample validation involves basing PWDM on an initial set of seed variables, then using this PWDM on *other* variables and comparing performance of EWDM on these other variables. This corresponds to the way PWDM is actually used. We can do this by splitting the set of seed variables into halves, initializing the model on one half and comparing performance on the other half. Of course, this requires a relatively large number of seed variables. There are 14 studies with at least 16 seed variables. One of these, "TNO dispersion", eluded conversion to the format of the windows software and currently cannot be read. This leaves 13 studies. Dividing the seed variables into half gives two validation runs, using the first half to predict the second and conversely. Note that the variables on which the PWDM is initialized in these two runs are disjoint. The item weight PWDM could not be computed without writing a new code, so the choice of item versus global weights denied PWDM on this exercise.

The data from the 13 studies are shown in Table 6. In 20 of the 26 studies, the out-of-sample PWDM outperforms EWDM. The probability of seeing 20 or more "successes" on 26 trials if PWDM were no better than EWDM is 0.0012.

Clemen reports results on 14 validation studies that are somewhat more pessimistic (9 "success" on 14 trials). His method involves removing seed variables singly, computing PWDM on the remaining seeds, and using this PWDM to predict the eliminated seed. On a study with 10 seed variables, there are thus 10 *different* PWDMs. Each pair of the 10 DMs share eight common seeds. The criteria for selecting the 14 studies are not specified. It is difficult to see how all these factors would affect the results. Perhaps the following reasoning partially explains Clemen's less optimistic result: With a small number of seeds, removing one seed favors experts who assessed *that* seed badly and hurts experts who assessed *that* seed well, thus tilting the PWDM toward a bad assessment of *that* seed. This happens on *every* seed thus cumulating the adverse effect on PWDM. This does not happen when *one* PWDM predicts the entire out-of-sample set of seeds.

Best performer is italicized. E1, the EWDM on the first half of the seed variables; E2, EWDM on the second half; PW(2)1, the PWDM constructed on the second half, predicting the first half; and PW(1)2, the PWDM constructed on the first half predicting the second half.

[a]PintDos involved 55 seed items, and 8 experts, but two experts assessed only a small number of seed variables. The other experts' seed assessments did not wholly overlap; 6 experts assessed 39 common seed variables used for this exercise. Similarly, AOT was restricted to 6 experts who assessed 20 common items. The Gas study was split into a corrosion and an environment panel. Many environment experts were also corrosion experts and their corrosion seed assessments were used in the original study. In this exercise, only the environment seeds were used for the environment panel. In the Dikering study, the multiple measurements from each measuring station were split.

In any case, Clemen's method is not the same as picking *one* PWDM and comparing it on new observations with the EWDM.

## 6 LESSONS LEARNED FROM ELICITATIONS

A detailed description of the design of an expert judgment study is given in Cooke and Goossens [34]. Suffice to say here that a typical study involves a dry run with one expert to finalize the elicitation questions. This is followed by a plenary meeting of all experts in which the issues are discussed, the study design is explained, and a short elicitation exercise is done. This involves a small number of seed variables, typically five. Experts are shown how the scoring and combining works. Afterwards, the experts are elicited individually. An elicitation session should not exceed a half day. Fatigue sets in after 2 h.

When experts are dispersed it may be difficult and expensive to bring them together. In such cases the training is given to each expert in abbreviated form. The EU-USNRC studies made the most intensive investment in training. In general, it is not advisable to configure the exercise such that the presence of *all* experts at one time and place is essential to the study, as this makes the study vulnerable to last minute disruptions.

The following are some practical guidelines for responding to typical comments:

**From an expert:** *I don't know that*

Response: *No one knows, if someone knew we would not need to do an expert judgment exercise. We are tying to capture your uncertainty about this variable. If you are very uncertain, then you should choose very wide confidence bounds*.

**From an expert:** *I can't assess that unless you give me more information*.

Response: *The information given corresponds with the assumptions of the study. We are trying to get your uncertainty conditional on the assumptions of the study. If you prefer to think of uncertainty conditional on other factors, then you must try to unconditionalize and fold the uncertainty over these other factors into your assessment*.

**From an expert:** *I am not the best expert for that*.

Response: *We don't know who are the best experts. Sometimes the people with the most detailed knowledge are not the best at quantifying their uncertainty*.

**From an expert:** *Does that answer look OK?*

Response: *You are the expert, not me*.

**From the problem owner:** *So you are going to score these experts like school children?*

Response: *If this is not a serious matter for you, then forget it. If it is serious, then we must take the quantification of uncertainty seriously. Without scoring we can never validate our experts or the combination of their assessments*.

**From the problem owner:** *The experts will never stand for it*.

Response *We've done it many times, the experts actually like it*.

**From the problem owner:** *Expert number 4 gave crazy assessments, who was that guy?*

Response: *You are paying for the study, you own the data, and if you really want to know I will tell you. But you don't need to know, and knowing will not make things easier for you. Reflect first whether you really want to know this*.

**From the problem owner:** *How can I give an expert weight zero?*

Response: *Zero weight does not mean zero value. It simply means that this expert's knowledge was already contributed by other experts and adding this expert would only*

*add a bit of noise. The value of unweighted experts is seen in the robustness of our answers against loss of experts. Everyone understands this when it is properly explained.*

**From the problem owner:** *How can I give weight one to a single expert?*

Response: *By giving all the others weight zero, see previous response.*

**From the problem owner:** *I prefer to use the equal weight combination.*

Response: *So long as the calibration of the equal weight combination is acceptable, there is no scientific objection to doing this. Our job as analyst is to indicate the best combination, according to the performance criteria, and to say what other combinations are scientifically acceptable.*

## 7 CONCLUSION

Given the body of experience with structured expert judgment, the scientific approach to uncertainty quantification is well established. This does not mean that the discussion on expert judgment method is closed.

First of all, we may note that a full expert judgment study is not cheap. Most of the studies mentioned above involved 1–3 man months. This cost could be reduced somewhat if we need not develop seed variables. However, simply using equal weights does not seem to be a convincing alternative. Other methods of measuring and verifying performance would be welcome, especially if they are less resource intensive.

The classical model is based on the two performance measures, calibration and information, in conjunction with the theory of proper scoring rules. It satisfies necessary conditions for rational consensus, but is not *derived* from those conditions. Other weighting schemes could surely be devised which do as well or better in this regard, and other performance measures could be proposed and explored.

Once we acknowledge that our models must be quantified with uncertainty distributions, rather than "nominal values" of undetermined pedigree, many new challenges confront modelers, analysts, and DMs.

Experts can quantify their uncertainty about potentially observable phenomena with which they have some familiarity. The requirements of the study at hand may go beyond that. For example, in quantifying the uncertainty of models for transport of radiation through soils, plants, and animals, it emerged that the institutes that built and maintained these models could not supply any experts who were able to quantify uncertainty on the transfer coefficients in these models. Experts could quantify uncertainty with regard to quantities, which can be expressed as functions of the transport models themselves. Processing data of this sort required development of sophisticated techniques of probabilistic inversion [43, 21].

Perhaps, the greatest outstanding problems concern the elicitation of, representation of, and computation with dependence. Everyone knows that the ubiquitous assumption of independence in uncertainty analysis is usually wrong, and sometimes seriously wrong. This is a subject that must receive more attention in the future [37].

## ACKNOWLEDGMENT

The authors gratefully acknowledge the contributions of many people who cooperated in developing this database. Willy Aspinall and Tim Bedford are independently responsible

for a quarter of the studies. This article is based on an article for a special issue, *Reliability Engineering and System Safety*, on expert judgment (doi:10.1016/j.ress.2007.03.001, available online 15 March 2007), which published reviewer comments. The present article incorporates part of the discussion with Clemen on out-of-sample validation.

# SECURITY AND SAFETY SYNERGY

NICKLAS DAHLSTRÖM AND SIDNEY DEKKER
*Lund University School of Aviation, Ljungbyhed, Sweden*

## 1 INTRODUCTION

Security and safety are concepts that share important features; they both involve the risk of occurrence of events with consequences that may range from trivial to disastrous. Yet as concepts they are also different, with security relating to intentional acts by individuals and safety relating to events caused by unintended consequences of a combination of a host of factors. In safety-critical industries, such as aviation and maritime transport, chemical and nuclear industry, and health care, safety is seen as the positive outcome of management of problems and trade-offs that are rooted in systems' complexity, goal interaction, and resource limitations. This perspective has led safety research to shift focus and go beyond individual acts (such as "human error") and move to systematic aspects of human, technological, and organizational performance [1]. It involves dealing with problems connected to regulations and standardized procedures, technology and automation, and efforts to understand the impact of communication, group dynamics, leadership, and culture on safety. The advancement of security issues in a complex modern society should be able to benefit from the knowledge gained through safety

industry operations in the field of Human Factors. This knowledge has the potential to make security more safe (for those who design and implement security measures as well as for those who are subjected to them) and effective (in terms of time and resources spent on security measures).

Organizations do not exist just to be secure or safe. They exist to produce or provide goods or services. Customers care about the goods or service—that is why they engage with the organization in the first place (Even where security actually is the goal of an organization it is provided as a complement to another product or activity—protection of property, transportation, etc.). This means that an understanding of the fundamental conditions for security and safety begins with an understanding of the balance between production and protection. Humans normally strive for an acceptable (rather than ideal) level of performance in relation to their goals and resources [2] and to not process all available data is a part of this resource-saving strategy [3]. Consequently, action is guided by an intuitive and implicit trade-off between cost and efficiency [4] or between thoroughness and efficiency [5]. However, this introduces the risk of overlooking possible consequences of these trade-offs, particularly long-term consequences [6]. From investigations of aviation accidents the systematic trade-offs in favor of efficiency/production versus safety/protection have been labeled as "drift" toward accidents [7]. The model of drift has been an important tool for increased understanding of accidents in the otherwise impressively safe global transportation system of aviation. Drift should also be a useful concept for understanding of failure of security systems. In the 24 months leading up to 9/11, there were 30 cases of passengers breaking through cockpit-doors [8]. This type of event may at the time have been recognized as an acceptable risk.

## 2 THE PRESENT SITUATION FOR SECURITY

Today, the situation is quite different. The pressure to respond quickly and decisively to perceived security threats can produce immense consequences—from severe disruption to significant financial loss. A recent example of this is the consequences of the events in the United Kingdom in September, 2006:

> "In the wake of the plot to smuggle liquids on board aircraft, mix them and use them as explosives the increased security measures during the following nine days meant that British Airway had to cancel about thousand flights resulting in estimated losses of 50 million pounds [9]."

In aviation, security is generally seen as an operational activity parallel and independent to safety. However, it is not unusual that security even by crews is seen as an intrusion (when performed by security staff) or as unwanted and unnecessary (when performed by crews themselves). There are even examples of how security and safety may conflict. The most prominent example, of course, is the locked cockpit door. The extra barrier can delay or interfere with cross-crew coordination, which has been identified previously as contributory to accidents [10]. A locked door can be especially problematic in case of escalating situations (disruptive passengers, or technical problems) where the threshold for coordinating may now have become higher. In a report by Nilsson and Roberg [11], crew members were unanimously negative in their view of the locked door. A manifestation of this problem occurred on an Air Canada Jazz flight in 2006. As a

captain returned from using the washroom in the cabin he could not get back into the cockpit. It was not possible to open the door:

> "For roughly 10 minutes, passengers described seeing the pilot bang on the door and communicating with the cockpit through an internal telephone, but being unable to open the cabin door. Eventually, the crew forced the door open by taking the door off its hinges completely, and the pilot safely landed the plane [12]."

The article also stated that "being locked out of the cockpit is a 'nonreportable' incident, there is no way of confirming their frequency as the airlines are under no obligation to report them". Beyond the entertaining qualities of this story, it raises questions regarding the parallel pursuit and of security and safety and their interaction.

## 3 EVOLUTION OF SAFETY, REVOLUTION OF SECURITY

Aviation safety has evolved, slowly but surely, over many decades. Technological, organizational, and regulatory developments, as well as greater insights into human and team performance, have all contributed to the steady "fly-fix-fly" improvement of aviation safety. Aircraft accidents have become a part of contemporary mythology—crowning heroes, identifying culprits and providing horror stories. All of this experienced and recounted by passengers to the rest of us; potential passengers who could have or may come to be caught up in similar events. There is not any abundance of similar stories and certainly not any similar mythology when it comes to aviation security. Although there certainly are hero stories (as that of the passengers of flight United 93), clear identification of culprits (as in cases of hijackings and bombings), and horrors to be shared also in this area the occurrence of such events have simply not been as frequent as safety-related accidents. Of course frequency alone explains little, but the abundance of safety-related accidents has produced numerous articles, books, documentaries, and movies that have helped to increase public awareness on safety issues. Such stories have also been successfully used in the training of airline crews in human limitations, communication, cooperation, and leadership for increased safety (Crew Resource Management (CRM) training). Security demands, in contrast to the gradual development of safety measures, have exploded dramatically over the past few years. This sudden tightening and acceleration could compromise the claim that security provides an essential service to society. See, as an example, this comment on the response after 9/11:

> "Confiscating nail files and tweezers from passengers seems like a good idea all around: The airlines don't mind because it doesn't cost them anything, and the government doesn't mind because it looks like it's doing something. The passengers haven't been invited to comment, although most seasoned travelers simply roll their eyes [13]."

Security measures can appear quite haphazard, arbitrary—capricious even—to passengers or crews or other people subjected to them. Computers that have to be taken out of bags at some airports but not at others. Elderly ladies must give up their knitting ware before entering an aircraft while other passengers do not need to give up elegant and equally sharp pens. "Incendiary material" may not be brought onto an aircraft but alcohol (to drink or to smell better) is accepted and even sold onboard. Every piece of such failing logic will gradually or quickly erode the willingness of those who are supposed

to be felt protected, to see themselves as participants guaranteeing their own security. Although the pictures from 9/11 will be remembered and should seem to provide more than enough of modern mythology the patience of passengers and willingness to accept current security measures is probably not endless. This is one perspective on the current status of security:

> It's been four years since the terrorist attacks of Sept 11, 2001, and backups at airport security checkpoint lines are growing, the army of federal airport screeners is still getting low performance marks and uncertainty dogs the contents of airline cargo holds. While the federal government has been spending about $4 billion a year on aviation security since hijackers transformed four jetliners into devastating weapons, critics say there aren't enough results to show for all that taxpayer money [14].

### 3.1 Production Pressures in Providing Security

As potential goodwill in regard to security might abate, there is a risk that mounting production pressures dictate the operational conditions for security operations. The effects of such production pressures have been seen in a vast number of aviation safety incidents and accidents and they are likely to have an influence also on security. A study of airport screening rather unsurprisingly found that "the longer passengers had to wait, the longer they were to be unsatisfied" and concluded that "There is little question that the effectiveness and efficiency of security screening is a key feature affecting passenger satisfaction" [15]. To reduce this problem computer-assisted passenger prescreening systems have been introduced and these "confirms passengers' identities, performs criminal and credit checks, and retrieves additional information, such as residence, home-ownership, income, and patterns of travel and purchases, used to construct a predicted threat rating" [16]. With the currently fierce competition in the aviation industry—between airlines (increased by the arrival of low-cost carriers), between airlines and business jets, and from high-speed trains (in many parts of Europe)—many security measures will be under pressure to adapt to the demands of "effectiveness and efficiency" from a short-term business perspective rather than to what passengers perceive as illogic and irrelevant threats stemming from vague and remote risks of criminal acts and terrorism.

A new segment of the aviation industry is partly based on the consequences of current security measures. An important reason for the emergence and anticipated success of a new type of small business jet aircraft (Very Light Jets, VLJs) is that the time demanded by security measures for scheduled flight at major airports is unacceptable for upper and middle management [17]. By operating or renting their own aircraft, flying direct and using small airports some of the time spent on security can be avoided or reduced for companies. The same reason has fueled a "remarkable upturn in business aviation" in Europe in recent years [17]. The experience from aviation safety is that this and other types of pressures on operations affect all organizational levels and induce risks of organizational drift toward future system failures.

To further understand the current relationship that passengers (or the public in general) have to security (as well as to safety) in aviation we can use two concepts from economic theory. The first is that of "externalities", that is a cost or benefit imposed on people other than those who purchase a good or service [18, 19]. Passengers buy a ticket to fly from A to B and expect this to be a secure and safe means of transportation (For the airline industry to imply anything else would be to discourage a substantial number of passengers.). Since security and safety are expected from this product and criminal

acts with severe consequences or accidents are rare (and this is stressed by the industry), consumers will see increased prices or procedural complications for flying as a negative externality. Of course, they do understand the need for baggage-screening and de-icing, but in day-to-day travel the meaning of these procedures often seems lost, as noted on consumer behavior "the tendency to trade-off costs and benefits in ways that damage their future utility in favor of immediate gratification" [20]. The paradox is that for the airline industry it is of great importance to be secure and safe to a level where passengers do not even consider potential threats when they make their decision to travel. As this level is achieved, however, passenger tolerance for increased costs and inconveniences to further reduce threats is declining. This explains the fundamental difficulties that everyone (security managers, pilots, cabin crew, screeners, etc.) involved in working with security encounters in day-to-day operations when trying to maintain the balance between production demands and the protection provided by the security system.

The tendencies described by the theory of externalities can be further reinforced by the theory of "lemons" [21]. This describes how interaction between quality differences and asymmetrical information can cause a market where guarantees are unclear to disappear. When quality is indistinguishable beforehand to the buyer (due to the asymmetry of information) incentives exist for the seller to pass off a low-quality good as a higher-quality one. Since the nonoccurrence of adverse security and safety cannot be guaranteed, the quality of security and safety operations is known to very few (and in the case of security we do want to keep this a secret) there is no incentive for any consumer of airline transport services to select airport or airline based on if they are more secure or safe than other. This explains the pressure put on the security and safety operations as it is unlikely that they ever will be able to provide evidence of the value they bring to the consumer [22].

## 4 EXPERIENCES FROM AVIATION HUMAN FACTORS OF RELEVANCE FOR SECURITY

### 4.1 Relation to Regulation, Standardization, and Procedures

Economic theories of human behavior provide us with some understanding of its potential problems with regards to security and safety. A seemingly reasonable response would then be to try to control human behavior. This means using laws, regulations, standardized procedures, manuals, guidelines, and other similar means to increase the reliability of human behavior and limit the risk it may induce in systems. Aviation has a long tradition of negotiating global regulatory frameworks that can ensure a high minimum level of safety [23]. Manufacturing and maintenance of aircraft, medical and other requirements for staff (pilots, cabin crew, air traffic controllers, etc.) selection and training as well as practically all operational aspects are guided by extensive regulation and enforced by aviation authorities. The regulations stipulate that all operators also should have standard operational procedures (SOPs) for all aspects of operation. In aviation these procedures are regarded by crews as the main source of safety and regulations demand that they are regularly practiced to a satisfactory standard in simulators, mock-ups, or classroom teaching.

Many think that regulation, standardization, and proceduralization are the main guarantors of aviation safety. Even though this might be historically true, the situation has always been more complex. While these efforts promote predictable organizational and

individual behavior and increase reliability they do not promote the flexibility to solve problems encountered in present complex sociotechnical systems [24]. Also, a blind adherence to regulations and procedures neglects the fact that much work has to be done in addition to, beyond or contrary to prescribed procedures [24]. A procedure is never the work itself, it cannot be that human intervention is always necessary to bridge the gap from written guidance to actual application in context. Note how the "work-to-rule" strike is not uncommon as a form of industrial action in aviation. Yet the commitment to rules and procedures is generally strong in aviation (although there are weaknesses in this commitment in some parts of the world). However, there are signs that further increase of aviation safety may need other methods than those used to achieve current levels of safety [25]. Most potential system failures in aviation have been anticipated and addressed by technical protection and procedural responses. But ill-defined, unexpected, and escalating situations have proved to be far more difficult to manage successfully and have resulted with tragic outcomes. An example of this is the in-flight fire on Swissair 111 [26], where the flight crew tried to follow procedures until the situation was entirely out of control. This accident showed that an overfocus on procedures and lack of training of general competencies needed in an emergency may conspire to turn a difficult situation to an unmanageable one.

When putting security systems together, training staff to achieve increased standardization and procedural adherence may be an intuitive and relevant first step. But further consideration is necessary. A profound understanding of human performance issues (including topics such as perception, decision making, communication, cooperation, and leadership) should be helpful to security staff for increasing the overall effectiveness of security operations. Such training should go beyond operational and procedural aspects, instead providing security staff with an increased awareness of the individual, group, and system limitations that may induce weaknesses in the security system. This training should be recurrent and closely integrated with other training as well as with an effective operational reporting system (see below).

### 4.2 Relation to Technology and Automation

As has been, and still is, the case for aviation safety, security seems to be driven by a reliance on technology to solve problems and increase efficiency (increased use of advanced identity cards, biometrics, surveillance cameras, sensors, background checks, data mining and for aviation specifically refined screening techniques, computer aided vetting of passengers, etc.). Focusing on technology is a prominent feature in the modern history of aviation safety [27]. The experiences of this development can provide some helpful guidance for security. Two important phases will be used as examples of the problems involved in the relation between aviation safety and technology.

The first great technological step of improving the safety of modern air transportation depended upon increased understanding of the physical stresses on aircraft frames as well as of fundamental physiological and psychological processes affecting pilots. As aviation entered the jet-age, safety increased due to the superior performance and reliability of jet engines compared to piston-engines. To be able to fly faster and higher than before did, however, have unforeseen consequences and in-flight break-up of aircraft (such as the Comet accidents in the 1950s) put the focus on the risks of structural failure. This focus on fundamental engineering and manufacturing issues corrected previous design flaws for coming generations of aircraft. Another accident type was that connected to

approaching an airport in darkness. This induces the risk of the so-called black-hole illusion, where the airport is perceived as being lower than it actually is. Accidents of this type were frequent until there was a push for instrument landing systems on more airports, improved instrument design, and more warning systems, which reduced the risk of this type of accident. Also, the opportunities for effective flight simulation provided by the technological development meant that this type of approach and landing could be practiced effectively. In both cases, the measures taken were relevant and had positive effects on aviation safety. However, aircraft accidents were steadily occurring even after these measures had been implemented. These accidents involved failures of communication, cooperation, and leadership problems, such as the United 173 accident at Portland airport or the Air Florida 90 accident at Potomac Bridge where the captain's decisions were accepted by other crew members in spite of their awareness of the risks involved. The existence of these types of problems was well known to the industry but previously obscured by the search for technological solutions. They did, however, become addressed through increased focus on Human Factors and the implementation of CRM-training in the industry.

In the 1980s, the arrival of modern computer technology in large transport aircraft was supposed to solve safety problems and reduce costs. New aircraft were equipped with computerized Flight Management Systems (FMS) which were supposed to not only reduce the workload of the pilots, but also monitor their actions and prevent actions that would risk the safety of the aircraft. The most important learning point to come out of the technological revolution in the cockpit was that changing the conditions for work always may solve some known safety problems but it will always create new ones [28]. Although the introduction of the new technology was a part of an overall trend toward greater safety it was also involved in a number of incidents and accidents where a mismatch between the human operator and the automation was the primary cause [29]. This included accidents with mode confusion (such as China Airlines at Nagoya and Air Inter at Strasbourg), programming errors of the FMS (Boeing 757 accident at Cali, Colombia), and aircraft upset (conflicting aircraft and operator control of the aircraft, such as the JAS Gripen accident in Stockholm). Again, the focus on technological solutions obscured the essential focus on its effects on the role of the human operator. There is a lesson here. As pressure mounts to make security more cost effective, time effective, and less inconvenient, the history of aviation automation may serve as a reminder that new technology alone is seldom the solution.

### 4.3 Human Performance, Communication, Cooperation and Leadership-Training and Reporting

An area where aviation safety has made significant progress is in training their operators in understanding potential safety risks associated with human performance, communication, coordination breakdowns, and leadership. Such training has been facilitated by the availability of well-investigated cases of aviation accidents. Gradually this type of training has gained increased recognition, both within aviation as well as in other safety-critical industries. The mandatory and recurrent training of Human Factors–related knowledge and skills is today a hallmark of the aviation industry and has become a model for similar training in maritime transportation, nuclear and chemical industry as well as health care.

The emergence of the concept of Cockpit Resource Management in the late 1970s was precipitated by a number of disastrous accidents (e.g. the most disastrous of them

all, where 583 persons became victims as two aircraft collided on the runway on the island of Tenerife). This became the start of a systematic approach to train crews to understand aspects of human performance, communication, cooperation, and leadership of importance to aviation safety. Later, the concept was renamed CRM, to involve also the cabin crew (This too was precipitated by accidents, such as the Kegworth accident, where information from cabin crew on visible effects of engine problems did not make it into the cockpit to augment the pilot's knowledge of the situation.). Analogously, engineering and technical staff have developed the concept of Maintenance Resource Management (MRM). In many countries, annual recurrent CRM courses are mandatory for maintaining active status for an airline pilot's license. Currently, there are ongoing discussions as to if CRM should be made available or even mandatory also for other categories of staff involved in operations, such as schedulers, coordinators, and management. The initials CRM would then stand for Company Resource Management.

Gradually, the focus of CRM-training has been turned to prevention and management of human error, based on the same content as previously but more explicitly framed around understanding error. This has included teaching of various accident models. Although the success of CRM is difficult to quantify in terms of fewer accidents or incidents or in any other measurable terms of increased safety or economic gain, the great interest from other industries (maritime transport, nuclear, chemical, and health care) in the concept seem to confirm its appeal.

One of the lesser discussed benefits of CRM-training is that it widens the understanding of human performance and, as a consequence, the willingness to report events and incidents. To create an overall effective system for safety (or security), it is important to first create an organization that is curious regarding error rather than one where punishment expected and thus reporting is avoided. Curiosity is a sign of willingness to learn why a certain event occurred and a starting point for learning for the whole organization. In aviation, it is not uncommon that crews report their own errors even though there would have been no way to detect that an error had been committed; since there is no good reason that other crews should have to experience the same error. The benefits of this type of reporting and of CRM-training are not easy to quantify and might be more convincingly argued in connection to examples from operations. In the period of 1997 to 2001 one of the four terminals at Sky Harbor airport in Phoenix, Arizona, had 125 security lapses [30]. The Transportation Security Administration (TSA) screener workforce alone consists of 45,000 employees at 448 airports [31]. From aviation safety we would conclude that this type of events will not disappear. But by complementing increasingly effective technological solutions with equally effective training and reporting there will be less of them.

Recurrent training of both security and safety (first aid, evacuation, fire-fighting, CRM) is mandatory for airline crews. These training events not only reinforce practical skills but also serve as important reminders of the threats and risks surrounding airline operations. It also gives crews the opportunity to discuss recent security- or safety-related events and come up with solutions to operational problems. If carried out according to its intentions, recurrent security, and safety, training strengthens organizational values and attitudes regarding their areas. Security staff could also benefit from systematic recurrent training of CRM-type, focused less on strict operation of technological equipment and more on Human Factors aspects of work.

### 4.4 Models and Culture

Beyond the training of individual operators, research efforts to understand (and increase) safety have focused on formulation of models that can explain how accidents occur and how they can be prevented. Traditional models have relied heavily on statistical analysis and vast representations of actions in search of a "root cause" for an accident. Also, they commonly rely on "folk models", that is general explanatory labels that only rename a phenomenon and do not actually provide any deeper analysis [32]. In recent times, highly influential models have focused more on "soft" organizational factors such as the norms and cultures in organizations and the effect of the balance between production and protection and how it is played out interactively between levels of an organization.

In the last decade, the concept of "culture" has received increased attention in safety research. People now refer to the lack of a sound "safety culture" as a reason for incidents and accidents. The focus on safety culture was preceded by attention in managerial literature on "organizational culture" or "company culture" [33]. From this the concept safety culture emerged and has been embraced in many industries. A safety culture is characterized as an "informed culture", that is the organization collects and analyses safety-related data to keep it informed on the safety status of the organization [34]. In particular, the following aspects of a safety culture are highlighted:

- *Reporting* — is considered of fundamental importance in the organization.
- *Just* — unintentional acts are not punished which creates trust to report.
- *Flexible* — ability to adapt to new information and changing circumstances.
- *Learning* — ability to extract learning from safety-related information.

There does not seem to be an equivalently researched and accepted "security culture", although this probably should be a term as relevant as it has proved to be for safety. Certainly, the concept seem to be implicitly present, as indicated by this statement: "because enhancing security depends on changing the beliefs, attitudes, and behavior of individuals and groups, it follows that social psychology can help organizations understand the best way to work with people to achieve this goal" [35].

Learning is, however, a dialectical aspect of culture. In the balance between production and protection the learning from day-to-day operations may easily be the contrary of that implied by Murphy's Law, that is, that things that can go wrong usually do. Actually, in normal operations things that can go wrong do not and there is a risk of learning the wrong lesson from this. Operators might interpret incidents as proof of safety and that it is ok to "borrow from safety" to increase production output. Production pressure on performance of "normal work" gradually effect standards and norms of this work in favor of production. This is the risk described by the model of "organizational drift" toward failure for complex sociotechnical systems. In security, drift of normal practice may create opportunities for those who deliberately want to cause harm to people and property.

Aspects of safety culture are present also in research on high reliability organizations (HROs) such as aircraft carriers and air traffic control [36]. One of the conclusions of this research is that stories that organizations tell about their own operations reveal something about their attitude and ability to learn from incidents. In HROs, incidents are seen as signs of weaknesses in the system and they are used by the organization to extract information about how to become safer. In other organizations incidents may be taken as evidence of the strength of the safety system and lead to the conclusion

that nothing needs to be changed. From this it could be claimed that something that is needed for security operations, particularly for training, is "good stories", both about the failure and success of its operations. While aviation safety has been able to use cases from well-investigated and publicly presented accidents, this is not the case for security.

There are a number of models and research results regarding safety culture and HROs that should be fruitful for security operations. The similarities of the conditions and performance of security and safety operations mean that learning from each other should be mutually beneficial. Both represent operations where seemingly everything is done to prevent adverse events, where adverse events are extremely rare (and potentially disastrous). Also, for both the operators have to maintain a high level of skills, knowledge, and awareness to keep day-to-day operation secure and safe as well as readiness to manage unusual and unpredicted events. The potential for systematic and recurrent Human Factors training for security as well as for joint security and safety training for staff from both types of operations should be explored.

## 5 CONCLUSION

Security and safety share fundamentally important features as operational activities with the goal to protect people, property, and the smooth economical functioning of organizations and society. Safety has been a focus of operations where risks have been overwhelmingly obvious since their inception (e.g. aviation, chemical, and nuclear industry) and demands on the safety of these operations have gradually increased. The demand for increased security has escalated recently and comprehensive development of it as a field of operations, beyond potential technological progress, is needed.

In spite of distinct differences in the nature of threats (intentional/unintentional), there are many areas (use of standardized procedures, human factors training, modeling for increased understanding of adverse events) where knowledge and experiences from safety operations can fruitfully spill over to security. To establish cooperation between these two fields, for example on regulatory and procedural development, training and simulation, as well as operational evaluation, would be to produce synergies not yet known today.

## 1 INTRODUCTION

The critical infrastructure protection decision support system (CIPDSS) is a Department of Homeland Security (DHS) risk assessment tool and analysis process that (i) simultaneously represents all 17 critical infrastructures and key resources [1] in a single integrated framework and (ii) includes a decision-aiding procedure that combines multiple, nationally important objectives into a single measure of merit so that alternatives can be easily compared over a range of threat or incident likelihoods. At the core of this capability is a set of computer models, supporting software, analysis processes, and decision support tools that inform decision makers who make difficult choices between alternative mitigation measures and operational tactics or who allocate limited resources to protect

the United States' critical infrastructures against currently existing threats and against potential future threats. CIPDSS incorporates a fully integrated risk assessment process, explicitly accounting for uncertainties in threats, vulnerabilities, and the consequences of terrorist acts and natural disasters. Unlike most other risk assessment tools, CIPDSS goes beyond the calculation of first-order consequences in one or just a few infrastructures and instead models the primary interdependencies that link the 17 critical infrastructures and key resources together, calculating the impacts that cascade into these interdependent infrastructures and the national economy.

## 2 BACKGROUND

Choices made and actions taken to protect critical infrastructures must be based on a thorough assessment of risks and appropriately account for the likelihood of threat, vulnerabilities, and uncertain consequences associated with terrorist activities, natural disasters, and accidents. Initiated as a proof-of-concept in August 2003, the CIPDSS project has conducted analysis on disruption of telecommunications services, a smallpox outbreak and an influenza pandemic, and the accidental release of a toxic industrial chemical. Partial capability does exist to support analysis of physical disruption; cyber, insider, radiological or nuclear threats; and natural disaster scenarios.

### 2.1 Decision Support System and Infrastructure Risk

The project was developed in a system dynamics language (Vensim) to facilitate rapid development of capability. This decision support system is designed to address various infrastructure- and risk-related questions, such as these example questions:

- What are the consequences of attacks on infrastructure in terms of national security, economic impact, public health, and conduct of government—including the consequences that propagate to other infrastructures?
- Are there critical points in the infrastructures (i.e. areas where one or two attacks could have extensive cascading consequences)? What and where are these points?
- What are the highest risk areas from a perspective incorporating consequence, vulnerability, and threat?
- What investment strategies can the United States make that will have the most impact in reducing overall risk?

### 2.2 Two Modeling Scales: National and Metropolitan

The system has been designed to operate at two distinct scales of modeling: the national scale and the metropolitan scale. The national model represents the critical infrastructures at the national level, with resolution at a state level. The metropolitan (metro) model is intended to represent the functions of critical infrastructures at the local level, in urban landscapes with a population of 500,000 or more.

Within these two modeling scales, many questions of critical infrastructure disruption can be addressed within a risk-informed framework. In general, both the models calculate the consequences of a disruption both within the affected sector and in related sectors linked by primary interdependencies. For example, a disruption in telecommunications could have an effect on banking and finance and even on traffic. Consequences are

computed in the broad metric categories of human health and safety, environmental effects, economic costs, public confidence, and national security.

### 2.3 Decision Model

Unique to CIPDSS is the coupling of the vulnerability and consequence simulation models with a decision model. This tool translates simulated fatalities, illnesses and injuries, economic costs, lost public confidence, and national security impacts into a single measure of merit for each mitigation measure, operational tactic, or policy option considered by a decision maker in a decision problem. Preferred options are plotted against threat or incident likelihood. As new intelligence information becomes available and as the view of the intelligence community evolves with respect to the near- and long-term capabilities and intentions of US adversaries, a preferred course of action that minimizes overall risk can be easily selected from a growing set of threat case studies.

## 3 INFRASTRUCTURE MODELS

Each infrastructure sector is represented by a model of the system that is captured in a system dynamics representation. Table 1 lists the critical infrastructures modeled in CIPDSS. The most common model form is a limited-capacity, resource-constrained model as shown in Figure 1. In this generic representation, the model is shown as a network of nodes, for example, variables that are linked by directed edges, or influences. The connection of variable A via a directed edge to variable B indicates that the value of A is used to calculate the value of B. This abstract relationship indicator hides the actual mathematical relationships, but serves as a graphical description of the workings of the model without delving into specifics. Nonetheless, it is the mathematical description,

for example, a system of coupled ordinary differential equations, embedded in the syntax of the Vensim model that defines the actual model.

A key aspect of the CIPDSS infrastructure models is the capturing of the primary interdependencies between infrastructures. In Figure 1, the dependencies are generically represented in the local availability of resources and materials and implicitly in the production operations. These functional dependencies are clearly called out in the infrastructure models. For example, the operation of telecommunication facilities depends on the supply of electrical power. Short durations of electrical power outages can be tolerated by the use of backup power generators. However, extended electrical power outages cause failure of selected equipment, which affects total communication capacity. The reduction in capacity may be compensated by other equipment with excess capacity (system resilience) or it may affect total throughput of calls. Because CIPDSS has a high level of representation of operations, not all dependencies are modeled, just the primary dependencies. Also, to maintain a consistent model resolution level, the effect of the dependency is modeled rather than the detailed interactions.

Each critical infrastructure sector is divided into a number of subsectors, which have a more uniform character and for which one or more separate Vensim subsector models are developed. For example, the emergency services sector is divided into (i) fire services, (ii) emergency medical services, (iii) law enforcement, and (iv) emergency support services. A Java-based program, the Conductor [2], is used to merge multiple system dynamics models, link variables that cross source code boundaries, and assemble a unified multisector model from individual sector model files. The Conductor identifies variables present in models with references to other source code files and resolves the references when the models are combined. As such, the program allows the models to be developed and tested at a modular level, but it enables simulation runs at the multisector level. The ability to develop modularly has allowed multiple developers from three geographically separated sites to codevelop the models.

### 3.1 Other Supporting Models to Represent Disruption Effects

Models of the infrastructure sectors and subsectors are in themselves insufficient to represent the full suite of effects and artifacts of a disruption. Since the output metrics of interest are human health and safety, a population model is used to account for those people injured by the disruption event compared with the natural processes of illness, injury, and death. Straightforward accounting of population groups in terms of birth/death processes and recovery from health impairment provide a basis for consequence modeling. To model the effect of scenario consequences on subcategories of the population, particularly workers in the critical infrastructures, the model uses occupation data from the US Bureau of labor statistics to estimate the initial size of the group. Because the scenario time frame that is modeled is usually on the order of a year or less, these models do not cover all of the dynamics that could arise in a disruption, for example, product substitution, restructuring of industry or practices, or evolutionary transformations that take years to manifest.

Economic modeling [3] assesses initial sector impacts from the incident in the individual sectors with interdependencies modeled to produce possible secondary effects. Most sectors compute revenue losses and other losses from clean-up, repairs, rebuilding, and so on. Other sectors, such as the energy subsectors, contain further information to give baseline revenue values with or without an incident. All of the metrics are passed into the economic sector model for further computation. Estimation of impacts to the rest of the economy is based on the North American Industry Classification System (NAICS) supersectors. Value-added, a measure of productivity in an industry is more conservative than lost sales or revenues since lost sales are often only temporary and can be recovered within a short period of time after an incident. Lost value-added tends to be permanent over short periods of time and is, therefore, a more accurate measure of the economic losses from temporary disruptions.

### 3.2 Scenario Models

While the infrastructure models exist as a body of interacting systems, the modeling of a disruption to one or more infrastructures often requires that specific code is developed to initiate a disruption event and stimulate the infrastructure models to render specific effects required by the disruption scenario. The models that accomplish these effects are called *scenario models*. Scenario models for biological threats, chemical threats, and telecommunications disruptions have been developed and form a robust basis for other threat scenarios listed in Table 2. For a given study, if an appropriate scenario model does not exist, it must be developed or adapted from a previously developed scenario model.

### 3.3 Consequence Models

Consequence models simulate the dynamics of individual infrastructures and couple separate infrastructures with each other according to their interdependencies. For example, repairing damage to the electric power grid in a city requires transportation to repair sites and delivery of parts, fuel for repair vehicles, telecommunications for problem diagnosis and coordination of repairs, and availability of labor. The repair itself involves diagnosis, ordering parts, dispatching crews, and performing repairs. The electric power grid responds to the initial damage and to the completion of repairs with changes in its operating capacity (the number of megawatts that can be distributed to customers). Dynamic processes like these are represented in the CIPDSS infrastructure

sector simulations by differential equations, discrete events, and codified rules of operation, as appropriate for the sector being modeled.

### 3.4 Decision Support

The CIPDSS team has conducted an ongoing series of formal and informal interviews of critical infrastructure protection decision makers and stakeholders to identify requirements for the decision support system, scope out the decision environment, and quantify the prioritization of consequences. The taxonomy of decision metrics derived from this research involves six categories: (i) sector specific, (ii) human health and safety—public and occupational fatalities, nonfatal injuries, and illnesses, (iii) economic—immediate and interdependent costs of event, including the implementation and operating cost for optional measures, (iv) environmental—air and water emissions, nonproductive land, and intrinsic value loss, (v) sociopolitical—perceived risk, public confidence, trust in government sector-specific effects, and market confidence, and (vi) national security—continuity of military and critical civilian government services. The preferences of three representative decision makers were encoded using structured interview techniques to arrive at multiattribute utility functions consonant with the output of the consequence models and applicable to the case studies described below.

The primary building block for decision analysis in CIPDSS is a *case*. A case consists of two or more scenario pairs (base scenario pairs and alternative scenario pairs); each scenario pair is composed of a *readiness scenario* and an *incident scenario*:

- Base scenario pair
  - *Base readiness scenario.* Business-as-usual conditions; consequences in the absence of terrorist events or other disruptions.
  - *Base incident scenario.* Postulated event occurs with no additional optional measures implemented, beyond what exists at the time.
- One or more alternative scenario pair(s)
  - *Alternative readiness scenario.* A specific set of additional optional measures are in place; postulated event is not initiated.
  - *Alternative incident scenario.* Optional measures are in place; postulated event occurs.

Each scenario requires a separate simulation over a period of time (defined by the case) with the detailed national and metropolitan models. By comparing the alternative scenario pairs with the base scenario pairs, decision makers can evaluate the effects that various investments and strategies could have, if implemented. (The various investments and

strategies, labeled here as optional measures include hardware, processes, and strategies related to prevention, protection, mitigation, response, and recovery.)

### 3.5 Uncertainty and Sensitivity Analysis

Aggregate models such as those in the CIPDSS model set embody a degree of uncertainty in their formulation. Both uncertainty and sensitivity analyses [4] are essential tools in assessing the uncertainties arising when applying computer models to meaningful analyses. Rather than considering single predictions from the input space, prudent analysis considers the range of possible inputs and maps those to a range of outcomes. Uncertainty analysis defines methods to estimate the distribution of the model outputs, given uncertainties in the model inputs. Sensitivity analysis specifies a process by which sources of variance in the model outputs can be identified with uncertainties in the model inputs. Such information is useful when it is desirable to reduce the uncertainty of the outputs, as the information indicates which input variables are the greatest contributors to output variance. Both uncertainty analysis and sensitivity analysis are supported by the CIPDSS architecture and routinely applied when performing analyses. Although arbitrary experiment designs are supported, orthogonal array (OA), Latin hypercube sampling (LHS), and hybrid OA-based LHS designs are commonly used to support uncertainty and sensitivity analysis.

## 4 CASE STUDIES

Throughout its development cycle, CIPDSS has been exercised by producing a case study for each disruption capability. Each case study is used to expose each capability's potential cascading consequences and place a disruption scenario in a risk-informed context.

In general, CIPDSS can address case studies to support decision making relative to a standardized set of scenarios defined by DHS (Table 2), although not all capabilities are currently well developed. Current work is focused on the physical disruption capability, where the disruption may be caused by explosive devices, assault teams, natural events, or accidents. The program's goal is to cover all types of disruptions of interest to DHS policy makers.

In this section, three case studies are briefly described: a telecommunications disruption, an outbreak of a contagious disease, and an accidental release of a toxic industrial chemical.

### 4.1 Telecommunications Disruption Case Study

The earliest version of CIPDSS was exercised in a proof-of-concept case study that demonstrated the project's feasibility. The case study—chosen to broadly perturb many infrastructure sectors—involved a telecommunications disruption that degraded the operation of other infrastructure sectors. In each of three northeastern cities, major telecommunication switching stations were bombed with explosives in a simultaneous attack. Significant switching capacity was lost at each site and a large number of casualties were inflicted. CIPDSS consulted with the National Communications System and Lucent Technologies to assure appropriate modeling of the disruption in telecommunication services. Decision metrics and utility values were computed for several investment alternatives that would mitigate the impact of the incidents.

For the telecommunications case study, two optional measures were examined: (i) improving the restoration capability of the system and (ii) consolidating the targeted facilities away from dense urban areas. The former alternative was expected to reduce the secondary economic impact of the incident, while the latter was expected to reduce the impact on human health and safety. While undergoing repairs, the telecommunications system loses revenue as well as requiring capital to replace lost capability. The impact on human health and safety was caused by casualties imposed by the bomb blast. Casualties were relatively high because one switching facility was near a metro mass transportation station and the blast occurred at a time of day when commuter traffic was heavy. The alternative to consolidate the switching facilities and move them to a less busy part of the metro region was expected to cost $7 billion. This posed an interesting trade-off between the mitigation alternatives. In improving the restoration capability, presumed to cost $1.5 billion, the economic losses from the incident would be lower. On the other hand, consolidation of facilities would reduce fatalities and injuries. In accounting for such trade-offs, the decision modeling method combines the primary metrics of the consequences of a scenario with the implementation costs associated with the scenario. Another way to represent the decision, depicted in Figure 2, is as a decision tree, which consists of decision nodes and chance nodes. The utility of the base readiness scenario is 99.2 for a given decision profile. This is the expected utility for the chance node for each decision alternative. The expected utility of the base incident scenario is 16.3. For an attack having the probability of 0.1, the expected utility of the base alternative is, therefore, 90.9. The utilities of all alternatives are calculated and shown in Figure 2.

Figure 3 depicts a *decision map* that provides a convenient mechanism for the decision maker to assess investment alternatives as a function of the expected annual likelihood of the threat event. Figure 3 illustrates how a risk-neutral decision maker would prefer no action so long as the annual likelihood of the event is less than one incident in 13 years. When the likelihood is between one in 13 years and one in 5 years, that decision maker would prefer to improve the restoration capability; when the likelihood is greater than one in 5 years, that decision maker would prefer to consolidate facilities. The relative

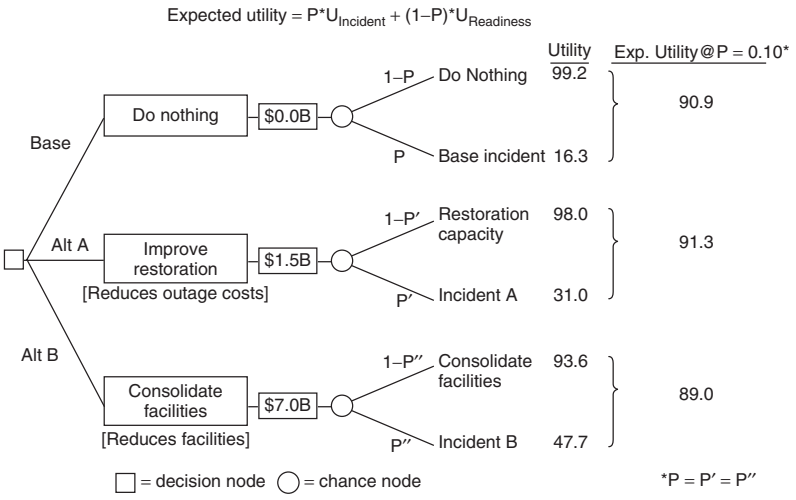

**FIGURE 2** Tree representation of decision alternatives.

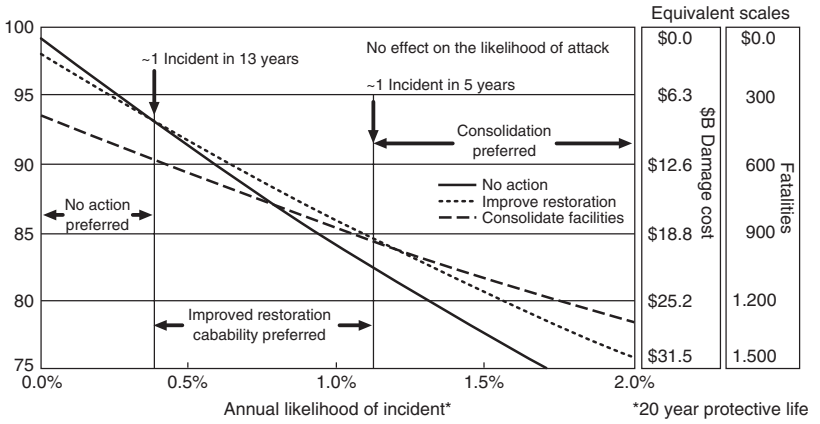

**FIGURE 3** Decision map of a scenario parameterized by the likelihood of the incident.

preferences are determined by the form of the decision maker's multiattribute utility function and risk tolerance profile.

### 4.2 Biological Pandemic Case Study

An analysis of a biological threat scenario was performed to assess infrastructure interdependency and economic effects resulting from the consequences of a highly infectious biological attack. To identify the conditions under which various alternatives are preferred, the consequences of the attack were combined with cost estimates for various protective measures within the decision model.

At the core of this case study is an infectious disease scenario model. The infectious disease model is a modified susceptible-exposed-infected-recovered (SEIR) model [5], based on an extended set of disease stages, demographic groupings, an integrated vaccination submodel, and representation of quarantine, isolation, demographic, and disease-stage-dependent human behavior. As a variant on the SEIR model paradigm, the CIPDSS model represents populations as homogeneous and well mixed with exponentially distributed residence times in each stage [6]. The use of additional stages and demographic groupings is designed to add additional heterogeneity, where it can be useful in capturing key differences in disease spread and response in different subpopulations.

The disease stages are generically represented so that the model can be used for a large number of infectious agents simply by adjusting the input parameters appropriately. For example, with the studied hypothetical biological agent like smallpox, the first stage is the exposed or incubating stage during which a vaccine can still be effective (about 3 days) and the next stage represents the remainder of the incubating period when the vaccine is no longer effective. This is followed by a prodromal phase when the disease is sometimes infectious and is symptomatic, but with nonspecific flu-like symptoms. The disease progresses into a rash stage, where the risk of contagion is highest, and then into the scab phase. The patient then either recovers from the disease, or dies.

The analysis specifically considered the following incident and alternatives:

- *Base incident.* 1000 people initially infected with smallpox and implementation of existing vaccination policies.

- *Alternative A.* Installation of biodetectors to provide early detection of the disease.
- *Alternative B.* Use of antiviral drugs to treat the disease.
- *Alternative C.* Mass quarantine to reduce the spread of the disease.
- *Alternative D.* Improved training of health care personnel to administer existing vaccines more rapidly.

Large-scale simulations were used to characterize the uncertainty in the consequence results and understand which model parameters had the strongest effects on the decision metrics. Considering uncertainities, the number of fatalities in the base incident scenario ranged from 277 to 7041. Incorporation of individual alternatives A–D reduced the lower end of the fatality range slightly and in all cases significantly reduced the maximum number of simulated fatalities. Primary economic costs in the metropolitan area, where 1000 persons are initially infected, were calculated to range from $7.5 to $9.5 billion, except for the mass quarantine alternative (Alternative C) where the primary economic costs would be up to three times greater because of loss of worker productivity during a quarantine. On a national scale, economic costs might easily be driven by a widespread self-isolation response resulting from the general population seeking to protect itself by reducing exposure to potentially infected individuals. A severe self-isolation response could significantly impact business and industrial productivity as workers stay home from their jobs and reduce normal spending by avoiding shopping and other commercial areas where they might come in contact with infected persons. The interdependent private sector economic costs and personal income losses associated with a severe, widespread self-isolation response were calculated to be as great as $450 billion, or 15–45 times the primary economic costs of the infectious disease event. Government costs could be similar.

Within the initially affected metropolitan area, the primary indirect or "cascading" effects of the incident involve the transportation and telecommunications sectors, with other sectors being affected by these in turn. Quarantine measures impact nearly half of the workers in the metropolitan area during the peak period of the crisis, resulting in much lower usage of the transportation system and losses in personal income because workers would not report to work and businesses would close temporarily.

In accordance with the numerous infectious disease model results that are currently available [7, 8], the CIPDSS results show that given the initiating event, a significant epidemic will ensue, with an average of 6100 nonfatal illnesses and 1500 fatalities in the base case. CIPDSS results particularly agree with Gani and Leach [9] who point out the importance of delays in detecting the first cases and the importance of setting up effective public health interventions. In the CIPDSS analysis, the addition of biodetectors provides a high degree of early warning, enabling a rapid effective response that almost completely stops the spread of the disease outside the initially infected metropolitan area, thereby significantly reducing the number of cases and subsequent mortalities. The study indicates that time to intervention and effective response is a critical component in controlling the health impacts resulting from a deadly infectious biological outbreak.

The national economic consequences are primarily caused by a behavioral response that could lead to widespread self-isolation and severe economic impacts. Because the magnitude of such a response is largely unstudied in the literature, the uncertainty surrounding this parameter is very great. Rather than assuming that more is known than is actually the case about the possible public self-isolation response to an intentional release of infectious smallpox virus, the analysis presents the decision model results parameterized with respect to the relative level of widespread self-isolation behavior.

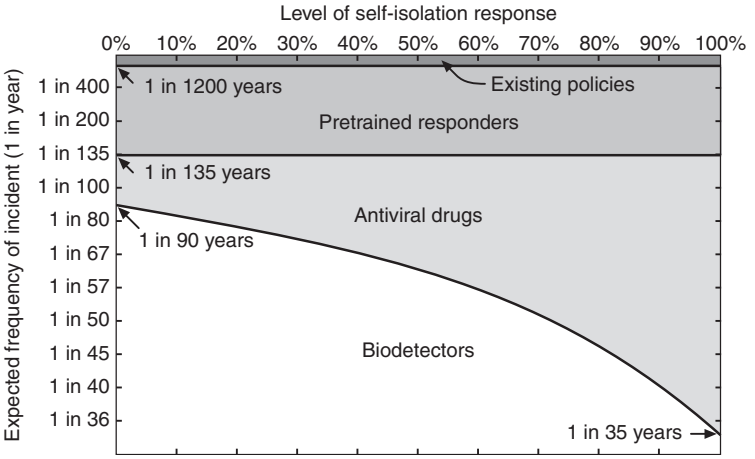

**FIGURE 4** A preference map for preferred alternatives in a biological disease case.

For a risk-neutral profile, a preference map was derived by combining the calculated consequences in a decision model based on multiattribute decision theory and by assigning the attribute trade-off values that are consistent with values suggested by several DHS decision makers (Figure 4). The preference map indicates that up to an expected likelihood of one incident in 1200 years, the preferred alternative would be to continue existing vaccination and quarantine policies, regardless of the level of national self-isolation response.

Likewise, between an incident likelihood of one in 1200 years and one in 135 years the preferred alternative would be to pretrain and implement a larger number of medical and emergency responders to vaccinate the public more rapidly, in the event of an intentional smallpox release. Without a widespread self-isolation response (0%), the antiviral drug alternative would be preferred when the incident likelihood increases to one in 90 years.

At greater incident likelihoods, the detector alternative is preferred because it produces the lowest level of combined consequences across all simulations of the scenarios. When the level of self-isolation response increases, the antiviral strategy is the preferred alternative at increasing incident likelihoods, being preferred over detectors at the maximum level of self-isolation and incident likelihood of one in 35 years. This trend in increasing self-isolation takes place because the biodetectors would result in earlier disease detection and thus public notification, which in turn would result in an earlier commencement of the economic impacts caused by the widespread self-isolation response.

### 4.3 Toxic Industrial Chemical Case Study

The chemical threat scenario analysis was performed to demonstrate the CIPDSS capability to provide risk-informed assessments of potential mitigation measures for this class of threats [10]. Coupled threat scenario, infrastructure interdependency, and economic effects models were used to estimate the consequences of an accidental release of a toxic industrial chemical, namely chlorine, in an urban setting. The consequences were combined with cost estimates for various protective measures within the decision model to identify the conditions under which various alternatives would be preferred. The analysis specifically considered the following incident and alternatives:

- *Base incident.* A large (70 percentile event) in a "normally prepared" community and a "normally trained" set of emergency responders.
- *Alternative A.* Installation of chemical detectors to detect the extent of spread of the chemical.
- *Alternative B.* Use of temporary or mobile triage/treatment sites to handle expected volumes of exposed persons.
- *Alternative C.* Application of comprehensive community preparedness training for chemical releases.
- *Alternative D.* Increased training and response preparedness for emergency responders and health providers.
- *Alternative E.* Application of comprehensive community preparedness training for chemical releases with an emphasis on significantly reducing the population response time.

The initiating event for the base incident and alternative mitigation measure scenarios is a statistical representation (model) of the *unmitigated* consequences of a large-scale chlorine release. The potential number of injuries and fatalities and the number of hospital beds and geographical areas rendered unusable during and some time after the passage of a toxic plume are estimated on a probabilistic basis. To accomplish this, historical accidental release data, maximum stored volumes, and meteorological data were used as inputs into a heavy gas dispersion model. Multiple runs were performed using plausible distributions on the dispersion model inputs to generate a generic statistical distribution of injuries and fatalities associated with specific toxic chemicals for four different regions of the United States, using actual geographic locations and population distributions as a basis for the calculations. The stochastic distributions of unmitigated injuries and fatalities were developed as a function of time, parameterized as a function of cumulative probability of the event, and normalized to a population base of 1 million persons in a 5-km radius from the release site to mask the identification of the actual site.

The analysis of health effects employed Acute Exposure Guideline Levels (AEGLs) developed by Environmental Protection Agency (EPA) and National Research Council (NRC) [11], for which six different averaging times ranging from 5 min to 8 h are given. Three AEGLs were used in the analysis as follows:

- Persons within AEGL-1 footprint could experience *adverse* effects such as notable discomfort, irritation, or certain asymptomatic nonsensory effects. The effects are transient and reversible upon cessation of exposure.
- Persons within AEGL-2 footprint could experience *irreversible* or other injuries, long-lasting adverse health effects, or an impaired ability to escape.
- Persons within AEGL-3 footprint could experience *life-threatening* health effects or death.

Furthermore, three additional health criteria that further disaggregate AEGL-3 were exercised to provide better definition of victim status or condition to the CIPDSS public health sector model. These additional criteria enabled a more complete modeling of healthcare response to the event.

In this analysis, an unmitigated base case is compared to each of five modeled mitigation measures with respect to key operational parameters in the CIPDSS models relative to the value of the same variable in the base incident scenario.

On the basis of the uncertainty analysis performed with the CIPDSS models, the minimum, mean, and maximum values for the mitigation measure costs, fatalities, injuries, economic losses, and losses in public confidence (decision metrics) for each of the above incident scenarios display virtually no variation in the results among the five alternative mitigation measure scenarios. Furthermore, there is almost no variation in the results between the alternative mitigation measure scenarios and the base incident scenario, which includes no additional mitigation measures. The reason for this is the rapidity with which the plume disperses; there is simply insufficient time to react. Even with accelerated response times, the majority of the population that would be exposed without additional mitigation measures would still receive exposure even with the additional mitigation measures.

Because all of the measures that were modeled had an insignificant effect on mitigating the consequences of a large-scale chlorine release, the various options differentiated on the basis of implementation cost alone. Thus, as calculated in the CIPDSS decision model, the order in which the measures would be preferred is in direct relationship to their implementation cost. The analysis indicated that investing in any of the mitigation options considered is less desirable than taking no action, regardless of how likely it may be that the incident would occur. Of course, this conclusion is obvious from the fact that none of the modeled measures had any significant mitigation effect on the consequences of an accidental release. The rank ordering of preference for the alternatives, shown in Figure 5, was (i) base case, no mitigation; (ii) alternative A, chemical detectors; (iii) alternative D, response preparedness and training; (iv) alternative E, community preparedness II; (v) alternative C, community preparedness I; and (vi) alternative B, mobile treatment facilities. These results are consistent with other studies of chlorine releases [12]. One conclusion to draw is that investment should focus on prevention of a chemical release rather than on improving mitigation efforts after a release.

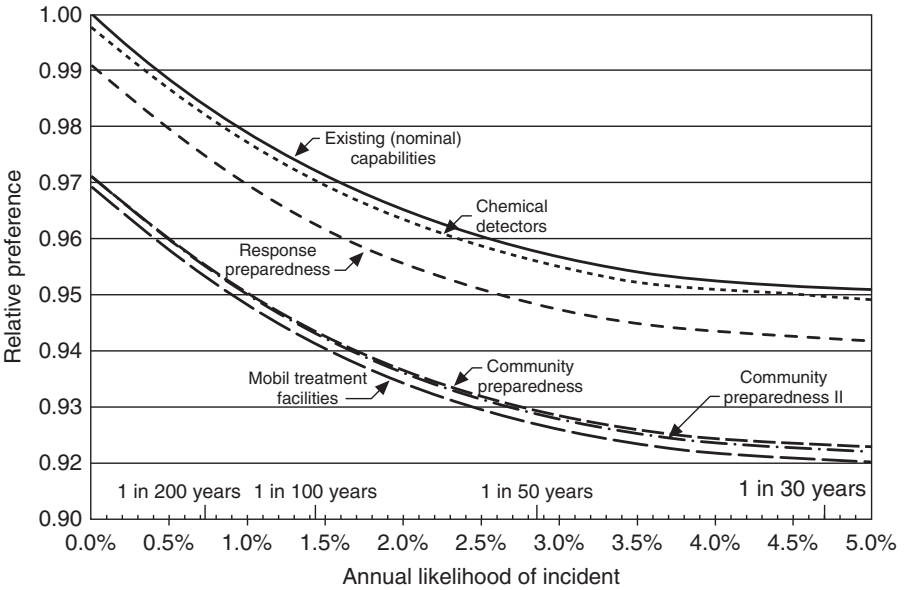

**FIGURE 5** The preference map for a chemical release scenario.

These results do suggest, however, that in the effort to protect the public from large accidental releases of chlorine, consideration should be given to measures designed to prevent the release rather than measures designed to mitigate the consequences of a release once it has occurred.

## 5 CONCLUSION

CIPDSS has demonstrated its capability to provide meaningful risk-informed decision support for several categories of threats of interest to the DHS. As a system dynamics suite of simulations, it has confirmed the ability of system dynamics to support a wide range of analyses of interest to policy makers through aggregate level simulation of multiple infrastructure systems.

Combined with the flexibility and extensibility conferred by the conductor, the uncertainty and sensitivity analysis capability, the decision model, and the breadth of coverage, including all 12 critical infrastructures and 5 key resource categories, CIPDSS is a unique capability for investigating consequences of infrastructure disruption. CIPDSS incorporates a fully integrated risk assessment process, explicitly and rigorously accounting for uncertainties in threats, vulnerabilities, and the consequences of terrorist acts and natural disasters. CIPDSS goes beyond the sole calculation of first-order consequences in one or just a few infrastructures. CIPDSS models the primary interdependencies that link the 17 critical infrastructures and key resources together and calculates the impacts that cascade into these interdependent infrastructures and into the national economy.

## 1 OVERVIEW

The United Nations defines terrorism as "any action that is intended to cause death or serious bodily harm to civilians or noncombatants, when the purpose of such act,

by its nature or context, is to intimidate a population, or compel a Government or an international organization to do or abstain from doing any act" [1].

On the basis of rational-choice considerations (compare [2]), an organization will choose terrorist actions in addition to other actions, if terrorism contributes to reaching their goals at a relatively low cost and has high impact. Hence, it would be rational for terrorists to attack a target, if this allows them to realize their goals to a larger extent with costs lower than that would be incurred by other means. However, it may be argued that our rational-choice model has limitations in explaining suicide attacks, although these may follow logically from the ideological or religious beliefs of those who carry them out.

The rational-choice considerations are important because terrorists will consider perceived vulnerability and consequences in deciding on whether to launch an attack. Therefore, the allocation of security resources to counterterrorism is a complex task that requires decisions on the risk allocation mechanism, estimation of risk, and tolerable levels of risk. Until recently, few papers have been published on ways to allocate security resources. Innovations have applied game theory [3], portfolio theory and risk analysis approaches [4–6] to the allocation of security resources (For an extensive literature review see the special edition of *Risk Analysis* **27**(3)).

In this article, the risk analysis approach taken by Willis et al. [4–6] is discussed. This approach, known as *threat–vulnerability–consequence* (*TVC*) *analysis*, is related to catastrophe modeling (see [7]). Both TVC analysis and catastrophe modeling are examples of a more general statistical theory known as the *theory of loss distributions*, which are widely applied by actuaries in the insurance and reinsurance industries. The theoretical development of loss distributions can be found in Cox et al. [8–10] Before outlining the essential elements of TVC analysis, it is useful to reflect on traditional definitions of risk as the approach taken by Willis et al. [4, 6] modifies the traditional definition of risk to reflect the underlying structure of the risks encountered in terrorism analysis.

Traditionally risk is defined as the triplet $\langle s_i, p_i, x_i \rangle$ where $s_i$ is the risk scenario, which has a probability $p_i$ of occurring and a consequence $x_i$ if it occurs [11, 12]. A useful risk metric is defined as the probability of an event occurring multiplied by its associated consequence, $p_i \times x_i$. It is common for the expected value of the distributions to be used as point estimates in the calculation of $p_i \times x_i$ [13]. However, the measure for risk is uncertain and should be represented by a probability distribution, not a point estimate [14]. The traditional definition of risk is modified by [4, 6] and is defined as a function of TVC. This definition is similar to others proposed in risk literature, for example see [15–17].

The remainder of this article provides an overview of the TVC analysis framework, discusses TVC analysis and the deployment of resources, elaborates some of the challenges and limitations of TVC analysis, discusses methods of dealing with uncertainty, provides a summary of the current state of practice, and suggests linkages between areas of research currently addressing similar issues.

## 2 THREAT–VULNERABILITY–CONSEQUENCES (TVC) ANALYSIS FRAMEWORK

Risk is measured as the probability of a terrorist "event" and the associated consequence. The probability of a terrorist event is measured as the threat and vulnerability of the target.

Threat is measured as the probability of a specific target being attacked in a specific way during a specified period. Vulnerability is measured as the probability of a damage that can occur, given a threat. Consequences are the magnitude and type of damage resulting, given a successful terrorist attack.

### 2.1 Assessing Threats

The purpose of the threat assessment is to gain an understanding of where terrorists are targeting their activities; typically this is based on intelligence information gathered from a variety of sources, both human and technological. Threats may be general or specific, and security responses are conditioned on the nature of the information received [6]. Typically, an analysis will first assess whether a country or region is under a general threat from terrorist attacks. Subsequently, a view is formed of the probability or likelihood that a specific target will be attacked in a specific way during a specified time period; mathematically,

$$\text{Threat} = p(\text{attack occurs})$$

However, it is essential to consider both the economic and the political dimension of costs and benefits in assessing the level of threat. For example, if a terrorist group has an antipoverty ideology, using a technique that hits mostly poor people implies a political cost, because it reduces the credibility of their cause. Thus, in the mid 1980s, the Liberation Tigers of Tamil Eelam in Sri Lanka threatened to use disease pathogens to destroy the economically important tea crop and to deliberately infect rubber trees with the leaf curl fungus [18]. One reason that the Tigers never made good on this threat may be that most of the low-income estate workers, who depend on tea and rubber cultivation for their livelihoods, are ethnic Tamils.

### 2.2 Assessing Vulnerabilities

Different definitions of vulnerability appear in the literature. Haimes [16] defines vulnerability as the probability that damages (where damages may involve fatalities, injuries, property damage, or other consequences) occur, given a specific attack type, at a specific time, on a given target, or vulnerability is the manifestation of the inherent states of the system (e.g. physical, technical, organizational, and cultural) that can result in damage if attacked by an adversary. Pate-Cornell [19] defines vulnerability as the capacity of a system to respond to terrorist threats. Adopting the approach taken by Willis et al. [4, 6], vulnerability is mathematically represented as the probability that an attack results in damage:

$$\text{Vulnerability} = p(\text{attack results in damage}|\text{attack occurs})$$

Vulnerability is an estimate of the likelihood of a successful attack resulting in damage. Vulnerability depends on the organization of the infrastructure, on the controls that are in place at the borders, and on the monitoring systems.

### 2.3 Assessing Consequences

A consequence is an assessment of the impact or loss from a terrorist event. Willis [6] defines "consequence" as the expected magnitude of damage (e.g. deaths, injuries, or property damage), given a specific attack type, at a specific time that results in damage to a specific target. Mathematically,

$$\text{Consequence} = E(\text{damage}|\text{attack results in damage})$$

One can also distinguish between the short- and long-term consequences, which may have both an economic dimension (loss of productive capacity and food availability) and a political dimension resulting in persistent periodic cycles of conflict. International efforts to promote increased security are inherently difficult, because conflicts typically occur in countries where national governments have limited legitimacy and where far-reaching governance problems persist [5].

### 2.4 Risk Estimation

Terrorism risk may be thought of as function of the threat level, vulnerability to the threat, and consequence from the terrorist action. For example, the risk estimate could refer to an attack by terrorists against food trade using a particular disease or toxin. The threat would then be an estimate of the terrorists' priority for such attack against the available alternatives. Vulnerability could be estimated as likelihood of port interception and the consequences would be an assessment of the impact of the disease. TVC analysis is an interactive approach designed to elicit areas where high threat levels, extreme vulnerabilities, and high consequences overlap (Fig. 1). It is the intersection of these events that cause security concerns. Mathematical risk is estimated as

$$\begin{aligned}\text{Risk} = \; & p(\text{attack occurs}) \times p(\text{attack results in damage}|\text{attack occurs}) \\ & \times E(\text{damage}|\text{attack results in damage})\end{aligned}$$

## 3 TVC ANALYSIS AND THE DEPLOYMENT OF RESOURCES

TVC analysis should be viewed as part of an integrated terrorism risk management and response system that continually review prioritization decisions based on new knowledge. Components of the system include risk analysis including target selection and resource prioritization, risk mitigation including prevention of attacks and protection of assets, responses to attack, and mechanisms for recovery. Risk analysis provides identification and understanding of threats, assessment of vulnerabilities, and determination of potential impacts. Prevention provides detection and intervention measures, which are used to mitigate threats. Protection provides physical safeguards for critical infrastructure, property, and other economic assets. Response and recovery provide for the short- and medium-term private and public sector measures used to recover from a terrorist attack. TVC is an important component of this cycle, but it is not an end in itself.

TVC analysis attempts to provide a loss distribution for use in decision making. In this application, the distribution is a function of the threat to a target, the target's vulnerability to the threat, and the consequences should the target be successfully attacked. Risk metrics

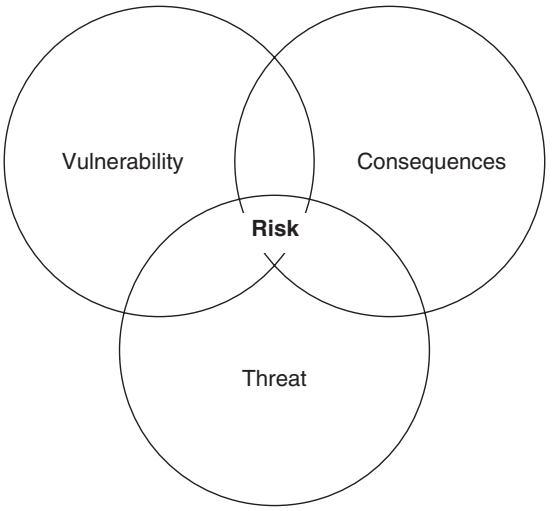

**FIGURE 1** Overlapping regions of high threat, vulnerability, and consequence of great security risk.

can be applied to the different loss distributions derived for different risks to facilitate risk-based prioritization of resources. Metrics may include expected value, variance, skew or skewness (a measure of the asymmetry of the probability distribution of a real-valued random variable), and kurtosis (observations are spread in a wider fashion than the normal distribution, fewer observations cluster near the average, and more observations populate the extremes), all of which can be used to compare different targets, thus facilitating the risk-based prioritization of resources. Alternative metrics used in applied finance include value at risk (VaR); for example, see [20].

## 4 LIMITATIONS OF TVC ANALYSIS

Willis [6] outlines two limitations for consideration when applying TVC analysis. Firstly, Willis [6] draws a distinction between risk assessment and resource allocation, and argues that an efficient allocation of homeland security resources should distribute resources where they can most reduce risks, not where risks are greatest. Secondly, Willis Willis [6] raises the difficult and contentious issue of establishing tolerable levels of risk, which is an important risk management decision. Both these issues are intertwined, as choices will depend on society's willingness to accept some types of risk and mitigate others.

The extent to which society self-insures risk and chooses to invest in risk mitigation is a complex issue. Willis [6] argues that risks may be tolerated simply because they are small compared to benefits obtained through the risky activity, and that risks may be tolerated because the available countermeasures could lead to equal or greater risks themselves. The extent to which rational choices will be made will depend on society's risk perceptions and on our ability to consider options. Simon [21] argues that individuals have a limited range of alternatives, that is we do not know all the decision options available to us, and, even if we do, our conceptual limitations and time prevent us from comparing all of the options available. Other evidence supports this view. For example,

Solvic et al. [22] argue that decision makers rarely have all options available to them. Given these constraints it may be difficult to rationally allocate resources according to the principle of greatest risk reduction.

## 5 APPLYING THE TVC ANALYSIS FRAMEWORK

In this section, we review various studies that attempt to address some aspect of the quantification of risk. Linacre et al. [5] provide evidence of the *ex-ante* consequences of agroterrorism in developing countries. Gordon et al. [23] provides an *ex-ante* economic consequence analysis of the impacts of a 7-day shutdown of the commercial aviation system in the United States. Rose et al. [24] use a computable general equilibrium analysis to quantify the economic effects of a terrorist attack on the electrical transmission system of Los Angeles. Simonoff et al. [25] provide a statistical analysis of electrical power failures, which can be used for risk scenario construction. Willis et al. [4, 6] provide guidance on developing risk-based allocation mechanisms for resource allocation and discuss some aspects of catastrophe modeling. Keeney [26] discusses how structuring of objectives can help in understanding the incentives of terrorists and defenders. Finally, Bier [3] provides a game-theoretic perspective on the issue where a defender must allocate defensive resources to a collection of locations and an attacker must choose which locations to attack.

## 6 DEALING WITH UNCERTAINTY

The methods above allow us to estimate risk, but we also need to put bounds on that risk. There are a number of ways of incorporating uncertainty about parameter values and assumptions in models. The following methods allow us to set bounds on our risk assessment results that represent the confidence we have in our answers.

Scenario (what-if) and sensitivity analyses are among the most straightforward ways to assess the effect of uncertainty, simply, by altering the parameter values and repeating the calculation [14]. Such an approach may become unwieldy when a large number of parameters are involved [14].

Worst-case analysis is the traditional approach to ecological risk assessment, which recognizes that uncertainty exists, but does not try to model it explicitly. Instead, the parameter values are set so that the overall risk estimate is conservative [14]. Many people argue that such approaches result in hyperconservative estimates of the risk and impose a high cost on society for little benefit.

Monte Carlo analysis uses probability theory and numerical analysis to combine uncertainty in a way that reveals how probable each of the possible outcomes is [14, 27–29]. Its usefulness depends on the availability of data to estimate parameters for statistical distributions. In many problems, the data will not be available to estimate the parameters or identify the distribution [30].

Interval Arithmetic provides another method to incorporate uncertainty. Most scientific disciplines quote best estimate values plus or minus an error term, expressing uncertainty in the best estimate. These measures can be expressed as intervals, which are a closed bounded subset of the real line $[a, b] = \{x : a \leq x \leq b\}$ [31]. Intervals have mathematical properties that allows us to propagate, or uncertainty about best estimate

**TABLE 1 Comparing TVC and Catastrophe Model Structure**

| TVC Analysis | Catastrophe Model |
|---|---|
| Assessing threats, for example, dirty bomb attack | Stochastic module randomly generates a catastrophic event |
| | Hazard module is used to determine the geographical effect of a catastrophic event brought about by variations in topography |
| Vulnerability analysis | Vulnerability module, which is used to calculate damage to buildings, contents, and business turnover, based on a number of factors including building type, design, and location |
| Consequence analysis | Financial module, which quantifies the financial loss to the insured |

numbers through a series of calculations [14]. Fuzzy Numbers are a generalization of intervals have mathematical properties that allow the propagation of uncertainty about best estimates numbers through a series of calculations [14].

## 7 FURTHER READING

As previously mentioned, there are a number of related developments in different subject areas that may have utility for researchers and decision makers involved in security resources prioritization. In the finance literature, the development of risk metrics such as VaR provide approaches for the comparison of different portfolios of risks (see [20]). Within the insurance and actuarial literature, loss distributions are relevant (e.g. [8–10]), extreme value theory [31], and catastrophe modeling. The structures of catastrophe models are similar to the structure of TVC analyses. Catastrophe models are composed of a number of modules and their relationship to TVC analysis is shown in Table 1 [7, 32, 33].

Catastrophe models may be used as a diagnostic tool to assess post event loss. The model may be designed to investigate ideas about the relationships between causal factors and, finally, the model may be designed to forecast the frequency and magnitude of events [32]. It is in this last use that TVC analysis and catastrophe models have a similar application.

The political risk literature also provides a theoretical and applied underpinning for quantitative valuations of risk associated with war and political instability. A useful starting point into this literature is [34]. Further background reading on risk provides important information on acceptable levels of risk (e.g. [35, 36]). Fischhoff et al. [37] provide a useful paper on expert and lay perceptions of risk. Kahneman and Tversky [38] provide a seminal paper on how people make risk decisions, and finally [14, 27] provide an important technical information on dealing with uncertainty.

## 8 CONCLUSIONS

TVC analysis offers a structured mechanism for addressing security resource allocations problems. However, it does not address the difficult and contentious issue of establishing

tolerable levels of risk, which is an important risk management decision. The extent to which rational decisions will be made over the choice of tolerable levels of risk will depend on societal perceptions of risk.

Rational-choice considerations also suggest that homeland security resources should be allocated to where they can most reduce risks, not necessarily where risks are greatest. The extent to which society is prepared to accept self-insurance of risks that cannot be readily mitigated is a complex issue and will also depend on societal perceptions.

Further limitations arise in TVC analysis because of uncertainty around the basic parameters used in the models. It may be that it is impossible, given the available data, to make confident decisions about the prioritization of security resources because of the level of uncertainty.

However, given all these limitations, TVC analysis remains an important methodological approach to assist decision makers, structure, explain, justify, and communicate decisions on security resource prioritizations.

## 1 INTRODUCTION

Over the past decade, the United States has moved to increase its ability to detect, prevent, and respond to terrorist threats and incidents. Much of this focus, which has involved considerable financial outlays, has aimed at upgrading public infrastructure through the development of vulnerability threat analyses designed to maximize both antiterrorist contingencies and consequence management modalities. Although many gaps remain, investments in preparedness, training, and response have helped with the development of at least nascent homeland incident command structures that have incrementally begun to span the ambit of potential terrorist attacks, from conventional bombings to more "exotic" biological, chemical, radiological, and nuclear incidents.

Agriculture and food production have received comparatively little attention in this regard, however. In terms of accurate threat assessments and consequence management procedures, these related sectors exist somewhat as latecomers to the growing emphasis that has been given to critical infrastructure protection (CIP) in this country. Indeed at the time of writing, total funding for protecting the nation's food supply stood at only $2.6 billion, a mere 2% of the US$130.7 billion in Congressional allocations earmarked for the United States Department of Agriculture (USDA) in Financial Year (FY) 2006.[1]

This article expands the debate on domestic homeland security by assessing the vulnerabilities of American agriculture and related products to a deliberate act of biological terrorism.[2] It begins by examining key attributes of contemporary US farming and food processing practices that make them susceptible to deliberate disruption. The article then examines the main impacts that would be likely to result from a concerted biological

[1]Agriculture, itself, was only included as a specific component of U.S. national counterterrorist strategy following al-Qaeda's attacks on the Pentagon and World Trade Center in September 2001 [1].

[2]For the purposes of this analysis, agro-terrorism will be defined as the deliberate introduction of a disease agent, either against livestock or into the general food chain, for the purposes of undermining national stability and/or engendering public fear. Depending on the disease agent and vector chosen, it is a tactic that can be used either to generate either economic, social, and political disruption or as a form of direct human aggression.

**TABLE 1 Selected FADs with Potential to Severely Impact Agricultural Populations and/or Trade**

| FAD | Mortality/Mortality | Zoonotic |
|---|---|---|
| Foot and Mouth Disease (FMD) | Less than 1%; however, morbidity near 100% | No |
| Classical swine fever (CSF) | High | No |
| African swine fever | 60–100%, depending on isolate virulence | No |
| Rinderpest (RP) virus | High | No |
| Rift valley fever (RVF) | 10–20% among adult populations; higher among young lambs, kids, and calves | Yes |
| Highly pathogenic avian influenza (AI) virus | Near 100% | Yes |
| Exotic Newcastle Disease (END) | 90–100% | Yes |
| Sheep and goat pox (SGP) viruses | Near 50%, although can be as high as 95% in animals less than one-year old | No |
| Vesicular stomatitis (VS) Virus | Low (however, morbidity near 90%) | Yes |

*Source:* Adapted from Committee on Foreign Animal Diseases, Foreign Animal Diseases.

attack against agriculture, focusing on both economic and political fallout. Finally an assessment of the operational utility of agro-terrorism is offered and contextualized in terms of the overall strategic and tactical calculations of the post-9/11 global jihadist militant movement.

## 2 VULNERABILITY OF US AGRICULTURE AND FOOD PRODUCTION TO BIOLOGICAL ATTACK

Agriculture and the general food industry are highly important to the economic and, arguably, political stability of the United States. Although farming directly employs less than 3% of the American population, one in eight people works in an occupation that is directly supported by food production [2]. In FY 2006, net cash farm gate receipts stood at over 64 billion, while a record US$68.7 billion was generated from agricultural exports—which, alone, equates to just under 1% of US Real Gross Domestic Product (GDP) [3].

Unfortunately, the mechanics for deliberately disrupting American agricultural and food production are neither expensive nor technically problematic. Many foreign animal diseases (FADs) can exist for extended periods of time on organic and inorganic matter and are characterized by rates of morality and/or morbidity (see Table 1 below), meaning that their latent potential to severely impact the health and trade in livestock is considerable. Significantly, the most lethal and contagious agents are nonzoonotic in nature, which necessarily precludes any need on the part of the perpetrator to have an advanced understanding of animal disease science or access to elaborate containment procedures (as there is no risk of accidental infection).[3]

[3]Analysis based on author interviews and field research conducted between 1999 and 2006.

Moreover, because contemporary farming practices in the United States are so concentrated and intensive,[4] a single point pathogenic introduction—if not immediately identified and contained—would be likely to spread very quickly. This is true both of crowded herds at the targeted facility and, due to the rapid and distant dissemination of animals from farm to market, to populations further afield. There is, in other words, no obstacle of weaponization to overcome as the primary vector for disease transmission is constituted by agricultural livestock itself.[5] This particular "facet" of agro-terrorism is noteworthy as the costs and difficulties associated with appropriately manufacturing viral and bacterial microbial agents for widespread dissemination are frequently cited as the most significant barriers preventing nonstate offensive use of biological agents.[6]

As noted above, early identification and containment of a disease is vital to physically check its geographic spread. However, there are at least three factors that work against such a (favorable) scenario. First, many veterinarians lack the necessary expertise and training to diagnose and treat Foot and Mouth Diseases (FMDs) of the sort that would be most likely to be used in a deliberate act of sabotage.[7] Second, producers are often reluctant to quickly report contagious outbreaks at their farms, fearing that if they do so they will be forced to carry out uncompensated (or at least undercompensated) depopulation measures.[8] Third, the possibility of emerging diseases being overlooked has steadily risen, largely because the scale of contemporary agricultural practices effectively negates the option of tending for animals on an individual basis.[9]

These various considerations have particular salience to FMD, which constitutes arguably the most threatening of all FADs. Although the disease is usually not fatal, it does cause the onset of rapid weight loss, oral/hoof lesions, lameness, and mastitis, effectively rendering any infected livestock population economically useless (in terms of milk and meat production).[10] More pointedly, FMD is extremely infectious,[11] environmentally hardy, frequently misdiagnosed,[12] and nonzoonotic—all of which directly contribute to its ease of management and potential rate of dissemination. The means for disseminating the virus could be as simple as scraping some vesicular droplets directly on to a cow (or other cloven hoof animal) or introducing the agent into a silage bin at a state agricultural fair or barn auction [6]. Given the intensive nature of contemporary American farming practices, a multifocal outbreak would be virtually assured: models developed by the USDA, for instance, have projected FMD that could be expected to spread to as many as 25 states in a minimum of 5 days.[13]

[4]Most dairies in the United States, for instance, can be expected to contain at least 1500 lactating cows at any one time, with some of the largest facilities host to upwards of 1000 animals.

[5]Analysis based on author interviews and field research conducted between 1999 and 2006.

[6]A good summary of the technical constraints inherent in weaponizing biological agents can be found in [4].

[7]Comments made by USDA officials attending the National Research Council National Security Implications of Advances in Biotechnology: Threats to Plants and Animals planning meeting, Washington D.C.:, August 1999.

[8]At the time of writing, no standardized or consistent system to compensate farmers affected by pathogenic outbreaks existed in the United States, with all indemnity payments determined on a case-by-case basis.

[9]Analysis based on author interviews and field research conducted between 1999 and 2006.

[10]For more on the etiology and effects of FMD see [5].

[11]FMD is one of the most contagious diseases known to medical science and has been equated as the animal equivalent to smallpox in terms of subject-to-subject spread.

[12]This reflects the general lack of expertise on the part of veterinarians in FAD identification as well as the fact that the clinical signs of FMD are not always immediately apparent (a pig, for instance, typically starts shedding vesicular droplets 7–10 days prior to symptoms becoming visibly evident).

[13]Author interviews with USDA officials, Washington D.C. and Maryland, 1999–2000.

Weaknesses and gaps are equally as pertinent to food processing and packing plants, particularly those that have proliferated at the lower to medium of the production spectrum. Thousands of these facilities exist across the United States, many of which exhibit uneven internal quality control,[14] questionable biosurveillance, and highly transient, unscreened workforces.[15] Entry–exit controls are not always adequate (and occasionally do not exist at all) and even basic measures, such as padlocking warehouses and storage rooms may not be practiced. Exacerbating problems are developments in the farm-to-table food continuum, which have greatly increased the number of potential entry points for easy to cultivate toxins and bacteria, such as botulism, *Escherichia coli*, and *Salmonella* (all of which are tasteless, odorless, and colorless).[16] Perishable, ready-to-eat products present a special hazard, largely because they are quickly distributed and consumed without cooking (a good "back-end" defense against microbial introduction) [8]. Moreover, because many small-scale operations do not maintain up-to-date (much less accurate) records of their distribution network, tracing exactly where a food item tainted in this manner may not be possible [9].

Underscoring these various difficulties is a dearth of definitive realtime technologies for detecting biological and chemical contaminants. As a result, possibilities for preemptive action are extremely limited as in virtually all cases health authorities would probably only become aware of an attack after it has occurred [10].

These gaps and weaknesses are particularly alarming given the lack of effective government regulation over food production and packing plants. While full implementation of the Hazard Analysis and Critical Control Points (HACCP)[17] is now theoretically in place at all factories that slaughter and process meat and poultry, the number of facilities that exist in the United States relative to available federal and state inspectors largely precludes options for enforced compliance and auditing.[18] Problems are even greater with regard to plants that deal with fresh-cut fruits and vegetables, most of which are devoid of any form of oversight or control [12]. Although a major food scare in 2006 involving spinach tainted with *E. coli* 0157:H7[19] has served to generate pressure for enhanced biosecurity and surveillance at these facilities, progress has been halting at best. Revised regulations issued by the Food and Drug Administration (FDA) in 2007[20]

[14]For instance, a facility manufacturing pre-packaged open-faced meat or poultry sandwiches fall under the authority of the USDA; those specializing in closed-faced varieties with identical ingredients come under the auspices of the Food and Drug Administration (FDA). The former will be inspected every day while the latter may only be checked once every five years [7].

[15]The Bush administration has pledged to upgrade the screening of workers employed at food processing and packing plants. At the time of writing, however, definitive checks had still to be put in place and it was still not apparent to what extent they would apply to small and medium scale plants throughout the United States.

[16]Analysis based on author interviews and field research conducted between 1999 and 2006.

[17]Under the HACCP rule, all meat and poultry producing facilities are required to identify critical control points where microbial contamination is likely to occur and enact Food Safety and Inspection Service (FSIS) designated systems to prevent or reduce the likelihood of it taking place. HACCP controls were introduced at the country's largest plants in January and have since been extended to all smaller facilities, including those with 10 employees or fewer.

[18]As of 2006, the number of inspectors at the USDA had declined from 9000 to 7500 and at the FDA from 2200 to 1962. See [11].

[19]The 2006 outbreak killed 3 and sickened 205. See [13].

[20]The 2007 guidelines are the first to have been issued since 1998. The new (voluntary) procedures call for constant monitoring and control of vulnerable places in the production cycle where bacteria are likely to form; urge regular record keeping for recalls; and outline recommendations relating to the health and hygiene of workers as well as sanitation operations. See [14].

remain voluntary; with the notable exception of California, most state governments have failed to put in place definitive guidelines of their own.[21]

## 3 IMPACT OF A MAJOR BIOLOGICAL ACT OF AGRO-TERRORISM

The ramifications of a concerted bioassault on the US meat and food base would be far-reaching and could extend beyond the immediate agricultural community to affect other segments of society. Perhaps one of the most immediate effects of a major act of biological agro-terrorism would be economic disruption, generating costs that could be expected to cross at least three levels. First, there would be direct losses resulting from containment measures and the eradication of disease-ridden livestock. Second, indirect multiplier effects would accrue both from compensation paid to farmers for the destruction of agricultural commodities[22] and revenue deficits suffered by both directly and indirectly related industries. Third, international costs in the form of protective embargoes imposed by major external trading partners would manifest.

As the 2001 FMD outbreak in the United Kingdom bears testimony, the overall extent of these costs could be enormous. The endemic, which led to the destruction of some 6,456,000 sheep cattle and pigs, is estimated to have cost the British government GBP2.7 billion (see Table 2), equivalent to over 0.2% of the country's GDP at the time. In addition, there were substantial knock-on effects to other sectors of the economy, impacting on even distantly related industries. Tourism, for instance, is projected to have lost between GBP2.7 and GBP3.2 billion of value added in 2001 as a result of the closure/quarantine of farms located in or near popular holiday destinations, such as the Lake District and Peak District [15].

The effects of a multifocal outbreak in the United States would far exceed these figures simply because the scale of agriculture in the country is far greater than that in the United Kingdom. The 1999 study that projected eight different scenarios associated with a theoretical FMD outbreak in California, for instance, concluded that losses from depopulation measures, quarantine, and trade/output disruption to this state alone would exceed US$13 billion [16].

The potential for punitive costs arising out of agro-terrorism are equally as pertinent to product contamination. At the time of writing, the projected costs to the American spinach industry of the 2006 *E coli* outbreak, noted above, were expected to be between $75 and $100 million, with each acre loss amounting to roughly $3700 for the farmer [17]. Although the incident was accidental, it provides a good data point to illustrate how quickly negative fiscal reverberations can ensue from cases of food poisoning.

Beyond its economic impact, a successful biological strike against agriculture could undermine confidence and support in government. Successfully releasing contagious agents against livestock might cause people to lose confidence in the safety of the food supply and could possibly lead them to question the effectiveness of existing contingency planning against weapons of mass destruction in general. Critics, perhaps unfairly

[21] Following the *E coli* outbreak, which originated from farms and production plants in Salinas and Oxnard, California moved to put in place stringent, mandatory rules covering water quality, worker sanitation, and wildlife control. At the time of writing, some 90% of the state's lettuce and leafy green processors were by these standards.

[22] Although the United States has no standardized system of compensation in place, Federal funds would be forthcoming in the event of a large-scale agricultural disaster such as a multifocal outbreak of FMD.

**TABLE 2 Expenditure by the United Kingdom Government in Response to the 2001 FMD Outbreak**

| Activity | Actual Expenditure to May 24, 2002 (GBP million) |
|---|---|
| **Payments to farmers** | |
| Compensation paid to farmers for animals culled and items seized or destroyedy | 1130 |
| Payments to farmers for animals slaughtered for welfare reasons[a] | 211 |
| **Total payments to farmers** | **1341** |
| **Direct costs of measures to deal with the epidemic** | |
| Haulage, disposal and additional building work | 252 |
| Cleaning and disinfecting | 295 |
| Extra human resource costs | 217 |
| Administration of the Livestock Welfare (Disposal) Scheme | 164 |
| Payments to other government departments, local authorities, agencies and others | 73 |
| Miscellaneous, including seriology, slaughterers, valuers, equipment, and vaccine | 66 |
| Claims against the Ministry of agriculture | 5 |
| **Total direct costs** | **1074** |
| **Other costs** | |
| Cost of government departments' staff time | 100 |
| Support measures for businesses affected by the outbreak[b] | 282 |
| **Total other costs** | **382** |
| **Total costs** | **2797** |

[a]Includes payments of GBP205.4 million under the Livestock Welfare (Disposal) Scheme and GBP3.5 million under the Light Lambs Scheme.
[b]Includes money available under European Union (EU) market support measures for agri-monetary compensation in respect of currency movements.

and with the benefit of hindsight, would doubtless demand why the intelligence services failed to detect that an attack was forthcoming and why the agriculture sector was left exposed. In an age where counterterrorism has emerged as arguably the country's single most important national security priority, such reactions could conceivably serve to undermine popular perceptions of state effectiveness, if not credibility.

The actual mechanics of dealing with an act of agricultural bioterrorism could also generate public criticism. Containing a major disease outbreak would necessitate the slaughter of hundreds of thousands of animals, particularly in cases where no concerted vaccination was in place. Euthanizing such volumes has the potential to generate vigorous opposition from the general population—not to mention farmers and animal rights advocates—particularly if slaughtering involved susceptible but nondisease showing herds (in so-called "stamping out" operations) and/or wildlife. To be sure, mass eradication has occurred in the past in the United States without triggering widespread civil disquiet. However, such operations have not involved large-scale husbandry (for the most part focusing on poultry flocks) nor have they been the subject of intensive media interest and scrutiny. It is these latter aspects that have relevance in terms of assessing the possible fallout from culling measures, largely because they necessarily mean there

has never been a visual point of reference to prepare the American general public for the consequences of eradicating highly visible animal herds [18].

The 2001 FMD outbreak in the United Kingdom, again, provides a salient example of the political ramifications that can result from mass animal eradication. The measures instituted by the Blair administration to stem the epidemic elicited significant criticism from farmers, scientists, opposition politicians (many of whom claimed that the government's actions were entirely unethical), and the public (especially after it discovered that FMD did not actually kill infected animals).[23] The following commentary in the Times newspaper is representative of the type of outrage that was expressed during the height of the crisis:

> Policy on foot and mouth disease is now running on autopilot . . . . Nothing in the entire history of the common agriculture policy has been so crazy. The slaughter is not declining but running at 80,000 a day . . . . At the last estimate, 95 percent of the three to four million animals dead or awaiting death are healthy . . . . The obscenity of the policy is said to be irrelevant "because of its success". Yet what other industry would be allowed to protect its profits by paying soldiers with spades to kill piglets and drown lambs in streams? What other industry could get civil servants to bury cattle alive or take pot shots at cows from a 60 ft range? What other industry can summon teams from Whitehall to roam the lanes of Forest Dean, as one frantic farmer telephoned me, "like Nazi stormtroopers seeking healthy sheep to kill on the authority of a map reference?" [19]

## 4 BIOLOGICAL ASSAULTS AGAINST AGRICULTURE AND TERRORISM MODUS OPERANDI

Despite the ease by which an act of agro-terrorism could be carried out and the severe political and economic ramifications that a successful assault could elicit, it is unlikely to constitute a primary form of terrorist aggression. This is because such acts would probably be viewed as "too dry" in comparison with traditional tactics in the sense that they do not produce immediate, visible effects. The impact, while significant, is delayed—lacking a single point of reference for the media to focus on (and highlight) [20].

In this light, it is perhaps understandable that biological attacks against agriculture have not emerged as more of a problem. Indeed, since 1912, there have only been 14 documented cases involving the substate use of pathogenic agents to infect livestock or contaminate related products (see Table 3). Of these, only three incidents could realistically be linked to a wider campaign of political violence and/or intimidation: the 1952 Mau Mau plant toxin incident in Kenya, the 1984 Rajneeshee Cult salmonella food poisoning in Oregon, and the release of sewer water onto Palestinian agricultural fields by Israeli settlers in 2000 (see Table 3).[24]

[23] Author observations, United Kingdom, June-July 2001.

[24] In addition to these cases, there have also been four confirmed uses of chemical agents to contaminate agricultural products: (i) The use of cyanide to poison the water supply of a 1000-acre farm owned and operated by Black Muslims in Ashville, Alabama (1970); alleged perpetrator: the local chapter of the Ku Klux Klan (KKK). (ii) The use of cyanide to poison Chilean grape exports (1989); perpetrator: antiPinochet militants. (iii) The use of chlordane (a pesticide) to contaminate animal feed manufactured by National By-Products, Inc. in Berlin, Wisconsim (1996); perpetrator: Brian "Skip" Lea, the owner of a rival animal food processing facility. (iv) The use of "black leaf 40" (an insecticide) to contaminate 200 pounds of ground beef in Michigan (2003); perpetrator: randy Betram, a disgruntled employee at the Byron Center Family Fare Supermarket. For further details see [21].

**TABLE 3 Nonstate Use of Biological/Toxic Agents Against Agriculture and Food, 1912–2006**

| Year | Nature of Incident | Alleged Perpetrators |
|---|---|---|
| **Confirmed use of agent** | | |
| 2000 | Contamination of Palestinian agricultural land with sewer water | Israeli settlers in the West Bank |
| 1997 | The spread of hemorrhagic virus among the wild rabbit population in New Zealand | New Zealand farmers |
| 1996 | Food poisoning using *Shigella* in a Texas hospital | Hospital lab worker |
| 1995 | Food poisoning of estranged husband using ricin | Kansas physician |
| 1984 | Food poisoning using *Salmonella* in salad bars in Oregon | Rajneeshee Cult |
| 1970 | Food poisoning of Canadian college students | Estranged roommate |
| 1964 | Food poisoning in Japan using *Salmonella* and dysentery agents | Japanese physician |
| 1952 | Use of African bush milk (plant toxin) to infect livestock | Mau Mau |
| 1939 | Food poisoning in Japan using *Salmonella* | Japanese physician |
| 1936 | Food poisoning in Japan using *Salmonella* | Japanese physician |
| 1916 | Food poisoning in New York using various biological agents | Dentist |
| 1913 | Food poisoning in Germany using cholera and typhus | Former chemist employee |
| 1912 | Food poisoning in France using *Salmonella* and toxic mushrooms | French druggist |
| **Threatened use of agent** | | |
| 1984 | Attempt to kill a racehorse with various pathogens (insurance scam); confirmed possession | Two Canadians |
| 1984 | Threat to introduce FMD into wild pigs, which would then infect livestock; no confirmed possession | Australian prison inmate |

*Source:* Carus, *Bioterrorism and Biocrimes*; Parker, *Agricultural Bioterrorism*, 2–21; CNS, "Chronology of CBW Incidents Targeting Agriculture and Food Systems, 1915–2006."

That being said, agro-terrorism could emerge as favored form of secondary aggression that is designed to exacerbate and entrench the general societal disorientation caused by a more conventional campaign of bombings. The mere ability to employ cheap and unsophisticated means to undermine a state's economic base and possibly overwhelm its public management resources give livestock and food-related attacks a beneficial cost/benefit payoff that would be of interest to any group faced with significant power asymmetries.

For at least two reasons, these considerations have particular relevance to the international jihadist movement that is ideologically personified by Al-Qaeda. First, Bin Laden has long asserted that using biological agents in any manner possible to harm western interests is a religious duty beholdent on all Muslims and one that is perfectly inline with religious precepts as set forth by Allah [22]. While the thrust of this message has undoubtedly been toward mass strikes intended to inflict large-scale loss of human life, the ability to pull off audacious operations on this scale is highly questionable given the tactical and strategic set-backs that have befallen Islamist extremists as a result of the Global War on Terror (GWOT) post-9/11.[25] Bioattacks against agriculture, however, would appear to be ideally suited to the operational constraints of the post-9/11 era in that they are cheap, low risk, easy to perpetrate, and well-attuned to the operational capabilities of locally based affiliates acting in a largely self-sufficient, if not fully independent manner.

Second, as discussed agro-terrorism has a genuine capacity to economically disrupt and destabilize. This would fit well with Al-Qaeda's self-declared intention to destroy Washington (and its western allies) through a concerted "bleed to bankruptcy" strategy. Initially enunciated by Bin Laden in 2004, this approach stems from a conviction that the United States is a "paper tiger" that can be crippled simply by removing the key anchors and pillars, which are critical to upholding the integrity of the country's fiscal base [24].[26] More specifically, it is a stratagem that seeks to impose a debilitating asymmetric cost-burden[27] on the American economy through the use of modalities that, while cheap, retain a realistic capacity to trigger cascading, ultimately nonsustainable monetary effects [26]. Disseminating biological agents against agricultural livestock and products would certainly fulfill such a requirement.

[25]These set-backs include the loss of safehaven in Afghanistan, the elimination/detention of senior midlevel commanders and the seizure of terrorist finances. The combined effect has been to transform Al-Qaeda into a movement of movements that has become more nebulous, segmented, and polycentric in nature and one which has, accordingly, been forced to focus on attacks that offer "the course of least resistance". For more on the operational dynamics of Al-Qaeda post-9/11 see [23].

[26]For Bin Laden, the American economy constitutes the principal anchor of a morally bankrupt and dysfunctional western system that he regards has prevented Islam from assuming its "rightful" place as the world's pre-eminent religion and culture.

[27]Al-Qaeda has made much of the economic burden imposed by the GWOT, stressing that for every US$1 spent by the international jihadist movement, US$1 million was being expended by the United States. In many ways this assessment has been borne out. A study by the UK-based International Institute for Strategic Studies (IISS), for instance, calculated the costs of the global war on terror to Al-Qaeda at roughly US$500,000 compared to US$500 billion for Washington (not taking into account budgetary allocations for the war in Iraq). See [25].

# THE GLOBAL FOOD SUPPLY CHAIN

JUSTIN J. KASTNER
*Kansas State University, Manhattan, Kansas*
COBUS L. BLOCK
*University of Wyoming, Laramie, Wyoming*

## 1 INTRODUCTION

Any attempt to understand the global food supply chain and its security must draw on multiple academic perspectives. Indeed, today's multidimensional global food supply chain—which features a range of state and private actors (e.g. producers, consumers, intermediary companies, and a cornucopia of regulatory institutions) and issues (e.g. social, economic, and political concerns)—is best understood using a multidisciplinary approach [1]. Perhaps fittingly, this article is authored by scholars affiliated with the expressly interdisciplinary *Frontier* program for the historical studies of border security, food security, and trade policy (http://frontier.k-state.edu). Drawing on food science, public health, history, political science, economics, and the discipline of international political economy, this article seeks to describe the inherent complexity of the global food supply chain including food security-seeking policies and programs that have been adopted by governments and food companies, external threats including, but not limited to, agroterrorism and bioterrorism, and novel approaches whereby public and private institutions and agents can better manage the safety and security of food supply chains that span borders. The article concludes with outstanding research questions and themes relevant to ensuring the safety and security of the global food supply chain.

## 2 THE GLOBAL FOOD SUPPLY CHAIN: A COMPLEX NETWORK OF INDUSTRY STANDARDS, GOVERNMENT REGULATIONS, AND BUSINESS PRACTICES

In today's globalized economy, food moves along a multisegmented production-to-consumption sequence: from primary producers to processors and manufacturers, to distributors and wholesalers, to retailers, and ultimately to consumers. This supply chain is further complicated when food crosses nation-state borders—perhaps multiple times. At different points, businesses and governments intervene in this flow to ensure food safety and food security.

The term *food security* is oftentimes contested and its meaning debated across history. Although previously food security connoted ensuring enough food for a population, today food security covers many different aspects of the global food supply chain—ensuring a safe, secure, adequate, as well as cost-effective food supply [2]. This comprehensive understanding of food security requires an appreciation that cross-border trade flows

*both* ensure food security through the provision of food imports and, potentially, can threaten food security through the introduction of accidentally introduced or deliberately introduced hazards.

The global food supply chain begins with the production-oriented foundation—agriculture. Agriculture, viewed by some as the "first step" in the supply chain, involves the growing of plants and raising of animals for food and other materials. Multiple countries are involved in agricultural production, and in many agricultural sectors production is concentrated in a relatively small set of geographically large countries. For example, in arable agriculture, China produces the most rice, wheat, and potatoes; the United States grows the most corn (maize) and soybeans (soya); and the Russian Federation produces the most barley [3].

From this, the first step of production is succeeded by a complex network of transportation, processing, manufacturing, packaging, distribution, retailing, and food service institutions. In the United States and elsewhere, history has witnessed the development of multiple laws, agencies, and regulations to help ensure the safety and security of the food supply. Although some countries (e.g. the United Kingdom) have since instituted efforts to consolidate governance (e.g. in the UK Food Standards Agency), others (e.g. the United States) continue to regulate the food supply chain with a litany of institutions and laws—arguably, as many as 15 agencies and 35 laws, depending on how one organizes and counts them [4, 5].

Although agriculture is viewed by some as the "first step" in the global food supply chain, attention is also due to those economic and technological realities at work that make agriculture—and, indeed, the subsequent steps of the global food supply chain possible—possible in the first place. Both economic forces (often through the form of foreign direct investment) and technology represent kinds of "prerequisites" that help ensure not only the production of food but also its distribution, safety, and security. In this regard, an historical perspective is illustrative. During the late nineteenth century, the agricultural production capacity of the United States expanded due in part to the provision of capital in the US agricultural enterprises. From ranches and meat-packing to farms and milling, Great Britain helped plant the seeds for food supply chains that would bring, to Britain and elsewhere, foodstuffs from the United States [6]. British investment in railroads and steamship transportation also assisted in the enabling of a supply chain that, in effect, helped ensure the provision of enough food for a growing British population [7]. The reality of foreign direct investment shows that there are, upstream from agricultural production, economic elements in the food supply chain.

Downstream from investment and agricultural production, one sees food transverse state borders. The volumes of food produced, exported, and imported are such that 100% inspection by food safety and food security officials is, quite simply, not possible [8]. Therefore, risk management—oriented approaches are needed. In recent history, many food companies and governments have adopted, for example, Hazard Analysis and Critical Control Point (HACCP) systems that can be used to manage risks in both domestic and global food supply chains. Broadly, the principles of HACCP were adopted in the United States and European Union (EU) in 1992 and 1993. The Codex Alimentarius Commission, which is one of the three food-trade standard-setting bodies recognized by the World Trade Organization (WTO), adopted HACCP principles in 1993 [9]. Since 1993, countries and companies across the globe have embraced HACCP through regulations as well as business practices.

Although HACCP deals with biological, chemical, and physical hazards in the food system, it does not necessarily ensure another key element of supply chain security: traceability and in-plant security. In a 2007 food industry magazine, Alan Naditz cites Washington State University food-bioterrorism expert Dr. Barbara Rosco Washington State University, in this regard; food-supply chain security requires knowledge of both the origin and status of food products and the only way to ensure that is to have robust programs that can trace food and ensure food-plant security [10]. Not surprisingly, recent years have witnessed ramped-up efforts to institute animal identification and crop traceability programs, as well as food defense planning designed to ensure food-plant security.

## 3 THREATS AND CHALLENGES TO THE NORMAL FUNCTIONING OF THE GLOBAL FOOD SUPPLY CHAINS

The global agricultural and food trade, long recognized as one of the most contentious areas of world economic affairs [11], has become more problematic as concerns about agroterrorism and bioterrorism have elicited new governmental regulations and business practices. In addition, health-protection regulations have spawned trade disputes,and previously excluded social considerations have entered into regulation and marketing activities along the global food supply chain. Today, economic and liability pressures are increasingly felt "upstream" in the supply chain. The example of China illustrates many formidable food-security challenges.

### 3.1 Agroterrorism and Bioterrorism

Since the terrorist attacks on the United States on September 11, 2001, renewed attention has come to the twin issues of "agroterrorism" and "bioterrorism." In this regard, the following definitions, courtesy of the Center for Food Security and Public Health at Iowa State University, offer an introductory explanation:

*Agroterrorism.* The use, or threatened use, of biological (to include toxins), chemical, or radiological agents against some component of agriculture in such a way as to adversely impact the agriculture industry or any component thereof, the economy, or the consuming public [12].

*Bioterrorism.* The use of microorganisms or toxins derived from living organisms to cause death or disease in humans, animals, or plants in civilian settings [13].

Agroterrorism threatens a nation-state's food security because it targets the ability of that nation to produce food—namely, the early production step in the food supply chain. An agroterrorist attack could, conceivably, lead to economic chaos in the form of higher food prices, unemployment, and disruption of international trade flows. Agriculture in geographically large countries is what security theorists term a *soft* target; it is virtually impossible to guarantee the protection of such geographically vast elements in the food supply chain. Bioterrorist attacks on the global supply chain involve intentional introduction of hazards into the food supply.

Concerns with agroterrorism and bioterrorism have spawned policy and regulatory responses by nation-state governments, worldwide. In 2002, the US Congress passed the *Public Health Security and Bioterrorism Preparedness and Response Act* (Bioterrorism Act). The Bioterrorism Act's third section, entitled "Protecting Safety and Security of Food and Drug Supply," granted new powers to the US Food and Drug Administration (FDA). These included the ability to detain suspect food import shipments and the

authority to mandate companies manufacturing food for US consumption to register their facilities. The US Department of Agriculture (USDA) Food Safety and Inspection Service, which regulates the meat and poultry industries, already had many of these new powers. Because of the Bioterrorism Act, the FDA can now detain food shipmentsif evidence indicates that they present a threat to humans or animals. Also, largely due to the 2002 Bioterrorism Act, hundreds of thousands of facilities—in the United States and abroad—must register with the FDA.

In addition to registration and detention authorities, the 2002 Bioterrorism Act has incorporated new regulatory steps into parts of the global food supply chain that cross the United States. The "prior notice" provision of the Bioterrorism Act requires that food companies notify the FDA of all food import shipments; the prior notice regulation is intended to help the FDA better manage risk. The detailed information submitted via "prior notice" is used by the FDA so they can better deploy resources to conduct inspections (e.g. targeting inspection resources toward new or unfamiliar food-shipping firms) and intercept contaminated products.

The Bioterrorism Act's food security provisions also included the development of new regulatory categories for threats and agents. The new categories address specific regulatory authorities. Department of Health and Human Service (HHS) agents include select agents, such as Ebola virus and *Yersinia pestis*, as well as toxins such as ricin; HHS has the sole authority over these agents. USDA-only agents include agents, such as foot and mouth disease virus and rinderpest virus that may affect animal or plant products; the USDA has the regulatory purview over these agents. Thirdly, overlap agents, including, for example, *Bacillus anthracis* (anthrax), may be subject to regulation by either or both HHS and USDA.

### 3.2 Trade Disputes Regarding the Use of Sanitary and Phytosanitary Measures

Global food supply chains have, in recent years, been complicated by disputes over import regulations related to sanitary (food safety and animal health) and phytosanitary (plant health) import-restricting measures. At the close of the twentieth century, transatlantic tensions over EU restrictions on the importation of North American beef produced with growth promoting hormones culminated in the first WTO ruling under the terms of the *Agreement on the Application of Sanitary and Phytosanitary Measures* (SPS Agreement) [14]. While typically adopted by governments to protect health, sanitary and phytosanitary regulations present a new kind of challenge for the global food supply chain; they offer a means by which nation-states can restrict trade under the guise of health protection [15].

International policy differences related to safety of genetically engineered organisms in food have also caused great consternation within supply chains [16]. In addition to fueling trade rows between, for example, the United States (US) and the EU, the GE issue has encouraged the adoption, in some countries, of technical standards designed to help companies ensure they are supplying and receiving food ingredients and products with especially particular (e.g. non-GE) specifications [3, pp. 95–96].

### 3.3 Social Regulations and New Upstream Pressures in the Global Food Supply Chain

The transatlantic divide over biotechnology policy, concurrent with a transatlantic rift of consumer views regarding GE foods, points to a broader trend within the global food supply chain: the adoption of business practices and government regulations that, for some, might be deemed as social regulations [16].

Today's food-trade agenda is increasingly dominated by such issues related more to production process preferences (e.g. organic agricultural practices) than end-product safety and security. (Organic agricultural practices, which are defined differently by different companies and nation-state governments, generally involves a system of farming that promotes "natural" rather than "artificial" forms of pest and disease controls and fertilizers [3].) Global activist and consumer-advocacy groups have exerted tremendous influence on companies—especially retailers in Europe—and a web of private and government standards have developed to cater to the organic and GE-free sentiments of consumers. Lamentably, this has resulted in some alarming consequences within the global food supply chain; for example, in 2002 shipments of North American food aid produced using GE technology were subject to import restrictions in Zambia, even during a time of famine and starvation [17]. Scholars writing for the *African Journal of Biotechnology* maintain that a balanced approach to the regulation of GE foods regulation is required [18].

Other upstream pressures—most notably, liability forces mediated by class-action and other lawsuits—are increasingly influential in the global food supply chain. As foodborne disease surveillance data has become more plentiful, and as public health authorities have become better adept at identifying sources of outbreaks, large-scale lawsuits have exerted new kinds of pressure upstream toward the agricultural production end of the food supply chain. The 2006 outbreak of *Escherichia coli* O157:H7, which cost the spinach industry millions of dollars through costs including, but not limited to, lawsuits, prompted produce-oriented firms to look further upstream and enhance microbial testing of irrigation water, soil amendments, and plant tissues [10].

### 3.4 Traceability and Transparency: the Example of China

China plays an important role in the global food supply chain as both a producer and a consumer. With 1.5 billion consumers, providing enough food in China represents a major policy challenge [19]. China is also a major exporter of agricultural and food products, including seafood that, in recent years, have fueled worries about food safety and security [20]. While countries in the developing world (e.g. the United States and Japan) that import products from China have cried for improved regulations, the growing "middle class" in China is also demanding better food, and higher safety levels. As told in a recent commentary by a *Frontier* research assistant studying food security and trade issues there, China is experiencing pressure from *both* foreign markets and its own people to offer a safer supply of food. To that end, a more secure food supply chain will be needed. Multiple challenges—amongst others, traceability, transparency, and time—require the attention of the Chinese government and agriculture and food sector. With 300 million low-income farmers, cash-based recordless transactions and slow distribution channels make it presently difficult to ensure supply chain traceability, as well as accurate records required for transparency, food quality, and business efficiency [21].

## 4 NOVEL APPROACHES TO MANAGING SUPPLY CHAINS ACROSS BORDERS

The multilateral trading system's framework for governing the global food supply chain features institutions and agreements that offer opportunities for uniquely managing food

security threats in international trade. Under the WTO *Agreement on the Application of Sanitary and Phytosanitary Measures* (WTO Agreement), WTO member countries have the right to establish regulatory measures to protect animal, plant, and human health on the basis of scientific principles; to facilitate trade, WTO members are encouraged to follow standards and guidelines developed by three international scientific standard-setting bodies (i.e. the World Organization for Animal Health (OIE), the Codex Alimentarius Commission, and the International Plant Protection Convention (IPPC)), often termed the *three sisters* [22].

The concepts of "regionalization" (also known as *zoning*) and "compartmentalization" are affirmed by the WTO, the SPS Agreement, and the three sisters. Both concepts present internationally endorsed means by which nation-states can preserve trade relations when sanitary (human or animal health) or phytosanitary (plant health) hazards threaten a country's trading status; however, the concepts are often difficult to implement. Because global agricultural biosecurity and food-safety concerns (such as highly pathogenic avian influenza, foot and mouth disease, and bovine spongiform encephalopathy (BSE)) persist, regulatory and business stakeholders have become increasingly interested in certifying subnational geographic disease-free zones (i.e. regionalization) as well as biosecure establishments, supply chains, and/or animal subpopulations (i.e. compartmentalization) for international trade.

Helpful definitions for the key terms for trade policy concepts of regionalization and compartmentalization include the following:

- *Zone/region.* A clearly defined part of a country containing an animal subpopulation with a distinct health status with respect to a specific disease for which required surveillance, control, and biosecurity measures have been applied for the purpose of international trade.
- *Compartment.* One or more establishments under a common biosecurity management system containing an animal subpopulation with a distinct health status with respect to a specific disease or specific diseases for which required surveillance, control, and biosecurity measures have been applied for the purpose of international trade [23].

Member countries of the OIE and WTO have, for years, used regionalization by defining disease-free areas with respect to, for example, particular animal diseases (foot and mouth disease, brucellosis, etc.). For example, both the USDA Animal and Plant Health Inspection Service and the EU Food and Veterinary Office have evaluated applications from trading partners seeking to certify, for trade purposes, disease-free regions or zones from which they can export animal products to the United States and EU.

The concept of compartmentalization is a recent addition to the OIE codes and "extends the application of a 'risk boundary' beyond that of a geographical interface and considers all epidemiological factors that can contribute to the creation of an effective boundary" [23, p. 873]. Compartmentalization may be applied to specific herds, feed supply chains, establishments, premises, etc. A disease-specific compartment might include a cattle establishment defined as a *bovine spongiform encephalopathy* free compartment through demonstrable feed source management, animal movement documentation, and livestock identification [23].

Interest in compartmentalization is growing. 2006 witnessed the development of general considerations for implementing compartmentalization. These guidelines include the

following factors: (i) the nature or definition of the compartment, (ii) epidemiological separation of the compartment from potential sources of infection, (iii) documentation of factors critical to the definition of the compartment, (iv) supervision and control of the compartment, (v) surveillance for the agent or disease, (vi) diagnostic capabilities, and (vii) emergency response, control, and notification capability [23]. Compartmentalization provides a unique opportunity for vertically integrated elements of the global food supply chain to, through business practices and regulatory oversight, insulate themselves from biosecurity problems experienced elsewhere.

## 5 FUTURE RESEARCH NEEDS

The global food supply chain will continue to develop by research and development (indeed, innovation and investment) into technologies that can help provide security. Among other research areas, how best to provide supply chain traceability and in-plant security are salient research questions. The trade policy concepts of regionalization and compartmentalization represent ways whereby governments and businesses (the key state and private actors involved in international trade) can better cooperate along the food supply continuum. However, important research policy questions remain. These include the following.

1. What challenges and opportunities do food companies perceive in the implementation of the concepts of regionalization and compartmentalization?
2. How are government policies, regulations, and workflows responding to regionalization and compartmentalization?
3. How can all actors involved with the global food supply chain work better together to ensure security?
4. How might tools such as traceability systems help develop compartmentalized segments of the global food supply chain?

# ECONOMIC IMPACT OF A LIVESTOCK ATTACK

AMY D. HAGERMAN, BRUCE A. MCCARL AND JIANHONG MU
*Texas A&M University, College Station, Texas*

## 1 INTRODUCTION

Livestock are a potentially vulnerable target for the introduction of animal disease-causing agents. Large events have occurred from apparently inadvertent introductions. For example:

- A 2001 UK Foot-and-Mouth Disease (FMD) outbreak led to the slaughter of 6.1 million animals [1]
- A Bovine Spongiform Encephalopathy (BSE) outbreak in the United Kingdom between 1994 and 2004 was associated with over 151 deaths [2]
- Avian Influenza (AI) outbreaks in China since 2003 have been associated with up to a 25% reduction in poultry trade and over 25 deaths [3].

Such vulnerability raises the issue of exactly how vulnerable we are and what types of pre-event action and/or planning can be done to limit risk and bolster resiliency. This article reviews a number of economic aspects related to these issues.

## 2 THE IMPORTANCE OF CONSIDERING ECONOMICS

Often, recommendations on the management of animal disease is based primarily on epidemic simulation models that minimize the time to control disease outbreaks by limiting the disease spread while treating or removing infected animals. After the 2001 UK FMD outbreak, such modeling was termed "armchair epidemiology" and was strongly criticized [4]. The reason for the criticism was the policy of contiguous herd slaughter used in addition to the slaughter of infected and dangerous contact herds, which was considered by many to be excessive since this caused unnecessary long term damage to the livestock industry. Following the outbreak, the United Kingdom exhibited a declining trend in animal agriculture [5] that indicated that some producers instead chose to scale- or shut-down operations.

Animal disease impacts extend beyond the number of dead animals. A strategy chosen solely because it quickly "stamps out" the disease may not be the strategy that minimizes the total economic impact in either the short or long run. It should be noted at this point that neither can economics alone be used to determine optimal response strategies to animal disease. Rather it is a combined approach using an integrated epidemic-economic model that should be used for this type of analysis.

Ideally, this integrated approach would be dynamic and spatial in nature, [6] taking into account both, the time it takes to control the disease and the economic implications of the control strategies chosen. Control strategy efficacy can be measured in terms of lost animals and direct costs of disease management as well as national welfare losses, short- and long-term trade losses, environmental consequences, consumer demand shifts, and local impacts in terms of average affects and the distribution of effects. The economic portion of the analysis can capture some or all of these loss categories and integrate them into a single measure used to quantify the distribution of outcomes from an animal disease outbreak in a particular region. The reason economic models have not been more extensively used in the past is the difficulty in developing a model that can quantify those impacts that extend beyond the primary livestock markets.

## 3 ECONOMIC IMPACT CATEGORIZATIONS

Economic impacts can be divided into two categories: direct and secondary. Most studies examining livestock disease have focused on direct impacts of the disease. Due to the highly integrated nature of the modern economy, consequences of agricultural contamination at any given point along the supply chain could be manifested in other sectors of the economy as well. For example in the recent foot FMD outbreak in the United Kingdom, the largest category of losses came from tourism. Such losses are termed secondary losses.

The losses that should be examined in any given epidemic-economic study will vary depending on the type of disease, species of animals impacted and the importance of those species to the economy, as well as regional and international animal disease policies.

### 3.1 Direct Losses

Direct losses accumulate to the livestock sector as a direct consequence of an animal disease attack. This category of losses has received the most attention due to the ease with which they can be quantified, particularly for the supply side. Direct losses are also of interest in establishing the cost of a particular response policy from the viewpoint of a governing agency.

***3.1.1 Lost Animals and Changes in Animal Value.*** The most obvious direct loss is the number of animals or herds that are removed from the supply chain due to the disease. This may arise from massive preventative slaughter, as in the case of FMD, or death due to the disease itself, such as with BSE. It also captures increased culling and abortion in animals for production operations, as would be the case with Rift Valley Fever.

The value of animals lost can be calculated using a schedule of market values based on pre-disease market conditions. This is often the method used in studies for calculating indemnity payments to producers from preventative slaughter. There are two issues with using this method. First, it does not recognize the role of livestock as a capital asset [1]. In particular for purebred animal producers, the value of an animal represents an investment in genetic improvements that may not be accounted for in a per pound cash market value as it would for a commercial animal. Second, producers who have animals not infected but expecting to absorb the full revenue loss from a negative price change may be tempted to claim their herd has been in direct contact with infected herds in order to collect a

higher price per unit. It is suspected that the payout schedule was set too high in the 2001 FMD outbreak, leading to slaughter levels greater than necessary for disease control [7].

Welfare slaughter is an issue that has not received much attention in the literature, but has proven to be a real issue in historical animal disease outbreaks that include quarantine zones and strict movement restrictions. These policies may prevent feed grains and premade feeds from being shipped into the restricted regions plus movement of animals to feeding or other operations. For enterprises employing confined feeding or those raising young animals previous to feeding, the amount of feed on hand and facilities to keep animals beyond normal movement times may be insufficient to allow the animals to be kept. This leads to additional slaughter, and consequently higher indemnity payment levels to producers. As discussed in previous sections, producers expecting lower prices for animals post-outbreak may volunteer animals for welfare slaughter to prevent additional price change losses.

***3.1.2 Costs of Disease Management.*** The direct costs of disease management account for the resources required for response to the disease outbreak including the cost of vaccination, slaughter, disposal, cleaning, disinfecting, and administrative costs. This would include cost for labor, equipment, and materials [8]. The market price changes will also impact the losses producers face. Prices could change as a result of the supply shift caused by slaughter of live animals, the destruction of milk, meat, and meat products ordinarily destined for the market and the time lag for operations to return to full production. Some studies have assumed prices do not change at the national level, but this would only be the case in a very small disease outbreak that does not change the aggregate national supply or affect demand.

Another cost producers absorb is the loss in quality from withholding market-ready animals from slaughter. The additional time to slaughter causes carcasses to be too large or not be at the optimal level of conditioning to achieve one of the premium grades, which leads to carcass discounts. For some diseases, in order to ship meat products out of the region where the infection occurs, carcasses must either be processed into cooked meat products to kill the disease-causing agent or be put in nonhuman consumption products such as pet food.

Carcass disposal becomes a serious issue in a disease outbreak, resulting in large-scale animal mortality or large-scale slaughter. Factors such as environmental regulations and public health impacts will also determine the disposal method hierarchy established [9] in addition to the cost per unit for disposal and the time required to dispose of all carcasses. The type of control strategy employed can also affect the carcass disposal method chosen since it will, hopefully, reduce the number of dead animals [10].

***3.1.3 Trade Losses.*** Animal disease often has significant impacts on international trade. Outbreaks in the last decade have increased the volatility in international meat markets through their effects on consumer preferences, trade patterns, and reduced aggregate supply [11]. Upon confirmation of an animal disease outbreak, restrictions are often placed on where livestock and meat products can be exported as well as what products are shipped. The extent of these damages will vary by disease and country, but in general countries experiencing an animal disease outbreak will experience immediate restricted international trade due to domestic supply changes and world demand shifts until the infected country is shown to be disease free for a predetermined amount of time. Domestic market impacts may be partially offset by imports [1].

If the disease is not carried in the meat, localized cuts in production will reduce the livestock and meat products available for export. In addition, movement restrictions in the country will prevent normal supplies from reaching the market, and export restriction shift meat normally shipped overseas to domestic supply [1].

If the disease is carried in the meat, it either must be cooked to destroy the organism or it must be removed from the meat supply chain. Avian influenza has affected the international poultry market reducing trade by at least $10 billion per annum [12]. As a result of Highly Pathogenic Avian Influenza (HPAI), Thailand lost its position as the worlds' fifth largest exporter of poultry meat and Brazil replaced China and Thailand as the world's largest supplier of frozen raw chicken products [12, 13]. Upon confirmation of BSE in the United States in 2003, more than 50 countries either completely stopped beef exports from the United States or severely restricted them resulting in beef exports at only 20% of the previous year's levels [14].

Even in the case of diseases that can be transferred to humans through the meat, markets have historically been found to recover within two years; however, the nation that experienced the outbreak may take longer to recover their share of the world market [11]. At particular risk are developing countries.

***3.1.4 Additional Direct Costs Associated with Zoonotic Diseases.*** In the case of zoonotic diseases (diseases that can be transferred to humans through direct exposure to the animals, disease transfer vectors like mosquitoes, or through meat consumption), several additional direct costs are accumulated. When humans can become infected from a disease, there are additional healthcare costs and loss in productivity resulting from sickness and death to be considered. In addition, reduced meat consumption will occur while meat recalls are in place in order to prevent infection. Examples of zoonotic diseases that have been under world scrutiny recently are BSE and Avian Influenza. In the 2003 US BSE case, negative price impacts may have been enlarged because of decreased consumer confidence in beef products, although that effect was short-lived [14].

## 3.2 Secondary Losses

Secondary losses are less easily quantified, but ignoring them in a study can lead to severe under-estimation of the total cost of the outbreak. These studies are often done separately from the integrated epidemic-economic model analysis; however, they should ideally be included in the integrated model as much as possible. In some cases, such as environmental costs and psychological costs, the estimation may have to be done separately.

***3.2.1 Related Industries.*** Disease outbreaks can have effects that extend well beyond the meat production chain [2]. While industries directly in the meat production chain will typically experience the greater loss and have consequently been the focus of disease outbreak economics literature, little work has been done to ascertain the impact on service industries linked to the meat industry. A good example is the feed industry. In countries with large concentrated animal feeding operations, such as the United States, a significant source of demand for feed grains is represented by livestock demand. Disease outbreaks leading to large-scale animal mortality will reduce the domestic demand for feed grains. In addition, movement restrictions in the quarantine zone will restrict not only the transport of livestock but the transport of feed grain supply trucks or unit trains coming into or out

of the region. These disruptions and demand shifts will be reflected in the price of feed grains. Other industries that would be impacted by a disease outbreak are transportation, veterinary service, supply industries, and rendering services [2].

*3.2.2 Local Economies.* Disease outbreaks will have the greatest per capita impact on the area where the outbreak occurs. Local producers whose premises are depopulated must wait to rebuild their operation, removing the money that would have been spent on feed, supplies, and livestock-related services at local businesses. Movement restrictions divert commercial and tourist traffic coming through the region, removing income to local businesses like gas stations, hotels and restaurants. Businesses may choose to shut down or livestock operations may opt not to repopulate, decreasing the number of jobs available to local residents. Alternatively, the process of controlling the disease may provide some increased local employment but this would be short-term only.

In the 2001, FMD outbreak 44% of the confirmed cases occurred in the county of Cumbria [15]. Farmers and businesses in the county were surveyed after the outbreak to ascertain their losses. Although 63% of farmers in the county said they would continue farming, only 46% planned to build back up to their previous level of operation. There was an estimated direct employment loss of 600 full-time jobs and an indirect employment loss of 900 jobs [15].

Depending on the area of the country impacted by the animal disease and the size of the outbreak, tourism can represent a serious source of secondary losses. Returning to the Cumbria county survey, after the 2001 UK FMD outbreak, the loss in gross tourism revenues in that county were expected to be around £400 million. Reports predicted the recovery of the county economy would largely depend on the long-term recovery of the tourism industry [15]. On a national level, tourism was the largest source of losses related to the FMD outbreak at £2.7 to £3.2 billion [1].

Page et al. [16] observed that Avian Influenza could have significant shocks on tourism and McLeod et al. [13] estimated that the 2004 AI outbreak in Vietnam led to a 1.8% decline in GDP, where a 5% decline in tourist arrivals could lead to an additional 0.4% decline in GDP [17]. Furthermore, Kuo et al. [18] found that Asian tourism demand is reduced by about 74 arrivals after an AI incident and this reduction was greater than the impact of AI on global tourism.

*3.2.3 Environmental.* There are two primary environmental impacts related to animal disease outbreaks: water and air quality. Ground water can be negatively impacted by disease carcasses being buried in areas where materials can leach from decomposing carcasses. Preventing this could restrict the amount of on-farm burial in the event of an animal disease outbreak, leading to additional spread risks by moving animals to suitable sites or delays in disposal by alternative methods. Water quality is also impacted by runoff from cleaning depopulated premises and from dumping infected milk as a result of movement restrictions. In a study of the 2001 FMD outbreak in the Netherlands, the illegal discharge of milk into sewage systems, rivers and smaller waterways led to a high to very high probability of spreading the disease to other cattle operations within 6–50 km of the dump site [19].

Air quality can be impacted when animal pyre burning or curtain burning of carcasses is employed. Curtain burning is preferred since it reduces the emissions into the air, but it is not always feasible since it requires more time and resources than pyre burning [9]. Studies in the United Kingdom, where pyre burning was used extensively at one

point in the outbreak, have examined the levels of dangerous compounds in livestock, dairy products, and eggs produced nearby. Slight increases in concentrations of dangerous compounds were found in lamb, chicken, and eggs, but these were not samples destined for the food chains. In milk, dangerous compound concentrations were within acceptable ranges. Overall, the study concluded that there is no evidence that the pyres were responsible for contaminating food produced in that region [20].

Human health has been another concern related to air quality. Pyre burning releases considerable amounts of ash and pollutants into the atmosphere that can be breathed in by carcass disposal workers and local residents. A study in Cumbria county in the United Kingdom found that levels of respiratory irritants, although elevated above normal levels from the pyres, did not exceed air quality standards or exceeded them by very little. Furthermore, the pollutants were unlikely to cause damage to all but the most sensitive individuals (e.g. asthmatics and those with weak lungs) [21].

***3.2.4 Demand.*** Consumer demand response comes from two sources in an animal disease outbreak. The first is the easier of the two to quantify, the adjustment in consumption patterns from price changes. Historically, consumers have experienced a small net loss in overall welfare although this is partially offset by lower domestic prices [1]. The second impact is substitution in consumption patterns as a result of changes in consumer confidence. How much of an impact reaches consumers depends on several factors such as industry organization, consumer demographics, and information release policies.

*3.2.4.1 Industrial Organization.* In countries with complex meat supply chains, such as the United States, Australia, and Europe, the extent to which consumers are impacted will depend on the number of bottlenecks in the supply chain and the level of vertical integration. In the United States there are a few meat-packers controlling a large portion of the livestock being processed [22]. This market power means greater pressure could be placed on producers and possibly consumers under an animal disease event. There is a greater vulnerability to that industry if one or more of those packers is forced to shut down during the outbreak or permanently remain shut. This would most likely have a greater impact on farmers than consumers.

In addition, the growing popularity of value-added or ready-to-eat meals means most of the value of the product on the grocery store shelf is from the inputs other than the raw agricultural product. This means a lessened sensitivity of prices consumers face in the grocery store due to shocks at the farm level [2]. While this could have an influence on the price change consumers face, industry organization is not likely to be a factor in consumer confidence.

*3.2.4.2 Consumer Demographics.* Considerable work has been done on the factors influencing demand for meat in the United States, Europe, and more recently Asia. In general there are differences in attitudes toward meat quality and safety, which means actual consumer response will vary on a case-by-case basis for animal disease outbreaks. Consumer response to BSE has had long-term negative effects in Europe and Japan [2]. In France, Adda [23] examined the effect of past risk exposure for beef consumers. Consumer sensitivity to food safety concerns has been heightened by past risk exposure leading to decreased demand for meat from consumers who previously consumed medium to small amounts of beef and an increased demand in those groups for high quality meat products. In the United States, responses to food safety concerns is small,

particularly in comparison to price effect sensitivity [24]. As the result of AI, there are losses of consumer confidence and losses of competitive strength of poultry meat in the meat market [25].

A limited amount of work has been done on willingness to pay by consumers for animal disease prevention activities like traceability and country of origin labeling. Willingness to pay for disease control could potentially be impacted by consumer demographics and risk perception as well. In order to guarantee the safety of poultry meat, providing the traceability label of poultry products is suggested as one of the incentives for farms and marketing firms to supply safer food [26, 27] and estimated results from the research done in China found that consumers in Beijing, on average, had stated a significant willingness to pay (WTP) for traceability of poultry products which was approximately 9-10% of the base price [28].

*3.2.4.3 Information Release Policies.* Considerable work has been done on the impact of information release policies in the event of a food safety risk. Pope [29] found transparency on the part of the government and industry, in the event of an animal disease outbreak, reduced negative consumer response in Canada after the 2003 BSE outbreak [2]. In the UK, a "food publicity index" was used to show the inward shift in consumer meat demand after the 1996 BSE outbreak was influenced by the publicity surrounding the outbreak [30]. Although AI information has relatively small impacts on meat demand, its effects would last three months and indeed decrease the demand for turkey and increase the demand for beef in the US meat market [25].

## 4 EPIDEMIC-ECONOMIC MODEL DEVELOPMENT

As stated earlier, to estimate potential economic losses of agricultural contamination from infectious animal disease spread, an integrated epidemic-economic model is needed. Epidemic simulation information is necessary to evaluate the extent of the physical damages [31, 32] and evaluate economic costs of a potential outbreak in an integrated framework. The type of economic model used will vary depending on several factors such as the geographic scope of interest (farm, region, nation, or world), economic factor of interest (employment changes, price changes, or trade changes) and the extent of damages expected from a particular disease.

Such integrated models are primarily used to predict what would happen in the event of an outbreak of a specific disease in a specific region, or to assess the sensitivity of an outbreak to various control strategies. Models should capture both, the recovery over multiple time periods from the outbreak over the period of restocking and, recovering trade relationships to the time of full recovery. Furthermore, they should capture the geographic implications of the disease in terms of spread to other regions or countries [6]. Moreover, to assess risk through both the epidemic portion of the model and the economic portion, the iterations from the epidemic portion may be run through the economic portion as statistically independent trials. This is opposed to the standard practice of running only the averages from the epidemic model through the economic model.

The stochastic parameters in the epidemic model deal with the rate of disease spread and the effectiveness of control strategies. The spread rate of an infectious disease will determine the severity of economic damages and the appropriate combination of necessary prevention and response actions. Prevention is perhaps the most desirable policy

option for livestock disease attacks. Some examples of these policies include employing antimicrobial livestock drugs and vaccination, storage and transportation facility security, and trade inspection. The purpose of prevention activities is to decrease the probabilities of intentional or unintentional agricultural contamination incidents. Response, control and recovery actions are indispensable policies in the face of agricultural sabotage. Essentially these policies are focused on minimizing damages by stopping the spread of a possibly infectious contamination and minimizing the scope of the sabotage, as well as fixing the source of the sabotage, restoring and replacing the lost livestock branches in the food supply chain, and rebuilding consumer confidence.

## 5 CONCLUSION

Thorough, in-depth studies that include the costs of animal disease and evaluate both vulnerability and the consequences of control strategies, giving implications for livestock death loss and wider economic costs, allow for a greater degree of preparation, effectiveness of response, and faster recovery. This article has given an overview of the economic impacts of an animal disease attack and the approach to appraisal thereof. We also discuss multiple areas that have received little attention.

Thorough analysis requires collaboration, drawing on expertise from epidemiology, sociology, biology, and economics. This level of collaboration is difficult, but indispensable in dealing with the necessary issues. Also key to a quality economic assessment is the integration of models and the identification of the right economic impact categories for the disease and region of interest.

# SOCIAL, PSYCHOLOGICAL, AND COMMUNICATION IMPACTS OF AN AGROTERRORISM ATTACK

STEVEN M. BECKER

*University of Alabama at Birmingham School of Public Health, Birmingham, Alabama*

## 1 INTRODUCTION

As policy makers, the agriculture sector, researchers, emergency planners, and communities prepare to meet the enormous challenge posed by agroterrorism, increasing attention

has been devoted to such critical issues as field and laboratory detection, surveillance, mapping, improved outbreak modeling, vaccine development and improvement, and disposal and decontamination options. Far less consideration, however, has been given to social, psychological, and communication issues. Yet, the manner in which these issues are approached will be one of the principal determinants of an agroterrorism event's outcome. The ultimate aim of an agroterrorism attack, after all, is not to harm crops or ruin agricultural products; rather, it is to destroy confidence in the food supply and in societal institutions, create fear and a sense of vulnerability in the population, reduce people's hope and resolve, and weaken the society and the nation. Effectively addressing key social, psychological, and communication issues will be crucial to the success of quarantines or other mitigation measures, and to efforts to minimize exposure to threat agents, reduce the impacts of an incident, maintain public confidence and trust, and better assist affected individuals, families, and communities [1]. It is no exaggeration, therefore, to say that social, psychological, and communication issues constitute "make or break" factors in any effort to manage an agroterrorism event. Without sufficient attention devoted to these issues, "response efforts after a terrorist attack might be successful in narrowly technical terms but a failure in the broader sense. In effect, the battle might be 'won,' but the war would be lost" [2, p. 16].

## 2 LEARNING FROM THE 2001 FOOT-AND-MOUTH DISEASE OUTBREAK

Among the best ways to understand the nature and extent of the social, psychological, and communication challenges that an agroterrorism attack could pose is to learn from recent experience with large-scale disease outbreaks. In this regard, the 2001 foot-and-mouth disease outbreak in the United Kingdom is probably the most instructive. Although the 2001 outbreak was not the result of terrorism, it "presented unprecedented challenges which no one in any country had anticipated" [3, p. 6]. This included a host of serious social, psychological, and communication impacts. In addition, because of the open, forthright and thorough way that British society has examined the successes and failures in the handling of the epidemic, others have a rich opportunity to learn from this experience.

Foot-and-mouth disease is a viral disease that mainly affects cattle, pigs, goats, and sheep. Its symptoms include fever, vesicles (blisters) in the mouth or on the feet, pain, lameness, loss of appetite, and loss of condition [4]. The virus can survive for long periods of time and is powerfully contagious. Indeed, foot-and-mouth disease has variously been described as "the most contagious of all diseases of farm animals" [5, p. 2], "the most feared infection of domestic livestock" [6, p. 1], and "the most contagious disease of mammals" [7, p. 425]. Not only can animals be infective without displaying signs of the disease, the virus can also be transmitted in a host of ways. "The virus is present in fluid from blisters, and can also occur in saliva, exhaled air, milk, urine and dung. Animals pick up the virus by direct or indirect contact with an infected animal. Indirect contact includes eating infected products and contact with other animals, items or people contaminated with the virus, such as vehicles, equipment, fodder and anyone involved with livestock." [8, p. 13]

The rapidity with which the 2001 epidemic spread was astonishing. British officials estimate that by the time the virus was confirmed on February 20, some 57 farms in 16 counties had already been infected. By February 23, when a movement ban was imposed, 62 more premises were thought to have been infected, involving seven more counties

[8, p. 14]. In addition, the scale of the outbreak was remarkable. At the height of the crisis, "more than 10,000 vets, soldiers, field and support staff, assisted by thousands more working for contractors, were engaged in fighting the disease. Up to 100,000 animals were slaughtered and disposed of each day" [8, p. 1].

By the time the outbreak ended—221 days after it began—the toll was enormous: animals were slaughtered at more than 10,000 farms and related agricultural premises in England, Scotland, and Wales. Approximately 2000 locations were "slaughtered out" because foot-and-mouth disease had been confirmed there, while another 8000 were targeted either because they neighbored an infected farm ("contiguous culling") or because it was suspected that animals could have been exposed to the virus ("dangerous contacts"). While efforts were made to reduce pain and suffering, there were all too many situations where this aim was not achieved due to the scale of the operation and a shortage of trained personnel. Reports of frightened animals taking flight, animals being wounded, or animals being shot multiple times were not uncommon. Piles of dead animals awaiting disposal were a regular sight in affected areas, particularly in the early days of the culling operation; so, too, were trenches where carcasses were buried and "funeral pyres" where carcasses were burned. In the end, the total number of animals slaughtered for disease control purposes was staggering—over 4.2 million. Beyond that, 2.3 million other animals were slaughtered under "welfare provisions" because strict movement restrictions in affected regions made it impossible to get feed to them.

People living in the midst of the epidemic and associated carnage were hit hard emotionally, as when farms that had been in the family for generations were wiped out or when children's pets were required to be slaughtered. In addition, people were battered economically. Agricultural communities, including farmers and their families, people employed in agriculture, and area businesses, saw livelihoods and financial security disappear virtually overnight. Tourism—a vital industry in many of the affected areas—dropped precipitously, causing even greater economic damage and dislocation. Before the outbreak finished, it had even gone international, spreading to a limited extent to France, the Netherlands, Northern Ireland, and the Republic of Ireland [3, 8].

It is common in most disaster situations for people's responses and reactions to be marked by resilience and helping behaviors. The foot-and-mouth epidemic was no exception. Many communities remained united in the face of the invisible threat and there were countless acts of assistance and support. Amongst farmers and farming families, there was a continuing commitment to agriculture as a way of life despite the tremendous difficulties caused by foot-and-mouth disease [9]. In addition, many veterinarians and other professionals endured difficult conditions and went above and beyond the call of duty to help bring the outbreak under control. Finally, there were many examples of public sympathy and support for affected farmers and farming communities. People in the Southwest and other parts of the United Kingdom, for example, participated in a huge fund-raising effort aimed at helping those whose livelihoods had been ravaged by the epidemic. The Green Wellie Appeal, launched in March by the Western Morning News, saw participation from celebrities, businesses, schools, and thousands of people sympathetic to the plight of affected farmers. More than £1 million was raised [10].

At the same time, the outbreak also caused new strains, sharp conflict and division, profound distress, widespread loss of trust, and a host of other serious social, psychological, and communication impacts. These were partly a result of the damage wrought by the outbreak itself, but they were also compounded by serious shortcomings in preparedness and response efforts. Initially, "no-one in command understood in sufficient detail what

was happening on the ground." By the time the extent of the problem was fully grasped, a cascade of social, psychological, and communication effects had already begun. "A sense of panic appeared, communications became erratic and orderly processes started to break down. Decision making became haphazard and messy . . . . The loss of public confidence and the media's need for a story started to drive the agenda" [3, p. 6].

While no two events are ever alike, the range of individual, family, community, and societal effects experienced during foot and mouth provides a clear indication of the kinds of social, psychological, and communication impacts that could result from a large-scale agroterrorism attack. Some of the most significant effects evidenced during the 2001 outbreak are reviewed below.

## 3 SOCIAL, PSYCHOLOGICAL, AND COMMUNICATION IMPACTS

### 3.1 Isolation

Efforts to control the spread of the virus had the unintended consequence of causing widespread social isolation. A ban on animal movements, the creation of large exclusion zones around affected farms, the posting of "keep out" signs, the placing of disinfectant baths and mats, the closure of footpaths, parks, tourist attractions and heritage sites, prohibitions against all nonessential travel, and the closure of widespread areas of the countryside often combined to bring community life to a standstill. Farmer's markets, fairs, art shows, and other events were cancelled, and many other facets of social life—visiting neighbors, going to the pub, attending religious services, shopping, participating in clubs and community groups—ceased. Even the utilization and delivery of health and social services were affected. In the words of one official report, "children and families could not conduct normal lives . . . ." [11, p. 9]. Thus, at a time of maximum difficulty and stress, people were often cut off from normal social outlets, from each other, and from their community support networks.

### 3.2 A Sense of Being under Siege

Even where some degree of movement or interaction was possible, fear that other people could potentially spread the virus caused many farmers, farming families, and others to barricade themselves off from the outside world. The farthest that one could safely venture was to the end of his or her property. Children were even kept home from school for an extended period of time.

The sense of being on edge and under siege was reinforced every time there was an instance of someone ignoring warning signs or violating a closure order. Such occurrences appeared to happen at a variety of times and in a multiplicity of locations [12]. Reported problems included walkers pulling down disease-warning signs, people entering closed areas/footpaths, and people crossing farm property. A spokesperson for one police department was quoted as saying that numerous complaints had been received alleging that "people are either ignoring the signs or ripping them down. On one occasion a man walking his dog ripped a sign down and went straight down the path. Another time, a man led a child on horseback down a path" [13, p. 33]. In some instances, there were direct conflicts when farming families trying to protect their property from the virus encountered outsiders. Among the incidents described in media reports were one where

a farmer's wife confronted cyclists with a shotgun, and another where a farmer was attacked by two men walking a dog after he asked them to leave his farmland [13].

### 3.3 Hoaxes and Threats

Compounding the fear, uncertainty, and distress experienced by farming communities were hoaxes and threats perpetrated in the wake of the outbreak. In one case, for example, a farmer reported having found a pig's head that had apparently been thrown into the middle of his field of dairy cows. In another case, a vial and bloodstained gloves were left near a sensitive area of a farm. The overall number of such incidents was relatively small; but in the context of the enormous worries and uncertainties already being experienced by much of the countryside, even this small number was sufficient to add greatly to people's fears and sense of being under siege [12].

### 3.4 Noncompliance with Infection Control Measures

Adherence to measures aimed at controlling the spread of infection is a key to crisis management during a large-scale outbreak. During the foot-and-mouth disease outbreak, cooperation and compliance were often good. However, many exceptions were seen over the course of the outbreak. At times, and in some areas, the lack of compliance occurred often enough and was sufficiently serious to constitute a major concern. Compliance problems, which were identified in relation to both farms and transport, included unlicensed movement of animals, dirty vehicles, and vehicles spilling organic material onto roads. Some of these problems might have stemmed from lack of awareness, lack of training, unclear instructions, or ineffective communication. There is evidence, for example, that words such as biosecurity, blue box, and red box were not always well understood. But other problems—including the deliberate alteration of movement licenses and illegal entry to infected premises—were clearly intentional violations of infection control measures. In a number of cases, violators were fined or prosecuted if they were caught [12].

### 3.5 Conflict within Communities

Differences between those involved in agriculture and those dependent on tourism, changes and perceived inconsistencies in valuation and compensation levels, and divergent views on approaches to dealing with the crisis sometimes created new tensions and sharp conflicts. These conflicts divided neighbors and friends and had broader impacts as well. As a member of one farming family explained, the situation was damaging "not just the farming lifestyle, but the farming communities, the farming relationship" (Quoted in [14], p. 274). One of the most powerful descriptions of the combined effect of isolation, the state of siege, and splits between people was given by a resident of Holne at the Devon Foot and Mouth Inquiry (2002, p. 58):

> Divisions occurred within people and between different groups—"us and them." The "us" became narrower and smaller—only the immediate family. Thus psychological isolation exacerbated physical isolation. People withdrew from the nurturing of the community. The dangerous "not us" became wider and bigger: farmers, walkers; MAFF/DEFRA; those with no bio-security and those with excellent bio-security; those who left, those who remained; organic farmers, postmen, people with dogs; horse drivers and horse riders; children at

school and not; open pubs and closed pubs; those compensated and those not; those who cheated and those who played straight. Suspicion, guilt, panic, fear and abandonment were all apparent. What is left is lack of confidence, depression, lack of ability to respond, and despair.

### 3.6 Psychological Impacts

As the Royal Society of Edinburgh [11, p. 9] summed up, "for those involved, or even those not involved but living in the locality, there was trauma . . . . For many of these people, and perhaps especially their children, the events of 2001 were a nightmare . . . " Only a relatively small number of systematic studies of the outbreak's psychological impact were conducted, perhaps in part because of the difficulties inherent in a situation involving severe travel restrictions. But the research that was conducted has reinforced the conclusion that this was a highly distressing experience. In a study carried out shortly after the official end of the outbreak, Peck et al. [15] compared psychological morbidity in a badly affected area (Cumbria) and an unaffected area (the Highlands) using a 12-item version of the General Health Questionnaire that was mailed to farmers. Though small sample size limits how far the results can be generalized, the study found that farmers in the affected area had significantly higher levels of psychological morbidity than those in the unaffected area.

Other research (e.g. [16]) carried out in various locations and using a variety of methodologies has also examined emotional well-being and mental health in relation to the outbreak. Olff et al. [17] studied farmers whose animals were slaughtered during the outbreak and found that approximately half had high levels of traumatic stress symptoms. Deaville et al. [18] carried out a health impact assessment of the foot-and-mouth outbreak in Wales. Using a multimethod approach that combined validated quantitative instruments with qualitative interviews, the assessment found significant mental health effects in the study sample and identified such symptoms as sleeplessness, tearfulness, frustration, anger, and lack of motivation. Hannay and Jones [19] used a mail survey to examine how farmers and tourism workers in Dumfries and Galloway, Scotland were affected by the outbreak. The results indicated that both groups had experienced negative impacts in the areas of daily activities, feelings, overall health, social activities, social support, and quality of life [20]. Finally, Mort et al. [21] conducted a longitudinal qualitative analysis of weekly diaries and concluded that the foot-and-mouth experience was accompanied by distress, feelings of bereavement, fear of a new disaster, and loss of trust.

Looking across the psychological impacts of the outbreak, Peck [20] concluded that, despite the high levels of distress, there had been no increase in demand for mental health services in affected areas. Rather, farmers turned to "family, friends and veterinary surgeons for support" (p. 272). In addition, noted Peck, there was "an expressed willingness to use anonymized sources of support, such as telephone or internet helplines" (p. 275). This is fully consistent with reports from the many organizations that provided support to farmers, farming families, and others in affected communities. Crisis hotlines and stress helplines were flooded with calls, so that hours had to be extended and staffing had to be increased. The Rural Stress Information Network, for example, reported that with the onset of the outbreak, it had received more calls in a single month than in the entire preceding year [12].

No direct, systematic studies of the outbreak's effect on children—generally considered a vulnerable population—were carried out [22]. Nevertheless, it was apparent that the situation took a significant emotional toll on them. Children were often nearby when

parents' and grandparents' farms were slaughtered out. They witnessed piles of dead animals, saw and smelled the funeral pyres that burned for days, and sometimes even lost their own pets as a consequence of the crisis. In addition, children shared in the isolation that affected farm communities. They missed school for extended periods of time, were unable to socialize with friends, and saw their families' own distress on a daily basis. As one parent told the Devon Foot and Mouth Inquiry, "my children had never seen me cry before" [23, p. 50].

Children's stress manifested itself in many ways, from angry e-mail postings [24] to problems with bed-wetting. As one rural nurse wrote, "as time passed we had an increase in referrals for children who were bed-wetting, often after long periods of being dry" [25, p. 60]. In a health assessment carried out in Wales by Deaville et al. [18], over half of the study's respondents indicated that the outbreak had affected their children.

Although most attention has focused on farmers and their families, it should also be borne in mind that foot-and-mouth was often a distressing experience for those charged with fighting the outbreak. Professionals on the front lines worked very long hours, were often away from home, and regularly witnessed horrific sights. Furthermore, although some frontline personnel felt that their work was supported by farmers, community residents, and the broader public, this was often not the case. Indeed, because of the high level of controversy, anger, frustration, and mistrust surrounding almost every aspect of foot-and-mouth, it was not uncommon for frontline staff to find themselves the target of relentless hostility and derision. Some professionals even reported that they were ashamed to be identified as government agency staff members. This state of affairs undoubtedly made an already emotionally taxing situation even more difficult for some frontline workers.

### 3.7 An Overwhelming Demand for Information

Just as the crisis developed with breathtaking rapidity, so too did the demand for information. Requests for information quickly exceeded all expectations, and communication resources and personnel were severely stretched. For example, during the early part of the outbreak, staff at the Carlisle Disease Emergency Control Centre found themselves having to field some 6500 calls per week even as they worked feverishly to deal with the outbreak. On the national level, the resources of a helpline at the headquarters of the Ministry of Agriculture, Fisheries and Food were quickly exceeded, as were those of a much larger governmental foot-and-mouth disease helpline that had been set up utilizing a call center at the British Cattle Movement Service. As a result, officials established an overflow service through a private contractor. By March–April, the national foot-and-mouth disease helpline was hitting 7000 calls per day. Over the course of the 31-week outbreak, government-sponsored helplines responded to literally hundreds of thousands of calls from farmers and the general public [8]; [12].

Aside from the overwhelming numbers of calls, one of the biggest challenges affecting the helpline effort was the difficulty those operating it had in obtaining information that was sufficiently detailed, accurate, and up-to-date. Helpline staff often had to rely on the website operated by the Ministry of Agriculture, Fisheries and Food. Although the Ministry had succeeded in quickly establishing the website after the outbreak began, and although it was widely used (by March–April it was seeing an average of 50,000 user sessions per day), the site did not always contain the most recent information [26, p. 321; 8; 12]. Particularly in situations where other sites were more up-to-date, this added to confusion and suspicion.

Poortinga et al. [27] carried out a multimethod study of how people ($n = 473$) in two communities—one potentially at risk from foot-and-mouth and another not close to any cases—viewed the trustworthiness of various sources of information about the outbreak. Among those scoring lowest on trust were government ministers and food manufacturers. The media fell exactly in the middle of the list (number 7 out of 13 information sources), perhaps because of concerns about sensationalism and exaggeration. Who, then, were seen as the most trustworthy sources of information? Topping the list were veterinary surgeons, followed by farmers, and then friends and family. In other words, people often trusted animal health professionals and *local* sources (e.g. word of mouth, the grapevine) far more than the national media and the national government. The crisis also saw the emergence of new "virtual" communities and networks that were able to link people despite the isolation created by the outbreak [28].

### 3.8 Conflict over Control Measures

Efforts to dispose of the huge number of slaughtered animal carcasses encountered significant community opposition. In part, this was due to a lack of consultation with stakeholders. "The speed with which decisions were taken, from site selection to construction and use, meant that there was little time for consultation . . . . The lack of consultation angered local communities . . . the lack of information and perceived insensitivity to local concerns aggravated the situation" [3, p. 114].

One major focus of opposition was the so-called funeral pyres (fires) that were extensively used in affected areas. Concerns included smoke contamination, dioxins, the powerful stench, and the problem of ash removal. In one locale, protests by business people and other residents forced officials to substantially reduce the size of a major burning operation. In another location, families blockaded trucks carrying carcasses to a funeral pyre. In yet another area, residents blocked trucks from entering a pyre site [12].

Plans for burial of carcasses also provoked anger and protest. People's concerns included possible transport leakage, seepage of leachate, and contamination of watercourses and drinking water supplies. Near one proposed site, for example, several hundred people from three villages came together to oppose burial plans. Although the vast majority of protests against burial sites were peaceful, there were isolated exceptions. In one situation, for example, earth-moving equipment was used to crush a police van after protesters attempted to stop plans for mass burial of animal carcasses [12].

At times, opposition and protest were local in nature. But at other times, the issue of what to do with the carcasses of dead animals pitted region against region. In one area, for example, hundreds of people marched to protest plans to bring dead sheep from other areas of Britain to their county for burial [12]. In such situations, there was a powerful sense that people were being asked to shoulder more than their fair share of the burden. As Bush et al. [29] commented, "in the final analysis, local hostility to the burial sites was not only about the shortcomings of consultation and the failure to take seriously local knowledge, or the doubts about possible risks to either human health or the local environment. It was equally about the injustice of being singled out as a local repository for the by-product" of a national disaster.

### 3.9 A Breakdown of Trust and Confidence

Despite dedication and hard work from many civil servants, disease control professionals, and frontline staff, strategic problems such as a slow recognition of the severity of the

outbreak, a slow early response, controversy over the mass slaughter policy, perceived inconsistencies in compensation procedures, conflict over carcass disposal, and a lack of adequate consultation with stakeholders, all contributed to a loss of faith in the overall handling of the situation. Communication problems further damaged public confidence [26]. In the end, the foot-and-mouth disease crisis resulted in a "breakdown of trust between many of those affected directly or indirectly and their Government" [3, p. 7].

## 4 IMPLICATIONS FOR AGROTERRORISM PREPAREDNESS AND RESPONSE

The 2001 foot-and-mouth disease outbreak in the United Kingdom—while not a terrorist event—provides a clear indication of the types of social, psychological, and communication impacts that could occur as a consequence of a large-scale agroterrorism attack. The spectrum of effects ranges from the distress suffered by individual farming families who see their life's work disappear overnight to broad social impacts such as community division, regional conflict, and loss of trust. Furthermore, as the 2001 experience makes clear, these impacts may be profound and widespread. Indeed, there is a real potential for the severity of social, psychological, and communication impacts of an agroterrorism attack to be even greater than what was seen during the foot-and-mouth epidemic. For example, an event involving a zoonotic agent would present an additional layer of challenges. Likewise, the possibility of multiple or repeated attacks could make it vastly more difficult to reestablish people's sense of security.

It will be crucial to learn from the foot-and-mouth outbreak and other experiences and incorporate these insights into agroterrorism contingency planning, training, preparedness, and response. Some of the key lessons that relate to social, psychological, and communication issues are discussed in the following sections.

### 4.1 Enlist the Public as a Partner

Although some level of disagreement and conflict is probably inevitable in a situation like the foot-and-mouth outbreak, it is now generally accepted that the situation was made far worse because of a lack of consultation with communities during the crisis. However, the problem ran deeper; even *before* the outbreak, there was failure to adequately engage stakeholders—including communities—in the emergency planning process. For example, stakeholders were "not formally consulted in preparing contingency plans" [8, p. 40]. Today, foot-and-mouth preparedness planners in the United Kingdom employ a much more inclusive, participatory approach.

Nearly every aspect of managing an agroterrorism event will depend upon gaining the cooperation and confidence of agricultural communities and the broader public. Thus, it is essential for agroterrorism planning and preparedness efforts to view them as full-fledged partners. Stakeholders need to be involved in plan development long before an event occurs [30], and their participation in training exercises is vital. Similarly, the development of emergency information and outreach strategies cannot possibly be fully effective without community input and feedback. More broadly, there is a need to engage agricultural communities and the public in discussions about the agroterrorism threat long before an event occurs. This will permit full consideration of different management strategies, disposal options, compensation issues, and other potentially controversial matters, and

facilitate the development of participatory decision-making processes that are seen as fair, transparent, credible, and effective.

### 4.2 Adequate Resources and Preparation for Information Hotlines

It is clear from the foot-and-mouth experience that, in the event of an agroterrorism attack, the demand for information from official hotlines will be massive. If public confidence is to be maintained, agencies will need to have well-rehearsed plans, phone facilities, and trained personnel to rapidly set up and operate such hotlines. Hotline arrangements—including mechanisms to ensure that accurate and up-to-date information is available—should be regularly and realistically tested through exercises. Depending on the nature of an agroterrorism event, there may also be substantial information demands from veterinarians, county extension agents, health departments, doctors, and others involved in responding to the situation. Thus, agencies will also need to be able to rapidly provide special hotlines and appropriate informational materials tailored to meet the needs of professionals.

### 4.3 Adoption of a Pre-Event Message Development Approach

An agroterrorism event and its resulting impacts could unfold with great speed, leaving agencies little or no time to develop effective communication strategies, informational materials, and emergency messages. In such a situation, events could easily outstrip communication efforts, leaving information vacuums that could quickly be filled with misinformation and rumors. This, in turn, could greatly complicate efforts to control an outbreak and contribute to the erosion of trust and confidence.

One promising solution that has broken new ground is to adopt what has come to be known as the "pre-event message development" approach. In a nutshell, the idea is to carry out research on the concerns, information needs, and preferred information sources of key audiences; utilize the findings to prepare emergency messages and other materials; and carefully test them long before an event occurs [31–33].

Interest in this approach developed out of the experience of the Centers for Disease Control and Prevention (CDC) during the 2001 anthrax letter incidents. With concern about the incidents growing rapidly, CDC found itself having to field large numbers of calls from the public, requests by health officials for real-time information, and inquiries from the media. With events moving quickly and with staff already stretched assessing and managing the incidents, it became difficult to keep up with the demand for information.

Reflecting on the experience, CDC later concluded that efforts to manage future emergencies would benefit from the use of a more proactive approach wherever possible. The agency enlisted the assistance of four US schools of public health, which carried out a multiyear, multisite research program to (i) understand the perceptions, information needs, self-protection concerns, preferred information outlets, and trusted sources for a range of population groups; (ii) identify core content for emergency messages; and (iii) pre-test draft message components (including the identification of confusing terms). CDC is now using these findings to craft more effective emergency messages, materials, and web content related to the human health aspects of unconventional terrorism agents.

The communication challenges associated with an agroterrorism event would be immense. So too would the stakes. Should public trust and confidence be lost, they will

be difficult to regain. The "pre-event" approach is not easy. It requires investment in research and a commitment to translate that research into practice. However, adoption of a "pre-event" approach increases the chances that agencies can stay "ahead of the curve" rather than falling hopelessly behind. Rather than starting from scratch and guessing what information key stakeholders and the general public want, the use of a "pre-event" approach enables agencies to build on an empirically grounded foundation. "During an actual emergency, the focus of attention can be on developing incident specific information" that can quickly be incorporated into already tested materials [31].

### 4.4 A Broader Approach to Communication

Clearly, a vital part of any effective communication strategy during an agroterrorism event will involve working closely with the news media to get needed information out to the public. As practical experience and the literature on risk communication have shown, this means having the infrastructure and trained personnel to rapidly respond to media requests for information; being able to provide experienced, credible, well-informed spokespersons for interviews; being able to provide opportunities for visuals; and having press kits with relevant statistics and succinct and clear resource materials available. In addition, an effective communication strategy also requires reaching out to different types of media, including television, radio, and newspapers [34].

However, as important as the media component of a communication strategy may be, it is essential to remember that some population segments may not be reached through the media or may prefer or trust other sources of information. As noted earlier, during the 2001 foot-and-mouth disease outbreak in the United Kingdom, it was not uncommon for people to give more credence to trusted local sources, word of mouth, and the "grapevine" than to the national media or national government. This is consistent with some recent research on bioterrorism issues suggesting that, in some situations, there could be urban–rural differences in terms of preferred information sources. For example, one recent study noted that, whereas urban respondents reported looking to the media first for information, rural respondents reported looking first to local authorities [35].

In light of these findings, it is critical for an agroterrorism communication strategy to complement the mass media component with a carefully thought-out community outreach component. This should include steps to ensure that accurate, up-to-date information is rapidly and continuously provided directly to trusted local figures (e.g. county extension agents and veterinarians) and trusted community organizations and networks (e.g. farming organizations, houses of worship). The extensive involvement of stakeholders well before an event should greatly facilitate the identification of community networks that may be important for such outreach efforts.

During the foot-and-mouth outbreak, parts of the farming community (particularly younger farmers and their families) also made extensive use of information technology. In an agroterrorism situation, it will be important to ensure that informational websites are easily found, user friendly, written in clear language, informed by an understanding of people's concerns, and regularly updated with the latest information.

### 4.5 Ability to Rapidly Expand Crisis Hotlines and Peer/Social Support

As noted earlier, many people having to cope with the impacts of the foot-and-mouth outbreak turned to crisis hotlines and stress helplines. With an agroterrorism attack likely

to produce widespread emotional distress, it will be vital for emergency response plans to include mechanisms for rapidly expanding crisis/stress hotline services. Facilities, needed equipment and resources, and trained personnel should be identified in advance, as should ways of communicating the availability of the services. In addition, strategies for facilitating peer/social support should be included in planning. For example, mental health professionals can play "an educational and consultative role for veterinary surgeons, farming organizations, self-help groups ... and local radio" [20, p. 275].

### 4.6 Special Services and Materials for Children

In any disaster situation, children have unique vulnerabilities. They may be exposed to the same frightening sights, sounds, and smells as adults, but not have the maturity or experience to interpret and understand what is going on around them. Although children are often resilient, there is no doubt that an agroterrorism event would be a highly distressing situation for them. It is important, therefore, for agroterrorism preparedness planning to include appropriate mental health support and interventions for children. This should include a particular focus on schools and day-care settings. "Children spend the majority of their waking hours at school or in a child-care setting. These settings are familiar and comfortable to children, and generally are experienced as safe, secure environments. As such, school and child-care settings are excellent locations for working with children before, during, and after a disaster" [22, p. 24]. In addition, it will be important to develop age-appropriate informational materials, explanations, coloring books, and messages to help children and families understand and cope with the situation [22].

### 4.7 Support for Frontline Personnel

As the foot-and-mouth epidemic demonstrated, the job of managing a large-scale outbreak can put frontline personnel under enormous strain. Likewise, during an agroterrorism event, long work hours, fatigue, extended periods of time away from home and family, the risk of injury, regular exposure to upsetting images, the uncertainty of the situation, and perhaps even public hostility could put frontline personnel at significantly increased risk for emotional distress. Agroterrorism planning, therefore, should include a robust mental health component aimed at supporting frontline personnel. This should include such measures as predeployment briefings, provision of self-care and stress management information, regular rest breaks, buddy/peer support arrangements, and support groups.

### 4.8 Human Health Issues

To the extent that human health concerns arise in relation to a suspected or actual agroterrorism attack (e.g. when zoonotic agents are involved or simply when rumors of possible human health effects gain prominence), it will be essential for agencies and spokespersons with a high level of credibility on health issues to be at the center of public communication efforts. Research on terrorism situations involving unconventional agents (including biological threats) has shown that many of people's concerns, and many of the questions they want answered, relate directly or indirectly to health [32, 35–37].

In addition, other research on terrorism in general has demonstrated that when people are asked who they would trust to "give accurate and reliable information about what is happening and what to do in the event of a terrorist attack," it was the professionals and organizations knowledgeable about health and health care that were ranked the highest [38]. The CDC was ranked the highest, with 84% of the population indicating it would

either "completely trust" or "somewhat trust" the agency to provide accurate and reliable information. Others on the list included "Doctor who is expert" (83%), the Surgeon General (76%), and the National Institutes of Health (75%). Figures such as the Secretary of Homeland Security and the Attorney General ranked much lower (68% and 65% respectively).

The lesson is clear. If human health issues are involved in an agroterrorism event, communication with the general public needs to put health issues at the center, messages need to be "front-loaded" with information that answers people's health questions, and the information should be provided by spokespersons recognized for having high credibility on health issues (e.g. the CDC).

### 4.9 More Realistic Plans and Exercises

There is a pressing need to better integrate social, psychological, and communication issues into agroterrorism contingency plans and training exercises. Many plans and exercises continue to give only minimal attention to these crucial considerations. Key areas (e.g. provision of appropriate services, development of an effective risk communication strategy, maintenance of trust and confidence) need to be explicitly addressed, and relevant roles and coordination issues need to be delineated and practiced on a regular basis. Without adequate consideration of relevant social, psychological, and communication issues, plans and exercises will be unrealistic and of limited value in preparing agencies and responders to deal with the complex challenges posed by an agroterrorism attack.

## 5 RESEARCH DIRECTIONS

In addition to implementing the lessons learned from the foot-and-mouth outbreak and other relevant experiences, it will be important in the coming years to carry out further research related to the social, psychological, and behavioral aspects of agroterrorism. In this regard, the topics identified in the 2002 National Research Council report on agricultural terrorism continue to be relevant [1]. For example, it would be useful to conduct additional work on how best to assist individuals and communities affected by an agroterrorism attack and how best to speed recovery.

Another key area of research involves improving our understanding of the factors that affect compliance with infection control measures during large-scale agricultural disease outbreaks. What factors serve to facilitate compliance and what factors make compliance less likely? How, for example, do different work practices, economic situations, or local customs come into play? A better understanding of such factors will aid in the development of more realistic and more effective infection control strategies.

Finally, it would be valuable to expand research on emergency communication during large-scale agricultural disease outbreaks. It is clear from the foot-and-mouth experience that communication problems exacerbated the outbreak's impacts and damaged public trust and confidence. The stakes and the costs of failure could be even higher in an agroterrorism event. There is, therefore, a pressing need for additional research to better understand people's concerns, information needs, and preferred information sources in relation to agroterrorism threats. Improved emergency communication—including the development of empirically grounded, pre-event messages—could play an important role in reducing an outbreak's spread, mitigating its impacts, and maintaining trust, social cohesion, and public confidence.

## ACKNOWLEDGMENTS

This article is based, in part, on fieldwork conducted by the author in the United Kingdom during and after the 2001 foot-and-mouth disease outbreak. The author is grateful to the many individuals and organizations that helped facilitate this work. Special thanks are due to the US Embassy in London, the Department for Environment, Food and Rural Affairs, the Rural Stress Information Network, the Ministry of Defence, and the National Farmers Union. Thanks are due as well to A. Becker, D. Franz, and R. Gurwitch, who provided helpful comments on earlier versions of the manuscript. Finally, the author wishes to thank the Lister Hill Center for Health Policy, and the Smith Richardson Foundation (International Security and Foreign Policy Program), which provided support for the research.

## 1 INTRODUCTION

Food safety and security takes many forms and requires differing methods, depending on the nature of the threat, the kind of agricultural commodity vulnerabilities involved, and

the consequences of the event. Major threats to western agricultural economies are foreign animal diseases (FADs), such as foot and mouth disease (FMD) or highly pathogenic avian influenza. In fact, such are the threats, through direct effects on food production and security, as well as through direct and indirect impacts on public health and economic stability, that all nations have developed major programs for detecting and eradicating these diseases as soon as is practicable. Most such programs are aimed toward quickly regaining international trade, and so, utilize severe control methods such as stop movement orders (SMOs) and "stamping out/eradication" (SOE) programs. However, SOE was designed and proven under market systems very different from those in modern agriculture. Further, the focus on international trade, at least for the United States (USA), is misguided. In the end, SOE programs have shown themselves to have the potential, if not the probability, to trigger cascades of unintended consequences;consequences that can destroy the farms and food security they were intended to protect. Modern agriculture requires that we rethink our focus and methods, such that the goal is to maximize farm survival through intelligent use of business continuity methods by accessing new technologies and tools, and through exploiting characteristics of modern agricultural markets.

## 2 BACKGROUND

To understand how SOE programs came to be, and why they no longer are fully appropriate in the modern age, we need to look back at agriculture as it was when the plans and perspectives were designed and initially used, and then see how the landscape has changed.

### 2.1 Agriculture in the Twentieth Century

For most of the twentieth century, agriculture was seen as ubiquitous, small-scale, and oriented or marketed locally: farms were relatively small, and much of the population was involved in agriculture; farms did not move; animals and products remained within a fairly local economy. FAD outbreaks that could result in a loss of foreign trade were considered to be one of the few threats that could create a national disaster. However, since FAD outbreaks were projected as local events, the solution to restoring trade was to quickly contain the small outbreak and eradicate the disease. Thus, FAD responses were aimed at identifying affected herds or flocks and destroying them to minimize impacts on trade agreements and markets [1]. Additionally, these programs carried unstated presumptions that the only risks agriculture faced were from accidental or natural threats, and these assumptions colored the scenarios against which programs were designed. The concept of intentional attacks or of accidental market-spread outbreaks were not serious considerations for researchers or decision makers.

### 2.2 Agriculture in the Twenty-First Century

Currently, agriculture is large-scale, highly mobile, and interdependent. Agriculture is dependent on transportation and just-in-time management. While agriculture is still a major economic sector across the country, a very small proportion of the population makes their living through farming. Exports are not primary aspects of US livestock; in 2007, the percent of domestic production going to exports for beef, pork, and poultry

were 5.4%, 14.3%, and 15.7%, respectively, yielding an overall export market for livestock products equaling approximately 12% of overall domestic production [2, p. 32]. This suggests programs whose aims are to protect exports at the expense of domestic production have their priorities misplaced.

Agriculture is now developing concentrated "production centers" (parts of the country where a type of production is concentrated and predominates, such as poultry in the Delmarva peninsula, corn in Iowa, or catfish farming in Mississippi), which operate and have resources and skills far beyond what twentieth century farms could imagine. Furthermore, ownership has concentrated, such that now majorities of primary production and processing are owned by a few small groups and companies, allowing for consistent management and rapid communications. Finally, agriculture is now highly integrated. For instance, in the large poultry production centers of the southeastern US, the companies involved in production also operate their own feed processing, transportation, and wholesale or retail divisions. These structural innovations change the risk profiles against which we should be defending.

### 2.3 Threat Profiles of Today

Reviews of recent FMD outbreaks in Taiwan (1997, [3, 4]), United Kingdom (2001, 2007, [5, 6]), plus bovine spongiform encephalopathy (BSE) in Canada (2003), United States (2004, 2005), [7, 8], with added insight from Newcastle Disease and highly pathogenic avian influenza outbreaks in North America (2003–2004, [9, 10]), have uncovered new considerations in regional or state disease control programs.

For instance, the United Kingdom experienced near wholesale destruction of its cattle markets with the 1985 discovery of BSE, and added damage to both cattle and swine with the destruction of over 6 million animals in the 2001 FMD outbreak, third of which were done for "welfare" reasons (Fig. 1, [11, p. 21]). Welfare slaughter occurs when, with markets shut down and animal movement stopped, farms soon run out of space, feed, and/or money, and have no option other than to destroy their animals or let them starve. The United Kingdom has experienced, as a result, a drop in domestic consumption, signaling that severe outbreaks can lead to such changes in demand that attempts to maintain supply are futile. In another example, the Taiwan FMD experiences in the late 1990s (Table 1, [3, 4]), demonstrate that agriculture is actually quite fragile in the face of major supply and demand perturbations. In 1996, Taiwan was one of the largest pork exporters in the Pacific Rim. After FMD, Taiwan became a net pork importer; as of 2009 they had not regained their production or market share.

Lastly, from documents found in Taliban sites in Afghanistan [12], to environmental or animal rights websites, it is apparent that agriculture, though a major critical infrastructure, is seen by its enemies as a large, soft target, susceptible to being a focus of politically motivated economic warfare. While none of the above disease events described were intentional in their origin, the results of the outbreaks are similar to what will be seen in a planned attack to either target an industry (state-level or locally) or a whole production system (nationally). The modern trend involving rapid and distant transportation of animals, feedstuffs, employees, and equipment, factored with collateral movements (wildlife, tourists, etc.), work synergistically to allow a disease agent to enter the production system by accident and create multifocal widespread outbreaks in a very short period of time (hours to days). Thus, accidental introductions of an FAD agent are likely to present the same disease management challenges that are found in intentional introductions.

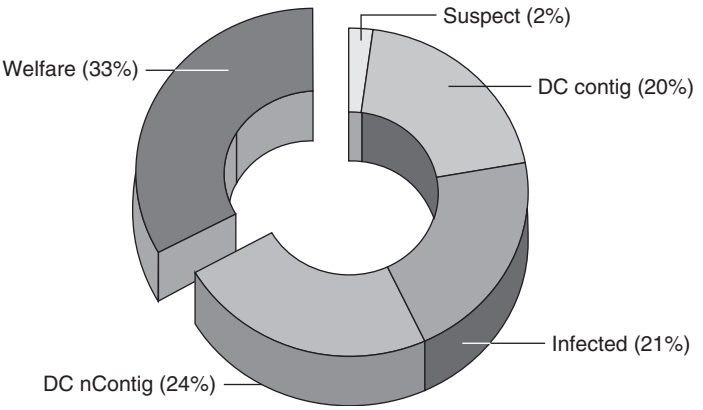

**FIGURE 1** Reasons for animal destruction (UK 2001). In the 2001 FMD outbreak in the United Kingdom, fully one-third of all animals destroyed were killed for "welfare" reasons—the animals had no markets to go to and the farms ran out of money and/or resources. Welfare, destroyed for welfare reasons; Infected, destroyed after confirmation of disease; DC Contig, destroyed as a contiguous dangerous-contact herd; DC nContig, destroyed as a noncontiguous dangerous-contact herd; Suspect, destroyed after classification as suspected of having disease. [Data from: Ref. [11]].

**TABLE 1 Breakdown of Costs As of 3 Years After the Taiwan Foot and Mouth Disease (FMD) Outbreak**

| Item or Activity | Cost | Percentage of Direct Costs (%) |
|---|---|---|
| Indemnity for pigs destroyed | $ 188 million | 49.5 |
| Vaccine costs | $ 14 million | 3.6 |
| Carcass disposal | $ 25 million | 6.5 |
| Miscellaneous | $ 28 million | 7.4 |
| Market value losses | $ 125 million | 33.0 |
| Total direct costs | $ 380 million | 100.0 |
| Total indirect costs (jobs, tourism) | $ 3,650 million | 961.0 |

*Note:* Taiwan used stamping out plus reactive vaccination protocols. Total direct costs of the disease response ($380 million) is only one tenth of the total indirect costs of this event. This means that major foreign animal disease outbreaks are *societal* catastrophes that come to society through agriculture. [Data from: Refs. 3, 4].

## 3 DETAILS AND CHALLENGES IN OPERATING STAMPING OUT/ERADICATION PROGRAMS

SOE programs are initiated to achieve very specific goals, and the prioritization of tools and methods are based on assumptions that are often unstated. However, those assumptions are then left untested, meaning that the outcomes of the program will be very different from what was originally envisioned. To better understand how this can happen, we need to look at the history of SOE: how it works and how it fails.

### 3.1 How Stamping Out Programs Work

Historically, programs for controlling FADs use the standard SOE approaches of quarantine (stop movements) and euthanasia as their primary tools [1]. In such a program,

animal and product movement are stopped, decreasing disease expansion, and allowing time for affected herds or flocks and likely to be affected herds or flocks to be identified. The animals are then destroyed and disposed of, to halt their ability to spread disease. After a period of strict surveillance, official movement permits allow markets to build back. In this way, such programs eradicate FADs by stopping agent replication and shedding, as depicted in the UK FMD 2001-based model shown in Figure 2 [13].

Some new measures have been added to the SOE approach in recent years. Emergency vaccination is one such advancement: "ring" or "fence" vaccination involves identifying an infected premise (IP) and vaccinating herds around the IP to limit opportunities for the agent to spread, analogous to setting backfires to stop forest fires. Interestingly enough, until recently, the SOE perspective limited the best use of vaccine (i.e. vaccine to protect and preserve life) and instead required that vaccinated animals be euthanized even though they were not infected [13, 14]. New technologies can now allow differentiation between vaccinated uninfected animals versus animals that are infected, making such "Vaccinate to Kill" strategies obsolete.

As a result of its long and proven track record in eradicating disease, its conceptual and logistical straightforwardness, and its clearly identifiable outcome, SOE has been the preferred tactic embraced by FMD-free countries since the mid-twentieth century [15]. Additionally, emergency vaccination is seeing increased interest from international FAD programs, and the World Organization for Animal Health (WOAH or OIE Office International des Épizooties), which is changing rules that have previously severely penalized vaccine-using countries [13].

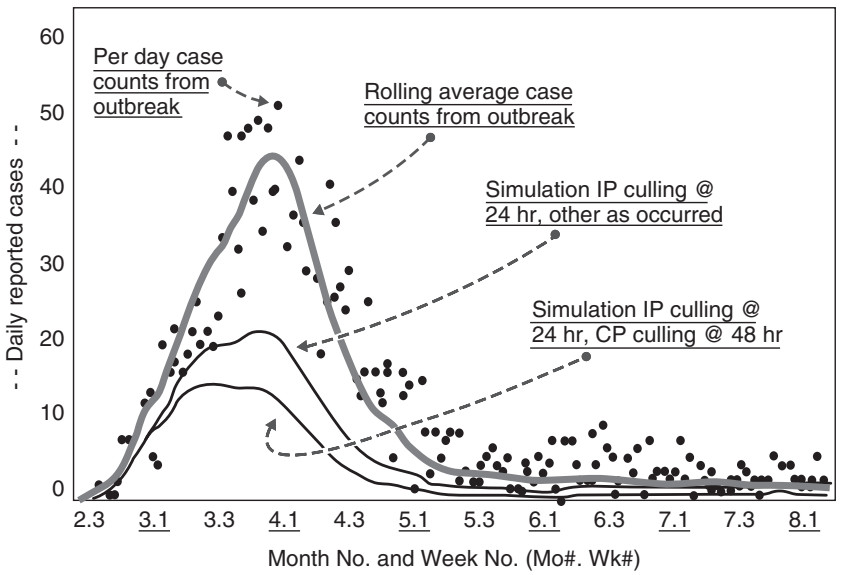

**FIGURE 2** SOE program goals and outcomes. Analysis of actual versus simulated epidemic curve for the 2001 UK FMD outbreak, assuming different levels of goal achievement for detection and slaughter. Actual did not achieve culling goals of infected premises (IPs) within 24 h of diagnosis, and contiguous premises (CPs) within 48 h. [Adapted from: Ref. [13] Chapter 10, Chart A, p. 94, with permission].

### 3.2 How Stamping Out Programs Fail

An SOE approach operated as the sole or primary tool for outbreak control has its problems [16]. For instance, the assumption that outbreaks will start small is likely to be false in today's mobile agriculture. Modeling of FADs suggests that either bioterror events or accidental market-driven outbreaks will not be present as small, local events. As an example, simulations suggest that an FMD outbreak starting in swine in eastern North Carolina (NC) could be in 5–7 states, affecting almost 500 herds in the first 10 days following exposure. Worst-case scenarios suggest an FMD outbreak could require destroying between 30 and 50 million animals, and would take more than 9 months (almost 280 days) to get under control [17, 18]. Thus, if SOE were to be used as the sole response tool, large numbers of animals, both of positive and negative nonexposed herds, will be euthanized. Additionally, to limit scavengers and potential public health concerns from the carcasses of euthanized animals, very rapid carcass destruction and disposal is required, usually by burial, composting or burning [19]. All carry public perception and environmental problems if done on a large scale, further limiting the attractiveness of an SOE approach. In the end, few workers believe that US society would tolerate that level of animal waste and destruction. Fewer still believe the United States could mobilize the necessary personnel to successfully execute and complete such a massive campaign.

Adding emergency vaccine to an already late SOE approach does little to help, because its only response to being "behind the disease curve" is to increase the size of the potential "rings." As shown in Table 2, however, increasing vaccination-ring size increases personnel and supply requirements by a square of the ring's diameter increase, at a time when both are likely to be very limiting.

Another problem is that SMOs required for SOE create massive damage in today's highly mobile "just-in-time" agriculture. Estimates from the NC dairy industry to the authors are that if interstate milk movement is stopped, the entire NC system milk storage capacity would be reached within 48 h—far short of a typical multiday SMO–there would be nowhere for milk to go, even if the state remained FMD-free, thereby jeopardizing a healthy dairy industry.

Even properly managed SMOs can create tremendous damage at the individual farm level. For example, Figure 3 illustrates a simple analysis done by us determining how many non-shipping days a dairy could absorb before its annual profit (measured as returns to management) reached zero. It suggests the average NC dairy in spring 2009 producing between 17,000 and 18,000 lbs of milk per cow, could survive an SMO up to 9–13 days, assuming all else is equal. Should the control and recovery program increase costs (or decrease milk prices) by a mere 3%; however, these farms will have zero returns to management within hours of instituting the SMO. Higher-producing farms, assuming similar debt and externals, survive longer, but the trend is relentless: The longer SMOs last, the more of the industry will fail, *even though they are doing everything right and remain uninfected*.

The SOE/SMO mind-set can permeate other disease control programs. For instance, in spring 2009, a commercial Canadian swine herd was infected with the novel H1N1 influenza virus by a worker. Although the disease ran its course in the herd (no animals died), and recovered animals are not infective, the government stopped all movement of animals from the farm. This introduced welfare degradation, which meant they had to slaughter animals for welfare purposes. Furthermore, animals were kept out of the human food chain, and even rendered product (a process that destroys all viruses) had to be disposed of by one of the most expensive means, landfilling. To explain the reasoning,

**TABLE 2 Demonstration of Logistical Problems with Increasing the Size of a Ring Vaccination Program's Area**

| Default Program | Proposed Program | Factor Increase | Item/Resource Measure/Count |
|---|---|---|---|
| 2 | 6 | 3.0 | Kill zone (KZ) radius (mi) |
| 6 | 18 | 3.0 | Control zone (CZ) radius (mi) |
| 13 | 114 | 8.8 | KZ area (sq. mi) |
| 101 | 905 | 9.0 | CZ area (sq. mi) |
| 26 | 227 | 8.7 | KZ swine farm count |
| 202 | 1810 | 9.0 | CZ swine farm count |
| 50,266 | 452,390 | 9.0 | KZ count pigs |
| 402,124 | 3,619,115 | 9.0 | CZ count pigs |
| 88 | 760 | 8.6 | Kill team personnel count |
| 448 | 4024 | 9.0 | Vaccination team personnel count |
| 9 | 26 | 2.9 | KZ roadblock count |
| 26 | 76 | 2.9 | CZ roadblock count |
| 34 | 101 | 3.0 | KZ roadblock personnel count |
| 101 | 302 | 3.0 | CZ roadblock personnel count |
| 706 | 5289 | 7.5 | Total personnel count |
| 50,266 | 452,390 | 9.0 | Total animal euthanasia sets required |
| 402,124 | 3,619,115 | 9.0 | Total vaccine doses required |

*Note:* Typical eastern North Carolina swine-farm size and density, and roadway density, plus standard response task force/strike team sizes and shift length used for both options. Counts rounded to next whole number.
DEFAULT: Assumes a program with a 2-mile radius for culling KZ, where herd destruction would occur and a 6-mile radius for vaccination CZ, where vaccination would occur;
PROPOSED: Expands KZ to a 6-mile radius, and CZ to an 18-mile radius (i.e. a threefold increase in radii compared to DEFAULT).
The PROPOSED increase results in a 7.5- to 9-fold increase in immediate needs for personnel, eqipment, and supplies. This increase provides a near tripling of the distance the virus must spread to break the ring vaccination program before animals respond to the vaccine, which does not translate to a threefold decrease in risk, let alone a ninefold improvement.

a Canadian official was quoted as saying " . . . The decision to cull the herd was to ease overcrowding . . . This doesn't have anything to do with the flu, . . . It has to do . . . with animal welfare . . . Due to the quarantine, these animals cannot be moved off the farm as they normally would. The living conditions would soon become unacceptable due to overcrowding and they (the pigs) would have been in distress . . . " [20]. As with the discussion of the dairies shut out of their market by SOE/SMO procedures above, we must be honest in recognizing that these animals, and these farms, are destroyed by our *programs*, not by the disease.

Lastly, a strong motivation to transition FAD response away from SOE/SMO policies stems from the observations that historical plans generated numerous unintended consequences beyond the direct market effects mentioned above. Two especially vexing issues include (i) that our programs induce paradoxical motivation for producers to seek ways for their herds or flocks to become infected or to bypass control measures in last-ditch efforts to avoid individual financial ruin by either gaining indemnities or selling product [21] and (ii) that we ignore the socioeconomic and political impacts on nonagricultural facets of communities and economies; impacts that are often several fold greater than the direct impacts on agriculture (see Table 1 as an example).

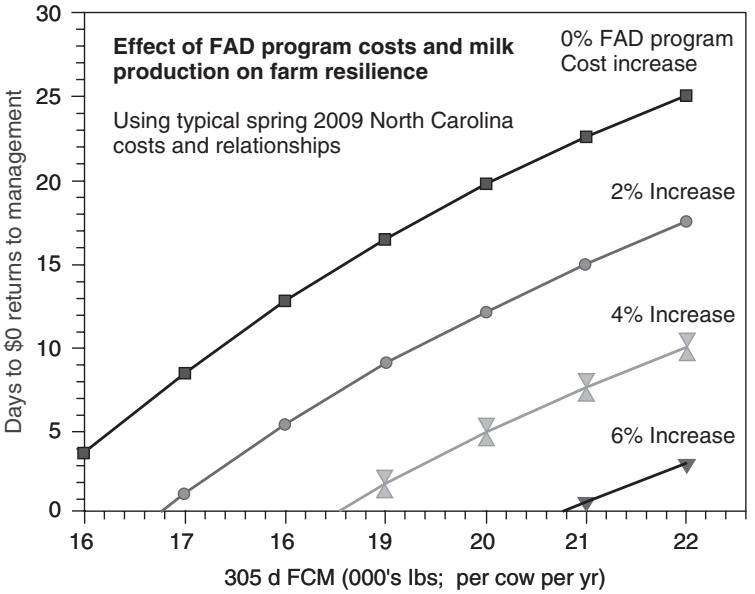

**FIGURE 3** Destroying uninfected farms through SOE programs. Economic prediction for dairies' resilience to stop movement orders (using typical NC dairy cost structures and trends), as a function of per cow milk production and across program-induced cost increases from 0% to 6%. The typical NC dairy produces almost 18,000 lbs FCM, meaning it would have mere days before a stop movement program would erase a total year's profit, assuming the program did not change the dairy's relative costs and income. However, if the SOE program decreased income relative to cost by 2%, its resiliency is halved. Should the SOE program imbalance costs and revenues by 4%; however, the farm will almost immediately become unprofitable. This damage occurs even though the farm is uninfected by the disease. FCM, fat-corrected milk production per cow per lactation.

## 4 KNOWLEDGE ADVANCES ENCOURAGING DEVELOPMENT OF BALANCED EVENT MANAGEMENT STRATEGIES

Many nations and trade blocks have reconsidered their FAD programs, and are considering a more managed strategy. For instance, WOAH/OIE has increased its interest in, and work with (i) regionalization within a country (declaring parts of a country free of disease and open to trade) and compartmentalization within industries (allowing unaffected segments to continue economic activity), (ii) decreasing the time-to-trade-resumption penalties that countries practicing FMD vaccination face, and (iii) updating their rules and policies regarding testing and vaccination technologies [22].

But these changes, though helpful, do not address fundamental issues causing SOE/SMO methods to fail. A major lack is in not recognizing how technologies offer improved methods and tools [23, p. 122]. Following are but a few of the disciplines and technologies that have recently advanced greatly. While many examples could be brought forth, here we only address vaccinology or immune enhancements, disease detection, and information technology. Together, they bring new tools and opportunities for prevention, response, and recovery.

### 4.1 Advances and Tools Ignored by Most Stamping Out Plans

Current vaccine development techniques include functional genomics and gene alteration techniques that produce live vector-based vaccines exploiting important gene expression and genetic recombination techniques to increase their safety and create readily identifiable genetic markers for differentiation from wild virus [24]. Subunit vaccines—products that do not involve the use of live agents—can take vaccine safety margins to levels unattainable by standard killed or attenuated techniques [25]. Novel methods of vaccine delivery—through feed, aerosols, or the previously mentioned vectors—promise to improve the ability to cover disparate populations. Further, improvements in lyophilization and sterilization have enhanced shelf life and stability, making long-term stockpiling of these tools in ready-to-deploy forms more feasible. Nonvaccine immune system enhancement opportunities have been augmented through expanding knowledge of general animal health, nutrition, and stressors. Direct oral or mucosal delivery of interferons have demonstrated themselves to be an effective and fast therapy against viruses, including FMD–without vaccine use. The ability to include such products in feed during an outbreak has experimentally shown efficacy in protecting swine from FMD infection, even without concomitant vaccines [26]. Developments in understanding and manipulating different parts of immune systems (e.g. cell-mediated vs. humoral) to optimize responses to different agents also show highly specific potentials for control applications. Finally, long-term genetic techniques and expanded genome maps promise new opportunities to create more disease resistant livestock.

Modern materials science, biochemistry, nanotechnology, mathematical pattern-recognition, spectroscopy, and molecular imaging systems have recently been combined to optimize approaches to rapid, high resolution, accurate, and efficient diagnostic and biosensor tools. Environmentally stable automated systems that can combine sampling and detection technologies have been commercialized and adapted to business, environmental, and military applications as well. Combined with previously mentioned genetically altered vaccines, these technologies potentially allow rapid and repeatable differentiation of vaccinated, recovering, and recently exposed animals [27].

The last innovation example, information technology, is perhaps the most obvious and socially permeating change that is not recognized in typical SOE plans. Field personnel now access and create information at speeds and distances unheard of only a decade ago. Global positioning systems incorporated into mobile wireless devices are currently in-field for military and government planners and responders. With the advent of national animal identification systems and shared multihazard data structures [28], these systems create new avenues for planning and executing trace-in/trace-out work, for monitoring animal flow, and for serving as the basis for syndromic surveillance systems, distributed databases, and "network aware" activities and coordination, where central decision makers and in-field workers have access to real-time updated data.

## 5 TRANSITIONING TO A STRATEGIC EVENT MANAGEMENT POLICY

Recent catastrophic FAD outbreaks from all parts of the globe have highlighted policy areas we need to improve (e.g. the lack of state or national consideration of business continuity issues for primary production, secondary handling or processing, and support industries) while designing and executing FAD control and eradication programs. A key driver to quickening the transition needed will be the realization that SOE policies as

stand-alone solutions are not the answer to the challenges presented to modern food and agriculture by FADs.

### 5.1 Regionalization, Compartmentalization, Proof-of-Status Testing

Consideration of both sides of a disease event (infected case management and uninfected premises administration) are critical to transitioning between SOE and an event management strategy. Approaches and tactics such as regionalization, compartmentalization, standardized biosecurity, and proof of negative-status testing are all part of a comprehensive managed response, and as mentioned above are experiencing interest internationally [22].

Modern agriculture continues to regionalize and compartmentalize itself into production centers, and will do so in the future due to a number of different factors adding to the validity of the approach [29]. While regionalization refers to geographic separation and specialization of production and processing, compartmentalization capitalizes on breaks that occur naturally in production processes. For example, in swine production many producers have breaks (physical, workforce, and management separations) among sows /pigs, nursery age pigs, and finishing pigs, producing essentially a three-compartment production system. Compartmentalization has been utilized by industry in day-to-day operations to protect the overall health of their animals and the system by safeguarding different segments, and improving organization and efficiency. This same strategy can be used during disease outbreaks to maximize response organization, effectiveness, efficiency and more importantly, to protect uninfected segments of agriculture.

Unfortunately, current SOE/SMO plans treat these densely populated and specialized production centers as if they were small and relatively isolated, that is, as if they were farms and companies from the 1950s. This results in current FAD response plans working against regionalization, and ignoring compartmentalization. However, understanding Production Centers, regionalization, and compartmentalization, can afford response officials the ability to designate zones for infected herds or flocks, as well as for negative herds or flocks. As regionalization and compartmentalization approaches are developed specific to a region and an industry, response actions such as proof-of-status testing and standardized biosecurity can support control activities, so that as response officials in infected states grapple with eradication, response officials in negative states can preserve their food production, processing, and related industries through business continuity efforts.

### 5.2 New Horizon: Programs and Tools That Can Aid the Transition

There are a number of programs and tools in existence or in development that can greatly aid the transition. Existing programs include Criticality, Accessibility, Recuperability, Vulnerability, Effect, Recognizability (CARVER) and Shock (a threat assessment tool that evaluates the vulnerability to, and the shock factor of, a successful attack on an entity) [30] and Food Agriculture Sector–Criticality Assessment Tool (FAS–CAT), a method to assess the subsystems comprising the overall food and agricultural organization [31]. Others in development offer new methods to help responders gauge readiness and develop standardized cross-jurisdictional plans. To insure that efforts are fully integrated, standardized exercises can be conducted in states, regions, and nationally through a program known as Homeland Security Exercise and Evaluation Program (HSEEP) [32]. Finally, recognizing that agriculture and food systems have outgrown local approaches

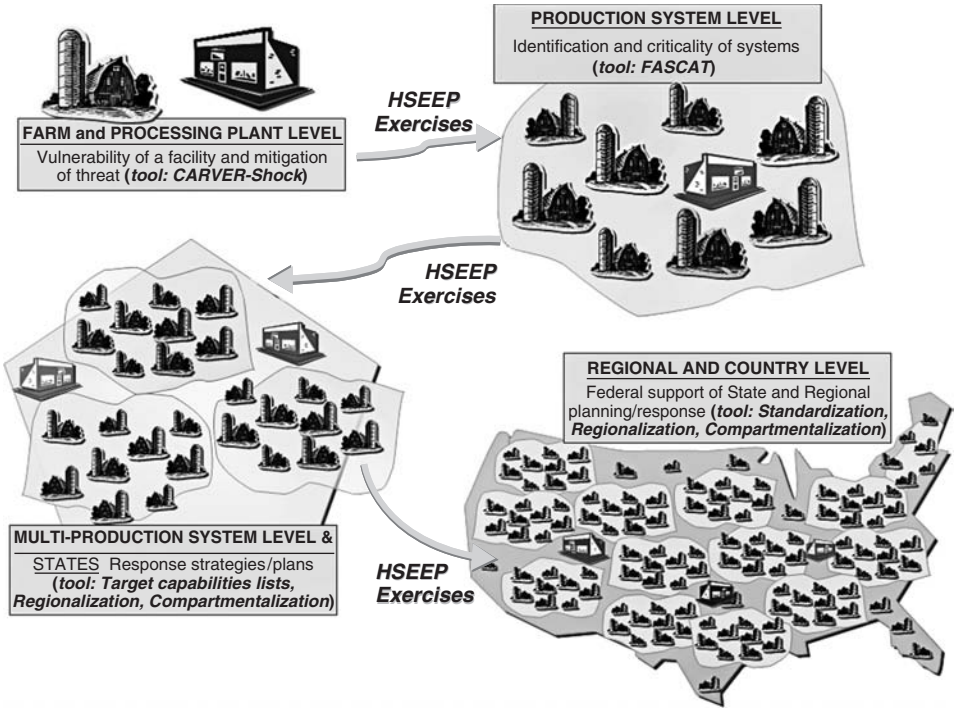

**FIGURE 4** Diagram of "farm to fork" resilience planning. Scalable processes and tools allow vulnerability analyses and prioritization at all levels of food security. However, some tools and methods will be appropriate at some levels, but not others. For descriptions of the tools listed, please see the text.

to FADs has led to regional planning efforts utilizing tools such as compartmentalization and regionalization. The keys will be to develop standardized approaches across states (i.e. regions) for biosecurity measures, proof-of-status testing (surveillance), zoning guidelines, and movement protocols, as illustrated in Figure 4.

## 6 CONCLUSIONS

The combination of new knowledge, tools, and economic environments has given rise to new considerations for disease control programs. It is now evident that the current plans to prioritize FAD eradication by only using strict SOE (Figure 5, [33]) in order to maintain agricultural trade, if applied in the many advanced agricultural regions of the United States, are likely to not only fail to contain the epidemic, but could so damage the industries that they will not recover.

Furthermore, given the concentration of production centers seen in NC swine, California dairies, or High Plains' feedlots, emergency ring vaccination strategies are likely to consume vast amounts of very limited early resources to achieve minimal results. From a systems' perspective, then, the unavoidable conclusion is that historical ideas on control of FADs are counterproductive and could well result in greater net harm to agriculture, to rural communities, and to regional economies, than they will alleviate.

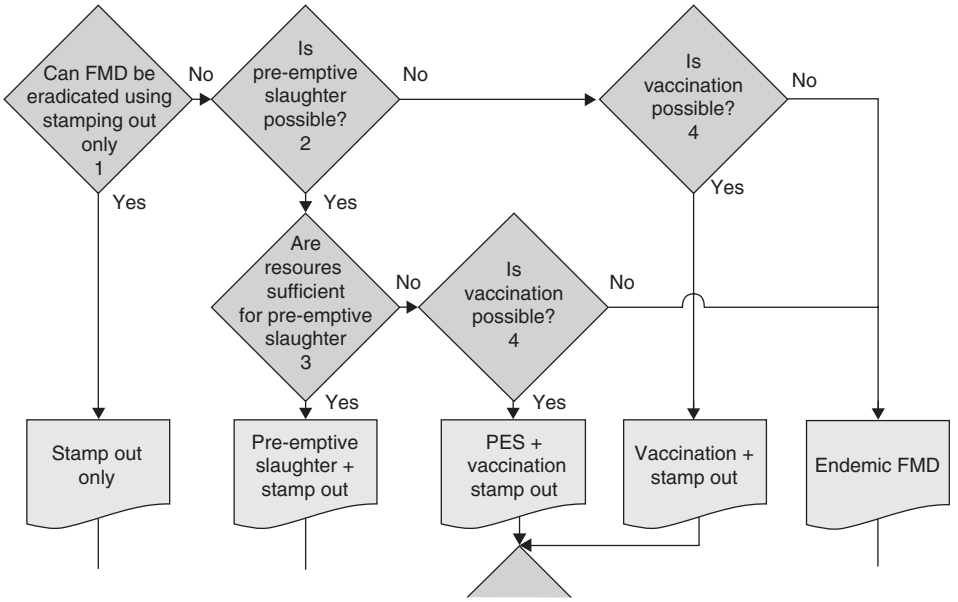

**FIGURE 5** Typical FAD response decision tree for a nonendemic country. Decision tree addressing foot and mouth disease assumes stamping out/eradication, which is the preferred course of action. Only until SOE is deemed infeasible can alternative methods be considered. This disallows risk-based decision processes, and limits decision makers to a single tool, until that tool fails. Such blind rigidity does not belong in decision making within a changing and dynamic event such as an outbreak. [Excerpted from: Ref. [29]].

Finally, in these days of heightened concern for terrorism, we must face the fact that if we can show that even a simultaneous multisite outbreak could be controlled with minimal disruption to production and markets, we will have gone a long way to making these pathogens low-yield tools for those wishing us harm.

Many workers have recognized that new technologies must be incorporated into a comprehensive event management strategy that would prevent and/or limit large-scale outbreaks.

Five characteristics of such a new strategy include the following:

1. *The goal should not be eradication at any cost, but instead, to best assure farm and market survival.* We exist to protect agriculture, not stamp out diseases. Eradication is but one tool we have available in order to accomplish our goals. Managed eradication with attention to business continuity issues regarding production, processing, and transportation will best assure that we protect agriculture and our food supply.
2. *Today's regionalized, compartmentalized, and concentrated production centers should utilize coordinated, facilitated, biosecurity and population health programs. potentially including preventive vaccination.* Production centers represent the largest single points of failure for US agriculture, while at the same time offering us the single best points for establishing targeted prevention and mitigation tools. If we protect production centers (the major population centers) ahead of time, we cut the chances of an uncontrolled epidemic.

3. *We should exploit new means to augment animals' immunities, with or without vaccines.* Using nonvaccine delivery systems will also decrease demands on specially trained personnel and equipment, both of which are always in very limited availability early in any outbreak. Nonvaccine methods also do not trigger trade issues, further helping to assure markets are maintained.
4. *We must minimize SMOs.* They can be minimized through genetically altered or vector vaccines and risk-based differential testing methods, aimed at controlled and permitted market maintenance–that is, we must allow likely negative herds and products to move through markets. A major issue here is in testing capacity, for most state and federal diagnostic laboratories do not have the authority to perform proof-of-status testing, while disallowing private laboratories access and authorities to do the same.

Hence, we must change our formal decision processes to incorporate the new technologies, methods, and opportunities, to better protect agriculture and food security. The decisions cannot presuppose any method as optimal, such as we currently do with SOE. It must be risk-based, with a view toward business continuity, if we are to truly succeed in our goals to protect US food security.

## 1 INTRODUCTION

Two areas of concern are discussed in this article. One, the major one, has to do with the contamination of food and food-contact surfaces by various insect pests often associated with human or animal foods [1]. The scenarios by which such contaminations occur are well known and are mitigated by strict adherence to sanitation standard operating procedures (SSOPs) and good manufacturing practices (GMPs), by the implementation of the hazard analysis critical control points (HACCP) program, and by the practice of Integrated Pest Management (IPM). We will not describe these four programs. The reader will find abundant resources about these programs on the Internet, from the Land Grant universities, scientific literature, and commercial providers of these programs [2, 3]. The lesser concern, a much less familiar one, deals with intentional food contamination mediated by insect agents. To deal with this threat, an equally proactive approach, similar to SSOPs/GMPs/HACCP/IPM, is essential. It involves a strategy we have termed AIM=F: anticipate, inform, mitigate equals frustrate, that is, the prevention, neutralization or control of intentional acts of food contamination by means of insect agents.

## 2 MUSCOID FLIES AND FRUIT FLIES

Muscoid flies and fruit flies represent a close association of insects with microbes, especially with bacteria originating from human and animal feces and other decaying organic materials. Moreover, muscoid flies have a great potential to contaminate human food and drink with bacteria, including foodborne pathogens, because of their developmental habitats, mode of feeding (regurgitation), unrestricted movement, and attraction to places occupied by humans and domestic animals.

### 2.1 Nutrition and Development

Virtually any environment rich in decaying organic matter harbors a diverse bacterial community and becomes a suitable substrate for development of muscoid flies, such as house flies (*Musca domestica*), stable flies (*Stomoxys calcitrans*), horn flies (*Haematobia irritans*), and face flies (*Musca autumnalis*) [4]. The primary larval developmental sites

for these flies include animal feces/manure and other decaying organic material (human garbage and compost).

The importance of bacteria in the development of muscoid flies has been reported in several studies that show that a live bacterial community is essential for the larval development of these flies. The nature of this symbiosis is unclear. The significance of bacteria for the development of larvae has been examined for house flies [5–7], stable flies [8, 9], horn flies [10], and face flies [11]. Digestibility of bacteria in the intestinal tract was demonstrated in house flies [12], stable flies [13], and blow flies [14, 15]. Other studies of morphological and physiological adaptations of muscoid flies for uptake, storage, and digestion of bacteria also emphasized the importance of bacteria in larval development [12, 16]. In addition, it has been demonstrated that the same bacteria that support the development of stable fly larvae also stimulate oviposition (egg laying) on the specific substrate and therefore indicate the suitability of the substrate for offspring development [9]. Studies on house flies and stable flies have demonstrated that bacteria in the larval gut can survive pupation and can colonize the digestive tract of newly emerged adult flies [17, 18]. This important finding supports the idea that adult muscoid flies serve as vectors of human and animal pathogenic bacterial strains.

Fruit flies do not require bacteria to successfully complete development; however, it has been shown that exogenous bacteria enhance the lifespan of *Drosophila melanogaster*, especially during the first week of adult life [19]; however, a more recent study did not confirm these results [20].

### 2.2 Dissemination of Pathogens and Antibiotic Resistant Strains

House flies and other muscoid (filth) flies are pests of great medical and veterinary significance [21]. House flies are important nuisance pests of domestic animals and people, as well as the main fly vectors of foodborne and animal pathogens [21–23]. Due to their indiscriminate movements, ability to fly long distances, and attraction to both decaying organic materials and places where food is prepared and stored, house flies greatly amplify the risk of human exposure to foodborne pathogens. House flies can transport microbial pathogens from reservoirs (animal manure) where they present a minimal hazard to people to places where they pose a great risk (food) [21, 22]. Stable flies are bloodsucking insects and important pests of domestic animals and people. Stable flies cause great economic losses in the animal industry, primarily in dairy and beef production [24, 25], and they can also play a role in ecology of various bacteria originating from animal manure and other larval developmental habitats [18]. The potential of adult house flies to transmit pathogens such as *Yersinia pseudotuberculosis* [26, 27], *Helicobacter pylori* [28], *Campylobacter jejuni* [29], *Escherichia coli* O157:H7 [30–32], *Salmonella* spp. [33], and *Aeromonas caviae* [34] has been also reported. Recently, it has been demonstrated that house flies are capable of transmitting *E. coli* O157:H7 to cattle, the major reservoir of this human foodborne pathogen [35]. Fruit flies, primarily the Mediterranean fruit fly (*Ceratitis capitata*) and the vinegar fruit fly (*D. melanogaster*), were also reported as potentially competent vectors for *E. coli* O157:H7 and were capable of contaminating fruits with this pathogen under laboratory conditions [36, 37].

Several studies reported a direct positive correlation between the incidence of foodborne diarrheal diseases and the density of fly populations. For example, suppression of flies in a military camp in the Persian Gulf region resulted in an 85% decrease in shigellosis and a 42% reduction in the incidence of other diarrheal diseases [38]. Esrey [39]

reported a 40% reduction of incidence of diarrheal infections in children after suppression of the fly population.

Additionally, the development of antibiotic resistance among clinical bacterial isolates and commensal bacteria of people and animals, as well as bacteria in other habitats, raises a concern that flies may be vector competent not only for specific pathogens but also for nonpathogenic bacteria carrying antibiotic resistance genes. A recent study reported that the majority of house flies collected from fast-food restaurants in the United States carried a large population of antibiotic resistant and potentially virulent *Enterococci*, primarily *Enterococcus faecalis*. The resistance genes were present on mobile genetic elements (plasmids, transposons) with a broad host range [40] that could be potentially transferred by horizontal gene transfer to more pathogenic strains. Additionally, it has been shown that ready-to-eat food in fast-food restaurants is more frequently contaminated by *E. faecalis* and *Enterococcus faecium* in summer months when house flies are more common in restaurants than in winter months [41], indirectly implicating house flies as a potential source of the contamination.

### 2.3 Homeland Security Aspects

It is becoming more apparent that muscoid flies, primarily house flies, and some species of fruit flies have the potential to play an important role in the dissemination of foodborne pathogens in both agricultural and urban environments. Consequently, both preharvest and postharvest food safety strategies will have to include the insect pest management approach. Unfortunately, the current mind set of many farmers and animal production managers is to tolerate insects such as house flies (and other pests that do not have direct and obvious economic impact on animal production) unless residents from surrounding urban sites complain about fly or other insect infestation problems.

House flies and fruit flies can be easily reared in large numbers in laboratory colonies and could be intentionally contaminated on the surface and in the digestive tract by various bacteria, including foodborne pathogens such *E. coli* O157:H7, *Salmonella* spp., and *Campylobacter* spp. Although muscoid flies and fruit flies have been shown to carry these bacteria in nature and have potential to contaminate the surfaces and food they feed on, the relatively short life span of these flies (up to 2–3 weeks) probably does not represent a viable prospect for domestic or international bioterrorist attack that would have serious consequences on a large scale. However, the AIM = F (anticipate, inform, mitigate equals frustrate) strategy has to be ready for this scenario because the typical integrated pest management (lPM) approach would be too slow to protect the public. Immediate quarantine and insecticide measures will have to be in place and ready to be implemented for such situations.

## 3 COCKROACHES

### 3.1 Nutrition and Development

Cockroaches (Blattaria, Dictyoptera) of many species are widely distributed in the natural world, but only a relatively few species have adapted to life within manmade structures or to the habit of frequently invading such structures from the outdoors [42, 43]. Foraging for food generally occurs at night. Cockroaches typically retire to dark, sheltered niches during the hours of daylight. Gradual metamorphosis being the rule in the Blattaria, nymphs

emerging from eggs lack wings and functional reproductive organs, but otherwise they are similar to the adult stage except for being smaller in size. All postegg stages have chewing mouthparts and all utilize similar kinds of food. They are omnivores; virtually any organic material, of either plant or animal origin and either solid or liquid, can be ingested.

Domestic cockroaches tend to require a daily ration of water. This may be supplied as liquid water, as in a floor drain or a puddle under leaky plumbing, or in the form of moist food (anything from food on a hospital food cart to rotting kitchen waste in a garbage can). Moisture, as well as food, may be acquired by ingesting human or animal feces, vomitus, blood, and pus on discarded wound dressings, and moist pet food, to name a few sources. When it comes to food and drink, cockroaches take whatever they can get wherever they can get it. This is where the problem arises for human and animal health: Like flies, cockroaches visit feces (and many other contaminated substrates) and food (that is, edible human or animal food) indiscriminately and their movements from one to the other may contaminate food-contact surfaces.

### 3.2 Dissemination of Pathogens

The cockroach gut is home to a bewildering array of naturally occurring bacteria, most of which are harmless to people and domestic animals [44–46]. But in their visits to substrates laden with pathogens, their exterior surfaces, especially the legs, become laden with pathogenic bacteria. Moreover, they can ingest pathogens, some of which may survive in the gut long enough to be egested with the fecal pellets or, occasionally, regurgitated during feeding. Thus, both clean surfaces and clean food may become contaminated.

Although some doubt about the importance of cockroaches as vectors of foodborne pathogens has been expressed [47], the larger body of published research, some of which is noted here, suggests that cockroaches should be given serious consideration by the public and by the guardians of the public's health. Concern over the role of flies, cockroaches, and ants as potential vectors of microbes pathogenic to humans and animals dates at least from very early in the 1900s and this concern is reflected in the many dozens of scientific papers published during the past century. There is much to be learned from these older papers; many of them are cited in more recent papers and several of them are appended in "Further Reading". For this section on cockroaches, we will bring to the reader's attention a few investigative reports published since the turn of the present century.

The essential thrust of these papers is that pathogens and cockroaches are intimately and consistently associated, a conclusion derived from multiple isolations of pathogens from cockroaches collected in places, such as hospitals and kitchens, generally perceived to be sanitary and sanitized. Cockroaches and their associated pathogens might be implicated in some way, either by direct contact with people (or domestic animals), or by contact with food or food-contact surfaces, is a premise supported by the observations that specific disease outbreaks waned when standard infection control procedures were complemented by elimination of cockroaches [48, 49]. None of these reports conclusively proves that the cockroach committed the "crime," but the correlation of the specific strain of the pathogen taken from the cockroach with the same specific strain taken from the sick patient seems to us to be very compelling circumstantial evidence implicating the cockroach. The authors of virtually every scientific paper on this subject published since 1900 have come to this understanding.

Two other factors add weight to the premise that cockroaches and food (or food-contact surfaces) should not coincide: (i) some strains of pathogens exhibit enhanced virulence, that is, even an immunologically competent host may be susceptible to a much lower than usual infective dose; and (ii) immunocompromised hosts are, of course, susceptible to the supervirulent strains and to lower than usual infective doses of the standard pathogenic strains.

All agree that the cornerstone of personal and community hygiene is hand-washing. Countless incidents of foodborne disease and nosocomial infections have been traced back to a simple behavioral flaw: hand-washing was omitted or done ineffectively. People can be trained to more consistently and effectively wash their hands. Although flies, ants and cockroaches engage in a lot of self-grooming, a behavior vaguely comparable to hand-washing, this does not render them clean in the microbiological sense, as has been graphically demonstrated in at least one instance for cockroaches [50].

We offer here a partial list of pathogens isolated from various species of common domestic cockroaches (locality information, given only after first mention of a given reference, is stated after the reference number); many other pathogen isolation reports may be found in the extensive literature on this subject [51]. Although the status of each of the several pathogens with regard to antibiotic resistance, a very common phenomenon, may be of special interest to clinicians, this information is omitted here because the matter does not seem essential to the purposes of this article.

[59]; yeast [56]; *Ballantidium coli* [53]; *Cryptosporidium parvum* [53]; *Entamoeba histolytica* [60 (Taiwan)]; *Ancylostoma duodenale* [53]; *Ascaris lumbricoides* [53]; *Enterobius vermicularis* [53]; *Strongyloides stercoralis* [53]; *Trichuris trichiura* [53].

### 3.3 Homeland Security Aspects

Our primary concern here is to keep our citizens healthy and productive by ensuring that their food is safe to eat. One of the many ways to do that is to prevent the convergence of food and cockroaches, a convergence that is still much too common.

Several species of domestic cockroaches, especially *Blattella germanica* (Blattellidae), *Blatta orientalis* (Blattidae), and *Periplaneta americana* (Blattidae), can be easily reared in huge numbers in the laboratory and are easily contaminated, either superficially or internally, with certain pathogens (such as avian influenza virus, SARS virus, foot-and-mouth disease virus, *E. coli* O157:H7, to name a few) that may cause disease in humans or in domestic animals (and then, in the latter case, may secondarily cause disease in humans). Cockroaches, upon their release from the rearing environment, typically

first seek shelter. As the light of day wanes, the cockroaches will venture forth in search for moisture. Some fall into and drown in the water supplies that serve the chickens, cows, or pigs, inadvertently releasing their burden of pathogens. Others are eaten by pigs or chickens or accidentally ingested by cows as they feed nose-to-nose with the cockroaches. Others seek out the darkness and moisture of the beverage and ice machines in the school, restaurant or company cafeteria. Again, pathogens are deposited on surfaces presumed to be clean. Whether this shotgun type of dissemination will result in human or animal disease, no one can predict. But the level of probability for that eventuality seems to be at least somewhat higher than what might occur during the normal course of farm and food service operations.

Now is the time for the AIM = F strategy to pay off. Thanks to the "A," our farmers, ranchers, factory managers, food service personnel, and school administrators are aware of the inventory of unfriendly interventions that might occur; they have been "I" (Informed) on how to recognize the signs of enemy interventions; they know that IPM is an effective form of "M" (Mitigation); and the combination of AIM results in the "F" (Frustration) of this assault on the public's health. In the bioterrorism scenario, it may not be feasible to wait for the slower pest control measures that are typical of the usual lPM approach. Immediate and thorough application of insecticides and immediate quarantine measures may be essential to quell an obvious threat; protocols for these interventions should be in place, practiced and ready for implementation.

## 4 ANTS

### 4.1 Nutrition and Development

Ants (*Formicidae*, Hymenoptera) are social insects, that is, they live in colonies, each colony responding to the control of (usually) only one queen. The worker ants are females. They are the ones that leave the nest and venture out on food-finding expeditions. Colony size varies greatly according to species and within species. Some are enormous, with thousands of workers; others, only a few dozen. Unlike the cockroaches, ants go through a complete metamorphosis—egg, larva, pupa, adult; but like cockroaches, most kinds of ants live in the natural world; only a relatively few species either nest in manmade structures or routinely forage within such structures [61, 62].

Structure-invading ants are omnivores. The animal proteins and fats in their diet are derived mostly from insects and other arthropods that fall prey to the foraging worker ants. Sugars and starches or foods containing those carbohydrates are often very attractive to ants. Kitchens, bakeries, restaurants, and food factories are typical venues where ants collect a variety of foods that are then held in their chewing mouthparts and transported to the home nest to become essential nutrients for the queen and her brood of larvae. Hospitals too, are often visited. Besides the usual floor feasts of bread crumbs, sugar granules, and fat droplets, ants, especially the pharaoh ant, *Monomorium pharaonis*, may annoy patients by nibbling on food around a patient's mouth; they also feed on exposed pus and dried blood, or they may be found on patient food trays. These ants (*M. pharaonis*) have been found in IV drips and inside packages of sterile dressings [63, 64]. Water is essential and this may be obtained from any exposed source such as floor drains, urinals, patient water flasks, unemptied bedpans, wound dressings, ice machines, plumbing drips, and so forth.

### 4.2 Dissemination of Pathogens

Like cockroaches, ants harbor many kinds of internal bacteria [65, 66], but, with a few exceptions, only the external surfaces, mainly the legs and mandibles, are of concern here [1, 67–69]. These appendages come into contact with substrates, such as the soil and pit latrines outdoors and, most commonly, floors indoors, from which the ants may pick up pathogens. As the ants forage over clean surfaces, such as dishes or cutting boards, or food conveyors in a factory, pathogens may be deposited and eventually become mixed in with a food destined, without a subsequent heat treatment, for human or animal consumption. Ants as pests in hospitals have been reported many times [70–74].

We offer here a partial list of pathogens isolated from various species of common pest ants (locality information, given only after first mention of a given reference, is stated after the reference number); other pathogen isolation reports may be found in the literature on this subject.

*Bacillus cereus* [70 (England)]; bacteria (Gram +) [72 (Brazil)]; *Clostridium perfringens* [70]; *E. coli* [70]; filamentous fungi [72]; *K. pneumoniae* [71 (Trinidad)]; *Micrococcus* sp. [72]; *P. mirabilis* [71]; *Pseudomonas* sp. [71]; *Salmonella* sp. [70]; *S. aureus* [70]; *Staphylococcus* sp. [72]; *Streptococcus pyogenes* [70].

### 4.3 Homeland Security Aspects

Although ants are good candidates for the role of accidental mechanical vectors of pathogens, they are poor candidates as pawns in an act of intentional food contamination. The principal homeland security concern here coincides with the universal objective of operating hospitals and food service facilities, including the home kitchen, in such a sanitized manner that food offered for human consumption is safe to eat, that is, at least it and the surfaces it has touched have been protected from exposure to the pathogens that ants and cockroaches are known to carry.

## 5 PANTRY PESTS

### 5.1 Nutrition and Development

The moths (Lepidoptera) and beetles (Coleoptera) that infest grains, flour, nuts, chocolate, dry dog food, and cereals in the kitchen storage cabinet are referred to as *pantry pests*. They are found in home kitchens, of course, but also in grain storage elevators, huge ships that transport grains, bakeries, restaurants, chicken ranches, dairy barns, food factories, food warehouses, transport trucks, and many other venues both large and small. The pantry pests noted here are holometabolous, that is, their life stages are egg, larva, pupa, and adult. The larva has chewing mouthparts; it is the stage that does the bulk of the feeding and the bulk of the damage to commodities.

### 5.2 Dissemination of Pathogens

Compared to ants and cockroaches, pantry pests are relatively free of pathogens that cause human or animal diseases. They do not usually get out into those venues where bacterial pathogens are common. Unfortunately, they often do not long remain free of pathogens [75] or spoilage organisms [76]. This is because their food sources, in which they live throughout their entire lives, are visited by those pests that commonly visit

pathogen-laden substrates. Cockroaches, ants, flies, rats, and mice bring pathogens to the home territory of the pantry pests. The latter, then, quite inadvertently spread these pathogens here and there as they move about within their food material [77].

The situation is quite different with regard to spoilage molds. The spores of these fungi are ubiquitous; they are produced most abundantly from grain substrates that are damp and deteriorating, that is, "out of condition." Grain spoilage represents economic loss; that explains why managers of grain storages, whether for bulk commodities or retail packages, go to great lengths to maintain a dry environment for these products. But beyond the economic consideration, moldy grain can become a health hazard for both people and domestic animals when certain fungi of deterioration produce aflatoxins.

### 5.3 Homeland Security Aspects

Our concerns here are similar to those faced with ants. The primary goal is to keep susceptible products—nuts, grains, beans, coffee beans, peanuts, and so forth—free of pantry pests, the objective being to produce end-product foods that are safe for human and animal consumption. Generally speaking, the better the storage conditions, the less likely that pantry pests will become established and the less likely that spoilage molds and aflatoxin-producing fungi will proliferate in the commodity. Pantry pests spread the spores of the aflatoxin-producing fungi [78, 79] through the commodity just as they do the spores of common spoilage molds.

Several kinds of pest beetles are easy to cultivate in very large numbers. It would be a simple matter to superficially contaminate adult beetles with some pathogen and release them at a vulnerable location. The sudden increase in the population of a pest around or within a food facility would be the signal to implement AIM = F, with emphasis on immediate, focused insecticidal treatment of the affected facility.

## 1 INTRODUCTION

Preventing the introduction of diseases, especially foreign animal diseases (FADs) and diseases that could cause food-borne illness, is critically important. Diseases of this type can be devastating to the individual farm, to the industries affected, and also to the overall

**TABLE 1 2002 Census of Agriculture Market Value of Agricultural Products Sold**

| Item | Number of Farms[a] | Sales ($000)[a] | Rank by Sales | Percent of Total |
|---|---|---|---|---|
| Cattle and calves | 851,971 | 45,115,184 | 1 | 22.5 |
| Poultry and eggs | 83,381 | 23,972,333 | 3 | 11.9 |
| Milk and other dairy products from cows | 78,963 | 20,281,166 | 4 | 10.1 |
| Hogs and pigs | 82,028 | 12,400,977 | 8 | 6.2 |
| Horses, ponies, mules, burros, and donkeys | 128,045 | 1,328,733 | 12 | 0.7 |
| Total animal and animal product sales | 1,142,357 | 109,494,401 | — | — |
| Total grain and crop Production | 986,625 | 93,789,281 | | |
| Total agriculture sales | 2,128,982 | 200,646,355 | — | 100.0 |

economy. The value of US animal production is substantial (Table 1) [1]. In the 2002 census of agriculture, the United States had approximately 1.1 million animal-producing farms with average assets (land, buildings, and equipment) exceeding $500,000 [2]. The market value of agricultural production sold from animal production farms in 2002 was approximately $107 billion, and including crops sold from these farms, the total sales was $109 billion. The animal-producing sector exceeds the crop sector in agricultural value of products sold by several billion dollars.

Current US policy is to have a variety of programs and methods to control the introduction of FADs to the United States by controlling importation of live animals and animal products that can present a risk of introduction of FAD. Science-based rules and regulations established by the United States Department of Agriculture (USDA) govern activities that could present homeland security risks. There are outbreaks of FADs around the world and in many countries diseases foreign to the United States are endemic and present a constant risk of introduction. Trade, movement of people, mechanical means of transmission, and biological vectors between the countries need to be monitored and controlled to decrease transmission risks. This article presents an overview of animal agriculture production in the United States, how animal production practices influence farm-level control of pathogens, how the structure of food animal-producing industries affects prevention and control of the introduction and farm-level vulnerabilities of FADs, and finally, farm-level control of contemporary critical FAD pathogens.

## 2 OVERVIEW OF ANIMAL AGRICULTURE PRODUCTION IN THE UNITED STATES

Agricultural production has increased in efficiency over the last several decades in the United States. Increased efficiency of production has been realized by use of inputs such

as growth promotants and growth promoting antibiotics, as well as changes in the organizational structure of the industries and ongoing improvements in animal genetics and animal husbandry. Many of these changes in animal husbandry practices and organizational structure have grown out of a desire to enhance productivity by limiting the amount of disease and the potential for disease transmission. Additionally, as the profitability per animal declines over time, it becomes uneconomical for smaller producers to be involved in production; hence, through time, the scale of production in the United States has become larger. Simultaneously, we have seen an increasing movement toward so-called intensive agricultural production, where large numbers of animals are located at one geographic site in environmentally controlled and confined housing where capital investment in facilities has replaced labor to the extent economical and possible. These large scale production systems have been made possible because of improvements in disease control, improved water and feed quality, enhanced labor efficiency, and improved technology in housing structures and equipment.

## 2.1 US Beef Industry

Beef production has the highest monetary value and is the most vulnerable of the US animal production sectors. It is also one segment of animal production where a major portion of the industry remains extensive in nature. Cow–calf operations, which are responsible for the breeding and early growing segment of beef cattle occurs typically on small farms on land that is marginal for crop production but which provides good grazing land with associated shelter due to the topography and trees on these premises. In 2002, there were 796,436 beef cow farms with an inventory of 61,413,259 beef cattle and calves [3]. The two herd size categories with the largest number of beef cattle and calves were the 215,320 farms having 20–49 head each and a total of 11,496,796 cattle and calves; and the 23,126 farms having 200–499 head each and a total of 11,852,703 cattle and calves. The largest size category (over 2500 head) had fewer numbers of animals in total than the smallest herd size category of 1–9 head. With such a large number of cow–calf premises, they are more widely geographically dispersed than other less extensive production systems. Annual US beef production is estimated at about 26 billion lb (2006), with an increase of about 2 billion lb from 2005 to 2007 projections [4]. Current projections of production are expected to be stable over the period from 2006 to 2008 [4]. Animals sold from cow–calf premises are typically sold through auction markets, with the larger-scale farms being less likely than smaller-scale farms to sell through auctions [5]. Congregation of animals from previously dispersed geographic areas, as happens at auction markets, increases disease transmission and disease dispersion risks.

Beef calves weaned from cows are typically placed in a stocker or backgrounding operation, which uses production practices and resources to grow calves slowly and inexpensively; or calves may be placed directly into a feedlot. For example, a stocker operation might turn calves onto corn stubble for the winter, or into other grazing environments, which will typically cause slower less expensive growth than in the feedlot. Most (over 80% of inventory) beef calves eventually are placed into large scale (1000+ head) beef feedlots for finishing [5]. The feedlot diet consists of a higher grain content than the previous diets, and animals are usually confined to pens with a high density of cattle.

Veterinary services and biosecurity practices are quite variable premises to premises in beef cow–calf production. Most beef cow–calf operations do not have individual animal

identification [6]. Most beef cow–calf operations have limited or no biosecurity practices, or regular disease prevention programs, have potentially regular contact with wildlife in the area (70% of producers report sightings of wild deer four or more times per month, [7]) and uncontrolled human access to the animals. Additionally, most (85%) cow–calf operations have animals other than beef cattle present [8], and there is regular contact between these different animals/species; not an insignificant percentage (30% in 1997) of cow–calf operations purchase cattle to add to the existing herd [8]. Replacement heifers and cows that calve most typically are raised on the premises where they calve [6]. Since introducing new stock is an important way that new diseases could enter a herd, separating newly purchased stock (quarantine) is important for disease control; within herd quarantines for any newly purchased, cattle and calves are provided by less than 40% of operations [8]. Most cow–calf operators are unaware of the distance to other premises that contain species such as captive *cervidae*, bison, or Mexican-origin cattle [7]. It is not uncommon for cow–calf herds to graze on public or privately leased ground, and to be commingled with herds owned by other individuals [7]. Some vector control is commonly practiced with over 80% of cow–calf premises reporting fly control and 75% reporting rodent control. Carcass disposal is important for disease agent containment; most common methods used are burial, rendering, and incineration [7].

In beef feedlots, most operations use veterinary services [5]. The majority of larger feedlots (8000+ head) have formal quality assurance programs, and collect and test a variety of environmental samples, and have at least some dust control practices in place. Such practices can decrease the transmission of diseases that can be spread by virus or bacterial particles (which can ride on dust plumes carried from a premises). Almost all cattle entering a feedlot are "processed" at or near arrival to the feedlot, using a variety of procedures which can include injections, topical or oral treatments, and implants of various kinds unless they receive such processing (or preconditioning) prior to arrival at the feedlot. The average distance cattle are shipped from the feedlot to a packing plant is shorter (100 miles) for larger feedlots, compared with smaller (144 miles) feedlots, and closer (110 miles) for the central region of the United States versus other regions (179 miles) [9]. The distance that animals travel to packing plants can influence disease transmission, especially in the early stages (prior to diagnosis) of an FAD event.

Biosecurity in beef feedlots is commonly practiced, with some farms restricting the movement of people, and most farms making some effort to control entry of other animals (including horses, dogs, cats, foxes, squirrels, coyotes, raccoons, skunks, rabbits, and birds) to varying degrees [10]. Nearly all (over 95%) feedlots have fly control measures, with most implementing more than one control measure.

In terms of general security, large scale production systems are more likely to have enhanced security with limited (e.g. gated) access to the premises, security cameras, night lights, etc.

### 2.2 US Poultry Industry

The commercial poultry industry in the United States is a fully integrated system of animal agriculture. Each poultry company has control over all fiscal and bird husbandry aspects of production, from the day-old parent breeders to the marketing and distribution of the final products to the retailer. The "poultry industry" is actually three different industries: commercial layers, broilers, and turkeys. Commercial layers are chickens of the leghorn breed that lay table or breaker eggs for human consumption. There are approximately

334 million table egg layers in production in the United States [11]. These birds begin laying eggs for human consumption at 18–19 weeks of age.

The US turkey (272 million) and broiler chicken (9.1 billion) [12] industries are similar to each other, with the company purchasing the parent breeders at one day of age, or hatching eggs from a primary breeder or genetic selection company. These birds are raised on farms contracted by the company under specific company guidelines. The offspring (broiler chickens or commercial turkeys) of these breeders are hatched in company-owned hatcheries, and placed on a contract or company-owned farm, where the farmer must follow strict company guidelines for husbandry. All feed that is fed to the breeders, broiler chickens, or commercial turkeys is manufactured in a company-owned (or contracted) feed mill under specific guidelines of the company. The company nutritionist(s) will specify the nutritional aspects of the feed, and the company veterinarian(s) will determine any vaccine, antibiotic, or anticoccidial usage requirements. The birds will then be slaughtered in the company-owned processing plant.

The typical US broiler chicken farm will have approximately 100,000 chickens, divided equally into four houses. As in a city of 100,000 people, disease prevention becomes imperative for the poultry industry. Poultry veterinarians practice preventive medicine, utilizing two primary tools, biosecurity and vaccination. The US average level of death loss (mortality) in the typical 100,000-bird broiler farm is 4–5% [13]. There is also a loss of approximately 0.5–1.0% of the birds for human consumption in the processing plant, when birds are condemned by the United States Department of Agriculture-Food Safety Inspection Service (USDA-FSIS) inspectors [14].

***2.2.1 Typical Poultry Company.*** A typical broiler (or turkey) company comprises one or more divisions, or in industry jargon "complexes". A complex is a self-contained integrated unit that has broiler birds (or turkeys) breeder birds, a hatchery, a feed mill, and a processing plant. The typical broiler complex will slaughter approximately 1 million broiler chickens per week.

Typically, the manager of a complex of broiler birds will have three to four persons as direct reports who are managing this finely tuned operation on a daily basis (Fig. 1).

The feed mill manager provides all of the feed to all of the immature breeders (pullets), the adult breeders (breeder layers), and the broiler chickens in the complex. The feed is very closely controlled and monitored by the Food and Drug Administration (FDA). All documentation is available for FDA when they inspect each feed mill. It is illegal for any unapproved drugs to be added to the feed or for the level of the drug to be different than the use limitations on the FDA approved label. This means there is no legal means of using any drug in an extra label manner in poultry feed.

The live production manager has the three segments of the business dealing with the live birds. The first direct report is the breeder manager who is responsible for acquiring the day-of-age breeder chicks from the primary breeding company. These chicks are raised by contract pullet growers in specially designed houses from day 1 to sexual maturity (approximately 22–24 weeks of age). At sexual maturity, these pullets are moved in trailers with cages to breeder farms to begin laying fertile eggs. These breeder farms are typically owned by a farmer contracting with the poultry company. These contractors are paid by the dozen for the eggs produced. There are approximately 10,000 hens (plus 1000 roosters) in each house and most typically two houses per farm. The feed for both pullets and breeders is weighed and distributed automatically at a specific time of day. The water is also automatically available to the birds. All of the eggs from

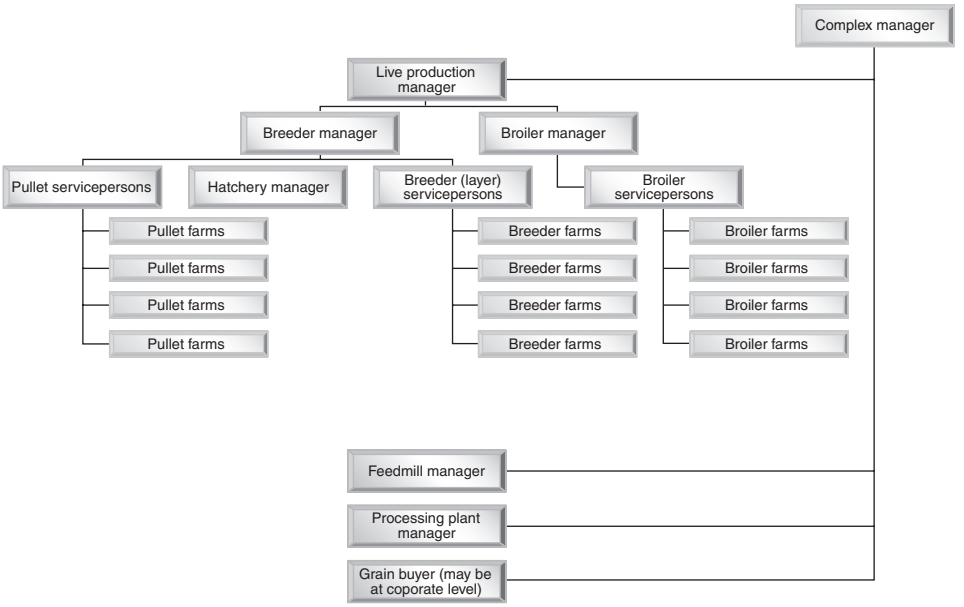

**FIGURE 1** Typical broiler chicken complex management structure.

a breeder farm are held in an environmentally controlled room on the farm for 2–3 days. An environmentally controlled truck goes to the farm, the eggs are loaded on to the truck, and then delivered to the hatchery. The hatchery manager receives the eggs from multiple broiler breeder farms and four times each week, sets eggs into incubators where they have a controlled environment. The broiler chicks hatch in 21 days (28 days for turkeys). These day-of-age chicks are typically vaccinated in the hatchery to help prevent two respiratory diseases, Newcastle disease and infectious bronchitis.

The day-old chicks are then delivered to a contract broiler grower farm where they go into an environmentally controlled house that is on average 40-ft wide and 500-ft long with approximately 25,000 broilers per house. Many of these houses have computers controlling the temperature and ventilation. An automatic feeder system maintains feed available to the birds 100% of their life. Automatic nipple or closed water systems are found in almost 100% of the houses. Fresh water from a municipal system or a potable well flows into the house and can only exit the system when a bird pecks or touches the nipple thus allowing water to go into its mouth.

The contract farmer or "grower" is responsible for the daily care of the birds, providing the building, equipment, heat, electricity, water, and litter handling. The company owns the birds and provides the feed, any medication or vaccines if necessary, and transportation of birds. The growers follow the poultry companies' husbandry guidelines. The broiler manager has many broiler servicepersons, who each have a number of farms where they provide any technical assistance to the contract grower. They visit every farm a minimum of once a week and usually twice a week. If a grower has birds that become sick, or an abnormal number dies ($>1$ bird/day per 1000, i.e. $>25$/day in a 25,000 bird house) then they immediately contact their broiler serviceperson (available 24 h/day). These broiler servicepersons are trained by veterinarians to perform necropsies or they

may deliver diseased or dead birds to a diagnostic laboratory veterinarian in order to identify the cause of excess mortality.

The broiler chicken growers' pay is based on the pounds of broilers delivered to the processing plant utilizing the least amount of feed for growth. They will have any birds that are condemned by the USDA as unwholesome for human consumption deducted from this weight. Therefore, it is important for growers to follow company husbandry guidelines. Also for many poultry company contracts, the use of any medication, insecticides, disinfectants, etc. will be strictly controlled by the company.

The birds on a broiler farm are of the same age (all in at the same time). When the birds reach slaughter age (on average ~49 days old) all birds are caught and loaded on to trucks and delivered to the processing plant (all-out at the same time). At the processing plant, the USDA-FSIS veterinarian is responsible for antemortem and postmortem inspection. The processing plant manager oversees all operations from slaughter to the final product leaving the plant.

### 2.3 US Pork Industry

The US pork-producing industry has also changed dramatically over the past few decades. What was once an industry dominated by small, independently owned operations now comprises fewer, larger operations that are concentrated in certain regions of the United States. In 1995, only 2.6% of swine operations had 2000 or more hogs and held 43% of the inventory. In 2006, 11.8% of swine operations had 2000 or more hogs, holding 80% of the hog inventory. Over 21.1 billion lb of pork was produced in 2006 [15]. As for the poultry industry, decreased production costs and increased efficiency obtained from using new specialized technologies and genetics, among other things, have contributed to the increased pork industry concentration [16].

Many parallels can be seen with the poultry industry as the pork industry becomes more specialized and vertically integrated. A previously open market industry has moved to one dominated by marketing and production contracts. In marketing contracts, producers agree to deliver a certain number and size of hogs to processors at a certain time. Prices received by producers may be determined in advance or be a formula-based price, such as a spot market price. Production contracts are becoming more common and are not dissimilar to production contracts in the broiler industry. In these contracts, an integrator (large producer or processor) provides the inputs such as the hogs, feed, veterinary, and management services. The contractor provides the land, facilities, and labor, and receives a fixed payment. In both types of contracts, premiums may be given for production efficiency or the quality and size of the hogs [16].

Total confinement and multiple-site production are commonly used in US swine production operations. Operations that specialize in a specific phase of production are becoming more common. Such operations take advantage of newer cost efficient technology and improved genetics in many aspects of production. The attractiveness of specialization has caused the number of farrow-to-finish operations to decrease [17]. Farrow-to-finish operations are generally less efficient and have an increased risk of disease introduction and spread due to the wide age range of pigs on a premises, and increased movement of pigs and personnel on and off these sites, as compared to operations that specialize in one phase of production. Farrow-to-wean, nurseries, and grower or finishing operations are three typical phases of specialized production and will be discussed next.

***2.3.1 Farrow-to-Wean.*** Artificial insemination is the primary technique for mating gilts and sows, especially in large and medium size operations. Semen is primarily purchased or collected off-site [18], eliminating the need to keep boars on-site except for checking if the gilt or sow is ready for insemination (in heat). Artificial insemination does reduce the risk of disease transmission. Semen should still be tested for certain diseases (e.g. porcine reproductive and respiratory syndrome; PRRS). In 2006, [18], the average number of piglets per litter was 11.5, with 10.5 being born alive and 9.4 weaned. Preweaning mortalities ranged from 8.5 to 11.3% per litter The most common reason for preweaning deaths is from being crushed by the sow. Piglets are injected with iron when they are 7–10 days old and are sometimes given antibiotics in the feed. Most breeding-age females are culled when there is a reproductive failure or when the age of the female becomes a risk factor. Carcasses are primarily disposed of by rendering or composting on-site [18]. There can be a high flow of new arrivals on farrow-to-wean production sites and proper biosecurity is important to decrease the risk of disease introduction. Isolating or quarantining, and disease testing of new breeding animals before they are introduced into the herd can help prevent the introduction of new pathogens. Newly introduced pigs are isolated for an average of 4–6 weeks. Administering vaccines to new arrivals is the most common acclimation method used. Other acclimation practices include exposing new arrivals to pigs on-site, and less commonly feedback of feces from other swine or feedback of mummies, placentas, or stillborn pigs [18].

Pigs are generally weaned between 16 and 27 days, although larger operations may wean at an earlier age (16–20 days). Pig flow is continuous during gestation phases and primarily continuous or all-in/all-out by room or building during farrowing phases. All-in/all-out management includes cleaning and disinfecting before the room or building is refilled which reduces the risk of disease spread [18].

***2.3.2 Nursery.*** Weaned pigs often move to a nursery, where they will stay for 6–8 weeks. Pigs leaving the nursery will weigh 30–80 lb. Annual mortalities in nurseries are typically 4–5%, with respiratory problems being the most frequent reason for deaths. Most operations use antibiotics in feed and vaccination as disease prevention methods during this phase of production. Nursery pigs are commonly vaccinated for *Mycoplasma* and erysipelas. Pig flow is mainly all-in/all-out. Pigs are primarily obtained off-site from another producer and come from a single producer (i.e. single source), although 25.4% of larger sites obtained pigs from three or more sources [18].

***2.3.3 Grower or Finisher.*** Pigs stay at a grower or finisher site for an average of 16–18 weeks. Annual mortalities and pig flow management are similar to nurseries. Also like nurseries, pigs are primarily obtained off-site from a single source. The most common disease prevention method used during this phase of production is antibiotics in feed [1]. Once they reach market weight (225–300 lb), most hogs will be sold to one or two packers, but may be sold to more depending on the geographic proximity of packers and production sites [19].

Hog production was previously mainly concentrated in the North Central regions of the United States (Iowa, Illinois, Indiana, and Minnesota), but has expanded to include the South Atlantic (North Carolina) and South Central (Oklahoma, Texas) regions [16]. Differences in operation types are seen between regions. For example, weaned pigs are commonly transported from the South Atlantic to the North Central region to be finished [18]. It has been estimated that 3.8 million hogs were shipped out of North Carolina in

2001 [20]. Based on the 2006 National Animal Health Monitoring System (NAHMS) study of the swine industry, 31.6% of sites shipped pigs across state lines [18]. Also, approximately 8% of hogs slaughtered in the United States are of Canadian origin. Most Canadian hogs are imported to the North Central region as feeder pigs, and the rest go directly to slaughter houses [17]. Livestock trucks transporting pigs between the different phases of production, both locally and regionally, can also spread pathogens in the process. Both local and regional animal movements can affect the extent of an outbreak, especially if there is delayed detection of disease. It is believed that a livestock truck that was not properly cleaned and disinfected was responsible for the spread of classical swine fever (CSF) from Germany to The Netherlands during the 1997–1998 outbreak [21].

Feral swine populations continue to grow in the United States, and their distribution is becoming more widespread. Estimates of their numbers are over 4 million, with the majority of feral swine located in Florida, Texas, and California. They pose a serious risk for transmitting endemic diseases of feral swine such as brucellosis and pseudorabies. FADs could also be introduced into the feral swine population and go undetected for some time. An FAD introduced into feral swine could fade out or become endemic. This represents a risk of disease transmission to commercial swine if biosecurity does not prevent direct or indirect contact between feral and commercial swine. In the 2006 NAHMS swine study, 25% of large sites and 12% of medium sites reported the presence of feral swine in their county, especially those facilities located in the southern regions [18].

Rodents can also spread disease, either as hosts or mechanical vectors. Most operations use some method to control rodents; bait or poison is most frequently used. The majority of swine operations only allow employees to come into contact with areas that house the swine. Some companies have their employees sign documents prohibiting them from owning swine of their own. Outside visitors that are allowed in areas where the swine are housed are usually required to put on clean boots and coveralls. Operations may require visitors to be without swine contact from other premises 24 or more hours before entering [18].

## 3 PREVENTING/CONTROLLING INTRODUCTION OF DISEASES AT THE FARM LEVEL

Production practices and the structure of the food animal industries imply many areas of vulnerability. Large numbers of animals are often housed at one geographic site, and often in a shared airspace, or in close confinement. Although such practices enhance the profitability of production and also decrease transaction costs for production companies (costs decreased or avoided with integrated production companies), they can increase disease transmission risk by making a larger number of animals at risk for becoming infected by a contagious disease. However, large integrated companies can also afford to have more stringent biosecurity practices through economies of scale in production. Large companies are more likely to have in-house veterinary staff, written and enforced biosecurity guidelines, in-house diagnostic laboratories, and other production inputs that are not possible for smaller scale production systems. The net impact then for disease risks implied by the current food animal industries' structure and production practices in the United States is unclear; there are forces that could increase disease transmission risks and forces that would decrease such risks. Similarly, the development of appropriate and

protective countermeasures can simultaneously have aspects that are of varying difficulty to implement.

The remainder of this section focuses on production inputs and ways to help harden these as sources of vulnerabilities. Obvious risks include genetic stock (both live animals and semen or eggs/embryos), vectors for disease transmission, feeds, supplements, water, vaccines and pharmaceuticals, and air.

### 3.1 Direct Animal Contact and Genetic Stock Vulnerabilities, Vehicles/Fomites, and Vectors as Sources of Pathogens

Goals for biosecurity of live animals include minimizing opportunities for disease transmission, decreasing sources of infectious agents, using methods such as vaccination and good husbandry to enhance the immune status of animals to prevent disease, and monitoring for the presence of disease while using appropriate diagnostic testing to become aware of the profile of pathogens and immune status. Infected live animals and direct contact are arguably the most likely source for introduction of many FADs to a herd or flock. By appropriately siting production facilities away from neighboring herds and flocks and then maintaining a closed herd/flock (i.e. no animals are admitted from outside sources) sources of infectious agents can be minimized. This means that no animals are admitted from outside sources. This practice may or may not be possible or appropriate.

The next alternative is to identify animals that will come to the farm that are from sources that have high biosecurity and that can certify the disease status of their animals and products (e.g. semen). It is important for farms to use transportation methods and routes that are safe and will limit potential exposure to infectious agents by limiting sources of infectious agents, for example, manure, animal hair, dander, and dust. This means transporting animals using thoroughly cleaned and disinfected trucks, and when possible, company-owned transportation. Quarantine of all newly arrived animals is needed so that there is adequate time for monitoring and testing for diseases that might have been carried to the farm by the new animals. Appropriate vaccination or processing prior to mixing new arrivals with any animals that are on the premises will further ensure the safety of adding new genetic stock to the farm. Biosecurity surrounding the introduction of live animals may be the most important area for protecting the farm from FAD risk.

Additionally, there are many other activities that are important to decrease the likelihood of FAD introduction to a farm. Control of traffic of all types to the premises is critical. Exclusion of unnecessary visitors, pets, and pests will decrease the likelihood that a disease is introduced accidentally. Disease can be introduced by animal or environmental exposure/contamination to vehicles/fomites such as boots or coveralls, pets or pests, or a variety of other mechanisms. Pests include vertebrate animals such as wild birds, rats, mice, and raccoons, as well as invertebrate vectors, which may transmit disease, such as flies and mosquitoes. As examples, poultry production systems and many swine production systems require the use of disposable coveralls, boots, gloves, face masks, and hair bonnets for all people entering the premises. Additionally, many swine production systems require shower in and shower out for all visitors to production facilities. Many systems stipulate and enforce a period of no animal contact prior to visiting the facilities for all noncompany personnel. Maintaining a record of all visitors is also a common practice on poultry and swine production systems.

Cleaning and disinfecting between batches of animals decreases the disease transmission risks between batches. Reporting of abnormal signs of disease and maintaining a veterinary–client relationship are all valuable practices so that if disease is present or introduced, it is treated promptly and when appropriate, the facility is depopulated, infected materials are appropriately disposed of, and the facility and all associated equipment and materials are cleaned and disinfected. These and many similar practices all contribute to enhanced biosecurity for the animals present in production systems.

The description of the goals of biosecurity should make it obvious why much of the US commercial agriculture, as explained in the previous section describing the US animal production sectors, has evolved to its current structures and practices. For example, the current structures and practices in commercial broiler and turkey production and larger-scale swine production have the same age animals that arrive from a single source, into facilities that are managed as all-in–all-out (or batch) production. Companies and production methods have been structured to avoid introduction of disease to the farm.

Genetic stock is an important source for meeting improved product standards driven by industry demands. Today in commercial agriculture, breeding companies develop and maintain pure breeding lines, which are used to create grandparent stock. Grandparent stock are the parents of so-called parent stock. Parent stock are then the parents of the commercial animals. Biosecurity for genetic stock involves similar functions to those applied directly to the commercial animals, except that the standards are even higher.

The use of purchased semen is a common practice to introduce new genetic stock or simply as the standard for parent stock breeding systems. Practices that will enhance biosecurity for semen include obtaining semen from known negative sources, from companies that practice high biosecurity and use extensive surveillance and testing, and ensure the safety and security of transportation and delivery of semen to the farm premises where it will be used. Frequency of disease testing and the openness of semen company records are some of the indicators that can be used to assess the biosecurity of semen providers.

Companies responsible for providing semen to producers must consider a variety of issues beyond the basic biosecurity and surveillance of their animals. For example, sources of equipment and products (e.g. semen extenders) must be thoroughly checked with ongoing methods to detect accidental or potential sabotage to materials that could contribute disease risks to the semen products they produce.

Studies help elucidate the risks for farms and on-farm production practices. For example, a risk analysis for the importation of CSF (also known as *hog cholera* and an FAD that was eradicated from the US swine population in 1976) demonstrated that CSF is spread by movement of live animals, especially wild boars, people, vehicles, equipment, or semen contaminated with virus [22]. These risk factors identified for the importation risk model apply also to potential spread within the US domestic herd.

There is a variety of other practices that can be implemented to help harden on-farm production systems. Examples include the following:

- Background checks for all hired personnel
- Enforcing company biosecurity policies/monitoring employee compliance of company biosecurity requirements
- Anticipating and watching for abnormal signs of disease and abnormal activity of people in and around the production facilities

- Establishing farm-specific emergency response plans
- Identifying animal disposal sites that meet Environmental Protection Agency (EPA) requirements
- Identifying depopulation, disposal, and disinfectant/decontamination methods and partner companies that could be worked with if needed
- Siting facility locations to minimize exposure to other herds/flocks including siting away from major roads/freeways
- Participating in and practicing with industry and local county animal response team (CART) and state animal response team (SART)
- Structuring the farm and animal production sector to provide for agility of response to outbreaks from a variety of considerations

### 3.2 Feeds/Supplements and Water Vulnerabilities

Feeds/supplements and water will be discussed from the perspective of the poultry industry, but the concepts and vulnerabilities identified apply generally to animal agriculture production. The two primary sources of water for poultry are also the same sources for the human population: municipal water and well water. Both sources should be potable drinking water. If a farm is near a municipal/local government water system, it may source from that system. However, because of the large amount of water usage, especially in the summer to aid in cooling birds, and because the location of production systems does not normally allow accessing municipal water systems, the source of water for the majority of farms is wells. Commonly, more than one well is required to supply water to a farm. In most cases, the well water would have been tested for potability when the well was first opened but may not be tested again unless a problem is suspected.

Many turkey farms and some broiler breeder farms have water treatment systems, primarily chlorinators. Few broiler or layer farms have any consistent water treatment occurring. Many newer farms have water meters in each house/barn and the farmer/grower/company will monitor water consumption.

From a biosecurity perspective, the water system is an area of vulnerability. Some diseases and chemicals could be transmitted by contaminating the water system. This can occur both naturally and by intentional introduction. The testing for potability is typically limited to looking at organisms that are indicators of fecal contamination, nitrates, and ion levels including sodium, chloride, sulfate, iron and manganese. For livestock, testing may also include pH, conductivity, potassium, total dissolved solids, and hardness. Potability testing does not generally indicate the presence of other disease agents, toxins, or chemicals that could cause a disease.

The water source should be secured and regularly checked. This will mean locking the well heads, and controlling the source, storage, and use of any chemicals and water processing systems that may be used. Water that is obtained from a municipal system, while perhaps more secure, can also be potentially contaminated. Given the ease of distribution and wide exposure contaminated water could cause, ensuring quality water in animal agriculture production is important.

The majority of feed provided to all segments of the poultry industry in the United States is obtained from large centralized feed mills specific to that location/company. Nearly all of the broiler chicken and turkey feed mills provide feed for only broilers or turkeys of that company. However, many of the commercial table egg-producing feed

mills are multiple species mills, producing feed for dairy cattle, beef cattle, etc. The ingredients are primarily corn (energy) and soybean meal (protein) with added vitamins, minerals, and any medications. The feed accounts for as much as 60% of the cost of producing the poultry or eggs, so feed ingredient prices significantly affect which ingredients are used. For example, as the price of soybean meal increases, more rendered by-products derived from animal processing plants are used as a protein source. Routinely now, ruminant rendered product (meat and bone meal) is used as a cheaper source of protein to add to poultry diets in addition to soybean meal.

The major raw ingredients arrive at the feed mill either by train or by truck in bulk. These will be offloaded and stored in large silos. The minor raw ingredients such as minerals, vitamins, or medications come in bags and these are stored usually in the warehouse section of the mill.

Feed mills will normally produce feed for 16+ h/day and feed is delivered in bulk tanker trucks which augers the feed into storage bins on the farm. The system on the farm is a closed auger system from the bin which supplies one to two houses (i.e. barns). The feed mills are an area of vulnerability for animal agriculture. Feed mills are operating 16+ h and have feed being delivered from the finished feed storage bins almost 24 h/day. Feed mills are usually open with few locks or security systems. Employees, feed trucks, raw ingredient vehicles, etc. are coming and going on an almost continuous basis. Thus, intentional introduction of pathogens, toxins, or chemical contaminants is possible.

Feeds have been shown to be a risk recently with the melamine contamination of poultry and pig feeds [23]. This contamination occurred through the use of feed ingredients imported from China used in producing pet foods. Left over pet food ingredients were then purchased by animal feeds manufacturers and used in the production of animal feeds. The contamination was traced to the use of a rice protein concentrate, wheat gluten, and corn gluten that evidently had melamine used to increase the apparent protein content of the feed. Hogs that fed the melamine were initially quarantined. They were eventually allowed to go to slaughter after a holding period and testing revealed they were safe for human consumption. There was significant market disruption and concern generated for the producers directly involved in this event and for the industries generally. Undoubtedly, there will be increased guidance and potentially increased regulations from the FDA, the agency responsible for oversight of animal feeds.

Animal feeds have a history of being a target for a terrorist attack [23]. Many poisonings have been accidental [23, 24]. Still these incidents are informative about the potential risk and the needs for improving feed security.

The use of garbage feeding of pigs is forbidden by federal law unless the garbage is treated (usually by cooking) to kill disease organisms. Garbage can be a source of transmission of animal diseases including FADs, such as foot-and-mouth disease (FMD). Additionally, human pathogens found in garbage can be transmitted to pigs if not killed by cooking the garbage, and might form the basis for a zoonotic cycle of disease transmission.

Salmonella is a zoonotic pathogen that can be transmitted in feeds. In poultry, it has been well documented that feed can be a source of salmonella [25, 26]. The primary source of salmonella introduced into feed is from a contaminated raw ingredient with animal protein sources often having high levels of salmonella [27]. Additional sources of salmonella introduction into finished feed can be from residual feed in the mill from passage of previously contaminated feed, from rodents living in or near the feed mill, and from wild birds [26].

### 3.3 Vaccine and Pharmaceutical Vulnerabilities

Vaccines and pharmaceuticals are a source of vulnerability for food animal production. These materials need to be kept in a secure location which holds the materials at appropriate conditions needed for the materials. Materials must be procured from reputable sources that conduct assessments for quality and safety of product. Clean injection equipment needs to be used with new needles used for each animal, or at least changed frequently if new needles are not used on every animal. Records need to be kept of all use of vaccines and pharmaceuticals.

### 3.4 Air Contaminants and Airborne Spread of Pathogens

Aerosol transmission of certain pathogens and contaminants can occur within and between farms. Successful transmission depends on many farm-level factors. Host factors include the animals' health status, species, age, density, and their behavior and interaction. Management factors include the building type (layout, floor type, dimensions, ventilation system), feeding system (equipment, time and duration, feed type), waste removal system, and bedding type. Environmental factors include temperature, relative humidity, concentration of gas, and the direction and speed of air [28, 29].

For airborne spread of pathogens, a sufficient amount of infectious particles must be generated by infectious animals and transported and inhaled by susceptible animals [30]. Infectivity must be maintained in order for susceptible animals to become infected. Airborne particles originating from droplets stay in the air for longer periods of time than particles originating from dry matter, such as dust. A high amount of aerosolized particles are generated from animals that sneeze or cough, and a lower amount from normally exhaled breath [28]. Aerosols can also be generated from urine or feces, especially from spraying slurry [31, 32], and from bedding and feed [33]. Airborne FMD viral particles may originate from incinerating infected carcasses [34]. Once in the air, pathogens undergo decay that is related to the amount of time they remain in the air, particle size, temperature, and relative humidity [35]. Influenza viruses are most stable in dry air, whereas FMD virus is most stable in moist air [28]. Airborne particle concentration has been shown to increase at lower temperatures [33], but this can be influenced by the type of farm management. Building design and ventilation systems are equally important as animal activity and density in determining airborne particle concentrations [36]. Cool and damp environments that are flat, with little to no wind and sunlight, favor the travel and survival of airborne particles over long distances [28].

Airborne disease transmission depends on the minimal infective dose of the agent needed to cause infection, as well as farm-level factors such as herd size and type/susceptibility of animals. Transmission is more likely to occur as herd size increases. Larger animals and older animals have a higher risk of becoming infected because they breathe in more air than smaller and younger animals. For example, there is lower risk of transmitting airborne FMD virus to hog farms than to cattle farms [37].

Airborne disease transmission risk can be reduced. Reducing dust, where feed is a major source, greatly reduces aerosol particles [28]. Dust can be reduced from feed by adding tallow, soybean oil, or water [38]. The amount of animal activity and movement should be decreased, when possible. Slurry and manure spreading should be done appropriately to limit the production of aerosol particles as much as possible. Facilities should be designed to allow for proper ventilation and space between animals; the relative humidity to decrease airborne transmission risk is 60% or above [39]. Strategically

placed air inlets can also be beneficial [40]. Although expensive, combining air filtration and positive pressure ventilation has also been suggested [28].

Facility dispersion (i.e. more space between facilities) will help decrease airborne disease transmission risk. However, appropriate spacing of housing is not always feasible, and this alone is not enough to prevent aerosol transmission [36]. Personnel on farms should always be vigilant and follow appropriate biosecurity protocols when entering and exiting animal houses. Movement between infected and noninfected houses by the same person should be minimized or avoided. Depending on the disease, vaccination as part of an overall animal health plan can also help prevent diseases caused by airborne pathogens.

## 4 PATHOGENS OF CURRENT CRITICAL IMPORTANCE FOR FOOD-PRODUCING INDUSTRIES

Infectious diseases and emerging pathogens are of critical importance in today's food animal-producing industries. Even endemic diseases have become of increased importance. For example, low pathogenic avian influenza (LPAI) is a disease which is endemic with periodic regional epidemics being experienced (for example in the turkey industry). However, LPAI has become of critical importance because of the potential for mutation to highly pathogenic avian influenza (HPAI). There are many endemic diseases of importance for food animal-producing industries. Indeed, there are so many that whole books are written on such topics. In this section, three FADs of contemporary importance are discussed: HPAI FMD, and CSF

### 4.1 Highly Pathogenic Avian Influenza

The two most important poultry FADs are exotic Newcastle disease (END) and HPAI. Since there is minimal zoonotic potential with END, the focus here is HPAI. However, END is a potentially devastating disease to the poultry industry as evidenced by the outbreak in Southern California, Nevada, Texas, and Arizona in 2002–2003 that cost an estimated $198 million [41]. This END outbreak was limited to a small segment of the commercial poultry industry and was primarily in game fowl and backyard flocks.

The last major outbreak of HPAI in the United States occurred in 1983–1984 in Pennsylvania [42]. This outbreak, caused by an H5N2 virus, affected 448 flocks with more than 17 million birds destroyed in Pennsylvania and Virginia. The virus began as an LPAI subtype H5N2 and then quickly mutated to the highly pathogenic form. The USDA spent over $63 million in 1983 to eradicate this virus from these two states and prevent further spread. This amount does not include the cost to the individual farmer (except indemnity for the affected flock), the losses for the poultry industry in lost revenue, and the many other costs that are not easily calculated.

In general, influenza viruses are very host specific; however, there have been some occasions when the virus has crossed between species as has been seen in the recent H5N1 in Asia crossing from poultry to humans [43]. The recent viruses that have been associated with bird to human transmission are of the H7 and H5 hemagglutination type. It is because of the recent Asian outbreak and concerns for a further change in the virus that many states have now begun programs for containment of low pathogenic H5 or H7 avian influenza viruses.

HPAI is a reportable disease [44]. The USDA is designated with the authority for containment, destruction, and indemnity. However, successful control of an outbreak will require close cooperation among the USDA, the state(s) where the outbreak is occurring, and the poultry industry. HPAI outbreaks also include notification of the US Department of Health and Human Services and the US Centers for Disease Control and Prevention.

There is a federal program for monitoring for LPAI called *US Avian Influenza Clean* for layer and broiler breeding birds. This is administered by the USDA's National Poultry Improvement Plan (NPIP) [45]. This program requires that a minimum of 30 birds be tested and antibody negative for avian influenza when more than 4 months of age. To retain negative classification, a breeder flock must have a minimum of 30 birds tested negative at intervals of 180 days. Also, before these birds are slaughtered, 30 days prior to the end of the laying cycle, 30 birds must be tested and antibody negative.

The USDA-NPIP also has recently begun a special program for the meat-type (broiler) chicken industry to monitor for H5/H7 subtypes prior to slaughter. This program requires a negative antibody test for H5/H7 subtypes of avian influenza from a minimum of 11 birds per flock no more than 21 days prior to slaughter.

In most states with large numbers of commercial poultry, there are also active surveillance of live bird auctions and markets, as well as passive surveillance programs. Passive surveillance programs include serological testing of all live birds submitted to state diagnostic laboratories for avian influenza.

In the event of a positive serological result, the confirmation of subtype will be done by a USDA authorized laboratory, frequently the USDA National Veterinary Services Laboratories (NVSL) in Ames, Iowa. NVSL will immediately report the results to the proper state authority. If it is an H5/H7 subtype of LPAI, then the state veterinarian will quarantine the farm and implement that state's avian influenza (AI) response plan. It should be noted that a serological surveillance program is not necessary in the event of an introduction of HPAI since there are normally morbidity and mortality rates approaching 100% [46]. In this event, the poultry producer will immediately notify either a company veterinarian or a local diagnostic laboratory.

HPAI can be readily diagnosed and would result in an immediate quarantine and depopulation of the affected premises by a cooperative effort of federal, state, and local authorities working closely with the poultry producers. The size of the affected premises or number of premises affected will determine the size of a testing and/or depopulation zone around the index premises. All of this will be decided by the response (also called *the incident command*) team of the federal, state, and poultry industry cooperators. LPAI cannot be clinically distinguished from other respiratory diseases. Therefore, the USDA and state programs for active serological surveillance are necessary and have been shown to be effective in identifying H5/H7 subtype affected flocks as seen in 2007 in West Virginia and Virginia. These birds were identified and depopulated. The virus did not spread.

The method of mass depopulation of floor reared poultry that is being developed is using foam [47]. Foam has been shown to be a faster depopulation method as group size increases and is no more stressful for the birds than $CO_2$ depopulation. Speed of response in an FAD event is critical to a successful response. Foam has the added advantage of needing fewer humans to depopulate larger houses, and thus may be preferred for HPAI.

Proper handling of depopulated birds and infected materials such as litter is also important for a successful response. Natural decomposition by on-site composting was the method used for the 2007 LPAI events in West Virginia and Virginia. The biosecurity

of on-site composting needs more research, but appears to have good potential for meeting the biosecurity goals of appropriate and safe carcass disposal [48].

### 4.2 Foot-and-Mouth Disease

A major epidemic of FMD in Taiwan in 1997 caused the death of approximately 184,000 pigs; additionally, almost 4 million hogs were slaughtered in the eradication program [49]. The previously robust Taiwanese pork industry has been restructured and downsized [50]. The FMD outbreak in the United Kingdom in 2001 had an estimated economic impact of £8.6 billion (equivalent to $17.4 billion US) [51]. There has been a second outbreak in 2007 in the United Kingdom that is substantially smaller, although still costly. Both of these economies suffered in major ways because of FMD. Additionally, there was serious animal suffering and human psychological problems, as well as serious restriction of a variety of activities. For example in the UK outbreak in 2001, the most important economic impact was associated with loss of tourism and recreational use of agricultural lands and the countryside.

FMD is considered an important contemporary FAD because of ease of access to the virus (there are many countries where FMD is endemic), extremely contagious nature of the agent and its ability to spread rapidly, the affect on multiple species (all cloven-hooved animals are affected, including dairy cattle, beef cattle, pigs, goats, and sheep to name a few), the high potential impact on international trade, and the potentially severe economic, social, and political consequences of the disease [52]. Epidemiological models have suggested that as many as 17% of all herds could become infected during a hypothetical outbreak of FMD in California [53]. Total eradication costs from the simulated FMD outbreaks ranged from $61 million to $551 million with mean herd indemnity payments estimated to be $2.6 million and $110,359 for dairy and nondairy herds, respectively [54]. Wind-borne spread of the virus contributes to a higher potential for more rapid spread since it can spread to 20 km [55].

The National Center for Animal Health Emergency Management (NCAHEM) has plans for handling an outbreak of FMD should it occur in the United States. Similarly, there are many states and state animal or agricultural response teams that have plans and have conducted exercises around FMD scenario outbreaks. The United States also maintains the North American FMD Vaccine Bank which provides ready access to FMD vaccine should this be needed as part of mounting appropriate countermeasures during the face of an outbreak of FMD should one occur. This vaccine bank contains contemporary FMD strains with sufficient cross strain immune protection to cover virtually any strain that might occur, either from a natural introduction or bioterrorist introduction of FMD. Additionally, it has been shown that use of an emergency vaccine will prevent or reduce virus replication dramatically reducing the amount of virus released into the environment [56]. This is critically important in the early stages of an outbreak, and suggests that vaccination can be used as an appropriate countermeasure even if animals receiving vaccine will be diverted to depopulation later in managing the outbreak. Animals might be diverted to depopulation rather than being sent through market channels because the rules established by the OIE (World Organization for Animal Health) currently require a longer period of time to elapse, from the identification of the last known infected animal, in order to be listed as disease free, if vaccination has been used as a part of the control measures employed during an outbreak. Since the OIE-disease free status provides access to markets which exchange at a premium rate over markets which involve other

designations, there might be times at which the most epidemiologically and economically sound decision would be to use vaccination to slow disease spread because depopulation could not proceed as rapidly as desired. This would make time for later depopulation, while simultaneously preventing the negative impact of having used vaccination as a part of the control strategy (since the vaccinated animals do not enter market channels).

### 4.3 Classical Swine Fever

CSF, also known as *hog cholera*, is a highly contagious disease of swine. CSF was first recognized in the United States in 1833. The United States was declared free of CSF in 1978 following an intensive 16-year eradication campaign, which cost $140 million. A similar eradication effort would have cost approximately $525 million in 1997 [57, 58]. The virus remains widespread throughout the world and is well established in the Caribbean basin and regions of Mexico despite extensive control and eradication efforts. Outbreaks continue to be reported in countries with control programs, while other countries simply consider the disease endemic. In many counties in Europe, CSF has become endemic in large wild boar populations [59]. The ease of access to the CSF pathogen in the Caribbean basin represents a significant threat to the United States for both intentional and nonintentional introduction. Any introduction of CSF could result in significant economic loss due to the subsequent need for massive control and eradication efforts, and the resulting loss of access to foreign markets. An outbreak in The Netherlands in 1997, for example, resulted in the destruction of almost 11 million pigs, of which almost 9.2 million were slaughtered for welfare reasons [60]. The cost of this epidemic has been estimated at US $2.3 billion, which included both direct costs and the consequential losses to farms and related industries [61].

Infected pigs shed virus in all excretions and secretions including blood, semen, urine, feces, and saliva. Oronasal is the most important route of transmission between pigs [62]. Transmission of CSF may occur through direct contact between domestic and wild/feral pigs, by feeding pig carcasses or infective pig products (especially swill feeding) to susceptible animals, or indirectly via contaminated clothing or equipment [63]. During the 1997–1998 CSF outbreak in The Netherlands, 17% of transmission was due to direct animal contact. The rest of transmission was due to indirect contact, primarily from transport lorries [64]. Illegal swill feeding is responsible for many outbreaks as the virus survives very well in meat. The virus has been shown to survive up to 4 years in frozen pork [65].

Clinical signs of CSF can be variable and depend on many factors, the most important factor being viral virulence. Although outbreaks of highly virulent strains characterized by high mortalities were common in the past, currently circulating strains are predominately mild to low virulence [66]. Introduction into the United States of low virulence CSF may delay detection. Such was the case in Europe. The approximate time from viral introduction until detection of CSF outbreaks was 3 weeks in Belgium (1993), 4 weeks in the UK (1986), 6 weeks in The Netherlands (1992 and 1997–1998 outbreaks), 8 weeks in Germany (1997), and 9 weeks in Spain (1997) [64]. Many other diseases in swine have clinical signs indistinguishable from these low to moderate CSF strains. These diseases include PRRS, erysipelas, *Salmonella*, *Pasteurella*, postweaning multisystemic wasting syndrome (PMWS) (all endemic in US commercial swine), and any enteric or respiratory disease with fever that is unresponsive to antibiotics [62]. Floegel-Niesmann et al. [66] evaluated the virulence of recent CSF strains and concluded that clinical diagnosis would

be difficult up to 14 days post infection. Still, 75% or more of outbreaks in Germany and The Netherlands were detected by clinical signs [67]. Fever and apathy or fever and ataxia were the most prominent clinical signs reported by veterinarians and farmers during the Netherland outbreak [64].

The United States does have a CSF surveillance plan. The objectives are to allow for rapid detection, monitor the risk of introduction and CSF status in other countries, and to demonstrate freedom of disease, which is especially important for trading purposes. A passive surveillance plan relies on reporting by veterinarians, producers, diagnostic labs, and slaughter plants of pigs with clinical signs similar to CSF. Once the area veterinarian in charge (AVIC) is notified, a foreign animal disease diagnostician (FADD) will be sent to investigate and collect appropriate samples which will then be shipped to the Foreign Animal Disease Diagnostic Laboratory (FADDL) at Plum Island, New York. The United States also actively performs surveillance of high-risk swine populations, such as waste feeding operations, condemned pigs at slaughter facilities and periodically, feral swine. Twenty-six high-risk states and Puerto Rico have been identified for sample collection. Eligible samples from sick pigs received by a CSF-approved National Animal Health Laboratory Network (NAHLN) laboratory can be tested [68].

CATHERINE H. STROHBEHN
*Iowa State University, Ames, Iowa*

## 1 INTRODUCTION

Projected sales for the foodservice industry for 2007 were $537 billion with $1.5 billion of food sold on a typical day. There is a great deal of concentration of ownership within the food industry at all levels: production, processing, distribution, and retail sales. With the population of Americans shifting from rural to urban locations, the majority of consumers' food is purchased from retail and foodservice establishments, which rely on food wholesalers to procure food from food manufacturing plants. These food facilities are inspected at least once per year, but potential for intentional contamination through physical or chemical agents can occur at any time.

The restaurant industry employs an estimated 12.9 million people, 9% of the US workforce, making it the largest employer outside of government [2]. The foodservice industry is expected to add two million jobs over the next decade, with total employment projected to reach 14.8 million in 2017. The majority of foodservice workers (83%) are employed in privately owned eating and drinking establishments.

The largest category of commercial eating places is restaurants, with projected market sales of $491 billion in 2007. Although more than 7 out of 10 eating and drinking places are single unit, independently owned operations [3], those establishments that are part of multiunit or chain organizations are serving food to greater numbers of people.

Census data from 2000 showed increasing diversity in the US population with an increase of 30% for Hispanics and growth in the other races of 29%. Data from the National Restaurant Association (NRA) in 2006 found about one of every four restaurant employees (26%) was reported as speaking a foreign language at home (predominately Spanish) compared to 18% of the overall population [4]. Foreign born workers represented 21% of foodservice employees in 2004 [2] Because the foodservice industry hires a large diverse population, reaches a large number of customers and generates a large market share, this industry may be potential target of intentional contamination of the United States food supply.

The World Health Organization [4] identified food terrorism as an act of deliberate contamination of food for human consumption with chemical, biological, or radionuclear

agents for the purpose of causing injury or death to civilian populations, and/or disruption to social, economic and political stability.

In a keynote address at Institute of Food Technologists (IFT's) Fourth Research Summit in April of 2005, Hedberg from the University of Minnesota's School of Public Health detailed challenges of defending global food systems from terrorist attacks: global sourcing, increased fresh produce consumption from nondomestic sources, increased number of meals consumed away from home, increased centralization of production (with larger batch sizes and distribution networks) [5]. Hedberg also commented on the paradigm shift from a food safety focus (which relies on forensic review of events) to a food defense approach (which predicts risks and implements prevention steps). Another speaker at the conference, Shaun Kennedy from the National Center for Food Protection and Defense, noted that terrorists do not fear retribution as many are committed to sacrificing their own lives to achieve their aims. Multiple detection techniques are being developed, which may provide methods to prevent catastrophic consequences of a terrorist attack on the food supply, yet there are limitations with these techniques [5].

These threats can be presented through physical infrastructures or through humans. The reality of potential threats to our food and water was intensified after the terrorist attacks of September 11, 2001. Federal legislation has been enacted to provide some degree of protection through the ability to trace back food products, as this has been identified as a critical step to mitigate public health impacts. The Bioterrorism Act of 2002 required those involved in the food chain (producer, processor, wholesaler, or retailer) to be able to identify their food sources, minimally to the immediate past link. The final rule issued in December, 2004, required establishment and maintenance of records by those who manufacture, process, pack, transport, distribute, receive, hold or import food in the United States. Country of origin labeling (COOL) legislation was passed to ensure that provenance of meat items was communicated to consumers.

Motivations to harm food include purposes of terrorism or criminal activity, such as corporate sabotage, yet results of causing harm or creating an atmosphere of fear and panic are the same. There are 15 reports of serious attacks on the food chain from 1961 to 2005. These have been limited in the United States with only two occurrences [6]. The most serious attack on the food chain in the United States was due to Rajneeshees (an Oregon-based cult) contaminating food at 10 restaurants with *Salmonella typhimurium*, causing 751 illnesses in 1984 [7]. Another attack was the intentional poisoning by a supermarket employee 250 lb of ground beef in 2002 which caused 111 cases of illness [6]. The scope of the threat to agriculture from bio- or chemical attacks. particularly for livestock producers, was illustrated in the United Kingdom with cases involving food-and-mouth disease (FMD) and oovine spongiform encephalopathy (BSE). Although uniteritional, the impact on the food producer and the food industry was wide spread.

Operators in the retail food industry need to assess risks, implement strategies to manage these risks, and identify the best practices that will prevent threats to food while in their custody. Organizational policies and written standard operating procedures (SOPs) can provide internal guidance. The food and drug administration (FDA) has developed an educational program to raise awareness among government agency and industry representatives about food defense issues and emergency preparedness. The ALERT program title is based on the acronym of key elements assure, look, employees, reports, and threats [8].

## 2 RISK ASSESSMENT

Emergency management literature emphasizes the importance of assessment as a means of developing response scenarios. These vulnerability assessments are a critical part of a food defense plan and several tools are available within sectors of the industry. One tool used is the CARVER+Shock process that can help organizations focus on intentional system vulnerabilities, which was discussed in an earlier article.

A traditional supply chain is the integrated network of entities involved in the manufacture of goods (which includes procurement of raw materials and assembly into final product), transportation to distributors, and ultimately preparation and/or sale to final customers. Multiunit corporate foodservice chains are coordinating their own supply chains as a control measure to ensure security and safety of the food product. The intention is to protect the safety, quality, and quantity of products. This includes maintaining product integrity so that it is tamper resistant and that substitution of ingredients or final products is prevented. Larger food-related organizations may be better positioned to implement assessment and prevention steps, yet their investment is likely to be driven by potential widespread impact and economic consequences should an attack occurs. Parallels can be drawn with outbreaks of food borne illnesses within one specific restaurant chain, and its resultant destruction [9].

Terrorists may not attack smaller food industry organizations as resultant impact would be low, both in terms of public health and economics. However, an orchestrated simultaneous attack on multiple, smaller food industries could achieve the same outcomes as one large attack on a multinational company. Thus, all food industries are advised to consider potential threats. For wholesale and retail (foodservice and grocery stores) links of the food chain, the focus should consider physical and human elements [10, 11, 12].

Foodservices vary considerably with regards to market niche, menu items and needed raw ingredients, amount of preparation required, hours of operation and service, access to storage and production areas, frequency of deliveries and regularity of these, and number of employees on any one shift. Generally, all employees receive some basic food safety training and are aware of some security issues. Enhancing the training to consider food defense is needed [13].

### 2.1 Perceptions of Risk

In an assessment conducted by one of the authors [14] at three Midwest supplier food shows 393 respondents representing a variety of institutional and commercial foodservices or retail grocery stores indicated their levels of concern about an attack on their food supply, their perceptions of the likelihood of this occurring, and whether any changes had occurred in the past year. Approximately 82% indicated they were very or somewhat concerned about intentional food contamination, although only 35% thought something could happen in their businesses. Approximately 25% reported that their organization conducts background checks on prospective employees, limits employee access within physical structures, and inspects their facilities. About 12% (50 of 393 respondents) reported that an identification system for employees is in place and 55 said that changes had been made in reporting systems, such as installation of security cameras and locks. Of the 393 respondents, 43 indicated that changes had been made with regard to customer access.

Food security practices in Kansas schools and health care facilities were investigated for foodservice directors' perceptions of their operations' risk of bioterrorism [15]. The

authors found that limited access to chemicals and storage was perceived as the most important practice to protect operations from food defense threats. The least important practices perceived by these foodservice directors to protect their facilities from possible food threats were updating contact information and building a network outside of their operation. In addition, Yoon and Shanklin reported that foodservice operators implemented preventative measures where they perceived a risk, that is, chemical use and storage. In their study, the largest gap between perception and practice was communication.

## 2.2 Assessment Steps

As part of the risk assessment phase, organizations are encouraged to (i) develop a response team, (ii) review and develop written policies and SOPs (focus on human element), (iii) assess vulnerabilities of physical elements (facility, equipment, utilities, and infrastructure), and (iv) review and develop a training program for all organizational staff.

***2.2.1 Response Team.*** It is recommended that a team should be formed representing all functional areas of the organization and all levels of employees. Team members should be knowledgeable about the operation and trustworthy, as risk assessments and management plans are considered confidential and available on a need-to-know basis. The team for smaller organizations might consist of three or four members. Infusion with an organization's food safety plan has been suggested [10]. Larger organizations have established Hazard Analysis Critical Control Points (HACCP) plans, albeit frequently only seen at the management level.

***2.2.2 Review Policies and Procedures.*** The foundation for any food safety plan is written policies and SOPs. Foodservice SOPs are available from a number of sources in the public domain, such as the National FoodService Management Institute and Iowa State Universities Food Safety Project (See www.nfsmi.org and www.iowahaccp.iastate.edu for SOPs available in Microsoft Word format so that organizations can easily modify as needed). Written documentation is needed for food defense as well. Current hiring procedures should be reviewed and job descriptions be updated to include responsibilities for food defense and safety. Documentation of current practices should also be reviewed, such as sign-in sheets and building entry logs. Restriction of employee access to designated work areas is suggested. Written policies and SOPs should also consider customers. The review should consider access by those internal (i.e. employees) and external (delivery personnel, repair workers and contract personnel, and customers) to the organization, and screening practices.

***2.2.3 Access.*** A photo identification badge easily seen on uniforms of employees is one way to verify access is valid. Job descriptions should include the statement that photo identifications are worn all the time while at work. Some organizations may issue color-coded uniforms to designate areas of operation the employee should be. Wholesalers who supply foodservice operations should have their own controls to ensure that employees are screened before hiring. A wholesale food distributor would want to limit access to inventory only to screened and bonded employees. Identification as an employee of the wholesaler company is frequently achieved with use of uniforms and wholesale company vehicles. However, because these could be hijacked, the use of photo identification is also recommended. Deliveries should occur ONLY while employees are present. In some

smaller school districts, the dairy vendor may request a key to make milk deliveries early in the morning before the opening of the building. This practice is not recommended.

Repair personnel and contractors should stop at the organizational office for check-in and be escorted to the work area by a supervisory employee. Their presence should be monitored while at the work site. Subcontractors, suppliers, repair persons, and others should not be given unrestricted access while on a wholesale or retail foodservice organizations' premises.

***2.2.4 Screening.*** As part of the selection process, employees should be screened for any physical or mental characteristics that may present a threat to the organization. The selection process should be documented so that the desired employee characteristics are tied to the job description and are a bona fide occupational qualification. Thus, the job description should include a statement regarding employee's responsibility in risk assessment. Often a financial background check is conducted on a person who will work with money just as organizations may periodically screen e-mail messages and internet traffic on workplace computers to ensure that inappropriate websites are not visited.

***2.2.5 Facility Assessment.*** An assessment of the operation considering the facility and property itself, layout and design of the building that allow for unchecked access, and infrastructure, such as utilities or transportation vehicles, should be conducted. Potential risks should be identified and procedures be developed to mitigate these risks [16]. All properties of the organization, including parking lots should be reviewed on a regular basis. Although there are governmental regulations that provide some safeguards, industry organizations should recognize the inherent benefits of regularly reviewing operations. Wholesalers and foodservices should incorporate risk assessments into the daily operational regime. Emergency contact information should be readily available in each work area for management fire, FEMA, police, building security, and so on, so that employees are knowledgeable about response authorities and response procedures.

***2.2.6 Facilities.*** Access onto the grounds of the retail foodservice and wholesaler should be screened so that only necessary individuals or vehicles are allowed to enter. Perimeter fencing should be in place and be regularly checked. Exterior lighting of the grounds and parking areas should be in place, particularly by entry areas. Access to facility grounds and to facilities should be restricted to individuals with a legitimate reason for their presence. Physical barriers, such as locked doors and keys restricted to a few screened individuals, can protect against tampering with equipment, theft or substitution of product, or adulteration of the food products. Unlocked doors during operation provide open access in many food and chemical storage areas and in the food production and service areas.

***2.2.7 Layout and Design.*** Identify areas for restricted access, such as food or chemical storage areas. In many organizations, access to these is open during working hours. Often, surplus inventory (food and chemicals) is kept in areas hard to monitor. It is recommended that employees, customers, and contractors/repair persons have access ONLY to areas necessary to complete their work. Addition of doors, security gates, or other physical barriers can help prevent transition. Reconfiguration of product flow may also improve work efficiencies and product safety.

***2.2.8 Infrastructure.*** Vehicles are used in transporting food ingredients and menu items to and from foodservices. All retail food operations need a potable water supply and an energy source (gas or electric). Mail and computer systems are other potential attack points.

***2.2.9 Training.*** In the food security plan, management needs to identify training needs (annual or semiannual of key points of the plan). The training program could include introduction and implantation of new policies and procedures that are made because of the food security plan, simulation of what to do in a tampering event, emergency procedures/evacuation simulations, and so on.

***2.2.10 Monitoring.*** Continual assessment of potential risks from employees, contractors, customers, or the public is needed. Some organizations utilize third party monitoring programs, such as undercover patrons, and receive reports on potential risks. The use of security cameras has also increased. These can be a valuable tool to document compliance and assess future training needs.

A checklist format can be used on a daily or weekly basis by rotating key personal to ensure that vulnerabilities have not been attacked and ownership is spread among all staff members (Table 1). Employees should be aware of any existing vulnerabilities and trained to report any observations. Responsibility to continually observe for vulnerabilities should be included in job descriptions and as part of the review process. These reports should be formalized with a written plan. Physical vulnerabilities can be minimized with prompt attention.

## 3 RISK MANAGEMENT

Many food defense action steps mirror those in place to ensure the safety of food products, such as a HACCP plan and SOPs. Although the food security and HACCP plans are similar in nature and development process, two separate documents should be prepared. The food security plan needs to be individualized for each organization. Foodservice and grocery store managers need to prepare for the possibility that tampering or other criminal and terrorist attacks could occur. A food security plan needs to be in place as a proactive measure—including elements for evacuation, segregation of affected products, local response network, and availability of emergency contact information as well as training for staff about communications internally and externally during a crisis. Retail food managers need to have a broader perspective—should think all possibilities and methods that can compromise integrity of products and facilities.

### 3.1 Plan Development

Managers should select a team of knowledgeable individuals to develop the food security plan and conduct assessments of food security procedures and operations. It is recommended that the plan be kept confidential, but the strategies for employee training and communication, both internal and external, should be included in the plan.

***3.1.1 Communication.*** The food security plan should lay out a strategy for internal and external communication.

**TABLE 1 Food Defense Checklist for Retail Foodservice Operations**

| | Yes | No | N/A |
|---|---|---|---|
| Facility security | | | |
| Facility has a written food defense plan | | | |
| A designated person or team plans and implements food defense policies | | | |
| Food defense practices are evaluated and documented at least annually | | | |
| Emergency contact list is available to all employees | | | |
| Managers conduct a daily walk-through inspection of the operation | | | |
| The outside of facility is adequately lighted | | | |
| Facility is locked and secured when closed | | | |
| Exterior doors are locked at all times (except customers' entrance) | | | |
| Keys to access kitchen and food and chemical storage areas are restricted to foodservice management staff | | | |
| Access to food preparation areas is controlled for all visitors and nonfoodservice employees, including cleaning crews, delivery vendors, and contractors | | | |
| Visitors are required to sign in at the main office, show picture ID, and explain the purpose of their visit. A visitor badge is worn | | | |
| Personnel | | | |
| References for new employees are verified and backgrounds are checked | | | |
| Managers are alert for unusual employee and customer behavior (i.e. workers staying after shift and arriving early) | | | |
| Personnel have been trained in food defense policies and procedures | | | |
| Customers are restricted from entering storage and preparation areas | | | |
| Visitors are supervised while in food production areas | | | |
| Terminated employees lose all means of access to facility (keys and passwords); this may mean locks are rekeyed and passwords are changed | | | |
| Storage is provided for employees' personal items so that these are not allowed in food preparation areas | | | |
| Receiving | | | |
| Food is purchased only from approved vendors | | | |
| A delivery schedule is maintained | | | |
| Deliveries are verified against purchase orders | | | |
| Delivery personnel are monitored while at the facility | | | |
| Packaging integrity of received products is verified | | | |
| Food and supplies are placed immediately in appropriate storage upon receipt | | | |

**TABLE 1 (*Continued*)**

| | Yes | No | N/A |
|---|---|---|---|
| Food preparation areas | | | |
| Self-service stations (such as food bars and buffets) are monitored at all times by foodservice employees | | | |
| Employees are trained to check ingredients before use to note unusual smells, defective products, and expiration dates, and to know appropriate actions to take if there is a problem | | | |
| Records are maintained to ensure traceability of raw ingredients back to suppliers | | | |
| Procedures are in place for safely handling and disposing of contaminated products | | | |
| Storage areas | | | |
| Access to all food product and chemical storage areas is secured and controlled | | | |
| Chemicals are stored in a locked area, outside of food preparation areas | | | |
| Chemical use is monitored to prevent deliberate food contamination | | | |
| Employees are trained to properly use chemicals to prevent food contamination and protect human safety | | | |

*Food Defense* in foodservice operations refers to the process of guarding the operation against intentional acts of contamination or tampering. This checklist will help you assess the security of your operation. Check YES, NO, or N/A (not applicable) for each practice in your operation. Develop a plan for addressing practices that were marked NO.

The *internal communication plan* should include training of supervisory staff to be observant of signs of tampering or unusual behavior. A clear reporting system of such events needs to be established so that information is transferred to the proper channels and appropriate actions can be taken in a timely manner. An updated list of key contacts (fire, police, etc.) should be maintained and readily available to key personnel. Employee training should include awareness about suspicious activity, the appropriate reporting channel, and response required of employees for the operation. Who and what will be communicated internally to employees should be included if an event occurs that jeopardizes the integrity of the facility or food products. In addition, signage at designated points to restrict access to employees, delivery and repair personnel, and the public should be an integral component of the communication plan.

The *external communications* section should identify a designated spokesperson knowledgeable about the organization and the plan. This person should be capable of effective communication with press and authorities. This part of the food security plan should include a crisis management strategy to prepare for and respond to any suspicious activity. This crisis management strategy may be similar to an existing natural disaster plan already in place in the food establishment.

***3.1.2 Procedures to Ensure Security.*** The food security plan should include procedures to ensure security of the physical facility and human elements.

*Facility security* should include access limited to only authorized personnel. At some locations, this may mean perimeter fencing and/or security guards and check-in stations or designated employee entrances. Lighting of outside areas should be evaluated and changes be made to provide adequate lighting for high visibility in parking lots, delivery areas, and other access area.

Designated parking areas for staff should be available. Swipe cards or pass codes should be used at employee entrances. Security badges with codes (uniform colors, electronic bar codes, etc.) to restrict access to only necessary areas. Use of security cameras external to the building and internally in staff and public areas is encouraged. These can be useful as a deterrent and as a reconstruction aid in the event of an incident and may lower insurance premiums. Door locks with limited distribution of keys is also recommended.

What we often see at retail foodservices, particularly those not part of multinational chains, is open access to food storage and production areas during hours of operation. Those intended for direct harm or theft can often easily enter the facility and access food and/or chemical storage areas. Posing as a customer, delivery or repair person, or new employee is a way by which access to vulnerable areas can be gained.

A defined product recall plan should be identified for any product that is considered unusual or suspicious. This recall plan may be similar to an existing policy for a product that is a food safety concern.

The food security plan should include routine security checks of facilities and of procedures established by the team and a third party may be employed to conduct such an audit.

***3.1.3 Training Programs.*** Training plans should raise awareness in staff about potential risks, and that natural hazards, such as a fire which would cause an evacuation, might be part of an intentional attack on the organization.

Management should provide training to all staff about need for building and product security. Part of the training should include importance of restriction to work areas, reasons for background checks and employee screening, and need to follow policy with regards to security measures (no loaning of keys or passwords). The job description should include a statement with regards to compliance with all operational policies, including consequences identified for noncompliance. Staff should also be provided with storage areas for personal items to limit what is brought into the production areas. Management should encourage all staff to be alert to actions of others and to report any unusual or suspicious behavior—such as reporting early or staying late without any reason, accessing files or information about areas outside of their work zones, asking questions about security measures or other sensitive issues, or bringing cameras to work. Management is advised to consider restricted use of cell phones during work day due to the ability to take photos.

***3.1.4 Implementation and Evaluation.*** After training, new policies and procedural changes can be implemented with subsequent changes introduced as steps are added to the food security plan. It is not necessary to have a complete plan in place with one rollout.

The team should consider an annual review of the food security plan. Reports of concern (inventory records, supplier receipts, etc.) should be evaluated by the appropriate management staff on a regular basis to verify that the plan is working. If the plan is not

working, the plan needs to be modified and changes be implemented to ensure the security of the facility and food products. The team should meet on a quarterly basis or as needed to consider events or changes noted/needed. An event that occurs nationally, such as a tampering activity in a similar industry, should trigger a review of the existing plan. Management should consider instituting a reward system for employee compliance.

## 4 PREVENTATIVE BEST PRACTICES

The Food Security Plan development should include the areas listed in Table 2. To aid in the development of your food security plan, current organizational policies and procedures should be reviewed. HACCP Plans and SOPs are important to review as part of the Food Security Plan development phase, and for continuous improvement of the plan.

**TABLE 2 Components of the Food Security Plan**

| Area of Concern | Check for Inclusion in Plan |
|---|---|
| *Human Element* | |
| Management | |
| Assemble a team | |
| Determine a designated spokesperson. Assign responsibilities for security to authorized personnel and incorporate into job descriptions | |
| Develop a crisis management strategy | |
| Review existing facility layout/design, policies and procedures, including food safety plans (i.e. HACCP) and SOPs | |
| Examine existing records related to security issues, such as receiving and purchasing. Establish appropriate records and/or revise existing records to be able to track previous link of the food chain | |
| Develop a system for reporting suspicious behavior | |
| Develop a plan for evacuation in light of various scenarios—fire, water outages, and so on | |
| Maintain a current list of emergency response organizations in the community | |
| Develop and post signage in facility restricting access as appropriate | |
| Provide training for employees at least annually | |
| Staff and employees | |
| Review existing policies and procedures about hiring practices including background checks, job descriptions, performance appraisals, reward systems, training logs, sign-in sheets, and so on | |
| Provide recognizable forms of identification for employees. These forms should include name badges with photo identification and may include specific uniforms | |

(*continued overleaf*)

**TABLE 2 (*Continued*)**

| Area of Concern | Check for Inclusion in Plan |
|---|---|
| Provide storage for employees' personal items. Restrict types of items that employees can bring to work | |
| Change locks, keys, combinations, codes, passwords, and so on, when employees discontinue employment | |
| Restrict access of employees, delivery, and repair personnel to areas of work | |
| Require annual training for employees, document training, and develop a reward system for application of training content | |
| Public | |
| Restrict access to nonpublic areas | |
| Monitor public areas | |
| *Physical Element* | |
| Physical facility | |
| Provide protection of nonpublic perimeter of facility | |
| Monitor access to nonpublic areas of facility | |
| Use lighting for perimeter of premises, such as parking, delivery areas, and so on | |
| Inspect and evaluate HVAC system, water, and utilities on a regular basis by screened personnel | |
| Operations | |
| Evaluate inspection procedures of incoming products, deliveries, supplies, mail, and so on | |
| Evaluate records for receiving | |
| Monitor food storage areas so access is restricted to authorized personnel only | |
| Monitor chemical storage areas so access is restricted to authorized personnel only. Implement security measures. MSD Sheets should be accessible to all employees | |
| Evaluate vulnerabilities of foodservice and/or retail display areas regularly | |
| Review potential vendors, suppliers, and contractors. Maintain an approved list and monitor access to operation to those on list | |
| Develop security for your computer system. Limit access by nonscreened personnel | |
| Develop a method to validate your program | |

## ACKNOWLEDGMENTS

# RISK ASSESSMENT AND SAFETY OF THE FOOD SUPPLY

LORNA ZACH AND VICKI BIER

*Center for Human Performance and Risk Analysis, University of Wisconsin-Madison, Madison, Wisconsin*

## 1 BACKGROUND

In their seminal paper, Kaplan and Garrick [1] define risk as involving both uncertainty and some kind of loss or damage. Moreover, Zimmerman and Bier [2] state that "Risk assessment is a means to characterize and reduce uncertainty to support our ability to deal with catastrophe through risk management." Thus, we view risk assessment as "a *decision-directed activity*, directed toward informing choices and solving problems," as suggested by the National Research Council [3].

Sometimes, the available choices include waiting for additional information before making a final decision; likewise, effective problem-solving can involve doing additional

research to identify the best solution. Therefore, assessing the uncertainties about the results of a risk assessment can be useful in determining whether additional information is needed, and if so, which information would be most helpful in making a good decision. In fact, the American Industrial Health Council and others [4] have stated that a good risk assessment "explicitly and fairly conveys scientific uncertainty, including a discussion of research that might clarify [and reduce] the degree of uncertainty." Likewise, the National Research Council [5] has recently gone further, recommending that risk assessments should "*characterize and communicate uncertainty and variability in all key computational steps of risk assessment—for example, exposure assessment and dose-response assessment"* (emphasis in original).

As Phillips [6] notes, "Quantifying uncertainty does not create uncertainty. It merely measures and reports the uncertainty that is always there . . . quantified uncertainty better describes what we know, and thus can facilitate better decisions, suggest improvements in our methods, and help direct new research to where it will provide the most benefit." In other words, if a particular risk is highly uncertain, then a good and accurate risk assessment should have large uncertainty bounds. While a lesser degree of uncertainty might be preferable, decision-makers faced with highly uncertain risks are not well-served by focusing on a single best estimate, since this can lead to undesirable "after-the-fact surprises" [4]. Rather, once the nature and magnitude of the uncertainties are known, this knowledge can help decision-makers prioritize not only which protective measures (if any) should be taken in the short term, but also how best to spend their research dollars to reduce risk in the long term, by considering whether the value of additional information [7] in supporting better decisions would outweigh the cost of collecting such information.

This article discusses one particular approach to characterizing uncertainty and variability, as recommended by the National Research Council [5] namely, the use of so-called "two-dimensional" or "second-order" Monte Carlo simulation. We also discuss applications of this method to food safety and related issues, such as agricultural animal disease. Two-dimensional Monte Carlo simulation is typically used in applications of risk assessment to health, safety, and environmental problems, to assess the desirability of possible preventive and/or mitigating measures to help reduce risk. However, it can also be used to assess the desirability of preventive and mitigating measures for intentional threats to homeland security (e.g. intentionally introduced foot-and-mouth disease or food contamination), as will be discussed below.

### 1.1 Uncertainty Versus Variability

When the National Research Council [5] talks about the need to "characterize and communicate uncertainty and variability," they have specific definitions of these terms in mind. For example, Kaplan [8] describes uncertainty assessment as characterizing the scientific "state of knowledge" about an uncertain quantity of interest (e.g. uncertainty about the *average* effectiveness of a vaccine that has not yet been fully characterized), and distinguishes this from "population variability" (e.g. differences in vaccine effectiveness from one person or animal to another). Similarly, Paté-Cornell [9] draws a distinction between "epistemic uncertainty" (i.e. "Uncertainties about fundamental phenomena reflecting incomplete knowledge") and the randomness or "aleatory uncertainty" used to represent "variations in samples (e.g. of temperature readings at a precise moment of the year over several years)."

It is, in principle, possible to have uncertainty with little or no variability; for example, if all people are believed to be equally susceptible to a particular disease agent, but little is known about their level of susceptibility. Similarly, it is possible to have variability without uncertainty; for example, if the dose of some microbial toxin required to cause disease is known quite accurately, but is known to vary based on the age or weight of the exposed individual. However, most real-world situations exhibit both state-of-knowledge uncertainty and population variability.

The distinction between variability and uncertainty is not necessarily fundamental. For example, some sources of uncertainty might be treated as (effectively irreducible) randomness if a decision has to be made in the short term (e.g. in less than a year), but could be researchable through programs that would yield answers in five to ten years. However, if uncertainty and variability are not clearly separated, analysis results can be misunderstood, and options for risk reduction overlooked. For example, for motor vehicles, as Thompson [10] points out, "simply saying that airbags save approximately 3000 lives each year fails to capture the significant threat that airbags pose to children and small-stature adults. Once this variability is acknowledged, however, opportunities for reducing the risks to those groups may be recognized and implemented."

Many current models analyze variability and randomness (e.g. using Monte Carlo simulation), but unfortunately omit any formal consideration of epistemic uncertainty about the parameter values of the simulation. Thus, Paté-Cornell [9] notes that randomness "is generally more easily acknowledged and integrated in mathematical models," while epistemic uncertainties "are sometimes ignored and tend to be under-reported, especially in public policy studies of controversial or politically sensitive issues." For example, epidemiological models of foot-and-mouth disease may devote a great deal of computation time to simulating the progression of an outbreak as a function of random fluctuations in the number of infectious contacts an animal may have per day and so on, but treat key uncertain quantities (such as the infectivity and latent period of the disease, or even the level of public and stakeholder cooperation with mitigation measures such as movement restrictions [11]) as if they were known constants.

Of course, sensitivity analysis [12] is often used to investigate the effect of key parameter uncertainties on the results of epidemiological models. However, sensitivity analysis on the effects of individual parameters or model assumptions does not yield an integrated statement on the level of uncertainty about the model results.

### 1.2 Two-Dimensional Monte Carlo Simulation

Monte Carlo simulation [13] is a mathematical tool commonly used to help predict what might happen in disease outbreaks or situations where the population is exposed to a disease or toxic agent. Two-dimensional Monte Carlo analysis [14–18] is a variation of this method, designed to create a single, overall statement of uncertainty, including not only the types of randomness and variability that are commonly taken into account in simulations, but also systematic scientific uncertainties (such as lack of knowledge about disease infectiousness).

The basic idea of two-dimensional Monte Carlo is similar to that of sensitivity analysis (namely, varying key parameters over their credible ranges). However, instead of doing a separate set of sensitivity runs for each parameter individually, two-dimensional Monte Carlo does this in an integrated manner, sampling randomly from the probability distributions for all uncertain input parameters before initiating any given simulation

run. In this manner, the methodology makes it possible to quantify and characterize the combined effects of numerous different uncertainties at the same time.

The fact that two-dimensional Monte Carlo analysis explicitly recognizes the uncertainty about key input parameters to the simulation is important in part because randomness and variability have different implications for policy than broader scientific uncertainties. So, while it is useful to have a single overall statement of uncertainty, it is also important to distinguish variability from scientific uncertainty in order to understand their policy implications. In the next section, we discuss several real-world applications of two-dimensional Monte Carlo analysis and their policy recommendations.

## 2 APPLICATIONS OF TWO-DIMENSIONAL MONTE CARLO SIMULATIONS TO FOOD SAFETY AND ANIMAL DISEASE

### 2.1 Fumonisin Toxin in Corn

One example of the use of two-dimensional Monte Carlo analysis from the food-safety literature [17] analyzes a naturally occurring toxin (fumonisin, a type of mycotoxin) in corn and corn products, and explores the associated potential for health concerns. This analysis addressed the uncertainty about the exposure to this toxin (both the quantity of the toxin in corn-based food products, and how much corn people in the United States consume), and also the variability in human susceptibility to the toxin (accounting for variability of response between individuals, and the inadequacy of the data on dose-response relationships).

Humphreys et al. [17] treated the uncertainty about the exposure of the US population to fumonisin as the "outer loop" in the two-dimensional Monte Carlo analysis. In the problem being described here, the lack of knowledge about both, corn consumption levels and the presence of fumonisin in corn, could result in up to 3 orders of magnitude of uncertainty about individual dietary exposure to fumonisin.

Figure 1 shows the concentrations of fumonisin that have been measured in different types of corn products in the United States [17]. Corn meal, for example has relatively high levels of fumonisin contamination, while popcorn, corn chips, and corn flakes have much lower levels.

Figure 2 shows fumonisin exposure per person per day as a function of both, the level of corn consumption (measured in a country-wide dietary survey) and several possible levels of a maximum allowable concentration of fumonisin in corn. The solid black line at the top of the figure shows the toxin consumption under circumstances with no regulatory limit on fumonisin concentration in corn products. As the limit of allowable fumonisin concentration in corn is reduced (from no limit to 2.0 ppm, down to 0.5 ppm), the exposure to the toxin decreases, as expected). However, reducing the allowable concentration level of the contaminant may not substantially reduce the exposure levels of individuals with extremely high levels of corn consumption. This suggests that those individuals with high levels of corn consumption may still be heavily exposed to fumonisin, even if the corn itself is less heavily contaminated.

Given these uncertainties, Humphreys et al. [17] compared two alternative policy measures for dealing with fumonisin toxins namely, limiting the allowable concentrations of fumonisin, and issuing consumption advisories (i.e. advising people to restrict their intake of certain corn products). Figure 3 illustrates the effects of differing consumption advisories on total fumonisin intake, as a function of people's (original) levels of corn

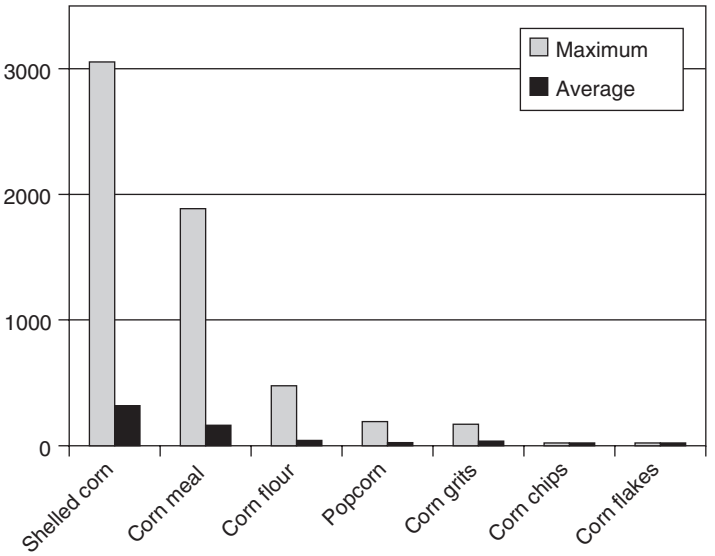

**FIGURE 1** Average Presence of Fumonisin B in U.S. Corn (based on surveillance data from the U.S. Food and Drug Administration, 1994–1995) and based on data published in Reference 17.

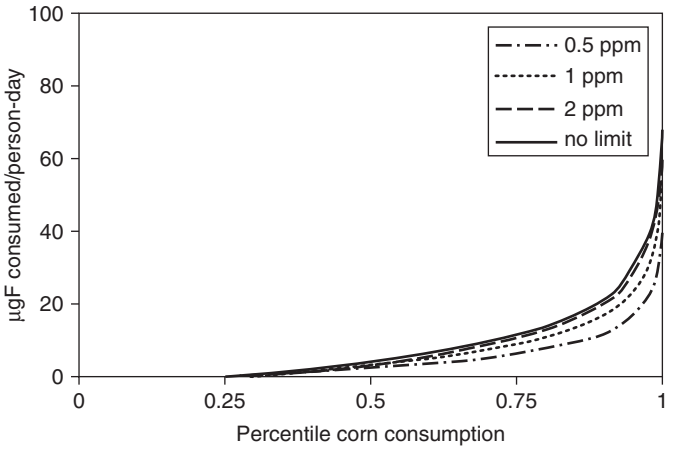

**FIGURE 2** Effects of Different Concentration Limits on Fumonisin Exposure per Person per day (in micrograms) as a Function of the Percentile of Corn Consumption, based on Data in Reference 17.

consumption. The solid black line at the top again shows the extent of fumonisin intake with no consumption advisory. As the recommended consumption limit in the advisory decreases, from no limit to 100 g of corn per day down to 25 g of corn per day, the daily toxin intake is markedly reduced. Thus, consumption advisories would seem to have a greater effect on reducing peak levels of fumonisin intake than contamination limits, because consumption advisories specifically address risks to those individuals who consume large amounts of corn.

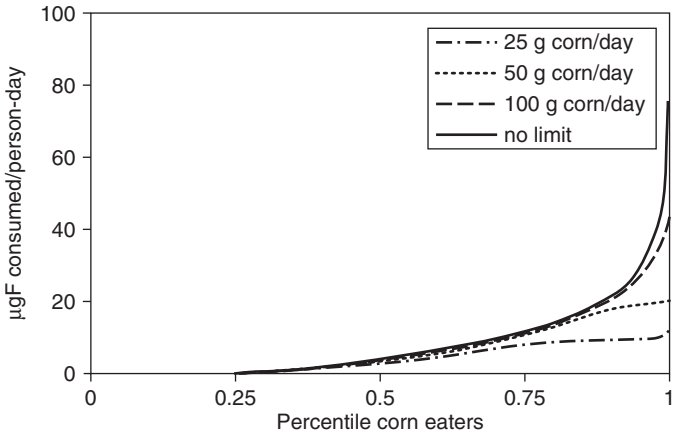

**FIGURE 3** Effects of Differing Consumption Advisories on Total Fumonisin Intake per Person per Day (in micrograms) as a Function of the Original Percentile of Corn Consumption, based on Data in Reference 17.

Humphreys et al. [17] also studied the effects of variability, or the "inner loop" of the Monte Carlo simulation. As noted above, the model input parameters designated as representing variability included different responses between individuals (for example, due to different body weights) and the inadequacy of the data available for characterizing the dose-response relationship to fumonisin.

Figure 4 illustrates the contributions of both uncertainty and variability, as defined by Humphreys et al., to human kidney toxicity in response to a variety of simulated regulatory scenarios. (The graph is dimensionless, because the units can be difficult to interpret.) In Figure 4, the black bars represent the effects of uncertainty with no variability; the gray bars represent variability with no uncertainty; and the white bars represent the effects of both uncertainty and variability. Thus, the black bars show the estimated health risk if both corn consumption and the levels of fumonisin concentration (treated as aspects of "uncertainty" in this study) were at relatively high levels. Conversely, neglecting the uncertainty (or "outer loop" of the Monte Carlo simulation) and setting only those factors treated as variability to high levels would give us the gray estimates of risk (rather than the white-colored estimates). This could result in estimates of risk that are low by about a factor of 10.

Thus, the results in Figure 4 demonstrate the value of two-dimensional Monte Carlo analysis: for example, by highlighting cases in which uncertainty is high, so that it may be worthwhile to conduct additional research before making a final decision. In this particular case, those factors categorized as "variability" appear to contribute more to the overall risk than those categorized as "uncertainty" (although, as noted earlier, there is reason to dispute the categorization of these terms). In any case, all of the risk estimates were low enough that no further regulatory action was judged to be necessary. However, in cases where the overall risk estimates were higher, it could be important to take uncertainty into account in order to avoid underestimating peak risks.

Moreover, in this case study, consumption advisories appeared to be more effective at controlling peak exposures than regulatory limits (presumably because of the wide variability in consumption levels within the population), although it is worth noting that

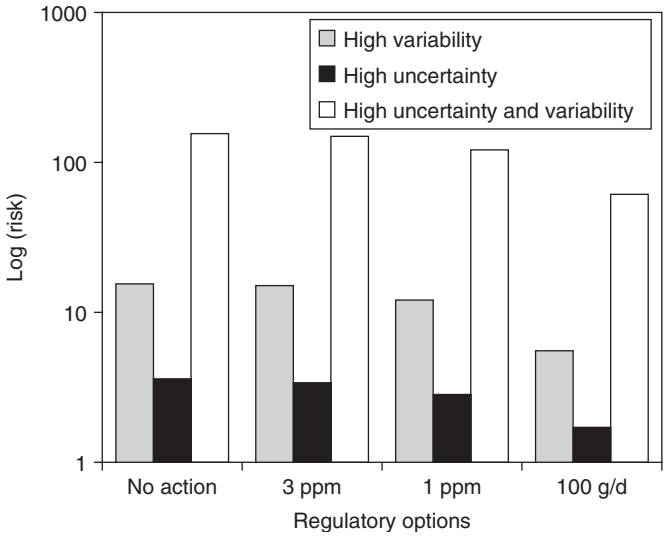

**FIGURE 4** Effects of Uncertainty and Variability on Risk as a Function of Regulatory Option (no action, 3 ppm limit on fumonisin concentrations, 1 ppm limit on fumonisin concentrations, and 100 grams/day consumption advisory), based on Data in Reference 17.

they put the burden of risk reduction on consumers rather than producers. If consumption advisories were to be adopted, it might be desirable to identify which population subgroups are most vulnerable to fumonisin, as well as collecting data on consumption levels by ethnicity and region. By contrast, if regulatory concentration limits were adopted, then additional information on toxin concentrations by production region might be more useful, along with information on how contaminated corn might flow through the supply chain.

To summarize, Humphreys et al. [17] found only low levels of risk in the United States, and therefore little reason for concern about fumonisin levels in the US corn supply. However, risks may not be as low as indicated above if the data on corn consumption were not representative of the entire country (for example, if high-consumption regions were omitted), and if the measured levels of fumonisin in corn crops did not include data obtained under drought conditions (under which fumonisin contamination is more likely). Finally, while Humphreys et al. [17] assumed that kidney lesions were the most sensitive toxicity endpoint in humans, the risks could turn out to be higher than indicated in their analysis if some other endpoint turned out to be more important clinically.

### 2.2 Patulin Toxin in Apple Juice

A similar analysis was performed by Baert et al. [15] to characterize variability and uncertainty regarding children's exposure to patulin toxin from consuming three types of apple juice in Belgium: organic; handcrafted; and conventional. Based on a survey of juice consumption in preschool children, and measured values of patulin in the three types of apple juice, they considered variability in both consumption and contamination levels, as well as uncertainty about these parameters due to lack of data. The resulting analysis showed that variability in the type of juice consumed did have a significant

effect on risk in this case, even considering the confidence intervals reflecting lack of knowledge.

In particular, patulin exposure was found to be higher in children consuming only organic apple juice, with 0.9% of children (90% confidence interval of 0.3% to 1.8%) estimated to exceed the tolerable daily intake of patulin. By contrast, 0.1% of children consuming conventional apple juice (90% confidence interval of 0–0.3%) and no children consuming handcrafted apple juice (90% confidence interval of 0–0.2%) were estimated to exceed the tolerable daily intake. The results reflect both the high variability of juice consumption between individuals, and the high variability of contamination levels in apple juice.

The use of two-dimensional Monte Carlo provided a significant methodological advance in the study of this risk. In particular, the authors noted that "a tendency exists to overestimate mean exposures when a deterministic approach is used." Thus, the probabilistic uncertainty analysis performed by Baert et al. [15] arguably provided a more realistic assessment of the range of exposures, and avoided unnecessarily conservative modeling assumptions and approaches.

The two risk mitigation strategies considered by Baert et al. [15] to reduce patulin intake were similar to the strategies evaluated in the fumonisin example above: either to reduce the allowable levels of contamination in juice, or to reduce juice consumption. Unlike in the fumonisin example, however, here the analysis concluded that regulatory limits would be more effective than consumption advisories. Presumably, this was because the variability of patulin concentrations in organic apple juice was sufficiently high that even with reduced consumption, some children could still be exposed to hazardous levels. In particular, the authors concluded that "a reduction of the consumption has more effect when the patulin contamination is lower."

### 2.3 Escherichia coli O157:H7 on Beef Trimmings

Cummins et al. [16] illustrate a slightly different approach to characterizing the role of variability and uncertainty in food contamination, focusing on the process of food preparation in the supply chain, rather than food consumption. In their work, a model was developed to estimate the prevalence of *E. coli O157:H7* on beef trimmings in Irish slaughterhouses by considering: initial contamination levels on hides; cross-contamination events; process steps at which microbial growth could occur; the results of decontamination efforts; and steps undertaken to reduce bacterial numbers. The output of the model was a distribution of the prevalence of *E. coli O157:H7* on beef trimmings, and also a distribution of the number of organisms on contaminated beef trimmings. The purpose of the model was to identify critical points in the process, and assess the impact of various process mitigations for this bacterial disease agent.

Variability and uncertainty were separated in this analysis in order to identify future data requirements and research needs for model improvements, and also to identify those input parameters that had a significant effect on risk, and should therefore be monitored. A total of 19 input parameters were categorized as representing uncertainty (e.g. test sensitivity, which was assumed to be constant but unknown), variability (e.g. number of contaminated carcasses, which was assumed to fluctuate from day to day), or both (e.g. *E. coli* counts on contaminated hides).

The results showed that uncertainty dominated the results, with variability having relatively little impact on model outputs. In fact, Cummins et al. [16] compared the results of

their two-dimensional Monte Carlo simulation (reflecting both uncertainty and variability) with empirical survey results (reflecting variability alone), and concluded that "the confidence bounds for the simulation are much wider due to parameter uncertainty." Thus, the use of two-dimensional Monte Carlo again arguably resulted in a more accurate statement of the true level of uncertainty about meat contamination in this instance, and avoided providing misleading results, indicating that the true prevalence of *E. coli* O157:H7 on beef trimmings could be almost twice as large at some slaughterhouses as would have been indicated by the results of the surveillance survey at a single slaughterhouse.

The results of the analysis indicated that uncertainty about microbial test sensitivity contributed significantly to the overall uncertainty about model results, and therefore required further experimental work to characterize it. However, the results also supported recommendations about specific risk-reduction measures that could be undertaken in the interim, such as minimizing hide contamination before slaughter and reducing cross-contamination during hide removal.

### 2.4 Application of Two-Dimensional Monte Carlo Simulation To Homeland Security

The above examples were primarily concerned with food safety. However, two-dimensional Monte Carlo can also be used to analyze problems of homeland security, such as intentionally introduced contamination. For example, consider an intentionally introduced outbreak of foot-and-mouth disease. An analysis of such outbreaks should ideally address not only the effects of variability and randomness (for example, due to differences in weather conditions and disease transmission contacts from day to day under various cattle-management strategies), but also key scientific uncertainties (such as lack of knowledge about the infectivity of the disease agent, or the effectiveness of proposed vaccines).

We have undertaken such an analysis [19], using expert opinion to quantify the uncertainty about simulation inputs such as disease infectivity, and differences in infectivity between species. This reflects the fact that such parameters are not known constants, and therefore are better represented by probability distributions rather than point estimates. As in Cummins et al. [16], we found that the results of the two-dimensional Monte Carlo simulation (taking into account the uncertainty about simulation inputs) were much broader than the results of a one-dimensional simulation (reflecting variability alone). For example, in one scenario, the 90% confidence interval for the duration of possible disease outbreaks increased from 1–2 months due to variability alone, to 0.5–4 months taking uncertainty into account, and up to 4 times wider.

In fact, for some input parameters, the ranges of values considered credible by the experts we surveyed were so broad that the inner loop of the simulation would not run for some combinations of parameter values, necessitating significant revisions to the computer code (AusSpread) that was used to model the spread of foot-and-mouth disease. Thus, the discipline imposed by the rigorous quantification of uncertainty and the use of expert opinion arguably helped to overcome any biases or overconfidence that could have resulted from relying on the opinion of a single expert or model developer, leading to a more accurate assessment of the possible extent of disease spread.

Of course, care must be taken in representing intentional malicious acts using probability distributions. Clearly, we do not have perfect information about what a potential attacker might do, so some representation of uncertainty is important. However, the

uncertainties about intentional acts will not necessarily follow the same probability distributions as uncertainties about the same parameters in an unintentional outbreak. For example, while various strains of foot-and-mouth disease may differ in their infectivity, potential attackers will not necessarily choose randomly among them, but may prefer to use strains that are believed to be more infectious. Similarly, the progression of an unintentional outbreak may vary significantly depending on whether the disease happens to emerge shortly before cattle are transferred to an auction barn (and commingled with large numbers of other animals); by contrast, intentional introduction of foot-and-mouth disease may be deliberately performed shortly before transfer to an auction barn, in order to maximize the likelihood of rapid disease transmission.

With such caveats in mind, though, uncertainty can be just as important in homeland security as in health and safety, if not more so. Critical uncertainties related to security might include factors such as how the food system (and consumers) would respond if an incident of intentional food contamination drastically reduced confidence in the security of imported food products, whether the public and stakeholders would cooperate with recommended mitigation measures [11] (such as movement controls, in the case of foot-and-mouth disease), and the secondary economic impacts of terrorism events (e.g. whether consumers resume buying products affected by contamination after the crisis is over, whether import or export markets suffer lasting losses after a contamination incident).

Moreover, variability and uncertainty still have different implications for decision-making in the homeland security context, as in the other examples discussed in this article. For instance, further research on issues such as whether foot-and-mouth disease is amenable to airborne spread could help to determine how severe an outbreak is likely to be, and hence how much effort is justifiable to reduce the risk of disease introduction. Likewise, if the severity of an outbreak of foot-and-mouth disease is found to be significantly affected by vaccine effectiveness, then further research to verify effectiveness might be desirable before committing to vaccination as a mitigation strategy. By contrast, if the severity of an outbreak is found to be influenced primarily by random fluctuations (such as differences in weather conditions at the time of disease introduction), that would argue for committing to a specific mitigation policy sooner, rather than waiting for further research results.

## 3 THE EFFECTS OF MODEL UNCERTAINTY

The applications described above consider primarily the effects of variability and uncertainty in the parameters of a single model. However, in some cases, there is also significant uncertainty about which model is most appropriate, especially if different models give quite different results. In fact, Box [20], an eminent statistician, pointed out that "All models are wrong, but some are useful."

A study by Linkov and Burmistrov [21] investigated model uncertainty in the context of radioactive contamination on fruit (such as strawberries) in the aftermath of a nuclear power plant accident. The authors found radically different predictions for the cesium concentrations in strawberries from the different models they considered. In fact, the results from the six different models initially varied by as much as 7 orders of magnitude.

Figure 5 shows the ratio of the individual model results to the median output of all six models for four different iterations of modeling effort. The iterations represent

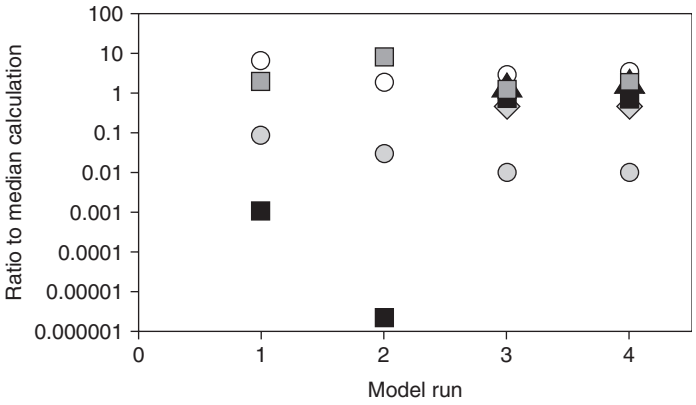

**FIGURE 5** Effects of Model Uncertainty for Strawberry Contamination (based on Data in Reference 21).

meetings in which the modelers discussed and agreed on their assumptions, and attempted to standardize modeling methods in order to achieve greater consistency. As shown in Figure 5, it was not until the third meeting that major disagreements among the results of the various models were substantially reduced. By iterations three and four, there was much closer agreement among most of the models, but one model still gave much lower predictions than the other five. Thus, even extensive interactions among the modelers did not completely eliminate model-to-model differences.

The above results suggest that model uncertainty can be a significant consideration in practice. In some cases, it may still be possible to address model uncertainty within the context of a two-dimensional Monte Carlo simulation. For example, if there is scientific uncertainty about whether foot-and-mouth disease is amenable to airborne spread, this could perhaps be treated as one of the uncertain parameters in the outside loop of a two-dimensional Monte Carlo, with some simulation runs being done under the assumption of airborne spread and others not (depending on how plausible airborne spread is considered to be). In other cases, however, model uncertainty may need to be treated merely as a caveat, or through more traditional sensitivity analysis, for example, if some models are too computation-intensive to be run numerous times, or if the researchers do not have access to all relevant models.

## 4 SUMMARY AND CONCLUSIONS

In summary, methods such as two-dimensional Monte Carlo uncertainty analysis [14, 18] can be a useful adjunct to more traditional Monte Carlo simulation in supporting decision-making. In particular, uncertainty analysis can help identify which areas are the most important focus for future research and data collection, and moreover avoids the problem of inadvertently claiming more than is actually known (which can occur if Monte Carlo simulation is used with point estimates rather than probability distributions for key input parameters).

The implementation of two-dimensional Monte Carlo can be mathematically complex, but ideally, the results should be communicated to decision-makers and stakeholders in

a form that is both informative and easy to understand [10]. This can be done by using probability distributions to show the overall uncertainty about the outcome of the analysis; for example, probability distributions for the number of infected animals in an outbreak of foot-and-mouth disease might be useful in understanding the range of possible scenarios that could occur, and hence how seriously to take the threat [19]. Graphics could also assist in risk communication by showing which sources of uncertainty contribute the most to the overall uncertainty about the outcome. This kind of information can shed light on the value of additional information, thereby helping to improve decisions about which uncertainties are the most important to study and resolve.

Eventually, the results of a risk assessment could be used as input to a formal decision analysis [example Refs. 3, 5, 13], in which stakeholder values are quantified as a basis for identifying the most desirable risk management options. However, in practice (as in several of the examples discussed in this article), it is often straightforward to identify the best (i.e. most effective and cost-effective) risk-reduction options once the risks have been thoroughly characterized. In that case, a formal decision analysis may never be necessary.

# MICROBIOLOGICAL DETECTORS FOR FOOD SAFETY APPLICATIONS

EVANGELYN C. ALOCILJA AND SUDESHNA PAL
*Biosystems and Agricultural Engineering, Michigan State University, East Lansing, Michigan*

## 1 BIOSECURITY AND FOOD SAFETY THREATS

The complexity of the US food supply chain from cradle to grave provides numerous entry points and routes in which (inadvertent and intentional) contaminants and pathogens can be introduced into the nation's food system. For example, a simple hamburger, consisting of a bun, a beef patty, tomato, lettuce, cheese, and onion, is made of at

least 50 ingredients which could include hundreds of sources when we consider the raw materials, processing, transportation, and finished product. Furthermore, these ingredients may come from across the globe, crossing the US border in less than 24 h. The recent scandal on melamine-tainted pet foods (and maybe human food through melamine-tainted animal feed) is one example of how the food supply can potentially be sabotaged.

The use of microorganisms as biological weapons has long been reported in history. One of the first major attacks that have been reported occurred in the 14th century with *Yersenia pestis* during the siege of Kaffa [1]. The most recent was the deliberate release of *Bacillus anthracis* spores through the postal system in the United States in October 2001, shortly after the terrorist attack, resulting in 22 cases of anthrax and five deaths [2]. Inhalational anthrax has a high mortality rate of about 100% and the spore forms of the bacteria are very stable under harsh environmental conditions. The Centers for Disease Control and Prevention (CDC, http://www.bt.cdc.gov/agent/agentlist.asp) and the National Institute of Allergy and Infectious Diseases (NIAID, http://www3.niaid.nih.gov/topics /BiodefenseRelated/Biodefense/ research/CatA.htm) have classified *B. anthracis* as a Biodefense Category A agent because it can be easily transmitted from person to person, can cause high mortality with potential for major public health impact, may cause public panic and social disruption, and requires special action for public health preparedness. It is estimated that the release of 50 kg of dried anthrax spores for 2 h can lead to a complete breakdown in medical resources and civilian infrastructure in a city of 500,000 inhabitants [3].

*B. anthracis* is a gram-positive, nonmotile, facultatively anaerobic, spore-forming, rod-shaped bacterium and is the etiological agent of anthrax. Anthrax is primarily a zoonotic disease but all mammals, particularly humans, are prone to this disease. The spore forms of *B. anthracis* are highly resistant to adverse environmental conditions, such as heat, ultraviolet and ionizing radiation, pressure, and chemical agents. They are able to survive for long periods of time in contaminated soils and this account for the ecological cycle of the microorganism. The vegetative cells of the bacterium are square-ended and capsulated having a size range of 3 to 5 μm while the spores are elliptical with a size range of 1 to 2 μm [4].

The primary virulence factors of *B. anthracis* are toxin production and capsule formation. Virulent strains of the microorganism carry two large plasmids pXO1 and pXO2 which encode these virulence factors. The plasmid pXO1 carries the structural genes for the anthrax toxin proteins *pagA* (protective antigen), *lef* (lethal factor), and *ef* (edema factor); two *trans*-acting regulatory genes *atxA* and *pagR*; a gene encoding type I topoisomerase, *topA*; and a three gene operon, *gerX*, which affects germination. Plasmid pXO2 carries three genes which encode capsule synthesis: *capA, capB*, and *capC*; a gene associated with capsule degradation, *dep*; and a *trans*-acting regulatory gene *acpA* [5]. None of the three toxin proteins are toxic separately. Toxicity is associated with the formation of binary exotoxins. The association of *pagA* and *lef* results in the formation of lethal toxin (LTx), which provokes lethal shock in animals, while the association of *pagA* and *ef* forms the edema toxin (ETx), which produces edema in the skin [6].

*B. anthracis* spores can enter the human host through the skin (cutaneous route), ingestion (gastrointestinal route), and inhalation (pulmonary route). Ingesting food products contaminated with the spores can lead to gastrointestinal anthrax. In this manner, anthrax spores may cause lesions from the oral cavity to the cecum [7]. Cases of gastrointestinal anthrax have been reported through ingesting undercooked meat from animals [8]. The disease is characterized by fever, nausea, vomiting, abdominal pain, and bloody

diarrhea [8]. Gastrointestinal anthrax has been reported to cause fatalities in 25-60% of cases (CDC, 2001). In some community-based studies, cases of gastrointestinal anthrax outnumbered those of cutaneous anthrax [7]. Awareness of gastrointestinal anthrax in a differential diagnosis remains important in anthrax-endemic areas but now also in settings of possible bioterrorism.

The inhalational form of anthrax is considered the most dangerous among the three routes, having a mortality rate close to 100% (CDC, 2001). The inhaled spores reach the alveolus where they are phagocytosed by macrophages and transported to the mediastinal lymph nodes, where spore germination can occur in up to 60 days. Following germination, the disease progresses rapidly resulting in the production of exotoxins that cause edema, necrosis, and hemorrhage [4]. Diagnosis is difficult in both gastrointestinal and inhalational forms, resulting in the disease rapidly becoming treatment-resistant and fatal.

In addition to intentional contaminations, we have recently faced unintentional food poisoning through pathogen-tainted products which caused recalls on these products. In September 2007, a major meat processing company recalled up to 9,843 mt (21.7 million lb) of ground beef due *E. coli* O157:H7 contamination; it was one of the largest meat recalls in US history. This contamination sickened 30 people in eight states. On October 5, 2007, that company announced that it was closing its business.[1] Contamination of meat products by foodborne pathogens is increasingly a major food safety and economic concern. Billions of dollars are lost every year in medical costs, productivity, product recalls, and jobs as a result of pathogen-contamination outbreaks. In the United States, there are up to 33 million cases of human illness each year from microbial pathogens in the food supply with an associated cost of $2–4 billion in 2006.[2]

NIAID has identified the following microbes as foodborne and waterborne pathogens: diarrheagenic *Escherichia* coli, *Salmonella* species, pathogenic *Vibrio*s, *Shigella* species, *Listeria monocytogenes*, *Campylobacter jejuni*, *Yersinia enterocolitica*, caliciviruses, Hepatitis A, *Cryptosporidium parvum*, *Cyclospora cayatanensis*, *Giardia lamblia*, *Entamoeba histolytica*, *Toxoplasma*, and *Microsporidia*. These organisms are classified as Category B because they are moderately easy to disseminate, result in moderate morbidity rates, and require specific enhancements of CDC's diagnostic capacity and enhanced disease surveillance (http://www.bt.cdc.gov/agent/agentlist.asp). In general, the causes of foodborne illness include viruses, bacteria, parasites, fungi, toxins, and metals with the symptoms ranging from mild gastroenteritis to life-threatening neurological, hepatic, and renal problems. It is estimated that foodborne diseases cause approximately 76 million illnesses, including 325,000 hospitalizations and 5000 deaths in the United States each year [9]. Of these, known pathogens account for an estimated 14 million illnesses, 60,000 hospitalizations, and 1800 deaths indicating that these pathogens are a substantial source of infectious diseases [9]. Researchers at the Economic Research Service (ERS) of the US Department of Agriculture (USDA) estimate that the total annual medical cost associated with foodborne illness caused by pathogens is $6.5–9.4 billion.

Recent foodborne disease outbreaks involved *E. coli* O157:H7 in spinach in 2007, and cookie dough in June 2009, and *Salmonella* in peanut butter in January 2009. *E. coli* are bacteria that naturally occur in the intestinal tracts of humans and warm-blooded animals

[1]http://www.msnbc.msn.com/id/21149977/

[2]http://www.ers.usda.gov/Data/FoodborneIllness/

to help the body synthesize vitamins. A particularly dangerous type is the enterohemorrhagic E. coli O157:H7 or EHEC. In 2000, EHEC was the etiological agent in 69 confirmed outbreaks (twice the number in 1999) involving 1564 people in 26 states [10]. Of the known transmission routes, 69% were attributed to food sources, 11% to animal contact, 11% to water exposures, and 8% to person-to-person transmission [10]. *E. coli* O157:H7 produces toxins that damage the lining of the intestine, cause anemia, stomach cramps, and bloody diarrhea, and a serious complication called hemolytic uremic syndrome (HUS) and thrombotic thrombocytopenic purpura (TTP) [11]. In North America, HUS is the most common cause of acute kidney failure in children, who are particularly susceptible to this complication. TTP has a mortality rate of as high as 50% among the elderly [12]. Recent food safety data indicates that cases of *E. coli* O157:H7 are rising in both the United States and other industrialized nations [13].

Human infections with *E. coli* O157:H7 have been traced back to individuals having direct contact with food in situations involving food handling or food preparation. The most recent *E. coli* O257:H7 outbreak covering 29 states involved eating raw refrigerated prepackaged cookie dough [14]. In addition to human contamination, *E. coli* O157:H7 may be introduced into food through meat grinders, knives, cutting blocks, and storage containers. *E. coli* O157:H7 has also been found in drinking water that has been contaminated by runoff from livestock farms as a result of heavy rains. Regardless of source, *E. coli* O157:H7 has been traced to a number of food products including meat and meat products, apple juice or cider, milk, alfalfa sprouts, unpasteurized fruit juices, dry-cured salami, lettuce, game meat, and cheese curds [11, 15]. Possible points of entry into the food supply chain include naturally occurring sources from wild animals and ecosystems, infected livestock, contaminated processing operations, and unsanitary food preparation practices.

*Salmonella enterica* serovar Typhimurium and *Salmonella enterica* serovar Enteritidis are the most common *Salmonella* serotypes found in the United States. According to CDC, salmonellosis is the most common foodborne illness [16]. Over 40,000 actual cases are reported yearly in the U.S. [17]. Approximately 500 [9] to 1,000 [18] persons die annually from *Salmonella* infections in the United States. The estimated annual cost of human illness caused by *Salmonella* is $3 billion [9]. *Salmonella* Enteritidis has frequently been observed as a contaminant in foods such as fresh produce, eggs, and poultry products. While various *Salmonella* species have been isolated from the outside of egg shells, presence of *Salmonella* Enteritidis inside the egg is of great concern as it suggests vertical transmission, that is, deposition of the organism in the yolk by an infected hen (prior to shell deposition) [19]. The recent outbreak of Salmonella involving peanut butter in January 2009 hit almost every state in the United States.

Human *Salmonella* infection can lead to enteric (typhoid) fever, enterocolitis, and systemic infections by non-typhoid microorganisms. Typhoid and paratyphoid strains are well-adapted for invasion and survival within host tissues, causing enteric fever which is a serious human disease. Non-typhoid *Salmonella* causes salmonellosis, which is manifested as gastroenteritis with diarrhea, fever, and abdominal cramps. Severe infection could lead to septicemia, urinary tract infection, and even death in at-risk populations (young, elderly, and immunocompromised individuals). Raw meats, poultry, eggs, milk and dairy products, fish, shrimp, frog legs, yeast, coconut, sauces and salad dressing, cake mixes, cream-filled desserts and toppings, dried gelatin, peanut butter, cocoa, and chocolate are some of the foods associated with *Salmonella* infection.

## 2 DETECTION

The detection and identification of these foodborne pathogens in raw food materials, ready-to-eat food products, restaurants, processing and assembly lines, hospitals, ports of entry, and drinking water supplies continue to rely on conventional culturing techniques. Conventional methods involve pre-enrichment, selective isolation, and biochemical screening, as well as serological confirmation for certain pathogens. Hence, a complex series of tests is often required before any identification can be confirmed. These methods are laborious and may require a certain level of expertise to perform. Though these methods are highly sensitive and specific, they are elaborate, laborious, and typically require 2–7 days to obtain conclusive results [15]. Their results are not available on the time-scale desired in the food quality assurance or clinical laboratory, which has safety, cost, and quality implications for the food, medical, and biodefense sectors. Rapid detection methods for pathogens have hence become a necessity.

Currently, the three most popular methods for detecting pathogens are: microbial culturing followed by biochemical identification, enzyme-linked immunosorbent assay (ELISA), and polymerase chain reaction (PCR) assay. Conventional microbial culturing techniques are very sensitive; however, they include multiple steps in the assay and require pre-enrichment steps and time consuming processes. For example, conventional detection and specific identification of *B. anthracis* require complex techniques and laborious methods because of the genetic similarities among various *Bacillus* species as well as their existence in both spore forms and vegetative state. *B. anthracis* is identified using standard biochemical techniques, such as its sensitivity to penicillin, nonmotility, non $\beta$-hemolytic behavior on sheep or horse blood agar plates, and its susceptibility to lysis by gamma phage. It has been reported that identification of *B. anthracis* by initial blood culturing requires 6–24 h for growth, which is followed by morphological and biochemical identification that requires an additional 12–24 h, and finally, definitive identification that requires an additional 1–2 days [20]. *B. anthracis* is also shown to selectively grow on polymyxin-lysozyme EDTA-thallous acetate (PLET) agar which requires 1–2 days for growth followed by further confirmation [21].

ELISA is a diagnostic tool to detect the presence of antibody-antigen reaction in a sample. An unknown amount of antigen is affixed to a surface, and then a specific antibody is washed over the surface so that it can bind to the antigen. This antibody is linked to an enzyme, and in the final step a substance is added that the enzyme can convert to some detectable signal. ELISA is becoming very popular for food safety monitoring.

PCR is gaining popularity in non-culture-based detection schemes. It is highly sensitive and able to detect the presence of just one cell. However, PCR technology has some disadvantages such as the requirement of expensive equipment, skilled personnel to perform assays, DNA extraction stages which increase the detection time, and prior information of target DNA sequences.

Biosensors can play a role in the rapid test market. Biosensor technology is emerging as a promising field for rapid detection of microbial pathogens. A biosensor is an analytical device that integrates a biological sensing element with an electrical transducer to quantify a biological event (e.g. an antigen-antibody reaction) into an electrical output. The basic concept of operation of a biosensor is illustrated in Figure 1. The biological sensing element may include enzymes, antibodies, DNA probes, aptamers, molecularly imprinted polymers, and whole cells. Depending on the transducing mechanism, biosensors can be electrochemical, electrical, optical, mechanical, and magnetic. They can be operated in a

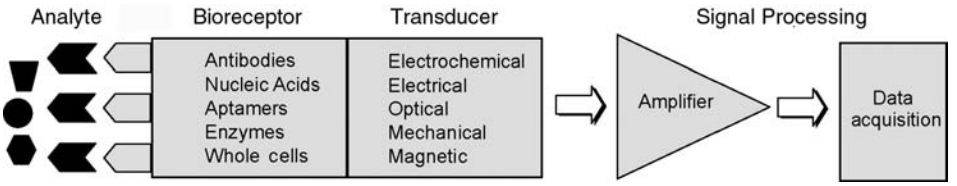

**FIGURE 1** Schematic representation of a biosensor.

reagent-less process enabling the creation of user-friendly and field-ready devices. Some of the major attributes of biosensor technology are its specificity, sensitivity, reliability, portability, real-time analysis, and simplicity of operation. Biosensors are needed to quickly detect disease-causing agents in food, in order to ensure continued safety of the nation's food supply.

Biosensors show high sensitivity and specificity to targets and can be used as simple one-step measurement tools or as multimeasurement devices. Moreover, biosensors can be designed to be operated on-site or at point of care, eliminating the need of expensive lab-based testing. The miniaturization ability of biosensors and their compatibility with data processing technologies, allow them to be integrated into small portable devices. This versatility in biosensors has prompted worldwide research and commercial exploitation of the technology. Recent trends (Fig. 2) indicate that biosensors are the fastest-growing technology for rapid detection of pathogens [22].

## 3 BIOSENSORS FOR MICROBIAL PATHOGEN DETECTION

In this section, we describe different types of biosensors for pathogen detection based on their transduction mechanism such as mechanical, optical, electrochemical, and magnetic approaches.

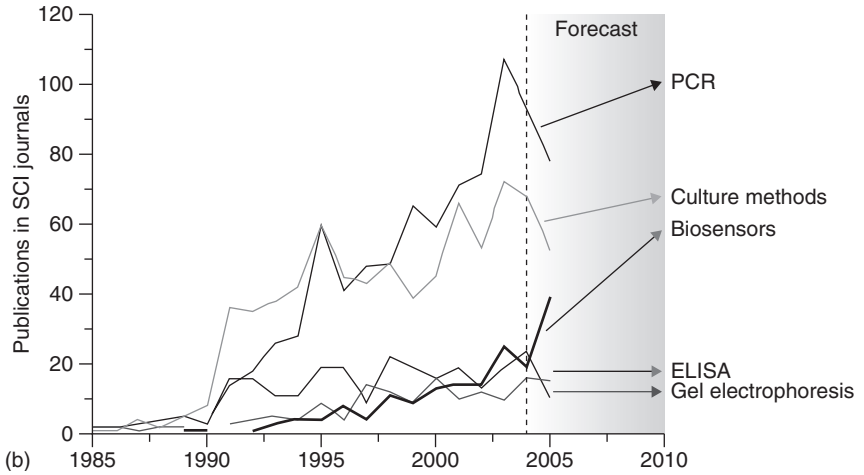

**FIGURE 2** Recent trends in pathogen detection [adapted from Lazcka et al. [22]].

### 3.1 Mechanical Biosensors

***3.1.1 Quartz Crystal Microbalance (QCM) Biosensors.*** Quartz crystal resonators form the basis of Quartz Crystal Microbalance (QCM) sensors. The term "QCM" is used collectively for bulk acoustic wave (BAW), quartz crystal resonance sensors (QCRS), and thickness shear mode (TSM) acoustic sensors [23]. QCM sensors are comprised of a thin quartz disc with electrodes plated on it. When an oscillating electric field is applied across the disc, an acoustic wave with a certain resonant frequency is induced. The disc can be coated with a sensing layer of biomolecules based on the analyte to be detected. The interaction of the analyte with the biomolecules on the disc surface causes a change in mass and a concurrent change in resonant frequency that can be directly correlated to the biomolecular interactions [24]. The relation between mass and the resonant frequency is given by the Sauerbrey equation:

$$\Delta F = \frac{-2.3 \times 10^6 F_0^2 \Delta m}{A} \tag{1}$$

where, $\Delta F$ is the change in frequency (Hz), $F_0$ is the resonant frequency of the crystal (MHz), $\Delta m$ is the deposited mass (grams) and $A$ is the coated area ($cm^2$). The quartz crystals are inexpensive, easily available, and robust, thus making them suitable for chemical sensors and biosensors. In addition, QCM-based sensors provide great flexibility, wide dynamic range of frequency measurements, and label-free detection [24].

A wide range of nonlabeled QCM biosensors have been reported in the literature for the detection of pathogenic bacteria and viruses. QCM sensors based on lectin recognition systems for bacterial identification have been studied by Shen et al. [25], Safina et al. [26]. Shen et al. have used a combination of mannose self-assembled monolayer (SAM) and lectin concanavalin A for the detection of *E. coli* W1485 in a linear range of $7.5 \times 10^2$ to $7.5 \times 10^7$ cells/ml. Safina et al. utilized lectin reporters to develop a flow injection QCM biosensor for detection of *Campylobacter jejuni* and *Helicobacter pylori*. The authors were able to detect $10^3$ to $10^5$ cells/ml in 30 min. A SAM based QCM immunosensor was developed for the detection of *E. coli* O157:H7 by Su and Li [27]. The immunosensor was able to detect the target bacteria in the range of $10^3$ to $10^5$ CFU/ml in 30–50 min. Detection of *B. subtilis* spores as a surrogate to *B. anthracis* was achieved by Lee et al. utilizing a QCM immunosensor to a detection limit of 450 spores/ml [28]. Furthermore, virus (dengue virus and hepatitis B virus) detection with QCM immuno- and nucleic acid- based sensors has been reported by Wu et al. [29] and Yao et al. [30].

QCM biosensors for the detection of DNA sequences have also been developed using nanoparticle labels as amplifiers. Mao et al. [31] reported the use of streptavidin conjugated $Fe_3O_4$ nanoparticles (NPs) for the detection of *E. coli* O157:H7 *eaeA* gene. The NPs acted as 'mass enhancers' and amplified the change in frequency. The biosensor could attain a sensitivity of $10^{-12}$ *M* synthetic oligonucleotides and $2.67 \times 10^2$ CFU/ml *E. coli* O157:H7 cells [31]. Similarly, Au NPs were employed by Wang et al. for real-time bacterial DNA detection in a circulating flow QCM biosensor. The authors reported a sensitivity of $2.0 \times 10^3$ CFU/ml for *E. coli* O157:H7 *eaeA* gene [32].

A QCM-based biosensor was used to detect *Salmonella* sp. in milk samples with detection limits around $10^6$ CFU/ml [33]. Tombelli et al. [34] developed a DNA piezoelectric biosensor for the detection of bacterial toxicity based on the detection of PCR amplified *aer* gene of *Aeromonas hydrophila*. The biosensor was applied to vegetables,

environmental water, and human specimens. The biosensor was able to successfully distinguish between samples containing the pathogen and those not contaminated. Zhao et al. [35] developed a QCM biosensor using 50 nm gold NPs as the amplification probe for DNA detection in the order of 10 fM of target, which was higher than what has been reported using the same method. The high sensitivity was explained by the weight of the larger particles, and the larger area occupied by the larger particles that needed less target DNA for their binding. Another QCM biosensor applied to the detection of *E. coli* in water in combination with PCR amplification (of the *lac* gene) was able to detect a 10 fg of genomic *E. coli* DNA (few viable *E. coli* cells in 100 ml of water) [36]. When used for detection of *Hepatitis B virus*, [37] observed that the QCM could detect frequency shifts of DNA hybridization as a linear relationship, in the range 0.02–0.14 μg/ml with a detection limit of 0.1 μg/ml, similar to the QCM biosensor developed by He and Liu [38] for *Pseudomonas aeruginosa*.

***3.1.2 Surface Acoustic Wave Biosensors.*** Surface Acoustic Wave (SAW) sensors are the second class of acoustic wave sensors that have found applications in biosensor devices. SAW sensors consist of two metal interdigital transducers (IDT) etched from a thin metal film deposited on a piezoelectric substrate. The sensing mechanism is based on the changes in SAW velocity or attenuation when mass is sorbed on the sensor surface. Since the acoustic energy is strongly confined to the surface, SAW devices are very sensitive to surface changes such as mass loading, viscosity, and conductivity changes [39]. It has been suggested that SAW based biosensors have good sensitivities because of their higher mass sensitivities [39].

SAW biosensors have been successfully applied for the detection of bacteria and viruses. *E. coli* detection using SAW biosensors have been reported in the literature by multiple authors [40–43]. The biosensors have used antibodies as the biological sensing element with sensitivities ranging from $10^6$ cells/ml to 0.4 cells/μl. Branch and Brozik have developed a 36° YX-cut $LiTaO_3$ based love-wave device for the detection of the *B. anthracis*, as simulated by *B. thuringiensis* spores in aqueous conditions [44]. The authors have investigated two waveguide materials polyimide and polystyrene for creating the love-wave sensors. Detection of *B. thuringiensis* spores at concentrations below the lethal dose of anthrax spores was possible using both waveguide materials. The sensor had a detection limit of a few hundred cells per ml and a response time of $<100$ s. Jin et al. [45] developed a SAW biosensor for detecting the gene of Staphylococcal Enterotoxin B utilizing ST-cut quartz and $SiO_2$ guiding layer. The biosensor had a sensitivity of 10 ng/ml and a linear range of 35–200 ng/ml [45]. Recently, SAW biosensors were used for detecting viral bioagents by Bisoffi et al. [46]. A lithium-tantalate based SAW transducer with $SiO_2$ waveguide sensor platform was used for Coxsackie virus B4 and Sin Nomber virus detection.

SAW resonators are suitable for use in simple electronic setups because of their low insertion losses and sharp resonance frequencies. As a result, insertion of such devices into oscillator circuits is beneficial as such circuits are commonly used in point-of-care diagnostics. Furthermore, the SAW-based biosensors can be prepared from cheap components thus making them suitable for integration into inexpensive sensor arrays [47].

***3.1.3 Microcantilever-Based Biosensors.*** Microcantilever-based biosensors are derived from microfabricated cantilevers used in atomic force microscopy (AFM). Detection is based on the bending induced in the cantilever when a biomolecular interaction takes

place on one of its surfaces which is translated into nanomechanical motion and is commonly coupled to an optical or piezoelectric readout system [48]. The cantilevers can be operated in the static deflection mode where analyte binding causes cantilever bending or in the dynamic resonant mode where analyte binding causes change in resonant frequency [49]. Microcantilever sensors are promising for biosensor applications since they can perform local, high resolution, and label-free molecular recognition measurements [48].

Davila et al. have demonstrated microcantilever-based biosensors in the detection of *B. anthracis* Sterne spores in air and water [50]. The detection scheme involved measurement of the decrease in resonant frequency driven by thermally induced oscillations as a result of the mass of spores measured by a laser Doppler vibrometer. The authors reported a minimum detection of 2 spores (740 fg) and 50 spores (139 pg) in air and water, respectively, using 20 μm long, 9 μm wide, and 200 nm thick cantilevers. Campbell and coworkers have utilized piezoelectric-excited millimeter-sized cantilever sensors for the detection of *B. anthracis* Sterne spores and *E. coli* O157:H7 cells [51]. The sensors consisted of a piezoelectric and glass layer and were able to detect *B. anthracis* spores at 300 spores/ml and *E. coli* O157:H7 cells in ground beef at 50 to 100 cells/ml. Extremely sensitive microcantilever-based biosensors capable of detecting a single pathogen have also been reported in literature [51]. Illic et al. was able to detect a single *E. coli* O157:H7 cell using low stress silicon nitride cantilever beams in air [52]. The mass of a single *E. coli* O157:H7 cell was found by the authors to be 665 fg. Similarly, Johnson et al. reported the use of microscale silicon cantilever resonators for vaccinia virus detection in air [53]. The authors measured the mass of a single vaccinia virus particle to be $12.4 \pm 1.3$ fg and $7.9 \pm 4.6$ fg using two different-sized cantilever beams [51]. The ability to detect small amounts of bacterial organisms was demonstrated using micro-electromechanical systems (MEMS) for the qualitative detection of specific *Salmonella enterica* strains with a functionalized silicon nitride microcantilever. Detection was achieved due to a change in the surface stress on the cantilever surface *in situ*, upon binding of a small number of bacteria with less than 25 adsorbed bacteria required for detection [54].

## 3.2 Optical Biosensors

***3.2.1 Surface Plasmon Resonance Biosensors.*** Surface Plasmon Resonance (SPR) is an optical technique for monitoring biomolecular interactions that occur in the close vicinity of a transducer surface. SPR-based biosensing can be subdivided into three categories depending on the mode of SPR detection: angular, spectral, and local SPR biosensing. Angular SPR biosensing is the most common form and involves attenuated total reflection approach using Kretschmann geometry [55]. Spectral SPR biosensing is conducted at a fixed incident angle and utilizes the wavelength dependence of the dielectric constant of the metal film to interrogate the surface plasmon coupling conditions. Local SPR (LSPR) biosensing or nanoparticle-based SPR involves coupling of surface-immobilized metallic NPs or nanostructures into a plasmon mode which results in a decrease in the transmitted power at a specific resonant wavelength dependent on environmental dielectric conditions [55].

SPR biosensors provide several advantages over conventional transduction techniques, such as capability of label-free detection, ability to produce continuous real-time responses, regeneration of the active sensor surface, feasibility for miniaturization, multiplexing ability, and sensitive detection of small molecules [56].

SPR-based immunosensors have been developed for the detection of *E. coli* O157:H7 by Irudayaraj and coworkers [57, 58]. The authors have demonstrated a sensitivity of $10^3$ CFU/ml for the pathogen using a SAM-based SPR biosensor and the commercially available Spreeta SPR biosensor [57, 58]. Detection of *Salmonella* Typhimurium in chicken carcasses was achieved using an antibody-based SPR biosensor by Lan et al. [59]. The SPR biosensor had a lowest detection limit of $10^6$ CFU/ml, and highly sensitive detection of *Salmonella* Enteritidis was attained by Waswa et al. using the commercial Biacore™ SPR biosensor [60]. The limit of detection (LOD) of the biosensor as reported by the authors was 23 CFU/ml for *Salmonella*. Chen et al. have demonstrated an immunomagnetic separation based SPR detection method for the foodborne pathogen *Staphylococcus aureus* [61]. The detection system involved an initial immunomagnetic bead-based separation step of 30 min and had a sensitivity of $10^6$ CFU/ml in a total assay time of 2 h. A SAM-based SPR immunosensor was developed by Jyoung et al. for the detection of *V. cholerae* O1 with a detection range of $10^5$ to $10^9$ cells/ml [62]. Detection of viruses using SPR-based biosensors have been reported by Chung et al. [63], Vaisocherova et al. [64]. Vaisocherova and coworkers developed an SPR biosensor for detecting antibodies against the Epstein-Barr virus. The antibody detection was performed using an immunoreaction between the antibody and a synthetic peptide for the virus. The sensor had a sensitivity of 0.2 ng/ml ($\sim$1 pM). Furthermore, multiplex detection of four foodborne bacterial pathogens (*E. coli* O157:H7, *Salmonella* Typhimurium, *Listeria monocytogenes*, and *Campylobacter jejuni*) was demonstrated by Taylor et al. using an eight-channel SPR biosensor [65]. The LOD for each of the four species of bacteria was in the range of $3.4 \times 10^3$ and $1.2 \times 10^5$ CFU/ml. Additional review articles focus on different SPR based detection techniques and their applications [56, 66, 67]. *Listeria* and *Salmonella enterica* were detected at $10^6$ CFU/ml by an SPR biosensor [68]. Additional SPR biosensors for different bacterial targets, such as *P. aeruginosa*, *B. cereus*, and *E. coli* O157:H7, were later developed by various researchers [27, 69–71], and showed similar detection limits.

***3.2.2 Fluorescence-Based Biosensors.*** Fluorescence is the radiative de-excitation of a molecule following the absorption of a photon. Generally, the emitted photon is of lower energy than the absorbed photon, and the fluorescence emission peak of a species is at longer wavelengths than the absorption peak, the wavelength separation being referred to as Stoke's shift. Fluorescence based detection systems have gained popularity in biosensors due to their high sensitivity and are mostly based on the detection of the fluorescent signal generated by fluorophores that are used to label the biomolecules [72].

Fluorescence detection techniques can be performed in high throughput mode in combination with platforms such as microarrays. Microarrays offer the advantage of using a two-dimensional layout of recognition elements for simultaneous detection and quantification. Taitt et al. have demonstrated a fluorescence-based microarray immunosensor for the simultaneous detection of nine targets comprising *B. anthracis* Sterne, *B. globigii*, *Francisella tularensis*, *Y. pestis*, *Salmonella* Typhimurim, Staphylococcal enterotoxin B, ricin, cholera toxin, and MS2 coliphage [73]. More recently, Li et al. have developed a DNA microarray based on fluorescent nanobarcodes, for the simultaneous detection of DNA of four targets (*B. anthracis*, *Francisella tularensis*, Ebola virus, and SARS coronavirus) [74]. The detection procedure involved confocal microscopy, dot blotting and flow cytometry, and resulted in sensitivity in the attomolar range.

Fluorescence resonance energy transfer (FRET-based) detection involves nonradiative energy transfer between a donor fluorophore and an acceptor fluorophore when they are in close proximity [75]. A fiber-optic portable biosensor utilizing the principle of FRET was developed by Ko and Grant for rapid detection of *Salmonella* ser. Typhimurium in ground pork samples [76]. The biosensor had a sensitivity of $10^5$ CFU/ml in a response time of 5 min. Kim et al. reported a molecular beacon (MB) DNA microarray system for fast detection of *E. coli* O157:H7 based on FRET [77]. In this system, unlike conventional fluorophore-quencher beacon design, two fluorescence molecules allowed active visualization of both hybridized and unhybridized states of the beacon. The target gene detection limit for the system was 1 ng/μl.

Fluorescence-based tapered fiber-optic biosensors have also been employed in pathogen detection. A fluorescence-based fiber-optic biosensor for detecting *E. coli* O157:H7 in ground beef samples was developed by Geng et al. [78]. The authors reported sensitivity of $10^3$ CFU/ml in pure cultures and of 1 CFU/ml in artificially contaminated ground beef samples after 4 h enrichment using a sandwich immunoassay. A fiber-optic biosensor was also developed by Geng et al. for detecting *L. monocytogenes* in hot-dog and bologna naturally contaminated or artificially inoculated with 10 to $10^3$ CFU/g, after enrichment in buffered *Listeria* enrichment broth [79]. A cyanine5-labeled antibody was used to generate a specific fluorescent signal. The sensitivity threshold was about $4.3 \times 10^3$ CFU/ml. Nanduri et al. developed an automated fiber-optic based immunosensor called RAPTOR$^{TM}$ for the detection of *Listeria monocytogenes* in food samples. The LOD of the system was $5 \times 10^5$ CFU/ml in food samples and $1 \times 10^3$ CFU/ml in phosphate buffered saline (PBS) solution [80]. In another study, a microcapillary flow injection liposome immunoanalysis system (mFILIA) was developed for the detection of heat-killed *E. coli* O157:H7. Liposomes tagged with anti-*E. coli* O157:H7 and an encapsulating fluorescent dye were used to generate fluorescence signals measured by a fluorometer. The mFILIA system successfully detected as few as 360 cells/ml with a total assay time of 45 min [81].

An automated optical biosensor system based on fluorescence excitation and detection in the evanescent field of a quartz fiber was used to detect 16-mer oligonucleotides in DNA hybridization assays. The detection limit for the hybridization with a complementary fluorescein-labeled oligonucleotide was $2 \times 10^{-13}$ *M* [82]. Another optical fiber evanescent wave DNA biosensor used an MB-DNA probe that became fluorescent upon hybridization with target DNA [83]. The detection limit of the evanescent wave biosensor with synthesized complementary DNA was 1.1 nM. Liu et al. later developed MB-DNA biosensors with micrometer to submicrometer sizes for DNA/RNA analysis. The MB-DNA biosensor was highly selective with single base-pair mismatch identification capability, and could detect 0.3 n*M* and 10 n*M* of rat gamma-actin mRNA with a 105-μm biosensor and a submicrometer (0.1 μm) biosensor, respectively [84].

Optical biosensors targeting RNA as the analyte offer an added advantage over traditional DNA-based detection methods, that is, viable cell detection. Baeumner et al. [85] detected as few as 40 *E. coli* cells/ml in samples using a simple optical dipstick-type biosensor coupled to Nucleic Acid Sequence Based Amplification (NASBA), emphasizing the fact that only viable cells were detected, and no false positive signals were obtained from dead cells present in a sample. The detection of viable cells is important with respect to safety, and also food and environmental sample sterilization assessments. Similarly, a biosensor for the protozoan parasite *Cryptosporidium parvum* was developed [86]. Hartley and Baeumner [87] developed a simple membrane-strip based biosensor for

the detection of viable *B. anthracis* spores. The study combined the optical detection process with a spore germination procedure, as well as a nucleic acid amplification reaction to identify as little as one viable *B. anthracis* spore in 12 h.

### 3.3 Electrochemical Biosensors

Electrochemical biosensors are based on the detection of electrochemical signals generated by consumption or production of electrons from biological interactions occurring at the sensor surface. Advantages such as low cost, high sensitivity, miniaturization ability, low power requirements, and simple instrumentation make electrochemical biosensors well-suited for clinical and environmental analysis. Electrochemical biosensors are generally classified as amperometric, potentiometric, conductometric, and impedimetric.

***3.3.1 Amperometric Biosensors.*** Amperometric biosensors are based on the measurement of current changes resulting from oxidation or reduction of an electroactive species in a biochemical reaction. The current is typically measured at a fixed potential (amperometry) or during controlled variations of the potential (voltammetry).

Theegala et al. reported an oxygen-electrode based amperometric biosensor for the qualitative detection of *E. coli* O157:H7 in water [88]. The biosensor detected changes in oxygen concentration due to decrease in enzymatic activity upon binding of bacterial cells. The biosensor could detect as low as 50 cells/ml in 20 min. A renewable amperometric immunosensor for the detection of *S. typhi* was reported by Singh et al. [89]. The detection technique involved a sandwich ELISA system with an LOD of $10^5$ cells/ml in 90 min. Amperometric detection of antibodies against *B. anthracis* protective antigen was also achieved by Aguilar et al. [90]. The antibodies were captured and detected using microcavities with an LOD of 10 fg in a 200 nl sample. A disposable amperometric immunosensor based on a screen-printed electrode (SPE) coated with agarose or nano-Au membrane and horseradish peroxidase-labeled antibody for specific detection of the foodborne pathogen *Vibrio parahaemolyticus* was developed by Zhao et al. [91]. The immunosensor showed a sensitivity of $7 \times 10^4$ CFU/ml for the pathogen with good consistency (97.5%) as compared to the ELISA results.

Lermo et al. described a genomagnetic assay for the electrochemical detection of *Salmonella* spp. based on *in situ* DNA amplification and magnetic primers [92]. Detection was achieved by double hybridization of the target on magnetic beads which were then separated by a magneto-electrode based on graphite-epoxy composite followed by electrochemical detection using an enzyme marker anti-digoxigenin horseradish peroxidase. The authors achieved a sensitivity of 2.8 fmol with PCR amplicons. Multi-analyte detection using electrochemical genosensors have also been studied by Elsholz et al. [93], Farabullini et al. [94]. Farabullini et al. achieved nanomolar detection limits for the toxin-producing bacteria such as *Salmonella* sp., *E. coli* O157:H7, *L. monocytogenes*, and *S. aureus*, using differential pulse voltammetry to detect $\alpha$-napthol signal in less than 1 h.

Additional biosensors (targeting DNA) that have been developed include MEMS-based amperometric [95] and high throughput PCR biosensors [96], microcantilever-based cyclic voltammetry biosensor [97], pulsed amperometry- [98], and capacitance-based biosensors [99, 100].

***3.3.2 Potentiometric Biosensors.*** Potentiometric devices are based on the measurement of accumulation of charge potential at the working electrode of an electrochemical cell

in comparison to the reference electrode with zero or negligible current flow between the electrodes. The measured potential is related to the concentration of the analyte through the Nernst equation:

$$E = E_0 \pm (\mathrm{R}T/n\mathrm{F}) \ln Q$$

where, $E$ is the cell potential at zero current, $E_0$ is the standard potential, R is the universal gas constant, $T$ is the absolute temperature, F is the Faraday's constant, $n$ is the total number of charges of ion, $Q$ is the ratio of ion concentration at the anode to that at the cathode [101, 102].

Among electrochemical transducing methods, potentiometric methods are the least exploited in pathogen detection due to their high detection limits and poor selectivity, the main advantage of these devices being wide detectable concentration range and continuous measurement capability [103]. Another approach involves ion selective filed effect transistors (ISFETs) that employ semiconductor field-effect to detect biorecognition events. However, the application of these devices in biosensors has been limited by production problems related to immobilization, fabrication and packaging, poor detection limits, and device stability [22]. An advancement that has evolved from the ISFET is the light addressable potentiometric sensor (LAPS) which combines potentiometry with optical detection [22, 104]. Ercole et al. reported an antibody-based LAPS biosensor for the determination of *E. coli* in food [105]. The biosensor detected variations in pH due to ammonia production by urease-*E. coli* antibody conjugates in commercial lettuce, sliced carrot, and rucola samples. The sensor was able to reach a sensitivity of 10 cells per ml in an assay time of 1.5 h.

***3.3.3 Conductometric Biosensors.*** Conductometric biosensors utilize the electrical conductivity of a sample to determine the components and their concentration [106]. Muhammad-Tahir and Alocilja [107–110] have developed a conductometric biosensor for the detection of pathogenic bacteria and viruses. The biosensor was fabricated using conducting polyaniline as an electronic label in a sandwich immunoassay scheme, and the authors demonstrated that polyaniline improved the sensitivity of the biosensor by forming a conductive molecular bridge between silver electrodes. The authors reported a sensitivity of $10^{1.8.3} \times 10^1$ CFU/ml for *Salmonella*, $7.9 \times 10^1$ CFU/ml for *E. coli* O157:H7, $7.5 \times 10^1$ CFU/ml for *E. coli*, and $10^3$ CCID/ml for BVDV virus in a detection time of 10 min. A conductometric immunosensor based on magnetic NPs has been recently developed by Hnaiein et al.,for the detection of *E. coli* [111]. The immunosensor was composed of streptavidin-modified magnetic nanoparticle layer immobilized on a conductometric transducer consisting of interdigitated gold electrodes. Conductivity measurements allowed detection of 0.5 CFU/ml of *E. coli* without the need for amplification.

***3.3.4 Impedimetric Biosensors.*** Impedance spectroscopy involves applying small amplitude, perturbing sinusoidal voltage signals to an electrochemical cell and measuring the resulting current response. The complex impedance, sum of real and imaginary impedance components, can be calculated as a function of the excitation frequency of the applied potential by varying it over a range of frequencies [112]. Impedimetric detection techniques provide the advantages of high sensitivity, linearized current-potential

characteristics, measurement over wide time or frequency ranges, and label-free sensing [22, 106]

Radke and Alocilja had developed a microimpedance biosensor for the detection of *E. coli* O157:H7 [113]. The sensor detected changes in impedance caused by the presence of bacteria immobilized on interdigitated gold electrode arrays fabricated from silicon. The biosensor was able to discriminate between different cellular concentrations of the bacteria ($10^5$ to $10^7$ CFU/ml) in 5 min. Nandakumar et al. have demonstrated the detection of *Salmonella* Typhimurium using electrochemical impedance spectroscopy based on Bayesian decision theory [114]. The technique detected the pathogen in 6 min at a lowest concentration of 500 CFU/ml. An impedance biosensor based on an interdigitated array microelectrode coupled with magnetic nanoparticle-antibody conjugates was developed for rapid and specific detection of *E. coli* O157:H7 in ground beef samples, by Varshney and Li [115]. Magnitude of impedance and phase angle was measured in a frequency range of 10 Hz to 1 MHz in the presence of 0.1 *M* mannitol solution. The lowest detection limit of the biosensor for *E. coli* O157:H7 was $7.4 \times 10^4$ CFU/ml in pure cultures and $8.0 \times 10^5$ CFU/ml in ground beef samples, the total detection time being 35 min.

An impedance biosensor chip for detection of *E. coli* O157:H7 was developed based on the surface immobilization of affinity-purified antibodies onto indium tin oxide (ITO) electrode chips, with a detection limit of $6 \times 10^3$ cells/ml [116]. Shah et al. [117] developed an amperometric immunosensor with a graphite-coated nylon membrane serving as a support for antibody immobilization and as a working electrode. This approach was used for detection of *E. coli*, with a low detection limit of 40 CFU/ml.

### 3.4 Magnetic Biosensors

Devices based on the detection of magnetic labels are emerging as a promising new approach in the field of biosensing [118]. Magnetic labels have gained popularity in biosensing because they are physically and chemically stable, are relatively inexpensive, and can easily be made biocompatible. Several approaches have been developed in the past few years for both direct and indirect detection of magnetic labels. Direct detection includes approaches for measuring magnetic parameters, such as magnetic permeability, magnetic remanence, magnetoresistance, and Hall Effect. The indirect detection methods are based on microcantilever-based force amplified sensors and magnetic relaxation switches [119]. However, the applications of these magnetic devices for detection of actual targets such as pathogenic microorganisms remain limited and require further research.

Edelstein et al. had developed a multi-analyte BARC (Bead Array Counter) biosensor using giant magnetoresistive (GMR) sensors to detect and identify biological warfare agents [120]. The prototype designed by the authors consisted of a microfabricated chip with GMR sensor arrays, an electronic chip-carrier board, a fluidics cell and an electromagnet. DNA probes were patterned onto the GMR sensor chips and hybridized with complementary PCR products. Micron-sized magnetic beads were then bound to the DNA sample by streptavidin biotin interactions and the unbound beads were removed by applying a magnetic field. The bound magnetic beads were then detected by the GMR sensors. The authors were able to demonstrate the detection of *B. anthracis* lethal factor and *C. botulinum* neurotoxin A using the BARC biosensor.

A mass-sensitive magnetoelastic immunosensor for the detection of *E. coli* O157:H7 was reported by Ruan et al. [121]. The detection was based on the immobilization of

alkaline phosphatase-labeled antibodies on the surface of a micrometer-scale magnetoelastic cantilever and amplification of the mass change associated with antigen-antibody binding reaction by biocatalytic precipitation of 5-bromo-4-chloro-3-indolyl phosphate. The minimum detectable level of the immunosensor was $6 \times 10^2$ cells/ml.

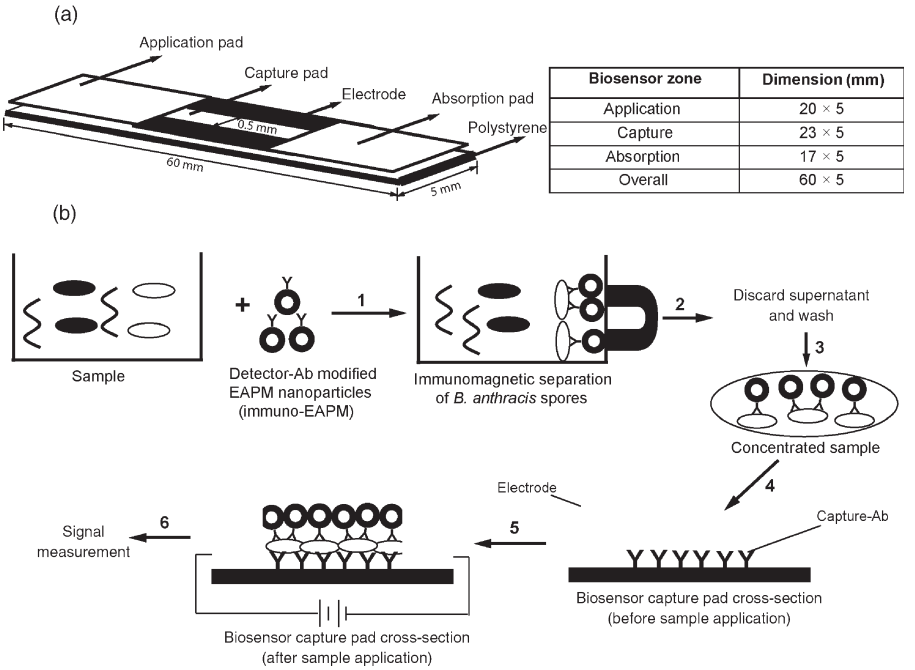
A high efficiency Hall-Effect microbiosensor platform has recently been developed for the detection of magnetically labeled biomolecules by Sandhu et al. [122]. In this system, the integration of Hall-Effect structures with microcurrent lines allowed manipulation of the magnetic beads position via field gradients. The authors studied the hybridization of fully complementary DNA strands of 20–25 bases using Dynabeads as magnetic labels with this platform. Although, the sensitivity of the sensor was not reported, the authors were able to demonstrate a quantitative relationship between the number of magnetic labels and the output signal.

## 4 INTEGRATED EXTRACTION/DETECTION MAGNETIC NANOPARTICLE-BASED BIOSENSOR SYSTEM

In this section, we illustrate an integrated extraction-detection system. Specifically we present how electrically active polyaniline-coated magnetic (EAPM) NPs are used in a direct charge transfer biosensor for the concentration and detection of *B. anthracis* spores from complex food matrices such as romaine lettuce, lean ground beef, and ultra-pasteurized whole milk. For lettuce and beef, 25 g samples were weighed, mixed with 225 ml of 0.1% (w/v) peptone water in a Whirl-Pak plastic bag, and stomached in a stomacher (Microbiology International, MD) for one minute. The milk samples were used as purchased. Nine ml of the liquid samples were thoroughly mixed with 1 ml of appropriate concentrations of *B. anthracis* spores stock solution in a vortex mixer (Fisher Scientific, IA). Finally, a series of 10 ml samples inoculated with *B. anthracis* spores at concentrations ranging from $10^1$ to $10^7$ spores/ml were obtained. For details of this illustration, please refer to Pal and Alocilja [123].

The biosensor design is shown in Figure 3a [123]. A three-component biosensor system is made up of a sample application pad, capture pad, and absorption pad. Silver electrodes are fabricated along both sides of the capture pad leaving an electrode gap of 0.5 mm. For data acquisition, the biosensor unit is connected to a handheld multimeter linked to a computer.

There are three important materials in the detection scheme: detector antibodies conjugated to EAPM-NPs ($Ab_d$-EAPM), capture antibodies immobilized on the nitrocellulose membrane ($Ab_c$), and target *B. anthracis* spores. Figure 3b is a schematic representation of the immunomagnetic separation and biosensor detection procedure. The biosensor detection involves a sandwich immunoassay to form the biological structure $Ab_c$-spore-$Ab_d$-EAPM. To start, EAPM-NPs are conjugated with mouse monoclonal anti-*B. anthracis* IgG molecules through direct physical adsorption (Step 1), forming $Ab_d$-EAPM. Then $Ab_d$-EAPM are used to immunomagnetically concentrate the spores from the complex food matrices (Step 2). The concentrated targets (spore-$Ab_d$-EAPM) are then washed to remove unbound materials (Step 3) and applied to the sample application pad of the biosensor (Step 4). The spore-$Ab_d$-EAPM complex flows to the capture pad by capillary action, where the antigen is anchored by the capture antibodies ($Ab_c$) and the sandwich structure $Ab_c$-spore-$Ab_d$-EAPM is formed (Step 5). The conductive EAPM-NPs bound to the spores in the sandwich act as a voltage-controlled "ON" switch



| Biosensor zone | Dimension (mm) |
|---|---|
| Application | 20 × 5 |
| Capture | 23 × 5 |
| Absorption | 17 × 5 |
| Overall | 60 × 5 |

**FIGURE 3** (a) Biosensor architecture and dimensions; (b) Schematic representation of the biosensor detection system [123].

resulting in a decreased resistance across the silver electrodes that is recorded electrically (step 6) [123].

Figure 4a shows the magnetization versus magnetic field i.e. the *M-H* loop measurements of both unmodified $Fe_2O_3$ and synthesized EAPM NPs, using a DC SQUID magnetometer at 300 K. Both systems start to saturate at 5 kOe. The saturation magnetization ($M_S$) for the $Fe_2O_3$ NPs is 64.4 emu/g, whereas the saturation magnetization of the EAPM-NPs is 44.1 emu/g. The decrease in $M_S$ value for the EAPM-NPs is expected due to surface interactions between the polymer (polyaniline) which is diamagnetic in nature, and iron oxide NPs [124]. The remanent magnetization $M_r$ for the $Fe_2O_3$ and the EAPM-NPs are 14.2 and 10.4 emu/g, respectively, and the coercive force $H_c$ for both NPs is 200 Oe. The low values of $M_r$ and $H_c$ suggest that the NPs are still in the ferromagnetic phase but approaching superparamagnetic behavior [125]. Figure 4b (inset) shows electrical conductivity measurements of both synthesized EAPM and unmodified $Fe_2O_3$ NPs compressed into pellets of 2000 microns thickness at room temperature. The $Fe_2O_3$ NPs have an electrical conductivity as low as $3.4/10^5$ S/cm whereas the conductivity of the EAPM-NPs is 5 orders of magnitude higher: 3.3 S/cm. This increase in electrical conductivity is expected and confirms the presence of electrically active polyaniline in the NPs.

Figure 5a and 5b reveal Transmission Electron Microscope (TEM) images of the unmodified $Fe_2O_3$ NPs and the polyaniline-coated EAPM-NPs. The iron oxide NPs have an average diameter of 20 nm according to manufacturer's specifications, which is consistent with the TEM image in Figure 5a, whereas the polyaniline-coated EAPM-NPs show a diameter ranging from 50 to 100 nm (Figure 5b).

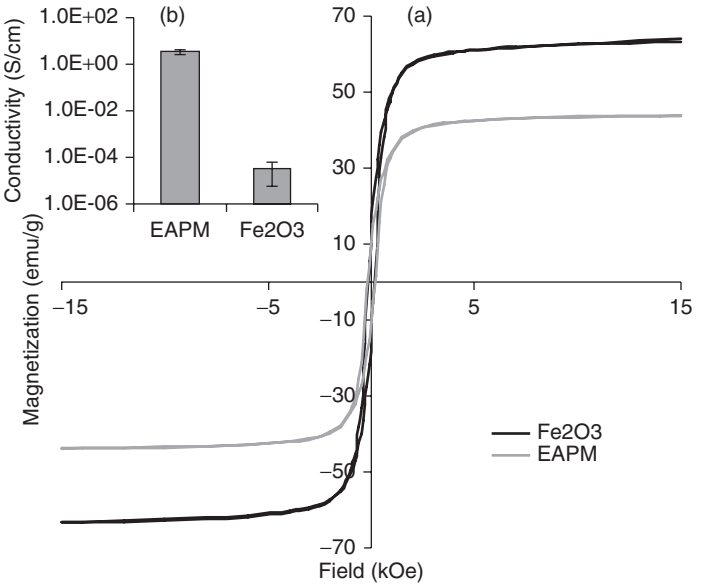


**FIGURE 4** (a) Experimental *M-H* curves of the synthesized EAPM and unmodified $Fe_2O_3$ nanoparticles at 300 K; and (b, inset) Electrical conductivity measurements for the EAPM and $Fe_2O_3$ nanoparticles at room temperature [printed with permission from Pal and Alocilja [123]].

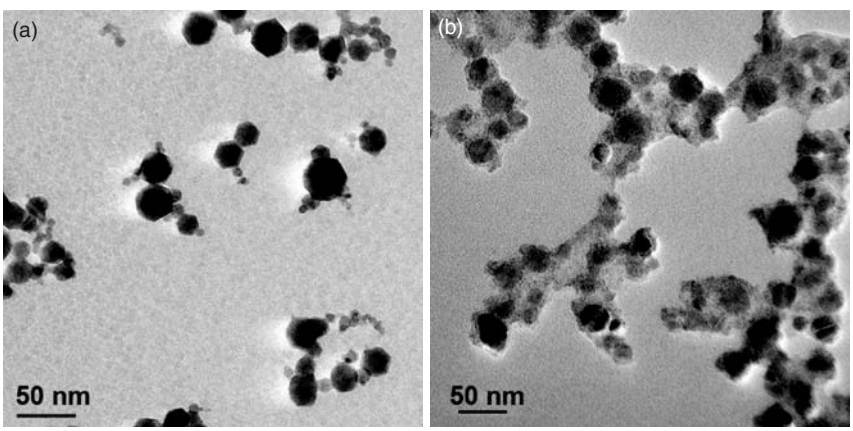

**FIGURE 5** TEM images of (a) unmodified $Fe_2O_3$ nanoparticles; and (b) Synthesized EAPM nanoparticles [printed with permission from Pal and Alocilja [123]].

The immunomagnetic capture of *B. anthracis* spores using EAPM-NPs from the three different food matrices was confirmed by microbial plating in TSA II blood agar plates and the capture efficacy of the NPs was evaluated. The capture ratio (CR) of the EAPM-NPs was evaluated using the formula $CR = C_{captured}/C_{actual}$, where, $C_{actual}$ is the actual concentration of viable spores in the sample, and $C_{captured}$ is the concentration of viable spores extracted from the food samples. The capture effects of the EAPM-NPs on *B. anthracis* spores from the lettuce and ground beef samples are quite similar. In

both samples, the capture effect is highest at a viable spore concentration of $1.52 \times 10^2$ CFU/ml with a CR value of 0.97 for lettuce and that of 0.72 for ground beef. Also, the EAPM-NPs could achieve an immunomagnetic capture at viable spore concentration as low as $1.52 \times 10^1$ CFU/ml from both lettuce and ground beef samples. However, for whole milk samples, the immunomagnetic capture of the viable *B. anthracis* spores could only go as low as $1.52 \times 10^2$ CFU/ml and the capture effects are observed to be similar for all viable spore concentrations with CR values in the range of 0.06 and 0.11. This could be explained by the high fat content of the whole milk samples which might have interfered in the immunomagnetic capture process.

Figure 6a, b, and c show the average resistance readings measured with the EAPM nanoparticle-based direct charge transfer biosensor in lettuce, whole milk, and ground beef samples inoculated with *B. anthracis* spores. The average resistance signals obtained from three replicates were plotted for the control and the food samples, contaminated with spore concentrations ranging from $4.2 \times 10^1$ to $4.2 \times 10^7$ spores/ml. As observed, the resistance values recorded for the different spore concentrations are much lower than the values for the control solution that has no spores in it. The average resistances for the control solutions for all three food samples are in the range of $288 \pm 50$ and $353 \pm 51$ kΩ, whereas the average resistances for the different spore concentrations in the three food samples vary from $75.1 \pm 14$ to $132.6 \pm 19$ kΩ. The reduced resistance values support the formation of a sandwich complex on the capture pad, where the conductive EAPM-NPs act as a charge transfer agent causing a drop in the resistance signal across the silver electrodes [126–129]. Single factor analysis of variance (ANOVA) to a significance of 95% ($P < 0.05$) was used to compare the differences in the resistance values between

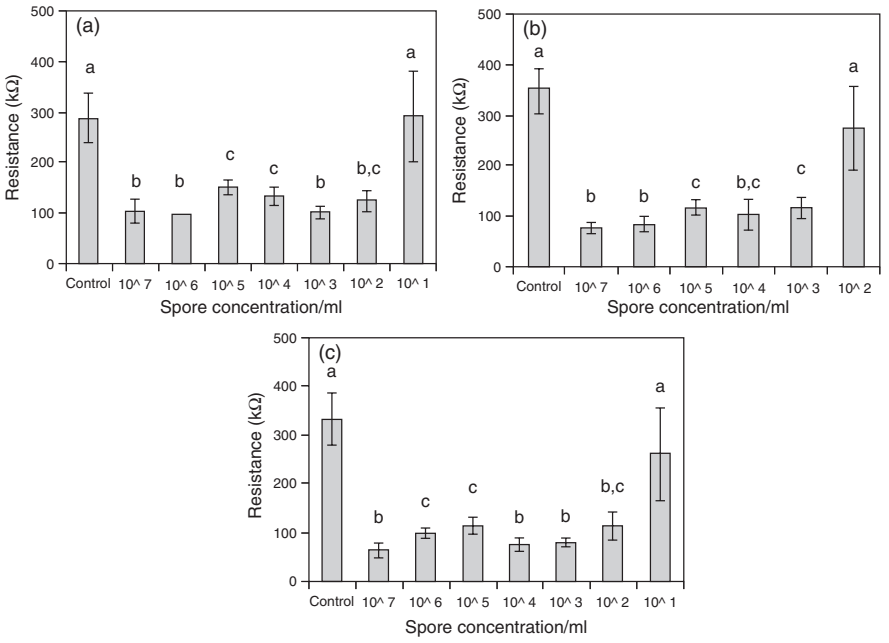

**FIGURE 6** The EAPM nanoparticle-based direct charge transfer biosensor resistance responses in (a) Romaine lettuce, (b) Whole milk, and (c) Ground beef samples contaminated with *B. anthracis* spores. Average resistances with the same letters are not significantly different ($P > 0.05$).

the control and the different spore concentrations. The lowest spore concentration that produced a resistance signal significantly different ($P < 0.05$) from the control was considered to be the sensitivity or detection limit of the biosensor. For the lettuce and ground beef samples, the biosensor sensitivity was $4.2 \times 10^2$ spores/ml with statistically significant differences from the control ($P$-value for lettuce at $10^2$ spores/ml was 1.79 E-05; $P$-value for ground beef at $10^2$ spores/ml was 2.63E-06). For whole milk samples, the biosensor could reach a sensitivity of $4.2 \times 10^3$ spores/ml where statistically significant differences could be observed from the control ($P$-value at $10^3$ spores/ml was 8.47E-08). The reduced biosensor sensitivity in the whole milk samples could be attributed to the high fat content in these samples. As observed in Figure 6, although the biosensor resistance readings recorded for the different spore concentrations were different from the control, statistical analysis did not reveal any significant differences between the concentrations. Artifacts in biosensor fabrication, probabilistic antigen-antibody interactions, antibody orientations, and stability of the sandwich complex on the capture pad might be some of the factors behind such biosensor performance. At this stage the biosensor is only considered to be a qualitative device for a yes/no diagnosis of *B. anthracis* spores. However, the biosensor shows excellent sensitivity and fast detection time in comparison to the very few rapid detection systems for *B. anthracis* in the food matrices that have been reported in the literature [130, 131].

Specificity evaluation of the biosensor is also presented here. A comparison of the biosensor resistance responses was made in pure cultures of *E. coli* with cell concentrations ranging from $1.7 \times 10^1$ to $1.7 \times 10^5$ CFU/ml, in pure cultures of *Salmonella* Enteritidis with cell concentrations ranging from $1.6 \times 10^1$ to $1.6 \times 10^5$ CFU/ml, and pure spore suspensions of *B. anthracis* with spore concentrations ranging from $4.2 \times 10^1$ to $4.2 \times 10^5$ spores/ml. The biosensor average resistance values for different concentrations of the nontarget bacteria (i.e. *E. coli* and *Salmonella* Enteritidis) are similar to the values observed for the control. Single factor ANOVA tests to a significance of 95% ($P < 0.05$) showed no statistically significant differences between the control and different cell concentrations of *E. coli* and *Salmonella* Enteritidis with $P$-values ranging from 0.278 to 0.887 for *E. coli*, and from 0.348 to 0.981 for *Salmonella* Enteritidis. The results indicate that the effects of nonspecific interactions are not significant for the range of cell concentrations tested on the biosensor. In comparison, for pure *B. anthracis* spore suspensions, the biosensor average resistance responses show significant differences between the control and spore concentrations ranging from $10^2$ to $10^5$ spore/ml ($P$-value range: 0.009−0.0009) which is expected since the antibodies used in the biosensor are specific for *B. anthracis*.

## 5 CONCLUDING COMMENTS

In this chapter, we attempted to present biosensors using various transduction mechanisms that have been developed for rapid detection of microbial pathogens of concern to food defense and food safety. These biosensors are designed for rapid, highly sensitive, specific, and user-friendly operation. While they are not exhaustive, the chapter provides a wide range and scope of the detection mechanisms that are novel and potentially market-ready. The illustrated biosensor on the EAPM-based system is an excellent demonstration on the potential speed, sensitivity, and specificity that can be achieved by biosensors in general.

## 1 INTRODUCTION

### 1.1 Threats to Food Safety

Every year, more than 76 million Americans suffer from foodborne illnesses that result in an estimated 325,000 hospitalizations and 5000 deaths [1]. Costs of these illnesses are between $9.3 and 12.9 billion in direct medical expenses [2]. Foodborne illnesses are primarily caused by four types of microorganisms (bacteria, fungi, eukaryotic parasites, and viruses) that are pathogenic, but commonly found in the natural environment.

The US Food and Drug Administration (FDA) and Centers for Disease Control and Prevention (CDC) have concluded that foodborne illness is one of the most serious, yet unavoidable, health problems facing the nation. The majority of foodborne illnesses can be attributed to changing human demographics, lifestyle choices, food consumption trends, mass transportation of food items, and microbial adaptation [3, 4]. In addition, the nation's aging population contributes to a rise in such illnesses; as one grows older, his/her immune system weakens, and, consequently, a further increase in the number of foodborne illnesses is anticipated. Another factor stems from new interests in international cuisines that increase the importation of exotic foods from many countries. These foods are grown, harvested, and often processed in foreign countries. Therefore, they must be shipped longer distances to reach the final consumers. As the health standards of foreign countries are often significantly different from those in the United States, food importation becomes an additional source of possible contamination. The greater transportation distances and longer-term storage of food may allow small amounts of bacteria and other pathogens to multiply and potentially reach their infectious doses.

### 1.2 Outbreaks of Foodborne Illnesses

Bacteria are responsible for more than 90% of the confirmed foodborne illnesses and deaths in humans reported to the CDC. Of the foodborne bacterial pathogens, *Salmonella* causes most of the foodborne illnesses worldwide [5]. For the nation's entire population, the CDC estimates that there are 173 cases of *Salmonella* illnesses per million people

each year [6]. In the United States, human gastrointestinal illnesses are most commonly due to *Salmonella* and *Escherichia coli* infections. *Salmonella* infection is usually caused by the *S. typhimurium*, *S. enteritidis*, or *S. heidelberg* serotypes [7].

In 1985, a large US outbreak of salmonellosis that occurred in Chicago was attributed to *S. typhimurium* in pasteurized milk from a single dairy plant [8]. In September 2006, the outbreak due to the *E. coli* O157:H7-contaminated fresh spinach resulted in 187 reported cases of illness in 27 states, including 97 hospitalizations, at least 29 cases of kidney failure, and 1 death. In December of the same year, another outbreak linked to Taco Bell restaurants in the northeastern United States was also caused by *E. coli* O157:H7. There were 71 people with illness reported from five states: New Jersey (33), New York (22), Pennsylvania (13), Delaware (2), and South Carolina (1) [9]. In 2008, several *Salmonella* outbreaks occurred in the United States. The most serious case of these occurred in the mid-April, when the *Salmonella* St. Paul outbreak involving contaminated tomatoes became one of the largest *Salmonella* outbreaks in the recent history, sickening at least 869 people and resulting in the hospitalization of 257 individuals. On the basis of the CDC's estimated ratio of nonreported salmonellosis cases to reported cases (38.6:1), around 52,826 illnesses resulted from the *Salmonella St. Paul* outbreak.

*Salmonella* and other foodborne pathogens (e.g. *E. coli* O157:H7) can be spread easily throughout the food chain. Daily consumed food items, such as oat cereal [3, 10], tomatoes [11], eggs [12], milk [13], vegetables and fruits (e.g. raw tomatoes), water [12], green onions, jalapeño peppers, red plum, peanut butter [14], and cilantro [15], have recently been found to be contaminated with *Salmonella*. Although it appears that more outbreaks are being linked to vegetable and fruit products, this has not been proven, because of the difficulty that scientists and inspectors often experience in locating the source of the pathogen contamination. Foodborne contamination is difficult to monitor because products may be cleaned at the harvesting site, transported to a warehouse, and then repackaged several times before reaching retail outlets. This leaves a lengthy trail that covers many states and often more than one country. In order to reduce the incidence of foodborne illnesses, there is an urgent need to develop a device capable of rapid, on-site detection of bacterial pathogens. The device needs to be inexpensive as well as easy to use so that it can readily be adopted by every link in the food chain, up to and including the final individual consumers.

### 1.3 Major Pathogenic Bacteria Studied for Food Safety

Pathogenic bacterial detection is of the utmost importance for the prevention and identification of problems related to health and safety [16]. Figure 1 summarizes the distribution of scientific literature covering bacterial detection, where *Salmonella is ranked as* the most commonly studied bacterium. Other than *Salmonella*, *E. coli*, *Listeria*, *Campylobacter*, and *Legionella* are also popularly studied.

### 1.4 Capability of Detectors for Foodborne Pathogen Detection

The prevention of foodborne illnesses depends on the availability of rapid, simple, and effective detection devices capable of identifying and distinguishing various pathogenic microorganisms in food, food production facilities, clinical medicine, and the natural environment. High sensitivity and selectivity are two important criteria for effective biological detection methods. Some pathogenic organisms, such as *E. coli* O157:H7, are

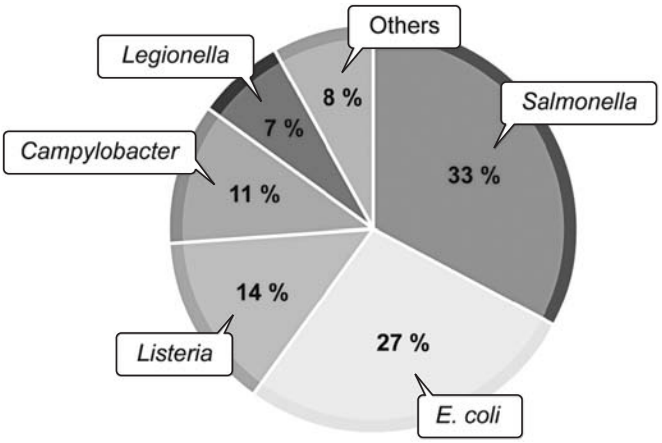

**FIGURE 1** The distribution of scientific literature covering the detection of pathogenic bacteria [16].

able to infect people at doses as small as a few cells. Hence, extremely sensitive methods are required to detect them [17–19]. At the same time, microbiological detection methods should be cheap and robust from a commercial applications point of view. For a pathogen detection method to be industrially successful, detection test equipment must be portable so that they can be taken outside of laboratory confines and used with a minimal need of skilled personnel [20, 21].

Today, intensive research is being conducted to develop new techniques for the early detection of the causes of foodborne illnesses. Traditional methods of identifying the pathogens responsible for foodborne illnesses are very time consuming (i.e. several days to yield results) and typically require highly trained personnel in laboratories with expensive equipment [22]. There is, therefore, a real need for the development of portable, rapid, specific, and sensitive biosensors to enable real-time, on-site detection of foodborne pathogens. To achieve the objective, various biosensing techniques have been developed and used in the food safety field. However, real-time biological monitoring remains a challenge. The ever-growing need for rapid detection of pathogenic microorganisms has resulted in an increased interest in the research and development of biosensor systems.

### 1.5 The Objective

In this review paper, we will provide an overview of general detectors that may be used to insure food safety and their capabilities. First, various bacterial detection methods will be classified and described. Next, the capability of each of the methods will be summarized, covering the working principle, detection limit, advantages, and weaknesses. Finally, phage-based detectors, especially one type of potential biosensor, phage-based magnetoelastic (ME) biosensors, will be discussed in detail.

## 2 DETECTORS FOR FOOD SAFETY APPLICATIONS

Figure 2 compares the number of articles using different bacterial detection methods. To date, polymerase chain reaction (PCR) [23] and culture-based methods (colony counting)

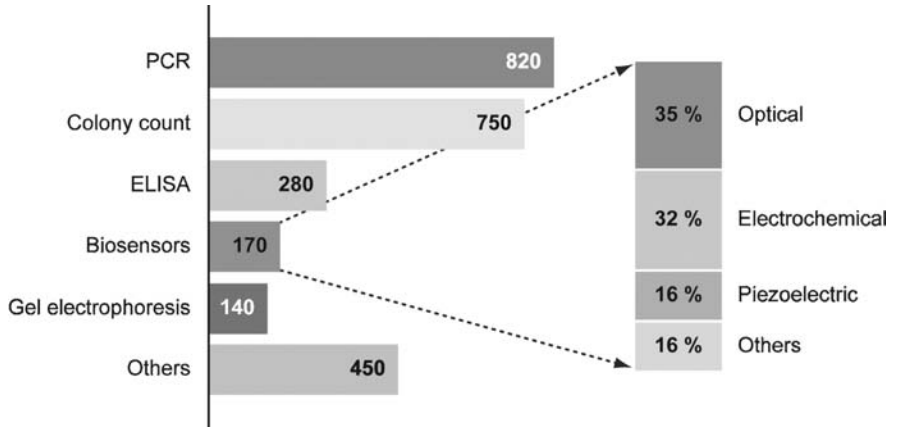

**FIGURE 2** Approximate number of articles using different techniques to detect and/or identify pathogenic bacteria [16].

[24] have been the most commonly used methods and are able to provide unambiguous results. Other than these methods, newly developed biosensor technologies and traditional enzyme-linked immunosorbent assay (ELISA)-based [25] methods are also promising and drawing a lot of attention.

### 2.1 Culture-Based Methods

Culture-based morphological evaluation has been one of the most commonly used bacterial identification methods for food safety. It relies on the use of microbiological media to selectively cultivate bacteria and colony count, followed by biochemical characterization. Although culture-based methods can be used to identify a very small number of bacterial pathogens (down to single pathogens) there are two major drawbacks: They are time-consuming and labor-intensive processes, which make them unsuitable for rapid, on-site bacterial detection methods that ideal future instruments must be able to perform. In culture-based methods, cumbersome and lengthy experimental steps such as pre-enrichment, selective enrichment, biochemical screening, and sometimes serological confirmation are required [26]. This may take 14–16 days to complete [27], depending on the target organisms. The second drawback is that no single culture-based test leads to the universal identification of unknown bacterial pathogens [26]. Some examples of culture-based methods used for detection of pathogenic bacteria in food are shown in Table 1.

### 2.2 Surveillance System

The surveillance system traditionally used to collect foodborne disease outbreak data has been overwhelmed by the emergence of megafarms, distribution centers, and transporters. To address these issues, an automated bioterrorism surveillance system, Real-time Outbreak Disease Surveillance (RODS), was implemented by the University of Pittsburgh in 1999. RODS collects data from multiple sources (e.g. clinics, laboratories, and drug sales) and uses this data to identify a bioterrorism event. Within a year, this system had been modified by RODS lab member Michael Wagner and his coworkers to collect data

**TABLE 1 Culture-Based Detectors**

| Year | Detection Method | Foodborne Pathogen | Source | Detection Limit | Reference |
|---|---|---|---|---|---|
| 1998 | Selective special media | *Legionella pneumophila* | Drinking water | <10 cfu/ml | 28 |
| 2001 | EN ISO-11290-1 | *Listeria monocytogenes* | Cheese, meat, eggs | <100 cfu/25 g | 29 |
| 2006 | NGFIS | *Listeria monocytogenes* | Minced meat, fermented sausage, and others | <10 cfu/g | 30 |
| | FDA | Listeria monocytogenes | Milk (goat) | <0.7 cfu/ml | |
| | USDA-FSIS Cold enrichment | | | | |

from 20,000 national retail locations and was being supported by a $300 million grant to equip all 50 states with biosurveillance systems [31].

### 2.3 Enzyme-Linked Immunosorbent Assay (ELISA)

ELISA, which may also be referred to as *EIA* (*enzyme immunoassay*), is a biochemical technique that is primarily used to quantify the presence of an antibody, hormone, or antigen in a sample [32]. In the food industry, ELISA is used as a rapid quality control test to identify the presence of allergens in foods such as milk, peanuts, walnuts, almonds, and eggs [33].

ELISA is based on the reaction between a substrate-specific enzyme and an appropriate antibody (specific to that antigen) to produce a visible signal. Older ELISA tests utilized a chromogenic or color-generation substrate to produce a visible signal, but newer ELISA assays employ a fluorogenic substrate, where the amount of fluorescence can be accurately quantified by a spectrophotometer, hence providing much higher sensitivity.

There are three types of ELISA: (i) "direct" or sandwich ELISA, which uses an immobilized antibody to detect the presence of a particular antigen in a sample; (ii) indirect ELISA, which uses an antigen to look for a specific antibody in a sample; and (iii) competitive ELISA, where the competitive binding abilities of two antibodies are determined by comparing the binding signals to their immobilized antigens.

Generally, indirect ELISA is used for determining serum antibody concentrations. This method, shown in Figure 3, involves five steps: (1) *Antigen immobilization*, (2) *Blocking*, (3) *Primary antibody immobilization*, (4) *Secondary antibody immobilization*, and (5) *Substrate reaction*. The specific substrate reacts with the antibody–enzyme complex and incubates for color development. This final signal can be viewed/quantified using a spectrophotometer or spectrofluorometer.

In most cases, this final signal is quantified by measuring the optical density (OD) with a microplate reader. A standard curve is plotted as the concentration of a standard antigen versus the corresponding mean OD value, and the sample concentration can then be interpolated from the standard curve. However, indirect ELISA suffers from two major

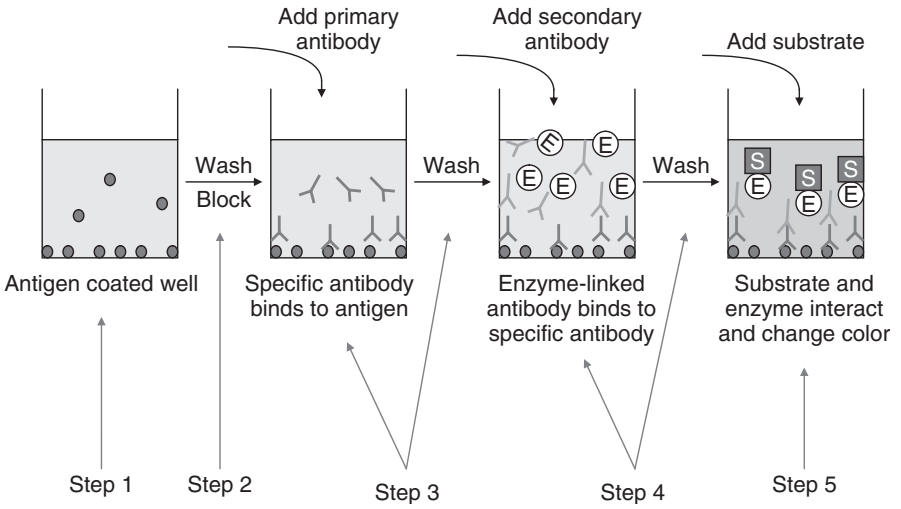

**FIGURE 3** Schematic of ELISA procedure for indirect ELISA.

disadvantages: (i) as the antigen immobilization on the well is nonspecific, any protein in the sample will bind to the plate and produce a noisy signal; and (ii) during the antigen immobilization, the analyte in the serum must compete with other serum proteins, thus decreasing the antigen–protein binding levels.

In order to overcome these problems, the sandwich or direct ELISA was developed and is used to detect sample antigens of biological warfare agents [34]. The procedure is shown in Figure 4 and is generally similar to the one used for the indirect ELISA. Compared to other ELISA methods, the sandwich ELISA has a higher binding affinity because, even for impure samples, the antibodies still bind selectively with any antigens that may be present. Moreover, by using the primary antibody, the chance that other proteins in the sample will adsorb nonspecifically to the plate well decreases when the quantity of immobilized antigens increases. Generally, using a polyclonal antibody for ELISA will increase the number of possible detection objects, while a monoclonal antibody will improve the specificity and lower the background noise.

The third type of ELISA uses competitive binding and is therefore referred to as *competitive ELISA*. This method is somewhat different from the previous ones. First, the unlabeled antibody is incubated with the antigen to form an antibody–antigen complex that is added to an antigen-coated well, and the unbound antibody is washed away. The secondary antibody (specific to the primary antibody) that has been conjugated with the enzyme is then applied to the well, and a substrate is added to react with the remaining enzymes to convert the bound antibody to a detectable signal (i.e. a chromogenic or fluorescent signal). This approach was dubbed "competitive" because when the complexes are formed, the more antigens exist in the sample, the fewer antibodies will be able to bind to the antigen in the well. As a result, the higher the original antigen concentration, the weaker the final signal.

Besides the stand-alone methods described above, ELISA can be combined with immunoseparation techniques. Mansfield et al. [35] have used immunomagnetic beads to separate *Salmonella* serovar cells, followed by ELISA to detect the cells in raw chicken.

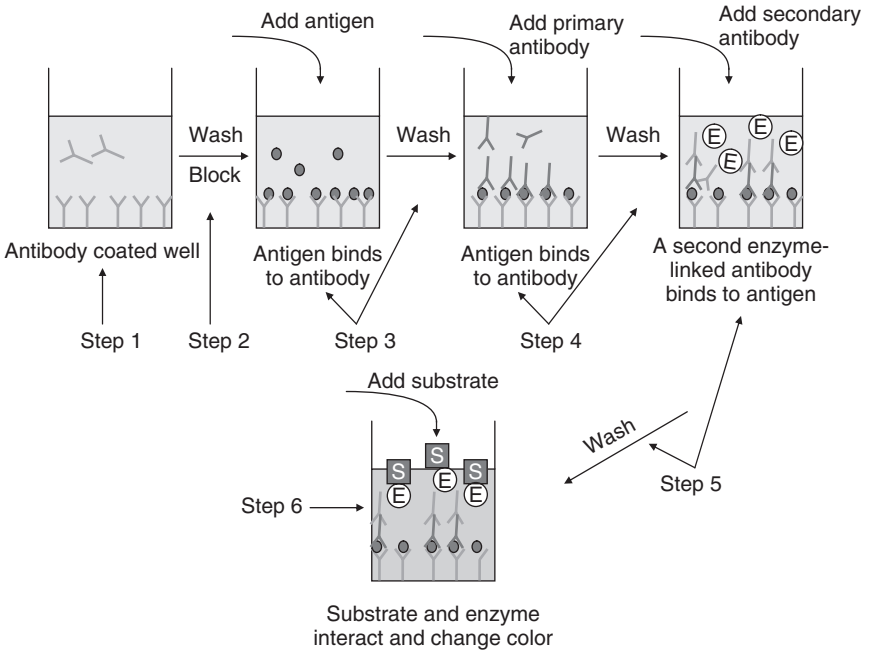

**FIGURE 4** Schematic of ELISA procedure for sandwich ELISA.

**TABLE 2 Bacterial Pathogen Detection Using ELISA**

| Year | Detection Method | Foodborne Pathogen | Source | Detection Limit | Reference |
|---|---|---|---|---|---|
| 1999 | Sandwich ELISA | *Listeria monocytogenes* | Milk (1:10 diluted) | $1 \times 10^3$ cells/ml | 36 |
| 2001 | IMS–ELISA | *Salmonella* serovars | Raw chicken | $10^6$ cells/ml | 35 |
| | Sandwich ELISA | *Salmonella* | Pork, chicken, beef | 1–10 cells/25 g | 37 |
| 2004 | ELISA | *Escherichia coli O157* | Ground beef | $1.2 \times 10^3$ cfu/ml | 38 |
| | | *Campylobacter fetus* | Bovine preputial washing and vaginal mucus samples | $10^5$ cells/ml | 27 |

Some examples of pathogenic bacterial detection using ELISA techniques are shown in Table 2.

### 2.4 Polymerase Chain Reaction (PCR)

PCR is a vital tool that is used to amplify specific regions of a DNA strand (i.e. a single gene, a part of a gene, or a noncoding sequence). The name was derived from DNA

polymerase, which is used to amplify a fragment of DNA by enzymatic replication. Generally, PCR methods require 20–40 thermal cycles of replication. As the number of cycles goes up, the target DNA fragments replicate. This replication is exponentially amplified and is therefore called a *chain reaction*.

In order to set up a PCR process, several components and reagents are required [39]. These include (i) a DNA template, (ii) thermoresistive DNA polymerase, (iii) a buffer solution, (iv) forward and reverse primers, (v) deoxynucleoside triphosphates (dNTPs), and (vi) divalent cations (i.e. $Mg^{2+}$ or $Mn^{2+}$) and a monovalent cation (i.e. $K^{+}$).

In PCR, a small amount of the DNA target is added to the six components listed above in a test tube. Each replication cycle of this mixture is composed of three steps (shown in Fig. 5) that are mainly controlled by the temperature: (i) *Denaturation*: separating dsDNA (double-stranded deoxyribonucleic acid) into ssDNA (single-stranded deoxyribonucleic acid) at a temperature of 94–96°C. (ii) *Annealing*: allowing the two primers to anneal their complementary DNA sequences, and (iii) *Extension*: extending the primers with the activity of DNA polymerase to synthesize complementary strands. The amount of DNA target will double after each cycle, resulting in exponential amplification of the DNA target. As each cycle requires several minutes, more than a billion molecules of DNA can be produced in hours. Following amplification, the final PCR products are analyzed to confirm that the DNA fragment has the original defined length. Agarose gel electrophoresis is used to determine the length of the DNA fragments through comparison with the migration of a DNA ladder, which is made up of molecular weight markers containing DNA fragments of a known size.

PCR has become a common technique and is widely used in fields such as molecular biology, clinical microbiology, forensic science, food safety, and many other applications [40]. In food safety, PCR is used to detect bacterial pathogens in water [21], milk, chicken

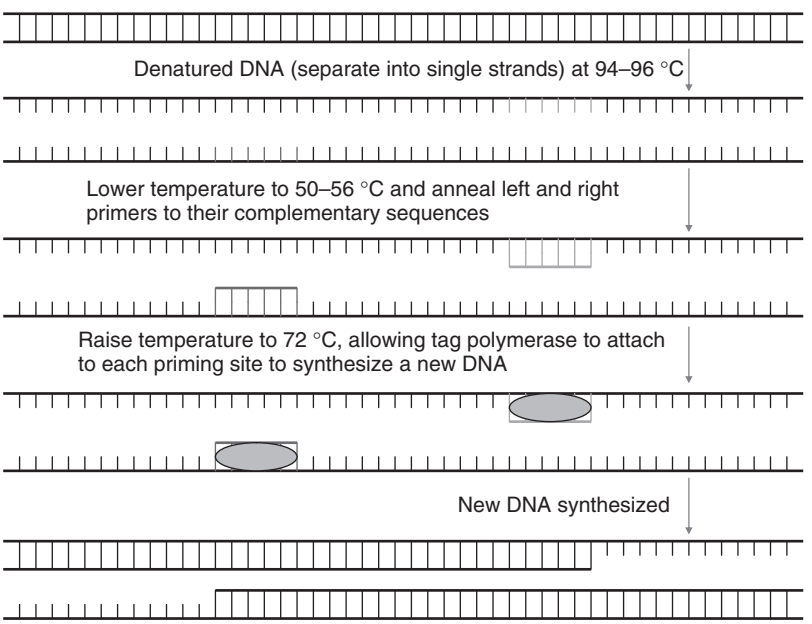

**FIGURE 5** Schematic diagram of PCR first replication cycle.

fecal samples [41], and ground beef [42] and has been used to detect *Bacillus anthracis* [43–45] in a variety of media.

Overall, PCR offers advantages such as low detection limits and rapid replication. It is also very robust and is capable of amplifying specific sequences from a few DNA molecules. However, several disadvantages do limit its use: (i) a number of techniques and procedures are required to optimize the PCR conditions, and even a minor contamination of sample DNA can yield spurious results; (ii) the selection of a suitable primer is also a challenge due to the need for some prior knowledge of the target DNA sequence; and (iii) trained personnel, along with extremely clean and controlled environments, are required.

On the basis of the "standard" PCR technique described above, small modifications in PCR protocol or components lead to a large number of variants of PCR, such as real-time PCR and multiplexed PCR. In general, real-time PCR employs a double fluorescent-labeled probe (labeled with a reporter dye and a quencher dye) complementary to a partial region of the target gene located between two primers. During the extension step of thermal cycling, the reporter dye departs from the quenching dye due to the cleavage of the probe by the activity of DNA polymerase. This results in fluorescence emission. DNA amplification can be monitored in a real-time manner by measuring the fluorescence signals. Multiplex PCR is another derivative that uses multiple pairs of primers designed to perform simultaneous amplification of different genes. Table 3 lists some applications of PCR techniques used for foodborne pathogen detection. PCR has been successfully combined with other techniques such as ELISA and immunomagnetic separation (IMS).

## 3 BIOSENSOR TECHNIQUES

The use of biosensors has increased dramatically in recent years. As defined in the Oxford English Dictionary, *a sensor is a device that detects or measures a physical property and records, indicates or otherwise responds to it*, and a biosensor does this by applying biological agents in the detection process. There are two main parts to a biosensor: a transducer and a bioreceptor. Figure 6 shows a schematic representation of a biosensor that uses a biosensing element as its bioreceptor, along with a transducer system and the associated electronics or signal processors that display the results in a user-friendly way [62].

When a specific biological reaction occurs between the biosensing element and the target antigens, a physical and/or chemical change takes place on the biointerface. The transducer is responsible for converting this change into a measurable signal. This signal will then be sent to the output system to be amplified, processed, and displayed [63].

Sensors can be divided into three types, namely, physical, chemical, and biological. As their name suggests, physical sensors measure physical quantities such as length, weight, temperature, and pressure, while chemical sensors respond quantitatively to a particular analyte in a selective way through a chemical reaction. Biosensors incorporate a biological sensing element, which is connected to the transducer.

Biosensors are now being used in many fields, for example, in industrial process monitoring, environmental monitoring, foodborne pathogen detection, and healthcare. The most popular medical application of biosensors is to monitor glucose levels in diabetic patients. One particularly desirable goal for medical biosensors is to create a type of implantable biosensor capable of continuously monitoring a metabolite; an implantable

**TABLE 3 Pathogenic Bacterial Detection Using PCR Methods**

| Year | Detection Method | Foodborne Pathogen | Source | Detection Limit | Reference |
|---|---|---|---|---|---|
| 1997 | Real-timePCR | *Listeria monocytogenes* | Ground beef | 3 cfu/g | 46 |
| 1998 | PCR | *Legionella pneumophila* | Water | <10 cfu/ml | 28 |
| 2002 | PCR | *E. coli* | Pasteurized milk | $10^3$ cfu/ml | 47 |

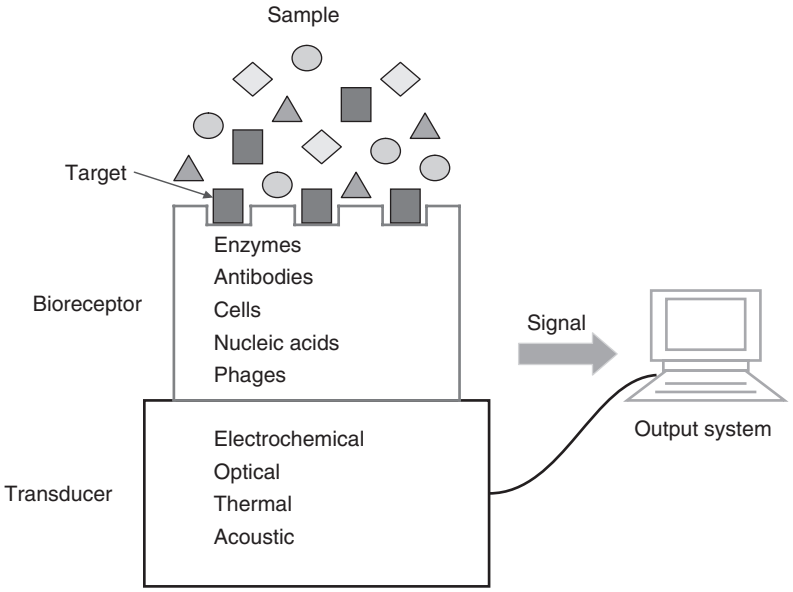

**FIGURE 6** Schematic configuration of a biosensor.

glucose biosensor would allow patients to continuously measure their glucose level in real time and adjust their medication accordingly. Biosensors also offer many advantages in detecting chemicals and foodborne pathogens. They are not only highly target specific and sensitive, but also respond rapidly, making them ideal for real-time detection. Some are even reusable and portable for on-the-spot analysis.

### 3.1 Biorecognition Elements

Biorecognition elements, generally referred to as *bioreceptors*, include enzymes, tissues, antibodies, and phages. Among these, antibodies and bacteriophages are the most commonly used biological components.

***3.1.1 Enzymes.*** Enzymes have been used as biorecognition probes for various biosensors. Enzymes usually aid in catalytic reactions to produce measurable signals. The catalytic power of enzymes, coupled with their high specificity of action, make them ideal biorecognition elements. Enzyme-based biosensors are used in electrochemical assays, for the detection of glucose, aromatic hydrocarbons, and monitoring of pH changes [64]. However, there is limited use of enzyme-based biosensors for the detection of bacterial pathogens [64].

***3.1.2 Nucleic Acid.*** Nucleic acid bioprobes have been widely used with different sensor platforms to detect pathogens in water supplies, food, and animals [65–67]. *Nucleic acid recognition element* refers to a segment of a nucleic acid (DNA/RNA) strand with specific sequences. Different nucleotides on the nucleic acid duplex make bonds only with counterparts with specific sequences. This property enables nucleic acid bioprobes to recognize the target nucleic acids of interested pathogens.

Aptamers, which are another group of nucleic acid bioprobes [64, 68], refer to nucleic acid ligands such as RNA, single-stranded ribonucleic acid (ssRNA), DNA, or peptides. They are selected from libraries of oligonucleotides with random sequences and synthesized against a broad range of molecules, proteins, and whole cells. Aptamers display high affinity and specificity toward the interested targets by shape instead of recognizing target species by DNA sequences [64]. Biosensors that combine aptamers as biorecognition elements with acoustic wave (AW) devices have been used to detect IgE antibodies [69] and HIV-1 Tat protein [70], and monitor blood-coagulation cascades [71].

***3.1.3 Antibodies.*** Antibodies, or immunoglobulins (Ig) [72], are produced by B cells, a type of white blood cell. These immune system-related proteins are present in the blood and other bodily fluids of vertebrates [72]. As antibodies are capable of identifying and neutralizing foreign objects, they have become widely used as diagnostic tools to detect bacteria and viruses.

Polyclonal and monoclonal antibodies are two kinds of antibodies, widely generated. Polyclonal antibodies are produced by injecting the target bacteria into an efficient antibody producing animal. The animal's immune system then builds a family of polyclonal antibodies with mildly varying specificities and affinities to the injected bacteria, after which the antibodies are extracted from the blood/serum. This process of immunization and extraction is time consuming and requires specialized facilities. To produce monoclonal antibodies, antibody-secreting lymphocytes are fused with a cancer cell line after isolation from animals, and then grown in a culture. Both polyclonal and monoclonal antibodies need to be purified by protein A/G or antigen-affinity chromatography [73]. In addition to the complexity of extracting and purifying, antibodies require controlled laboratory environments that are extremely sensitive to temperature and pH changes. Hence, there is a need for a more robust biorecognition elements that can withstand conditions in the field.

Currently, antibodies are being applied as a biorecognition layer on sensors for the specific capture of analytes [74]. Antibody-based sensors offer several advantages: there is no need for extensive sample clean-up and they require only limited hands-on time, while at the same time they offer high-throughput screening, real-time analysis, label-free detection, and the possibility of quantification [74]. There are several different types of antibody-based biosensors in use, namely, surface plasmon resonance (SPR) sensors, quartz crystal microbalances (QCMs), and cantilevers. They have become well-established techniques for the detection of the pathogens *E. coli* [75], *Salmonella* [76, 77], *Bacillus cereus*, and *Listeria monocytogenes* [78, 79]. Overall, antibody-based sensors are quite effective, adaptable for many applications, and hold great promise in the field of research. However, antibodies are sensitive to environmental conditions such as heat and pH.

***3.1.4 Bacteriophages.*** Bacteriophages, or phages, are viruses that infect only bacteria, but are much smaller in size (20–200 nm). Phages are absolute parasites, found ubiquitously wherever their bacterial hosts live (soil, sewage, animals [80], deep sea vents, water, food, and other environments [81]). Consequently, phages are estimated to be the most widely distributed and diverse entities (ranging from $10^{30}$ to $10^{32}$ in total population) on the earth [82].

Each bacteriophage contains an outer protein hull (or lipoprotein coat or capsid) and an enclosed nucleic acid genome. The enclosed genome can be ssRNA, dsRNA

(double-stranded ribonucleic acid), ssDNA, or dsDNA. These RNA/DNA strands have a circular or linear arrangement that is 5–500 kb long. On the basis of their life cycle, phages can be classified as either lytic or lysogenic. Lytic phages multiply only by a cycle, where the phage first attaches to the host cell and injects its own genome to take over much of the host metabolism, after which new phages are liberated after the host cell lyses. Lysogenic phages, in contrast, have modes of replication that do not destroy the host bacteria and bind with part of the bacterial genome. Lysogenic phages are sometimes referred to as *temperate*, but they can revert to a lytic cycle.

Classification of bacteriophages is difficult but practical for phage research. The International Committee on Taxonomy of Viruses classifies bacteriophages based on their morphology and the type of nucleic acid they enclose. Recently, Ackermann studied 5000 bacteriophages by electron microscopy, making this the largest category of viruses examined by microscopy methods so far [81]. Table 4 provides an overview of bacteriophage classification. These phages take one of four different shapes: tailed, polyhedral (with cubic symmetry), filamentous (with helical symmetry), and pleomorphic (without obvious symmetry). Most of these classified phages contain dsDNA, while only a small group contains ssDNA, ssRNA, or dsRNA. The dsDNA tailed phages are the major phages (95% of all those reported) on the planet [82] and also the oldest viruses [83]. Tail-less phages only include about 190 known viruses and account for less than 4% of the currently recognized bacterial viruses. They are classified into 10 families [84].

Bacteriophages have many applications. They have been successfully used for treating bacterial infections in the medical field due to their antibacterial activity. Environmentally, bacteriophages have been used in hydrological tracing in river systems and as dye markers due to their low adsorption when passing through ground water and ease of detection at low concentrations [85]. Phages also have many uses in food production. In 2006, the FDA approved the use of bacteriophages to kill *L. monocytogenes* bacteria on cheese [86]. Fluorescently labeled phages can serve as a recognition element for the detection of *S. typhimurium* and *E. coli* [71, 87].

**TABLE 4 Classification of Bacteriophages**

| Shape | Family | Morphology | Nucleic Acid |
|---|---|---|---|
| Tailed | *Myoviridae* | Nonenveloped, contractile tail | Linear dsDNA |
| | *Siphoviridae* | Nonenveloped, long noncontractile tail | |
| | *Podoviridae* | Nonenveloped, short noncontractile tail | |
| Polyhedral | *Microviridae* | Nonenveloped, isometric | Circular ssDNA |
| | *Tectiviridae* | Nonenveloped, isometric | Linear dsDNA |
| | *Corticoviridae* | Nonenveloped, isometric | Circular dsDNA |
| | *Leviviridae* | Nonenveloped, isometric | Linear ssRNA |
| | *Cystoviridae* | Enveloped, spherical | Segmented dsRNA |
| Filamentous | *Lipothrixviridae* | Enveloped, rod-shaped | Linear dsDNA |
| | *Inoviridae* | Nonenveloped, filamentous | Circular ssDNA |
| | *Rudiviridae* | Nonenveloped, rod-shaped | Linear dsDNA |
| Pleomorphic | *Fuselloviridae* | Nonenveloped, lemon-shaped | Circular dsDNA |
| | *Plasmaviridae* | Enveloped, pleomorphic | Circular dsDNA |
| | *Guttaviridae* | Droplet-shaped | Circular dsDNA |

Antibodies were the first proteins to be displayed on the surface of a phage [88]. This was achieved by fusing the coding sequence of the antibody variable regions to the amino terminus of the phage minor protein coat pIII. This type of phage–antibody combination is particularly useful for biological detection and has been demonstrated to have higher performance than monoclonal antibodies when used in several different assay formats, including SPR, flow cytometry, ELISA, and handheld immunochromatographic assays [89, 90].

### 3.2 Transducers

The transducer is the most important part of a sensor because it is responsible for detecting the analyte. There are four main classifications of transducers, namely, electrochemical transducers, optical transducers, thermal sensors, and acoustic devices. Figure 7 lists these, along with some sensor examples of each type. Among these, ME material as the transducer is considered to be a novel type of AW device.

***3.2.1 Electrochemical Biosensors.*** Electrochemical biosensors are the most commonly used class of biosensors [91]. Their working principle depends on a biointeraction occurring where electrochemical species (e.g. electrons) are generated or consumed to produce an electrochemical signal that can be measured by an electrochemical detector. On the basis of the type of electrical signal, electrochemical sensors can be classified [91, 92] as either *potentiometric*, where the potential difference between an indicator and a reference electrode is measured; *amperometric*, where the current produced by an electrochemical oxidation or an electroactive species reduction under a constant potential is measured; or *conductometric/impedimetric*, where the alternating conductance between a pair of metal electrodes is measured [93, 94].

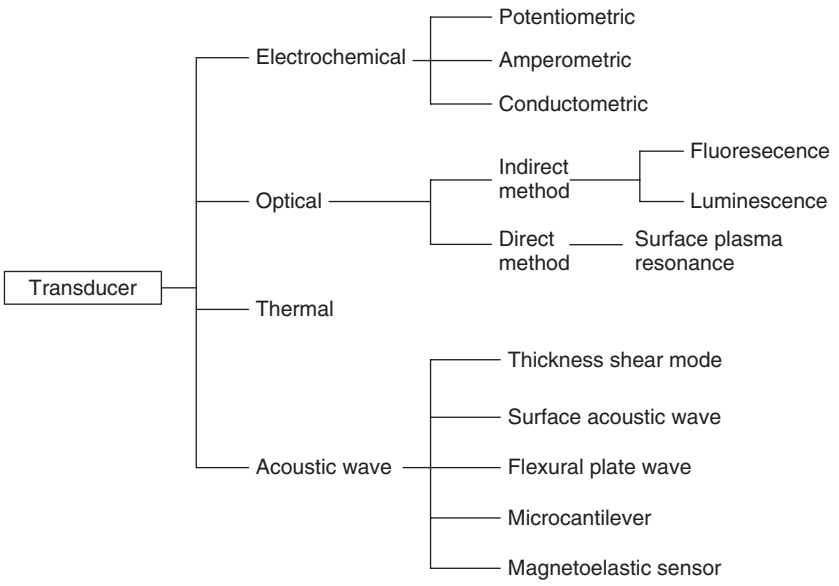

**FIGURE 7** Classification of sensor transducer types.

When the biological components interact, the conductance or capacitance of the medium will increase with decreasing impedance. Therefore, by measuring this change, a conductometric biosensor is able to detect the concentration and physiological state of foodborne pathogens [95].

In potentiometric biosensors, the transducer can be either an ion-selective electrode (ISE) or an immunoelectrode. For ISE, when the target ions bind to the selective membrane at the indicator electrode, a detectable difference in the potential between the indicator and reference electrode that is proportional to the logarithm of ion activity is realized [91]. For the immunoelectrode, enzymes or antibodies are usually immobilized on the electrode surface, and when target antigens in the sample interact with enzymes or antibodies, there is a detected potential shift. This method is useful in biosensing [92, 96].

An amperometric biosensor measures the current generated by a chemical/biological reaction rather than measuring the potential change. By using an enzyme to catalyze electrooxidation or electroreduction, almost all microorganisms can be sensed by amperometric biosensors. An amperometric system has a linear relationship with the analyte concentration, which makes it particularly convenient and suitable for bacterial detection [96] with species such as *Staphylococcus aureus* [97, 98], *Salmonella* [99], and *E. coli* O157:H7 [100, 101].

Some advantages of electrochemical sensors include their high sensitivity, small size, low cost, versatility, rapid measurement time, and capability of stand-alone operation [102]. However, amperometric sensors suffer from poor selectivity, which is controlled using the redox potential of the electroactive species in the sample solution. Table 5 lists the capability of different electrochemical sensors for pathogenic bacteria detection.

***3.2.2 Optical Biosensors.*** The working principle of optical biosensors is based on the modulation of optical properties that occurs when the biorecognition element interacts with the target analytes on the interface. These optical properties include UV absorption, bio- and chemiluminescence, reflectance, and fluorescence [119–123]. Applications of optical sensors include the measurement of pH, oxygen, carbon dioxide, and ions. Moreover, they are very attractive for label-free and quick detection of bacteria [63].

Depending on the type of interaction that produces the output signal, optical devices are classified as either *indirect* or *direct*. Methods that utilize the fluorescence or bioluminescence that results from antigen–probe interactions are defined as indirect methods, while those based on a direct change in the light properties due to the analyte–probe interactions are defined as direct methods. The total internal reflection of light incident at the interface, which depends on the refractive index, is an example of a direct optical method.

Some biospecies emit light with a lower wavelength when exposed to ultraviolet light, which is known as *fluorescence* [96]. Fluorescence biosensing is a type of optical biosensing method by frequency change, which includes direct sensing, indirect sensing, and fluorescence energy transfer. Fluorescence spectroscopy is widely used for analytical chemistry and offers a sensitive technique for low concentration analyte detection.

Some living microorganisms emit light when a biochemical reaction takes place, which is known as *bioluminescence*, and this is important for real-time monitoring. Luminescence biosensors have very high specificity, but suffer from poor sensitivity when the concentration of the target analyte becomes low [124]. Biosensors that monitor the color

change in response to toxins produced by microbial pathogens in the presence of test analytes are known as *colorimetric biosensors*. For example, a colorimetric whole cell bioassay [125] can be used for the detection of environmental pollutants.

Optical transducers incorporate optic fibers, which allow for greater flexibility and miniaturization. SPR, where the surface plasmons are excited by light, is an attractive optical biosensor transducer for many applications. The operational principles of an SPR biosensor are shown in Figure 8. It consists of two types of material with two different refractive indices: metal (gold) and glass. On the metal (gold) surface, incident light energy excites electrons to oscillate resonantly forming surface plasmons. SPR is excited along the metal surface at a specific incident angle ($\theta$), at which the intensity of the reflected light reduces to minimum. As this surface wave is on the boundary of the surface, the oscillation becomes sensitive to the environment of the metal surface. Any change on the metal surface such as an antibody–antigen interaction results in a change in the SPR angle ($\theta$). Therefore, SPR biosensors can be used to detect foodborne pathogens by measuring this shift [126]. The advantages of SPR biosensors are that they are simple, can be used in real time, and are label-free. However, they are relatively expensive, and it is hard to measure the target species when the concentration is very low. Also, the signal of SPR biosensors is vulnerable to interference from the environment [96, 127]. Table 6 lists the capabilities of optical biosensors used for pathogenic bacteria detection.

***3.2.3 Thermal Biosensors.*** Thermal transducers involve the production or absorption of heat. They measure the concentration of analytes based on the amount of heat adsorbed by a thermistor. Thermal sensors can be used either to measure the change in temperature of a substance directly during the course of a reaction or to measure the enthalpy of change in an enzymatic reaction.

***3.2.4 Acoustic Wave Sensors.*** Recently, a great deal of attention has been devoted to efforts to develop simple and inexpensive microsensors. Among these, the AW sensor is a common device that has been used for many chemical and biological applications.

Examples include sensors to monitor pressure, vapor, humidity, temperature, and film characterization. AW devices are sensitive to small changes in many different physical parameters [151]. They have been commercially available for more than 60 years because they offer real-time and fast detection, and are sensitive, simple to use, intrinsically reliable, and cost-effective [151]. Some can also be used wirelessly.

*3.2.4.1 Operating principles and performance criteria.* AW devices typically generate a mechanical or AW that propagates either through the bulk material or on its surface. The velocity and/or amplitude of this wave will change if the propagation path or its characteristics change in any way. Consequently, any variation that is observed in the properties of the AW, that is, its velocity and/or amplitude, can be linked to corresponding changes in the material's physical characteristics, thus allowing them to be monitored in real time by the AW sensor.

AW sensors usually use a piezoelectric material as the platform. When an oscillating electrical field is applied to the piezoelectric platform, a mechanical wave is generated. This phenomenon is known as the *converse piezoelectric effect*. The "direct piezoelectric effect" is the reciprocal of this and refers to the application of strain to the material, which results in the creation of an electrical change. The direct piezoelectric effect was discovered by brothers Pierre and Paul-Jacques Curie in 1880 and is defined as piezoelectricity [152]. Most AW piezoelectric sensors utilize the principle of converse piezoelectricity. When the AW produced propagates through or on the surface of the substrate, the velocity or amplitude of the wave will change if the characteristics of the propagation path change. The frequency or phase characteristic of the sensor is measured to monitor such changes, which can then be correlated to the corresponding physical quantity.

An AW sensor can also be used as a mass sensor; when an AW device is used as a resonator, the resonance frequency of the AW device will change when there is a mass load on the device surface. On the basis of this principle, different biosensors can be developed by immobilizing a biomolecular recognition layer (i.e. antibody, bacteriophage) on the AW sensor surface. When the target pathogen and the biomolecular recognition layer undergo a chemical reaction or sorptive interaction (i.e. adsorption/absorption) on the sensor's surface, the surface mass changes. This mass change can be detected by measuring the resulting shift in the characteristic resonance frequency of the sensor. Therefore, the majority of analytical applications of AW sensors are based on changes in mass loading.

*3.2.4.2 Different types of AW devices.* An AW can propagate in an elastic medium, causing the device to vibrate. The direction of vibration can be either parallel or perpendicular to the direction of propagation. The types of elastic waves that may propagate in a solid are shown in Figure 9 [151], and these depend on the properties and the boundary conditions of the solid [153]. There are four AW devices that are most commonly utilized and investigated for sensing applications, namely, the thickness shear mode (TSM) resonator, the surface acoustic wave (SAW) device, the flexural plate wave (FPW) device [151], and the microcantilever (MC) [154, 155]. As depicted in Figure 9a and b, bulk waves exist in a medium without any boundaries, such as a TSM resonator. When a single plane boundary exists, the wave will propagate along that boundary, for example, in a SAW device (Figure 9c). If two boundaries exist, the wave will propagate within the thin plate, as in an FPW device (Figure 9d).

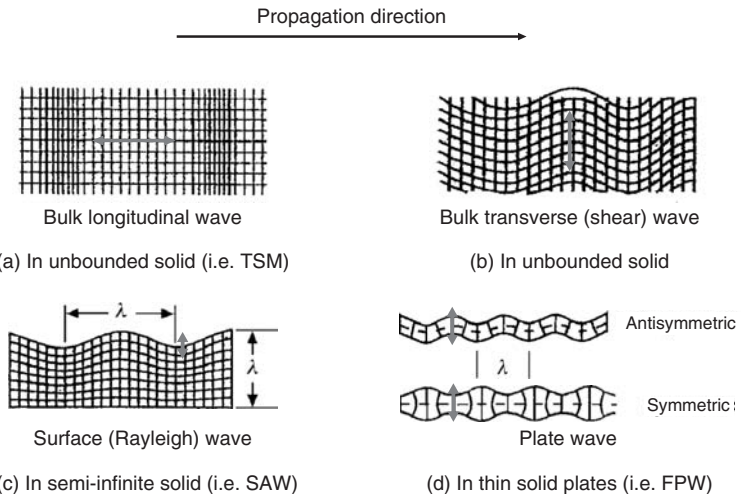

**FIGURE 9** Types of elastic wave propagation: (a) and (b) in an unbounded solid, (c) in a semi-infinite solid with a single boundary, and (d) in a thin solid plate with two boundaries. Vertical and horizontal displacements are exaggerated for clarity. The red (nondimensional) arrow represents the direction of vibration. (See online version for color.)

**Quartz Crystal Microbalances (QCM).** The familiar QCM, also commonly referred to as a *TSM resonator*, is one of the most widely used AW sensor platform in both research studies and commercial applications for biological threat detection. It typically consists of a thin AT-cut quartz disk with circular electrodes patterned on both sides [151]. When applying a voltage between these two electrodes, the crystal will undergo shear deformation due to the piezoelectric effect and will be electrically excited in a number of resonant TSMs, allowing the mechanical resonance frequencies to be detected. When there is a uniformly distributed thin film deposited on the crystal surface, the added mass of the thin film results in a change in TSM resonant frequency, which can be expressed by the Sauerbrey Equation [156]:

$$\Delta f = -\frac{2 f_0^2 \Delta m}{A\sqrt{\mu_{\mathrm{q}}\rho_{\mathrm{q}}}} \tag{1}$$

where $\Delta f$ is the frequency shift, $f_0$ is the fundamental mode of the crystal, $\Delta m$ is the mass change per unit area (grams per square centimeter), $A$ is the active area on the surface, $\rho_q$ is the density of quartz, and $\mu_q$ is the shear modulus of quartz. Mass sensitivity can be derived from the equation:

$$S_{\mathrm{m}} = -\frac{f_0}{(t\rho)_{\mathrm{quartz}}} \tag{2}$$

where $t$ and $\rho$ is the thickness and density of the thin film layer on the crystal. A TSM resonator can be operated in a liquid in order to determine its properties (i.e. viscosity, density [157, 158]) by measuring the mass loading on the crystal surface from the liquid environment. TSM resonators have also been used for microbial contamination detection (i.e. *S. typhimurium*, *B. anthracis* spores) by immobilizing biological active elements on the surface (i.e. antibody, phage) [159–162].

**SAW Devices.** SAW devices are usually composed of ST-cut piezoelectric crystals with two patterned gold/titanium-interdigitated transducers (IDTs) (emitter and receiver) deposited on the same side of crystal surface. This SAW, also known as a *Rayleigh wave* [163], is utilized for sensor applications because the propagation of waves is confined to the surface, making the AWs extremely sensitive to surface perturbations and allowing them to be detected by lithographically patterned interdigital surface electrodes [164]. SAW sensors exhibit the highest sensitivity of the acoustic sensors reviewed [162], because the AW confines all the acoustic energy to the zone within one wavelength of the surface. When applying an alternating voltage on one of the electrodes, an AW will be produced that propagates along the surface until it reaches the other electrode [151]. However, when the SAW sensor is placed in a liquid medium, the waves will be strongly damped, because they are surface-normal waves, making SAW sensors unsuitable for liquid sensing. One of the most common applications for SAW sensors is to detect the interaction, in terms of the fundamental resonance frequency change, that results from changes in the areal/mass density on the sensor surface.

**FPW Devices.** In an FPW device, the AW is excited in a membrane that is relatively thin compared to the acoustic wavelength. An FPW sensor is usually fabricated by a micromachining process and uses silicon nitride, silicon dioxide, oxynitride, aluminum nitride, or diamond as the membrane layer. This membrane is deposited onto a silicon substrate for ease of handling, and then the substrate is etched away. After depositing a conducting layer, a layer of piezoelectric zinc oxide will be sputtered on, followed by sputtering of a second conducting layer. Two interdigitated conducting electrodes are formed in the conducting layer, one of which is used as a wave generator (output) and the other as the wave receiver (input). The piezoelectric film is deformed and excited by the interdigitated conducting electrodes in order to generate and detect AWs. When a wave propagates, the membrane moves both perpendicularly and parallel to its surface such that the shape of the entire membrane is like a flag waving in the wind [151, 165]. FPW has high sensitivity compared to other AW devices. As the operating frequencies are of the order of few megahertz or even lower, this makes it relatively easy to design the electronics for the operation. Also, the wave propagates at low speeds in the plate; therefore, it is possible to use FPW sensors in liquids. However, the fabrication of FPW devices is difficult as it is hard to make a low stress membrane layer with a thickness of few microns, and the resulting membrane is fragile. Because of this, FPW sensors have not made much progress in terms of miniaturization.

**Microcantilevers.** Micromachined cantilevers were first used as force probes in atomic force microscopy. Owing to their extremely high sensitivity to a variety of environmental factors, including acoustic noise, temperature, ambient pressure, and humidity [166], researchers at Oak Ridge National Laboratory and IBM Zurich investigated converting them into a new sensor platform [167, 168] and found that this standard cantilever provided a substantial improvement (i.e. sensitivity) over more traditional approaches (i.e. QCM, SAW). A MC also acts as a mass sensitive device, producing a frequency shift when there is a mass loading on the device [169–171]. In the last decade, with the development of microelectromechanical systems (MEMSs) that integrate electronics and micromechanical structure on chips, MCs have become one of the simplest MEMS-based devices. A large number of papers have reported on the potential of MCs for physical, chemical, and biological sensing [172–176]. Moreover, nanocantilevers have been

successfully fabricated in the last few years, significantly increasing the sensitivity for sensing applications and allowing the detection of even smaller masses, ranging from several molecules to a single bacteria cell (i.e. *E. coli* [177]) or spore [178, 179]. Recently, it was reported that a mass sensitivity of as low as a few femtograms can be achieved using nanocantilevers [180]. Sensors using cantilevers as a platform have a high sensitivity and a good safety record, as well as being cheap, simple, fast, low power, and having a low analyte requirement for testing. These advantages make them very promising for the next generation of miniaturized and highly sensitive sensors [181].

A fundamental cantilever is constructed from a long and thin microbeam with one end fixed by a support. The readout schemes for a cantilever can be broadly classified into two types: optical and electrical. Depending upon the parameters measured (i.e. cantilever tip position, spatial orientation, intrinsic stress, or radius of curvature) [154], cantilever operation can also be divided into static and dynamic modes. The static bending mode is used to detect cantilever deflection, which can be caused either by external forces added to the cantilever (i.e. adsorption of molecules) or intrinsic stresses produced in the cantilever (i.e. thermal expansion, physicochemical changes). In the dynamic mode, the MC operates as a mechanical oscillator whose resonance frequency changes due to three main mechanisms: (i) the mass loaded on the beam; (ii) the viscosity of the medium; and (iii) the environmentally induced elasticity changes in the MC material [154, 182]. When the target binds to the cantilever beam, the frequency shifts from $f_0$ to $f_1$ due to the additional suspended mass ($\Delta m$), and the relationship can be expressed as [154]

$$\frac{1}{f_1^2} - \frac{1}{f_0^2} = \frac{\Delta m}{\left(4\pi^2 K\right)} \tag{3}$$

Here, $K$ is the spring constant of the cantilever. In order to obtain an appreciable mass sensitivity, high frequencies are required.

Dynamic MCs can also be divided into three types: single beam MCs (i.e. silicon-based MCs), composite-beam MCs (i.e. piezoelectric/piezoresistance MCs), and ME MCs.

Silicon-based MCs are driven by mechanical force and the deflection is detected by optical methods, which includes optical beam deflection [183] and optical interferometry [184, 185]. A typical optical method applies a position-sensitive photodetector (PSD) and a laser beam of very low power. The laser beam falls on the cantilever beam surface and the reflected beam is then captured by the PSD. If an additional mass loaded on the beam has caused the deflection of the cantilever, the reflected beam falls on a different part of the PSD and the magnitude of this deflection can be calculated by appropriate electronics. Optical methods offer significant advantages of miniaturization, batch fabrication, and integration of signal-processing circuitry with a relatively high mechanical quality factor (Q), which greatly increases the sensitivity of the device. However, a high Q value is likely to adversely affect the stability of device by acting to promote mechanical coupling, resulting in a change in the vibration mode. The system is also complex, expensive, and bulky, and requires a sophisticated data acquisition system and extra driving equipment to make it vibrate. Optical methods are of particular importance for many applications, because of the dispersion of the laser beam in a liquid, although they are limited for in-liquid applications [183].

Compared with silicon-based cantilevers, piezoelectric cantilevers are optimized by using electrical means, which overcomes the need for complex optical detection equipment. It can be used electrically for both actuation and sensing and is able to integrate

the driving and characterizing circuits in the chip with MCs. By applying an AC voltage to the driving electrode, the cantilever vibrates due to the converse piezoelectric effect. At resonance, these vibrations produce piezoelectric voltages that can be detected by the direct piezoelectric effect at the sensing electrode. An impedance analyzer can also be used to measure the resonance frequencies and characterize the sensor using the impedance spectrum (impedance vs. frequency). As only one electrode is needed, the measurements can all be obtained conveniently using an impedance analyzer.

The two types of platforms employed by piezoelectric-based MCs are unimorph and bimorph. Unimorph MCs are composed of one piezoelectric layer bound to a substrate layer (stiff metal). There are two types of bimorph connections, parallel and series, and these consist of two piezoelectric layers with different pole directions bonded together. When mass is added to the cantilever, the oscillation of the cantilever is damped. Thus, a piezoelectric actuator can be used as a viscosity-meter or as a microbalance to detect mass change. No external detection devices or tedious alignment are required, and they are also capable of enclosing an integrated electromechanical system. Piezoelectric cantilevers not only act as mass detectors, but also function well in liquids by monitoring peak broadening and the resonance frequency shift. As MCs are highly mass sensitive, their length, width, and resonance mode all have an effect on an individual cantilever. Mutharasan and coworkers at Drexel University successfully utilized piezoelectric-excited millimeter-sized cantilever (PEMC) sensors that consisted of a piezoelectric and a borosilicate glass layer immobilized with different biorecognition elements to develop a sensitive, reliable, and near real-time method for the detection of *Cryptosporidium parvum* oocyst [186], airborne *B. anthracis* spores in conjunction with a commercial air sampler (at 5 spores/l) [187], *Staphylococcus aureus* enterotoxin B (SEB, at 12.5–50 pg/ml) [188], and *E. coli* O157:H7 in ground beef samples (50–100 cells/ml) [189].

**Magnetoelastic (ME) Sensors.** ME materials are generally amorphous, soft ferromagnetic materials. Nickel, laminated metallic glass alloys, and rare-earth iron compounds are common ME materials. This class of materials is a subset of magnetostrictive materials, which undergo a change in dimensions when exposed to a magnetic field. ME materials can be made to resonate in a time-varying ("AC") magnetic field at a specific frequency that is dependent on their geometry and mass. For rectangular sheet sensor platforms, varying the magnetic field can be used to cause oscillations mainly along the length direction. Table 7 summarizes the AW sensors used for foodborne pathogen detection.

## 4 POTENTIAL BIOSENSORS FOR FOOD SAFETY APPLICATIONS

### 4.1 Modified Filamentous Phage fd as a Biorecognition Element

***4.1.1 Landscape Phages.*** Phages play an important role in molecular biology. For example, they are commonly used as a vector to infect the standard recombinant DNA host (*E. coli*) in recombinant DNA research. The method of using a phage as a vector to connect proteins to display genetic information is called *phage display*. Tens of billions of heterogeneous phage clones can be collected together to create a "phage display library." Each clone displays multiple copies of a specified peptide on the virion surface [200–202], and a phage display library can be used to select high specificity phages to an immobilized molecule and then multiply these phage clones for further study.

**TABLE 7 Acoustic Wave Sensors for Foodborne Pathogen Detection**

| Year | Detection Method | Foodborne Pathogen | Source | Detection Limit | Reference |
|---|---|---|---|---|---|
| 1998 | FPW sensor | *E. coli* | Culture | $3.0 \times 10^5 - 6.2 \times 10^7$ cells/ml | 190 |
| 2000 | QCM | *S. typhimurium* | Culture | $3.2 \times 10^6$ cfu/ml | 191 |
| | Love wave immunosensor | *Legionella* and *Escherichia coli* | Culture | $10^5 - 10^6$ cells/ml | 192 |
| 2001 | QCM | *Listeria monocytogenes* | Culture | $1 \times 10^7$ cells/ml | 193 |
| 2002 | QCM | *E. coli* | Drinking water, milk, rice, dumplings, and others | $1.7 \times 10^5 - 8.7 \times 10^7$ cfu/ml | 194 |
| | | | Culture | $10^4$ cells/ml | 195 |
| 2004 | QCM | *E. coli* O157:H7 | Culture | $10^3$ cfu/ml | 196 |
| 2005 | QCM combined with resistance measurement | *S. typhimurium* | Chicken meat samples | $10^5 - 10^8$ cells/ml for frequency measurement<br>$10^2$ cells/ml for resistance measurement | 197 |
| 2007 | Piezoelectric cantilever | *E. coli* O157:H7 | Ground beef | 50–100 cells/ml | 189 |
| | Love wave imuunosensor | *E. coli* | Culture | $10^6$ bacteria/ml | 198 |
| 2006 | SH SAW LGS biosensor | *E. coli* O157:H7 | Culture | $10^6$ cells/ml | 199 |

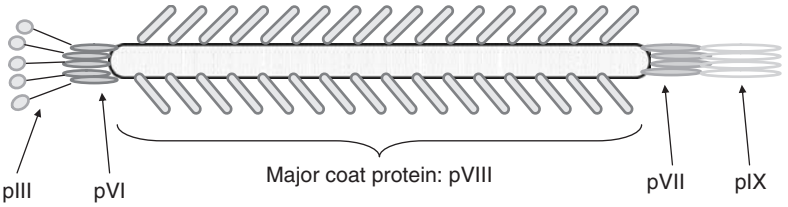

**FIGURE 10** Schematic showing filamentous phage structure. pIII, pVI, pVIII, pVII, pIX represent phage proteins. Exogenous peptides are usually displayed on protein pIII and pVIII.

The filamentous phage Ff class, which includes M13, f1, and fd phages, has been subjected to extensive research for phage display applications [202, 203]. Filamentous phage fd is a phage shaped like a rod filament, as shown in Figure 10. Each phage filament is generally about 7 nm wide and 800–900 nm long. The outer coat is a tubelike structure composed of a major protein coat pVIII, which has an ssDNA buried inside. At the tip ends of the phage particle, there are several copies of four minor proteins, pIII, pVI, pVII, and pIX [204, 205]. The major protein coat occupies 98% of the phage's mass and is present in 2700 or more copies per phage.

Studies have shown that the common filamentous phages can be modified by using phage filaments as the framework and then fusing eight foreign random amino acids to the N-terminus of every copy of the major protein coat pVIII [200, 202, 206]. The replacement of three or four amino acids at the N-terminus of the protein pVIII with 12–19 foreign amino acids in a filamentous phage will not disturb the general architecture of the virions [207]. As the array of thousands of copies of these guest peptides appear in a repeating pattern, a dramatic change in the phage surface architecture occurs, resulting in the number of major protein coat subunits increasing to 4000. The major protein coat now comprises up to 50% of the phage surface [200, 206]. This modified phage is called a *landscape phage* and a mixture of a large number of such landscape phages is named a *landscape phage library*, encompassing billions of phage clones with different surface structures and biophysical properties [208].

Landscape phages are now being investigated as a possible alternative to antibodies for detection probes, as they are more stable, reproducible, and inexpensive to produce [159, 200]. These phage bioprobes have begun to be used as a biological recognition molecule for AW devices such as SPR [209], TSM quartz sensors [159] and ME sensors [210–212] for the real-time detection of a range of pathogens or the adsorption of biochemical macromolecules [213]. Landscape phages are extraordinarily robust in harsh environments and can be heated up to 80°C [202]. They are also resistant to organic solvents (e.g. acetonitrile), acid, alkali, and other chemicals [214]. Purified phages can be stored indefinitely at moderate temperatures without loss of infectivity and probe-binding activity. More importantly, phages have a high affinity to target antigens. This is because phages have an extremely high surface density (300–400 $m^2/g$) and up to 50% of the surface can be subtended by peptides to form the "active receptors" sites. This high density of binding sites exceeds that of the best-known absorbents and catalysts. The thousands of phage filaments also provide far more opportunities for binding.

***4.1.2 Phage Immobilization.*** To form phage-based biosensors for the detection of foodborne pathogens, a specific phage needs to be selected and immobilized onto the sensor platform surface to capture/react with the target pathogens. The immobilization of phage

should meet several requirements: (i) desorption of phage from the sensor surface should not occur in the analyte solution (such as aqueous buffers or food products containing target pathogens) during the detection process; (ii) the immobilized phage should not lose its binding affinity and specificity toward the target pathogen in the daily environment; and (iii) ideally, the immobilized phage should be strongly attached to the sensor platform surface with high coverage and uniform distribution.

Several phage immobilization techniques have been explored by Petrenko, Weiss, Wan, Huang, Lakshmanan et al. [159, 210–212, 215–219]. These techniques can be classified into two distinct methodologies: (i) phage was indirectly immobilized on the sensor surface by attaching on an anchor layer, which had been coated on the sensor platform surface; and (ii) phage was directly immobilized on the sensor surface by physical adsorption.

Langmuir–Blodgett (LB)-coated monolayers have been used to immobilize phages on sensor platforms. To attach phages, Petrenko et al. [215] deposited biotin-modified phospholipid monolayers on the gold surface of the sensor using the LB method and then treated the monolayer with streptavidin. The biotinlyated phage was then immobilized on the sensor through biotin/atreptavidin coupling. By using this LB-coated monolayer, phages selected for affinity to $\beta$-galactosidase were immobilized on QCM sensors. Experiments showed that phages immobilized on QCM sensors using this method exhibit a better affinity to $\beta$-galactosidase than the same phage used in ELISA [215].

Vodyanoy and Petrenko [159, 220] showed phages can be simply immobilized on the gold surface of the sensor platform by physical adsorption. In this method, a phage was immobilized on the clean gold surface of the sensor by incubating the sensor in the phage suspensions in TBS solution (25 m*M* Tris, 3 m*M* KCl, and 140 m*M* NaCl at a pH of 7.4) for about 1 h at room temperature. On the basis of physical adsorption, this immobilization technique avoids complex surface modification procedures, which considerably simplify the immobilization process and reduce the immobilization time. Using physical adsorption, the phage was successfully immobilized on different sensor platforms, such as SPR [209], QCM [159, 220], and ME sensor platforms [210–212, 217, 221, 222] to detect different pathogens. For example, Olsen et al. used QCM coated with phages by physisorption to detect *S. typhimurium*, and a detection limit of 100 cell/ml was achieved [159]. Using this method, Chin's group immobilized the JRB7 phage and the E2 phage on ME biosensors and successfully used them to detect *B. anthracis* spores [210, 217, 222] and *S. typhimurium* [211, 212, 217].

### 4.2 Magnetoelastic (ME) Material as the Sensor Platform

Recently, the use of ME materials as transducer platforms for the remote monitoring of foodborne pathogens [210–212, 217, 222] and other applications in chemical detection and environmental monitoring [223–228] have attracted considerable interest.

ME materials have an interesting and potentially useful property in that the material's physical dimensions change in response to variations in its magnetic environment: this is the direct ME effect, known as *magnetostriction*. Unlike piezoelectric materials, which need external electrical connections, ME materials can be monitored wirelessly as they are activated remotely by a magnetic field. When a time-varying AC external magnetic field is used to resonate the ME platform, the resulting magnetostriction causes the ME platform to exhibit a pronounced ME resonance, and hence change the magnetic flux that can be remotely detected using a pickup coil. As no physical connection is needed

between the ME platform and the device, a biosensor based on this ME platform can be conveniently used in difficult environments such as sealed containers and packages.

The precise mechanical resonance frequency of an ME sensor is based on its physical characteristics, and it can be made to vibrate at this frequency by applying an oscillating magnetic field to cause an elastic length change. For a thin, planar, ribbon shaped sensor of length $L$, vibrating in its basal plane, the fundamental resonant frequency of longitudinal oscillations is given by [229, 230]:

$$f = \sqrt{\frac{E}{\rho(1-\sigma^2)}}\frac{1}{2L} \tag{4}$$

where $E$ is Young's modulus of elasticity, $\rho$ is the density of the sensor material, $\sigma$ is the Poisson's ratio, and $L$ is the length of the sensor.

Any non-ME mass added to the sensor surface reduces the mechanical oscillations causing the resonance frequencies to shift to a lower value. If the mass increase ($\Delta m$) is small compared to the mass of the sensor ($M$) and it is uniformly applied on the sensor surface, the shift in resonant frequency ($\Delta f$) is given by:

$$\Delta f = -\frac{f_0 \Delta m}{2M} \quad (\Delta m << M) \tag{5}$$

where $f_0$ is the initial resonance frequency, $M$ is the initial mass, and $\Delta m$ is the added mass. The negative sign means the resonance frequency of the ME resonator decreases with an increase of the mass load. Thus, the mass load on the ME resonator can be very easily obtained by simply measuring the shift in the resonance frequency.

The mass sensitivity of the ME sensor can be expressed as

$$S_{\mathrm{m}} = \frac{\Delta f}{\Delta m} = -\frac{f_0}{2M} = -\frac{1}{2M}\frac{1}{2L}\sqrt{\frac{E}{\rho\left(1-\sigma^2\right)}} = -\frac{1}{4l^2 wt\rho}\sqrt{\frac{E}{\rho\left(1-\sigma^2\right)}} \tag{6}$$

where $S_m$ is the mass sensitivity of ME sensor, and $w$ and $t$ are the width and thickness of sensor respectively. From this equation, it is clear that when a small mass is loaded on the sensor, the mass sensitivity depends primarily on the length of the sensor and is inversely proportional to $l^2$.

### 4.3 Phage-Based Magnetoelastic Biosensors

In order to detect the presence of selective and specific pathogens (which may be spores, bacteria, or viruses), biomolecular recognition elements (phages, antibodies, or enzymes) will be coated onto the surface of the ME platform to form an ME biosensor. A time-varying (AC) magnetic field, supplied by a network analyzer, is used to resonate the ME biosensors. Before loading the pathogens, the frequency of the ME biosensor is recorded as $f_0$. Upon coming into contact with the biosensor, the target pathogens are captured by the specific recognition elements immobilized onto the biosensor's surface, resulting in an increase in the mass on the ME biosensor. This added mass will cause a corresponding decrease in the biosensor's resonance frequency ($f_{\mathrm{mass}}$). These measurements are performed remotely and wirelessly.

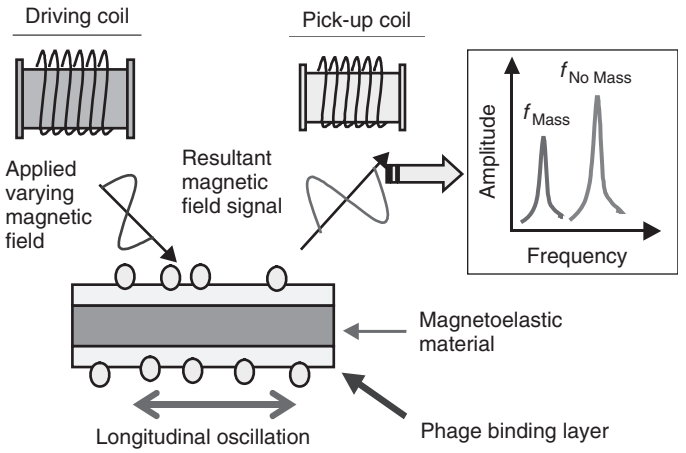

**FIGURE 11** Wireless ME biosensor operation and the basic principle for detecting bacterial cells and spores. The fundamental resonant frequency of the biosensor $f_{\text{No Mass}}$ without target binding decreases to $f_{\text{Mass}}$ due to target binding.

Figure 11 illustrates the wireless nature of the individual ME biosensor and the basic principle for detecting bound mass (target pathogens).

The frequency spectrum of the biosensor can be obtained by sweeping an AC magnetic interrogation field over a predetermined frequency range while monitoring the response of the biosensor using a pickup coil. At the resonance frequency of the biosensor, the conversion of the magnetic energy into elastic energy is maximal and the biosensor undergoes a maximal oscillation.

***4.3.1 ME Sensor Platform.*** Compared to other AW sensor platforms, the simple strip-shaped configuration makes the ME platform easier to be fabricated. The fabrication methods can be divided into three types depending on the desired size of the sensor platform.

Generally, sensor platforms with lengths longer than 500 μm can be fabricated by simply mechanically polishing and dicing commercially available amorphous alloy ribbons. Figure 12 shows the procedure of fabricating ME sensor platforms using the polishing/dicing technique [210–212, 216, 217]. In order to fabricate the ME sensor platform, it was cut off the roll and hand polished to 15 μm using grit paper of 1000–2000 μm. This polishing provided a smoother surface for biorecognition element immobilization and also a thinner platform, decreasing the initial mass of the sensor in order to increase its sensitivity. After polishing, the ME alloy was sandwiched between two sheets of polymer film and cut by a microdicing saw to obtain sensor platforms with the desired sizes. All the platforms were fabricated with a length ($L$) to width ($w$) ratio of 5:1. In order to remove any residual film after dicing, the ME sensor platforms were ultrasonically cleaned in acetone with micro-90 solution for 1 h, in ethanol for 0.5 h, and then dried in air. After dicing, the cleaned ME sensor platforms were annealed to relieve residual internal stress and correct defects due to the mechanical polishing and dicing operations. Annealing was carried out at 220°C for 2 h in a vacuum oven (Fisher Isotemp Model 281A, Vacuum Oven) under a vacuum of at least $10^{-3}$ Torr [231]. Afterwards, the sensor platforms were cooled to room temperature in the oven while still under vacuum. Then,

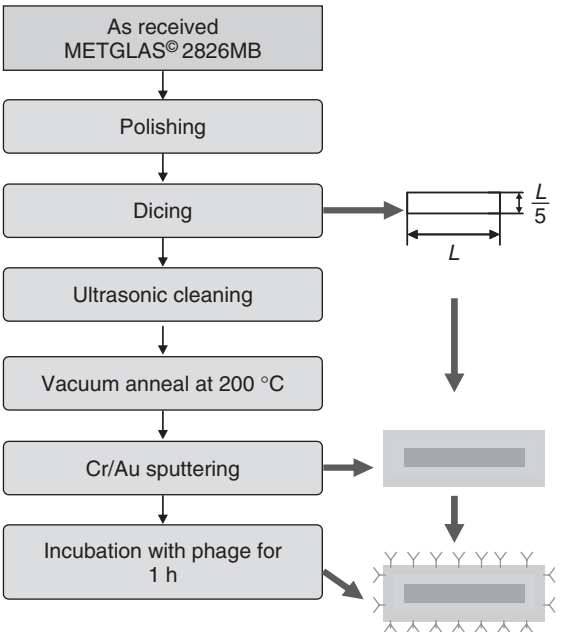

**FIGURE 12** Steps in the fabrication of a magnetoelastic resonator using the polishing/dicing technique. This method is limited to fabrication of resonators greater than 500 μm in size.

thin films of chromium followed by gold were deposited onto both sides of the ME platforms using a Denton™ Vacuum Discovery-18 sputtering system (Moorestown, New Jersey) with two cathodes (RF and DC). All deposition of metals was conducted in a vacuum chamber evacuated to a background pressure of no more than $5 \times 10^{-6}$ Torr. Argon was used as the sputtering gas to bring the deposition pressure up to between 5 and 6 mTorr. On each side of the ME platforms, Cr was deposited first after which the Au layer was deposited without breaking the vacuum. The fabricated platforms were then stored in a desiccator until use. Prior to immobilization of the biorecognition element, the sensor platforms were washed with hexane and air dried.

When the length of the sensor platform is smaller than 500 μm, it is very difficult to fabricate using this mechanical polishing and dicing technique. Therefore, a method employing microelectronic fabrication techniques was developed by Johnson et al. [232, 233] and successfully fabricated the platform with a size down to $50 \times 6 \times 3$μm. Figure 13 shows the microfabrication process. A wafer was patterned with rectangular shapes of the desired size using a photolithography process. Photoresist SPR-220 and developer 453 from Rohm & Haas Electronic Materials LLC (Philadelphia, Pennsylvania) were used to form the pattern. Amorphous iron–boron thick films were magnetron sputtered onto silicon wafers using a Discovery-18 sputter system from Denton Vacuum USA (Moorestown, New Jersey) at a base pressure $7 \times 10^{-7}$ Torr. Thin gold films that serve as a corrosion protection layer for the resonator and form a biological compatible surface were deposited onto the wafer before and after the Fe–B film deposition. A lift-off process employing a wash with solvent was used to remove the resonators from the wafer. The sensor platforms were then cleaned with acetone. More details of the fabrication process are described in Ref. 232.

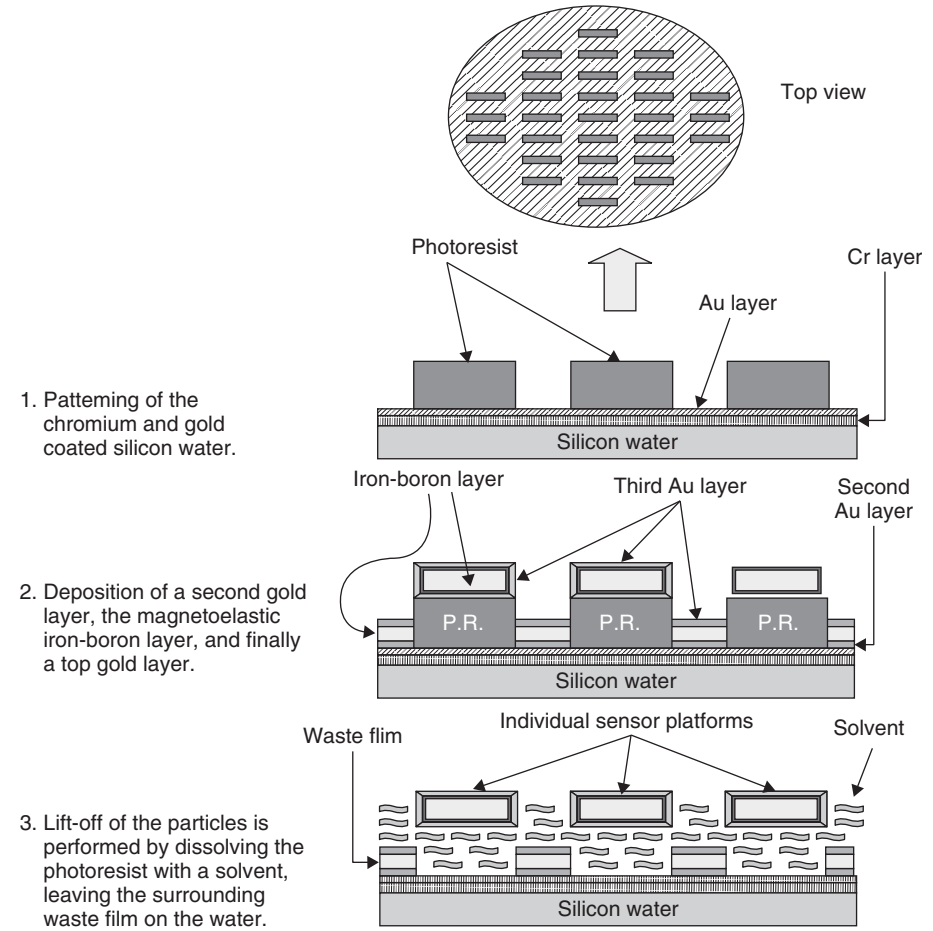

**FIGURE 13** Diagram of the microelectronics fabrication process used to make micron-scale magnetoelastic resonators.

To obtain a sensor platform with nanoscale dimensions, Li et al. fabricated ME nanobars using template-based electrochemical deposition [234, 235]. As seen previously in Section 4.2 the sensitivity of the sensor will increase as its size and characteristic mass is decreased. In order to directly detect the presence of a small amount of pathogenic bacteria (e.g. of the order of 100 or less), the sensor must theoretically be limited to a maximum dimension (length) in the range of 100 μm.

***4.3.2 Fabrication of Phage-Based ME Biosensors.*** So far in the investigation of phage-based ME biosensors, two kinds of affinity-selected phages have been used as bioprobes: the JRB7 phage against *B. anthracis* spores and the E2 phage against *S. typhimurium*. Both the JRB7 phage and the E2 phage were selected from the f8/8 landscape phage library by Dr. Valery Petrenko of Auburn University. The selection procedures have been described in detail in a previous article [236, 237]. To form phage-based ME biosensors, the phage was immobilized on the gold coated surface

of the resonators (sensor platforms) by physical adsorption. In order to prevent nonspecific binding of target pathogens on the gold surface, the phage-immobilized biosensors were coated with 1 mg/ml BSA. Detailed phage immobilization procedures for these biosensors are available in several articles [210–212, 216, 217, 221, 231].

### 4.4 Phage-Based ME Biosensors for Foodborne Pathogen Detection

Wan, Lakshmanan et al. immobilized the JRB7 phage [210, 216] and the E2 phage [211, 212] onto ME platforms to form biosensors to detect *B. anthracis* spores and *S. typhimurium* cells, respectively. The performance of the biosensors, including sensitivity, detection limit, specificity, and longevity (thermal stability), was systemically characterized. Also, a phage-based ME biosensor has been demonstrated to detect *S. typhimurium* cells in fat-free milk or apple juice [212]. Huang et al. developed a multisensor detection system that allows detecting two different pathogens simultaneously [217]. This system is composed of two phage-based ME biosensors and one reference sensor.

In the studies mentioned above, the biosensors were tested in both static and dynamic modes. Static testing involved exposure of the biosensors to static suspensions containing the target pathogen in known concentrations. Dynamic testing involved exposure of the biosensors to flowing suspensions containing known concentrations of target pathogens in a single flow-through mode. The details of the measurement system and experimental procedures have been described in several papers [210–212, 216, 217]. Both JRB7 and E2 ME biosensors exhibit good sensitivity, specificity, and selectivity toward the target pathogen, as well as excellent longevity.

#### *4.4.1 Dose–response of ME Biosensor to Target Pathogen.*

*4.4.1.1 JRB7 phage–based ME biosensor for B. Anthracis spores detection in a static mode.* Wan et al. [210, 216] have successfully employed a JRB7 phage–based ME biosensor to detect *B. anthracis* spores within a static mode. In their research, microelectronically fabricated ME particles ($500 \times 100 \times 4$ μm and $200 \times 40 \times 4$ μm) were immobilized with the JRB7 phage. These formed ME biosensors were sequentially exposed to static *B. anthracis* spore suspensions of increasing concentrations ($5 \times 10^1 - 5 \times 10^8$cfu/ml). The biosensors were exposed to each concentration for 30 min. Figure 14a and b shows the frequency responses of the JRB7 phage–based biosensor with the size of $500 \times 100 \times 4$ μm and $200 \times 40 \times 4$ μm, respectively. The response of reference sensors (no phage coating, with BSA blocking) were also measured under the same experimental conditions. In both cases, as the concentration of the spore suspension was increased, the resonance frequency of the JRB7 phage–based ME biosensors experienced the expected decrease. During the entire test, the frequency of the reference sensor exhibited no appreciable change regardless of the composition of analyte introduced. This showed that nonspecific binding had been blocked during testing by BSA pretreatment.

After the spore exposure tests, the sensor surfaces were observed by scanning electron microscopy (SEM). The SEM studies (Fig. 14) clearly demonstrate that JRB7 phage–based biosensors have good ability to capture *B. anthracis* spores. Only a few spores were observed to have bound to the reference sensor surface, which demonstrates that the nonspecific binding was effectively blocked by precoating the control sensors with 1 mg/ml BSA.

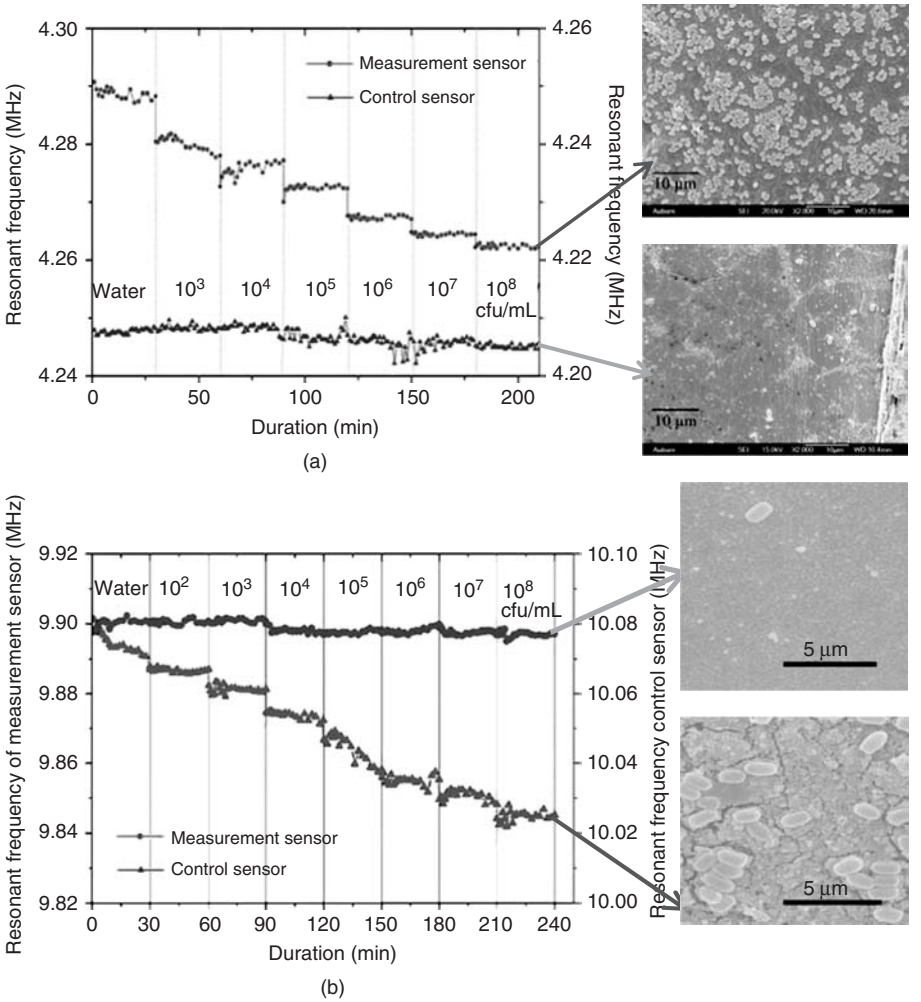

**FIGURE 14** The biosensor response curve (frequency shift as a function of time and concentration) of both measurement and control sensors for (a) $500 \times 100 \times 4$ μm size sensors and (b) for $200 \times 40 \times 4$ μm size sensors [210, 216].

Table 8 summarizes the sensitivity and detection limits of different sized JRB7 phage–based ME biosensors. The results show that the sensitivity, detection limit, and dose–response of the biosensor improved as the size of the biosensor decreased. This result is consistent with predictions of Eq. (6).

Wan et al. [216] also tested biosensors made using mechanically polished/diced ME platforms ($5 \times 1 \times 0.02$ mm) that were immobilized with the JRB7 phage. The dose–responses of these biosensors after exposure to static *B. anthracis* spore suspensions of increasing concentrations ($5 \times 10^1 - 5 \times 10^8$ cfu/ml) are shown in Figure 15. The smooth lines are the sigmoid fits of the experimental data, and each data point is a mean value of the steady-state frequency readings from 50 sensors. The sensitivity of the biosensor, measured as the slope of the linear portion of dose response, was calculated to be 130 Hz per decade or 0.14 cfu/$\mu m^2$ per decade of spore concentration.

**TABLE 8 Table Summarizing the Sensitivity and Detection Limits Achieved for JRB7 Phage-Based Biosensors with Different Dimensions**

| Sensor Dimensions | Sensitivity (Hz/decade) | Detection Limit (cfu/ml) |
|---|---|---|
| $5.0 \times 1.0 \times 0.02$ mm | 130 | $10^3$ |
| $500 \times 100 \times 4$ μm | 6,500 | 850 |
| $200 \times 40 \times 4$ μm | 13,100 | 105 |

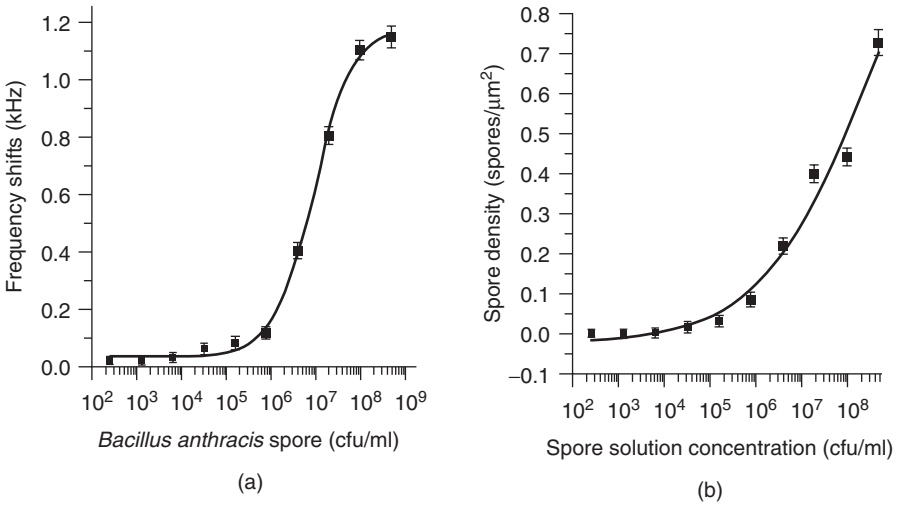

**FIGURE 15** The dose–response of JRB7 phage–based biosensors for detection of *Bacillus anthracis* spores with dimensions of $5 \times 1 \times 0.02$ mm. (a) The mean values of the resonant frequency shifts as a function of spore solution concentration from $10^2$ to $10^8$ cfu/ml. The smooth line is the sigmoidal fit to experimental data points ($\chi = 6.06$, $R^2 = 0.97$). (b) The mean values of bound surface spore density as a function of spore solution concentration from $10^2$ to $10^8$ cfu/ml. The smooth line is the sigmoidal fit to experimental data points ($\chi = 0.043$, $R^2 = 0.98$) [216].

The detection limit of the biosensor was estimated to be $10^3$ cfu/ml, which corresponds to a minimal observable frequency shift of 25 Hz. The dose-dependence curve shows a trend toward saturation at $10^8$ cfu/ml and above.

SEM analysis was used to quantify the number of spores bound to the phage-immobilized ME biosensors, as well as to obtain a visual verification of phage distribution on the sensor surface. In order to count the numbers of spores bound to the biosensor's surface, SEM photographs were taken at 10 randomly chosen regions on the sensor surface, and spores were counted individually. The average number of bound cells per unit area was calculated. The resulting number was multiplied by the entire surface area of the sensor to obtain the total number of bound spores. Figure 15b is the measured density of spores attached to the sensor surface. The results indicate that the measured frequency shifts are due to the additional mass of the bound *B. anthracis* spores.

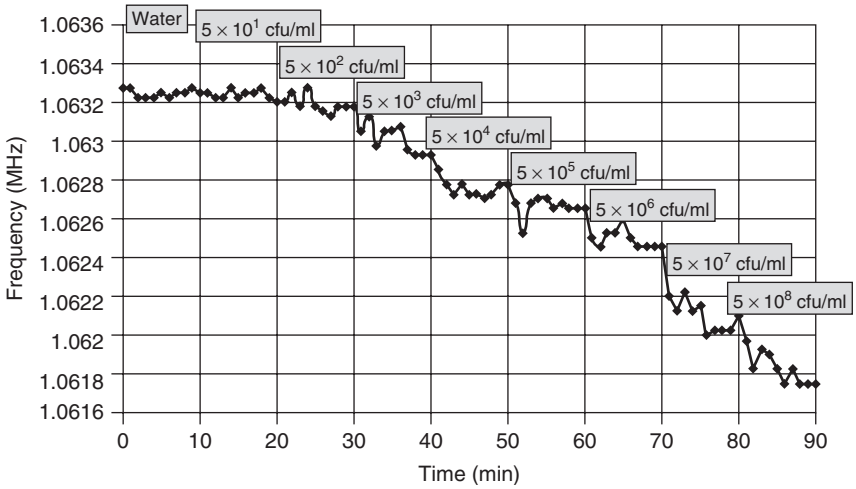

**FIGURE 16** Response of a ME biosensor exposed to different concentrations of *B. anthracis* spores ($5 \times 10^1 - 5 \times 10^8$ cfu/ml) [221].

*4.4.1.2 JRB7 phage–based ME biosensor for B. anthracis spores detection in a dynamic mode.* Huang et al. [221] have demonstrated that *B. anthracis* spores can also be detected by JRB7 phage–based ME biosensors within a dynamic mode. In their research, a mechanically polished/diced ME sensor platform with the size of $2 \times 0.4 \times 0.015$ mm was immobilized with JRB7 phage to form the ME biosensor. Figure 16 shows the dynamic response of a biosensor to increasing concentrations of *B. anthracis* spores ($5 \times 10^1 - 5 \times 10^8$ cfu/ml). As the concentration of the spore suspension was increased, the resonance frequency experienced the expected decrease. The initial frequency remained stable until the solution with a spore concentration of $5 \times 10^3$ cfu/ml was introduced, where the first detectable drop of frequency can be seen. At the end of the test, after introduction of the highest spore concentration, the total resonance frequency shift for this biosensor was 1420 Hz. SEM images (Fig. 17) show the interaction of spores with JRB7 phage on the biosensor surface where the spores were uniformly distributed on the surface. Figure 18 shows the dose–response curve of the ME biosensor dynamic response and represents the sigmoidal fit of the data.

*4.4.1.3 E2 phage-based ME biosensor for S. typhimurium detection.* Lakshmanan, et al. [211, 212] have characterized E2 phage–based ME biosensors for the detection of *S. typhimurium*. Figure 19 shows a typical resonance frequency response as a function of time for an E2 phage–based biosensor ($2 \times 0.4 \times 0.015$ mm) exposed to different solutions containing known concentrations of *S. typhimurium* bacteria. The biosensor's resonance frequency was recorded every 2 min. Exactly 1 ml of each concentration was allowed to flow over the sensor at a flow rate of 50 l/min before the next highest concentration was started. At the flow rate used, it takes 20 min for 1 ml of the analyte to flow over the biosensor. The resonance frequency at the end of every 20 min was used to calculate the resultant frequency shift for that particular concentration. The resonance frequency decreased with the introduction of each successive concentration ($5 \times 10^4$ cfu/mlthrough $5 \times 10^8$ cfu/ml) of *S. typhimurium*. The reference sensor

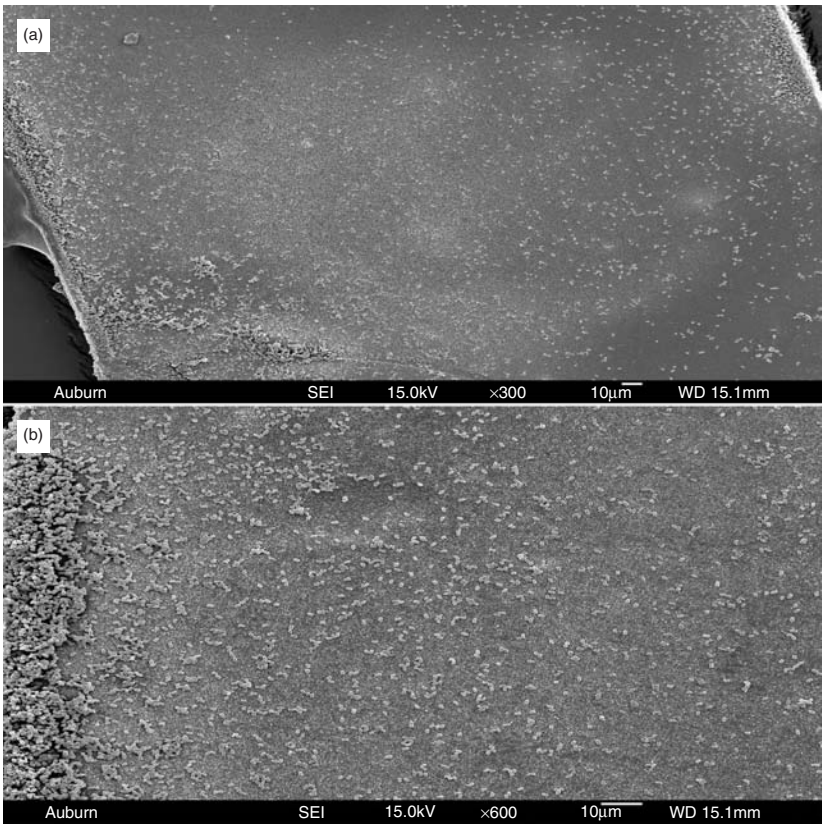

**FIGURE 17** SEM photographs of ME sensor surface after exposure to different concentrations of *B. anthracis* spores ($5 \times 10^1 - 5 \times 10^8$ cfu/ml) dynamically.

(no coating of phage but blocking agent) showed a negligible change in resonance frequency, even upon exposure to very high concentrations ($5 \times 10^8$ cfu/ml) of bacteria. SEM photomicrographs were taken after the exposure experiments to confirm the measured frequency shifts were due to binding of *S. typhimurium*.

Lakshmanan's results showed results similar to the JRB7 phage–based ME biosensor results obtained by Wan and Huang. The smaller the dimensions of the biosensor, the higher the sensitivity and lower the detection limits that were obtained [211, 212]. The dose–response tests were conducted for E2 phage–based ME biosensors with four different lengths (5, 2, 1, and 0.5 mm). Table 9 summarizes the measured sensitivity and detection limits for these E2 phage–based ME biosensors dependent on different sizes. The results showed that as the length of the biosensor decreased from 5 to 0.5 mm, the E2 phage biosensor became more sensitive (sensitivity of 1150 Hz/decade) and was able to detect *S. typhimurium* at a concentration of 60 cfu/ml. Lakshmanan counted [211, 212] the number of bacteria bound to the biosensor surface using SEM micrographs. The results showed that the number of attached *S. typhimurium* cells on the biosensors agrees with the measured frequency shifts of the E2 biosensors. This is consistent with Wan's investigation [216].

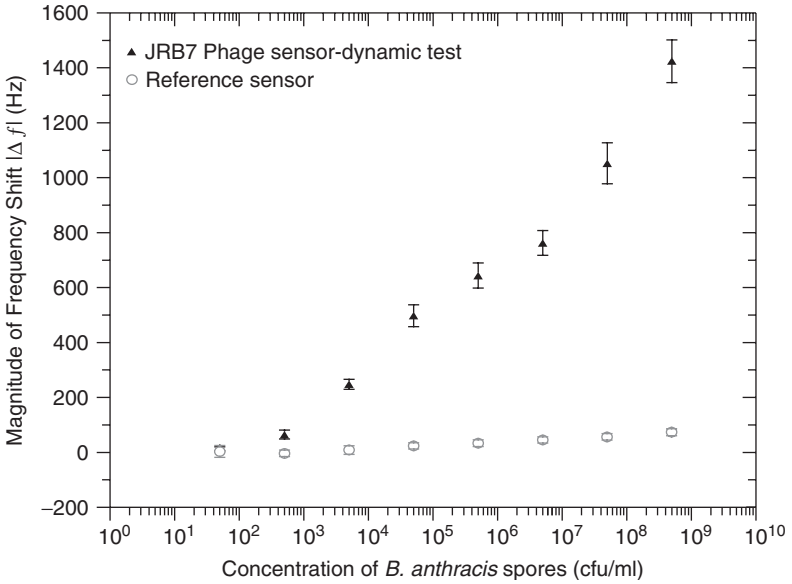

**FIGURE 18** Dose–response curve of ME biosensor ($2 \times 0.4 \times 0.015$ mm) coated with $5 \times 10^{11}$ cfu/ml phage suspension (contain 420 m*M* NaCl) and then exposed to increasing concentrations ($5 \times 10^1 - 5 \times 10^8$ cfu/ml) of *B. anthracis* spores suspensions in water [(▲) ($R^2 = 0.984$)]. Reference sensor (○) represents the uncoated (devoid of phage) sensor's response. The curve represents the sigmoidal fit of signals obtained [221].

***4.4.2 Specificity of Phage-Based ME Biosensors.*** The specificity of phage-based ME biosensors can be evaluated by exposing them to similar pathogenic species, to examine the cross-reaction between a specific phage with nonspecific pathogens. Further investigation can be established by measuring the phage-based ME biosensor's response to specific target pathogens masked with one similar species.

*4.4.2.1 JRB7 phage-based ME biosensor. B. anthracis* spores belong to the *Bacillus* species and have physical characteristics similar to *B. subtilis*, *B. cereus*, *B. licheniformis*, and *B. megaterium* spores. In order to study the specificity of JRB7 phage–based ME biosensors toward *B. anthracis* spores, Wan et al. [210, 216] studied the specificity of JRB7 phage–based ME biosensors by exposing them to concentrated solutions ($10^8$ spores/ml) of various *Bacillus* spores mentioned above (see Figure 20). SEM was used to determine the surface density of bound spores with JRB7 phage. The JRB7 phage–based ME biosensors showed about 40-fold better binding to *B. anthracis* than *B. licheniformis* and *B. megaterium*, and about 15-fold better than *B. subtilis* and *B. cereus* spores. This demonstrated that the JRB7 phage preferentially bound to *B. anthracis* spores better than other *Bacillus* spores. Although the JRB7 phage clone does have some cross-reaction with spores of other *Bacillus* species, compared to the specific binding with *B. anthracis* spores, this cross-reaction is weak enough to be negligible.

In order to further demonstrate the specificity of the JRB7 phage-coated ME biosensors, the biosensor was exposed to increasing concentrations of *B. anthracis* spores suspension ($5 \times 10^3 - 5 \times 10^8$ cfu/ml) in a mixture of a fixed concentration of *B. cereus* spores ($5 \times 10^8$ cfu/ml). Each test suspension was pipetted off followed by adding a new

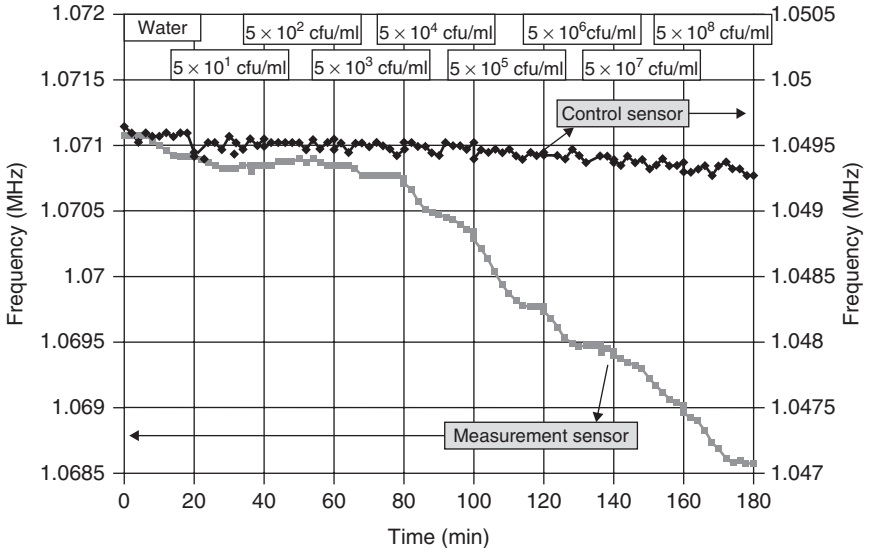

**FIGURE 19** Typical frequency—response curve for an E2 phage–based biosensor for *S. typhimurium* with dimensions $0.015 \times 0.4 \times 2$ mm. 1 ml of each concentration of bacteria containing solution was passed over the sensor at a flow rate of 50 l/min. The control sensor is not coated with the phage [238].

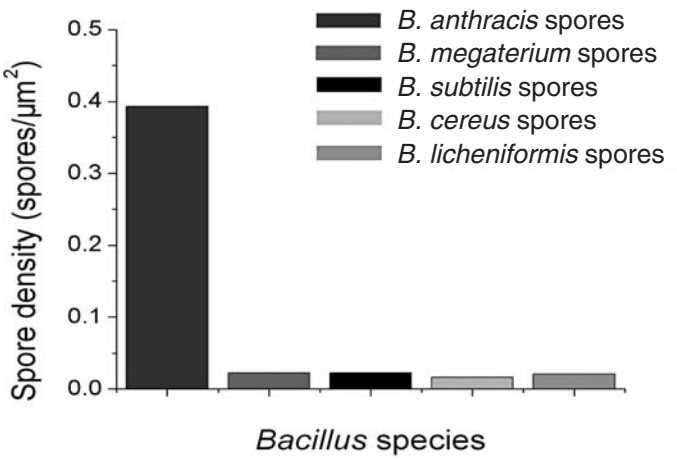

**FIGURE 20** Biosensor. specificity: phage-coated sensors were exposed to solutions containing $10^8$ spores/ml. Density of attached spores were measured using SEM. Tween-20 with 1% BSA was used for blocking [216].

suspension of a different concentration at 30-min intervals. The results of this set of experiments conducted by Wan et al. are shown in Figure 21 [216]. After the frequency of the biosensor is stabilized in water, a small frequency shift was observed after the sensor was exposed to the initial concentrated *B. cereus* suspension ($10^8$ cfu/ml). The frequency shifts were caused by the nonspecific binding between phage and *B. cereus* spores. This is consistent with previous results that showed the JRB7 affinity-selected

**TABLE 9 Summary of Sensitivity and Detection Limits Achieved for E2 Phage Biosensors with Different Dimensions**

| Sensor Dimensions (mm) | Sensitivity (Hz/decade) | Detection Limit (cfu/ml) |
|---|---|---|
| $5.0 \times 1.0 \times 0.015$ | 98 | $10^4$ |
| $2.0 \times 0.4 \times 0.015$ | 161 | 950 |
| $1.0 \times 0.2 \times 0.015$ | 770 | 100 |
| $0.5 \times 0.1 \times 0.015$ | 1150 | 60 |

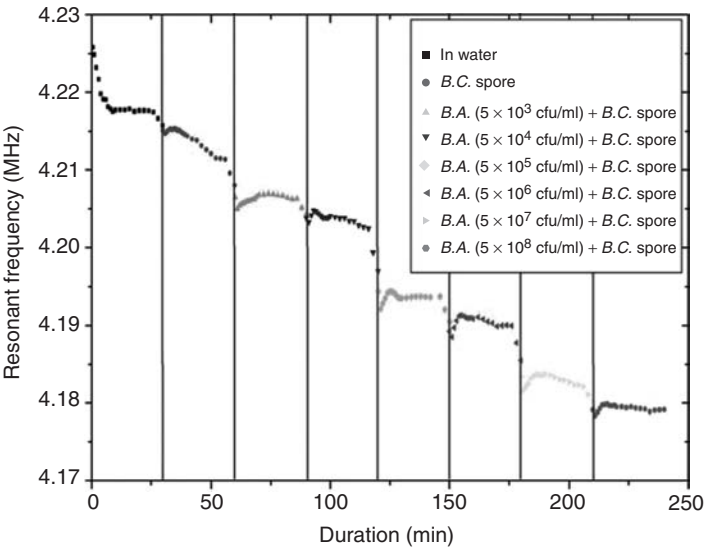

**FIGURE 21** The response curve of a MEP ($500 \times 100 \times 4$ μm) as a function of time and spore concentration in a mixed solution of *Bacillus anthracis* and *Bacillus cereus* spores. The concentration of the *B. cereus* spores is $10^8$ cfu/ml [216].

phage clone does cross-react with the *B. cereus* species. Upon increasing the concentration of *B. anthracis* spores, the JRB7 phage–based ME biosensor showed progressively larger frequency shifts. This was because *B. anthracis* spores were bound to the biosensor's surface even in the presence of a background of $10^8$ cfu/ml of *B. cereus* spores. Compared to total frequency shift caused by the specific binding between the JRB7 phage and *B. anthracis* spores, the frequency shift due to the nonspecific binding is small enough to be negligible.

*4.4.2.2 E2 phage-based ME biosensors.* Lakshmanan et al. [239] used similar experimental methods as Wan et al. to evaluate the specificity of the E2 phage–based ME biosensors by exposing them individually to static suspensions of *S. typhimurium*, *E. coli, S. enteritidis*, and *L. monocytogenes*. In their study, SEM images of 10 random regions of the biosensor surface were taken. The number of bacteria cells bound to those regions was counted. The sensor surface area coverage density (number of cells per unit area) was then calculated and multiplied by the total surface area of the sensor to obtain the total number of bacteria bound to the sensor. Assuming that the average weight of a

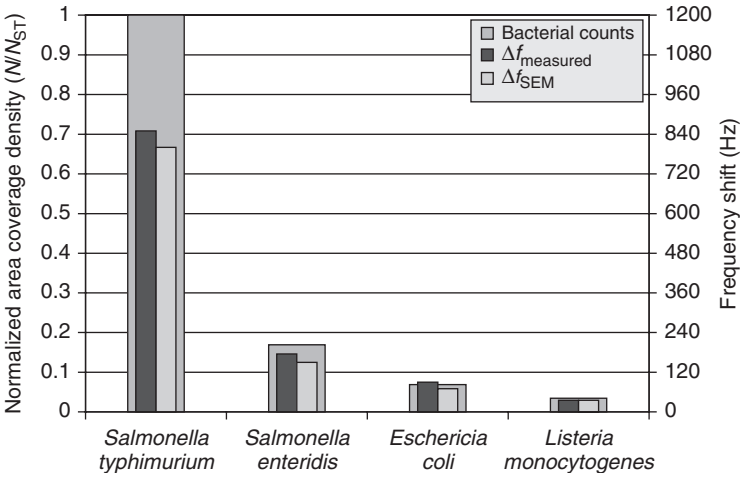

**FIGURE 22** Specificity of phage-immobilized sensors exposed to different pathogens at a concentration of $5 \times 10^8$ cfu/ml. The normalized area coverage density was calculated from SEM photomicrographs of the sensor surface (an average of five sensors each). $\Delta f_{measured}$ and $\Delta f_{SEM}$ are shown on the right side [239].

*S. typhimurium* cell is 2 pg, the total mass change ($\Delta m_{SEM}$) can be obtained. Based on Eq. (5), the theoretical frequency shift caused by $\Delta m_{SEM}$ was calculated as $\Delta f_{SEM}$. Before and after exposure to bacteria pathogens, the frequencies of E2 phage–based biosensors were measured. The frequency shift ($\Delta f_{measured}$) was then calculated and compared with $\Delta f_{SEM}$ obtained above. Figure 22 [239] shows the comparison results of E2 phage–based ME biosensors exposed to different pathogens at a concentration of ($5 \times 10^8$ cfu/ml). The result showed that $\Delta f_{measured}$ and $\Delta f_{SEM}$ have similar values, which demonstrates that the frequency shift of the biosensor was caused by the binding between the E2 phage and bacterial pathogens. The normalized area coverage density shown in Figure 22 was calculated as the ratio of the area coverage density of a certain pathogen ($N_P$) to the area coverage density of *S. typhimurium* ($N_{ST}$). The normalized area coverage density of the biosensors exposed to *S. typhimurium, S. enteritidis*, *E. coli*, and *L. monocytogenes* were 1.00, 0.17, 0.06, and 0.03, respectively. Lakshmanan's results (Fig. 23) showed significantly lower affinity of the immobilized phage to pathogens other than *S. typhimurium*, which demonstrated that E2 phage–based ME biosensors have excellent specificity.

The effect that masking bacteria has on the detection of *S. typhimurium* by the E2 phage–based biosensor was studied. Lakshmanan [239] exposed the E2 biosensors to three different sets of prepared suspensions: (i) *S. typhimurium*, (ii) *S. typhimurium* + *E. coli*, and (iii) *S. typhimurium* + *E. coli* + *L. monocytogenes*. On the basis of the resulting dose–response curve, Lakshmanan constructed a hill plot [212, 215, 220, 240] and determined the binding kinetics of the testing biosensors. The binding valency was similar for all the three prepared suspensions. Overall, Lakshmanan [212] determined the E2 phage–based ME biosensor with the size of $2 \times 0.4 \times 0.015$ mm was capable of detecting small amounts of *S. typhimurium*, even in the presence of high concentrations of masking bacteria. This established that the E2 phage–based ME biosensor could detect *S. typhimurium* with high specificity and selectivity.

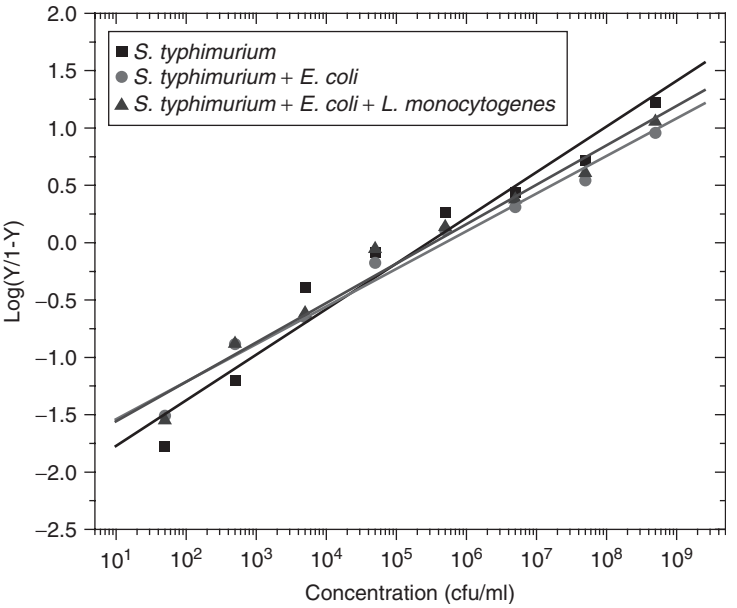

**FIGURE 23** Hill plot constructed from the dose–response curves, showing the ratio of occupied ($Y$) and free phage sites ($1-Y$) as a function of bacterial concentrations in different mixtures. The straight line is the linear least squares fit to the data (*S. typhimurium* (■): slope $= 0.40 \pm 0.03$, $R^2 = 0.97$; *S. typhimurium* + *E. coli* (•): slope $= 0.33 \pm 0.02$, $R^2 = 0.98$; and *S. typhimurium* + *E. coli* + *L. monocytogenes* (▲) slope $= 0.34 \pm 0.02$, $R^2 = 0.97$) [239].

Table 10 summarizes the sensitivity, dissociation constant, and binding valence of the biosensor in the different mixtures. The binding valencies obtained from the hill plots were 2.42, 2.79, and 2.91 for suspension 1, suspension 2, and suspension 3, respectively. This reaffirms the multivalent nature of the phage–*Salmonella* interaction on the biosensors. A summary of results obtained from the real food products detection using E2 phage biosensors are also presented in Table 10 [212].

***4.4.3 Stability of Phage-Based ME Biosensor.*** To evaluate the capability of a biosensor, it is essential to establish the storage life and longevity of the immobilized biorecognition element. Brigati and Petrenko [241] have demonstrated that a phage is more robust than other commonly used biorecognition probes, such as polyclonal and monoclonal antibodies. In order to investigate the stability of phage-based ME biosensors, Wan et al. [216], Lakshmanan [211, 212], and Guntupalli [242] prepared a set of ME biosensors, including JRB7 phage–based ME biosensors, E2 phage–based biosensors, and antibody-based ME biosensors. Three types of biosensors were all incubated under three different temperatures (25, 45, and 65°C). The biosensors were removed at specified times of 1, 2, 3 days and so on, and tested at room temperature by exposing them to the specific target pathogens suspensions (*B. anthracis/S. typhimurium*) at a concentration of $10^8$ cfu/ml. The number of cells/spores bound per unit surface area on the specific biosensor was determined by SEM. Figures 24–26 show the change in bound spore densities, that is, the sensor's binding affinity with storage time at different temperatures for both phage-coated and antibody-coated sensors.

**TABLE 10 The Sensitivity, Dissociation Constant, and Binding Valence of E2 Phage–Based ME Biosensors in Different Bacterial Mixtures**

| Bacterial Mixtures | *S. typhimurium* Detection Sensitivity (Hz/decade) | Binding Valence ($1/n$) | $K_d$(cfu/ml) | $K_{d(\text{apparent})} = K_d^n$ (cfu/ml) |
|---|---|---|---|---|
| S. typhimurium | 161 | 2.42 | 149 | $1.82 \times 10^5$ |
| S. typhimurium + E. coli | 131 | 2.79 | 82 | $2.19 \times 10^5$ |
| S. typhimurium + E. coli + L. monocytogenes | 127 | 2.91 | 87 | $4.41 \times 10^5$ |
| Spiked apple juice | 155 | 2.77 | 89 | $2.51 \times 10^5$ |
| Spiked milk | 118 | 2.5 | 136 | $2.16 \times 10^5$ |

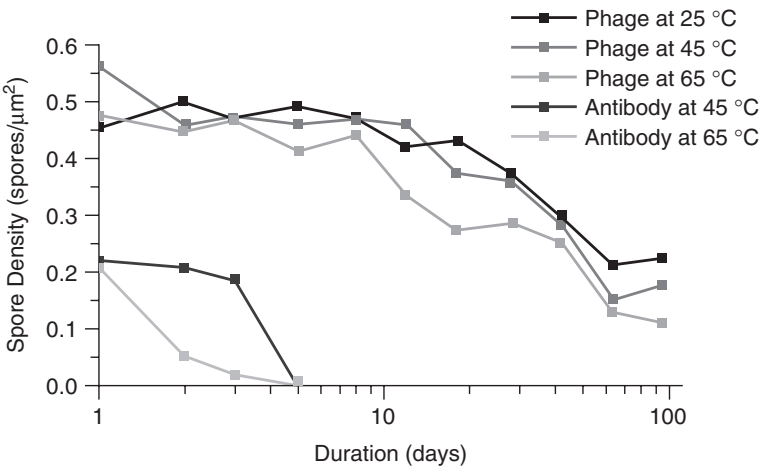

**FIGURE 24** The bound surface spore density, which represents the binding affinity of the specific bioprobes as a function of time at different temperatures for both phage and polyclonal antibody. The antibody-based sensors lost all binding activity after 5 days of storage at 65°C and 45°C [216].

Overall, the results showed a general decrease in the binding affinity of phage-based ME biosensors with increased storage time and temperature. Phage-based ME biosensors have better stability, longevity, and binding affinity to specific target pathogens compared to antibody-based ME biosensors.

Wan et al. [216] observed that after 100 days of storage, the JRB7 phage–based biosensors preserved about 49, 40, and 25% of their original binding affinity, respectively for temperatures of 25, 45, and 65°C. While the antibody-based ME biosensors showed no binding affinity after only 5 days at 65°C and 45°C. SEM images (Fig. 25), where both JRB7 phage–based biosensors and antibody-based biosensors were incubated at a temperature of 65°C and then exposed to the same *B. anthracis* spores suspension

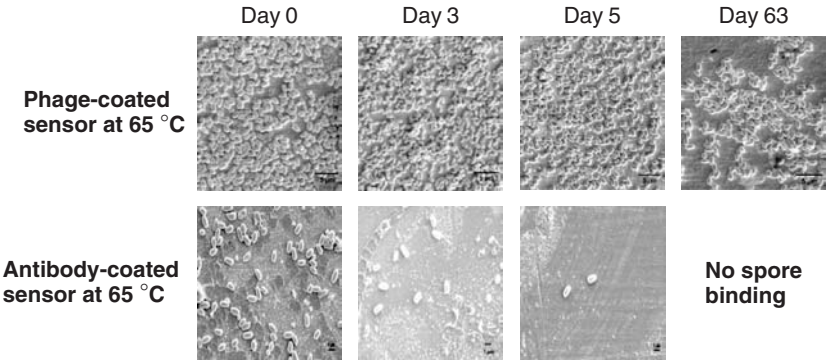

**FIGURE 25** SEM photomicrographs of JRB7 phage-coated sensors and antibody-coated sensors after storage at 65°C. Compared with phage-modified biosensors, the binding affinity of antibody-coated biosensors dropped to zero after being stored at 65°C for 5 days. JRB7 phage-coated biosensors still showed good binding affinity after 2 months [216].

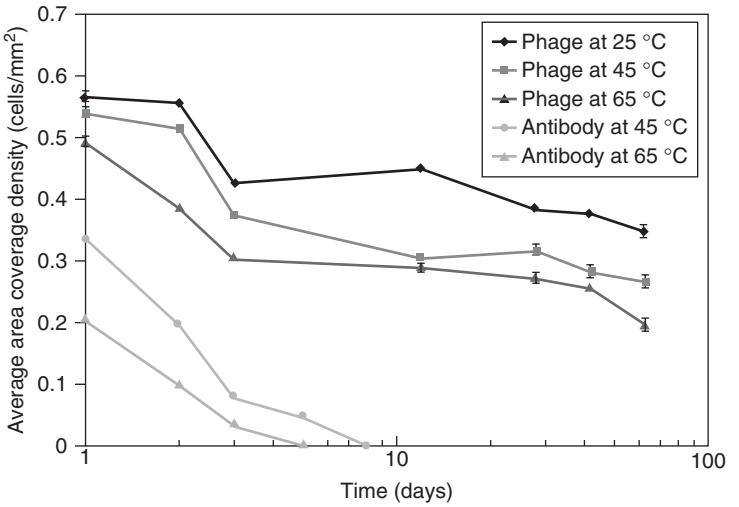

**FIGURE 26** E2 phage–based ME biosensor surface coverage densities (average number of cells per square micrometer) calculated from SEM micrographs of stored magnetoelastic biosensors (25, 45, and 65°C) after exposure to *S. typhimurium* ($5 \times 10^8$ cfu/ml) [239, 242].

($5 \times 10^8$ cfu/ml), demonstrated that the JRB7 phage clone used in this research has a better binding ability than some of the best commercially available antibodies.

Figure 26 shows the study results that compare the longevity of E2 phage–based ME biosensors with antibody-based ME biosensors at three different temperatures (25, 45, and 65°C). Similar to the longevity results from JRB7 phage–based ME biosensors mentioned above (Fig. 24 and 25), the area coverage density (number of bacteria bound to the sensor per unit surface area) of E2 phage–based biosensors was observed to decrease with increasing time and temperature. The E2 phage–based biosensors retained 59, 45, and 33% of their binding affinity at 25, 45, and 65°C, respectively, after a period of 63 days. The antibody-based biosensors showed a rapid loss of binding affinity, with all

binding affinity lost after 8 days at the elevated temperatures of 45 and 65°C. The initial binding affinity of the E2 phage–based biosensors was observed to be much higher than the antibody-based biosensors.

***4.4.4 Detection of S. Typhimurium Bacteria in Food Products.*** Most of the biosensors for food pathogen detection are used in water. It is also essential to establish the field applicability of ME biosensors for applications in other media (i.e. apple juice, milk). Therefore, the work published by Lakshmanan et al. [212, 239] was extended to examine the viability of testing for *S. typhimurium* suspended in the real food product. The biosensors with the size of $2 \times 0.4 \times 0.015$ mm were exposed to milk and apple juice spiked with increasing concentrations of *S. typhimurium* ($5 \times 10^1 - 5 \times 10^8$ cfu/ml). The biosensor response was studied by flowing food liquids containing increasing concentrations of bacteria over the sensors at a flow rate of 50 μl/min. This flow rate was chosen in order to ensure that laminar flow was maintained. Exactly 1 ml of a specific concentration of bacteria in the food liquid was allowed to flow over the sensor (20 min at the specified flow rate). The biosensor's frequency shift was calculated by subtracting the final measured frequency from the initial frequency measured at the introduction of the food liquid.

Figure 27 represents the average response of five different biosensors. Similar dose responses were observed for the biosensor exposed to spiked apple juice and water samples. The resonance frequency shifts obtained for spiked milk samples were lower than that of spiked water and spiked apple juice samples. The dose response was linear over five aliquots of concentrations ($5 \times 10^3$ through $5 \times 10^7$ cfu/ml) for the three different media. The sensitivity of the biosensor was calculated as the slope of the linear region of the dose–response curve (Hz per decade of concentration change). The sensitivity of biosensors exposed to spiked water, apple juice, and milk were 161, 155, and 118 Hz/decade, respectively. The control sensor had a negligible change in resonance frequency in response to even high concentrations of *S. typhimurium*. The control sensor showed a maximum resonance frequency shift of 50 Hz, while a maximum resonance frequency shift of 980 Hz was observed for the biosensor. This significant difference in the measured frequency shifts (control vs. measurement sensor) indicates negligible, nonspecific binding of bacteria to the bare gold surface. SEM photomicrographs of the assayed biosensors were used to provide visual verification of bacterial binding to the sensor surfaces.

***4.4.5 Sequential Detection of S. Typhimurium and B. Anthracis Spores Using Multiple Phage-Based ME Biosensors.*** Utilizing multiple phage-based ME biosensors, Huang et al. [243, 244] demonstrated the simultaneous detection of different pathogens that were sequentially introduced to the measurement system. In their experiments, the detection system included a reference sensor as a control, an E2 phage-coated ME sensor specific to *S. typhimurium*, and a JRB7 phage-coated ME sensor specific to *B. anthracis* spores. The JRB7 and E2 biosensors possessed separate characteristic resonance frequencies; therefore, two different pathogens can be simultaneously monitored and discriminated. In order to prevent nonspecific binding during exposure to multiple analytes, BSA solution was then immobilized on the sensor surfaces to serve as a blocking agent. Huang et al. sequentially exposed this multiple detection system to increasing concentrations of *S. typhimurium* ($5 \times 10^1 - 5 \times 10^8$ cfu/ml) and *B. anthracis* spores ($5 \times 10^1 - 5 \times 10^8$ cfu/ml) suspensions in water. The flow rate was 50 μl/min and, for

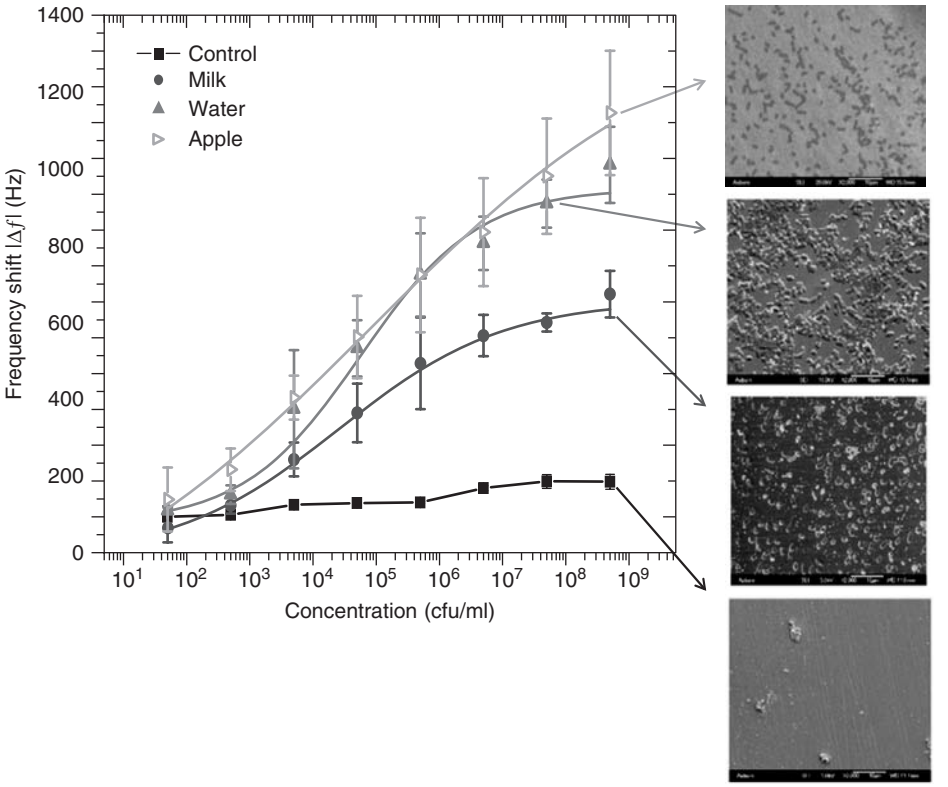

**FIGURE 27** Comparison of the dose responses of magnetoelastic biosensors ($2 \times 0.4 \times 0.015$ mm) when exposed to increasing concentrations ($5 \times 10^1 - 5 \times 10^8$ cfu/ml) of *S. typhimurium* suspensions in water [(▲)$\chi^2 = 0.442$, $R^2 = 0.99$], apple juice [(▼)$\chi^2 = 0.237$, $R^2 = 0.99$], and fat-free milk [(•)$\chi^2 = 0.194$, $R^2 = 0.99$]. Control (■) represents the uncoated (devoid of phage) sensor's response. The curves represent the sigmoid fit of signals obtained.

each concentration, a 1-ml suspension was used. Figure 28 shows the typical response of the multiple phage-based ME biosensors to water, *S. typhimurium*, and *B. anthracis* spore suspensions ($5 \times 10^8$ cfu/ml each) [217]. The steady-state response of all the sensors in water is observed during the first 10 min of the test. After the introduction of *S. typhimurium*, the E2 phage-coated sensor showed a smooth decrease in resonance frequency due to the binding of these bacteria onto the sensor surface. Similarly, the subsequent exposure to a $5 \times 10^8$ cfu/ml *B. anthracis* spore solution caused a sudden drop in the resonance frequency for the JRB7 phage-coated sensor. On exposure to either analyte, the decrease in frequency only occurs when bacteria cells or spores bind to the specific phage on the sensor's surface. Overall, the frequency shift was about 1280 Hz for the E2 phage-coated sensor, and about 1120 Hz for the JRB7 phage-coated sensor for $5 \times 10^8$ cfu/ml analyte solutions.

The SEM photographs (also shown in Fig. 28) of the reference and phage-coated sensors confirmed that the frequency shifts were due to the spores/bacterial cells becoming attached to the corresponding sensors.

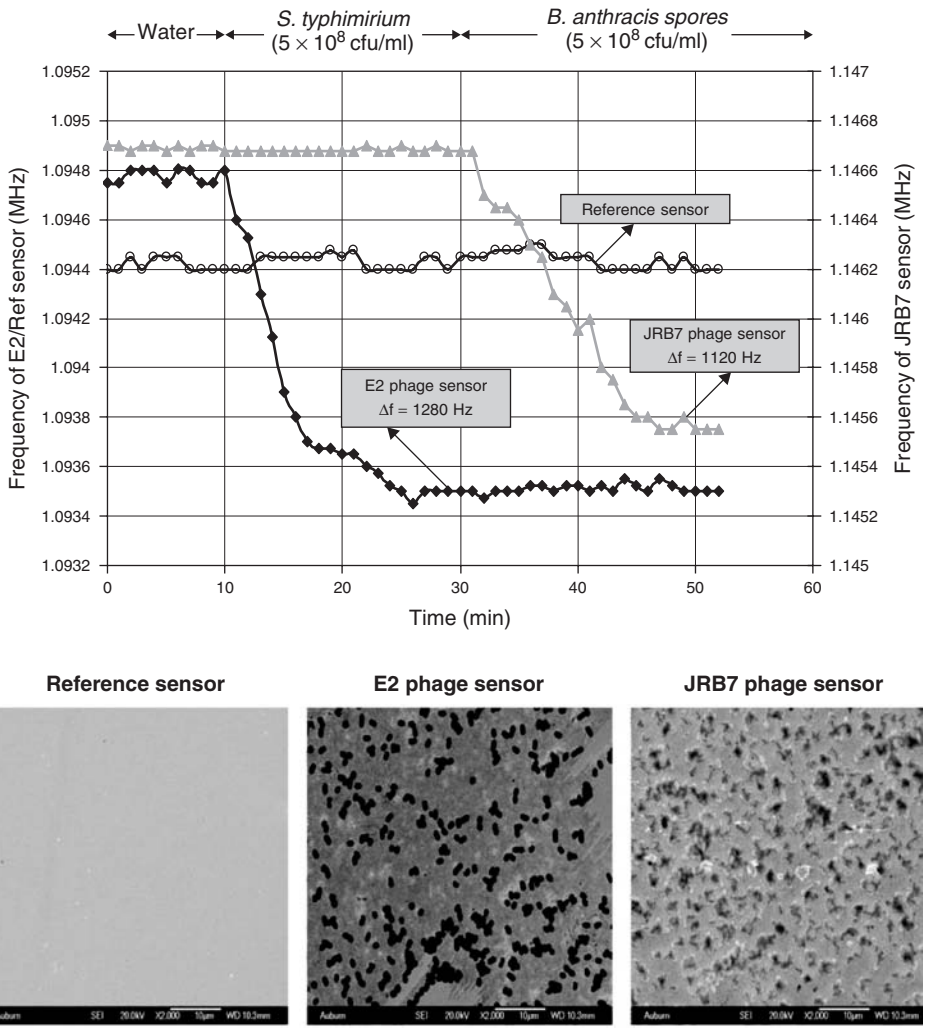

**FIGURE 28** Response curves and SEM pictures for three-diced ME biosensors tested simultaneously when exposed to the bacterial/spores suspension with the concentrations of $5 \times 10^8$ cfu/ml [217].

## 5 OTHER DETECTORS USING PHAGE AS A BIORECOGNITION ELEMENT

### 5.1 Phage Used for Electrochemical Sensing

Bacteriophages have been used as biorecognition elements for other types of biosensors. Neufeld et al. [245] developed a novel amperometric detector by combining phage typing and the related release of an intrinsic enzyme to specifically identify and quantify *E. coli* bacteria. In their work, the enzyme markers ($\beta$-galactosidase), released due to a specific phage-bacteria lytic interaction, react with the substrate *p*-aminophenyl-$\beta$-D-galactopyranoside ($\beta$-PAPG) to produce *p*-aminophenol (PAP).

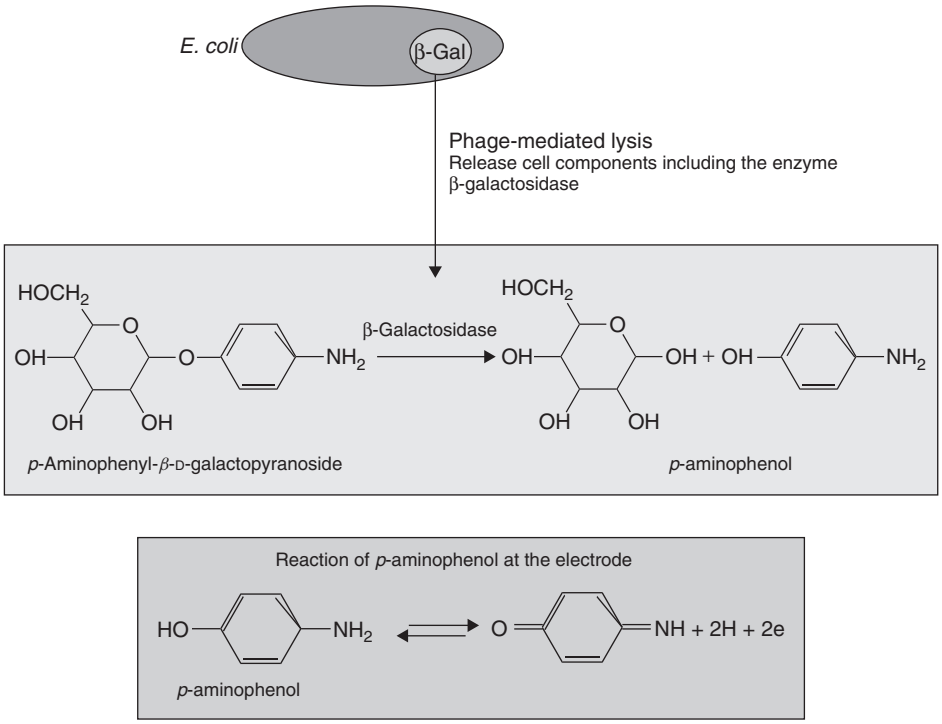

**FIGURE 29** Basic reactions involved in amperometric detection of *E. coli* [245]. In this technique the intrinsic enzyme from the bacteria is released by phage-driven lysis of the cells.

PAP is oxidized at the carbon anode of the amperometric sensor, resulting in an electric current that is proportional to the target bacteria concentration. Figure 29 shows the reaction between enzyme and the substrate that is involved in the detection of *E. coli* using an amperometric biosensor. A similar approach was developed by Yemini [246] for the detection of *B. cereus* and *Mycobaterium smegmatis*. The intrinsic enzymes $\alpha$-glucosidase and $\beta$-glucosidase, released respectively by a specific phage-pathogenic bacteria interaction, catalyzed the hydrolysis of their corresponding substrate to yield PAP. Although the detection limit of this method was 10 cfu/ml, the preincubation step (about 8 h) was required in order to detect the lowest concentration of bacterial suspension. Recently, Seo et al. [247, 248] fabricated a nanowell sensor as potentiometric sensor platform to utilize biochip techniques. After immobilization with a phage, the interaction between target bacteria and the phage results a transitory ion efflux that can be detected by the sensor. This combination provided a rapid pathogen detection technique with good sensitivity and specificity.

## 5.2 Phage Used for Optical Sensing

Affinity-selected phage is a bioprobe used to detect various antigens by labeling with fluorescent/luminescent markers [249]. Goodridge et al. combined fluorescently labeled phage with the antibody-immobilized immunomagnetic beads and successfully detected the *E. coli* O 157:H7 in inoculated ground beef and milk [250, 251]. In their work, the labeled phage interacted with the target pathogen to produce optical signals that are related

to the amount of pathogens present in the food product sample. Goldman et al. [252] employed an optical fiber sensor composed of dye Cy5 labeled phage-displayed peptides as the bioprobe to detect SEB, a causative agent of food poisoning. The phage-displayed peptides used in this method are formed by fusing the binding peptides to the PIII minor protein coat that is located on the tip of the phage capsid. This expression format was less optimal compared with the landscape phage described in Section 4.1.1 above, where the multiple binding sites are realized after modification. The high detection sensitivity of 1.4 ng/well was achieved for this optical fiber method. However, compared to the sensor that utilized antibody as the bioprobe, the signal was weaker and less specific. Blasco et al. [253] and Wu et al. [254] used the phage-mediated release of the enzyme adenylate kinase (AK) as a cell marker for *E. coli* and *Salmonella newport*. In their works, adenosine diphosphate is used as a substrate, while the phage-mediated lysis is used to release AK and adenosine triphosphate (ATP) from the interior of the cells. AK catalyzes to produce large amounts of ATP, which will then react with luciferase to produce luminescence. A detection limit of $10^3$ cfu/ml was reported [253] for this method. Recently, advances in nanotechnology have resulted in a new class of fluorescence-based assays [255–257]. Edgar et al. [258] utilized filamentous phage with surface peptides that were able to interact with the target pathogen cells if there was biotin present in them. Subsequently, quantum dots were used to bind with the phage, and the amount of the target pathogen was analyzed using flow cytometry and fluorescence microscopy.

The examples described above are the indirect phage-based optical methods for foodborne pathogen detection. Direct phage-based methods were also developed where the biological recognition event was measured directly based on the changes in the properties of the light used. Balasubramanian et al. [259] reported a lytic phage-based SPR for the detection of various concentrations of *S. aureus*. In their work, the phage was immobilized onto the gold surface of SPR by physical adsorption. The detection limit of $10^4$ cfu/ml was achieved.

### 5.3 Phages Used for Acoustic Wave Sensing

The combination of phages with AW detectors provides the capability of detecting pathogenic bacteria with high sensitivity and specificity. This advantage makes phage-based AW sensors useful for food safety applications. Petrenko et al. [159] coated a selected phage on a QCM surface for the detection of *S. typhimurium*. Fu et al. [260] immobilized affinity-selected phage on ME MC for the detection of *B. anthracis* spores and *S. typhimurium*.

Table 11 summarizes the literature reports of various assays by using the phage as the biorecognition element for foodborne pathogen detection.

## 6 SUMMARY

Biosensors hold much potential for real-time, field applications to insure the security and safety of our food supply. The development of biosensors is rapidly progressing and within 5 years several biosensors should be commercially available. The development of an alternate to antibody-based detection, that is, phage detection, should greatly improve the robustness and longevity of future commercial biosensors. By using in combination, several different techniques such as biosensors in the field and PCR/ELISA

**TABLE 11 Phage-Based Bioassays for Foodborne Pathogen Detection**

| Transduction | Assay Type and Mechanism | Target | Detection Limit | Reference |
|---|---|---|---|---|
| Amperometric electrode | Phage-induced cell lysis causing release of components (such as $\beta$-galactosidase, $\alpha$-glucosidase, and $\beta$-glucosidase) | *E. coli* (K-12, MG 1655) | 1 cfu/100 ml | 245, 246, 261 |
| | | *B. anthracis* | 10 viable cells/ml | |
| | | *M. Smegmatis* | 1 cfu/ml | |
| Bioluminescence | Luciferase reporter phage | *M. tuberculosis L. monocytogenes* | | 262 |
| Fluorescence | Fluorescently labeled phage in combination with immunomagnetic beads | *E. coli* O157:H7 | $10^2 - 10^3$ cells/ml | 250, 251 |
| Quantum dots | Biotinylated phage and streptavidin conjugated quantum dot | *E. coli* BL-21 | 10 cells/ml | 258 |
| SPR | Affinity-selected phage-immobilized using physical adsorption/SAMs | *S. aureus L. monocytogenes* | | 209, 263 |
| QCM | Phage display technology to engineer display peptides specific to the target analyte. Affinity-selected phage-immobilized using physical adsorption | *S. typhimurium* | 100 cells/ml | 159, 215 |
| Magnetoelastic cantilever | Phage display technology to engineer display peptides specific to the target analyte. Affinity-selected phage-immobilized using physical adsorption | *B. anthracisS. typhimurium* | $10^4$ cells/ml | 260, 264 |
| Magnetoelastic particle resonators | Phage display technology to engineer display peptides specific to the target analyte. Affinity-selected phage-immobilized using physical adsorption | *B. anthracisS. typhimurium* | Depends on size of sensor | 210–212, 216, 217, 221, 232, 264 |

and cultures in the lab, a robust and effective method of detecting food contamination can be implemented.

# MITIGATING PUBLIC HEALTH RISKS FROM AN AGROTERROR ATTACK

CRAIG HEDBERG

*Division of Environmental Health Sciences, University of Minnesota School of Public Health, Minneapolis, Minnesota*

## 1 INTRODUCTION

The public health risks from a potential agroterror attack directed against crops or vegetation could be viewed in a very broad sense as defined by the World Health Organization, or more narrowly in terms of the effects of exposure to specific agents. While it is necessary to consider the social impact of potential agroterrorism attacks when evaluating risk communication strategies for moving from response to recovery, the task of mitigating public health risks needs to start from the perspective of specific agents and exposure pathways.

The first step of mitigation is recognition. The public health system in the United States operates as a highly distributed network of local and state public health agencies that collect information from laboratories, clinicians, and individual citizens. The process of surveillance involves the ongoing collection, analysis, and dissemination of this information to form the basis of public health action [1]. In the surveillance of foodborne diseases this may range from an intervention at a restaurant identified as the source of a highly localized outbreak, to a multistate outbreak investigation involving the Centers for Disease Control and Prevention (CDC) and the federal food safety agencies. Any intentional contamination event would also involve the Department of Homeland Security and law enforcement officials.

## 2 POTENTIAL ROUTES OF CONTAMINATION AND CONSEQUENCES OF AN ATTACK ON CROPS AND VEGETATION

The list of potential agents that could be used in an agroterror attack on crops and vegetation is quite broad. The World Organisation for Animal Health (OIE) publishes a list of animal diseases that are notifiable on an international basis [2]. CDC, similarly maintains a listing of bioterrorism diseases/agents by category [3]. These lists contain a number of infectious agents that could be spread by contamination of crops prior to harvest, at the point of harvest, or during storage and transportation (Table 1). However, the consequences of potential attacks using these agents would be limited by the ability of the terrorists to gain undetected access to the crops and by the stability of the agent on the crop during harvest, transportation, and subsequent processing. For most of these potential agents there is a high degree of uncertainty that an attack would be successful. However, since there could be major consequences from an outbreak associated with

**TABLE 1 Potential Routes of Contamination and Consequences of an Attack on Crops and Vegetation**

| Objectives of Attack | Potential Agents | Routes of Contamination | Consequences |
|---|---|---|---|
| Destruction of crops intended for human consumption or animal feed. | Commercially available herbicides, plant pathogens. | Direct application to crops by hand, water, or aerosol. | Local or regional disruption of supply chains, availability of food or feeds. |
| Contamination of animal feed ingredients with agent intended to harm or kill domestic food animals. | OIE listed diseases transmissible through oral ingestion. | Application to field crops prior to harvest, at the point of harvest, or during storage and transportation. | Direct impact on exposed animals, disruption of trade following diagnosis of disease. |
| Contamination of crops with zoonotic agents intended to harm or kill domestic food animals, and people. | *Bacillus anthracis*, Brucella, Salmonella, Nipah virus. | Application to field crops prior to harvest, at the point of harvest, or during storage and transportation. | Direct impact on exposed animals and humans. Secondary human exposures from affected animals. |
| Contamination of crops and vegetation with bioterrorism agents or diseases intended to harm or kill people. | Botulism toxin, Ricin, *Salmonella typhi*, other foodborne disease agents, chemical toxins, and radiologic agents. | Application to field crops prior to harvest, at the point of harvest, or during storage and transportation. | Direct impact on exposed humans. Possible secondary transmission of typhoid fever, other foodborne disease agents. |

these agents, it is important to understand our ability to recognize and mitigate a potential agroterrorism event.

As described in Table 1, the potential choice of an agent could depend on the intended target for the attack. An attack intended to destroy crops could use a range of commercial herbicides applied directly by hand, water, or aerosol. This type of attack would not even require a high degree of stealth, as once the treatment is applied the consequence would be inevitable. For attacks designed to directly or indirectly affect food, animals, or humans, detection of the contamination event itself would allow for direct abatement of the hazard. The potential for these types of attack is dependent on the availability of an agent and access to a suitable point of contamination. Thus, the relative availability of common foodborne pathogens also increases the likelihood of their use in an agroterror attack.

Most of the relatively few documented intentional contamination events involving food have occurred at the point of retail sale or food service [5]. However, numerous outbreaks of foodborne diseases have resulted from contamination of fresh produce items in the field or at the point of harvest. These serve as useful models for the size and scope of potential agroterror attacks, and for the ability of the public health system to detect and respond to its occurrence.

## 3 DETECTION OF AN EVENT THROUGH FOOD AND ENVIRONMENTAL SAMPLING

Microbiological testing of foods and environmental samples is conducted for a variety of purposes [6]. Testing of food processing lines and environments is generally conducted to monitor critical control points and to validate cleaning and sanitation programs. This type of testing relies on the detection of indicator organisms. Thus, it would not be useful to detect the presence of an intentional contaminant. Pathogen testing of ingredients or end products may be conducted by industry as part of Hazard Analysis Critical Control Point (HACCP) verification, or for lot acceptance purposes mandated by purchasing specifications. Food regulatory agencies sample products in commerce as part of compliance surveillance.

Food monitoring has theoretical potential to prevent an outbreak of disease due to the natural or intentional contamination of foods because it is conducted before the contaminated product reaches consumers [7]. However, many practical issues make it unfeasible to build a robust monitoring program to safeguard the supply of fresh fruits and vegetables. To start with, approximately 70 billion pounds of fresh fruits and vegetables are produced each year in the United States United States Department of Agriculture, Economic Research Service (USDA, ERS). Given the large number of potential introduction points for contamination, some prior knowledge of actual threats would be needed to guide sample selection and test methods. In contrast to many natural contamination events, it is thought that intentional events will involve relatively high levels of contamination. While this will reduce the need for sensitivity in the test methods, it is still likely that the distribution of the agent in the sample will be uneven. In addition, the food matrix and inhibitory substances in the sample could further reduce the sensitivity of the assay [7]. Although an in-line monitoring system for potential bioterrorism agents may be feasible for milk or other fluids, no such system is likely to be useful for fresh produce items.

## 4 DETECTION OF AN EVENT THROUGH MONITORING OF ANIMAL POPULATIONS

Animals represent a potential end target for intentional contamination of crops. Animal feeds could be contaminated with agents intended to directly harm food animal populations or to serve as a transmission pathway for zoonotic diseases to humans. Because of the high population densities of confined animal feeding operations (CAFOs), such an attack would likely result in a localized outbreak of disease among the animals that would be recognized by producers. Depending on the severity of the disease in the animals, diagnostic evaluation by veterinarians supported by state veterinary diagnostic laboratories (VDL) would likely be initiated. In conjunction with the National Veterinary Services Laboratory, in Ames, Iowa, the state VDL would work to identify the agent, and if it were an OIE listed disease, report the event to state and federal animal health officials [8].

Intentional contamination of crops or vegetation could also result in contamination of pet foods. Because pet foods tend to be widely distributed using similar distribution channels as human foods, these events would not be detected because of the localized outbreaks that would be associated with CAFOs. Events involving chemical agents or toxins

would likely resemble the outbreak of illnesses associated with melamine contamination [9]. Detection of this event required the clinical recognition of kidney failure occurring among cats and dogs that consumed a particular brand of pet food. A second example of the impact of pet food contamination was the occurrence of a multistate outbreak of Salmonella serotype Schwarzengrund infections in humans. At least 62 persons from 18 states were infected as a result of direct or indirect exposure to Salmonella-contaminated dry dog food [4]. Interestingly, no illnesses were reported among the dogs in the households. The detection of this event highlights the importance of human disease surveillance systems to detect and mitigate public health risks associated with animal feed as well as human foods.

## 5 DETECTION OF AN EVENT THROUGH HUMAN DISEASE SURVEILLANCE

Given our limited ability to detect contaminated food products before they enter commerce, the interval between the occurrence of a food system event, its detection, and the subsequent response by the public health system is a key determinant of the potential impact. Most foodborne outbreaks are localized and are investigated and controlled by local or state public health authorities. However, as demonstrated by the dog-food associated Salmonella Schwarzengrund outbreak, multijurisdictional events may be large, widespread, and require coordination between multiple state and federal agencies.

In the United States, foodborne disease surveillance is generally conducted under the authority of communicable disease reporting rules [10]. These rules are established under individual state laws, and vary by states. In many states, responsibility for foodborne disease surveillance is assigned to local health jurisdictions. In some states it is either shared between local and state levels or retained by the state. Disease reporting rules typically identify a list of specific diseases that should be reported to local or state officials when they are clinically diagnosed or confirmed by laboratory testing. The lists of reportable diseases vary by state, but typically include diseases for which some specific public health intervention is needed. The states and CDC have developed a list of diseases for which information should also be collected on a national basis. Table 2 lists selected nationally notifiable diseases that may be transmitted by food. States voluntarily report to CDC the numbers of these cases reported at the state level. However, due to state privacy laws, and federal Health Information Privacy Assurance Act (HIPAA) regulations, identifying information from individual cases is not generally reported to CDC.

Three main types of surveillance have been used for the detection of foodborne disease infections and outbreaks (Table 3). These include consumer complaints, pathogen-specific surveillance, and syndromic surveillance.

Most foodborne outbreaks are identified as a result of consumer complaints. These complaints are generated after two or more people become ill with similar symptoms after sharing meal(s) together. In most cases the complaints are made within a couple days following onset of symptoms, and the complainants have usually not sought medical care or had any laboratory testing done. Occasionally the complaint will be made after an individual consulted a health care provider and was given a diagnosis of “food poisoning”, and rarely, will a health care provider notify public health officials that they suspect a patient may be part of a foodborne outbreak. While complaints are a timely way of identifying outbreaks associated with individual events or establishments, complaint

**TABLE 2 Selected Nationally Notifiable Diseases which may be Foodborne. From CDC [4]**

- Anthrax (gastrointestinal)
- Botulism (foodborne)
- Cholera
- Cryptosporidiosis
- Cyclosporiasis
- Giardiasis
- Hemolytic uremic syndrome, postdiarrheal
- Hepatitis A, acute
- Listeriosis
- Salmonellosis
- Shiga toxin-producing *Escherichia coli* (STEC)
- Shigellosis
- Typhoid fever

systems are generally operated by local public health agencies with no aggregation of data on the state or federal levels. These independent complaint systems are unlikely to detect multijurisdictional events of the type that may be expected from intentional contamination of a food product at the point of production. To do so would require linking multiple outbreak events to a common agent and then to a common food item or production source.

One important quality of complaint-based detection systems is the ability to identify a new disease causing agent. Because the occurrence of the outbreak is based on similar symptoms occurring following a common exposure, the investigation of the outbreak can also involve a detailed laboratory-based search for the agent. For example, *Escherichia coli* O157:H7 was identified as a foodborne pathogen following the investigation of several outbreaks of bloody diarrhea associated with fast-food hamburger restaurants [11].

In contrast to the flexibility of complaint-based surveillance to identify new agents, pathogen-specific surveillance involves the reporting of individual cases of diseases such as *Salmonella enterica* or *E. coli* O157:H7. Because molecular subtyping of these organisms can be conducted to provide a very specific case definition, it is possible to link cases over a multistate area to a potential common source. CDC has established a public health laboratory-based molecular subtyping network for foodborne disease surveillance (PulseNet). PulseNet combines standardized methods for subtyping foodborne disease pathogens by pulsed-field gel electrophoresis (PFGE) with electronic file sharing to provide a national framework for pathogen-specific surveillance [12]. Specific exposure information must be separately obtained through follow-up interviews with individual cases. PulseNet also provides opportunities for linking data on pathogens identified as part of food, animal, or environmental monitoring programs to enhance human disease surveillance.

The third major type of surveillance for food event detection involves the monitoring of clinical events independently of a specific etiology. This is called *syndromic surveillance* because it tracks the occurrence of disease by manifestation of symptoms such

**TABLE 3 Characteristics of Outbreak Detection Systems Used in Foodborne Disease Surveillance, and their Potential to Mitigate Public Health Risks from an Agroterror Attack**

| Characteristic | Consumer Complaints | Pathogen-specific Surveillance | Syndromic Surveillance |
|---|---|---|---|
| Diagnostic information | Set of symptoms experienced by persons following a common food exposure. | Diagnosis of specific foodborne agent. May include detailed subtype information to facilitate cluster detection. | Increased occurrence of disease (e.g. diarrhea) in reference population, without identification of specific agent. |
| Exposure information | Common food exposure—subject of complaint. Additional exposure information may be obtained through interview at time of initial complaint. | Demographic information reported. Specific exposure information may be obtained through follow-up interview. | Identity, demographics, and contact information regarding individuals may be obtained by review of records following signal detection. Specific exposure information may be obtained through follow-up interview. |
| Outbreak types detected | Outbreaks associated with facilities or events. Can detect outbreaks caused by new or unknown agents. | Local or widespread outbreaks caused by specific pathogen under surveillance. | Outbreaks involving unusual clinical manifestations suggesting a new disease, or very large, community-wide outbreaks due to norovirus. |
| Potential to mitigate public health risks from agroterror attack | Multiple outbreak events could be linked to a common agent and then to a common food item or production source. | Widely dispersed, individual cases could be linked to a common food item of production source. | Cases with new disease syndrome may be linked to a common food item or production source. |

as diarrhea. As seen in the example of kidney failure in dogs and cats associated with melamine-contaminated pet food, surveillance for unusual syndromes can be very useful. However, syndromic surveillance for gastrointestinal illness has not proved effective at detecting specific foodborne disease events. For example, in 2001, the New York City Department of Health implemented a surveillance system for gastrointestinal illness seen in hospital emergency departments [13]. Over a period of 3 years, 98 citywide signals indicating increased occurrence of gastrointestinal illness were received. Seventy-five percent of these occurred during seasonal outbreaks, and none of the 49 actual outbreaks of gastrointestinal disease reported to the City Health Department during this time period was detected by the syndromic surveillance system [13]. Thus, this surveillance was neither sensitive nor specific for the occurrence of foodborne outbreaks, and unlikely to be useful for mitigating public health risks associated with an agroterror event.

## 6 OUTBREAK INVESTIGATIONS: THE ROLE OF EPIDEMIOLOGIC METHODS TO RAPIDLY IDENTIFY THE SOURCE AND GUIDE CONTROL STRATEGIES

Many of the agents responsible for outbreaks of foodborne disease may also be transmitted by other routes, such as waterborne, zoonotic, and person-to-person. It is not always possible to determine the route of transmission by identifying the agent or the clinical presentation of the outbreak. Thus, identifying the route of transmission is an important objective in many outbreak investigations and is critical for implementing effective control measures. The overall goal of an outbreak investigation should be to rapidly obtain sufficient information to implement specific interventions to abate the outbreak, or to determine that no specific interventions are warranted.

The process of epidemiology involves the careful description of events and comparison of rates between groups. In foodborne outbreak investigations this involves comparing food histories between outbreak-associated cases and a comparison group of controls who do not appear to be part of the outbreak.

The epidemiological investigation proceeds as follows:

(a) An outbreak case definition is established based on characteristics of the agent that led to detection of the outbreak. For many bacterial pathogens this is based on PFGE patterns or other reproducible molecular characteristics.
(b) Outbreak-associated cases are characterized by person, place, and time to identify patterns that may be associated with particular food items or diets.
(c) Individual cases are interviewed as soon as possible, with a standardized "trawling questionnaire" to identify potential common exposures.
(d) "Trawling questionnaire" exposure frequencies are compared against FoodNet Atlas of Exposures to identify the suspect food item.
(e) Nonill community controls or nonoutbreak-associated cases are interviewed to obtain detailed exposure information to be used in a case-comparison analysis of exposures.
(f) Brand names and product code information for prepackaged food items are documented; distribution sources for commodity food items are identified.
(g) Exposure information is analyzed to compare cases with relevant comparison groups (e.g. nonill controls or nonoutbreak-associated cases) to implicate the food item or nonfood exposure source.

Using these methods, commercial ice cream was identified as the source of a nationwide outbreak of *Salmonella enteritidis* infections within 2 days of the start of the investigation, and 10 days before the outbreak strain of Salmonella was isolated from intact packages [14]. More recently, pot pies were identified as the source of a nationwide outbreak caused by a monophasic Salmonella strain within 2 days of the start of a multistate case-control study, even though pot pies had not been identified by previous hypothesis generating interviews [15]. Furthermore, details of the exposure histories provided important clues to identify how the products became contaminated.

The speed with which outbreak investigations are conducted depends on the agent, the number of cases associated with the outbreak, and where the cases occur. Since

most foodborne illness investigations are conducted by local or state public health or food regulatory agencies, the resources available to the agency and the motivation of the agencies staff are important considerations. In a study of the timeliness of enteric disease surveillance in six US states, the median interval from onset of symptoms to collection of stool sample was 3 days for *E. coli* O157:H7 and 4 days for Salmonella [16]. Cases of both pathogens were reported from the clinician to the health department 2 days after the culture result was available. Approximately half of the *E. coli* O157:H7 cases, but only 20% of Salmonella cases were contacted by the health department on the same day the report was received. The differences in response between Salmonella and *E. coli* O157:H7 are a clear reflection of the increased public health importance that is placed on *E. coli* O157:H7. Differences in response to sporadic infections also affect the speed with which outbreaks are identified. In the same timelines study, the median interval from onset of symptoms to outbreak detection was 8 days for outbreaks due to *E. coli* O157:H7 and 16 days for outbreaks due to Salmonella. These time intervals reflect delays both in conducting interviews and in PFGE subtyping.

Because of the importance of molecular subtyping to outbreak detection and response, the speed with which public health agencies respond to detected clusters of cases determines the potential to mitigate the public health risks from an outbreak. In 2001, the National Food Safety System (NFSS) Project, Outbreak Coordination and Investigation Workgroup published guidelines to improve coordination and communication among multiple states and federal public health and food regulatory agencies investigating multistate foodborne outbreaks.

From 1998 to 2003, 56 multistate outbreaks with known etiology were investigated. Of these, 31 (55%) were due to Salmonella and 10 (18%) were due to *E. coli* O157:H7. These accounted for 4% of Salmonella and 7% of *E. coli* O157:H7 outbreaks reported to CDC's Foodborne Outbreak Response and Surveillance Unit during this time period. However, these estimates do not account for other outbreaks with multistate distributions of cases that were not identified as multistate outbreaks. Since surveillance methods employed at the state level are not tracking exposure sources, *per se*, it is important that public health officials account for outbreaks with multistate distributions of cases from a common exposure, as well as outbreaks resulting from multistate exposures.

The median intervals (and ranges) from onset to outbreak recognition were 18 (8–19) days for *E. coli* O157:H7 and 23 (10–48) days for Salmonella. Median intervals (and ranges) from onset to outbreak recognition were 21 (2–24) days for outbreaks detected by complaint, 10 (5–12) days for case report and follow-up, and 22 (7–48) days for PFGE subtype.

Median intervals (and ranges) from outbreak recognition to intervention were 7 (1->72) days for outbreaks investigated by a single state and 18 (6–62) days for multistate outbreak investigations. Interventions were made within 8 days in 8 of 21 multistate outbreaks reviewed. Investigations were conducted primarily by single states in six (75%) of these. Thus, where individual states can take a lead role in multistate outbreak investigations, this appears to be a more efficient investigation strategy. Strong leadership by individual states in multistate investigations will promote faster and better targeted mitigation strategies.

## 7 MITIGATING PUBLIC HEALTH RISKS: MOVING FROM RESPONSE TO RECOVERY

Following an attack on the food system, there will be several key elements involved in the move from response to recovery. Most importantly, these include the size, scope, and severity of the event. However, the speed with which such an attack is recognized and controlled will certainly affect all of these measures. In this regard, enhancing the capacity of our foodborne disease surveillance system to rapidly investigate all foodborne disease outbreaks will be critical to positioning our food system for a rapid recovery from an agroterrorism event.

Communication with the public will be critical in our efforts to recover from an agroterrorism event. The public will look for assurance that we have identified the problem, effectively abated it, and developed plans to prevent its recurrence. The effectiveness of these communication strategies will depend on how well our investigations address these issues. Rapid and comprehensive epidemiologic investigations with detailed exposure assessments will be critical to finding the answers of when and where the attacks occurred, if not always the who and why.

## 8 SUMMARY AND CONCLUSIONS

The threat of an agroterrorism attack against crops and vegetation poses a great risk to public health and the integrity of the food supply. Our ability to keep contaminated foods and animal feeds out of the marketplace is limited. The lessons we can take from our experience investigating large widely distributed outbreaks are directly relevant to the challenges of agroterrorism.

Our detection methods must be sensitive and our investigation methods specific. We must conduct our investigations with a sense of urgency and the belief that we can make a difference. Epidemiology can be a powerful tool to detect events, identify their source, and mitigate their consequences.

# PROCESSING AND PACKAGING THAT PROTECTS THE FOOD SUPPLY AGAINST INTENTIONAL CONTAMINATION

SCOTT A. MORRIS

*University of Illinois at Urbana-Champaign, Urbana, Illinois*

## 1 INTRODUCTION

Too often, the first reaction to a social problem is to attempt to find a technical solution, when technology cannot overcome social problems, only their means and circumstances. Although there are some processing and packaging steps that can be taken to indicate intentional contamination of food, it is not possible to add a simple, inexpensive component to existing systems to prevent a determined attack: real solutions are always imperfect, often more complex and usually more difficult.

Quite apart from malicious human efforts, nature has been attempting to contaminate food products since the first drying and salting of grains, meats and vegetables provided for a longer-duration food supply, and most food processing operations have a culture of quality that is intrinsically designed to work against these threats. Many of the efforts in large-scale food contamination have been directed at detection of outbreaks of food poisoning in the population and then remediation after an outbreak occurs. The food industry, which is usually quite careful about quality and safety, already has coding and recall management practices in place. These have historically worked very well after problems are detected, but assume that the producer is acting in good faith; that the inspection, notification and recall systems operate as they are supposed to; and that the product itself is not counterfeit.

Packaging, which is intrinsically designed to protect the product against many natural and man-made hazards, may protect against pilferage or low-level postprocessing contamination of products, but the most that can be achieved for many products at any practical cost and production level is an indication of tampering. Additionally, the requirements for global outsourcing of manufactured products, ingredients and components; global markets for finished goods, the persistent push to minimize the

costs of ingredients and packaging systems; ceaseless just-in-time logistics systems that have replaced warehouses; and perpetual demands to maximize productivity impede many types of proactive contamination prevention.

As a result of these and other factors that are discussed in this article, there is no magic gadget that can be added to the food processing packaging and distribution system to make it perfectly safe against intentional contamination. What can be done is to assess and manage risks responsibly and appropriately, implement detection steps and improvements in technology where needed to make contamination difficult at all points in the food system, and to ensure that a response system that is capable of remediating problems on a timely basis is in place. This would represent a substantial improvement on the current system.

## 2 PROCESSING

Intentional contamination or destruction of the food supply, usually through "agroterrorism" (malicious disruption at the crop level) has been a historic strategy for the disruption of populations and a long-standing fear during wartime. In a world increasingly occupied with asymmetric warfare on many different levels, the threat of a subtle toxin or custom-tailored organism pervading the food system is an increasingly viable threat. These agents may be introduced at some point in the manufacturing and distribution process, between harvesting the raw commodity and consuming the finished product, in order to reach a much larger percentage of the population with less chance of detection than with simple package tampering.

Food processing systems are designed to produce a product that is safe and stable within its distribution environment. That environment might range from long-term shelf-stable foods such as cans, jars and Meals, Ready to Eat (MRE) rations for the military to shorter-duration products such as dairy products, bagged salads and refrigerated "fresh" pasta. Historically, processing has involved either altering the food to make it inhospitable to spoilage organisms with processes such as drying or pickling, or applying thermal sterilization (and moderate toxin denaturation in some cases) followed by containment in a hermetically sealed container that prevents recontamination. Newer preservation methods have involved controlling the temperature throughout the distribution cycle to retard growth, and alternative methods of sterilization and containment have been developed, but the principle remains essentially the same.

The implementation of Hazard Analysis and Critical Control Point (HACCP) requirements for food processing plants has provided tools to find and manage vulnerabilities to naturally occurring hazards. HACCP can also provide optimal points for assaying for contaminants or inspection for disrupted seals or counterfeit goods, if analytical tools are available that can detect the agent used. Increased registration and security requirements for food processing plants have reduced access to the production facilities and the use of operational risk management (ORM) strategies taken from the aerospace industry (which faces critical dangers as a matter of course) have provided tools to help develop situationally appropriate safeguards [1]. Balancing this are high employee turnover rates and the difficulty of documenting workers, the broad range of ingredients from multiple sources that may be shipped without tamper indication or verification systems, as well as reliance on Certificates of Analysis for ingredient safety rather than verifiable in-house testing. Many of these factors leave the system open to attack.

On a larger scale, processed food production is run on a "Just-in-Time" paradigm that distributes product as quickly as possible and makes "catching" contaminated products before sale very difficult if there is any delay between detection of contamination or illnesses and the issuance of a recall and warnings. This delay may allow a contaminated product to be distributed and consumed by a broad segment of the population, turning a containable incident into a debacle. An example of this is discussed subsequently.

### 2.1 Counterfeit Products and Ingredients

Counterfeit products in the United States precede the revolutionary war; one of the complaints Britain had against its colonies was that British containers were being refilled and resold with a variety of products of dubious quality. Indeed there is evidence that colonists imported empty bottles from Britain for the sole purpose of counterfeiting or mimicking British products [2]. Since then, most counterfeit products have been concentrated around objects of small physical size, difficulty of verification and very high value which maximizes the return/risk benefit for the counterfeiter. Counterfeit designer watches are much more lucrative that counterfeit potato chips and counterfeit pills are very easy to make and immensely profitable. Because of this, governmental anticounterfeiting efforts in the food, drug and cosmetic milieu have been prominently focused on the pharmaceutical industry due to the immediate harm done to the consumer, although the cosmetics industry faces a booming expansion in counterfeit, copycat and "parasite" goods, that are often severely contaminated (and often attract buyers who are not willing to pay for the "real thing" but are unaware of the risks) [3, 4].

Counterfeiting of drugs in the United States has become an item of considerable concern since diluted and nonsterile Procrit® and Epogen®, were held responsible for deaths and illnesses in 2002 and Lipitor® tablets in 2003 were found to be counterfeit [5–7]. This has been addressed by increased requirements for verification and distribution traceability, something that the pharmaceutical industry had avoided on a cost basis for some time but is finally coming into practice with bar codes and other technical additions in Europe and elsewhere [8].

Counterfeiting (or product swapping) of foods items has long been a problem with luxury items such as high-value spirits, wines and foods. Counterfeiting of more general foods is less likely unless there is a combination of high financial or tactical value and ease of manufacturing counterfeits [9]. One of the food categories that shows an ongoing problem with counterfeiting is seafood, of which approximately 80% is imported into the US. Because seafood is difficult to identify after processing, it has been misrepresented for years and can be deliberately mislabeled as a high-value species to increase profitability. This fraudulent mislabeling carries the risk of illness or death from both intrinsically toxic species, and species that have absorbed dietary toxins. In 2007, a seafood importer was found to have mislabeled seafood containing puffer fish (which carry tetrodotoxin, a potent neurotoxin with no antidote) as monkfish [10]. Subsequent congressional inquiries highlighted the low rate and poor coordination of safety or security inspection in seafood imports [11].

## 3 PACKAGING

Packaging plays three general primary functions in modern consumer usage; protection, utilization and communication. While the protection function is often thought of

as protecting a product against damage or contamination, in the case of a particularly dangerous material (nuclear fuel rods, for instance) the primary purpose is just the reverse—protection of the general environment against the product itself. Beyond that, the most fundamental function of nearly any type of food packaging is to protect the product against postprocessing contamination and quality loss. Since Mother Nature is constantly providing clever and relentless threats to degrade or contaminate products, packaging has always had a role to play in this regard, and the intentional human element is a very small component of the challenges that most food packaging resists on a continuing basis.

From a security standpoint, packaging can thus be thought of as implicitly resisting intentional contamination to a large degree, but with the added utility of potentially being able to indicate when intentional tampering has occurred, either as an intrinsic feature of the design or as a result of an added component or design feature. This capability is usually balanced against the perception of packaging as an expense to be minimized during high speed production, and the requirement that the indicator must be both robust and accurate.

Packaging also has the capability of communicating, most often using label copy or other printed material but other communication measures may be used as well. Part of a security system for particularly vulnerable assets may thus involve communicating a verification code, as well as displaying an intact tamper-evident device, although these approaches have many weaknesses as well.

Finally, packaging must have some utility. It is possible to create an impenetrable package for food products, but they would be prohibitively expensive, difficult to mass-produce on the astronomical scale required for some food packages (the United States alone consumes more than a quarter-trillion packaged soft drinks per year), and would defeat use by the consumer.

### 3.1 Packaging and Safety Assurance

For packaging systems, the assurance of a product's integrity and safety is involved in several roles—borrowed from cryptography—that can be described as authentication, integrity and non-repudiation [12]. The first of these, authentication, is the assurance that the product is that which is described on the label and not a counterfeit from another producer. As is discussed in more detail, this is the more likely scenario for a broad-scale breach of food integrity at the ingredient level, since it is both easier to implement and more effective in disrupting entire segments of the food supply.

The second, integrity, assures the customer that the product in the package has not been modified after production whether by the substitution of other goods or contamination of the existing product. There are historical precedents for this, the most notorious being the contamination of Tylenol in the 1980s that led to stricter requirements for over-the-counter (OTC) drug packaging and began the process of tamper-indicating packaging components. Although this particular method of disrupting consumer confidence in a product may be somewhat effective and is very expensive to the product manufacturer, it is less effective at inflicting actual widespread harm or disrupting sales of a broad class of products since tampering is typically tightly confined to a single geographic region or product.

The final function, non-repudiation, ensures that the original manufacturer cannot deny producing the product (in effect, verifying that they have produced it). Non-repudiation is seldom considered in manufacture of physical items, but warrants discussion since it

bears directly on the issue of plausible deniability by a manufacturer that the product is not something that they are responsible for, and are therefore absolved both from the responsibility for its production and from any liability from the harm it caused. In a litigious economy that is increasingly outsourcing its consumer goods and many kinds of food from a broad multitude of globally distributed manufacturing operations and contract operations, this issue may prove increasingly important.

### 3.2 Requirements for Tamper Evidence

The first tamper-evident requirements were applied to OTC drugs after the Tylenol tampering episode in 1982. Few, if any, of these devices provide substantial protection against even a marginally skillful person with modest resources; this is a favorite challenge for clever students who generally have little trouble with them. While other countries that have adopted tamper-evident packaging requirements have been much more specific in their material, structure and printing requirements [13], current regulations for OTC drugs in the United States simply demand that

> "Each manufacturer and packer who packages an OTC drug product (except a dermatological, dentifrice, insulin, or lozenge product) for retail sale shall package the product in a tamper-evident package ... having one or more indicators or barriers to entry which, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has occurred [14]."

Many of the tamper-evident and "freshness" seals on foods and pharmaceuticals can be defeated quite easily, although they do provide indication of pilferage to consumers (and a very good seal for many products, at the expense of annoyance at having to remove them). Unfortunately, there is no legal requirement for tamper evidence or counterfeiting protection in the food supply chain beyond due diligence, good manufacturing practices, record-keeping and perhaps quality assurances for ingredients and components. There are only voluntary guidelines and similarly worded guidelines for food importers, dairy processors, and general food producers, processors and transporters to address this issue:

> "inspecting incoming products and product returns for signs of tampering, contamination or damage (for example, abnormal powders, liquids, stains, or odors, evidence of resealing, compromised tamper-evident packaging) or "counterfeiting" (inappropriate or mismatched product identity, labeling, product lot coding or specifications, absence of tamper-evident packaging when the label contains a tamper-evident notice), when appropriate." [15–17]

While these guidelines urge reliance on broadly based ORM strategies rather than singular technical devices—an effective strategy when properly implemented—one of the most prominent weaknesses in the integrity of the food supply is the specter of unremediated, ingredient-level contamination. Tampering with a single product may destroy sales of that particular product until the crisis is resolved, but tampering with a commodity-level ingredient can result in a broadly distributed incident that not only harms consumers but can destroy confidence in the entire class of materials.

### 3.3 Tamper Indication Devices

Some tamper indicators have been successfully used for many years. The vacuum in traditional canned foods has been seen to be an indication of both physical and microbial

integrity, and consumers are almost universally aware that a swollen or damaged can or a jar with without a vacuum should be discarded. As packaging moves to lower cost and more material-efficient structures, the indications of integrity are much simpler; for example, an undamaged or unopened pouch or aseptic pack, but there is no secondary indicator (such as vacuum) to indicate integrity and the seals are easily duplicated or repaired after tampering.

By contrast, a package that is intrinsically difficult to construct, fill and seal such as a modern soft drink can, provides a much higher degree of resistance to intentional contamination. The delicacy of the structure, pressurized contents and single-use opening would require the use of extremely specialized equipment and processes to duplicate effectively. While this is not completely unlikely, since everything from nuclear reactor parts to hundred dollar bills are counterfeited on a regular basis [18, 19], it raises the stakes considerably and drives serious tampering efforts toward a more efficient, upstream means of disrupting food supplies. Many of the most effective tamper evidence devices are integral parts of the package that must be visibly and irreversibly damaged to gain access to the contents of the package. The most annoying of these can actually restrict access to everyone—the theft-resistant clamshell packaging around small electronic devices is a good example—but they are effective. Some of these date back before the Tylenol incidents created a flurry of new devices, and were intended to prevent pilfering, or dilution of alcoholic beverages [20]. Newer developments are aimed at a broader market, but operate in a similar manner of permanently locking or fusing together during assembly and requiring obvious destruction to access the contents. For tamper evidence to really come into its own, it must be something other than an afterthought in a product component that is often regarded as an annoying expense to be minimized while choosing among standardized components and processes. Designed-in rather than added-on tamper evidence that requires irreversible disruption of the basic package structure to gain access to the product would be a considerable improvement for many stock package types and components.

### 3.4 Add-On Indicators

Add-on indicators are usually shrink bands around the package closure, a tape seal that may include a holographic pattern, laminate, or other optical feature that is relatively hard to duplicate by a casual tamperer, or a seal under the main closure that is inductively fused to the container and must be removed before the product can be used. Hidden coding on the package or optical microparticulate taggants in the product itself may also be added to make tampering or counterfeiting more difficult. This will deter casual pilfering or tampering but is unlikely to defeat the use of duplicate packages or other more complex attacks. Often these seal indicators can be "lifted"; removed and transferred to another package as well.

Most of the add-on indicators are very low cost and require very few resources to defeat. Moreover, consumers are not readily aware of them unless they create a nuisance factor. Most consumers would presume that a first squeeze of catsup that occurred without stopping to remove the seal to be a blessing. Further, since there are few requirements and no standardization, a case or shipment of bottles with a uniform type of seal added to the entire lot after contaminating the product would not be recognized as different or as unsafe. What is required is a move to higher design standards, already achieved in many industries from automobiles to electronics, where quality of tamper evidence is

designed in from the start rather than added as an afterthought. This, like the soda can, will require a much higher level of infrastructure to duplicate, and will therefore further deter the casual tamperer.

Unfortunately, tampering indicators and particularly add-on tamper indication such as holographic films and patterned adhesive tapes suffer from a form of the "banknote paradox". They need to be so well standardized that they are well known to the users (and can easily be spotted when something is amiss), but that standardization makes their counterfeiting more beneficial since there will be a wider range of products for them to be used on. This in turn drives the engraving and printing of banknotes into an ever-escalating spiral of elegant anticounterfeiting technology with counterfeiters often close behind (or in some cases ahead of) the legitimate users. For a single-use item that must be of minimal cost such as antitampering tape, bands or stickers—primarily added to demonstrate due diligence—the same kind of spiral could drive it out of existence. Manufacturers are already increasing the level of printing sophistication and therefore, cost in some types of seals.

The main reason that this has not been a substantial problem to date is that there have been few store-level malicious tampering attacks. Also there is little direct benefit from counterfeiting the tamper evidence devices (unlike counterfeiting currency), and obviously damaged products produced by clumsy tamperers are not recognized as such and are quickly discarded at some point in the distribution chain as having been damaged in transit or during display.

### 3.5 Proactive Devices

Although still experimental, work has been done to develop packaging structures and materials that will actively indicate other conditions that pose a threat to the safety of products. In the food industry, there is a great deal of interest in indication of microbial growth and temperature abuse. Temperature abuse, which may result in spoilage, must integrate time and ambient temperature exposure to create a thermal profile. This has been achieved relatively inexpensively with electronic devices, but most devices that have been marketed use a chemical reaction analog that attempts to mimic the heat transfer and thermodynamic properties of the product-package system. Other RFID-based devices have been developed to indicate tampering via RFID signal, or use GPS data to report or record distribution route disruption but are typically used on large, high-value products. On-package indicators that are accurate and cheap enough to be widely used are still being pursued and must meet an extraordinarily low price level.

Similarly, work is being done on indicators that use binding-site chemistry to indicate specific spoilage organisms or toxins, but these suffer from the threat of false-positive indication as well as their own specificity; a broad spectrum detector would require a broad array of specific indicators and would be complex and prone to a high false-positive rate. Single-hazard detectors are finding potential markets in rapid detection testing for production systems to provide fast, accurate quality control and indication of contamination [21]. Having rapid detection methods will lower the cost and increase the accuracy of screening for some hazards to the point where even small manufacturers can have a good degree of product safety assurance based on their own data, rather than assurances from suppliers that deflect liability. This would be an enormous "grass roots-level" improvement for detection, interruption and containment of contamination episodes.

### 3.6 Optical Systems

Since many of the systems rely on customer inspection, specialized readers may not be available, but there is a wide range of sealing materials and devices that can aid in authentication as well as tamper detection if properly constructed. These usually depend on specialized printing processes and materials that require technical sophistication to produce, which will reduce the likelihood of casual counterfeiting and tampering, but as with the $100 "supernotes", are not impossible to duplicate given sufficient resources. Indeed, many of the "speciality" features such as color-shifting inks and fracture-evident dyes can be approximated with materials purchased in art supply stores. Holographic images, microprinting, frequency-specific pigments or additives that react to certain wavelengths of light and may change when damaged, and retroreflective or interferometric imagery that may contain both overt and covert features—often requiring a specialized viewer to resolve—can reduce counterfeiting or alteration. Many similar features are used to authenticate drivers' licenses.

### 3.7 Physical "Token" Systems and RFID

Wax and clay seals date into prehistory as a means of guaranteeing the authenticity of documents and products, and the inclusion of a physical verification token that is difficult to reproduce might offer some protection against counterfeit products. Software from major manufacturers has often been shipped with a complex authenticity seal that includes activation codes useable only with that copy. RFID devices carrying an authentication code encrypted in memory also have been proposed but neither of these systems, nor most systems relying on a physical object, eliminate the problems of "lifting"—removal of the token or indicator from one product to use in another—very well, and are still too expensive for individual consumer food package use. Additionally, some simpler RFID systems are quite easily cloned or have their encryption broken, even at a distance, and are the subject of a great deal of controversy because of their widespread use in passports, bank cards and other devices [22–24].

### 3.8 Product Authentication

For products such as pharmaceuticals that are increasingly targets of counterfeiters and potentially targets for attack, authentication systems have begun to be implemented. For food products, most of which already carry batch coding of some type, there is less impetus for these both because of complexity and cost. These systems typically depend on one or several systems for authentication which may include bar codes, special printing features such as moiré images and light-frequency-specific inks and product taggants that require a reader to translate, or numeric codes that can be verified via websites.

A more intriguing possibility lies with the potential to trap contaminated products during distribution or at the final point of sale by interfacing with inventory or point of purchase data systems to flag products as they are being shipped, shelved, and checked out of the store. This would require that current Universal Product Code (UPC) coding schemes include batch number information, but would also return low-cost data about batch shelf-time and turnover of product, something that still is often tediously hand-collected by manufacturer's representatives in stores.

### 3.9 Multipart Authentication

Many secure systems already require multipart identification and authentication. The combination of usernames and passwords on e-mail accounts is a good example. Similarly, the addition of secure authentication methods for encrypted data transfer systems such as PayPal® and others have made electronic commerce possible. Modern combinations of identification and authentication have made the use of private information fairly secure.

For packaged goods, it may be possible to utilize a matched coding system where customers or retailers can authenticate code numbers against batch numbers to verify their authenticity [25]. Similar systems have been used to activate software, cell phones and credit cards for some time. In theory, this could be almost entirely automated and only require a web page lookup for authentication, although this might present other vulnerabilities (website hacking or posting a false authentication webpage and then printing the counterfeit product with the false webpage's address to fool the consumer). The addition of additional features (such as product type, size, count that should be present in the validated product) can add another layer of security since a mismatch of product type or size even with an authenticated code would immediately raise suspicions.

The problem with these types of systems that may be quite useful with relatively low-volume items like pharmaceuticals, is the sheer quantity of material that is handled. Very few busy people will spend time authenticating a week's worth of groceries for a large family, and restaurant operations would be even more hectic than they are already. Instead, most consumers (if they consider it at all) depend on the historical use of media dissemination of information about product recalls based on lot numbers or code systems already used by manufacturers. While this is useful to consumers when problems are spotted and disseminated properly, it does not help to prevent the initial outbreak often required to flag the problem along with the attendant illnesses.

### 3.10 Security and the Base Rate Fallacy

For a security authentication or tamper evidence system to be acceptable, it must both very reliably detect attacks and even more reliably reject "false alarms" and it is usually the latter condition that is hardest to satisfy. Much as a smoke alarm that goes off at the slightest provocation is quickly disabled, safety indicators or systems that are constantly inaccurate are quickly disabled, discarded or ignored. Given the billions of units of packaged food handled daily, even an improbably small percentage of false alarms can cause large numbers of people to ignore the indicators or, worse, to panic over many perfectly good products being flagged. For example; if a detection system has a 0.1% false-positive rate, and the rate of actual occurrence (tampering or contamination) is one in a billion units, surveying a billion units will trigger 1,000,001 alarms (one "true" alarm plus 1,000,000 "false" alarms) and will still only give a one in a million chance of being correct.

For this reason, nearly all attempts at safety measures to ensure rigorous 100% inspection and validation in food manufacturing fail, and indeed this is the reason that many medical tests are repeated after a serious condition is diagnosed [26]. Risk management therefore becomes more a matter of building security into the system beforehand using ORM principles, rather than relying solely on inspecting it after the product is completed, a lesson taken from the "Total Quality Management" (TQM) principles that transformed Japanese manufacturing into exemplars of production quality [27].

## 4 SYSTEM FLEXIBILITY AND RESPONSE

While postprocess contamination is an ongoing concern, the realities of the tactical effectiveness of a contamination, package tampering or counterfeiting episode must be considered in a larger context of both, effectiveness in disrupting confidence in the food supply and ease of implementation. For an attacker to be effective these are both highly desirable results and a food safety system must likewise work to minimize these benefits.

As has previously been discussed, the ability of the existing food safety system to respond in an appropriate and timely manner is a primary component of any food system's security. While it may be minimally possible to shut down an airport in the event of a person bypassing security screening, it would be impossible to shut down the entire food production system. Additionally, few food customers would endure the kind of security screening required at airports to buy a liter of milk on their way home from work. Thus, access control for the food system is only feasible at the production and transportation level, although communication and indicators can be used at the consumer level.

Most retail-level food tampering is either accidental damage or the result of pilfering, often the result of putting candy and cereals on low shelves that children can easily reach. These and other "naturally" spoiled products are usually discarded or held for replacement on discovery by the store staff unless there is an obvious, recurring problem that requires contact with the manufacturer. This provides very little systemic information to guess where failed attempts at malicious tampering may have occurred.

It is difficult to determine under the best of circumstances which of those problems may have been caused by shipping damage, in-store damage or pilfering, or might have been the result of an attempt at malicious tampering. It is similarly unrealistic to expect every food retailer to accurately diagnose and report problems with every unsaleable product they discard. Thus we are left with examining those cases which are clearly the result of contamination or tampering, unfortunately too often involving incidents of injury, illness or death. Once the determination of a contamination or tampering outbreak has occurred, the resilience and responsiveness of the system is an utterly critical part of providing a timely response that does not shut down the entire national food supply.

Because of this, good security systems avoid "brittleness" that is, abrupt shutdown of the asset they are designated to protect when an incident occurs and to fail to or isolate the problem in a "resilient" fashion (i.e. a timely, useful and resource-efficient manner) [28]. Designing these responses in all types of industries is an ongoing, adaptive process (and is somewhat predictive in the best situations) that seeks to minimize the contamination or failure "space" after an incident while maintaining as much of the surrounding network of supply as possible [29]. Unfortunately, incidents that have occurred highlight the fragmented, opaque, uncoordinated, and unresponsive nature of the food safety system which makes it highly vulnerable to a systemic attack even using very simple methods.

### 4.1 Cascading Failure in the Food Processing and Packaging System

Cascading failure is generally defined as a failure that triggers a succession of downstream failures in other elements in a system of some type, such as a failure at a single electrical switching station that triggers a more massive power outage [30]. The food industry processes and combines a myriad of both naturally occurring and synthetic materials to provide our modern diet and this provides a target-rich environment for intentional contamination. Fortunately, nature has preceded this by providing a huge

range of naturally occurring hazards ranging in scale from oxidation to vermin. The food processing industry has had mechanisms in place for many years to inspect critical points during production and then initiate recalls in the event of accidental misprocessing or contamination. It generally works quite well if used in a timely manner.

However, for a response system to be effective it must be used and it must actually respond. Beginning before the events of 9/11, the Government Accounting Office has repeatedly highlighted the fragmented, uncoordinated and resource-poor nature of the food safety system with regard to intentional contamination [31–34]. Additionally, the opacity of the system contributes to delay and inaction. Under current regulations, disclosure of internal safety audits to government officials are not required, and recalls must be requested from company officials, slowing notification and adding delay during outbreaks of contamination [35]. This delay and restriction slows the response of the food safety system, adding to the severity of outbreaks and threatening whole commodity sectors when simple product recalls might have sufficed. No simple change or device for the processing or packaging technology can overcome this. A culture of quality and safety improvement based on improved practices, technology and regulation will have the biggest impact.

### 4.2 Safety System Failure Case Study: Peanut Corporation of America

The incidents of Peanut Corporation of America (PCA) intentionally shipping salmonella-contaminated peanut butter ingredients to other packers and food manufacturers showed the infrastructural weaknesses that may occur when safety measures break down. Inspectors of the plant failed to change practices at the facility, despite a similar incident beginning in 2004, in a similar processing plant owned by Con Agra only 75 miles away that had gone uncorrected for three years after notification of the FDA by a whistleblower, and subsequent company refusal to release test results. Con Agra's problems were only addressed when illnesses were finally reported, and even then their test records were never made public [36]. Although Con Agra completely rebuilt and improved its facility and operating procedures, PCA continued to operate with apparent impunity until deaths and illnesses were reported in 2008–2009, and the failure cascaded outward [37, 38]. A second PCA plant in Texas that was operated producing other nut products was never inspected at all, since it was never registered with the Texas Department of Agriculture although it shipped products nationally. As health problems came to light, other food manufacturers that used ingredients supplied by PCA were abruptly forced to recall nearly 4000 distinct products at tremendous expense, depressing peanut product sales by nearly 25% [39–41].

Many of these products had depended on the supplier's assurance—either informally or with Certificates of Analysis—to ensure the safety of their ingredients (or at least the absolution of liability) since many small operations do not have the capacity to do safety analyses. Thus, a supplier who ships contaminated product as an ingredient that is subsequently used in a plethora of other products highlights both the complexity and vulnerability of the food manufacturing system, and how a brittle failure could cripple an entire commodity sector by destroying public confidence.

From this we can see how an intentional incident could easily be caused by simple contamination or counterfeiting of a commonly used ingredient that is distributed through a system where the safety measures have broken down or are being ignored. Since food ingredients are not subject to even the minimal regulatory requirements of tamper

evidence applied to other products, and since there is often very little distinctive printing or packaging involved, the potential for contamination and counterfeiting are enormous. Often the only motivation for ingredient manufacturers to supply validation or tamper evidence features is the threat of involvement in legal action, and so as with consumer products, they tend toward the minimums necessary to prove due diligence on the part of the supplier. This may be a numbered tag or seal that must match the invoice that may have been sent separately by e-mail or fax; an excellent start, but hardly proof against a diligent tamperer.

## 5 CONCLUSION

While there are many types of technology that are being developed to make the food production and packaging system more secure, most of these fail in some aspect of reliability, simplicity, dependability, or consumer recognition. To balance this, the food processing, packaging and distribution industries have been fighting a pitched battle against numerous naturally occurring hazards on an ongoing basis for centuries. This has provided some remedial mechanisms for dealing with contamination incidents once they are detected and reported. The most useful practical approach is to assess threats accurately and manage risks appropriately, implement practical and useable detection methods where needed to make contamination difficult at all points in the food system, and to ensure that a response system that is both capable and operational is in place to contain and remediate intentional incidents on a timely basis.

An ORM strategy may provide a very good measure of prevention against casual tampering, but will likely not prevent a carefully targeted attack, particularly from intentionally contaminated ingredients that are created at a high level and widely distributed to product manufacturers. On-package detectors and tamper indication can "keep honest people honest" and give some indication of contamination, but are subject to all kinds of errors and lack of consumer awareness. There is a need for better design and a higher degree of upstream integration of tamper evidence in the package design process, rather than simply discharging fiduciary duty with adhesive tape and shrink wrap.

Detection methodologies, while being developed for rapid detection in plant operations and other inspections, may never pass into in-package use because of the combination of cost, possible toxicity, specificity of test and unacceptable false-positive rates. These can be extremely useful in the detection of contamination during spot checks as ingredients move from supplier to production lines. This is a function that has been abandoned in many operations in favor of "paper" assurances that avoid liability, creating enormous security loopholes; besides, small-manufacturer testing could be an enormously lucrative market for testing-kit manufacturers. Validation of products via multipath (package coding plus lookup lists on-line) might allow retail checkout or consumer screening of products once alerts have been sounded, but are unlikely to be used on a persistent basis by many consumers in the course of their day-to-day lives except as a spot check in the event of well-publicized recalls.

Finally, remediation systems exist, and can work quite well if used properly. A well-publicized recall can remove products from circulation very quickly, though perhaps at the cost of some good product being discarded. For a broad class of alerts such as the peanut butter outbreaks discussed in this article, it could also cause a depression in the sales for that particular item, but these are typically short-lived phenomena and

might be considered an acceptable and insurable security cost. Most importantly, if the detection-remediation system continues to be opaque, failing to act or delaying action for a very long time as it has done very badly in the given case and others, an outbreak may proliferate for months or even years until the symptoms, illnesses or deaths accumulate to a significant level, and the massive response is cripplingly brittle rather than adaptive. As has been too-adequately demonstrated, there is little difference in method between a malicious manufacturer operating for profit and a malicious fabricator trying to generate the public fear that is the hallmark of terrorism.

# EARLY DETECTION AND DIAGNOSIS OF HIGH-CONSEQUENCE PLANT PESTS IN THE UNITED STATES

KITTY F. CARDWELL AND WILLIAM J. HOFFMAN
*United States Department of Agriculture, Washington, D.C.*

## 1 EARLY DETECTION AND DIAGNOSIS OF HIGH-CONSEQUENCE PLANT PESTS IN THE UNITED STATES

There exists well-documented historic precedent of the intentional use of biological organisms as weapons to strike against a target enemy either directly (human pathogens) or by

adversely impacting its agricultural security (animal and plant pathogens) [1–3]. Government sponsored research into the development of biological weapons for use against humans, livestock, and crops was prevalent during the early decades of the twentieth century. Most government bioweapons programs included research on the culture and testing of disease agents intended specifically for use against livestock and food crops. There is concern because no elaborate delivery technologies or methods are necessary for clandestine, economically targeted bioweapon attacks on agricultural crops [2]. Many exotic plant pathogens are already highly infectious with high reproductive potential that facilitate rapid exponential epidemic development when environmental conditions are favorable [3, 4]. Furthermore, plant pathogens are generally not infectious to human handlers; inocula are available from infected crops around the world; and collection, increase, and delivery to a target crop and region is not technologically difficult. The US National Research Council concluded in a 2002 report that the potential and (consequences of) deliberate bioterrorism attacks directed at US agriculture needs to be recognized as a serious threat to the United States and its agricultural economy [3, 5]. Bioterrorism is perhaps the most extreme example of the larger issue of invasive species of exotic pests and pathogens to new areas as a result of deliberate or inadvertent human activity or of more ”natural” spread [2].

Agricultural emergencies, whether deliberately caused or natural, follow the same notional phases as any disaster, including biological and chemical attacks on agriculture, animals, or civilians. Phase 1 includes detection and diagnosis; phase 2 involves a systematic monitoring to characterize and delimit the area of outbreak and mitigation in the outbreak area; and phase 3 is the longer-term response and recovery activities. This article concerns phase 1—early detection and diagnosis of a new biological threat to agriculture or valuable natural resources [6].

In the United States, there are an estimated 1 billion acres of crop, forest, and range lands. It is physically impossible to closely monitor all of this area to achieve early detection of newly introduced pests or pathogens. As such, these resources make strategically and tactically attractive targets to those who would strive to provoke food shortages, loss of valued ecosystem, economic damage either through loss of trade or loss of competitiveness, public loss of confidence in food safety and security, or direct damage to humans and/or animals [3]. Agricultural crops are particularly vulnerable due to ease of access and to the logistical challenges of continuous surveillance. In 2004, an estimated 155 million acres were planted with corn and soybeans, alone. Numerous other crops are grown over large acreages and/or are high-dollar intensively grown specialty crops such as grapes, citrus, and vegetables.

Because of the challenges of surveillance over such a vast area, there is the potential of a long lag time between the introduction of a pathogen or pest (intentional or natural) and the detection. Likewise, any delay in diagnostic processing once detected, would further delay appropriate response. For example, citrus canker, a bacterial disease of oranges, is believed to have been in Florida at least 2 years before it was detected and diagnosed [7]. Likewise, the emerald ash borer, a devastating invasive insect pest of ash trees, was estimated to have been in Michigan 5 years before it was discovered near Detroit, Michigan [8]. During this time, these pests and diseases spread to the extent that there is little hope that containment and eradication can be successful. Once an exotic or invasive organism has been detected, the need for intensive monitoring and sample diagnosis during a phase 2, also creates significant logistical challenges. Successful execution of a

monitoring, early detection, and diagnosis program improves the chances of responding quickly, minimizing impact, and reducing time to total recovery.

The purpose of this article is to explore the technical and infrastructural challenges to early detection, and rapid and accurate diagnosis of high-consequence exotic pests and pathogens.

## 2 DETECTION: MONITORING AND SURVEILLANCE

High-consequence pest monitoring and surveillance is a series of activities that combines biological science and human performance. This section will examine three different subsets of these efforts: formal human (active) systematic surveillance, nonformal human (passive) surveillance, and remote or automated surveillance. The terms *formal* and *nonformal*, indicate the level of government oversight and organization. These activities will be analyzed using a variation of Gilbert's behavioral engineering model [9]; examining the capacity, knowledge, and motivation of the individuals and organizations involved.

### 2.1 Formal (Active) Human Surveillance

Formal human active surveillance of high-consequence exotic crop pests are led by the US Department of Homeland Security (DHS)'s Customs and Border Inspection (CBI) Program and the United States Department of Agriculture (USDA)'s Animal and Plant Health Inspection Service (APHIS). These organizations work together in surveillance attempts designed to *exclude* pests from coming into the country. APHIS works to *monitor* regulatory pest problems for domestic establishment [10].

***2.1.1 Exclusion.*** The homeland security act of 2002 transferred federal agricultural port inspection responsibility from APHIS' Plant Protection and Quarantine (PPQ) division to the DHS-CBI [11]. The bulk of these activities to exclude 6000 miles of borders and 100,000 miles of shoreline [12] take place at 317 border inspection stations, 161 of which are staffed with agricultural specialists [11]. The daily traffic across these borders includes 1.1 million people, 45,000 trucks, 550 vessels, 2500 aircraft, and 341,000 personal vehicles [12]. Each day, an average of 1145 food product seizures take place as a result of short range electronic surveillance, interviews, canine sweeps, and hand searches. APHIS conducts an extensive training program and procedure manual development, provides guidance on inspection targeting and alert notification, and collaborates on port of entry review in order to bolster Customs and Boarder Patrol (CBP) efforts [11]; and thus remains involved with border pest exclusion.

*Capacity.* While efforts of the CBP agricultural specialists are laudable, there are two important reasons why they cannot possibly exclude all high-consequence pests and pathogens from entering the country. First, not all such pests enter the United States through registered border crossings. This includes pests that may enter the country naturally through the air or are carried by those crossing the border illegally [13]. Second, to intercept those pests and pathogens that do go through the inspection process, additional requirements would be needed to include fumigation of all manner of conveyances from countries where target pests are found as well as more intensive questioning and inspection of foreign visitors and returning citizens [14].

*Knowledge.* The CBP agricultural specialists are adequately trained [11] to carry out their mission. However, cross agency communication has impeded implementation of procedure manual updates and agricultural pest alerts. This has caused delays in getting timely information to those on agricultural homeland security's front lines [11].

*Motivation.* Legislators, farm organizations, and the National Plant Board have argued that agricultural border protection would be better off with the USDA, a department more focused on pest exclusion and food security [15–17]. Agricultural pest exclusion is one of many important priorities of CBP, an organization focused on the broad mission of ensuring safety and security while facilitating trade and travel. Within CBP, agricultural related border security competes for resources in an extremely broad and high consequence threat pool. District CBP agricultural liaisons provide regular communication to field managers, which helps pest exclusion receive the operational focus it deserves [11].

After a high-consequence crop pest does cross the US border, detection depends on domestic monitoring systems, both formal and nonformal surveillance activities.

***2.1.2 Monitoring.*** The USDA estimates that introduced plant pests account for annual agricultural losses of $41 billion and it provides leadership for monitoring domestic and regulated pests. An important formal monitoring program is the Cooperative Agricultural Pest Survey (CAPS) operated by APHIS. The CAPS provides resources to state departments of agriculture in all 50 states and 3 US territories to track more than 400 pests [18]. Approximately 40 of these pests are identified as national priorities by the CAPS program and the balance are proposed as local priorities. Detected high-consequence crop pests that are subject to regulatory action are immediately reported by CAPS survey participants to APHIS/PPQ emergency programs staff and are sent for confirmation by that group's national identification services. All survey data is submitted to the National Agricultural Pest Information System to contribute to national analysis.

Soybean rust, a serious soybean pathogen, was detected late in 2004. Prior to the 2005 soybean growing season, the USDA developed a sentinel plot based surveillance system to monitor disease progress throughout the year and provide near real-time information for pest managers. This has developed into the integrated pest management Pest Information Platform for Extension and Education (ipmPIPE), a partnership funded by the USDA and client industry, and managed by the cooperative extension systems across the country [19].

*Capacity.* In 2006, the CAPS program distributed approximately $5 million to all of the states and US territories combined. The state departments of agriculture participants in the CAPS program have lamented that the cooperative agreements they receive can only fund one survey coordinator and a few survey programs [18]. Similarly, the ipmPIPE has yet to achieve a stable funding source for the $2.277 million needed for core operations. While these efforts are highly leveraged through state government and land grant university funds, this level of funding does not purchase the type of capacity needed to thoroughly and systematically monitor high-consequence pests.

*Knowledge.* These programs thoughtfully set national priorities and the decentralized nature provides the ground truths from the states and regions. State departments of

agriculture and state cooperative extension service's often work hand in glove with land grant university researchers so that pest monitoring programs are informed by timely research [21].

*Motivation.* State Plant Regulatory Officers who participate in the CAPS program are the lead state government officials in PPQ issues. These individuals are highly motivated to monitor plant pests and correct problems before they are uncontrollable. Cooperative extension officials are motivated to collect data from an academic perspective and to act as an information hub in service to their clientele. This motivation is particularly keen when their clientele faces an imminent threat. However, focus on such a threat could draw attention away from other vulnerable pathways.

### 2.2 Nonformal (Passive) Human Surveillance

There are many people involved with crop pest management who are not involved with government sponsored surveillance. Approximately 90% of row crops and vegetable acres are scouted for endemic weeds, insects, and/or diseases that routinely threaten their crop's profitability. The vast majority of this scouting is performed by owner operators. Approximately 10% of the row crop acreage is scouted by chemical dealers and a similar amount is scouted by independent crop consultants. Certified Crop Advisor (CCA) utilization increases significantly for vegetable and other high-value crops [22].

During the last 5 years, cooperative extension services have conducted a campaign to incorporate exotic and invasive weed, insect, and disease detection into normal scouting activities. Training "first detectors", an activity led in part by the National Plant Diagnostic Network (NPDN), includes instruction on (i) the importance of high-consequence exotic plant pest detection; (ii) what scouts should do if they see something they do not recognize; and (iii) exotic pests that crops scouts should be on the lookout for in addition to routine pests. Many training participants were added to a first detector "registry" that will allow the NPDN to alert them based on recent pest finds and conditions favorable to disease presence [23]. Timely communications from the NPDN, coupled with information from the ipmPIPE, farm press county extension agents, and other information sources, could help crop scouts keep alert for exotic pests as they perform regular scouting activities.

*Capacity.* In addition to the operators of the 2 million US farms [24], there are 14,000 certified crop advisors [25] who make regular continuing education a part of their professional development. These crop advisors include chemical manufacturer representatives, chemical retailers, extension agents, and independent consultants. This is a massive capacity for nonformal surveillance if it can be properly marshaled, that has the potential to provide more surveillance samples than could be diagnosed. Therefore, diagnostic capacity must be maintained and improved as nonformal surveillance develops.

*Knowledge.* Reaching this prospective surveillance force with timely and crop specific information is a significant challenge. While the aforementioned groups who typically participate in the CCA program have made great progress as information conduits, providing information to growers and other pest management players is a limiting factor in nonformal surveillance.

*Motivation.* Growers are profit motivated and must attend to a complex set of details within a crop year if their bottom line is to be optimized. While some exotic pests

**TABLE 1 The degree of challenge (high, medium, or low) associated with national workforce capacity, knowledge, and motivation related to plant pest detection strategies**

| Strategy | Capacity | Knowledge | Motivation |
|---|---|---|---|
| Offshore and border monitoring for exclusion | *High*: extensive borders, coastline, and import volume | *Medium*: inter-and intra governmental communications | *Medium*: Agricultural pest detection competes with other priorities |
| Formal domestic monitoring | *High*: large geographic area to cover | *Low*: well established formal agricultural education system | *Low*: local and state-based practitioners driven by local economy and client needs |
| Nonformal domestic monitoring | *Medium*: first detector volume can create overwhelming diagnostic surge | *High*: large and diverse population needing real-time information | *Medium*: profit impact of exotic pest(s) must be clear to first detectors |

may pose a threat to the current year's yield, they may not be the bottom line threat that first comes to mind.

A summary of the challenges for each of the types of surveillance activities is found in Table 1. The remainder of the article will discuss how risk analysis, remote electronic or automated surveillance, increasing laboratory throughput, and diagnostic networks are integral to surveillance programs.

## 3 ESTIMATING RISK TO ORIENT SURVEILLANCE

The surveillance systems mentioned in the previous sections are highly dependent on human resources, which are dependent on the capacity, knowledge, and motivation of system players. Whether it is DHS and APHIS inspectors at points of entry, county extension agents monitoring sentinel plots, industry experts, university extension specialists conducting mobile surveillance, or farmers and their advisors walking into fields to take samples, a large number of trained people are required in the field. For best results their efforts must be coordinated [21, 26] and guided by the best available information about risk. Given that the largest constraint to monitoring agricultural resources in the United States is the tremendous area that must be covered, and that human resources are limited, ideal monitoring systems must also rely on technology(ies) capable of anticipating threat and risk levels and automated detection processes. In this section we will discuss risk/threat evaluation techniques and remote sensing technologies that promote efficient and timely field-based surveillance by delivering biological and/or probability information prior to physical field scouting.

### 3.1 Threat analysis

There are a range of approaches to threat analysis beginning with monitoring offshore pest movements [27], aerobiological modeling [28] and pathway analyses to determine

possible modes of arrival [29–36], population dynamic models to assess threat of given plant pathogens as biological weapons [4], and disease progress models linked to climate models and geographic information systems (GIS) to predict probability of infection/establishment and direction of spread once introduced [3, 37].

### 3.2 Pathway Analyses

Pathways of pest entry and spread are anticipated and assigned risk values by pathway analyses [38]. These analyses assign probabilities to natural entry, deliberate or unintentional introduction, establishment in the environment, rate of spread, and epidemic potential. Pathways can include commodity and seed trade, movement of plants and animals, conveyances that harbor hitchhiking biota; people who smuggle, travel with native plants or plant parts, traffic in traditional medicinal plants, or intend to commit sabotage; and packing materials (particularly wood), potting media, even garbage. Target pests analyzed by APHIS are primarily regulatory threats as established by pest risk analyses. Knowing the most probable entry pathway(s) allows APHIS and DHS to focus interception efforts critical points. An indicator of deliberate introduction of a damaging pest would be if it were to occur outside of the most probable entry pathways [39].

### 3.3 Models

Plant pests and pathogens that are amenable to increase by scaled-up *in vitro* production, are stabile in storage, easy to transport and deliver are most likely to be developed as biological weapons. Whether the delivery results in establishment, dispersal, and damage, however, depends on the disease triangle: availability of susceptible host, climatic factors, and the inherent biology and physical characteristics of the organism [3, 4, 28]. The probability of any of these processes can be analyzed using mathematical models to assess risk of damage by a biological agent were it to be introduced intentionally. The most basic models used to assess potential impact of an introduced organism are "simple interest" (in the case of point source introductions of high levels of initial inoculum) or "compound interest" (where there would be cycles of inoculum build up over time) [3]. In the simple interest model, high risk is assigned to organisms that have highly effective inoculum (a high ratio of infection achieved over total inoculum propagules) over the broadest possible range of environments (which includes host genetics). For the compound interest model, high risk is assigned to those organisms that have a high rate of reproduction and infection over a broad range of possible environments. In this model, low amounts of inoculum could be introduced and would be hard to detect until an epidemic was fully blown, potentially causing impact in an area much larger than the original inoculation points.

Modeling to assess risk of an invasive pest/pathogen (intentionally produced as a bioweapon or inadvertent), which establishes and damages the population growth rate ($R$), is the driving variable. Persistence of an organism over season can also be a function of $R$ as overseason survival is a probability function of mortality of progeny. Thus high $R$ pests and pathogens are generally assessed as higher risk of becoming endemic under appropriate climatic conditions, particularly if the dispersal is aerobiological. High $R$ pests with a persistent overseasoning structure, that is a structure that ensures durability of the propagule, are the most likely to become established.

***3.3.1 Aerobiological Models.*** Aerobiology is the study of the physical process of movement of organisms from one geographic location to another by floating, soaring, or flying through the atmosphere [28]. Pests and pathogens that disperse long distances readily are most likely to have wide-spread impact. Many plant pests and pathogens are physically designed for long-distance aerial transport, and these are subject to the dynamic but definable routes created by planetary airflows [28]. Aerobiological models are used to predict when and where a target organism might reach a location, and this helps establish the "normal" probability of appearance by natural processes. Many organisms that move long distances in the air, also move locally between the infected source and new locations. For the purpose of surveillance advisories, the probability of arrival of a given invasive organism to a new location can be forecast once host availability and climate variables are integrated with the knowledge of the biology of the organism. Likewise, an unknown source of origin can be estimated by a trace backwards of atmospheric pathways. The most widely used atmospheric transport model for aerobiological applications is the National Oceanic and Atmospheric Administration (NOAA)'s HYSPLIT (hybrid single-particle Lagrangian integrated trajectory) model. Both APHIS and PIPE use this type of modeling [3, 24, 37].

***3.3.2 Weather-based GIS and Disease/Pest Warning Models.*** Climate-based disease and pest forecast models are dependant upon accurate climatological data on a meaningful geographic scale. Precision of climate data such as 24/7 temperature, dew point, and duration at or below dew point is a function of density of weather station data loggers and edaphic/topographic conditions of a region [40]. Relatively flat terrain such as the great plains and Midwestern region of the United States can expect reasonable precision of forecast with fewer data points over a larger scale. Conversely, complex topography can present highly diverse conditions on a fine scale. Thus, climate-based disease forecast in areas such as the Pacific northwest must take into account topography, altitude driven temperature and dew point variations, precipitation shadows, and so on. A denser network of weather data stations is required and interpolation between these cannot be generalized. Customized climate forecasts can be developed for specific production zones.

Once climate model uncertainties and errors are understood, accurate disease severity forecasts can be generated based on biological characteristics of the organism or a proxy with similar attributes and known environmental parameters (Figure 1). The primary attribute that describes epidemiologic potential of an organism is its fitness or basic reproductive number (R), defined as a mean of new infections that result from an individual infection locus, or basically, the average number of progeny that an individual produces on a susceptible host under average (climatic) conditions [4, 41, 42]. Modelers understand how the R of each organism is affected by a range of climatic conditions. Some plant pathogens are highly dependent on climatic conditions during the process of infection of the host; so the probability of infection is a function of a threshold of effective inoculum and promoting climatic conditions. Other organism attributes that relate to R are length of latency or incubation, and short- to long-term progeny survival.

***3.3.3 Population Dynamics Models:.*** Pest/pathogen population dynamics models can incorporate the final side of the triangle, the host. Host plant growth can be modeled based on factors such as phenology, degree days, and precipitation. The within- and between-season dynamic between host plant and pathogen can be simulated using reciprocal, coupled differential equation models [4, 44, 45]. The susceptible host is the essential

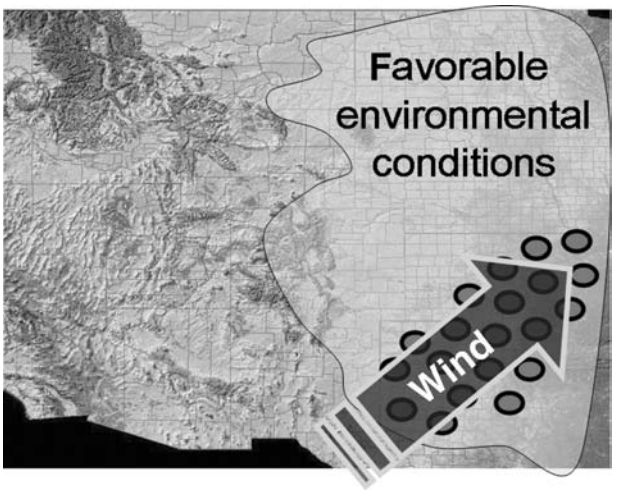

**FIGURE 1** Mitigation efforts are most efficiently implemented when ground and remote surveillance inform aerobiological and HYSPLIT models to predict likely disease spread.

environment for the pathogen to develop, and successful development of the pathogen may have deleterious effects on its host. Strain composition and virulence diversity in populations tend to be well understood. Some pathogens are highly mutable and exist in populations polymorphic in virulence and aggressive on their host. These are managed by shifting host plant resistance to new varieties as resistance is defeated. In the presence of these types of pathogens, host resistance may break down gradually, over several years, or abruptly resulting in significant crop losses. Any sudden shift in virulence under these conditions could not be easily attributable; however, highly mutable pathogen populations are among some of the most destructive in the world. Other classes of pathogens have more stable population composition so that resistant varieties are more durable. Any sudden shift in virulence or aggressiveness of this type of pathogen would raise questions about how/why it happened, and often can be attributable to the specific introduction of a different strain.

***3.3.4 Syndromic Analysis:.*** Intentional introduction of a plant pest or pathogen is likely to result in a pattern of disease outbreak that does not conform with the expected [3]. Pests and pathogens that are airborne and expected to fall out of air currents should distribute in a normal or random pattern across a predictable geographic swath. If the pattern of discovery is discrete and geographically distinct, this would fall outside of the expected and raise suspicion. Delivery of spores via a ground sprayer would result in a nonrandom disease presentation, such as in a line pattern along a fence row or road [3]. Other anomalies would be temporal and based on the likelihood of severity of outbreak at any given time. These anomalies are evaluated in real time on the basis of current diagnostic data, such as generated by NPDN labs (Figure 2), against the backdrop of historic data and/or climate-based forecast models of disease and pest outbreak. An outbreak that is too severe, too early in a growing season is a temporal anomaly [39]. Any departure from usual in disease or pest outbreak aggressiveness, severity, or incidence should trigger an investigation. Any change in intensity of mycotoxin production, particularly in the absence of a corresponding causal climatic factor, should be immediately investigated.

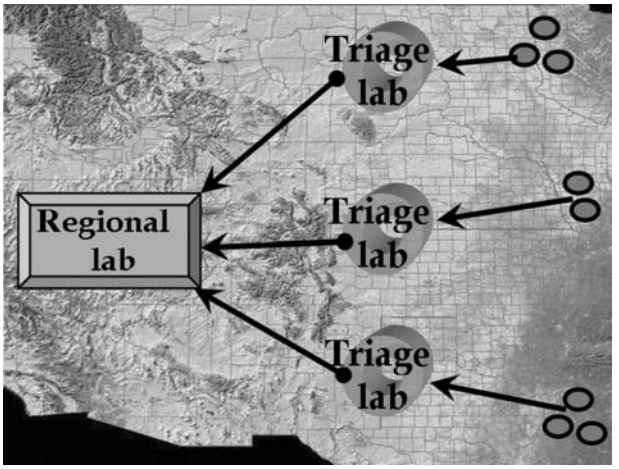

**FIGURE 2** Syndromic analysis of data collected at state-based (triage) diadnostic laboratories. Triage labs conduct preliminary analysis. Regional and national labs perform confirmatory assays.

It is paramount that analysts are trained, and automated analytical software developed to identify such anomalies, and that background data be archived in a format that is standardized for analysis.

### 3.4 Remote or Automated Surveillance

Another way to supplement and focus monitoring and surveillance to narrow down the search parameters to manageable dimensions is to develop and deploy remote and/or automated sensing devices. This not only has the greatest immediate potential to supplement active surveillance capacity but also a long-term potential to supplement passive surveillance and exclusion.

The research community is developing parameters required for detection, for example, specific nucleic acid, proteomic, or spectral signatures of specific organisms [6]. Technologies for monitoring and notification about biological organisms in plant systems must be sensitive enough to identify the signature at very low concentrations, be associated with understanding of effective inoculum levels on available hosts (infectivity relative to environment), and be prompt enough to effect a successful control response. Ideally, such sensing devices could be designed to emit a signal to a remote monitor when a positive reaction or detection has occurred [45]. However, most sensors for environmental biological monitoring still require at least some human manipulation such as substrate collection and transport for laboratory analysis. For example, fungal spores can be collected in outdoor aerial traps [46, 47], water traps [48], indoor suction traps [49] (Zhou). Krupa et al. have used the National Oceanic Atmospheric Deposition (NADP)/National Trends Network (NTN) water traps to monitor rain-deposited soybean rust in samples of rainwater [50, 51]. As few as two soybean rust spores can be detected with polymerase chain reaction (PCR) in rainwater samples collected in NOAA, National Atmospheric Deposition Program traps [51, 52]. Although spore capture has not yet been significantly correlated with crop disease, spores have been detected as far north as Canada.

Nevertheless, atmospheric trapping of specific plant pathogens can only be a useful monitoring tool if there is no bottle neck in sample analysis. In the absence of *in situ*

analysis systems, all remote trap samples must be collected and returned to the lab for processing. Therefore, the last aspect that we deal with in this paper is actually one of the most rate limiting aspects of all surveillance and monitoring programs, that of laboratory throughput capacity.

## 4 DIAGNOSTICS

### 4.1 Laboratory Throughput

Whether by trapping, sentinel plot, mobile random survey, systematic survey, or by heightened awareness of a cadre of public and private first detectors, the consequence of regular monitoring can be an exponential increase in the numbers of samples requiring rapid diagnostic analysis [53].

When there is an emergency, and either a high-consequence biological agent or a new find of other high-consequence or quarantined pest has been detected, a surge of samples flowing into laboratories can be expected. Sampling needed to characterize and delimit an important outbreak, can result in a surge of samples and quickly overwhelm the capacity of the laboratory to process the material opportunely. This is especially true when those who develop the sampling plans, for active surveillance either before or after first detection, do so without consideration of existing surge capacity.

Surge management is dependent on human resources, physical space, reagent, and equipment availability within a laboratory [39, 54]. Table 2 shows a comparison of the three most common diagnostic methods for plant pathogen diagnosis. Traditional (incubation, microscopy, and taxonomic identification), molecular, and antibody-based diagnostics form the basis of the standard operating procedures (SOPs) that are developed for plant pathogen Select Agents and other high-consequence pathogens and pests. All plant diagnostic clinics are prepared for the traditional cultural diagnostic tests, and may use these as a first-order assay in the absence of a risk alert or other indication of unusual outbreak. PCR and immunoassay techniques are relatively quicker, more accurate, and preferred for high-consequence diagnostics. However, during a sample surge these techniques may be limited due to the level of training and testing (certification) required for personnel and inadequate supply of reagents [54]. Often, diagnostic confirmation requiring a high level of confidence will employ various technologies concurrently. An example of this was the SOP developed for diagnosis of the Sudden Oak Death pathogen, *Phytophthora ramorum*, which allowed for cultural, immunological, and nested PCR methods, depending on the level of capability and accreditation of the lab [55–57].

The challenges to large-scale screening of agricultural biological samples have been demonstrated both in simulated and actual surge events (refer to ICLN chapter). Individual laboratories, by themselves, can become overwhelmed in the case of a sudden influx of samples. Fulfilling the US biodefense strategy requires that laboratory response systems become capable of detecting biological agents from large numbers of samples quickly and cost effectively [54]. Alternative options exist, which range from investing in automated biological agent testing systems to increasing the throughput of national laboratories [53, 54, 58], to developing cascade protocols whereby diagnostic laboratories experiencing a surge can distribute samples over a network of laboratories significantly increasing the number of technical hours that can be brought to bear. Either of these options requires a national investment and would be effective regardless of the original cause of the surge (from intentional to natural).

**TABLE 2 Comparison of Diagnostic Methods**

| Variables | Traditional | Immunoassay | PCR |
|---|---|---|---|
| Personnel needed | 4 | 2 | 4 |
| Analysis time | 2–10 d | 2 h | 12 h |
| Throughput/day | >100 | | >200 |
| Upfront costs | Modest | | Moderate |
| Sustained costs | Low | | Low |
| Confidence | Agent may not grow on media | Are specific to genus with high confidence, can be very specific to viral strains | Cross contamination moderate, high human error |
| Key characteristics | Ultimate diagnostic tool for confirmation | Quick assay to confirm presence/absence of specific genera | Flexible conditions for assay development |
| Pros | Gold standard, positive identification of organisms | Confirmation and diagnosis inexpensive, relatively simple; monoclonal antibodies can be developed to be general or specific, polyclonal antibodies can be developed quickly | High system flexibility, protocols easily modified, detects killed organisms |
| Cons | Toxins not detected, very slow, may require more extensive testing, agent may not grow in artificial media, unable to detect killed organisms | Multiple steps increase opportunity for human error | Many opportunities for human error, flexibility increases the opportunity for applying wrong protocol |
| | | Variability in access to standard pathogens/ clonal cell lines among manufacturers, more strain specificity with monoclonal antibodies, but there are no standard US cell lines. | |

## 4.2 US Laboratory Network System

The NPDN [20] is a hub and spoke system of non-Federal laboratories distributed across the United States and territories, with varying capacity to effect determinant diagnoses (Figure 3). Every state and territory has at least one public diagnostic laboratory (Land Grant University plant clinic and/or State Department of Agriculture regulatory laboratory) which is a member of the NPDN. There are five regional hub laboratories that, in addition to processing samples submitted from within their state, coordinate diagnostics

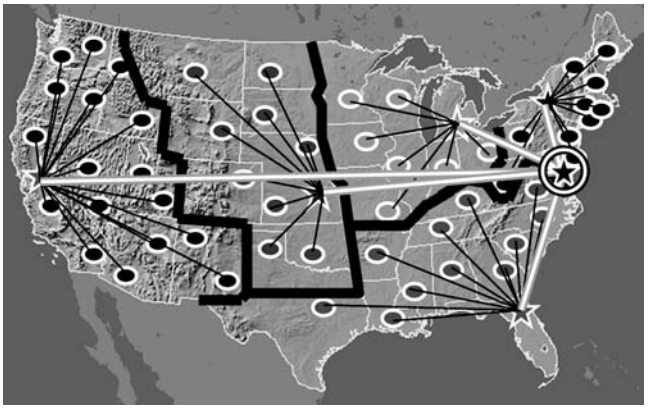

**FIGURE 3** The "hub and spoke" structure of the NPDN allows: (i) regional coordination; (ii) surge overflow, and (iii) national sample triage.

and information flow within each region. All of the laboratories are linked by a secured messaging system designed to alert diagnosticians of an increased risk of seeing a specific high-consequence biological agent. Protocols are in place for every state defining communications and information pathways and sampling flow operating procedures. By employing this network of existing public plant diagnostic laboratories, the United States has increased surge capacity for a moderate Federal investment.

Some NPDN laboratories are PCR trained and certified; others will be able to provide triage by examining and eliminating lower-consequence endemic pests and pathogens. However, when a triage laboratory receives a sample that it suspects to be an agent of national concern (whether homeland security or regulatory quarantine), the communications protocol for that state and region kicks into operation. One aspect of that protocol is to consult with the regional hub diagnostician and/or the specified Federal Reference Laboratory for the suspect agent. All presumptive positive samples of regulatory agents are forwarded to APHIS PPQ National Identification Services Laboratories for confirmatory diagnosis (Figure 4).

All NPDN labs have digital diagnostics capability that allows real-time viewing of the same diagnostic features in two or more geographically separate laboratories via the Internet (Figure 5). This distance consultation provides first detectors and state diagnosticians local access to national diagnostic expertise in real time. Digital diagnostics have proven to reduce overall laboratory burden through triage, while improving diagnostic turn-around time on critical, presumptive high-consequence samples [23].

## 5 CONCLUSIONS

The United States have over a billion acres of food, fiber, feed, and fuel production agriculture. Agriculture and forestry products combined are a cornerstone of the North American economy, providing social stability through food security and natural environments. Production agriculture is also being tapped to produce combustible fuels, exponentially increasing its overall value to producers and the American people. US agriculture could be considered a large, soft target to those who would want to strike at

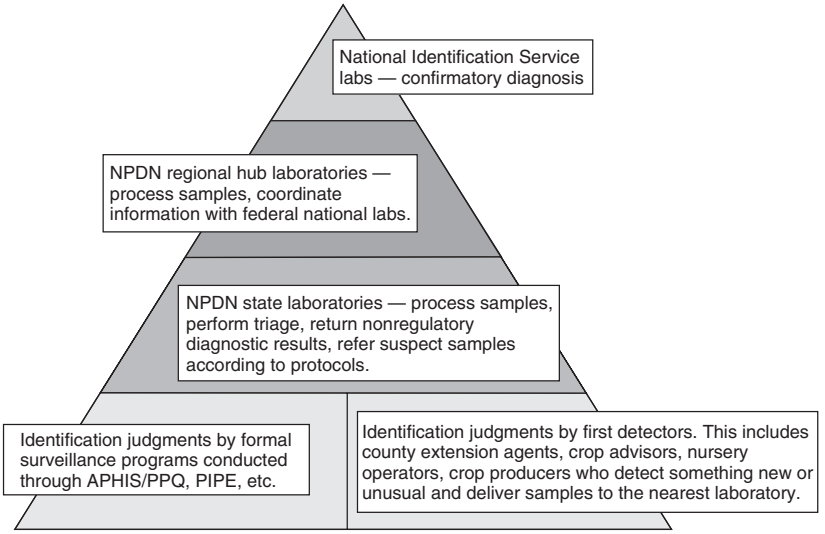

**FIGURE 4** Diagnostic and triage hierarchy for US plant pest detection.

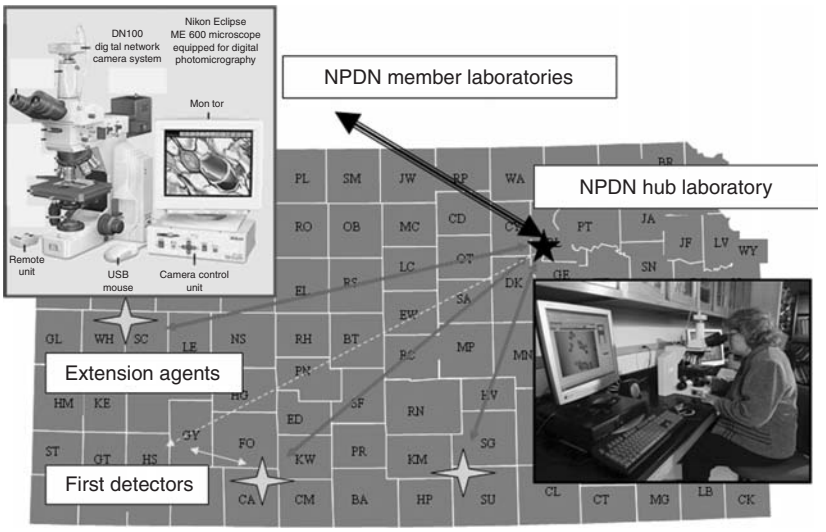

**FIGURE 5** All NPDN member laboratories and properly equipped county extension offices can receive distance diagnostic support through digital image sharing on a state, regional, and national level.

the economy, the social stability, or the sense of safety of the US citizenry. It would be technically easy to do this.

Early detection and diagnosis of pests and diseases of plants is the best way to limit spread and impact, whether they arrive naturally or are introduced deliberately. This article has described the US plant pest detection and diagnostic systems. These systems are good, but vulnerability has increased due to globalization, terrorism, and the increasing

value of agricultural products around the world. This increasing vulnerability will exacerbate current challenges. Therefore, it is in the country's best interest to pursue research and infrastructural improvements to foster the security of that system.

### 5.1 Research

Monitoring and surveillance needs:

- improved biologically based survey, sentinel, and sampling protocols
- field-based diagnostic kits
- ongoing threat and pathway analyses
- epidemiology and aerobiology
- syndromic analysis—the study of populations within communities and environments
- remote/automated surveillance (microarrays and conductors).

Diagnostic needs:

- additional validated diagnostic assays
- automation systems.

### 5.2 Infrastructure

Planning and practice are essential to ensure an effective response to urgent public health threats [39]. This is true also for plant health threats. Integral to planning are education and policy. Needs are as follows:

- highly trained agricultural officials at ports of entry whose mission is a Cabinet-level priority;
- a new cadre of people educated in Agriculture Homeland Security that includes regulatory sciences, pathway and risk analysis, diagnostics, forensics;
- field workers, particularly growers, crop advisors, extension agents, who are knowledgeable about diseases that could be the result of use of biological agents, how to distinguish from the norm, and what to do when they encounter something suspicious.
- quantitative biological scientists, epidemiologists, aerobiologists, and so on, for plant-based agriculture
- alert and knowledgeable clinicians and laboratory diagnosticians, vital to disease surveillance efforts and recognition of new diseases and syndromes; and
- automated laboratory high throughput equipment and operating procedures.

# MITIGATING CONSEQUENCES OF PATHOGEN INOCULATION INTO PROCESSED FOOD

JAMES S. DICKSON

*Department of Animal Science, Iowa State University, Ames, Iowa*

## 1 INTRODUCTION

Pathogens occur in processed foods as a result of the natural occurrence of these organisms, and also as a result of failures in both processing and sanitation. The intentional introduction of pathogens into processed foods is an unlikely but plausible event, given an individual or individuals with sufficient motivation. The response to either an accidental or intentional event would be similar, although there would be more significance to an intentional event. However, the basic response would include the recovery of the affected products, a reevaluation of the process, and a public relations effort to restore public confidence in the specific food type or processor.

## 2 SCIENTIFIC OVERVIEW

### 2.1 Processed Foods

The processing of foods ranges from very minimal to technologically advanced. An example of minimal processing would be fresh vegetables, such as green beans. In this case, the food is simply washed to remove physical contaminants, and may be prepackaged for retail sale. Alternatively, some foods, such as canned vegetables, may be processed and preserved to a degree that they are shelf stable and ready-to-eat. Because

of the diversity of food types and processing, the potential for an intentional introduction of pathogens is great.

***2.1.1 Historical Precedence.*** Upon leaving the post of Secretary of the US Department of Health and Human Services, Secretary Thompson commented "I, for the life of me, cannot understand why the terrorists have not, you know, attacked our food supply because it is so easy to do, and we are importing a lot of food from the Middle East, and it would be easy to tamper with that." [1]. There have been historical examples of deliberate contamination of food products in the United States. Perhaps the largest incident was in State of Oregon in 1984 [2], where *Salmonella* was deliberately introduced into salad bars at local restaurants. In this case, the incident was intended to affect the outcome of a local election. In another incident, a disgruntled employee deliberately contaminated muffins and doughnuts with *Shigella dysenteriae* and left them in an employee break room [3]. Potassium cyanide has been used to contaminate over-the-countermedications on several occasions, leading to the deaths of several unsuspecting consumers [4]. One of the earlier documented cases of this type of product tampering or contamination was an incident which occurred in Chicago in 1982, where seven people died after ingesting deliberately contaminated products [5]. Although some of these contamination events were attempts to gain financially from the event (extortion), the motivation for the Chicago event is still unknown.

***2.1.2 Potential Biological Agents.*** Biological agents that could be used as potential contaminants include bacteria, viruses, and parasites. In addition, microbial toxins could also be introduced into processed foods [6]. The information needed to select, isolate, identify, and cultivate these organisms is readily available within the public domain. Bacterial agents are more likely to be used as deliberate contamination agents, simply because a person with rudimentary microbiological skills and facilities, along with equipment and supplies purchased from readily available sources, can produce sufficient quantities of bacteria to be used to deliberately contaminate foods. The techniques and requirements to produce sufficient quantities of viruses and parasites would require more sophisticated skills and facilities.

Bacterial agents may be divided into two general categories: those which cause infections and those which cause intoxications. Infectious agents require the presence of a live organism. Since most of these bacterial agents are sensitive to heat, they would be most effective with foods that do not undergo thermal processing or a final cooking step. The historical example of *Salmonellae* introduced into salad bars [2] illustrates this point. Bacterial toxins can also be produced, albeit in crude form, with rudimentary skills and facilities. Some bacterial toxins are heat stable, which would allow them to be used in foods that do undergo thermal processing. In 1989, mushrooms were held under conditions, which allowed for the growth and toxin production by *Staphylococcus aureus*. These mushrooms were subsequently canned, destroying the live bacteria, but allowing the toxin to remain present and cause illness [7]. The mushrooms were grown and canned in another country and then imported into the United States, where the illnesses occurred.

***2.1.3 Food Processing Systems—Threat Assessment.*** Food processing may be separated into several distinct phases: production, processing, secondary processing, distribution, sale, and consumption. In addition, transportation is a critical factor at all stages, as food is often produced in one location and then distributed nationally or internationally.

Most production sites have minimal security, and are often located in rural settings, where there is a relatively low population density. This leaves the production sites vulnerable to intentional contamination, as most of these locations are easily accessed by a determined individual or group of individuals. Intentional contamination could be carried out at most of these locations with a minimal risk of detection.

Processing and secondary processing facilities also offer opportunities for intentional contamination to a determined individual or group of individuals. Although most food processing establishments review potential employees prior to hiring, it is quite possible for an individual or individuals with criminal intent to become employed at a food processing facility. There have been several video recordings demonstrating insanitary or inhumane conditions made in secret inside meat processing facilities in the last few years, and it has been suggested that some of these videos may have been made by individuals who sought employment at the facility, specifically to record the video. If an individual can obtain employment with the intent of secretly recording a video, then an individual motivated to deliberately contaminate food could also presumably obtain employment.

Virtually, all types of food processing systems incorporate steps during processing to assure the safety of the food product. Although these are designed to address naturally occurring contamination, they are also well suited to address intentional contamination. The more comprehensive food safety systems are based on either the Hazard Analysis Critical Control Point system (HACCP) [8] or the International Organization for Standardization [9]. The disadvantage of these programs is that they are well documented within the processing establishment, and are therefore readily available. A determined individual would be able to evaluate such systems, and devise a way of introducing contamination in a manner that would not allow rapid detection.

The food distribution network raises additional concerns. The opportunities for intentional contamination increase, as the food may pass through a series of transportation and storage stages and is potentially available for a variety of individuals to have access to. As with processing, these individuals could conceivably be either employees of the transportation and storage companies or simply determined individuals who gain unauthorized access to the food. A further concern with the distribution network is that most if not all of the microbiological testing of foods is done at the processing level, meaning that foods contaminated during distribution would be unlikely to be tested before they reach the consumer.

Foods may be exposed to potential intentional contamination at the point of preparation (food service) or retail sale. At retail, the food is accessible not only by employees of the retail establishment but also by other consumers. It would be very difficult to identify and stop a determined individual from entering a retail establishment and deliberately contaminating food, especially produce that is presented for sale without primary packaging. Previous product tampering cases have involved contamination at the point of sale, and have proved to be difficult to stop.

Foods that undergo less processing fall into a higher risk category. Several foods of this type of minimally processed food have been involved in naturally occurring foodborne illnesses in recent years, including lettuce [10] and spinach [11]. Since these types of foods rarely receive additional processing by the consumer before consumption, any pathogen introduced has the potential to cause human illness.

***2.1.4 Avoidance Strategies.*** The primary assumption for evaluating a deliberate contamination event is that it would be carried out by an individual or individuals with criminal intent. Because of this, most of the avoidance strategies are based on controlling access of unauthorized individuals to food production and processing areas. Physical security of the food production or processing locations is the first step in avoiding a deliberate contamination event. As previously mentioned, food production sites are difficult to secure, although there are some notable exceptions. Some concentrated animal feeding operations for dairy cattle, poultry, and swine have elaborate physical security measures in place, primarily to prevent the unintentional introduction of animal diseases. These biosecurity measures secure the facility and rigidly control personnel access to the animals. By their nature, locations producing grain crops, leafy green vegetables, or other produce are virtually impossible to secure against unintentional access because of the size of the land mass associated with the growth of these crops.

Most food processing and secondary food processing establishments have some degree of physical security. Most are surrounded by perimeter fences and have sufficient exterior lighting to provide for visual examination of the premises. Many employ security guards to regulate access to nonpublic areas of the processing establishment. However, there are practical limitations to all of these measures. There are many people who are not employees of a company, but who have legitimate business within a food processing establishment. These would include, but not be limited to, delivery persons, maintenance and construction personnel, contract pest control and sanitation personnel, customers, and suppliers. Given the intent, any of the individuals could potentially have access to food products.

Persons employed by the food production or processing industry have been previously mentioned as potential threats for deliberate contamination. Preemployment screening is vital for many reasons, but even more so to avoid potential contamination. Employees should verify previous employment, and addresses, to assure that the applicant does have a documented history of employment. In addition, preemployment drug screening is widely used to verify that the individual is not currently using illegal drugs. Employees should be adequately trained in the general aspects of food safety, and the impact of a foodborne disease outbreak should be made clear as part of the training. Large foodborne disease outbreaks from natural sources have forced companies to go out of business, resulting in all of the employees becoming unemployed. Emphasizing this point to all employees makes employees more aware, and may result in the reporting of an odd or unusual event witnessed by one of the employees. This empowers employees to become part of the internal monitoring system, and may alert management to an event before the food leaves the processing facility.

## 3 RESPONSE TO AN INCIDENT

The response to an intentional food contamination event would most likely follow a similar pattern as the response to a naturally occurring contamination event. Regrettably, unless a specific threat has been communicated from the individuals responsible or another method has given some warning, the first indication of a deliberate contamination event would be through public health departments. Standard epidemiological investigations and syndromic surveillance should indicate a common source for the disease outbreak [12]. Once a common source is identified, the response by the food industry should be immediate.

The initial response would be to immediately remove all of the food processed in the establishment from commerce, essentially following the practices of a recall. Some of

the more specific guidelines for food recalls have been published by the Canadian Food Inspection Agency [13]. The food would then be categorized into specific production lots or code dates to determine which code dates were contaminated. The public health investigation should be helpful in identifying whether there were multiple code dates involved, either by recovering intact packages from the homes of the consumer or by investigating the geographical distribution of the disease in relation to the distribution of the food product. This presumes that the food product in question had sufficient lot coding in place to segregate the product. Lot coding becomes more problematic with bulk or commodity items. Extensive microbiological testing would be required to assure that product code dates that are not directly associated with human illnesses were in fact free of the intentional contamination.

The deliberately contaminated product must be disposed of in such a way as to assure that it will not pose any additional health or environmental effects. Unlike naturally contaminated product, intentionally contaminated product will likely contain high populations of the pathogen, or high levels of the toxin. Depending on the nature of the contaminant, the food may not be able to be disposed of through the usual methods of rendering, thermal processing, or burying in a land fill. Additional methods may need to be employed to assure that the food poses no further hazard to human health. Commercial irradiation, commonly used to sterilize pharmaceutical products and medical devices, may need to be employed to eliminate the contaminant from the food before final disposal. In the case of biological toxins, chemical methods such as those used to destroy animal carcasses infected with bovine spongiform encephalopathy, may have to be employed to ensure the destruction of the toxin. The safety of the workers handling and disposing of the infected products must be considered in the overall plan for disposal.

Once the immediate public health crises has subsided, the food industry as a whole should evaluate what happened so that similar incidences may be prevented in the future. Previous historical events have shown that "copycat" events may follow an initial event, and the industry should evaluate the processing systems to prevent a similar incidence from occurring. Naturally occurring contamination events have often identified shortcomings in the current processing systems, especially in lot tracing and logistical control of the food product. An intentional contamination event would identify any weaknesses within a given processing system, and an evaluation of the overall event would help to make the industry better prepared for future events.

## 4 RESEARCH AND FUNDING DATA

The type of research needed to address the concerns of deliberate food contamination is similar in many respects to that needed to address naturally occurring contamination. Consequently, the common sources of funding for food safety research are also likely to fund research on intentional contamination, simply because the outcome of the research will be applicable to many situations. The primary government source of research funding for food safety endeavors is the US Department of Agriculture (USDA) Cooperative State Research, Education and Extension Service (CSREES). Major funding programs include the National Research Initiative and the Integrated Research, Education, and Extension Competitive Grants Program. For the updated current request for proposals for these programs, see http://www.csrees.usda.gov/foodsafetybiosecurity.cfm. In addition to the government funding, many of the trade associations offer competitive grants programs in the area of food safety. Although these awards from these grant programs tend to be smaller than those from the federal programs, they are still a useful source of funding for this type of research.

## 5 CRITICAL NEEDS ANALYSIS

The potential for a deliberate act of contamination to occur is well documented. Historically such events have taken place, although usually perpetrated by an individual intent of financial gain or by a disgruntled employee [14]. The potential disruption that could be caused by an organized group, for example for contaminating multiple foods in various locations with different agents, is great. Protecting the food supply from a deliberate contamination event is one of the priorities of the US Department of Homeland, as well as the other agencies that are responsible for the safety of the food supply (USDA Food Safety and Inspection Service (FSIS), Food and Drug Administration (FDA), Environmental Protection Agency (EPA), etc.). The food industry is global in its operations, with food being one of the main commodities traded internationally. A deliberate act of contamination in a specific food could have far reaching impacts not only on human health but also on international trade. A recent incident involving naturally occurring *Salmonellae* contamination of cantaloupe illustrates this point [15]. One of the key components in research is that the outcome of virtually all of the programs will have applications not only for deliberate events but also for contamination that occurs as part of the overall food process.

## 6 RESEARCH DIRECTIONS

Future research needed to address the needs of both regulatory and public health officials in the event of a deliberate event falls into several categories, but can be broadly classified as scientific or technical, logistical, and societal. These are the same research needs for naturally occurring contamination events, so previous, current, and future research programs serve both purposes.

The scientific or technical issues relate to sampling and detection methods. Improvements need to be made in sampling techniques, as well as the statistical sampling plans needed to determine the extent of contamination. One of the weaknesses of the current detection methods is the lack of an adequate understanding of sampling, with the end result being no better than the quality of the sample collected. Additional resources also need to be applied to detection methodologies. Although significant advances have been made in the area of detection, most notably with the commercialization of polymerase chain reaction (PCR) technology, many of the methods still require an overnight incubation of the sample to increase the number of target cells. In the event of a deliberate contamination event, timing will be essential, and an ideal method would be one that could be performed on-site without a prolonged incubation. Methods that meet these criteria are under development, but have not been entirely successful.

The logistical issues that should be addressed include the ability to locate and recover all of the affected food. Recent events, especially with produce and meat [16], have shown how difficult it is to locate and retrieve all food involved. Further research is needed to improve the ability of food processors and federal agencies to track and identify food products to assist in the ability to identify and recall intentionally contaminated food.

Once contaminated food has been recovered, there is an issue of disposal. Depending on the nature of the contaminant, the food may require special processing to render it safe for disposal. In addition, the safety of the workers handling the contaminated food must be considered. As an example, food contaminated with a high population of pathogenic bacteria may require methods of disposal beyond rendering or burying in a land fill.

Although it is relatively simple to dispose of small amounts of contaminated food, scale of a potential disposal operation must be considered. The recent actions by USDA in recalling more than 140 million pounds of product [16] illustrate this point. There is a need to study the logistical and technical issues involved in rendering large quantities of food products safe for subsequent disposal.

A final research topic would be the effects of an intentional contamination event on society and consumers. An intentional event would raise questions not only about the specific food or foods affected but also about the food supply in general. It would be reasonable and prudent to determine what methods could be used to restore consumer confidence in the general food supply, as well as with a specific commodity. Consumer research could be conducted to determine the most effective means of communicating with consumers after an intentional contamination event, and what messages would be most effective in conveying that the emergency has passed. Presumably, this type of research has been conducted for other natural and intentional catastrophes, and this information could be applied to a food contamination event.

## 1 INTRODUCTION

The US food system is among the safest and most secure, worldwide. Yet, because plant-based systems are essential components of the nation's farm-to-table food supply

system, they may be potential targets for the deliberate introduction of pathogens or pests by those intending harm [1–6]. In addition, plants comprise our fiber, forests, and rangelands—and may play an increasingly important strategic role as a source of biofuels. Possible impacts of intentional tampering include loss of product quality or availability, economic hardship for farm and market sectors and rural communities, and distrust of US produce and value-added products. National biosecurity capabilities must include scientific knowledge, technologies, and procedures to effectively trace the origin, timing, and site of introduction of a plant pathogen or pest, and the collection of evidence that ultimately will allow successful criminal prosecution of those responsible [7–10]. The general application of science to legal practices is termed *forensic science*, and if the activity focuses on pathogenic agents, it is called *forensic microbiology*. We will discuss the application of microbial forensic principles and activities to plant-based agricultural systems, and introduce the emerging subdiscipline of forensic plant pathology.

## 2 SCIENTIFIC OVERVIEW

### 2.1 Agriculture as a Target

The vulnerability of agricultural production systems to natural or intentional threats has long been recognized ([1]; *see also Stack, this volume*). Plant-based agriculture in the United States includes 382 million acres in crop production, 737 million acres in forests, and 525 million rangeland acres for grazing [11]. Complete security for such a vast area is not feasible. Biowarfare programs against plants and livestock were sponsored by governments of several countries during a period encompassing and following World Wars I and II, and deployment of animal pathogens including the agents of glanders and tularemia has been documented [12]. The purposeful introduction of plant pathogens to negatively affect crop production has not been confirmed, but some government-sponsored programs included plant pathogens in their bioweapons development programs [12]. Although most such programs were terminated after the 1972 Biological Weapons Convention, signed by 142 countries, the potential for application of agricultural pathogens for harmful purposes remains. The US security community has called for focused consideration of our capabilities to attribute a purposeful event that could threaten US agriculture, including our critical plant-based resources.

### 2.2 Impacts on Various Sectors

Millions of dollars are lost as a result of plant diseases each year, including loss of the commodity itself as well as downstream impacts and the costs of preventative measures. Loss estimates for new or emerging diseases can vary widely. For example, possible losses due to soybean rust, calculated before its arrival into the United States, were estimated at $240 million–$2 billion [13]. Fortunately, actual losses to date from the establishment of this pathogen have been at the low end of this range.

Introduction of foreign crop pathogens inevitably impacts domestic commodity markets and futures. In some cases such impacts may turn out to be positive for producers, as anticipated supply shortages can result in higher prices. However, impacts on export markets are often negative, possibly including temporary halts in exports of produce or commodities or imposition of costly phytosanitary inspections. Negative impacts may also reach the consumer, with adverse public reaction to diseased commodities and concomitant drops in food product sales. Such events tend to promote tighter information management policies during future episodes.

### 2.3 Resolution and Recovery

Recovery from a new introduction of a foreign crop pathogen is generally time consuming and costly. Site recovery may include quarantine regulations to limit spread of the new pathogen to nearby regions and states, implemented by state authorities or by the United States Department of Agriculture (USDA), although many pathogens have proved impossible to contain once introduced. Actual decontamination of agricultural biocrime sites is feasible only in a limited number of scenarios, such as storage or transportation facilities. Actual field sites may remain infested or contaminated for long periods of time, depending upon the climate and biological cycle of the microbe.

The USDA has invested much effort into the development of National Plant Disease Recovery System (NPDRS) plans for high-threat pathogens (http://www.ars.usda.gov/research/docs.htm?docid=14271). Each plan includes methods, practices, and recommendations for short- and long-term management of a specific disease. Many of the NPDRS plans identify critical gaps in knowledge that must be filled before recovery would be likely to be successful, recognizing that true recovery often requires years of research toward the development of customized disease management and control practices, with the eventual deployment of genetic host resistance, where feasible.

### 2.4 Detection of a Deliberate Event

The first question facing law enforcement personnel investigating a potentially suspicious plant disease outbreak is whether a crime actually has occurred. Responsibility lies with the USDA Animal and Plant Health Inspection Service (APHIS) and the Federal Bureau of Investigation (FBI) to decide quickly whether to sequester the site and surrounding evidence as a crime scene. If an outbreak has been threatened or announced, the question becomes whether the situation is real or a hoax. Hoaxes may have impacts as serious as those of a verified disease. While obvious physical evidence, such as microbiological or laboratory materials, may be present at an agricultural scene, early clues to discriminate between an intentional plant disease introduction and one that is natural or accidental often come from spatial or epidemiological patterns or signatures. Because the recognition of anomalous patterns requires baseline data on temporal and spatial patterns of disease incidence for all diseases, research on rapid recognition of deliberate events will require a prioritization of pathogens for targeted study and a focused, large-scale research effort to map worldwide disease outbreaks and determine "normal" baseline patterns for high-priority diseases [14, 15].

### 2.5 Responses to First Detection

Immediate challenges would ensue as a result of declaring an agricultural field or storage site as a crime scene. The extent or scope of the delineation must be estimated rapidly, and sampling strategies developed to cover the affected areas. Genetic background information on relevant pathogens must be gathered or accessed, and a careful plan developed for preservation of evidence. Microbial sampling may be driven to larger scale by factors of pathogen epidemiology and population dynamics, but limited by practical forensic sample preservation capacities. Critical factors and limitations in sampling schemes devised for agricultural settings include the advantages of maintaining live samples, the requirement for stringent chain of custody, and the limitations of sampling time frames. Research to improve statistical pathogen sampling with applications in natural,

accidental, and deliberate outbreak scenarios has been conducted and disease parameters modeled based upon modes of dissemination (soil-borne, wind, rain, insect vectors, etc.) [16, 17], environmental factors, cropping practices (spacing, canopy parameters), and genetic susceptibility of the host. However, more research is needed, with an emphasis on high-threat plant pathogens and on specific applications for forensic investigation.

The USDA-APHIS, the FBI, and the Department of Homeland Security (DHS) will share responsibility for providing and implementing incident command at an agricultural crime scene, although it is not clear whether an incident command structure has been fully optimized and coordinated among the three federal agencies. Clearly, all agencies would benefit from field simulation exercises focusing on deliberate introductions. Crop disease outbreak simulation exercises have been, and continue to be planned and overseen by the National Plant Diagnostic Network (NPDN) Exercises Committee ([18]; personal communication, Carla Thomas, Western Plant Diagnostic Network). Crop disease scenarios have been carried out with or by the NPDN in 49 states, involving county, state, and federal agricultural and law enforcement officials, including tabletop and field exercises, simulating a deliberate event, it is time to focus on issues and problems related to conducting a criminal investigation in an agricultural setting. Major issues for such an exercise include information management, media briefings and access, and decisions on levels of access and knowledge. Decisions on "right to know" are relevant to local, state, and national interests, such as county and state agricultural extension specialists and commercial crop consultants (who may be the first detectors), State Plant Health Responsible Officials (SPRO), State Plant Health Directors (SPHD), and diagnosticians at NPDN laboratories, who may see similar or associated diseased plant samples for diagnosis during the crisis. The site may be subjected to quarantine or regulation by APHIS plant protection and quarantine (PPQ) and/or state officials, introducing a second level of issues related to site accessibility and information management.

### 2.6 The Emerging Discipline of Forensic Plant Pathology

How does forensic plant pathology differ from what plant pathologists do every day? The science of plant pathology is the study of plant diseases and their causal agents, which include fungi, oomycetes, bacteria, viruses and viroids, nematodes, and a few protozoa and parasitic plants. Most plant pathology research is directed at understanding the relationships between pathogens and their plant hosts and, if involved, their insect vectors, with the goal of identifying potential disease management strategies as well as points in the disease cycle at which such strategies are likely to be most effective. Among the most important components of any plant disease management program is early diagnosis, because of its potential to limit the spread and impact of a disease. However, due to the vast and widely distributed nature of US agricultural production, plant diseases may not be noticed for days or weeks. Early diagnosis often is unlikely and when a disease is finally noticed, it may be difficult to identify the site and the means of initial pathogen introduction. Fortunately, the plant disease diagnostician focuses primarily on pathogen identification, and a selection of the best control strategy does not usually require complete knowledge of the disease event or fine discrimination among plant pathogen strains.

In contrast, a forensic scientist investigating a potential crime involving a plant pathogen in a natural or field setting will need to understand as much as possible about the crop or landscape history and management, pathogen introduction and establishment, disease development and spread, and pathogen identification [19]. Although much

knowledge, technology and expertise in plant pathogens already exist and can be accessed in a forensic investigation, special features characterize their application in a forensics setting. As a criminal case is likely to be tried in a court of law, where testimony is subject to vigorous cross-examination, all evidence and information must be collected using highly standardized and validated procedures. The standardization of procedures presents a daunting challenge due to the variety of environments and infrastructures at agricultural sites, and the absolute requirement to preserve microbiological characteristics and molecules required for downstream sample analysis. Development of strict standard operating procedures (SOPs) for such settings could actually hinder sample collection, preservation, and analysis [20]. It may be more appropriate to develop a set of generalized "best practices" for certain agricultural settings (e.g. for fields, postharvest storage facilities, transportation vehicles and containers, etc.), which could be applied and refined on site with experts on scene. More defined SOPs could be developed for extraction and analytical phases, depending upon the type of molecule to be analyzed, from specific procedures that have been published in the plant pathology diagnostics literature.

## 3 ELEMENTS OF A STRONG MICROBIAL FORENSICS CAPABILITY

### 3.1 Sampling and Evidence Handling

Although many features of sampling for investigation of microbial incidents will be similar among incidents involving humans, livestock, or plants, details will differ [19]. After initial infection and before symptoms are evident, sick people and animals are likely to move (or be moved) and interact with one another, and once symptomatic, encounter health professionals. Plant production systems are immobile (although factors that impact them, such as insects and other animals, humans, wind, and water are not) and involve huge acreages and very large numbers of individual plants. Significant time may pass during pathogen establishment and spread before a plant health care professional is involved. Crime investigators, who may have little training in, or understanding of, agricultural systems, must be prepared to sample large land areas and know what constitutes a useful sample and how such samples should be collected, packaged, transported, and stored. Sampling techniques must be reliable, standardized, and validated, and their limits known. Stringent chain-of-custody records are necessary to document sample handling and movement from the field to the laboratory to the courtroom. The precise identity of the pathogen and its relationship to all known microbial relatives becomes critically important. Careful preservation of the evidence, including molecular signatures, and its suitability for downstream reexamination are all required. Yet, very little research has been done to establish optimal sampling strategies in agricultural settings. For example, current diseased plant sampling techniques may involve collection of various plant organs (leaves, stems, roots, fruits, etc.) and organs of various ages (young to old). Samples might be placed into bags of plastic or paper, and might be stored on ice or maintained at ambient temperature. Depending upon circumstances and the experience of the collector, relevant samples may be taken from field soil and from nearby water sources (streams, farm ponds, or irrigation sources). If an insect vector may be involved in the disease, the field may be swept with insect collection nets, or yellow sticky traps or vacuum traps may be deployed; depending upon the insect and its behavior. Needed are specific data on optimal field sampling patterns, sampling tools, such as swabs, knives, bags or containers, storage temperatures and humidity, and other parameters of sampling.

### 3.2 The Role of Plant Disease Epidemiology

The processes and time course of progression and spread of diseases are diverse and complex [14, 16]. Pathogen generational cycling, dispersal, transport, deposition on the host, and disease initiation and progression are unique to each pathogen–host pathosystem. Fungal, oomycete, virus, bacterial, and nematode pathogens occupy unique niches within the agroecosystem, so disease initiation and spread may be influenced by completely unique combinations of macro- and microclimatic factors (air, soil and/or leaf moisture, temperature, solar radiation), arthropod vectors, and/or cropping and cultural practices. The genetic structure and ecology of pathogen populations in their crop hosts and weedy relatives play an important role in the epidemiology of each associated disease.

Modern plant pathogen epidemiology focuses on the development of models that describe and predict diseases on the basis of measurements of the above mentioned factors. To identify anomalous patterns in the introduction and spread of plant pathogens, baseline data on pertinent epidemiological factors and fully developed disease models will be necessary for each high-priority pathosystem in each major climatic region of the United States. Additionally, the development of statistically sound sampling strategies for forensic analysis will require detailed knowledge of epidemiological factors, particularly disease dispersal, and subsequent predictive models to identify the potential scale of an agricultural crime scene [14–16]. Application of baseline epidemiological data to a suspicious event could, for example, recognize that multiple widespread simultaneous disease foci for a pathogen normally spread naturally by wind represent an anomalous pattern, indicative of suspicious origins.

### 3.3 Current Microbial Forensic Identification and Typing Methods Applied to Plant Pathogens

Although evaluations of the event site and disease epidemiology are critical, identifying the pathogen and discriminating among very similar strains are generally among the most important components of a forensic investigation. Analysis beyond visual or microscopic inspection will likely result in the destruction of at least a part of the sample for analysis of its component macromolecules, primarily nucleic acids or proteins. If the sample is very small, choice of analysis for one macromolecule may preclude the ability to analyze the sample for another macromolecule. For example, RNA, the infectious molecule of many plant viruses, is more labile in plant samples than DNA and requires conversion to DNA before PCR can be utilized. Test validation is necessary to assure repeatability, efficacy, and reliability. Validation criteria and procedures for plant pathogens are in a state of development, presently led by USDA-APHIS with multiple agencies developing the National Plant Protection Laboratory Accreditation Program (NPPLAP), which is developing standards and criteria for accreditation and validation to be applied at the NPDN diagnostic laboratories. Criteria and procedures will largely follow those developed in methods validation for animal disease diagnostics [21–23]. To date, such standards for plant pathogen diagnostics have generally been determined individually by the developer of the test or reagent, and “affirmed” by the procedure being published in a peer reviewed journal. Only recently have steps been taken to certify labs or individuals for specific tools and procedures.

### 3.4 Genome Dynamics, Phylogeny, and Systematics

Ideally, an SOP for identifying and typing plant pathogens would be applicable to any microbe. Unfortunately, because microbes vary greatly in gene content, in the mechanisms by which genes change sequence, and in rates of sequence change, it is impossible to choose a single small set of genes shared among all microbes as targets for forensic analysis. Insertion and deletion of large or small DNA fragments and nucleotide substitutions occur at different rates in different organisms and under different conditions. In addition, a variety of DNA rearrangements leading to duplication of genes, deletion of genes or gene segments, inversion of chromosome sections, and translocation or transposition of large pieces of DNA can occur within a cell or its descendants. These changes are mediated by homologous recombination, site-specific recombination, and illegitimate recombination. Overlaid on the genomic changes that can occur in any cell and its progeny are events in which additional DNA is added. Such events include fertilization, heterokaryon formation, (with subsequence homologous recombination), conjugation, natural transformation, and phage or virus infection. Similarly, for diploid cells or nuclei, meiotic processes halve the complexity of DNA such that gamete chromosomes are chimeras of parental chromosomes. Thus, while substitutions may be better indicators in some organisms, in others, examination of the sizes of genomic regions may yield more reliable information.

Microbial forensics research and technology have focused on identifying suspect pathogens to strain level, to establish with reasonable certainty that the pathogen that caused an outbreak came from pathogens in the hands of the suspect. Often this is done by examining one or a limited number of genetic loci. However, the recent demonstration that the entire genome of an organism can be replaced with that of another [24] removes one barrier to creating designer pathogens by fusing genome parts of several different organisms, possibly with some totally synthetic DNA. As a result, the forensic microbiology investigator must be able to survey the causative agent's entire genome to identify the sources of each of its parts. Considering the diversity of microbes, SOPs must be devised for multiple narrow groupings of microbes and/or pathogenicity components, and they must address multiple genomic regions.

If cost is no object, complete genome sequencing will be most useful in pinning down the construction of a genetically engineered pathogen. Complete genome sequencing of several *Bacillus anthracis* strains was part of the anthrax investigation. Recent developments in nucleotide sequencing [25], such as emulsion PCR and the application of pyrosequencing to glass fiber bundles, have already lowered the cost and are making the sequencing of multiple isolates of bacterial species routine and facilitating complete genome analysis of multiple fungal species. Additional high throughput methods including the use of cleavable terminators and ligation-mediated sequencing are under commercial development.

Currently preferred methods of testing matches between DNA from a crime scene and that in a suspect's hands are based upon nucleotide sequences. Whether they can demonstrate absolute identity between two samples depends on the rate at which that DNA changes. As the rates of change are typically high for viruses, due to the error-prone nature of replicative enzymes and the rapid replication of many viral genomes, achieving absolute virus identity is not practical. For bacteria, as demonstrated by research in the anthrax incident [26], the rate of strain divergence is much lower. However, detailed investigations of genomic changes over time are available only for a handful of organisms, and it is likely that many bacterial species undergo mutation at rates higher than those

seen for anthrax. Changes in genomes during laboratory propagation also have been reported [27]. Better understanding of the rates of change and the mechanisms that generate them (substitutions, insertions, and deletions) is needed to judge which changes might be expected in short time frames and which are highly unlikely [28].

Multiple locus approaches to microbial typing include complete genome sequencing, multiple locus sequence typing (MLST), multiple locus variable number of tandem repeats analysis (MLVA), random amplification of polymorphic DNA (RAPD), amplified fragment length polymorphism (AFLP), PCR approaches targeting repeated sequences, DNA–DNA quantitative hybridization and microarray methods involving Single nucleotide polymorphisms (SNPs), whole genome chips, and pathochips. MLST involves determining the nucleotide sequence of a few genes conserved within the taxon being tested [29]. Absence of an expected gene in a sequencing attempt may reveal man-made recombination events. A disadvantage of this approach is that different gene sets appear to be ideal for different species. In MLVA (for example, [30]), the genome sequence of one strain is searched for simple sequence tandem repeats and primers designed to amplify across the region of repeats are then tested on a panel of strains to reveal which loci naturally exhibit polymorphism. If enough such polymorphic loci can be identified, they will likely be distributed over the whole genome and can thus also be identifiers for recombination events. The disadvantage is that the development of such typing systems takes time and would need to be developed for every potential problem microbe. RAPD and AFLP methods [31], though useful in individual laboratories, are difficult to standardize for routine validated use in multiple laboratories. Rep-PCR methods, which amplify repeated sequences in bacteria, are limited to certain species. SNPs, detectable by DNA synthesis methods from small primers such as SNaPshot [32] are useful when dealing with genomes with known fixed polymorphisms, particularly for rapidly evolving viruses having small genomes. DNA–DNA hybridization will readily reveal large replacements (insertions and deletions) in genomes. Microarray applications [33–35] include those in which whole or pathogenically important regions of select agents' genomes are arrayed on slides. Arrays useful for detecting and characterizing synthetic genomes also can be developed. SNPs can also be surveyed by microarray methods [36].

### 3.5 Gene Expression and Protein Modification—Plant Pathogen and Plant Host

An organism's genome provides insight into the potential transcripts that can be produced for subsequent translation, but the final complement of transcriptional and translational products in a pathogen or host can be significantly influenced by the interaction of organisms and the environment. The field of proteomics is rapidly expanding our ability to assess the impact of such regulation. In addition, as the cost of DNA sequencing declines and more sequences become available, their analysis can inform the characterization of genome transcription, providing information about environmentally influenced gene expression. High throughput microarrays can yield transcriptional signatures for both host and pathogen. Antibody microarrays and application of mass spectrometry to small samples have permitted significant advances. Thus, obtaining a "pathoprint" of a specific disease, i.e. all the biomolecules in a specific host–pathogen interaction, may be possible, providing greater precision in attributing or excluding a specific pathogen isolate as the cause of the disease.

### 3.6 Informatics and Data Analysis

Informatics plays a large role in forensic microbiological investigation, and agricultural crimes are no exception. At the level of genomes and genome sequences, although many useful comparative tools and databases have been developed, further refinement may be required. Major developments are needed at the organismal and ecosystem levels to interrelate information about pathogen distribution, vector distribution, and weather patterns into easily accessible models that allow comparison of natural versus man-made outbreaks.

## 4 CURRENT CONTRIBUTIONS OF THE FIELD TO HOMELAND SECURITY AND CRITICAL NEEDS ANALYSIS

### 4.1 Recent and Current Federal Initiatives

The US bioforensics capacity has been substantially enhanced in recent years. A significant new component is the DHS' () National Bioforensics Analysis Center (NBFAC), established at Fort Detrick, MD as part of the National Biodefense Analysis and Countermeasures Center (NBACC). The NBFAC mission is to be the lead federal agency in conducting forensic analysis on materials recovered following a biological attack, and to provide data from analyses to law enforcement agencies for prosecution of biocrimes. The creation of NBFAC presents an opportunity to develop a cooperative federal program addressing forensics gaps for high-priority microbial plant pathogens.

The Laboratory Division of the FBI has played a central role in the development of the emerging discipline of microbial forensics [7, 8]. FBI scientists organized and led a productive Scientific Working Group on Microbial Genomics and Forensics (SWGMGF), which has brought together individuals from various federal agencies involved in national security, the National Laboratories, academia, and industry. The SWGMGF identified research and training needs, set priorities, and provided information to agency administrators and funding units.

The USDA also has created new infrastructure in response to concerns about the security of US plant production systems. In 2002 the USDA Cooperative State Research, Education and Extension Service (CSREES) established the NPDN, a collective network of Land Grant University plant disease and pest diagnostic facilities located in each state [18], enhancing national agricultural security by facilitating rapid detection of introduced pests and pathogens. CSREES' National Research Initiative, a competitive grants program, created a small new, targeted program in Plant Biosecurity that supports integrated projects to facilitate research, extension, and education projects directed at assuring a safe, high-quality, affordable food and fiber for consumers in the United States and its international trade partners.

APHIS' PPQ program safeguards US agriculture and natural resources from the introduction, establishment, and spread of plant pests and noxious weeds (http://www.aphis.usda.gov/plant_health/plant_pest_info/biosecurity/index.shtml). APHIS emergency response is outlined in a National Response Plan, released in 2004 as directed in Homeland Security Presidential Directive (HSPD)-5. APHIS responsibilities, as outlined in the plan, include: "(i) Implement an integrated national-level response to an outbreak of an economically devastating or highly contagious animal/zoonotic exotic plant disease, or plant pest infestation, and (ii) In response to a biohazardous event, the decontamination and/or destruction of animals and plants as well as associated facilities

(e.g. barns, processing equipment, soil, and feeding and growing areas) may be required." As of 2007, a National Response Framework is under development to replace the National Response Plan.

Finally, in addition to conducting its own research relevant to plant biosecurity, the USDA's Agricultural Research Service (ARS) is responsible for implementing the new NPDRS, which was mandated under HSPD -9 (Agricultural Biosecurity). Plant Disease Recovery Plans are being developed for plant pathogen "select agents" listed under 7 CFR part 331 (seven plans developed to date) and for other high-priority threat agents. These plans have been developed by teams of plant pathology experts in government, academic, and private companies, under the direction of the USDA Office of Pest Management Policy. NPDRS resources are also directed at research gaps on new and emerging pathogens by the ARS National Program Staff.

### 4.2 Recent and Current Academic Efforts

Plant pathologists in several of the USDA-supported system of Land Grant Universities, as well as researchers in other academic institutions, have contributed significant research relevant to the emerging field of forensic plant pathology, addressing issues of plant disease epidemiology, diagnostics and pathogen strain discrimination, pathogen evolution and microbial background, and basic pathogen and vector biology. Such efforts are generally independent and focused within the investigator's specific area of expertise. The National Institute for Microbial Forensics and Food and Agricultural Biosecurity (NIMFFAB), established recently at Oklahoma State University to be a component of an overall national effort to safeguard plant and food resources, will provide a synergistic focal point to conduct interactive research, address policy issues, provide cross-disciplinary education and training, and participate in outreach activities, in plant pathology and forensic sciences. Rapid progress by either independent investigators or collaborative ventures has been constrained by the extremely limited amount of targeted funding, both federal and local, for plant biosecurity and agricultural bioforensics initiatives.

### 4.3 The Role of Professional Societies

The American Phytopathological Society (APS), a 5000-member international professional organization dedicated to plant health, has been a significant resource and scientific voice in US plant pathology research, education, outreach, and policy making. APS utilizes its strong publication house and press, interactions with related scientific societies and coalitions, and value-rich annual meetings that serve to bring plant pathology professionals together for scientific exchange. Since 2002, the APS Plant Pathogen Forensics Interest Group, composed of members from various Federal agencies, academic institutions, industry, and others, has met annually in conjunction with the APS Annual Meeting to review and plan US and global initiatives related to forensic plant pathology [19].

## 5 FUTURE RESEARCH–BUILDING CAPACITY AND SCIENCE

### 5.1 Gaps Assessment and Recommendations

*Prioritization of plant pathogens and threats.* With dozens of potential high-value crop targets capable of hosting thousands of pathogens [37] the amount of

information required to develop a comprehensive forensics information baseline in plant pathology vastly exceeds the capacity of the federal agricultural research funding base. Highest priority pathogens must be identified and prioritized. Criteria for plant pathogen prioritization have been developed using external funding [38], and refined in workshops sponsored by USDA and hosted by the American Phytopathological Society, under the NPDRS. Future prioritization efforts will focus on pathogens most likely to be applied in a biocrime, requiring a unique subset of criteria and focusing on deliberate introduction scenarios. The resulting list of highest priority plant pathogens should be forwarded to agricultural and biosecurity research program leaders for their use in developing and applying research priorities for forensics applications.

*Training and education.* Education and training are critical to a strong capability in the emerging discipline of forensic plant pathology [19]. Extant graduate plant pathology curricula are strong in molecular technology and basic sciences, both of which are necessary components of forensic science, but many have moved away from the field-based and applied plant pathology that must underpin targeted forensic investigations. A new paradigm of education, blending the disparate disciplines of plant pathology and forensic sciences, is needed to prepare a new cadre of plant pathologists having the range of expertise necessary for attribution of agricultural crime. Such a program will require close collaborations among educators, and must incorporate epidemiology, botany, biochemistry, microbial ecology, and phylogeny, and other relevant disciplines. Training cannot stop with graduate student education. Extension educators and staff, crop consultants, master gardeners, and others who may be called first in the case of a new and threatening agricultural emergency, also must learn key indicators of intentional pathogen release and appropriate reporting steps. Law enforcement personnel need to know how to recognize an agricultural crime and respond appropriately. These education needs pose challenges at a time when the Land Grant University system, primarily responsible for education in agriculture-relevant disciplines, are suffering from financial cutbacks, reduced faculty numbers, and falling research budgets.

*Forensic tools and procedures.* Better background knowledge of key plant pathogens is essential. Knowing whether a pathogen was present in the vicinity of the outbreak before the outbreak occurred is important when deciding whether a disease occurrence was natural or man-incited. For that reason it is important to consolidate scattered worldwide information on the occurrence of pathogens and potential pathogens in a structured, easily searchable database. Further surveys of what potential pathogens exist in natural and managed ecosystems is also needed to obtain a complete picture of the background against which outbreaks occur.

*The decision tree.* Deciding whether a crop disease is natural or man-made may be very challenging for law enforcement personnel. A series of criteria for making such a decision, or "decision tree," could facilitate this crucial early step, as happened during the investigation of a tularemia outbreak among residents of Kossovo, a nation in strife from 1999 to 2000 [39]. To assess allegations that the outbreak was the result of biowarfare, a series of 12 nonconclusive questions was devised. Answers were rated to reflect characteristics, such as "uncertain and indistinct" "peculiarities or suspicions"; "obvious peculiarities or indications"; "considerable peculiarities or deviations", or "no data available." Formulas converted the data to conclusions having a specified degree of confidence. A current NIMFFAB initiative

is to develop a similar decision tree for use in plant disease outbreaks, and to test the tree using, as a model, a common, endemic plant disease for which a direct comparison can be made between a natural outbreak and an intentional, man-made event (such as those commonly created for assessment of disease-resistance or pesticide efficacy among crop cultivars). Criteria by which an outbreak would be considered potentially intentional could include, but are not limited to, factors such as (i) disease occurrence in a new geographical location; (ii) pattern of disease in the field unexpected based on normal pathogen dissemination methods; (iii) if an insect vector is required for dissemination, disease present without evidence of vector; (iv) disease appears at an unusual time of year, or under normally unsupportive climatological conditions; (v) pathogen is unusual in some way; (vi) pathogen has unusual features; or (vii) evidence of unauthorized human presence is found.

### 5.2 Targeted Funding for Research and Education/Training

Unlike diseases of humans and production animals, those of plants are usually managed within large host populations. Since eradication of infected host plants is generally unsuccessful, most of the limited funding for plant biosecurity-related research and education has targeted the development of new approaches for pathogen detection, understanding plant pathogen epidemiology, or identification of disease resistant plant material. That a plant disease could result from a criminal act has been a new perspective within the plant pathology community. The plant pathology and US security communities now recognize and support the emergence of a new discipline of plant pathogen forensics, but the lack of targeted funding for research and education efforts directly related to forensics for plant diseases has constrained progress. The focused adaptation and extension of our national plant pathology capabilities to meet the needs of microbial forensic investigation will require the attention of Federal funding agency decision-makers and the creation of targeted funding opportunities for development of technologies and resources to enhance national capability to identify, trace, and attribute criminal assaults on plant-based resources.

### 5.3 Cross Communication Among Plant, Veterinary, and Human Systems

Although specific case details and appropriate responses will differ, the needs of the plant pathologist–forensic scientist will be very similar to those of forensic investigators in public health and veterinary sciences with respect to disease epidemiology, molecular biology and detection technologies, sample collection and handling, and other forensic tools, as both seek to determine the origin and source of an outbreak [19]. Close communication among microbial forensics investigators in all three areas will promote synergy and optimization in the use of limited resources. Encouragement of collaborative research, especially by the creation of targeted funding programs, the development of blended and forensics-focused scientific meetings, and other cross-disciplinary activities will facilitate effective communications.

# POTENTIAL FOR HUMAN ILLNESS FROM ANIMAL TRANSMISSION OR FOOD-BORNE PATHOGENS

DAVID M. HARTLEY

*Department of Radiology, Georgetown University School of Medicine, Washington, DC*

## 1 INTRODUCTION

Humans become infected with pathogens via aerosol, oral, and percutaneous pathways. Infection may produce a spectrum of outcomes, ranging from asymptomatic and self-limited disease, to long-term sequelae, to death. During the Cold War, several nations exploited these facts to develop biological weapons for use against humans. Designed to achieve specific strategic or tactical military objectives efficiently, weapons were based on a limited number of agents and designed to be delivered primarily as small particle aerosols [1, 2]. In contrast, bioterrorists may employ a multiplicity of microbial agents, delivered via diverse pathways, against civilian populations. The diversity of entryway and a spectrum of outcomes makes bioterrorism a difficult problem to characterize and defend against.

In this article we focus on diseases of humans associated with animals or food and foodstuffs, which have demonstrated potential to disrupt populations and societies. Human illness could result from a bioterrorist infecting animal species (e.g. livestock,

wildlife, and insect vectors) or food and foodstuffs with biological agents aimed at human populations, or as "collateral damage" in a biological attack aimed at domestic livestock. Volumes have been written on zoonotic and food-borne illnesses; this is a brief resume. However broad, three underlying themes are evident: (i) the threat spectrum is very broad; (ii) options for disease control are diverse and often problematic; and (iii) there is a need for creative approaches to both threat analysis and control and prevention.

## 2 SCIENTIFIC OVERVIEW

This is a brief overview of zoonotic and food-borne threats. Details regarding individual agents and diseases can be found in the References and Further Reading sections.

### 2.1 Zoonotic Threats

***2.1.1 Scope of the Problem.*** Diseases of humans acquired from animal sources or reservoirs—zoonoses—have figured prominently in human health historically. For example, *Yersinia pestis*, the causative agent of plague, is carried by different rodents, lagomorphs, and feline species and vectored to humans by fleas. In the fourteenth century an epidemic of bubonic and pneumonic plague caused the death of an estimated one-third of the population of Europe [3]. Reverberations from this event lasted for centuries; even today the word plague carries the connotation of a disastrous affliction.

***2.1.2 Agents.*** The United States Department of Health and Human Services (DHHS) has published a list of agents important for biodefense (Table 1), many of which are zoonotic. The United States Department of Agriculture (USDA) has an analogous list of agents relevant to livestock health, the majority of which do not cause human disease. The intersection of these describes some 20 zoonotic pathogens of public health importance. The threat to human health, however, is much broader. A standard reference describes approximately 150 zoonoses and communicable diseases common to man and animals, and new and novel zoonoses continue to be recognized [4–8]. Table 2 contains additional threat agents that do not appear on the HHS and USDA lists, but nonetheless command respect.

***2.1.3 Transmission.*** Many zoonotic agents infect humans via multiple pathways. *Y. pestis*, for example, can be transmitted from rodents to humans via biting fleas, droplets, and aerosols. Rift Valley fever (RVF) virus is transmitted to humans from ungulate species via mosquitoes, via aerosolized blood or body fluids from a viremic animal or abortus, and possibly through contact with infected meat. *Bacillus anthracis*, which often spreads from animals to humans via direct contact, can also infect humans via contaminated food and inhalation. *Francisella tularensis* can infect humans via biting arthropods, aerosols, or by handling and consuming infected meat and water. Severity of illness can depend upon the route of infection. In the case of *B. anthracis*, for example, cutaneous anthrax has a much lower case fatality rate (CFR; ~20%) than inhalation anthrax (~90%) [10]. Similar remarks apply to bubonic versus pneumonic plague and vector-borne versus pneumonic tularemia.

**TABLE 1 HHS Select Agents and Toxins**

| Non-Overlap Agents and Toxins (HHS list only) | Overlap Agents and Toxins (common to HHS and USDA lists) |
|---|---|
| **Bacteria, Fungi, and Rickettsia** | |
| Coccidioides posadasii | *Bacillus anthracis*[a] |
| *Rickettsia prowazekii*[a] | *Botulinum neurotoxin producing species of Clostridium* |
| *Rickettsia rickettsii*[a] | *Brucella abortus*[a] |
| *Yersinia pestis*[a] | *Brucella melitensis*[a] |
| | *Brucella suis*[a] |
| | *Burkholderia mallei* (formerly *Pseudomonas mallei*)[a] |
| | *Burkholderia pseudomallei* (formerly *Pseudomonas pseudomallei*)[a] |
| | *Coccidioides immitis*[a] |
| | *Coxiella burnetii*[a] |
| | *Francisella tularensis*[a] |
| **Toxins** | |
| Abrin toxin | Botulinum neurotoxins |
| Conotoxins | *Clostridium perfringens* epsilon toxin |
| Diacetoxyscirpenol | Shigatoxin |
| Ricin | Staphylococcal enterotoxins |
| Saxitoxin | T-2 toxin |
| Shiga-like ribosome inactivating proteins | |
| Tetrodotoxin | |
| **Viruses** | |
| Cercopithecine herpesvirus (Herpes B virus) | Eastern Equine Encephalitis virus[a] |
| Crimean-Congo hemorrhagic fever virus[a] | Hendra virus[a] |
| Ebola Virus[a] | Nipah Virus[a] |
| Lassa fever virus[a] | Rift Valley fever virus[a] |
| Marburg virus[a] | Venezuelan Equine Encephalitis virus[a] |
| Monkeypox virus[a] | |
| Reconstructed replication competent forms of the 1918 pandemic influenza virus containing any portion of the coding regions of all eight gene segments (Reconstructed 1918 Influenza virus) | |
| South American hemorrhagic fever viruses (Flexal, Guanarito, Junin, Machupo, Sabia)[a] | |
| Tick-borne encephalitis complex (flavi) viruses (Central European tick-borne encephalitis, Far Eastern tick-borne encephalitis, Kyasanur forest disease, Omsk hemorrhagic fever, Russian spring and summer encephalitis)[a] | |
| Variola major virus (Smallpox virus) | |
| Variola minor virus (Alastrim) [9] | |

[a]Zoonotic agents

| Emerging and yet-to-emerge influenza |
| SARS coronavirus |
| **Prion** |
| vCJD prion |
| **Parasite** |
| *Trypanosoma cruzi* |

***2.1.4 Disease Ecology.*** Many zoonoses are transmitted in distinct areas suited to their transmission and persistence. If such agents are translocated to new geographic areas, they may be successful if ecologic conditions are suitable. Many factors contribute to suitability, including *inter alia* land use, host population abundance, climate, presence and density of reservoir species, and vector capacity among indigenous arthropods. For example, in the 1999 North American introduction of West Nile virus (WNV), the agent found a diverse set of wildlife hosts and competent mosquito vectors, facilitating effective local and long-range spread (and thereby increasing human morbidity). Other examples of the translocation of pathogens to immunologically naïve regions include *Y*. pestis, which entered the Western United States in the late nineteenth century, finding wildlife and domestic hosts, and persists to the present; and RVF virus, which entered the Arabian Peninsula in 2000, and continues to circulate [11]. In general, the interactions between, and the relative importance and significance of, specific ecologic factors will differ from agent to agent.

A zoonosis introduced into an immunologically naïve population may behave differently, epidemiologically, than it does in endemic regions [12]. In the case of WNV in North America, for example, disease in both humans and wildlife species was more severe than recent observations in Europe and the Middle East would have suggested [13]. Transmission and disease severity are complex functions of environment, host resistance, and immunity, and properties of the agents themselves (all of which are dynamic).

***2.1.5 Disease Diversity.*** As a whole, zoonotic agents cause a spectrum of disease. Toward the less virulent end of the spectrum is WNV, in which the proportion of asymptomatic infections may be as high as 80%; neuroinvasive disease occurs in a small minority of cases. More virulent RVF is rarely asymptomatic, typically resulting in self-limited febrile illness; a minority of cases results in severe complications including

**TABLE 3 Human Vaccines for Zoonotic Threat Agents**

| Agent | Vaccine Type | Status |
|---|---|---|
| Eastern equine encephalitis virus | Inactivated | IND[a], but no longer produced |
| Japanese Encephalitis virus | Inactivated | US licensed vaccine |
| Junin virus | Live attenuated | Not US licensed. Meets requirements for IND application |
| Kyasanur virus | Inactivated | Not US licensed. Shown to be effective in field trials in India |
| Monkeypox virus | Live attenuated | Same as smallpox virus vaccine (and thus part of the US Strategic National Stockpile) |
| Rabies virus | Inactivated | US licensed vaccine |
| Rift Valley fever virus | Inactivated | IND |
| | Live attenuated | Under IND |
| Tick-borne encephalitis virus | Inactivated | Not US licensed. Available in Europe |
| Yellow fever virus | Live attenuated | US licensed |
| Venezuelan equine encephalitis virus | Live attenuated | IND, but no longer produced |
| | Inactivated | IND, but no longer produced |
| *Bacillus anthracis* | Inactivated cell-free | US licensed vaccine. Part of the US Strategic National Stockpile |
| *Coxiella burnetii* | Inactivated | IND, but no longer produced |
| *Francisella tularensis* | Live attenuated | Not currently available in the US |
| *Yersinia pestis* | Inactivated | Effective against bubonic but not pulmonary plague. No longer produced |

[a]IND is required in the United States before a product undergoes human testing. [See 22 - Refs 3, 10, 14–16, Chapter 3]

hepatitis, retinal hemorrhage, and hemorrhagic fever. At the most virulent end of the spectrum are Marburg virus and Ebola virus, fatal in as much as 90% of all cases.

***2.1.6 Therapy and Prevention.*** Antimicrobial and vaccine prophylaxis is available for a subset of the agents shown in Tables 1, 2. Antibiotic resistance is observed in some pathogens. Multidrug-resistant *Y. pestis* has been observed in outbreaks in Madagascar [17]. Vaccines exist for a small subset of the zoonoses (Table 3); many possess poor epidemiologic properties (e.g. low protective efficacy, short period of protection) and undesirable side effects (e.g. teratogenisis, severe local tissue reaction). Personal protective measures including barrier precautions, breathing apparatus, and vector repellent can have good protective efficacy; which are appropriate are agent- and scenario-dependent.

At the population level, public health measures including vector and reservoir species control can be effective. However, such measures can have unintended consequences and should be considered with respect to the scenario. Theoretically, for example, indiscriminant rodent culling in plague-endemic areas could result in a shortage of natural hosts for vectors carrying *Y. pestis* [18]. Fleas abandoning dead rodents could instead infest human habitations, spawning transmission of bubonic plague. In other cases it may be possible to protect humans by controlling disease in intermediate hosts. For example, in

the case of RVF it is theorized that the most effective approach for human protection is to vaccinate domestic livestock populations.

## 2.2 Food-Borne Threats

***2.2.1 Scope of the Problem.*** Modern food production and storage technology has caused massive declines in food-borne illness. Nonetheless, outbreaks continue to occur, facilitated by, *inter alia*, centralized food production and supply systems; the growing frequency of imported food and foodstuffs from nations with less-developed agricultural and production procedures and practices; and lapses in good preparation and serving practices in dining establishments and homes. These and related avenues represent potential targets of bioterrorism [19].

***2.2.2 Agents.*** Foods ready to eat as well as their ingredients can carry a large number of pathogens and toxins. There is no analog of the DHHS select agent list for food-borne pathogens; Table 4 contains a representative collection. Generally, pathogens must pass the gastric barrier successfully and colonize the gut to produce disease. Disease can (but need not) be toxin-mediated, meaning that toxins are produced as a by-product of microbial growth in the gut. Foods contaminated with toxins at the time of consumption can produce disease regardless of microbial growth in the gut (food-borne intoxication).

***2.2.3 Transmission.*** Poor food sanitation and handling practices are important causes of disease. Secondary transmission via fecal—oral routes is possible for many viral and bacterial pathogens, due to a combination of high levels of pathogen shedding, viability and persistence of the agents in the environment and the low infectious dose. For example, depending on the age and condition of host, the infective dose for *Shigella* species may be as low as 10–100 cells. The $ID_{50}$ (dose sufficient to infect 50% of exposed persons) infectious dose of *Vibrio cholerae* may be as high as $10^3$ organisms, but recent observations imply a "hyperinfectious" state of the organism in which this is reduced by 1–2 orders of magnitude for a short time after the pathogen is shed by the host [20]. Whether hyperinfectious states exist for other enteric pathogens of humans remains unknown. Generally, the $ID_{50}$ of food-borne organisms are incompletely known and variable, depending, *inter alia*, upon the food matrix within which they are consumed and the acidity of the gastric environment. Toxins can be extremely potent; botulinum toxin A (a protein neurotoxin), for example, possesses a mean lethal dose $<0.001\,\mu g/kg$ and has been called *the most lethal substance known to humans* [21].

***2.2.4 Disease Ecology.*** Many enteric pathogens are ubiquitous in the natural environment. *Clostridium botulinum*, for example, is found commonly in soil and can contaminate food or foodstuffs anytime between harvest and preparation. *C. botulinum* spores can germinate and grow, producing toxins, in anaerobic environments. Home and occasionally commercially canned products have been implicated in botulism cases; other foods associated with botulism include herb-infused oils, bottled garlic, and baked potatoes in aluminum foil that have been held warm for extended periods of time. *C. botulinum* subtypes may produce one or more of seven types of toxin that readily cross the gastric acidic barrier. *Vibrio* species (including *V. cholerae*, *Vibrio parahaemolyticus* and *Vibrio vulnificus*) are common in estuarine and marine environments, frequently contaminating water and shellfish. *V. cholerae* is also a major cause of disease in areas lacking effective water treatment and sanitation systems.

***2.2.5 Disease Diversity.*** Food-borne agents cause a broad spectrum of disease. Toward the less virulent end of the spectrum are the Norwalk-like viruses and enterotoxigenic (ETEC) strains of *Escherichia coli* (CFRs in nonpediatric and nongeriatric populations near 1%). More virulent are the enterohemorrhagic *Escherichia coli* (EHEC) and other shigatoxin-producing *Escherichia coli* (STEC), often associated with hemolytic uremic syndrome (HUS), kidney failure, and death. Toward the most virulent end of the spectrum are *Shigella dysenteriae* and *E. coli* O157:H7, associated HUS; *Campylobacter jejuni*, associated with Guillain—Barre syndrome; and variant Creutzfeldt—Jakob disease (vCJD) prion ($PrP^{Sc}$), which may be latent for years but conveys near 100% mortality.

***2.2.6 Therapy and Prevention.*** Antibiotics may be indicated for some bacterial infections (e.g. *Listeria monocytogenes, Brucella* spp., *B. anthracis*) but are contraindicated for many others (e.g. EHEC). Many agents are developing antibiotic resistance. For viral diseases and nonviral diseases if antibiotics are contraindicated, therapy is limited to supportive measures. Vaccines exist for very few agents as seen in Table 4. A rotovirus vaccine was approved for infants in the United States in 1998 but was removed in 1999 when it was found to be associated with intussusception. Currently, available cholera vaccine provides weak (~50%) protection 3–6 months after administration; new vaccines are under development [22]. Investigational vaccines exist for ETEC and *Shigella* strains. Investigational antitoxins exist for botulinum toxin, but must be given early in the course of the disease.

Given the limited chemoprophylactic and chemotherapeutic options, preventive measures are central to avoiding food-borne illnesses. Food inspection and good practice in food sanitation and hygiene may be the first line of defense in preventing an introduced food-borne illness, especially secondary cases of infection. With few exceptions, proper food manufacturing, storage, and preparation practices can prevent illness. Exceptions include *Staphylococcus aureus* and some *Bacillus* species, which produce heat-stable toxins. At the population level, the "hazard analysis and critical control point" (HACCP) approach has proven effective in reducing the microbial load of foods and foodstuffs, and thus the incidence of disease.

As the comments of this section suggest, a bioterrorist attack on livestock could result in human illness via multiple pathways, including vector-borne transmission (e.g. RVF, eastern equine encephalitic (EEE)), aerosols (e.g. RVF), infected meat or milk (e.g. brucellosis), and direct contact (e.g. anthrax, glanders). People at primary risk would include agricultural and abattoir workers and those associated with handling animals and raw foodstuffs. Introduction of multiple agents into wildlife species could similarly result in human disease in anyone exposed to wildlife or wildlife-feeding vectors. Regarding food-borne attacks, proper production, preservation, and preparation practices can safeguard against contamination (but may not render heat-stable toxins inert). Post-production contamination, or contamination of foods that are traditionally not cooked or are eaten raw (e.g. lunch meat, fruits, and vegetables), may have a high probability of producing human disease.

## 3 CURRENT RESEARCH

In this section we highlight research directly related to detection, control, and prevention of human illness events (i.e. sporadic cases or outbreaks).

### 3.1 Detection

Early outbreak detection can reduce human illness. There are two essential approaches to event detection: detection by health care providers and detection via the exploitation of surveillance data. In the first category, the incidence of disease in individual health care facilities is detected by clinical laboratory tests. For most organisms of interest, sensitive, and specific microbiologic tests provide results within minutes to days of specimen collection. Higher performance tests are under development (discussed elsewhere in this *Handbook*). Typically, infections are noted by periodic manual chart review or computer

data mining and reported, as appropriate, to public health agencies. In the United States, "notifiable diseases" vary between states; if a particular disease is not notifiable, cases may be reported weeks or months later, and possibly not at all.

Surveillance is the "ongoing, systematic collection, analysis, and interpretation of outcome-specific health data, coupled with the timely dissemination of these data and their analyses" to medical, public health, and homeland security stakeholders [23]. Surveillance can entail the active or passive collection of data such as laboratory-confirmed cases (the most common), incidence of disease syndromes, human behavior thought to be associated with outbreaks, or environmental specimens. In the United States, public health surveillance data regarding many of the agents discussed in this article are reported to different Centers for Disease Control and Prevention (CDC) national surveillance systems (e.g. the National Notifiable Diseases Surveillance System [NNDSS] and the Food-borne Disease Active Surveillance Network [FoodNet]). No single surveillance system in the United States conducts surveillance for all bioterrorism-related agents or conditions [24]. A recent study, for example, identified more than 20 US-based networks for food-borne diseases alone [25]. Syndromic surveillance and human behavior/social disruption surveillance are under active development at present [26, 27].

Surveillance of air samples is carried out in various US cities. Specimens from collectors are removed periodically and analyzed for the presence of certain agents [28]. Details regarding this system, known as *BioWatch*, are scarce. However, the system has produced a number of alerts in different cities, all focused on the zoonotic agent *F. tularensis*. Domestic or wild animals can serve as sentinels of infection (e.g. avian influenza virus [29] and arboviruses [30]). A recent analysis [31] reviewed the potential of animals as sentinels of bioterrorism agents, concluding that "for certain bioterrorism agents, pets, wildlife, or livestock could provide early warning" of an attack.

Event detection from surveillance data is a complex function of measured observables and analytic methodology. The main objective is to identify a signal corresponding to a biological event of interest in a noisy and often ill-defined background. Mathematical and statistical approaches to analyzing such data at present include: spatial, temporal, and spatio—temporal clustering analyses; data mining; multivariable monitoring; and data fusion. Some approaches can be automated and/or executed in real- or near real-time. A review the statistical issues and challenges associated with timely integration of multiple data sources for purposes of detecting epidemiologic events can be found in reference [32, 33]

### 3.2 Control and Intervention

Control and intervention research focuses on discovering new chemoprophylactic and chemotherapeutic agents and identifying public health measures. Gaps revealed in Table 3 are the reason for current emphasis on developing new and improved vaccines. Such efforts, however, are not as vigorous as they could be due to the economic situation facing pharmaceutical companies. Lang and Wood [34] note that "costs from research to licensure, the risks inherent in vaccine development (e.g. technological constraints, regulatory approval), and the short- and long-term market financial evaluations (e.g. net present value, return on investment) are key factors in the decision to develop a vaccine" for rare diseases. Despite efforts to offset these risks (e.g. the Orphan Drug Act of 1982, the BioShield Act of 2004), discovery and development of new vaccines in the United States remains depressed. Similar comments apply to antibiotics.

To spur research and development in drug and other biodefense technology development, the US National Institutes of Health (NIH) and Department of Homeland Security (DHS) sponsor academic "Centers of Excellence" in bioterrorism defense research. Each center is a consortium focused on either a specific topic (DHS centers) or serving specific geographical regions (NIH centers). (See URLs listed in Further Reading.) Among others, vaccines for tularemia, RVF, and brucellosis are being studied at these centers. Additional researches focus upon diagnostic technology and analytic methodologies.

Identifying effective (or finding new) public health measures involves a range of analytic activity. Traditional epidemiologic observational studies identifying infection risk factors are useful, particularly for newly recognized agents about which little is known. Mathematical modeling and simulation techniques have led to fundamental insights regarding contagion processes and the applied practice of public health [35, 36]. Mathematical models enable evaluation of control and intervention measures such as vaccination (e.g. impact of protective efficacy, time-to-protection, and rate of administration), vector control (e.g. impact of adulticides vs. larvicides, spraying frequency, spraying concentration), host culling (e.g. impact of the rate of culling, effects of incomplete culling), and reduction in exposure rates, without costly or difficult laboratory experiments.

Models are built upon knowledge of the epidemiology of specific diseases. If properly constructed and analyzed, they can provide information on the effects of different controls or other quantities of interest. Thus, models can guide further laboratory research as well as provide defense planners with valuable guidance. At present, the literature reveals a paucity of applications to zoonoses. Current work by modelers at the DHS National Center of Excellence for Foreign Animal and Zoonotic Disease Defense [37] is noteworthy because it involves experts in human and agricultural medicine, human and agricultural epidemiology, microbiology, mathematics, ecology, geography, and information technology. The effort is addressing aspects of spatio—temporal vulnerability to RVF introduction, the relative payoff of possible control and intervention measures, and the economic impacts of an introduction into the United States.

A related methodology is risk assessment (RA), which aims to identify what events can happen, their likelihood, and their consequences. RA grew out of methods developed for assessing health impacts from chemical exposure. Typically, there are four stages to RA: hazard identification, exposure assessment, dose-response assessment, and risk characterization. Qualitative RA is descriptive and indicates whether disease is likely under specified conditions of exposure, whereas quantitative RA provides numerical estimates of risk [38]. Both types are relevant for risk management and communication in biodefense. RA has been applied to several bioterrorism issues, including the risk of a RVF incursion and its persistence within the European Community [39]. However, methodological and data gaps exist that continue to limit researchers ability to complete comprehensive RAs for most biothreat agents.

Regarding food safety and microbial contamination, microbial risk assessment (MRA) is under active development at present. MRA recognizes the biologic nature of organisms and accounts for it in the analysis. Typical facets of MRA include (i) the dynamic concentration of biologic agents due to growth and death; (ii) the heterogeneous distribution of biologic agents on/in food and water media; (iii) the potential for secondary (e.g. person-to-person) transmission; and (iv) the role played by immunity [40]. MRA studies have been carried out on a relatively small number of food-borne pathogens; the extent to which the methods developed for food-borne diseases can be utilized in assessing homeland security risk remains undemonstrated. There are substantial uncertainties

regarding the use of animal models to inform human RAs; the viability and infectivity of pathogens in environmental media; and the use of potential sampling and detection methods for RA. To address these and related issues, the US DHS and the Environmental Protection Agency have recently founded the Center for Advancing MRA.

## 4 CRITICAL NEEDS

More is needed to assess the homeland security implications of the above discussion. Here, we consider three broad categories.

### 4.1 Data Needs

Robust, real-time surveillance systems capable of accurately and precisely estimating baseline values of human and veterinary disease incidence in both time and space are needed. In addition to looking "inward" at local, regional, and national disease activity, surveillance must look "outward" to identify the potential of threats being imported from distant regions. This requires up-to-date knowledge of disease transmission in foreign areas as well as data on the ecological conditions that might support the emergence and transmission of zoonoses. Analytic methods and effective concepts of operations to exploit early warnings of diseases effectively must be developed in conjunction with public health and homeland security stakeholders.

Mathematical modeling and RA methodologies require a range of data on different threat agents, such as distributions of latency and incubation periods; identification of the competent vectors of different agents in terms of temporal (e.g. seasonal) and spatial distributions; periods of disease, attack rates, and related epidemiological quantities, especially for exotic diseases; and dose-response functions. At present, such data are not often available. Both laboratory and field studies are needed. In the case of livestock diseases, up to date data on the location or probable location of livestock populations are needed, as are reliable data on livestock transportation between farms, feedlots, stockyards, and slaughter facilities.

### 4.2 Analytical Needs

While RA and mathematical modeling can both contribute to vulnerability analysis (e.g. identification of ecological areas, distribution nodes, or manufacturing systems that are particularly vulnerable to bioterrorism), only a small number of such analyses have appeared from the list of agents appearing in Tables 1–4. Analyses of the potential economic impact of these diseases must be elucidated. Only if such data are available that it will be possible to identify priorities and understand the need for vaccines and other public health prevention and control efforts. Comprehensive analyses involving more agents are needed; and it is vital that stakeholders and experts from all relevant technical fields participate.

Collaboration from related fields (e.g. ecology, microbiology, and psychology) is needed to resolve challenges facing mathematical epidemiologic modeling, including identifying methods to integrate data collected at different temporal and spatial scales into models; identifying of surrogates for data that do not exist; refining the multimodeling

approach (i.e. integration of models into larger models); and finding how best to communicate the results of models to decision makers, policy makers, planners, and public health operations personnel. Similarly, approaches to model validation must be developed for the rare and foreign diseases of highest interest, for which limited data is available.

### 4.3 Basic Science Needs

Questions regarding how a variety of zoonotic agents are maintained in natural populations; how they respond to changes in the environment; and what causes them to emerge and be transmitted remain unanswered. Lederberg and Shope [41] notes that "the precise ecological factors that lead to human infection . . . are murky, and textbook descriptions of the epidemiology of most zoonotic diseases are at best simplistic." In order to effectively counter threats from these diseases, we must understand the ecology of such agents better.

## 5 RESEARCH DIRECTIONS

In the short term, a central question is how to bring current and nascent capabilities to bear on public health preparedness so that effective interventions can be made in the event of a bioterror incident. Research into public health systems engineering should have a high priority. For example, how might current sensors be employed (e.g. in animal and food settings) in optimal spatial and temporal sampling strategies to detect threats at the earliest time possible? And given detection, what are the appropriate actions to initiate, given existing treatment and prophylactic options and logistic limitations on delivery and administration? It is unclear whether, for example, the BioWatch system has been designed according to such concerns, or whether surveillance systems that are under development aim to address such questions.

Such questions could be investigated with current analytic methods. A first step entails the refinement and validation of analytic tools. Mathematical approaches are, arguably, the only way to identify vulnerabilities, opportunities for prevention, and candidate control options in a systematic, unbiased way. However, models must be validated if they are to be credible. Validation is difficult for rare food-borne infections and zoonotic diseases that exist only in foreign nations. Prospective field studies in endemic areas must be undertaken in order to validate models of important threat agents.

In the longer term, effective vaccines, antibiotics, and antivirals must become available if we are to increase public health preparedness. Research to identify generalizable programmatic approaches to commercialization of new solutions would be of immense use. Research from the US Centers of Excellence, for example, must be transitioned and commercialized if new products are to become available at the clinical level. One way forward may be to focus on public—private partnerships for purposes of technology transfer and product transition. However, the economic disincentives facing pharmaceutical companies must be solved if these products are ever to be mass produced.

## 1 INTRODUCTION

"Agroterrorism" evokes images of sick and dying animals, forlorn farmers, and burning cow carcasses. The public health risks associated with agroterrorism are typically described as the spillover human illness associated with agroterrorism agents that are zoonoses (diseases shared by domestic animals or wildlife and humans), such as anthrax or cattle brucellosis, the human form of which is undulant fever. However, public health is more than simply the illness and death directly caused by infectious diseases. The World Health Organization (WHO) defines health as "a state of complete physical, mental, and social well being and not merely the absence of disease or infirmity" [1]. The potential public health risks of livestock agroterrorism must be evaluated in this broader context.

Agroterrorism is the intentional use of chemical, biological, radiological, nuclear, or explosive weapon or device against the nation's agricultural industries with the goal of generating fear, causing economic losses, and/or undermining social stability [2]. Livestock agriculture presents a comparatively easy target for intentional disease introduction. The widespread distribution of farms and ranches across the country, relatively easy access to fields and buildings, high density husbandry, concentrated feed production and distribution, livestock and poultry marketing and transportation channels, imperfect traceability of farm inputs and livestock, and inadequate biosecurity represent significant vulnerabilities. Consequently, the threat of agroterrorism is real and the potential public health consequences must be considered.

## 2 AGROTERRORISM DIFFERS FROM NATURAL DISASTERS

No nation has suffered a major agroterrorism incident in recent times and the refereed scientific literature is lacking in scientific studies of the public health implications of natural, accidental, or intentional animal health catastrophes. The impact of agroterrorism is informed by examining other types of catastrophic events such as natural disasters and government reports on major animal disease outbreaks and their control. Natural disasters and agroterrorism differ in a number of ways (Table 1).

**TABLE 1 Similarities and Differences of Natural Disasters and Agroterrorism (Adapted from Hall, 2003)**

| Dimension | Natural Disaster | Agroterrorism |
|---|---|---|
| Threat/risk | Local | Local or widespread |
| Knowledge of responders/physicians | High | Low |
| Knowledge of veterinarians | High | Moderate |
| Public health preparedness | Moderate | Low |
| Impact phase | Sudden | Variable |
| Duration | Acute | Variable |
| Hoaxes/copycats | No | Yes |
| Altered perception of safety | Local | Widespread |
| Potential for altered trust in officials | Moderate | High |

### 2.1 The Characteristics of Natural Disasters

Floods, fires, droughts, earthquakes, tornados, typhoons, hurricanes, volcanic eruptions, and tsunamis are natural disasters with which we all are familiar. Natural disasters have a known *beginning* and *end*, that is, hurricanes and tornados strike and then move on or floods and fires begin and then subside or are managed. The patterns of natural disaster have been widely studied, so that the geographic areas prone to these events can be mapped. Southern California is prone to wildfires and mud-slides, Florida and the Gulf Coast to hurricanes, and Bangladesh to typhoons. These natural disasters usually have a sudden impact on a circumscribed geographic area. Although potentially devastating for those involved, the public health risks are well characterized, with a whole emergency responder network and preparedness protocols in place. Even though the magnitude of the disaster may initially overwhelm responders, the mechanics of response are universally understood so that reinforcements can be solicited from other localities, states, and even countries. Natural disasters are so much a part of everyday life that the public response is a collective resolve to aid those affected and speed recovery, to get life "back to normal".

### 2.2 The Characteristics of Agroterrorism

Agroterrorism is not commonplace. Given the motivations of the perpetrators, the beginning and/or end of the event may never be known. Intentional acts can take place anywhere. The intent may be harm to animals, people, the economy, the public sense of security, or all of the above. The terrorist's target can be local, like an individual community or farm, or widespread, with multiple sites attacked across a wide geographic area. Not only can these events be devastating, but we are also largely unprepared for handling agroterrorism events because of the large number of uncertainties described above and because these events cut across multiple jurisdictional lines, including animal health, public health, and law enforcement. Traditional approaches to investigating a crime such as roping off an area and leaving it undisturbed to facilitate evidence collection may be exactly the wrong response to an infectious disease or chemical attack where rapid action including cleaning and disinfection may be critical to contain the potential damage. Unlike natural disasters, intentional acts are often followed by copycat actions including threats and hoaxes, which themselves have potential consequences in terms of mental health. Furthermore, the opportunity costs of responding to the livestock agroterrorism event,

copycat action, threat, or hoax may be significant, redirecting scarce public health dollars away from programs with a greater public health impact. Finally, intentional acts of agroterrorism have the potential to dramatically alter our collective perception of safety. The uncertainties surrounding the event likely will exceed the certainties, further altering the trust people have in the ability of government to respond effectively. While the danger of the event is real, the multiple uncertainties and the intentional nature of the event will stimulate a wide array of emotional reactions including anger, frustration, dread, and anxiety. In the language of risk communication, the public "outrage" will be huge.

## 3 AGROTERRORISM AND THE PUBLIC'S PERCEPTION OF RISKS

Given that terrorism by definition is an act intended to create "terror", the public's response to the agroterrorism event is critical. Risk communication experts know that our personal perception or interpretation of risk involves not only the available scientific data concerning the likelihood and consequences of something bad happening, but also our personal value system and the degree to which we feel that the risk is important, a subjective assessment variously called *dread* or *outrage*. Although scientists tend to focus on what is known about the likelihood and consequence of something going wrong, humans are influenced, often disproportionately, by their feelings.

A whole range of outrage factors have been catalogued [3]. Germane to this discussion of agroterrorism are factors such as the degree of personal control (uncontrollable risks are perceived to be more important), intentionality (intentional acts of terrorism stimulate more dread than a similar event caused by an accident), and the newness of the risk (new risks evoke more outrage). Acts of agroterrorism will ignite public outrage and foster elevated perceptions of risk.

## 4 THE IMPACTS OF AGROTERRORISM

The direct impacts of agroterrorism reach far beyond the animal health impacts (i.e. illness and death of affected animals). Affected producers bear some or all of the costs of treatment and response. The standard response to outbreaks caused by many of the agroterrorism agents such as foot-and-mouth disease (FMD) and highly pathogenic avian influenza (HPAI) is "stamping out", the systematic depopulation of affected herds and flocks. Although the government may offer indemnity for all unaffected animals destroyed and the costs of cleaning and disinfection, these represent only a fraction of the overall costs of the incident. No compensation is usually provided for dead and diseased animals or for the loss of anticipated income. Losing animals means a loss of investment and potential loss of valuable genetics in the case of purebred or breeding animals. Producers may also have a significant emotional attachment to the animals. Additional costs of recovery may include the forced "resting" of the facilities to assure the death of any remaining pathogens before they can be restocked (down time).

### 4.1 Impacts Extend Beyond the Producers Experiencing the Disease

The producers experiencing the disease are not the only ones affected. In cases of exotic disease introduction, those farms with potential exposure (epidemiologic links) and geographic proximity are quarantined and the herds and flocks are then often destroyed to

prevent spread. Movement of animals and animal products are restricted and additional health requirements may be put in place. These additional control efforts will increase the cost of production for livestock, reducing the producer's net income and adding to the logistical challenges of production, harvesting, and processing. Evaluating the public health risks must include those who are not experiencing the disease but whose livelihoods and sense of security also are affected.

### 4.2 International Implications for Trade

On the global scale, livestock agroterrorism can affect international trade. Introduction of a new livestock disease changes the disease status of a country as it can no longer claim disease freedom. A change in disease status of the country can cause major disruption in the export of animals and animal products. Trade issues are rarely quickly resolved. Once established, trade bans often take months to years to resolve such that reestablishment of historical levels of export is achieved.

Even the control strategy chosen to address the introduced disease can have trade implications. For example, a country that chooses to use vaccination as a strategy for dealing with FMD can only achieve a classification of "free with vaccination", which still has negative trade implications.

The economic impacts of trade disruptions can be huge. Agriculture remains one of only a handful of sectors in which the United States and many other nations maintain a positive trade balance, due, in part, to international trade in animals and animal products. The ripple effects of trade bans secondary to livestock agroterrorism may extend throughout the nation.

## 5 EVALUATING POTENTIAL PUBLIC HEALTH RISKS OF LIVESTOCK AGROTERRORISM

Based on current knowledge of natural disasters and natural or accidental animal disease outbreaks, livestock agroterrorism will have both direct and indirect impacts on public health. Victims can be described on many levels from those directly involved with the event to concerned and caring people outside of the affected area [4]. These risks include human illness and death from zoonoses, individual mental health impacts, and societal impacts including social well being and the secondary impacts of economic disruption on rural communities and the stability of agricultural industries.

### 5.1 Direct Public Health Impacts of Livestock Agroterrorism

The direct public health impacts of agroterrorism are those where the intentional act of terrorism itself, whether introduction of the chemical, biological, radiological, nuclear, or explosive agent, affects livestock and their producers. The direct public health impacts of livestock agroterrorism also extends to first responders including the animal health professionals and law enforcement agents who would visit the scene of the incident(s), handle the diseased animals, and investigate the criminal act. The direct public health impacts can also extend to others along the food chain, such as abbatoir workers who harvest the animals.

***5.1.1 Physical Health Impacts.*** The agent used by the terrorist can have direct impacts on farm workers and those present at the time of attack plus first responders. Five of the six Category A bioterrorist agents are zoonoses (i.e. diseases that affect both humans and domestic animals). Many zoonotic agents can serve as potential agents of agroterrorism. For example, natural exposure to Nipah virus has a high case mortality rate in humans working with affected pigs. Although Nipah has not been shown to transmit from human-to-human, this agent can be easily produced in large quantities in cell culture and does not have effective treatment. Other agents that could cause illness and death from zoonoses include tularemia, plague, brucellosis, and Q fever.

Some agroterrorism agents themselves can cause neurologic disease such as encephalitis. Neuropsychiatric syndromes or symptoms are associated with anthrax, brucellosis, Q fever, botulinum toxin, and viral encephalitides [5]. Neuropsychiatric sequellae also have been noted in people infected with Nipah virus [6].

***5.1.2 Mental Health Impacts.*** The mental health impacts of an agroterrorism attack likely will exceed the physical health impacts, perhaps by several orders of magnitude. Mental health issues may increase the case load and diagnostic challenges on healthcare providers as well as redirect resources that may be important for prevention and control actions related to the incident.

Disasters are stressful situations and individuals respond differently to these traumatic events. Increased depression is one of the psychological and psychiatric impacts of natural disasters that has been studied [7]. The stress of the agroterrorism event may be even greater due to the newness of the threat and its unique characteristics [4]. Man-made disasters, especially intentional ones like bioterrorism, cause more psychological and psychiatric problems than natural disasters. Since no country has modern experience dealing with a livestock agroterrorism event, it would generate unique stressors. Social isolation also may contribute to this stress as quarantines and movement restrictions may preclude normal community interactions, with some agricultural workers under virtual house arrest.

Most people suffering stress recover without any long-term psychiatric sequellae. Nevertheless, long-term psychiatric illness can also be expected, like depression, post-traumatic stress disorder, substance abuse, anxiety, and somatization, where psychological stress is expressed as physical problems [4].

## 5.2 Indirect Public Health Impacts of Livestock Agroterrorism

The indirect public health impacts of livestock bioterrorism include the secondary public health impacts precipitated by the illness and/or death of livestock and/or producers, the economic losses suffered by individuals and the community, and the societal disruption. Indirect public health impacts may also result as unintended consequences of the animal health, law enforcement, and public health response to the agroterrorism event [4].

***5.2.1 Indirect Physical Health Impacts.*** While humans are the dead end host for many zoonoses, others have significant potential to spread from human-to-human. These secondary cases could include healthcare workers and the extended family, neighbors, or community members who provide support for the affected farm workers and/or first responders. Theorists also speculate that sophisticated terrorists might genetically engineer an agroterrorism agent to enhance its potential to spread from human-to-human.

Fomites may play a role in secondary spread of zoonoses or other chemical or radiological agent. Contaminated equipment leaving the affected premise could expose others. Contaminated clothing of farm workers or first responders could expose other livestock populations or "foul the nest", taking the agent home to expose family members. Biological vectors such as insects may also play a role.

Although less likely in developed countries with robust food systems, an agroterrorism event could lead to significantly increased costs of protein from animal sources (meat, milk, poultry, and eggs). These cost increases may precipitate substitution of other protein sources or reduction in dietary protein altogether which can contribute to malnutrition. The 1983 HPAI outbreak in Pennsylvania, while not agroterrorism, caused an increase in poultry prices, costing consumers an additional $548 million in food expenditures [8].

***5.2.2 Indirect Mental Health Impacts.*** Disasters, regardless of their cause, evoke an outpouring of care and concern not only in the affected communities but also among those far removed from the event. Some people far distant from the event will experience the disaster vicariously with such intensity that it creates psychological health problems for them. Still others will develop mental health problems due to the ripple effects of the disaster on the agricultural community and economics.

In the case of agroterrorism, the first discussion topic is usually economics. The economic impacts not only have direct effects on the farmer's mental health but they also affect individuals and businesses along the entire food chain including input suppliers, food processors, transportation, retailer, and food service providers [2].

Producers who lose animals or suffer direct or indirect economic damage may in turn have less money to spend on healthcare and other related costs. In some cases producers never recover from the loss of their animals or income and may lose their livelihood and have to turn to other types of employment. The social disruptions secondary to agroterrorism events or large-scale animal disease outbreaks have not been documented.

The economic impacts of agroterrorism extend far beyond the farming community itself. Agriculture provides the primary employer and largest source of economic activity for many rural areas. Decreased agricultural revenue has a trickle down effect on goods and services. Local community businesses may suffer sufficiently to have to lay off employees, adding to unemployment. Tourism, too, can be affected if the response to the disease outbreak limits access to the area or negative publicity from the event discourages visits. The tax revenue generated by an agriculture-based economy fuels public services and community improvements. Economic instability also decreases local philanthropy, negatively affecting charities that pick up where government services stop. Taken together, the economic impacts of agroterrorism have the potential to adversely affect the public health infrastructure of rural communities.

An agroterrorism attack with widespread impact may disrupt the food system and/or cause an increase in food prices that may affect discretionary income and diets. For animal products that are often produced, processed, and consumed in a defined geographic area like dairy products and eggs, an agroterrorism attack may disrupt local supplies. Consumers confronting empty food shelves in the local grocery will have a heightened sense of the impact of the event, which in turn may lead to anxiety and other psychological manifestations.

More difficult to estimate are the psychological impacts that may follow from the increased sense of vulnerability of the food supply and the loss of trust that the food supply is safe. An agroterrorism event could seriously disturb the community's sense

of optimism. The event may shake public confidence with political ramifications for the party in power at the local, regional, or national level.

## 6 CRITICAL NEEDS ANALYSIS AND RESEARCH DIRECTIONS

Preparedness in the context of the public health impacts of agroterrorism is hampered by the paucity of scientific literature. Even studies of public health impact of natural or accidental livestock disease outbreaks are limited. An agroterrorist event would have a higher impact than an unintentional outbreak because a terrorist would make an attempt to create maximum damage. Recognition of this difference highlights the need for additional research exploring the adaptability and flexibility of public health to address these types of situations including provision of broad-scale psychological and psychiatric support in situations where the healthcare providers themselves are also experiencing unprecedented collective stress due to the intentional nature of the event and its impact on the core need we humans have for food [9]. Furthermore, given the global nature of our food supply, consideration must be broadly given to addressing the needs of consumers as well as the affected producers and their communities. Methods for effective risk communication and the use of transdisciplinary approaches need to be explored.

# THE ROLE OF FOOD SAFETY IN FOOD SECURITY

JUSTIN J. KASTNER, ABBEY L. NUTSCH, AND CURTIS L. KASTNER
*Kansas State University, Manhattan, Kansas*

## 1 INTRODUCTION

Today's agricultural security and food safety and security discussions are, admittedly, burdened by confusion of terminology. Therefore, this article necessarily begins by addressing the terms "security" and "defense" in the context of the agricultural and food industry. Some definitions that have been used by food regulators include the following:

- *Food security.* Activities associated with ensuring the adequacy of the food supply.
- *Food defense.* Activities associated with protecting food from intentional contamination.

The term "food security" has been contested in recent years. In the post-9/11 era, new understandings of security have influenced the interpretation of both "homeland security" and "food security" [1, 2]. Indeed, the adoption, by such regulatory agencies as the US Food and Drug Administration, of the term "food defense" stems from confusion surrounding the term "food security" [3].

While some contend that "food security" ought to be strictly the domain of international-aid and economic-development policy communities, others have used the term "food security" to encompass international food defense issues as well as unintentional incidents that impact the adequacy of the food supply. Rather than letting semantics unduly complicate more important issues, leaders should support—or, at least, tolerate—the use of either "food security" or "food defense" in discussions devoted to

how to protect the food supply and ensure food safety as well as food-supply sufficiency. Quite simply, knowledge of and practices regarding food safety are applicable regardless of one's understanding of food security or food defense. The purpose of this article is not to debate the correct terminology but to show how food safety knowledge serves the broad objectives of food security/defense. Whether or not a food industry professional is concerned about bioterrorism, quality assurance, sanitation, physical site security, border security, supply chain management, or international trade, he/she will find that food safety capabilities and strategies are almost, if not always, applicable.

The historical development of preventive, process-oriented food control systems notably includes the Hazard Analysis and Critical Control Point (HACCP) system; in the next section, the advent of HACCP and its application to food safety/defense is discussed. In order to paint a picture of the relevance of food safety principles, practices, and research to food security/defense, a situation- and commodity-specific example is offered in the next section. Finally, food safety education and its application to food security/defense is highlighted.

## 2 FOOD SAFETY PREVENTION, HACCP, AND FOOD SECURITY/DEFENSE

Food safety and control systems have developed in concert with better understanding of foodborne hazards [4]. Prior to the mid-nineteenth century, for example, a lack of epidemiological knowledge about microbiological pathogens left public health officials wondering what was the cause of diseases, including those brought on by the ingestion of particular foods. However, during the second half of the nineteenth century—and, indeed, up to the mid-twentieth century—particular foodborne illness cases were tied to particular agents (e.g. between 1850 and 1880, trichinosis and other diseases' link to parasites was confirmed; between 1880 and 1950, specific bacterial diseases were tied to specific meat-borne pathogens). Between 1950 and 1985, food safety researchers continued to identify new microbiological (and chemical) hazards in food, and they became intrigued with the idea of intervening in food processing to *reduce* the likelihood (i.e. risk) of such hazards occurring [4].

By the mid-1980s, more deliberate process-oriented (as opposed to merely inspection-oriented) systems came into being [4]. One program—HACCP—had been developed previously to ensure food safety in the US Space Program; during the 1980s and 1990s, food companies and federal regulators began to insist on the seven principles of HACCP as a way to systematically control hazards (whether biological, chemical, or physical) in the food supply. The principles include the following:

1. Conduct a hazard analysis (identification of biological, chemical, and physical hazards that may cause food to be unsafe).
2. Identify critical control points, that is, steps or procedures in which a hazard can be prevented, eliminated, or reduced.
3. Establish critical limits for each critical control point (e.g. specific temperature or processing parameters that ensure reduction of risk to an acceptable level).
4. Establish critical control point monitoring requirements.
5. Establish corrective actions in the event monitoring to indicate a violation of a critical limit.

6. Establish record keeping systems.
7. Establish validation procedures to demonstrate the HACCP system is in fact working.

HACCP is notably different from inspection-oriented food safety systems. HACCP's introduction into the food industry has helped foster a prevention-oriented mindset amongst food professionals. Prevention-oriented food safety systems like HACCP are an invaluable asset in larger food security/defense efforts. Food safety systems can, in a sense, provide a kind of proverbial "downpayment" on ensuring that a food plant is culturally open to systematically considering, reducing, monitoring, and documenting risks of all kinds.

## 3 CARVER + SHOCK AND THE EXAMPLE OF THE KANSAS MEAT INDUSTRY

Examples are illustrative of wider concepts, and this section considers how food safety efforts can help address food-security vulnerability concerns. In 2006, Kansas State University (K-State) conducted a vulnerability assessment of the meat processing industry in Kansas. The assessment revealed several instances in which food safety focused initiatives could be adapted to address food security/defense issues. Similarly, the assessment underscored how university-based food safety research could contribute to larger objectives of food security and food defense. This section explains the relevance of food safety efforts—including research efforts to broader activities designed to ensure a more secure food supply.

CARVER + Shock is one of several tools and resources available through the US Food and Drug Administration [5]. CARVER is an acronym for six factors used to evaluate the attractiveness of a target for attack: Criticality (assesses the public health and economic impacts), Accessibility (the ability to physically access and egress from a target), Recuperability (ability of a system to recover from an attack), Vulnerability (ability to accomplish a successful attack), Effect (amount of direct loss from an attack as measures by loss of production), and Recognizability (ease of identifying a target). "Shock" assesses the combined health, economic, and psychological impacts of an attack within the food industry.

Food safety systems (including HACCP) and food safety educational efforts (discussed at the end of this article) minimize food safety hazards and help provide an initial obstacle to achieving any significant consequences through intentional contamination. With regard to Criticality, the size of the meat processing industry in Kansas is consistently ranked among the top 3 in the nation. Indeed, the processing plants operated in Kansas by the world's largest processors account for the bulk of that ranking; however, medium, small, and very small processors also contribute significantly to the high national ranking. Regardless of the relative contributions (i.e. whether production stems from large or small plants), Kansas is a major contributor to the totality of the United States and global meat industry. What happens in Kansas—whether in a large or small plant—impacts not only the state but also the entire domestic and international meat industry. Therefore, the safety of meat products processed in Kansas has far reaching implications that can impact both public health and economic stability. Regarding the safety and security of the meat supply, the US meat industry recognizes that all of its members could be "painted with the

same brush" if meat safety were compromised. When considering meat processing along with allied livestock production, the total system is the number one revenue generator in Kansas. The value of livestock, poultry, and their products in 2002 was $6.3 billion in Kansas alone [6].

The second element of CARVER + Shock—namely, Accessibility—also falls within the domain of traditional food safety efforts. Food safety officials are concerned about hazards and how they might be introduced into a food production system. The concept of food defense more purposefully addresses the issue of intentional actors who might introduce a hazard into the food supply. Terrorism, whether instigated by a transnational terrorist organization, a disgruntled employee, or a hired perpetrator, can result in similarly chaotic, catastrophic consequences for the food industry. Classically motivated terrorists prefer to destroy life as well as economic stability with an emphasis on taking as many lives as possible. Though the emphasis on protecting public health is a primary concern, an attack on the economy alone could, indeed, be devastating in and of itself.

Because of the meat processing protocols being similar for beef, pork, lamb, and poultry, the following scenario was viewed as generically applicable to all species in the Kansas meat industry. Animals are normally held and rested for a period of time at the slaughter facility before being processed. A hazard could be introduced at that point and carried into processing. An externally administered hazard would be removed or at least diluted during dehiding, dehairing, pelting, or defeathering. Internalized hazards would be largely removed during evisceration. Therefore, to have the greatest impact, introduction of these later in processing was assessed as being more likely.

Intact carcasses would be the next opportunity for cross contamination during slaughter or initial intentional contamination. However, this would primarily be limited to the surface of the carcass and subsequent food safety interventions (e.g. trimming, washing, and decontamination) would reduce or eliminate the hazard.

It is the further processing of lean trim and particularly in comminuted systems (i.e. ground beef and wieners) that offers the greatest opportunity for introducing a hazard that would be uniformly incorporated into a large quantity of meat. Formulation ingredients (i.e. water and spices) would also widely distribute a hazard if contaminated. Further processing operations are readily accessible to workers and introduction of a hazard during mixing and blending would be relatively easy and effective. Smaller, isolated-yet-devastating episodes could be perpetrated at, for example, retail stores where grinding and mixing occurs [7].

With regard to the issue of Recuperability, food safety systems and food safety education place an emphasis on how to institute "corrective measures" in the event of a food safety violation. Traceability, mediated through attention-to-detail management and appropriate lot and date coding, would allow for product recall while the product is in storage or transit. All companies should have this capability to address food safety issues. However, if the hazard persisted undetected for a period of time, much of the product would be consumed prior to the recall. Even though it may not always be possible, consumers could use coding information to avoid consumption. Directions for disposal would also be required. Effective, appropriately crafted communications would be imperative to ensure an orderly and effective response.

With regard to Vulnerability, those studying the Kansas meat industry concluded that a hazard introduction, while feasible, was likely to be less attractive than other segments of the food industry. (Indeed, if a widespread impact on public health was the terrorists' goal, the beverage industry would be a better choice and terrorists have indicated their

awareness of that.) Nevertheless, the impact of the livestock and meat industry on the economy could be dramatic. In fact, it was proposed that the following scenario would be feasible and have an impact on the economy. A hazard that both (a) has notable "shock value" and (b) is considered an adulterant (i.e. *Escherichia coli* O157:H7) in ground beef would, in the eyes of a terrorist, be a hazard of choice. The vulnerability assessors assumed that *E. coli* O157:H7 was evenly mixed by terrorists into a defined lot of ground beef. Finished packages of that ground beef containing the lot identification would be taken by the terrorist(s). One week from that time a sample package would be submitted to the authorities. The product lot that is now on the retail shelves would then be verified as containing the hazard. Even though the hazard is diluted, and possibly of little or no public health consequence, consumer confidence in the US meat supply could be dramatically impacted. Indeed, the mere presence of *E. coli* O157:H7, regardless of the concentration, would initiate a recall of *all the product* in that lot and would impact the *consumer demand for beef in general*. The infective dose of *E. coli* O157:H7 is very low, and if the product was not cooked properly, it could cause foodborne illness. This scenario has been chronicled by the US Department of Homeland Security [8].

Additionally, terrorists might *falsely claim* that they had randomly contaminated more than the one lot and product type; under such a scenario, the economic impacts would be even further widespread. Large-scale meat recalls experienced by the US meat industry further illustrate the costs of such a scenario.

In such scenarios, traditional food safety programs devoted to microbiological pathogens will be critical to minimizing vulnerability.

Focusing on Effect, the vulnerability assessors discovered that if a meat product (processed by even a small meat processor in Kansas) could be verified as contaminated and is in the distribution chain, the effects would be dramatic. Even in the absence of a public health impact, the economic effects could be devastating. Here, food safety risk communication would be especially relevant.

The vulnerability assessment did not address Recognizability in the sense of CARVER + Shock; officially, Recognizability relates to whether or not a perpetrator can identify the point for contamination. In addition, but in a different and sense of "recognizability," the vulnerability assessors concluded that those interested in intentionally contaminating the food supply recognize the economic as well as potential public health impact. An in-line, real-time surveillance/detection device that could sense any level of any abnormal ingredient (i.e. the hazard) would be an ideal counter measure. Even though that does not currently exist, progress is being made in development of this capability. Prevention is preferred, but imperfectly effective in the real world.

Therefore, a short-term strategy would be to train the work force to be aware of physical site security vulnerabilities, unusual behavior of co-workers, and security around processing areas of highest risk (e.g. mixing and blending operations). The assessors concluded that awareness, though not the ultimate answer for prevention, could help achieve that goal. To assist in this effort, a series of food safety and security modules on a variety of topics such as physical site security, threat recognition, response, and so on were made available in 2006 for Internet delivery from Kansas State University's Division of Continuing Education.

At this point, education to heighten awareness to recognize potential threats is an excellent first step. Dr. David Franz, an internationally recognized expert on bioterrorism,

noted that education was the number one strategy based on effectiveness, including cost effectiveness [9].

With regard to the final element (Shock), the vulnerability assessors noted that an attack on the food supply could wreak economic, public health, and sociological havoc. The economy that the United States presently enjoys is implicitly reliant on a plentiful, affordable food supply. The magnitude of US discretionary spending is a result of an inexpensive food supply. Disruption of that food supply and its affordability would result in a chaotic situation that would rival any parallel loss of life [10]. For such sectors as the Kansas meat industry, responsive food safety systems could, potentially, help minimize economic, public health, and mental health consequences.

### 3.1 Food Safety Research and Food Defense

Local-area, university-based food safety research can help meet food defense/security concerns identified in the above CARVER + Shock vulnerability assessment.

Shortly after the *E. coli* O157:H7 outbreak in the Northwest United States in 1993, K-State researchers set to work with an engineering firm and a major meat processor to help prevent such future safety outbreaks. In response to this food safety issue, steam pasteurization of beef carcasses was developed, validated, and widely employed in the meat processing industry for food safety purposes. Though directed at an incidental food safety event, the strategy of steam pasteurization of carcasses would also eliminate intentionally added hazards if they were susceptible to steam pasteurization. Assuming that an added hazard was eliminated by steam pasteurization, added hazards up to carcasses fabrication would be eliminated. Stated alternatively, a food safety solution developed by K-State researchers could help address food security/defense issues. To be sure, the opportunity exists for incidental as well as intentional contamination beyond other intervention strategies; in these cases, steam pasteurization of meat trimmings before grinding could prove valuable.

By "hardening" (through the steam pasteurization of all beef carcasses and beef trim) a target, both food safety and food security/defense could be improved. This is but one example in which research to address food safety has come to address food security/defense concerns. Significantly, resources and practices serve a dual purpose and will make the food supply safer even if a terroristic event never occurs.

K-State is but one of many universities across the United States where food safety programs are being used to address food security/defense issues. K-State is part of the Food Safety Consortium, a program that has been funded by the US Department of Agriculture since 1988 to address the safety of beef and beef products (at K-State), pork (at Iowa State University), and poultry (at the University of Arkansas). While the original Congressional mandate to the Consortium was to develop and validate methods and technologies to isolate, identify, and eliminate microbial and chemical hazards, those important areas have been enhanced through the addition of new research programs regarding the food safety challenges associated with food security/defense. Meanwhile, a joint K-State-New Mexico State University *Frontier* program for the historical studies of border security, food security, and trade policy (http://frontier.k-state.edu) seeks to inject interdisciplinary and social-science perspectives into traditional food safety and food security research.

The National Center for Food Protection and Defense, based at the University of Minnesota, provides leadership in the overall food defense research and educational effort in the United States.

## 4 FOOD SAFETY EDUCATION IN FOOD SECURITY/DEFENSE

Traditional food safety related courses, such as food microbiology, food chemistry, epidemiology, toxicology, and so on are integral to food security/defense strategies and are part of most food science—related curricula. Food security/defense curricula can be easily augmented with these existing courses. Examples of this augmentation include a Food Safety and Defense Masters Certificate offered by K-State, the University of Nebraska at Lincoln, Iowa State University, and the University of Missouri. A similar initiative with Purdue University and the University of Indiana will lead to a graduate curriculum in Food Safety and Defense. These initial initiatives are being replicated and integrated with the educational efforts of the Department of Homeland Security Centers such as the University of Minnesota based National Center for Food Protection and Defense.

## 1 CARVER BACKGROUND

The US Food and Drug Administration (FDA) is tasked with protecting the nation's food supply [1]. The acronym CARVER represents the steps in a threat analysis exercise: Criticality, Accessibility, Recognizability, Vulnerability, Effect, and Recuperability. The CARVER+Shock methodology was employed by the FDA and the US Department of Agriculture (USDA) to assist in defending food production systems from malevolent acts. Shock is added to incorporate the intangible focus of a terrorist in frightening a targeted group. The method was recently incorporated into stand-alone software by Sandia National Laboratories, which is user-friendly and is designed to remove the biases that can occur by group execution of the CARVER+Shock methodology. The algorithms that give rise to scores for two of these properties are described below, followed by a case study. The group execution of the CARVER+Shock methodology, a part of the Strategic Partnership Program Agroterrorism (SPPA), typically takes 2 to 3 days work by 15 to 30 experts [2].

Use of the software does not require expertise in risk assessment, chemical processing, or computer science. Rather, the goal of the software is to allow food production personnel to execute the CARVER+Shock method in a few hours. With the software, a user can modify production design specifications as needed and can evaluate various options as a function of security.

## 2 ALGORITHMS

A CARVER+Shock user session starts by gathering information about the process, facility security, and safety of the product being dealt with. The three steps in the session are building a process flow diagram, answering questions regarding the process nodes, and evaluating the results. The major challenge in designing the software is to ensure that the questions, subsequent answers, and reported scores adequately reflect the results of the SPPAs, of which over 20 have been done to date. To do this, algorithms were developed to depict the information flow from the user answers to preliminary calculated variables,

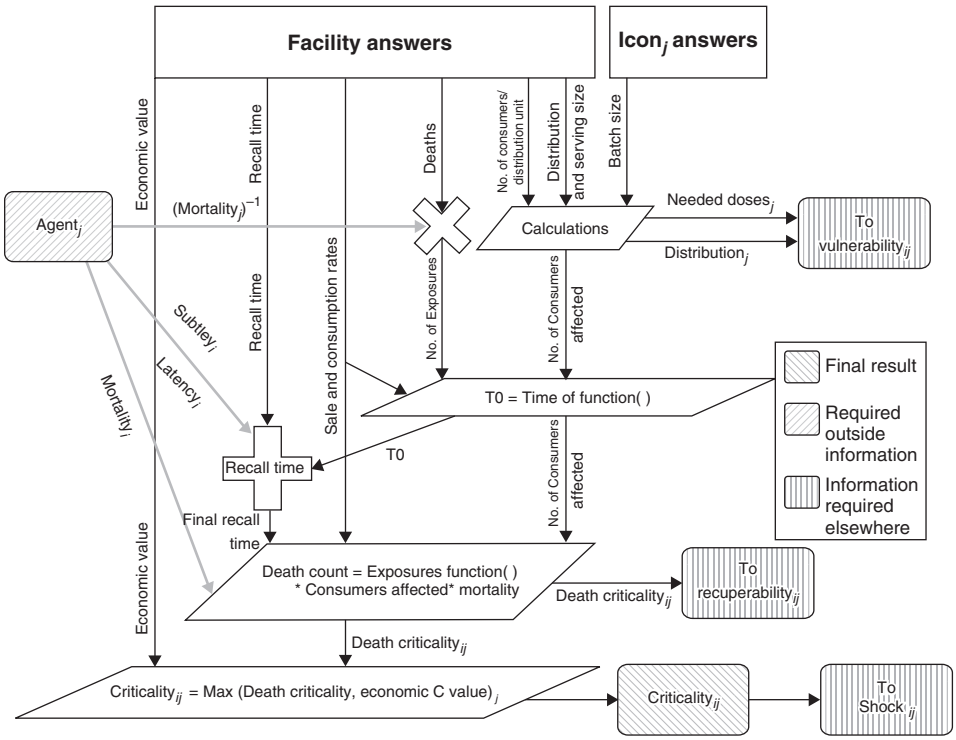

**FIGURE 1** Algorithm for criticality.

and finally to a score for each node in a process flow diagram. Figures 1 and 2 show the algorithms for Criticality and Accessibility. The complexity of each gives the reader an idea of how many questions may be required to determine the score for each property. Note that scores from one property may be used in other scoring algorithms.

## 3 TEST PROCESSES

These case studies consider two idealized processes: apple packing and yogurt production. Apple packing was chosen because of its simplicity and lack of food processing steps or ingredient additions. Yogurt production was chosen because it includes steps for simple food processing and ingredient addition. Each process is examined on three levels, a small scale representing a local provider, a medium scale representing a regional provider, and a large scale representing a national provider. The batch size for each increment of scale increases by a factor of 10. Each process was also examined under the assumptions of best case and worst case security practices. The CARVER+Shock score was calculated using CARVER+Shock Version 1.0.

The process flow diagram for apple packing is shown in Figure 3. The process is very simple, with no added ingredients. The fruit is sorted for size and quality, packed, and placed in storage until delivery to the retailer. The local supplier is assumed to have no refrigerated storage; therefore, packed apples are moved directly to the truck for delivery.

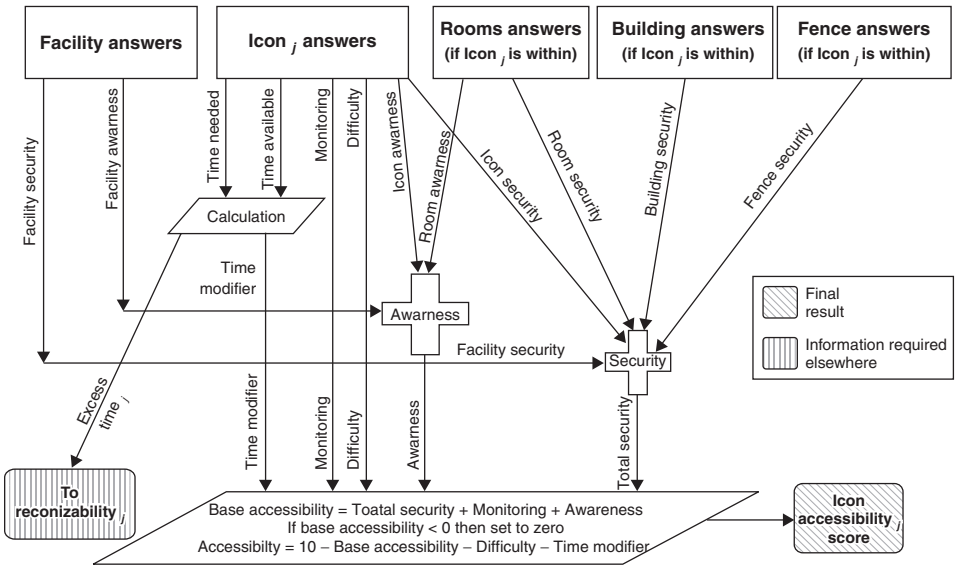

**FIGURE 2** Algorithm for accessibility.

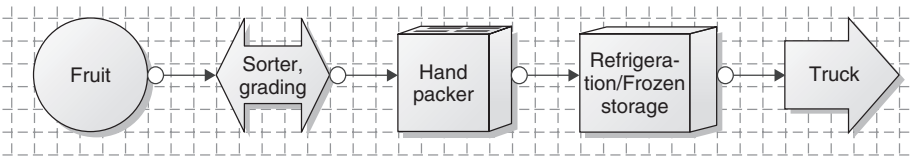

**FIGURE 3** Apple packing process.

Contamination would not easily taint an entire batch of apples; so, it is assumed that a contamination attempt would affect only 1 to 10% of the batch.

The process flow diagram for simplified yogurt production is shown in Figure 4. Raw milk is filtered, chilled, and then pasteurized, which raises the temperature to 85°C for 30 min. This heat treatment is much more severe than regular milk pasteurization. The pasteurized milk is cooled and transferred to the culturing tank, where the yogurt culture is added, and the mixture is held at 43°C for three to four h. The yogurt is packaged directly from the culturing tank with the fruit being added directly to the containers at the time of packaging. The packaged yogurt is placed in refrigerated storage before distribution. Since yogurt is a fluid product, it is assumed that a contamination event prior to packaging would be uniformly distributed in the entire batch. A contamination event after packaging is assumed to affect only 1 to 10% of the batch based on the educated guess of the CARVER+Shock user.

### 3.1 Production Scale Attributes

Both apple packing and yogurt production were analyzed at three levels of production. Table 1 summarizes the general attributes of each production level. The smallest level

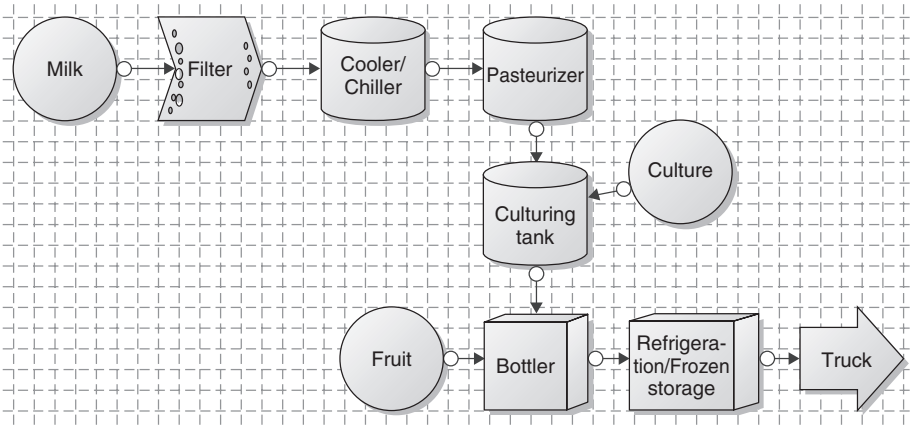

**FIGURE 4** Yogurt production process.

**TABLE 1 Production Attributes of the Three Production Scales Considered**

| | | Production Scale | | |
|---|---|---|---|---|
| Production Attribute | | Local | Regional | National |
| No. of cities supplied | | 1 | 4 | 15 |
| No. of outlets/batches | | 2 | 10 | 50 |
| Market share | | <1% | 1–9% | 10–25% |
| Name recognition | | No | No | Yes |
| Percentage of production loss | | >75% | >75% | 15–24% |
| Batch size: | Apples (lb) | 500 | 5000 | 50,000 |
| | Yogurt (fluid oz.) | 1280 | 12,800 | 128,000 |

represents a local producer who sells to one or two stores in a single locale. This producer operates a single small production line and has negligible market share and name recognition. The local producer's batch size is assumed to be 500 lb of apples or 1280 fluid oz. (10 gal) of yogurt. The medium level represents a regional producer who sells to a few stores in four regionally located cities. This producer operates a single, large production line and has established a small market share, but has little name recognition. The regional producer's batch size is 5000 lb of apples or 12,800 fluid oz. (100 gal) of yogurt. The large-scale operation distributes to many cities nationally. This producer operates multiple, large production lines and has established name recognition and an appreciable market share. The batch size for a single production line is 50,000 lb of apples or 128,000 fluid oz. (1000 gal) of yogurt.

### 3.2 Contamination Agents

The properties of the five toxic agents considered in each scenario are summarized in Table 2. All agents, except Agent 1, survive the heat treatment conditions of the

**TABLE 2 Summary of Toxic Agent Properties**

| Toxic Agents | Maximum Temperature (°C) | Solubility | Relative Toxicity |
|---|---|---|---|
| Agent 1 | 80 | Water | High |
| Agent 2 | 100 | Water and Oil | Medium |
| Agent 3 | 100 | Oil | High |
| Agent 4 | All temperatures | Water | Low |
| Agent 5 | All temperatures | Water | Very high |

pasteurizer (85°C for 30 min). The relative toxicity provides a measure of the quantity of the agent required for acute poisoning. In particular, the relatively low toxicity of Agent 4 limits the batch size that can reasonably be contaminated.

### 3.3 Security Practice Scenarios

All of the production scenarios were analyzed for "best" and "worst" security practices. Table 3 summarizes the essence of the two security scenarios. The best security practice scenarios included security personnel and perimeter fences, although the sophistication of the security at the perimeter increased with the size of the operation (local producers had a basic 6-ft fence; regional producers included perimeter lighting; and national producers included security patrols). In the worst security practice scenarios neither perimeter fences nor security personnel were included. The best-case security practice included operation plans—such as plans for food defense, continuity of operation, product recall, and health department coordination plans—along with employee training and practice drills. They also had tight control on shipping and receiving. The best-case practice did not publish any information about the production process or plant location on the internet and did not allow visitors on site.

### 3.4 Production Scale and Security Practice Results

The results of the CARVER+Shock analyses for apple packing and yogurt production are shown in Figures 5 and 6, respectively. These plots show the maximum CARVER+Shock score as a function of batch size for the best and worst security practices. The maximum CARVER+Shock score is taken as the greatest CARVER+Shock score of all the process icons used and all the agents considered.

As expected, for both apple packing and yogurt production, the CARVER scores for the worst security practices are significantly higher than for the best security practices. The best security practices CARVER scores were all below 50, which is generally considered acceptable; however, the results indicate there is possible benefit with improved security practices. The benefit gained by improved security for the yogurt operation (18 points) was greater than the benefit gained for apple packing (13 points). The difference in the improvement may be attributed to the difference in the nature of contamination spreading in apples (15 to 10%) versus yogurt (100%). For both apple packing and yogurt production, the CARVER+Shock score increased with the scale of the production. This

**TABLE 3 Operation Summary of the Best-Case and Worst-Case Security Practice Scenarios**

| | Security Practice | |
|---|---|---|
| Operation Attribute | Best Case | Worst Case |
| Perimeter fence | Yes | No |
| Security personnel | Yes | No |
| Plans (defense, continuity of operation, product recall, health department) | Yes | No |
| Training/drills (security, defense, recall) | Yes | No |
| Product traceability | Good | Poor |
| Customer support line | Yes | No |
| Background and drug use checks | Yes | No |
| Uniforms required | Yes | No |
| Internet information published | No | Yes |
| Visitors allowed | No | Yes |
| Shipping schedule enforced | Yes | No |
| GPS tracking of shipments | Yes | No |
| Tamper resistant seals used | Yes | No |
| Driver ID required | Yes | No |
| Acceptance testing performed | Yes | No |

GPS, global positioning system.

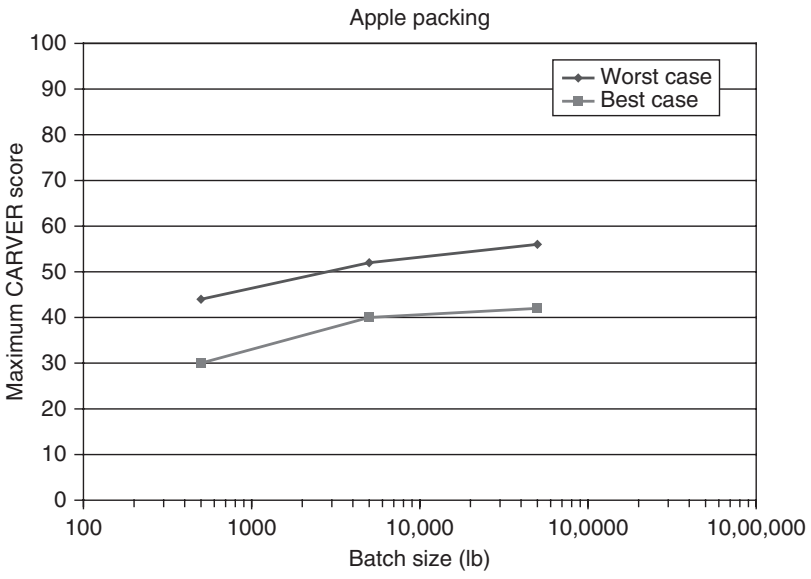

**FIGURE 5** Batch size dependence of total score for best/worst security practice.

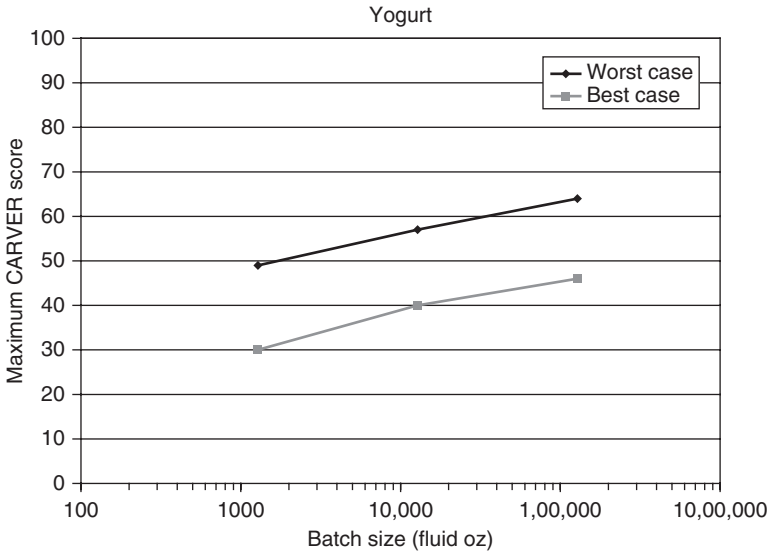

**FIGURE 6** Batch size dependence of total score for yogurt production security.

trend is expected, because the number of affected individuals scales with the size of the contaminated volume.

### 3.5 Toxic Agent Effects

The effects of the different properties of the various toxic agents considered are best illustrated in the yogurt production process. Table 4 shows scoring details for the best case scenario of the three levels of production of yogurt for toxic Agents 1, 2, and 4. As shown previously in Table 3, Agent 1 is the most temperature-sensitive and would be destroyed in the pasteurizer. Agent 4 is the least toxic and is subject to dilution by large batch sizes. Agent 2 is not destroyed in the pasteurizer and is toxic enough to be effective in the batch sizes considered. The scoring trends of Agents 3 and 5 were similar to Agent 2.

The differences in the toxic agent properties are best seen in the vulnerability scores for the process icons. The effect of temperature susceptibility can be seen by comparing the vulnerability scores for Agent 2 and Agent 1. The vulnerability scores for Agent 2 are high for the culturing tank and other process steps upstream. The vulnerability scores for Agent 1 are high only for the culturing tank, which is immediately downstream from the pasteurizer. The algorithms used in CARVER+Shock look downstream for higher-temperature processing steps and adjust scores accordingly, based on the properties of the toxic agent. Since the pasteurizer will destroy Agent 1, only process steps downstream from the pasteurizer have high scores.

Dilution effects are illustrated by the vulnerability scores for Agent 4. The maximum vulnerability score is 6 at the local scale, drops to a score of 4 at the regional scale, and reaches 1 at the national scale.

**TABLE 4 Scoring Details for Best Case Yogurt Production**

## 4 RESULTS OF CARVER + SHOCK ACTIVITY

In analyzing the effectiveness of the CARVER+Shock activity, we see that the software program allows users to identify the most critical, vulnerable, or accessible steps in the food processing systems. The variation of recuperability, effect, and shock scores is negligible amongst the nodes, as is found in many of the SPPA exercises. This lack of variation suggests that modifications of the methodology or possibly, the scoring mechanism should be considered.

Following identification of nodes with high scores, the program also gives mitigative information on how to reduce and even prevent potential threats (Fig. 7). The culturing tank had the highest score for the yogurt example and the individual attribute scores are listed along with the mitigation recommendations for reducing recognizability.

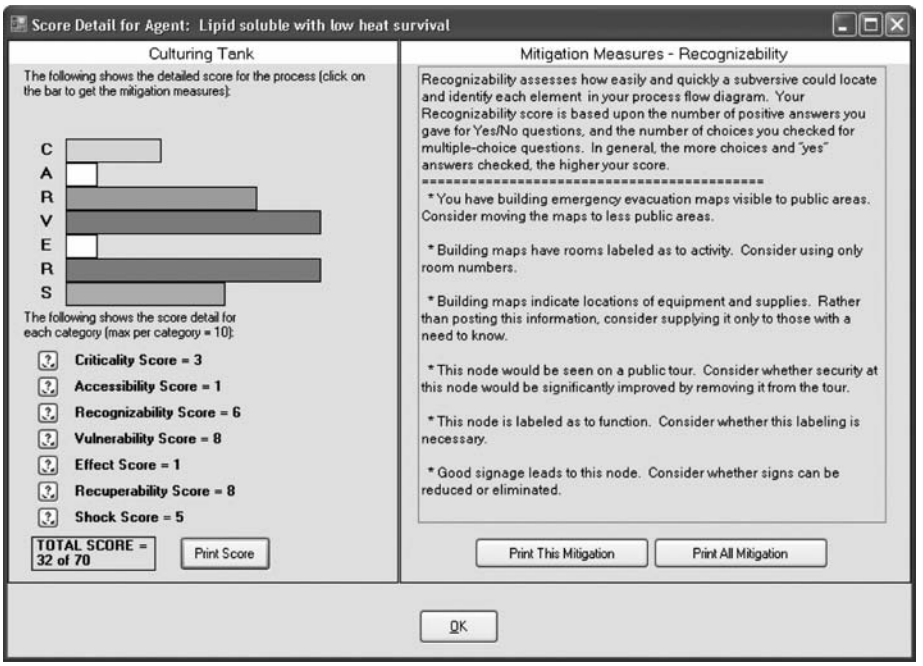

**FIGURE 7** Culturing tank score detail for yogurt production security.

## 5 DISCUSSION

The CARVER+Shock scores show variability among processes and among steps within processes with regard to the seven attributes analyzed by the SPPAs. Changing the batch size can affect Criticality. Increasing security can reduce Accessibility or Recognizability. Changing the nature of process steps, if feasible, can reduce Vulnerability or Effect. Modifications of the methodology or the scoring mechanism could increase the sensitivity of Recuperability, Effect, and Shock.

In future versions of the software, the output will be connected to a database of mitigation steps that can be further pursued. This database is near completion by the FDA and the scheduled release of version 2.0 of CARVER is early Spring 2009. This version of the software will also include preharvest (horticulture and anumal husbandry) as well as retail and restaurant modules [3].

# THE EDEN HOMELAND SECURITY PROJECT: EDUCATIONAL OPPORTUNITIES IN FOOD AND AGROSECURITY

STEVE CAIN

*Extension Disaster Education Network, Purdue University, West Lafayette, Indiana*

## 1 INTRODUCTION

The Extension Disaster Education Network (EDEN) Homeland Security Project (see logo in Fig. 1) provides research, materials, and educational courses to enhance Extension's abilities to deliver disaster and emergency management education. This article offers an overview of those efforts, provides insight into key issues, and information on the development of EDEN Homeland Security information and educational products.

EDEN reduces the impact of disasters through education. EDEN provides Extension, nationwide, with a network of specialists and a shared database of educational tools.

Extension has been involved in disaster education for decades, and in homeland security in a different form, since the civil defense days. Since 1993 EDEN, as a collaborative multistate effort, has improved the delivery of services to citizens affected by disasters. To learn more about United States Department of Agriculture (USDA)'s Cooperative State Research, Education and Extension Service (CSREES) visit: http://www.csrees.usda.gov/qlinks/extension.html.

EDEN primarily functions as a network of professionals with more than 75 subject-matter specialties, ranging from human development to crop and livestock development. Resources from the land grant, sea grant, and related institutions are shared through a national EDEN web site: www.EDEN.lsu.edu. This site provides Extension agents and educators access to resources for all phases of disaster management. EDEN also partners with USDA-CSREES.

**FIGURE 1** Logo of the EDEN homeland security project.

EDEN's mission is carried out through:

- interdisciplinary and multi-state research and education programs addressing disaster mitigation, prevention, preparation, response, and recovery;
- linkages with federal, state, and local agencies, and organizations;
- anticipation of future disaster education needs and actions;
- timely and prompt communications and delivery of information that meets audience needs; and
- credible and reliable information.

This article focuses on and highlights relevant EDEN homeland security efforts and findings. By design, EDEN is a multidiscipline, all-hazards network. Therefore, the varied topics covered here are homeland security-related.

## 2 CHILDREN AND TERRORISM

EDEN lunged into homeland security mode within moments of the 9/11 attacks. While hundreds of millions of people watched the horrific scenes of the destruction of the twin towers, thousands of first responders rushed to help. At the same time, EDEN responded by identifying pertinent educational information.

Public information officers (PIOs) for emergency management know that one of the primary needs of people in the event of a disaster is information. Mobilizing information helps people. It save lives, reduces the impact of the disaster, and helps with a quick recovery.

Within a few hours of the 9/11 attacks, EDEN made web resources available to help parents explain the disturbing events that were unfolding on television. Through the EDEN network and web page, day care centers and schools across the nation had access to handouts for parents on talking with their children about terrorism. By the end of the day, thousands of schools, day care centers, and news media had downloaded the vital information.

Studies have found that parents' levels of functioning, along with their relationships with each other, can be a buffer against the negative impact that disasters have on children. Thus, it was important after 9/11 that parenting partners pay attention to each other's needs, their own individual needs, and their children's needs. Because terrorism is still relatively new to the United States, many families do not necessarily have the skill sets to help children cope with terrorism. EDEN offers so many resources to help families cope, see Ref. 1.

## 3 AGROTERRORISM

Records captured in Afghanistan show that terrorists plotted to strike at the United States' agricultural system, not only to spread terror, but to hit the United States in this important economic sector. Within days of 9/11, EDEN's efforts produced a back-grounder for Extension educators to talk with farmers, ranchers, and producers about terrorism. This backgrounder, simply called *Agroterrorism*, www.ces.purdue.edu/eden/

disasters/agro/**Agroterrorism**.doc was used nationally and internationally by educators and the news media. It was developed from work done by the USDA and land grant universities to better understand and develop ways to cope with agroterrorism. It also helped unify use of the term *agroterrorism*, which was a newly evolving term. Other forms of the word included hyphenation and use of "agri" instead of "agro", which is helpful information for those doing research on the web.

The article explained that potential economic costs for an agroterrorism event could cost the United States more than $100 billion in short- and long-term losses in livestock and crop production and industries related to farming, such as transportation, processing, and retailing. Information is also given to help size up the possibility or probability of an agroterrorism event. The critical issue with agroterrorism is the low level of technical knowledge required to implement it. Any person with minimal understanding of microbiology can acquire the organisms and spread them, needing less technical know-how than what is required for other forms of bio-warfare, including that against humans.

When most people think of agroterrorism they probably think of extremist groups as being the major threat, when in reality agroterrorism, in many forms, has been around since people first began to till the soil, for example, burning or poisoning a rival's crops.

In Ref. 2, Anne Kohnen states that "Terrorists' motives vary widely . . . . The two most common today are the profit motive and the anti-GMO (genetically modified organism) motive." After the events of September 11, 2001, that list expanded to include international terrorists bent on harming the US economy and creating fear and mistrust toward governing agencies.

Today, the types of people who might instigate an agroterrorism attack fall into three categories:

- a criminal or activist with idealist motives;
- a criminal with economic motives;
- in international terrorist with motives against the United States.

### 3.1 Counterattack on Agroterrorism

Agricultural economists noted in Ref. 3:

> Given the potentially devastating impact, the best procedure is not only to increase our border defenses against Foot and Mouth Disease, but also plan and organize in advance to combat it effectively when it arrives.

Otto Doering, Purdue Extension agricultural economist, noted that the key determinants of the economic impact are:

- *Geography.* Where and over what area will the outbreak (contamination) occur?
- *Timing.* How quickly will outbreaks be detected and dealt with?
- *Strategy.* What strategy will be used to respond to the outbreak?

To prevent or reduce the impact of diseases, Kohnen listed four areas of USDA concentration:

1. the organism level, through animal or plant disease resistance;

2. the farm level, through facility management techniques designed to prevent disease introduction or transmission;
3. the agricultural sector level, through USDA disease detection and response procedures; and
4. the national level, through policies designed to minimize the social and economic costs of catastrophic disease outbreak.

For example, Kohnen recommended that to reduce the threat and costs of an attack at the organism level, the USDA should be ready with vaccines for the major forms of diseases affecting animals. Other mitigating actions would include training veterinarians, veterinary students, and plant pathologists on countering agroterrorism with emphasis on early diagnosis of potential diseases. At the farm level, the USDA should establish a biosecurity program to educate farmers on biosecurity best management practices.

In addition, Ken Foster, from the Department of Agricultural Economics at Purdue added, "It is important to place great emphasis on a detailed plan which clearly spells out the degree and mechanisms by which producers will be compensated for losses. The compensation plan has to clearly eliminate the private economic incentive to hide an outbreak that a producer faces. The cost of many contagious livestock diseases is so great that the rest of society can easily justify compensating individuals for early reporting."

At the national level, contingency budgets should be in place to fund disease eradication and compensation costs for producers who have a loss, and public affairs campaigns that bolster public confidence in the food production system. At the state level, laboratories should be given diagnostic capabilities and screening authorities to facilitate rapid diagnosis. At the local level, communities should identify a coalition of local officials, such as law enforcement, emergency managers, Extension, American Red Cross, and other leaders to address and respond to local disasters.

People concerned with potential agroterrorism should take steps to be informed. The USDA, the Department of Homeland Security (DHS) (and other federal departments), and land grant universities, including Extension, can be excellent sources of objective information. Also, concerned individuals may want to be involved at the local level to be sure that community disaster plans are addressed. There should be discussions with key people about their concerns and they should be encouraged to share their opinions with lawmakers.

Agricultural leaders, key stakeholders, and lawmakers must work together to make sure that the proper laws, procedures, and resources are in place to mobilize quickly and resolve any infestation or contamination. This includes rapid detection and containment to reduce the spread of infection and impact on the US economy. In addition, specific measures must be in place so that farmers, ranchers, and others in the agricultural sector have the proper education for detection and eradication. The information flow must convince farmers who are victims of an attack, that the proper eradication steps and economic reimbursements are in place. Once the proper steps have been taken, a consumer awareness and public education campaign must take place to restore domestic and international consumers' confidence in the food supply and the regulatory agencies.

## 4 EDEN HOMELAND SECURITY PROJECT

Immediately after 9/11, program leaders at the CSREES realized that EDEN could play an important role in homeland security education. The network applied for and received a $600,000, 2-year grant to examine homeland security educational needs and to begin building a bank of educational programs and courses to address those needs.

Since 2002, USDA-CSREES has supported the EDEN Homeland Security—Food and Agricultural Defense projects. The USDA-CSREES grant funded the development of several homeland security-related courses, research on interagency communication, basic EDEN communication support (at Purdue University), and web management support (at the Louisiana State University Agricultural Center). At the same time, EDEN established the EDEN Homeland Security Project Team.

### 4.1 EDEN Homeland Security Surveys

In 2002, EDEN conducted Homeland Security surveys of Extension educators, across the country, who represented the educational program areas of:

- Family and Consumer Sciences,
- Leadership and Community Development,
- 4-H and Youth Development, and
- Agriculture and Natural Resources.

The main goal of the surveys was to determine county-based educators' needs for educational materials regarding homeland security. Homeland security topics regarding how urgent they were to the educator's community were rated. The ratings (shown in Table 1) have guided the search for usable materials and the development of new materials.

At the same, time EDEN conducted a national survey of farmers, ranchers, and producers about their homeland security concerns (Table 2). The participants were asked if they had discovered a crop disease outbreak on their farm that was not recognizable and to whom they would turn to for advice. They were asked to check off the top

**TABLE 1 Results of Surveys to Determine Needs of County-Based Educators for Educational Materials Regarding Homeland Security**

| Security Topic | Urgent, 1–3 (%) | Not Urgent, 7–9 (%) |
|---|---|---|
| Drinking water | 78 | 4 |
| Food | 64 | 9 |
| Individual's role | 57 | 14 |
| Government's role | 55 | 14 |
| Animal biosecurity | 50 | 12 |
| Personal | 48 | 13 |
| Farm | 45 | 12 |
| Financial | 42 | 15 |
| Plant/crop biosecurity | 37 | 16 |

**TABLE 2 Result of a National Survey, Conducted by EDEN, of Farmers, Ranchers, and Producers about their Homeland Security Concerns**

| Agency/Person to Contact | Percentage |
|---|---|
| Cooperative Extension service | 79 |
| State department of agriculture | 42 |
| Another farmer/rancher | 32 |
| Pesticide dealer/representative | 31 |
| Consultant provided by dealer | 28 |
| Hired crop consultant | 10 |

three. Among many findings, the survey showed the majority of farmers would turn to Extension first, for a crop biosecurity concern that might be homeland security-related.

With the survey of urgent educational needs identified, EDEN began to address the issues. Instead of developing new, resources, the first goal was to find resources that matched the identified needs.

A publication from the Federal Emergency Management Agency (FEMA) [4] addressed many of the top priorities, including drinking water security, general information on the government's and the individuals' role in a world threatened by terrorism, and personal security. The DHS took steps to address food security needs by funding a DHS Academic Center of Excellence on Food Security at the University of Minnesota.

Having identified existing resources and making them available through the national EDEN web page www.EDEN.lsu.edu, the Homeland Security Project team began to allocate resources in the areas of most interest that were identified in the survey by farmers, ranchers, and producers.

## 5 INTERAGENCY RELATIONS IN ANIMAL DISASTER MANAGEMENT

One of the first efforts was to find more specific information on the government's role in an agricultural disaster. While FEMA's "Are You Ready" [4] had good information on general preparedness, more information was needed on the government's role in a terrorist attack on animal agriculture.

### 5.1 Defining the Issues

In 2003, Borron and Cain started a research project examining local, state, and federal regulations in the event of massive animal death. This work became part of a larger project for the USDA, which was lead by Kansas State University, Texas A&M University, and Purdue University [5].

Their goal was to identify all of the key agencies that might be involved in the response to massive animal die-off and examine the nature of the partnerships for such an event. For this project, the key people from those agencies were asked to spell out their roles and responsibilities in a fictional case of dead animal disease (DAD) that crossed species and occurred on several farms in Indiana. Those agencies submitted their

reports, which were shared with all the other agencies. Two weeks later, a roundtable discussion was conducted in which the agencies discussed how their role might change with consideration of what the other agencies said and as the scenario changed.

The results showed that there are significant tools to help agencies understand who plays what role, but not enough is being done to ensure that all agencies use those tools. Though not all potential problems can be anticipated and addressed in advance of a major biosecurity event, two overall actions might prevent a massive animal disaster from taking larger tolls. They are education and facilitation.

Factors related to education for better understanding include

- the Incident Command System (ICS) by agricultural industry leaders and participants;
- the ICS, standard operations procedures (SOPs), and agriculture by county governments and agricultural groups;
- agriculture by the emergency management and county government systems; and
- agricultural, disaster response by state, and local agencies (public health, legal, etc.).

A primary factor related to facilitation is encouragement of periodic (annual or semi-annual) meetings for all agencies at the state level to discuss specific operational, legal, and future research needs in the area of animal disaster management. These actions would also include exercising existing agreements.

In Indiana, two specific actions will enhance the response efforts during a major disaster.

- First, the necessary agencies need to know they are part of the Comprehensive Emergency Management Plan (CEMP) plan, and what role they play.
- Second, more people within agencies should have a comprehensive awareness and understanding of other agencies involvement, in addition to understanding their own agency's SOPs.

In 2003, US President George W. Bush issued directives that provided the Secretary of Homeland Security with the responsibility to manage major domestic incidents by establishing a single, comprehensive National Incident Management System (NIMS). The introduction of NIMS provides organizational muscle to the ICS, but still, not enough has been done to ensure NIMS and ICS, and subsequent agreements are well spelled out and exercised, especially at the county level, in response to major agricultural disasters.

An idealistic approach to a disaster would be to know, in detail, what needs to be done, what protocols need to be enacted, and who is going to take the lead. However, no real-life disaster plays out as a textbook example. General disaster plans are created with a number of annexes and SOPs attributed to specific situations. Regardless of the tragedy or the number of agencies involved, there are several areas that should be addressed to achieve a higher level of preparedness and response.

An interagency working group should be created that meets two times a year and consists of at least the state environmental, animal health, public health, contract service, emergency management, Extension service, transportation, and wildlife agencies.

An analysis should be conducted of the agencies' (county, state, and federal) awareness level of the functionality of the CEMP and its components related to agriculture, as well

as the overall functions of the ICS and NIMS. Questions that must be asked include the following:

- Have the correct agencies been included?
- Are there appropriate training opportunities for agency employees?
- Do the involved agencies have a well-established representation of their SOPs within the annexes of the CEMP?
- Are memorandums of agreement (MOAs) and other agreements tested through exercises.

A training program should be initiated that:

- requires ICS training for all agencies involved in the CEMP—state and country level;
- includes adequate representation from various agencies to ensure a widespread understanding of the ICS and various agencies roles;
- establishes programs at the county level to bridge the gap between the legal system and agricultural issues in a biosecurity event so that legal countermeasures to stop control efforts are made based on informed decisions.

Results of this roundtable discussion demonstrated that (i) more could be known about how critically involved agencies will react to a massive animal carcass disposal situation, and (ii) in an environment of short-staffing and high workloads, agency personnel will likely not place a high priority on planning for theoretical animal carcass disposal issues.

Therefore, to facilitate planning efforts and provide structure for interagency discussions and exercises, research into (and summarization of) the actual laws, regulations, guidelines, and SOPs of key agencies is warranted on a state-by-state basis.

This type of research is critical to the development of comprehensive plans for state and county governments to more easily identify their roles. These could be used in training programs for state and local agencies to develop pertinent SOPs and MOAs.

### 5.2 Agrosecurity Workshops for Interagency Relations

Extension professionals throughout the country recognized the need to better define their roles—and the roles of other agencies and organizations—before, during, and after an animal agrosecurity event. In addition, those roles vary from state to state, so there is a need to help agencies and organizations to fully understand the capacity to which Extension can serve in this arena.

With support from the Cooperative State Research, Education, and Extension Service, EDEN offered six regional conferences in 2007 and 2008, focusing on animal agrosecurity.

By the end of each conference, attendees are able to describe the roles of Extension and other agencies/organizations in an animal agrosecurity event within their region. Conference attendees can identify key roles and players in:

- emergency and disaster management in an animal agrosecurity event;
- education during all phases of emergency and disaster management;

- partnership development within and across states;
- crisis communication related to an animal agrosecurity event;
- state animal response team development;
- educational program and material development/delivery for an animal agrosecurity event.

For an analysis of outcomes of these events and a lisitng of conference hosts see Ref. 6.

## 6 EDEN COURSES

The following describes several courses developed by EDEN to help various audiences understand and prepare for natural disasters and homeland security events. All courses mentioned here are free of cost and are available on the EDEN web site at www.EDEN.lsu.edu/LearningOps.

### 6.1 Plant Biosecurity Course

In 2004, the EDEN Homeland Security Project released the EDEN *Plant Biosecurity Management Course*. EDEN focused on the plant course because Extension was identified as the preferred source of information if farmers or ranchers suspected an unrecognized crop disease outbreak on their farm.

A major attack or natural outbreak on US farms could cost the economy millions in control responses and billions in economic damages. Further, mismanaging a crop or plant biosecurity outbreak by not detecting it, or not communicating appropriate information, could increase damages.

The *Plant Biosecurity Management Course*, developed by a team at the University of Missouri, was designed to help Extension educators across the country better participate in all phases of a crop biosecurity disaster. Those phases included mitigation, preparedness, response, and recovery.

Anyone completing the on-line course will be better prepared to plan for and contribute to recovery efforts of a plant or crop biosecurity event.

The team's primary audience for the course was crop advisors, Extension professionals, and specialists who understand the urgency of plant protection and will have the opportunity to teach plant biosecurity management to those involved in the US plant sciences agricultural sector. This course enables Extension professionals to teach agricultural producers, workers, and others who are involved or have a vested interest in the US plant sciences agricultural sector on how to:

- prepare for a plant biosecurity event;
- appropriately respond and recover from a plant biosecurity event;
- reduce the effects of future plant biosecurity events.

The course was originally offered in 2004, but a new edition was released in 2006. Though the course aims to provide Extension educators and specialists with pertinent information, it is readily usable by agricultural and horticultural producers, emergency managers, and public health officials who have a vested interest in plant biosecurity.

Developed for EDEN by the University of Missouri Extension with support from the USDA, the 2006 edition provides updated and timely resources, as well as preventative activities, and current response efforts of the soybean rust monitoring and protection program. The course is free of charge and designed to be taken at a user's own pace. Completion time is approximately 8 h.

The six lessons focus on:

- the threat of both intentional and unintentional introduction of pests and pathogens to crops;
- how to mitigate plant biosecurity hazards and security risks to farm operations and agribusinesses;
- how to prepare for a rapid and appropriate response to a suspected plant biosecurity problem;
- what recovery activities to expect in the event a plant biosecurity problem is confirmed; and
- how to reduce the impact of a biosecurity event on humans, crops, property, and the environment.

### 6.2 Food Protection Course

The next EDEN course, *OnGuard: Protecting America's Food System* helps explain the protection of the United States' food production system and helps explain the consumer's role in food protection. Understanding how the US food system works and protecting the system against intentional attacks is the responsibility of all citizens.

This course is geared toward the general public through the facilitation of an Extension office in local, county-based meeting. The course focuses on:

- how specific food products are created and how they move through the food system;
- how our government protects against threats to the US food system;
- food-related actions a family can take to prepare for any type of disaster or emergency;
- what consumers and agricultural producers can do to protect against intentional threats to the food system; and
- lessons learned from actual cases of intentional attacks on our food systems.

This course was developed for EDEN at the University of Minnesota.

### 6.3 Business Preparedness

In 2005–2006, EDEN collaborated with the DHS to develop *Ready Business: Preparing a Disaster Business Plan*. The course helps businesses prepare for all-hazard disasters, including homeland security-related events. This course ties in closely with DHS's Ready campaign (www.ready.gov).

At one time or another, every community will be affected by an emergency or disaster. It is important for business owners and operators to understand how to prepare and manage their businesses through difficult times including disasters.

By preparing for emergencies and disasters in advance, businesses can save time and money in extreme situations. Therefore, EDEN developed the *Ready* Business course, enabling businesses to better understand this issue.

The course is geared toward small- and medium-sized business owners through the facilitation of a local Extension professional or volunteer group. Created to be taught in a classroom setting, this 3–4-h course helps participants walk away with the beginning of a disaster plan.

The course covers:

- developing a basic understanding of disaster preparedness and the importance of business planning;
- uncovering the significance of communicating regularly with employees before, during and after an incident;
- recognizing the need for evacuation and shelter-in-place plans; and
- taking steps to safeguard companies and secure physical assets.

This course was developed for EDEN by Purdue Extension, with support from the DHS and USDA and a team of experts from universities around the United States and CSREES.

### 6.4 Pandemic Preparedness for Businesses

At about the time that the Ready Business course was being developed, news of a potential pandemic surfaced. In fact, authorities continue to state that it is not a matter of "if" a pandemic strikes, but "when." Because DHS played a major role in supporting pandemic preparedness efforts, the EDEN Homeland Security Project team decided to take the *Ready Business* materials one step further and develop the *Pandemic Preparedness for Business Course*.

EDEN felt it was important for business owners and operators to understand how to prepare and manage Their business through a pandemic.

By preparing for a pandemic in advance, businesses can save time and money in extreme situations. The course is geared toward small- and medium-sized business owners through the facilitation of a local Extension professional. Created to be taught in a classroom setting, this 90-min course is available on-line and can be taught be any volunteer or professional with emergency management background.

The course focuses on:

- developing a basic understanding of pandemic preparedness and the importance of business planning;
- uncovering the significance of communicating regularly with employees before, during and after a pandemic; and
- understanding how businesses can help employees deal with a severe pandemic.

This course was developed for EDEN by Purdue Extension, with support from USDA and the same team that developed the Ready Business course.

### 6.5 USDA and the National Response Plan

Late in 2006, EDEN introduced a course titled USDA's Roles in the National Response Plan.

Because the National Response Plan is a comprehensive plan that establishes a single framework for the management of domestic incidents. it is imperative that Extension professionals understand their responsibility in the response efforts.

This plan relates how the federal government coordinates with state, local, and tribal governments and the private sector during incidents.

This course was developed for EDEN at North Dakota State University.

Through this course participants will:

- develop a basic understanding of the field of emergency management;
- increase awareness of the National Response Plan and NIMS;
- recognize the potential roles of Extension professionals in the National Response Plan, and disasters in their communities;
- discover potential resources for Extension staff members on hazard and disaster issues.

The materials provided in the course are intended for use at Extension workshops and/or staff development presentations with other local, state, and federal USDA agencies:

- Ready-to-use presentations with available audio
- Master documents for handouts

### 6.6 Pandemic Preparedness for Faith-Based Organizations

In 2007, enhancing the work previously done on pandemic preparedness, EDEN released a course targeting faith-based organizations (FBOs). The course is titled *Pandemic Influenza Preparedness for Faith-Based Organizations*.

This course was designed by EDEN, in collaboration with the Centers for Disease Control and Prevention, to enable congregations, synagogues, mosques and other places of worship to (i) protect the health of their staff and the communities in which they serve and (ii) fulfill their organizational mission during an influenza pandemic. The course is divided into two sections:

*Section 1.* Participants learn about pandemic influenza and infection control measures to use in their organization to protect themselves and their community before and during a pandemic.

*Section 2.* The course highlights organizational measures in which participantsl learn about the potential impact of pandemic influenza on their organization. They also learn to write a basic pandemic influenza preparedness and response plan to maintain the critical functions of the organization.

Extension educators, public health officials, and others with an interest in teaching FBOs to be better prepared for a pandemic can download all needed curriculum materials from the EDEN web site. FBO leaders, staff members, or volunteers charged with

pandemic influenza preparedness can also walk themselves through the on-line materials, rather than taking it in a classroom setting, if they prefer.

Through instructional design, course participants will be tested frequently on the material they are learning and encouraged to begin writing their pandemic influenza preparedness and response plan.

This course was developed by EDEN with help from the Centers for Disease Control and Prevention.

### 6.7 Animal Biosecurity and Emergency Management Course

The latest course to be developed is titled *Animal Biosecurity and Emergency Management Course*.

The ultimate goal of the course is to educate Cooperative Extension Service personnel and first responders so they may collaborate effectively during an animal agricultural emergency. In addition, producers acquire an awareness of their role in the phases of animal emergency management.

The course covers animal biosecurity and emergency management during natural and man-made disasters. Topics include interdisciplinary and interagency collaboration; prevention/mitigation, preparedness, response, and recovery measures; and biosecurity management. The course ends with several discussion-based scenarios depicting simulated animal emergencies, which allow students to apply course concepts.

Supplemental materials include:

- PowerPoint presentations and Instructor's Guides for use in face-to-face trainings;
- checklists including a facility vulnerability assessment, animal emergency action plan, off-farm risk assessment, and so on;
- fact sheets on animal diseases, animal handling, emergency fencing, and so on.

The course was developed at the University of Kentucky.

Technical support was provided by University of Kentucky Agricultural Communications Services and the Creative Applications for Learning Environments Laboratory.

The ultimate goal of the course is to educate Cooperative Extension Service personnel and first responders so they may collaborate effectively during an animal agricultural emergency. In addition, producers will acquire an awareness of their role in the phases of animal emergency management.

The lesson titles are as follows:

- Animal Emergency Management: Natural Disasters
- Animal Emergency Management: All Hazards
- Interdisciplinary Components of Animal Emergency Management
- Animal Management: Prevention/Mitigation and Preparedness
- Farm Management: Prevention/Mitigation and Preparedness
- Incident Management: Response and Recovery
- Off-Farm Biosecurity Management

The course was developed at the University of Kentucky.

# DECONTAMINATION AND DISPOSAL OF CONTAMINATED FOODS

M. Ellin Doyle, Seung Hak Lee, Craig H. Benson, and Michael W. Pariza
*University of Wisconsin, Madison, Wisconsin*

## 1 INTRODUCTION

Widespread contamination of the food supply with a hazardous agent would be an effective way for a terrorist to induce panic in the general population and cause great economic losses. Food processing and distribution have become more centralized, such that contamination in one plant may result in multistate and even international outbreaks of illness as occurred in 2006–2007 with spinach contaminated with *Escherichia coli* O157:H7, peanut butter containing *Salmonella*, and pet food with melamine. Food companies have developed procedures for recalling foods containing undeclared allergens, foreign material, or pathogenic bacteria but may not be equipped to handle large volumes of foods containing a terrorist agent. Such an event could present a substantial waste disposal problem for landfills and wastewater treatment plants (WWTPs) as well as for public health authorities. Representatives from disposal facilities, food companies, and government agencies participated in three meetings and voiced concern about a variety of issues that need to be addressed.

## 2 OVERVIEW

### 2.1 Agents

Disposal options for contaminated foods will be determined to some extent by the nature and concentration of the agent and its expected fate in landfills and wastewater treatment systems. Potential biological and chemical agents have been listed by Centers for Disease Control (http://www.bt.cdc.gov/agent/agentlistchem.asp, http://www.bt.cdc.gov/bioterrorism/) while toxic industrial chemicals that could pose a threat are listed by Occupational Safety and Health Administration (OSHA) (http://www.osha.gov/SLTC/emergencypreparedness/guides/chemical.html), and the most commonly encountered radionuclides are listed by Environmental Protection Agency (EPA) (Table 1). Some of these agents are inappropriate for poisoning food because their sensory characteristics would so alter the foods that they would not be consumed. Some microbes are not transmitted effectively through consumption of food and other agents are not soluble or stable in particular foods thereby precluding their use. There are also a number of other toxic chemicals and pathogens that terrorists may have access to, which are not on these lists. Accurate identification of the agent(s) used to contaminate food and their concentrations is necessary for making appropriate disposal decisions.

### 2.2 Food

A variety of foods could be contaminated by a terrorist and several factors, including the goal of the attack that will affect which food(s) might be chosen. If the goal is to cause widespread illness and death, then a highly infectious agent may be added to a commonly eaten, perishable food so that the agent will be widely dispersed and consumed before an alarm is raised. Massive economic losses and disruption of the food supply would be caused by contamination of animals in large rearing facilities or large areas of crop plants. Another goal may be to attack some American "icon" such as popular soft drinks, snacks, or fast foods. All of these possibilities should be considered in planning a response.

Target foods must be reasonably accessible. Although many processing plants have instituted strict in-house security practices, places where liquids or other foods are mixed in large tanks or vats may provide an opportunity to deposit some hazardous agent into food. Imported foods and food ingredients may be more easily contaminated in their country of origin or during transport from overseas locations. An imported contaminated spice, for example, may then be added to many different foods. One potential weak link in many food supply chains occurs during transport from farms to food processors. A mathematical model simulating contamination of milk with botulinum toxin demonstrated that a single addition of toxin, occurring at a holding tank on a dairy farm, in a truck transporting milk to a processing facility, or in a raw milk silo at a processing plant, could poison up to 142,000 gallons of milk [2].

Quantity of food requiring disposal as well as its nature (solid, liquid, acidic and fatty) will affect disposal decisions. Relatively small amounts of food containing very hazardous agents may be incinerated but usually solid foods would be sent to a landfill and liquids to a wastewater treatment plant. Recent recalls of "naturally contaminated" foods have involved millions of pounds of ground beef and millions of cases of canned products (http://www.fsis.usda.gov/Fsis_Recalls/index.asp) and a deliberate terrorist attack may contaminate even more food.

**TABLE 1 Radiological Agents: Potential sources, Disposal Limits in Wastewater, and Partitioning in Incinerators**

| Radionuclide | Chemical Formula | Source | Half-life | Concentration Permitted (Bq/ml)[a] | Estimated Partitioning (%)[b] | |
|---|---|---|---|---|---|---|
| | | | | | Combustion residues | Fly ash |
| Americium | $^{241}Am$ | Industrial/medical | 432.7 yr | 0.006 | 98 | 2 |
| Cesium | $^{137}Cs$ | Industrial/medical | 30 yr | 0.3 | 85 | 15 |
| Cobalt | $^{60}Co$ | Industrial/medical | 5.3 yr | 0.9 | 60 | 39 |
| Iodine | $^{129}I$ $^{131}I$ | Industrial/medical | $^{129}I$ ($15.7 \times 10^6$ yrs) | 0.06 | 2 | 68 |
| | | | $^{131}I$ (8 d) | 6.0 | | |
| Iridium | $^{192}Ir$ | Industrial/medical | 73.83 d | 3.0 | | |
| Plutonium | $^{238}Pu$ | Military/industrial | $^{238}Pu$ (87.7 yr) | 0.006 | 98 | 2 |
| | $^{239}Pu$ | | $^{239}Pu$ (24,100 yr) | 0.006 | | |
| | $^{240}Pu$ | | $^{240}Pu$ (6560 yr) | 0.006 | | |
| Polonium | $^{210}Po$ | Military | 138 d | 0.012 | | |
| Strontium | $^{90}Sr$ | Industrial/medical | 29.1 yr | 0.15 | 95 | 5 |
| Technetium | $^{99}Tc$ | Industrial/medical | 212,000 yr | 18.0 | 40 | 50 |
| Tritium | $^{3}H$ | Military/industrial Medical research | 12.3 yr | – | 0 | 0 |
| Thorium | $^{232}Th$ | Industrial | $1.4 \times 10^{10}$ yr | 0.009 | 98 | 2 |
| Uranium | $^{238}U$ | Military/industrial | $4.47 \times 10^9$ yr | 0.09 | 98 | 2 |

See http://www.epa.gov/radiation/radionuclides/index.html.

[a]Monthly average concentration limits for radionuclides disposed in sanitary sewers (10CFR20.2402).

[b]Predicted partitioning of radionuclides in an incinerator [1].

If contamination is discovered while the food is still within control of the food processor, it may be contained as a point source, secured and stored while disposal decisions are made. But if contaminated food were already distributed to retail stores and sold to the public, then the hazardous agent could be widely dispersed throughout the country. Consumers would be likely to throw the food in the trash or pour it down the drain unless a convenient, efficient collection system were organized to prevent indiscriminate disposal and further dissemination of the agent.

## 2.3 Decontamination

Neither municipal solid waste (MSW) landfills nor WWTPs would willingly accept foods with exotic terrorist agents if the fate of these agents during disposal were unknown. Effective decontamination or inactivation of agents may therefore be necessary before disposal. In a crisis situation, time constraints, cost, material limitations, and available diagnostic capabilities could limit decontamination options and it is not always clear what concentration of agent will be considered "clean enough" after decontamination [3].

Extensive information is available on destruction of many pathogens. However, some techniques are less effective when microbes are mixed with foods. EPA, the military, and some industries have had experience cleaning up chemical spills and deactivating chemical weapons and have developed decontamination procedures.

Biological agents are generally susceptible to heat, irradiation, and disinfectants. Vegetative bacteria are readily killed by thermal treatments although the actual time/temperature requirements for different species vary somewhat depending on the concentration of fats, sugars, and salts [4]. Vegetative bacteria are also readily inactivated by ionizing radiation and by chlorine (residual chlorine of $\sim$1.1 mg/l) if the organic load is low [5]. Viruses, protozoan parasites, and biological toxins are somewhat more heat stable in foods but, with the exception of some toxins, they are inactivated by cooking and thermal processing of foods. Chlorine bleach solutions inactivate botulinum toxin, viruses, and vegetative bacteria on surfaces and in water but do not destroy protozoan parasites, mycotoxins, or ricin [6, 7].

Bacterial spores are much more resistant to environmental stress, including heat, desiccation, and sanitizers [8]. *Bacillus anthracis* spores can survive pasteurization and other thermal processing methods [9]. Autoclaving with steam and pressure (135 °C, 217.2 kPa) for 40 min is generally effective in destroying all pathogens in medical waste. However, heat-resistant spores in building debris were completely destroyed only by two rounds of autoclaving [10]. Formaldehyde (final concentration of 5%) for 1–4 days can kill *B. anthracis* spores in liquid manure and sewage sludge (http://www.fas.org/nuke/intro/bw/whoemczdi986.htm).

Ozone and ultraviolet (UV) light can also kill pathogens but high concentrations of organic matter in foods reduce their effectiveness significantly [11–13].

Chemical warfare agents can be inactivated by oxidizing agents such as hypochlorite and peroxides and by hydrolysis under alkaline or acidic conditions. Degradation products are usually less toxic than the parent compounds, but in some cases further treatment is necessary [14, 15]. Industries using toxic industrial chemicals have developed procedures to deal with accidental spills and releases of these chemicals.

Radionuclides cannot be destroyed or inactivated. There are some methods, such as microfiltration and the use of magnetic particles to remove radionuclides from foods, which decrease the levels of contamination [16, 17] Following the Chernobyl accident,

some of these procedures were used to remove radioisotopes in milk. Some processing methods significantly reduce radioactivity in edible parts of foods. For example, processing of milk into butter and cheese significantly reduces radiostrontium levels because this isotope partitions primarily into the aqueous fraction [18]. These methods would still leave radioactive materials that required disposal.

## 3 FATE OF CONTAMINATED FOOD DURING DISPOSAL

### 3.1 Food

The food matrix itself consists of organic compounds that would be easily degraded in landfills, WWTPs, or incinerators. Since foods contain high moisture levels, their decomposition will produce relatively large amounts of leachate and may rapidly deplete oxygen and increase acidity in landfills. Some liquids with a high organic load (such as milk) may disrupt microbial processes in activated sludge tanks and therefore may be added directly to an anaerobic digester in a wastewater treatment plant.

### 3.2 Biological Agents

MSW landfills and WWTPs) regularly receive pathogenic bacteria, parasites, and viruses in human excreta, pet waste, disposable diapers, and spoiled foods. These are not a problem for well-run disposal facilities. But the presence of some bioterrorist agents in a large volume of food may present risks to workers and to public health if the agents are not inactivated or contained during the disposal process. Data are available on fate of some microorganisms under different disposal scenarios but few studies have investigated the fate of bioterrorist threat agents.

Bacteria, viruses, and prions can attach to soil particles and potentially to landfill materials and may survive for extended periods in landfills [19–22]. Depending on the organism and landfill conditions, pathogens may also be carried in liquids that percolate down through the landfill material (leachate).

Viruses appear to be the least hardy pathogens in landfills. No infective enteric viruses were cultured from fecally contaminated disposable diapers buried in landfills 2–10 years previously [23]. Hepatitis A virus and poliovirus survived more than 3 months in diapers and in landfill leachate at 5 °C but were inactivated within a month at 40 °C [24]. Viruses also persist in soil longer at cooler temperatures and when they adsorb to soil particles, but landfill temperatures are usually in the range of 40–50 °C [19]. Enteric vegetative bacteria appear to survive longer than viruses in landfills with significant numbers of fecal organisms detected in 9–10-year-old landfill samples. Lysimeter studies with simulated refuse showed that survival of bacteria was related to rainfall, refuse content, temperature, and toxicity of leachate. Spores, however, are very resistant to environmental stress and are known to survive for centuries in soils [8].

Pathogens may attach to solid particles during wastewater treatment and settle into sludge. Size and surface properties of microbes as well as pH, ionic strength, and polyvalent cation concentrations in the matrix determine attachment to particles [25]. WWTPs using only primary treatment remove about 12% of *E. coli*, 27% of *Cryptosporidium* oocysts, and negligible amounts of viruses indicating that many pathogens do not bind well to larger particles in settling tanks [26].

Some pathogens are destroyed during aerobic and anaerobic digestion of secondary/tertiary treatment processes but others survive typical wastewater treatment and are present in effluent and/or biosolids [27]. Chlorination and UV light can disinfect effluent before discharge but neither completely inactivate spores, oocysts, and all viruses [28]. Advanced processes, particularly chemical lime treatment combined with chlorination, can drastically reduce levels of bacteria, viruses, and parasitic oocysts in sludge [29].

During the outbreak of foot-and-mouth disease (FMD) in 2001 in the Netherlands, milk was illegally discharged into the sewer system. Since the virus might survive in WWTP and be present in effluent, a quantitative risk assessment for FMD virus transmission to cattle drinking surface water was conducted. Based on available data and estimates for water and virus consumption by cows, it was concluded that discharge of contaminated milk into the sewer system could pose a high risk to cattle farms within 50 km of effluent discharge to surface waters [30].

According to the EPA, more than 90% of medical waste that may contain infectious agents is currently incinerated because temperatures in properly run incinerators are hot enough to destroy all pathogens and toxins. Spore-forming bacteria can be killed within 30 min at 150 °C while other bacteria and viruses are inactivated at temperatures of $<100$ °C. However, an assessment by the EPA of the effectiveness of a medical waste incinerator in destroying heat-resistant bacterial spores demonstrated that some spores may survive in porous or moist materials where microenvironments do not reach the target temperature. In most cases, incineration caused $>6$ log kill of added spores but in some cases only about a 3 log kill occurred [31].

### 3.3 Chemical Agents

Most chemical warfare agents and toxic industrial chemicals would be considered hazardous and food contaminated with them should be sent to hazardous waste landfills or incinerated. However, only about 21 commercial hazardous waste landfills and about 28 hazardous waste incinerators (that normally accept off-site generated wastes) are currently operating in the United States. Disposal of contaminated food in these hazardous waste facilities may not be a practical option due to distance from the contamination incident, volume of the food, and the need for rapid disposal.

Physical and chemical properties of chemical agents deposited in MSW landfills or WWTP are important in determining whether they are volatilized, remain in aqueous or solid phases, or are inactivated by abiotic or biological reactions. Some studies on the behavior of chemical agents have been conducted in aqueous and soil systems but very limited information is available on the phase and fate of chemical agents in landfills and WWTP [32]. Although microbes possess enzymes that can degrade some chemical agents, it is not known whether they would significantly detoxify these agents under natural conditions in a landfill or WWTP [33].

Phase distribution and fate of some potential chemical terrorist agents in a landfill was modeled using Model for Organic Chemicals in Landfills (MOCLA)) [34]. Input parameters for the model include physical and chemical properties of the agents and landfill conditions derived from field data. The expected behavior of other chemical agents in landfills was estimated using MOCLA with similar landfill conditions and physicochemical properties obtained from the literature or estimated by EPI Suite v. 3.20 (Table 2).

According to MOCLA, over 90% of most chemical agents, with the exception of sodium fluoroacetate, the cyanides, Amiton (VG), and VM would be distributed to the solid phase. Most of the remainder would be present in aqueous phase (leachate) with a negligible fraction in the gaseous phase. Even though a large fraction of most agents would be sorbed to the solid phase and therefore presumably be immobile, this does not guarantee that landfill disposal of these agents is safe. It merely represents the phase distribution of the chemicals remaining in a landfill. To address the total risk, the fate of the chemical agents, including transport and degradation, must also be considered.

MOCLA calculates the fate of chemicals in a landfill, including advective transport of volatilized agents into the landfill gas collection system and through the soil cover, diffusive transport of volatilized agents through the soil cover, diffusive transport of soluble and volatilized agents through the composite liner, transformation of aqueous agents by biotic and/or abiotic mechanisms, and transport of soluble agents into the leachate collection system. A general half life of these compounds, obtained from EPI suite, was used in these simulations. This parameter includes oxidation/reduction, hydrolysis, and other reactions. Carbon disulfide and furan are predicted to move through landfills by gas-phase advection and according to Table 2, nearly 60 % of the initial amount would disappear within 5 years. At the end of landfill operations and 30 years of postclosure care, little of these chemicals would remain. However, attention should be directed to the gas monitoring/collection wells.

MOCLA predicts that the cyanide agents will move through liquid-phase advection. Their disappearance rates are relatively slow due to their longer hydrolysis half life and lower Henry's law constant. Nearly 90% would remain after 5 years with about 50% still present after 30 years. Leachate should be monitored for these compounds and properly treated.

For most of the other chemicals, MOCLA indicates that hydrolysis will be the primary fate. Blister agents and most of the nerve agents degrade so rapidly that more than 95% of these chemicals would disappear from a landfill within 5 years. However, information is also needed on the fate of hydrolysis products. Previous studies have reported that some environmentally persistent hydrolysates, lewisite oxide and EA 2192 from VX, are highly toxic to mammals [35].

Thallium and other heavy metals are likely to persist for a long time in landfills and are known to concentrate in biosolids of WWTP.

Fugacity-based analytical models can be used to predict the partitioning, transport, and transformation processes of organic chemicals in an activated-sludge wastewater treatment plant. EPA developed the Sewage Treatment Plant Fugacity Model (STPWIN) in EPI Suite v.3.20 to predict the multiphase partitioning and fate of chemicals in a sewage treatment plant (http://www.epa.gov/opptintr/exposure/pubs/episuite.htm).

STPWIN was used to estimate the fate of chemical terrorist agents (Table 2). Most of the carbon disulfide and some of the furan would be volatilized while much of the fentanyl would be adsorbed on sludge particles. Microbes would degrade substantial amounts of the blood agents, some nerve agents, and warfarin. However, the model indicated that less than 30% of the blister agents and some nerve agents (GD, VG, VM and VX) would be removed and a large fraction of these chemicals would pass through the treatment plant intact and be present in effluent. Effluent would then require additional treatment to remove the residual chemicals.

The major drawback of the STPWIN model is that abiotic transformation is not included in calculations but many blister and nerve agents are known to hydrolyze in

**TABLE 2 Fate of Potential Chemical Terrorist Agents in Landfills and WWTP (estimated by MOCLA and STPWIN)**

| Chemical Agent | | Landfill Phase Distribution (%)* | | Remaining in Landfill (%)* | | Estimated Fate in WWTP (%) | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | In water | In solids | 0.5 yr | 5 yr | Bio degradation | Adsorption to sludge | Volatilized | Present in effluent |
| TICs | Carbon disulfide | 0.5 | 98.8 | 90.1 | 35.7 | 32.7 | 0.58 | 57.4 | 9.36 |
| | Furan | 1.3 | 98.8 | 90.1 | 35.2 | 75.89 | 0.35 | 17.59 | 6.17 |
| Blood Agents | Potassium (sodium) cyanide | 66.4 | 33.6 | 98.9 | 89.6 | 91.72 | 0.33 | 0 | 7.94 |
| | Sodium fluoro-acetate (1080) | 98.4 | 1.6 | 59.5 | 0.4 | 74.43 | 0.62 | 0.02 | 24.93 |

| | VM | 30.1 | 69.9 | 93.6 | 51.7 | 20.63 | 1.50 | 0 | 87.87 |
| | VX | 9.5 | 90.5 | 66.4 | 1.7 | 21.22 | 1.88 | 0 | 76.90 |

*Some data from Reference [34].

aqueous systems with half-lives on the order of minutes and days. Some hydrolysis products are also toxic. Biodegradation rate is also a key parameter in this model but little information on the half-life of most chemical agents is available. Half lives for these chemicals were estimated using BIOWIN and the EPA draft method but any inaccuracy strongly affects STPWIN estimates of removal efficiency. The model also assumes complete mixing in the tanks fails to recognize the existence of layers or blankets of settled sludge.

Hazardous wastes can be burned in specially designed incinerators that operate at higher temperatures than medical and municipal waste incinerators. A typical incinerator consists of a gas powered rotary kiln maintaining a temperature $>980\,^{\circ}C$ and an afterburner with a temperature $<1200\,^{\circ}C$. Gases from the afterburner pass through an air pollution control system to remove particulates and other pollutants [36].

Incineration has been used by the US Army as a proven and reliable method for destroying the stockpile of chemical nerve and blister agents [37]. The ash and slag produced during incineration are sent to a hazardous waste landfill and emissions from the stacks pass through a pollution abatement system. A model simulation of destruction of chemical agents showed that, based on the incinerability indexes, an incinerator should be able to destroy chemical warfare agents easily and efficiently [38].

### 3.4 Radiological Agents

Concentration of radioactivity and the isotopes present will determine disposal options for contaminated food. For radioisotopes with short half-lives, contaminated food may be stored securely until radioactivity decayed to very low levels.

WWTP and MSW landfills may be acceptable sites for disposal of foods containing very low levels of radioactivity. The Nuclear Regulatory Commission permits discharge of water soluble radionuclides into sanitary sewer systems within certain limits (Table 1). If food contained greater levels of radioactivity or certain more toxic isotopes, alternative methods of disposal would be needed.

Low levels of radioactivity, from naturally occurring isotopes, industrial waste, and excreta of people undergoing medical procedures, normally pass through WWTP. Some isotopes ($^{131}I$, $^{60}Co$, $^{241}Am$, $^{40}K$, $^{226}Ra$, $^{228}Ra$, $^{89}Sr$, and $^{201}Tl$) are known to settle out with sludge particles and others have been reported to pass through the plant and are present in the discharged effluent [39, 40]. High levels of radionuclides, including $^{60}Co$ used in cancer treatment and $^{241}Am$ in industrial sources, were detected in sewage sludge in the past. In some cases, diluted radioactive materials were discharged into the sanitary system and diluted by millions of liters of liquid from other sources but radioisotopes became concentrated in sludge necessitating expensive cleanup operations [41].

Low level solid radioactive waste in the United States is normally deposited in one of the three operational radioactive waste landfills (Utah, Washington, and South Carolina). Both the concentration of the radionuclides and half-lives of the isotopes determine whether wastes are permitted in these landfills (http://www.nrc.gov/reading-rm/doc-collections/cfr/part061/part061-0055.html).

Potential radiological impact of disposal of large quantities of very low level solid radioactive waste (not more than 4 MBq/metric ton of $\beta/\gamma$ activity in $10^8$ kg/yr) in municipal landfills has been assessed by the UK government [42]. The assessment considered potential exposure of workers at a landfill site, the impact if the leachate from a landfill were directly deposited in a river, and problems that might occur after closing

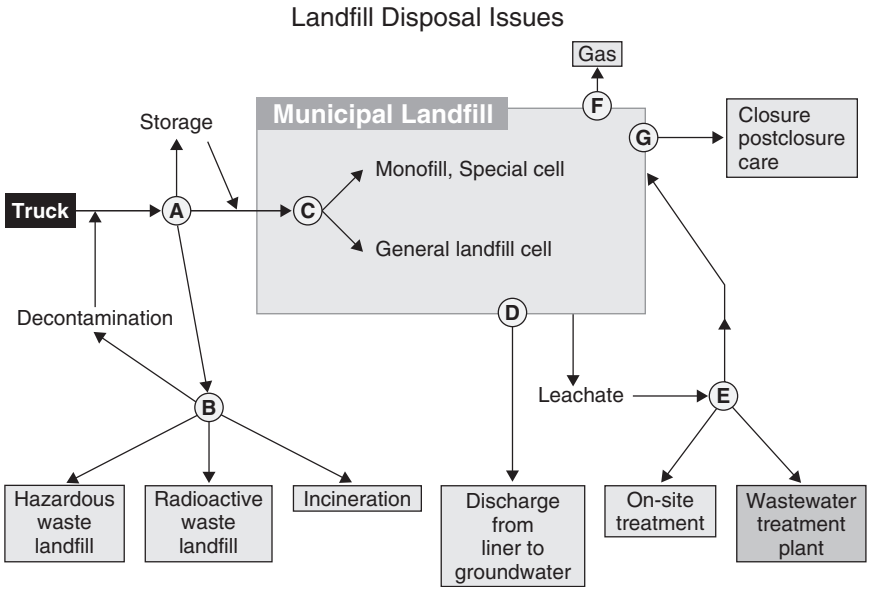

**FIGURE 1** Landfill disposal issues

the site. Results from the study indicated that disposal of $^{3}H$, $^{36}Cl$, $^{90}Sr$, $^{238}U$, $^{239}Pu$ or $^{241}Am$ in landfills at this rate would be safe but disposal of $^{14}C$, $^{60}Co$, $^{137}Cs$, $^{226}Ra$ and $^{232}Th$ may not be safe.

Incineration prior to disposal may be useful in reducing the expected large volume of contaminated food. Incineration does not destroy radioactivity but eliminates organic material, and radioisotopes are then present in a much smaller volume of residual ash, fused slag, fly ash, and volatile compounds. Expected partitioning of different isotopes has been modeled (Table 1). Radioactive and toxic materials can be removed from gas emissions by scrubber filters and will require disposal. The radioactive ash can be immobilized in cement and then transported to a disposal or storage site [43]. Treatment capacities of controlled air incinerators for low level radioactive waste range from 200 to 700 kg/h.

## 4 CRITICAL NEEDS

Landfill operators have long-term responsibility and liability for their sites and depend on the good will of their neighbors and government agencies. WWTPs operate continuously and, as part of the public health system, have a very limited ability to refuse or redirect liquids that they receive. Neither would willingly accept foods containing terrorist agents without sufficient information about survival and fate of the agents. Escape of the agent from a landfill through gases, leachate, or leakage into groundwater is a major concern (Figure 1) as are the costs of increased monitoring for exotic agents, liability issues, risks to workers, and post-closure care and land use. If an agent is not degraded in a WWTP, it will be present in the effluent discharged to surface waters and/or in the biosolids normally spread on agricultural land. An agent may disrupt the metabolic activities of the bacteria performing the important tasks of degrading organic compounds, producing

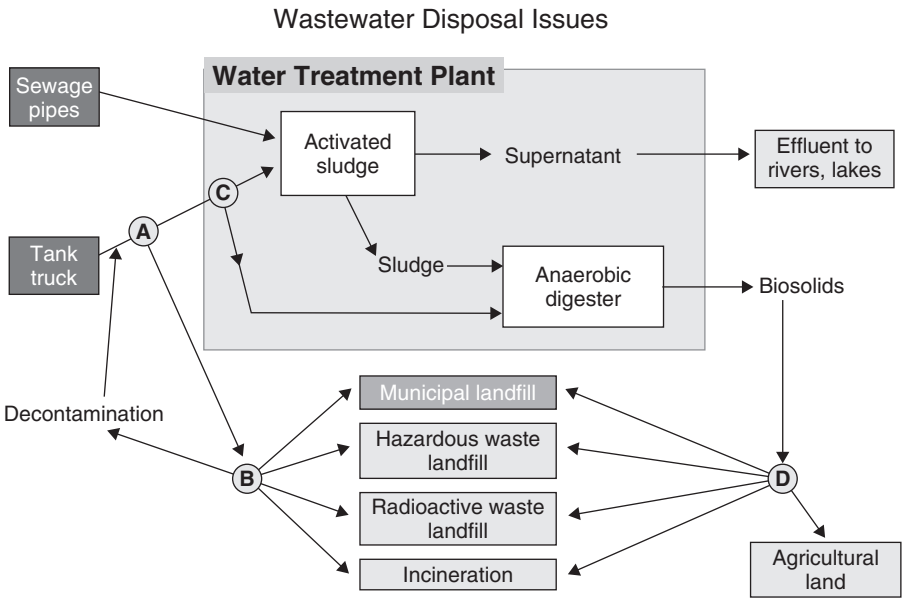

**FIGURE 2** Wastewater disposal issues

methane, and removing nitrogen from wastewater. Vapors or aerosols from activated sludge tanks may present a risk to workers (Figure 2).

Perceived risk for some agents may be greater than the real risk but such issues must be addressed. Despite scientific evidence, neither the waste disposal operators nor the public may trust that the agent has been completely inactivated. Public health and public relations will require long-term monitoring to demonstrate that risk is minimal.

Critical needs include the following:

- greater coordination and communication between federal and state agencies that manage and regulate food and those that manage the environment and security;
- development of regulations, policies, and procedures to define how terrorist wastes are to be managed, where they can be disposed, how they will be monitored, and what liabilities associated with managing these wastes will be assumed by the government and by industry;
- more information is needed regarding the fate of terrorist agents and their degradation products in conventional pollution control systems, such as landfills and WWTPs, so that rational decisions can be made regarding the impacts of accepting contaminated foods;
- planning by pollution control facilities to ensure worker safety and address the potential for inadvertent releases to ensure public safety and protection of the environment;
- increased communication among all stakeholders including food companies, pollution control facilities, renderers, transportation industry, and diagnostic laboratories;
- risk management strategies must be developed to communicate openly and honestly with the public.

## 5 RESEARCH DIRECTIONS

Research on the fate of various terrorist agents in pollution control systems should be investigated soon before the society and disposal industry are faced with a daunting disposal problem. A sound technical basis is needed so that rational decisions can be made about the disposal of large volumes of food contaminated by terrorists.

Future research should be directed to the following:

- investigation of the fate of various agents in different food matrices under conditions similar to those encountered in landfills and WWTP;
- improved analytical methods for various agents in different food matrices;
- feasible methods for decontaminating large volumes of contaminated food;
- effective risk communication strategies.

# CARCASS DISPOSAL OPTIONS

ABBEY L. NUTSCH AND JUSTIN J. KASTNER
*Kansas State University, Manhattan, Kansas*

## 1 INTRODUCTION

The US agricultural sector represents one of the world's most bountiful and economically valuable food and fiber systems. Animal agriculture comprises a substantial portion of the overall agricultural sector, with the value of US livestock, poultry, and their products sold in 2002 amounting to over $105 billion [1]. However, as delineated in Homeland Security Presidential Directive 9 [2], "The United States agriculture and food systems are vulnerable to disease, pest, or poisonous agents that occur naturally, are unintentionally introduced, or are intentionally delivered by acts of terrorism." The enormity, complexity, and diversity of US animal agriculture systems magnify a number of agricultural security challenges, one of which is carcass disposal. Whether at the hand of accidental disease entry, the weather, or an act of bioterrorism, widespread livestock deaths pose daunting carcass disposal challenges that, if not met quickly and effectively, can spiral into major food agricultural security problems and result in devastating economic losses. This article provides an overview of the options, considerations, and challenges associated with the disposal of large numbers of animal carcasses.

## 2 BACKGROUND

US livestock inventories in 2002 included more than 95 million cattle and calves, over 60 million hogs and pigs, and more than 8 billion broilers and other meat-type chickens [1]. Inevitably, routine animal-production mortalities occur and, as a result of the sheer scale of operations, equate to billions of pounds annually. For example, in 2002, routine mortalities requiring disposal totaled approximately 3 billion pounds [3]. This volume could be multiplied many times over in the event of natural disasters or the intentional or accidental introduction of foreign animal disease. The ever-increasing concentration of modern animal-production operations, combined with the tremendous mobility of food-animal populations, accentuates the country's vulnerability to high death losses due to disease outbreaks. Rapid depopulation and disposal are integral parts of effective disease eradication efforts.

In recent years, various incidents have served to spotlight the challenges associated with carcass disposal; perhaps the most notable and reported-upon is the 2001 foot and mouth disease (FMD) outbreak in the United Kingdom, which saw the disposal of more than 6.5 million animals, primarily sheep [4]. Examples in the United States include outbreaks of low pathogenic avian influenza (AI) in Virginia in 2002, exotic Newcastle disease (END) in southern California in 2002–2003, and the ongoing effort to address chronic wasting disease (CWD) in deer and elk populations. Additionally,

highly pathogenic AI has emerged as a global issue of concern, with more than 40 countries having reported outbreaks of H5N1 in poultry as of early 2008 [5]. The threat of this disease has stimulated a host of planning efforts directed toward responding to potential outbreaks, including the disposal of infected flocks.

Common methods of carcass disposal include, but are not limited to, burial, landfilling, incineration, composting, rendering, and alkaline hydrolysis. A brief overview of these alternatives, including advantages and disadvantages, is provided in this article. More detailed summaries of these and other methods are available from several sources provided in "References" and "Further Reading" [6].

## 3 PLANNING CONSIDERATIONS

With respect to disease or disaster incidents involving animal agriculture, a rapid and effective response is vital to minimizing livestock losses, economic impacts, and public health hazards. Strategies for carcass disposal—especially on a large scale—require preparation well in advance of an emergency in order to maximize the efficiency of response. The roles and responsibilities at the federal level for decontamination and disposal in response to animal, crop, and food incidents have been described in the document "Federal Food and Agriculture Decontamination and Disposal Roles and Responsibilities" [7]. This document is in accordance with the strategies outlined in the US National Response Plan (and its successor, the National Response Framework), and provides additional detail with respect to the key processes, and responsible parties, involved in the disposal of animal carcasses during an animal health emergency. As this document states, "appropriate decontamination and disposal decisions, and the resulting operations, involve multidisciplinary expertise and teamwork" [7, p. 9].

Managing disease eradication efforts is a complex endeavor requiring coordination and cooperation among many parties. Realization of a rapid response requires emergency management plans that are based on a thorough understanding of disposal alternatives that are both appropriate and available in various circumstances. Effective means of carcass disposal are essential regardless of the cause of mortality, but are perhaps most crucial for disease eradication efforts. It may seem straightforward to develop a generic, stepwise disposal-option hierarchy, outlining the most and least preferred methods of disposal. However, for a multidimensional enterprise such as carcass disposal, generic hierarchies may be of limited value as they may not fully capture and systematize the relevant dimensions at stake (e.g. environmental considerations, disease agent considerations, availability of the technology, and cost). Even with a disposal-option hierarchy that, for example, ranks the most environmentally preferred disposal technologies for a particular disease, difficulties arise when the most preferred methods are not available or when capacity has been exhausted. In these situations, decision makers may have to consider less preferred options. In such a scenario (one that is likely to occur in the midst of an emergency), there are tremendous benefits of being armed with a comprehensive understanding of an array of carcass disposal technologies. During times of emergency, it is possible that no single method of disposal will be sufficient and, whether ideally suited or not, multiple disposal options may be necessary.

Numerous issues will impact decisions about large-scale carcass disposal efforts. For any policy designed to provide decision-making guidance, it is necessary to identify the numerous factors that must be considered. The selection of an appropriate disposal

option must incorporate the scientific basis for the technology along with the associated needs of security, transportation, location, and decontamination. An understanding of the regulatory factors, the importance of cooperation and coordination among stakeholders, and the consideration of public opinion are all keys to successfully handling a carcass disposal emergency.

## 4 OVERVIEW OF DISPOSAL ALTERNATIVES

Within the limitations of this article, it is possible to provide only a brief overview of various carcass disposal alternatives. For additional details the reader is referred to "References" and "Further Reading" of this article. Because additional resource materials are continuously being developed, the interested reader is also encouraged to seek newly available materials that may not be reflected in these lists. Following are key attributes, advantages, and disadvantages associated with various disposal options.

### 4.1 Burial

Burial has historically been a common means of disposing of animal carcasses, particularly for routine mortality losses. On-site burial continues to be identified by various state and local authorities as a preferred means of carcass disposal in the event of a disease eradication effort. The suitability of a site for burial can be assessed using a host of characteristics—soil properties; slope or topography; hydrological properties; proximity to water bodies, wells, public areas, roadways, dwellings, residences, municipalities, and property lines; accessibility; and so on. Although many sources concur that these characteristics are important, the criteria for evaluating each can vary considerably among different localities (see Chapter 1 Burial, Appendix A1, in [6]). In some states, geographic information system technology has been used to preidentify sites that are suitable or unsuitable for burial [8–10].

Various sources have estimated the land area that may be necessary for burial (see Chapter 1 Burial, Appendix A2 in [6]), as well as the resources required for excavation [6, 11]. Volume estimates range from 1.2 to 3.5 $yd^3$ per mature cattle carcass (with one adult bovine approximately equivalent to five adult sheep or five mature hogs). One source estimated that an excavation volume of about 92,000 $yd^3$ would be required to bury 30,000 head of cattle; assuming an excavation depth of 8.5 ft, this would be equivalent to about 7 acres of land [12].

Burial as a carcass disposal option is cited as relatively economical, convenient, logistically simple, and relatively quick, as the necessary equipment is generally widely available and the technique is relatively straightforward. If performed on-site, it eliminates the need for transportation of potentially infectious material. These attributes have resulted in burial being a traditionally favored option for carcass disposal.

However, a key drawback of burial is the potential for negative short- and long-term environmental impacts resulting from the products of carcass decomposition. Although much of the pollutant load would likely be released during the earlier stages of decomposition, impacts could continue for many years [13]. Furthermore, the excavation of previous burial sites has demonstrated that carcass material can remain relatively intact in burial sites for very long periods of time, even decades [14, 15].

Other concerns relate to the potential for persistence of disease agents in the environment. Generally, the conditions of burial are thought to limit the survival of the majority of bacterial and viral organisms; however, precise survival times are unpredictable, and spore-forming organisms are known to survive in the environment for very long periods of time. Particular concern surrounds the agents known as *prions*, which are believed to be responsible for transmissible spongiform encephalopathies (TSEs) such as bovine spongiform encephalopathy (BSE) in cattle, scrapie in sheep, CWD in deer and elk, and Creutzfeldt–Jakob disease (CJD) in humans. These agents have been demonstrated to be highly resistant to inactivation processes effective against bacterial and viral disease agents [16], and the scrapie agent has been demonstrated to retain at least a portion of its infectivity following burial for 3 years [17].

The availability of burial as a viable disposal option may be limited by regulatory constraints, lack of sites with suitable geological and/or hydrological properties, or the fact that burial may be prohibitively difficult when the ground is wet or frozen. In some cases, the presence of an animal carcass burial site may negatively impact land value or options for future use. Lastly, as compared to some other disposal options, burial of carcasses does not generate a useable by-product of any value.

One permutation of the burial option is a mass burial site (that is, a site developed specifically for the burial of significant numbers of animal carcasses). The distinction between a large on-site burial location and a mass burial site is not necessarily clear and may simply be a matter of opinion. A mass burial site that employs a more sophisticated approach and incorporates containment measures similar to a landfill would perhaps more appropriately be termed an "*engineered mass burial site*". During the 2001 outbreak of FMD in the United Kingdom, six mass burial sites were created with a collective capacity of 3.5 million sheep carcasses; ultimately about 1.2 million carcasses were disposed in these sites [18]. As evidenced by the UK experience, such sites can play a critical role in disposal efforts during a time of emergency; however, hastily planned or inadequately assessed sites can create significant operational and management problems. There was tremendous public opposition to the use of these mass burial sites in the United Kingdom, sometimes even escalating to the point of violence and vandalism. Opposition was fueled by a failure of authorities to consult and communicate with surrounding communities and local regulatory bodies, as well as a lack of appropriate and thorough site assessments prior to commencing burial operations. If the burial of significant numbers of carcasses is anticipated in the event of an emergency—creating a de facto mass burial site—advanced planning and communication with all stakeholders will be essential.

### 4.2 Landfill

In many US states, disposal of animal carcasses in landfills is an allowed option. However, it may not be an available option, as individual landfill operators can decide whether or not to accept carcass material. Whether real or perceived, potential risks to public health from disposing of animal carcasses in landfills will likely be the most influential factor in the operator's decision to accept carcass material. Depending on the situation, the role of public perception and/or the degree of opposition to the use of landfills for disposal of animal carcass material may be significant or essentially negligible. For example, although landfill capacity could have accommodated 100% of the carcass mate-

rial requiring disposal during the 2001 UK FMD outbreak, only about 16% was disposed of via this route, primarily due to significant local opposition [13]. Conversely, the vast majority of carcass material disposed during the 2002 California END outbreak was disposed of by landfill with little public opposition.

During an emergency or instance of catastrophic loss, time is of the essence, and therefore landfills offer the advantage of disposal infrastructure that is preexisting and immediately available. Furthermore, the quantity of carcass material that can be disposed of via landfills can be relatively large. For example, over 3 million birds were depopulated during the 2002 END outbreak in southern California, with landfills serving as a primary means of disposal. In addition to carcass material, other outbreak-associated materials, such as eggs and litter, were also disposed through landfill.

Landfill sites will have been previously approved with the necessary environmental protection measures, thus representing a disposal option posing little risk to the environment. (Note that risks to the environment may vary depending on the type of landfill and may be greater for small arid landfills that rely on natural attenuation to manage waste by-products.) Another advantage of landfills is the fact that they are present in most locations (although proximity varies). The cost to dispose of carcasses by landfill has been referred to as both an *advantage and a disadvantage*, and would likely depend on the situation. Fees assessed by landfills for disposing of poultry during disease outbreaks in 2002 and 2003 were reported to be about $40–45/t [19]. However, the overall cost of landfill disposal of poultry during the 2002 outbreak of AI in Virginia was reported to be approximately $122/t, when costs of other equipment and transportation of carcass material were considered [20].

Even though disposal by landfill may be an allowed option, and a suitable landfill site may be located in close proximity, landfill operators may not be willing to accept animal carcasses. Additionally, because approval and development of a landfill site is lengthy, difficult, and expensive, landfill owners and planning authorities may not want to sacrifice domestic waste capacity to accommodate carcass material. As landfilling of carcasses represents a means of containment rather than of elimination, long-term management of the waste is required. Another disadvantage associated with landfill disposal is the potential spread of disease agents during transport of infected material to the landfill (a potential concern for any off-site disposal method).

Special procedures may be necessary at the landfill to prevent the spread of diseases. During the 2003 outbreak of END in southern California, the Riverside County California Waste Management Department developed a training video to educate landfill operators and employees on appropriate biosecurity and operational procedures to prevent disease spread [21]. The Virginia Department of Environmental Quality has also developed guidance materials for the disposal of poultry in landfills [22].

Carcass material infected (or potentially infected) with TSE agents may be of special concern. The United States Environmental Protection Agency (US EPA) has outlined recommended practices for disposal of carcasses potentially contaminated with CWD agents [23]. Various risk assessments have concluded that disposal of potentially TSE-infected carcasses in an appropriately engineered landfill site represents very little risk to human or animal health [24, 25]. However, because these agents are not well understood, research is ongoing to determine the mobility and survival of prions in landfill environments [26, 27].

### 4.3 Composting

Composting is a process of aerobic degradation of organic material by microbes; for optimal performance, it requires an appropriate balance of carbon and nitrogen sources, as well as appropriate oxygen and moisture conditions. As a means of carcass disposal, composting has increased in popularity with the decreased availability, increased cost, and/or environmental concerns associated with alternative methods. Composting is also attractive because it can be performed on-site, eliminating the need to transport infected or potentially infected material during a disease outbreak. Where large numbers of carcasses are concerned, composting is generally better suited to the disposal of small- to medium-sized carcasses (e.g. poultry and swine) than large carcasses (e.g. cattle). For disposing of routine mortalities, the use of composting is more common in poultry and hog production than in cattle production [3].

Considerations for the use of composting for disposing of animal carcasses have been summarized by various authors [6, 28–30]. Within the past decade, composting has been used to dispose of poultry during disease outbreaks in the United States and Canada; these experiences have provided valuable insights into the potential issues associated with composting during a disease eradication effort. In 2002, an outbreak of low pathogenic AI affected nearly 200 poultry farms (approximately 4.7 million birds) in Virginia [19, 31]. Composting was used with some success to dispose of a small percentage ($<1\%$) of the resulting carcasses [14]. However, this event highlighted the potential advantages of composting poultry, particularly in-house. In 2004, in-house composting was used to dispose of poultry carcasses resulting from an outbreak of low pathogenic AI on the Delmarva Peninsula (Maryland and Delaware); the outbreak was contained to three poultry farms, despite these operations being located in a dense poultry-production area [31]. In 2004, British Columbia, Canada experienced an outbreak of highly pathogenic AI; composting was used to dispose of approximately half of the 1.2 million birds impacted by the outbreak [30].

Researchers at Iowa State University recently completed an extensive 3-year investigation into the environmental impacts and biosecurity issues associated with composting of mortalities during a time of emergency [32]. During this study, 54 t of cattle carcasses were composted to assess the performance of various cover materials; the potential for soil, water, and air pollution, as well as the survival of the vaccine strains of viruses causing avian encephalomyelitis and Newcastle disease. Under the conditions of their study, the composting process inactivated both viruses within 1 week, regardless of the season of year or the cover material used. On the basis of the results of this project the researchers provide suggested guidelines for composting cattle mortalities during emergency situations. Their results suggest that composting can be a relatively biosecure process when performed properly.

### 4.4 Incineration/Thermal Methods

Thermal means of carcass disposal include open-air burning, fixed-facility incineration, and air-curtain incineration. Because carcasses are composed of approximately 70% water, they are somewhat challenging to incinerate, regardless of the method.

Open-air burning of carcasses—including the burning of carcasses on combustible heaps known as *pyres*—dates back to biblical times. As recently as 2001, it was used as a key means of disposal in a large-scale disease eradication effort, namely the 2001 outbreak of FMD in the United Kingdom [4]. During this outbreak, approximately 30% of

6 million carcasses were disposed of by open-air burning on some 950 burn sites; although some sites featured mass pyres, most were smaller, on-farm burns [18]. Open-air burning may be appealing as a means of disposing carcasses on-site, thereby avoiding the need to transport carcasses to an off-site disposal location. Open-air burning is labor and fuel intensive, can present environmental concerns and public perception issues, and can even precipitate mental health challenges in the agricultural community involved. During the 2001 UK FMD outbreak, carcasses burning on mass pyres "generated negative images in the media" and "had profound effects on the tourist industry" [18, pp. 7, 74]. Other disadvantages of open-air burning include the fact that it is dependent on favorable weather conditions, unsuitable for managing TSE-infected carcasses [33], and may be prohibited by environmental regulations.

Examples of fixed-facility incinerators include crematoria, small carcass incinerators at veterinary colleges, large waste incineration plants, on-farm carcass incinerators, and power plants. Unlike open-air burning and air-curtain incineration, fixed-facility incineration is wholly contained and, usually, highly controlled. Fixed-facility incinerators have been used in the United Kingdom to dispose of BSE-infected carcasses as well as rendered by-products from cattle carcasses considered to be at risk of BSE. Fixed-facility incineration is highly biosecure, as it is capable of inactivating agents of disease including TSEs. However, fixed-facility incinerators are expensive and difficult to operate and manage from a regulatory perspective. Most on-farm and veterinary-college incinerators are of insufficient capacity to be of value during carcass disposal emergencies, and larger industrial waste incinerators are typically not configured to handle carcasses as an input [33].

Air-curtain incineration involves equipment that fan-forces a mass of air through a manifold, thereby creating a "curtain" that traps smoke and significantly reduces the amount of pollutants released into the atmosphere. The process also provides a turbulent environment in which incineration is greatly accelerated—up to six times faster than open-air burning [34]. The process can be accomplished in-ground (trench burners or pit burners) or above-ground using fireboxes. Disposal of carcasses is a relatively new application for air-curtain incineration technology; it has traditionally been used for eliminating land-clearing debris, reducing clean wood waste for landfill disposal, and eliminating storm debris [19, 33].

Air-curtain incinerators have been used for carcass disposal in the wake of natural disasters in the United States [33], and were used to a small degree during the 2001 UK FMD outbreak [4, 18]. Air-curtain incinerators were used to dispose of more than 2000 t of poultry carcasses during the 2002 outbreak of AI in Virginia [14], and have been used in Colorado and Montana to dispose of animals infected with CWD [35]. Air-curtain incinerator capacity depends on the type of equipment and on-site management of the process; throughput capacity has been estimated to be approximately 4 to 6 t of carcasses per hour [34].

Air-curtain incineration is mobile, usually environmentally sound, and suitable for combination with debris removal (e.g. in the wake of a hurricane). However, air-curtain incinerators are fuel intensive (requiring not only a sufficient quantity, but also quality of fuel materials), and can be logistically challenging [33]. Although air-curtain incineration achieves temperatures of 600–1000 °C, because temperatures fluctuate during the process and vary within the burn chamber, there is debate about whether the process is sufficient to ensure the destruction of TSE agents. The cost of air-curtain incineration depends on variables such as carcass species, fuel costs, and equipment type; cost estimates range from about $150 to about $500/t of carcass material [6, 19, 34].

## 4.5 Rendering

Rendering uses physical, thermal, and chemical processes to convert waste animal by-products and mortalities into usable proteins and fats. A detailed history and summary of the rendering industry has been published by the National Renderers Association [36]. According to this report, approximately 40–60% of the live weight of livestock and poultry are not consumed by humans and therefore represent raw materials in the rendering process [36]. From approximately 54 billion pounds of raw materials, about 11 billion pounds each of animal derived proteins and rendered fats are produced annually in the United States, with a production value of about $2.7 billion. About 85% of this output is used as animal feed ingredients [36, 37].

In the wake of the UK BSE epidemic in the mid to late 1980s—which is thought to have been precipitated by the presence of TSE-infected meat and bone meal in cattle feed—concerns about TSEs have resulted in various restrictions on how rendered products can be used in animal feeds. Since 1997, US regulations have prohibited the use of most mammalian protein in ruminant feed. Since BSE was discovered in the United States in 2003, regulatory authorities have sought to strengthen protections against BSE in United States cattle. The appropriateness and availability of rendering as a means of disposal in the event of emergency will depend on many factors, including the nature of the emergency (i.e. whether a disease incident or natural disaster; if a disease event, whether TSEs are of concern) and how the resulting rendered product might be used.

The cost of rendering is influenced by many factors, including the location of the facility in relation to the carcasses' point of origin, energy costs, and the value of the rendered end product. If the end products derived from mortalities cannot be used for feed ingredients, the cost of rendering increases significantly.

The advantages and disadvantages of rendering have been outlined by various sources [14, 38]. Rendering facilities represent preexisting infrastructure, with plants often located near areas of food-animal production. There are few environmental concerns associated with rendering and it requires no long-term management. In some cases rendering could provide a usable end product, which could help off-set carcass disposal costs. However, not all locations are served by a rendering facility, and facilities in close proximity may not have sufficient surge-capacity and/or may not be willing to accept carcasses that result from a disease outbreak. Carcasses must be transported to rendering facilities, which may not be desirable, especially if a rendering facility is in close proximity to other at-risk operations. If rendering is being considered as a possible disposal option in the event of an emergency, discussions with rendering companies should occur at the highest levels prior to an outbreak.

## 4.6 Alkaline Hydrolysis

Alkaline hydrolysis, a relatively new disposal technique pioneered by a private company ($WR^2$), uses alkali and heat to break down biological materials (e.g. proteins, carbohydrates, and lipids); the primary by-product of the process is a sterile liquid effluent consisting of small peptides, amino acids, sugars, and soaps [39]. This effluent must itself be disposed of and/or discharged into municipal waste water treatment systems. Equipment for disposal of animal carcasses by this process is commercially available

in capacities up to 10,000 lb/cycle for fixed-base systems and up to 4,000 lb/cycle for mobile systems. The process has been validated to completely destroy prions; for this reason it has been used to dispose of deer confirmed or suspected of having CWD. At present, because of capacity constraints, the most likely application for this technology is the disposal of TSE-infected materials, rather than the disposal of mass quantities of carcasses during times of emergency. According to the equipment manufacturer, systems large enough to process ruminant carcasses range in cost from about $500,000 to $2 million, with operating costs of approximately $0.07/lb.

## 5 CONCLUSIONS

The ability to respond quickly and effectively to an animal agriculture emergency in which large numbers of carcasses must be disposed of requires management plans that are developed well in advance of an emergency. Although generic guidance documents can provide valuable insights for those tasked with planning for disposal emergencies, the most appropriate event-specific disposal options "will depend on numerous factors, such as the type of disease (e.g. is it contagious to humans or animals), the number of carcasses for treatment/disposal, transportation issues, and availability of treatment/disposal capacity" [7, p. 20]. Disposal plans must also be tailored to the unique conditions existing in each local area at the time of an event. Although disposal of carcasses can present enormous challenges in a time of emergency, effective planning at the local level will help responders manage the process in a way that prevents the spread of disease and protects public health and the environment.

## 1 INTRODUCTION

Agroterrorism, or a terrorist attack on the food supply, has become a major concern since the September 11, 2001 attacks. Terrorism directed toward the food system could have extremely large human health, economic, and psychological consequences, such as loss of human life, economic disruption, and negative impacts on consumer confidence [1]. Consequently, if there is any intentional tampering by terrorists on the US food system, it could cost the country billions of dollars in order to control or stabilize the situation [2].

This study provides a framework to value investment strategies to mitigate possible agroterrorism occurrences in the food supply chain and to determine where these investments would reduce the most risk. Such a framework could be applied to any food sector at risk from agroterrorism. This study applies the framework to the milk industry. Previous health scares related to milk illustrate the potential for human harm and economic damage. The discovery of the pesticide heptachlor in over 80% of the milk produced in Oahu, Hawaii in 1982 and the resulting drop in milk consumption showed how contamination can financially handicap the milk industry. It could also result in a number of casualties. Wein and Liu [3] illustrate the possibility of a deadly bioterror attack on the milk supply chain, as the botulinum toxin could be released at the holding tank at a dairy farm, a tanker truck transporting milk from the farm to the processing plant, or a raw milk silo at the processing facility.

The current method of record keeping and maintenance is called the *one-step forward/one-step backward* (OSF/OSB) method. This method requires persons who manufacture, process, pack, transport, distribute, receive, hold, or import food into the United States to keep records of the immediate previous sources and immediate subsequent recipients of food [4]. However, this method may be costly, and it could significantly hinder global food trade. The annual total record keeping cost is estimated to be $1.41 billion [5]. In recent years, alternative tracking devices such as radio frequency environmental monitoring(RFEM) technology have emerged as an alternative to track and prevent agroterrorism risks along food supply chains. The potential benefits

of the RFEM technology are that: (i) record real-time data that can be downloaded and analyzed during the process; (ii) could be used to screen for malicious tampering of food containers or packages; (iii) could pinpoint the location of tampering or more importantly could indicate the possibility that a toxic material or infectious agent was added to the product; (iv) could be used for traceability from production to commercialization; and (v) could be used to monitor and record weather conditions, types, amounts, and timing of chemicals applied, disease incidence, insect infestations, and harvest dates [6].

The primary objective of this study is to evaluate the cost-effectiveness of the use of alternative tracking strategies intended to mitigate agroterrorism risks along the milk logistic system. The specific objectives are to determine the costs and risk premiums that the private sector is willing to pay for alternative tracking strategies along the supply chain and where and when along the supply chain investments in alternative intervention strategies will reduce the most risk. The framework developed in this study consists of a stochastic optimization model, a real options model, and the "tomato garden" portfolio of options framework.

## 2 THEORETICAL MODELS

Investment decisions to mitigate agroterrorism risk are made under conditions of risk and uncertainty. Several conceptual frameworks have been used in the literature to model and evaluate investment decisions under conditions of risk and uncertainty [7–11]. These frameworks range from simple mean-variance graphical comparisons of risk and returns to robust development of the expected utility maximization framework. The framework used in this study consists of two steps: (i) quantifying the cost and risk premium associated with alternative tracking technologies; and (ii) identifying areas where investment will reduce the most risk along the supply chain and the incentives to invest in security measures. The first step is accomplished by using stochastic optimization and the expected utility framework, whereas the second step uses real options and the portfolio of options framework.

### 2.1 Stochastic Optimization Model

A stochastic optimization model of a vertically integrated firm is developed to determine the costs, risks, and optimal strategies associated with four alternative tracking technologies: (i) random testing with no lock-out tag or RFEM system installed; (ii) OSF/OSB tracking for bioterrorist events; (iii) tracking with RFEM installed, with testing for contaminants when RFEM signals tampering and random testing elsewhere; and (iv) tracking with RFEM installed with required testing for contaminants at the milk plant and import facilities. The advantage of stochastic optimization over alternative valuation models is that a risk premium can be estimated with multiple stochastic variables in the model [2].

In this model, the total system costs and optimum premium for each strategy are estimated. Stages along the milk supply chain where testing can be implemented include the farm, transport from farm to processing facility, milk silo, pasteurization, postpasteurization tanks, bottling, and transport for export. The total system cost ($C_i$) is defined as:

$$C_i = \sum_{j=1}^{n} T_{ij} \cdot TC_{ij} \cdot S_{ij} \cdot V_{ij} + Q_{ij} \cdot L_{ij} + RFEM_{ij} \tag{1}$$

where $i$ varies from one to four, indicating alternative tracking technologies; $j$ is the location where tests are conducted; $T_{ij}$ is a binary variable indicating test/no test at location $j$; $TC_{ij}$ is the cost of testing per unit (dollars per test) at location $j$; $S_{ij}$ is the sampling intensity at location $j$; $V_{ij}$ is the volume of milk flow at location $j$; $Q_{ij}$ is the volume diverted (quantity not meeting specifications) at location $j$; $L_{ij}$ is quality loss cost per unit at location $j$; and $RFEM_{ij}$ is the cost of installing RFEM or alternative tracking devices at location $j$.

The model is used to estimate the certainty equivalent and quantify the risk premium for the four alternative systems. The risk premium is the difference required for the investor to be indifferent between the alternative tracking strategies. The objective function uses a von Neumann–Morgenstern-type utility function, with increasing relative risk aversion and decreasing absolute risk aversion [12]. This model chooses the optimal testing strategy (where to test and the testing intensity) that maximizes the utility of a vertically integrated firm. The objective is:

$$\begin{aligned} \mathrm{Max}U = E(U(W)) \quad &= \quad \lambda - \exp(-\Phi W^{\eta})) \\ &\text{Subject to } X_j \in Y_j, \end{aligned} \tag{2}$$

where $U$ is utility; $EU$ is the expected utility of the vertically integrated firm; $W$ is the wealth of the vertically integrated firm; $\lambda$ is the parameter determining positiveness of the utility function; exp is exponential power function; $\Phi$ and $\eta$ are parameters which affect the absolute and relative risk aversion of the utility function; $X_j$ is the decision variable vectors of the model; and $Y_j$ is the opportunity cost of the model.

The advantage of using this utility function in the stochastic simulation model is that it is flexible and allows for changes in absolute and relative risk aversion. This utility function also allows us to quantify the cost and risk premium that would make the vertically integrated firm indifferent between a base model (random testing) and the alternative tracking technologies. The parameters of the utility function $\lambda$, $\Phi$, and $\eta$ are fixed and set to 2, 0.01, and 0.5, respectively.

The risk premium is defined as:

$$\pi_i = EV_{\mathrm{BCM}} - C_i \tag{3}$$

where $\pi_i$ is the risk premium for strategy $i$; $EV_{\mathrm{BCM}}$ is the expected value of the base case model with random testing; and $C_i$ is the certainty equivalent of the strategy $i$. The validity of the expected utility framework requires a test for robustness of the results to be evaluated. This is accomplished by performing sensitivity analysis under relative and absolute risk aversion parameters. Cost and risk premium results are used in the real options model to determine the timing of investment decisions.

### 2.2 Real Options Model

The real options approach to agroterrorism prevention assumes that an investor has the opportunity to invest in a prevention strategy and the investor prefers to reduce income volatility. The effect of the uncertainty associated with an agroterrorism event can be valued using a real options valuation procedure, which is a form of a European call option, even though the value of the project is not clearly recognized at the time of the investment. The returns from the real options model work similar to returns from car

insurance investments. Such an investment is made with the intention of never having to use it, but when an attack does occur, a positive payoff is the result from the investment. The model assumes that returns follow a Poisson (jump) and a mixed Brownian motion (continuous) process. The continuous movement of the process is due to production and price variability whereas the discrete jump process can be credited to uncertain agroterrorism actions [10].

The Poisson jump process assumes that the amount of time a firm operates before an agroterrorism event occurs follows an exponential distribution, and if an agroterrorism event occurs, returns are reduced. The advantage of using the Poisson jump process over typical binomial distributions is that it can account for a specific time period and extreme events that typical binomial distributions may miss.

Mohtadi and Murshid [13] used extreme value statistics to evaluate the probability of an attack that would cause the number of fatalities plus injuries to exceed 5000. These probability forecasts were determined for now, 5 years, 10 years, and 25 years into the future. The forecasts were broken down into different categories: chemical agents, biological agents, and radioactive or nuclear agents (CBRN). The results showed that the probability of attack increased if no action is taken to prevent an attack. These results were 0.18, 0.22, 0.26, and 0.35, for now, 5 years, 10 years, and 25 years, respectively. These results were for a CBRN attack in general and were not targeted toward the food sector. However, it was determined that the probability of attack will increase over time in the absence of preventive measures. The probability of an attack on the milk supply chain is scaled down and assumed to be 0.01 and sensitivities are performed for a range of probability values.

The amount of time it takes before a "jump" to a lower level of returns is assumed to be a random variable with a range on the interval $[0, \infty]$. Thus, the probability of the jump occurring at time $T$ is:

$$P(a < T \leq b) = \int_a^b \lambda \, \mathrm{e}^{-\lambda t} \, dt \tag{4}$$

where $t$ is the current time, $\lambda$ is the positive exponential hazard rate parameter, and e is the natural exponential function. The value $\exp(-\lambda t)$ measures the probability of occurrence of an agroterrorism event sufficient to affect firm revenue, whereas $\lambda$ measures the probability of the event occurring just after time $t$. The expectation of $T$ is inversely related to $\lambda$; therefore a subjective determination of the size of $\lambda$ can be made using the investors' prior beliefs [14].

Brownian motion is used to model continuous movement in future returns from an investment. This is also used to describe the probability distribution of the future price of a commodity. Commodity price movements are assumed to follow a log normal distribution, with the amount of time that has passed being dependent on the mean and standard deviation. The following is a typical Brownian motion process equation:

$$dV = \alpha V \, dt + \sigma V \, dz \tag{5}$$

where the increment of the Brownian motion process is represented by $\mathrm{d}z$, with drift parameter $\alpha$ and variance rate $\sigma$. According to Eq. (5) the expected growth rate of $V$ is equal to the sporadic variability plus volatility in the price of the commodity.

The value of an option or an investment opportunity in an agroterrorism prevention strategy, $F(V)$, is defined as the expected present value from investing at the optimal time [10, 15, 20]:

$$F(V) = \max_T E_0[(V_T - K)\mathrm{e}^{-\rho T}] \tag{6}$$

where $T$ is the optimal time to invest; $V_T$ is the expected present value of the investment made at time $T$; $K$ is the sunk cost of the project; e is the natural exponential function; $\rho$ is the discount rate; and $E$ is an expectation operator. The expected present value of the option or investment is a function of state variables (e.g. the decision to not invest or invest in alternative security measures), as well as choice variables (e.g. the amount to spend) at current time $t$. The objective is to maximize future cash flows from the investment.

This study covers two cases: the impact of an intentional attack in the supply chain, and the impact of an unintentional attack in the supply chain. The unintentional attack case is modeled as a dynamic process, which becomes a Bellman equation in continuous time.

$$\rho F(V(x,u,t)) = \max_u \left[\pi(x,u,t) + \frac{1}{dt} E\left[df(V)\right]\right] \tag{7}$$

According to Eq. (7), the normal return per unit time that is required to hold the commodity value $F(V)$ is equal to the immediate profit if the investment is made ($\pi(x,u,t)$), plus the capital gain or loss expected from holding the option ($E[\mathrm{d}f]$). The profit is zero if the investor holds on to the option, and this is the case for the periods before the investment is made. Multiplying this equation through by d$t$ yields

$$\rho F(V(x,u,t))\, dt = E\left[dF(V)\right] \tag{8}$$

This implies that the return on the investment opportunity equals the expected gain from holding the option, which in turn depends on the future value of the commodity. As stated earlier, it is assumed that the expected present value of the investment $V$ develops according to a combined geometric Brownian motion and Poisson jump process of the structure

$$dV = \alpha V\, dt + \sigma V\, dz - V\, dq \tag{9}$$

The term $V$ d$q$ is the Poisson jump process, defining the probability of the agroterrorism event occurring during an extremely small interval of time, d$t$. If d$q$ and d$z$ are independent, then d$q$ can be defined as

$$dq = \begin{cases} 0 & \text{with probability } (1-\lambda) \\ \phi & \text{with probability } \lambda, \end{cases} \tag{10}$$

where $\phi$ is the percentage by which $q$ will change if the agroterrorism event or Poisson occurs ($0 \le \phi \le 1$). The firm quits operating and continues to remain closed if $\phi = 1$.

Hence, in the Bellman equation (8), dF can be expanded using Ito's lemma. This is used for the differentiation of stochastic processes. Now an expression in terms of d$V$ is obtained

$$\rho F(V)\,dt = E\left[F'(V)\,dV + \frac{1}{2}F''(V)\,dV^2\right]$$

$$\rho F(V)\,dt = \alpha V F'(V)\,dt + \frac{1}{2}\sigma^2 V^2 F''(V)\,dt - \lambda\left[F(V) - F((1-\phi)V)\right]\,dt \quad (11)$$

$$0 = -(\rho+\lambda)F(V) + \alpha V F'(V) + \frac{1}{2}\sigma^2 V^2 F''(V) + \lambda F((1-\phi)V)$$

This second order homogeneous differential equation is solved for the value of the investment opportunity, *F(V)*, subject to the following constraints

$$\begin{aligned} F(0) &= 0 \\ F(V^*) &= V^* - K \\ F'(V^*) &= 1 \end{aligned} \quad (12)$$

where $V^*$ is the optimal expected net present value of the project. Numerical simulation methods with Risk Optimizer [16] are used to obtain $V^*$ because of uncertainty in returns and prices that result from agroterrorism. Risk-neutral valuation techniques are used to estimate the real options values for all economic entities along the milk supply chain using a portfolio of options framework.

### 2.3 "Tomato Garden" Option Space Framework

The "tomato garden" option space model, also known as *the portfolio of options*, involves the estimation of two variables: the volatility matrix (product of square root of time and the standard deviation of the net present value (NPV)) and the value-to-cost matrix (ratio of the NPV of the agroterrorism investment to the cost of the investment). Both variables are graphed into a two-dimensional illustration called *the option space*. The value-to-cost variable contains all of the data normally detained in NPV and real options problems, but adds the time value of being able to postpone the investment. The volatility variable measures how much the condition of the world can change before an investment decision must be made. The option space is portrayed by these two variables, with volatility on the vertical axis and NPV/cost on the horizontal axis (Fig. 1) [17].

Typical NPV models used in real options formulations provide only two options: invest or do not invest. By extending the real options analysis into the portfolio of options framework, the investor has the added advantage of having the NPV, two extra metrics, plus six possible actions that reflect what should be done right away, and also indicate the likelihood that an agroterrorism investment will be beneficial in the future. One more advantage of the portfolio of options matrix is that public investment strategies to all economic sectors of the milk supply chain can be represented as nested options. The nested options formulation allows the total investment on agroterrorism to be evaluated more effectively. With this strategy, a sequence of unforeseen events at alternative economic entities can be added into private or public sector investment decisions. For

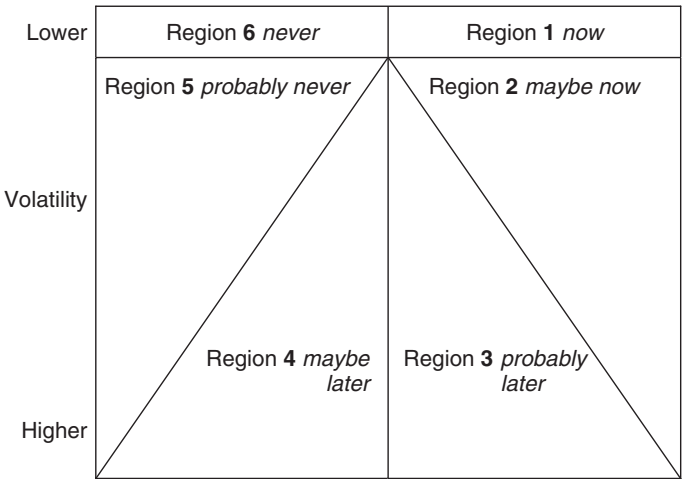

**FIGURE 1** "Tomato garden" option space framework. (Source: Luehrman [17]).

example, public investment may target sectors with the greatest amount of risk, evaluate how the investments in these sectors mitigate agroterrorism risk, and then decide to invest in other sectors with the possibility to further diminish those risks [10].

## 3 DATA AND SIMULATION PROCEDURE

Data were collected for the lot sizes for each of the economic entities (farm level, processing, and retail) of the milk supply chain; tracking and data management costs, including the lock-out tag and RFEM costs; recleaning costs; the quality loss costs; and milk prices. The average on-farm lot size is approximately 1200 gal. This is calculated using the number of farms and total milk cows from 2002 to 2005 [18, 19] and the average milk produced daily, 10 gal, which was obtained from Wein and Liu [3]. The lot size used for the milk truck is 5500 gal and the lot size for the milk silo is 50,000 gal. The pasteurization lot size used is a uniform distribution between 50,000 and 60,000 gal. The postpasteurization tank lot size is 10,000 gal. The bottling for domestic user lot size equals the postpasteurization tank lot size, and the loading lot size for the export user equals the milk truck lot size [3] (Cooper, M. 2006, Personal Communication) [20].

The lock-out tags are placed on the trucks transporting the milk from the farm to the processing facilities. This tag is used on the manhole and the back outlet of the milk truck and is applied after each cleaning. The tags provide security during transportation. The average cost per tag is about $0.21. The average cost of an RFEM unit is approximately $0.45 [6]. The RFEM units provide similar functioning as the lock-out tags but can be used to store data on the origin and quantity of milk from each farm or economic unit to another. They can also be programmed to relate real-time data if tampering occurs at any point along the supply chain. Recleaning costs occur if one of the lock-out tags is broken before the next pickup of milk. The average recleaning cost is approximately $45.00 per cleaning.

The quality loss cost consists of the recall/dumping costs and the lost sales costs. The recall/dumping costs are represented by a triangular distribution with most likely cost of

$1.17/gal. These costs are calculated using the minimum, average, and maximum prices received by farmers from 1995 to 2004 [21]. The lost sales costs are based on the past contamination and sales loss incident in Hawaii and are calculated to be approximately $0.075/gal of contaminated milk [22]. The average preprocessing and postprocessing prices of milk from 1998 to 2004 are $1.18 and $2.84/gal, respectively [21, 23].

Testing costs, test accuracies, RFEM reliability, and the probability of contamination at each stage in the milk supply chain are assumed random and represented by distributions. Testing costs for pathogens and toxins are represented by a triangular distribution with a most likely cost of $25 per test. Testing accuracies are assumed to be uniform distributions ranging between 0.9 and 1.0. The reliability of signaling tampering with the RFEM units is assumed to be uniformly distributed between 0.95 and 0.99 [6]. The probability of intentional contamination is reflected at each stage of the milk supply chain by a Poisson distribution with a mean probability of 0.01 [2]. The size of contamination, if contamination occurs, is assumed to be equal to the lot size and introduced at the point of occurrence.

Real options values are calculated for the vertically integrated supply chain using the data generated from the stochastic optimization model. The average discount rate used is 0.07 and sensitivities on the probability of contamination (the same probabilities as in the stochastic simulation sensitivities) are run to explore their impacts on the real options values. Real options values are also calculated for three major participants along the supply chain: the farm, processor, and importer/retailer.

### 3.1 Simulation Procedures and Assumptions

Three tracking strategies are evaluated for the domestic supply chain. Any testing conducted is assumed to be for *salmonella* and botulinum toxin. The base strategy consists of mandatory testing when the milk arrives at the milk plant for both the domestic and export supply chains and mandatory testing when the milk arrives at the importing facility in the export supply chain. This strategy also includes random testing elsewhere along the supply chain and does not contain the lock-out tag or RFEM unit. It is the common tracking practice in the milk supply chain.

The second tracking strategy is to implement the lock-out tag in the domestic supply chain and the lock-out tag along with RFEM in the export supply chain. This strategy consists of mandatory testing when the milk arrives at the milk plant in the domestic and export supply chains. However, in the export supply chain two different scenarios are examined. The first is to continue to require mandatory testing at the import facility whether or not the RFEM unit signals tampering, and the second is to only require mandatory testing at the import facility when the RFEM unit signals tampering. Random testing is still used for all points along the domestic and export supply chain that did not require mandatory testing.

The third tracking strategy is the OSF/OSB strategy regulation, requiring mandatory record keeping. With this strategy, each sector of the domestic and export supply chains is tested to meet the specifications of the record keeping requirements and other product quality and marketing requirements. This strategy does not contain the lock-out tag or RFEM unit.

Sensitivities are conducted to examine effects of critical parameters, such as costs and risks, on the optimal strategies. These parameters include the probability of

contamination, cost of the lock-out tag/RFEM, reliability of the lock-out tag/RFEM, and the cost of recalls.

The optimal NPV and standard deviation values are simulated using @Risk decision tool software [24]. These values are then used to determine the two main variables used for the portfolio of options framework: NPV/cost and volatility. The portfolio of options model is used to determine whether or not to invest and when the RFEM/alternative strategy should be implemented to reduce most of the risks.

## 4 STOCHASTIC OPTIMIZATION MODEL RESULTS

### 4.1 Domestic Milk Supply Chain

The optimal tracking strategy for the base case in the domestic milk supply chain model is to test only where it is mandatory to test, when milk is received at the milk plant (Table 1). Table 1 shows the buyer and seller risks under each strategy. Buyer risk is the risk that product exceeding tolerances will get into the buyer product stream, and seller risk is the risk that product thought to be within tolerances will be rejected. Buyer and seller risks are minimal in the base case with mean values of 1.10504 E-07 and 2.05301E-17%, respectively. These results indicate that 1.10504 E-07% of lots entering the domestic user flows might be contaminated (buyer risk) and 2.05301E-17% of the lots might be rejected (seller risk). Average systems costs for conducting random testing for pathogens, recleaning, and quality loss are \$0.004545452, \$3.43173E-11, and \$0.00/gal, respectively. The certainty equivalent is \$0.004545452/gal, indicating that the decision maker would require a premium of this amount to be indifferent between this system and one with no testing.

In the second model a lock-out tag system is installed on truck shipments picking up milk from the farm. A mandatory test is applied when the truck arrives at the milk plant and a mandatory recleaning is applied when the lock-out tag is broken before milk pickup. The optimal tracking strategy for the domestic lock-out tag system is to test only when mandatory testing is required. Buyer risks for the lock-out tag system average 1.11372 E-07% with a 95% confidence interval of 6.54687E-08 to 1.13491E-07%. Seller risks average 2.05959E-17% with a 95% confidence interval of 4.98362E-18 to 2.59288E-17%. With the lock-out tag system, buyer and seller risks, although still minimal, are larger than those in the base case. The more security put on the supply chain, the more the risk of rejection of products. The average costs for lock-out tags, testing, recleaning, and quality loss are \$7.63637E-05, \$0.004545452, \$3.43173E-11, and \$0.00/gal, respectively. The results indicate that there is a 95% confidence interval for quality loss costs to be \$0.00/gal and for total system costs to lie between \$0.004617117 and \$0.0046543/gal.

Installing a lock-out tag system increases the certainty equivalent to \$0.004621816/gal from the domestic base case of \$0.004545452/gal. This indicates that the decision maker would require a risk premium of \$0.0000763637/gal to be indifferent between the lock-out tag system and the base case.

The third model simulated is one where tests are applied and information passed OSF/OSB. This requires tests on all lots along the domestic milk supply chain. No lock-out tag or RFEM system is installed and there are no optional testing locations. Average buyer and seller risks are 1.19377E-07 and 5.32244E-07%, respectively. Costs for the OSF/OSB system are the highest of the three domestic systems. Costs for testing, quality loss, and recleaning are \$0.035793613, \$1.83705E-06, and \$3.43173E-11/gal,

**TABLE 1 Domestic Milk Model Optimal Testing Strategy Results**

| | Base Case Random Testing No RFEM/Tag Mandatory Testing at Milk Plant | Random Testing with Tag and Mandatory Testing at Milk Plant | OSF/OSB |
|---|---|---|---|
| Utility | 1.2004 | 1.2004 | 1.2004 |
| Test (1 = yes, 0 = no) and intensity % sampled | | | |
| On farm | 0–NA[a] | 0–NA | 1–100% |
| Milk silo | 0–NA | 0–NA | 1–100% |
| Pasteurization | 0–NA | 0–NA | 1–100% |
| Postpasteurization | 0–NA | 0–NA | 1–100% |
| Bottling | 0–NA | 0–NA | 1–100% |
| Milk plant-truck no signal | 1–100% | 1–100% | 1–100% |
| Milk plant-truck signal | NA | 1–100% | NA |
| Buyer risk | 1.10504E-07 | 1.11372E-07 | 1.19377E-07 |
| Seller risk | 2.05301E-17 | 2.05959E-17 | 5.32244E-07 |
| Costs ($/gal) | | | |
| Cost of testing | 0.004545452 | 0.004545452 | 0.035793613 |
| Cost of tag | 0 | 7.63637E-05 | 0 |
| Cost of recleaning | 3.43173E-11 | 3.43173E-11 | 3.43173E-11 |
| Cost of quality loss | 0 | 0 | 1.83705E-06 |
| Certainty equivalent ($/gal) | 0.004545452 | 0.004621816 | 0.035795458 |
| Comparison to base case | NA | 0.0000763637 | 0.031250006 |

[a]NA is not applicable

respectively. The OSF/OSB system has a certainty equivalent of $0.035795458/gal and a risk premium of $0.031250006/gal. The tighter the security measure results in a greater risk premium.

The buyer risks are similar in all three systems. The seller risks are similar between the base case and the lock-out tag system, but, although still minimal, are higher in the OSF/OSB system. When comparing the costs (testing, lock-out tags, recleaning, and quality loss) and risk premiums, the base case has the lowest total costs and risk premium as expected, followed by the lock-out tag system, and the OSF/OSB system has the highest total costs and risk premium. Decision makers would require a risk premium of $0.03125/gal to be indifferent between the OSF/OSB system and the base case and $0.031173642/gal to be indifferent between the OSF/OSB system and the lock-out tag system.

Sensitivities are conducted for the domestic model on the probability of intentional contamination, cost of the lock-out tag, reliability of the lock-out tag, and the recall costs to determine their impact on the optimal strategies, costs, and risk premiums. Alternative probabilities of contamination ranging from 0.0001 to 0.1 are examined to determine their effect. Over this range of probabilities for contamination, the optimal tracking strategy does not change. Results show that as the probability of contamination in the supply chain increases, buyer and seller risks and certainty equivalents increase, but minimally.

By doubling or halving the cost of the lock-out tag, the buyer and seller risks show no change and the certainty equivalent has minimal changes. When changing the reliability of the lock-out tag, minimal changes occur in the buyer and seller risks, and the certainty equivalent does not change. When fixing the cost of recalls to the minimum, most likely, and maximum values instead of the triangular distribution, the buyer and seller risks and the certainty equivalent show minimal changes. In each of these sensitivities, the optimal testing strategy does not change. One possible explanation for the observed minimal changes is that participants may view terrorist attacks on the food supply as extreme events. Their expectation that the milk supply chain may be attacked carries more weight than the frequency of attack. Similar analyses are performed for the milk export supply chain.

### 4.2 Export Milk Supply Chain

The export base case model also depicts a vertically integrated firm in the milk supply chain that does random testing for pathogens and toxins. This system contains no lock-out tag or RFEM unit and mandatory testing is applied on all lots arriving at the milk plant and the importing facility. The optimal testing strategy for the base case is to test only where it is mandatory, at the milk plant when milk is received and at the import facility when milk is received (Table 2). Buyer and seller risks are minimal with mean values of 1.49081E-13 and 2.22251E-23%, respectively. Average costs for conducting random testing for pathogens, recleaning, and quality loss are \$0.009009742, \$6.70864E-11, and \$0.00/gal, respectively. The certainty equivalent is \$0.009009743/gal, indicating that the decision maker would require a premium of approximately \$0.009/gal to be indifferent between this system and one with no testing.

In the second model, a lock-out tag system is installed on truck shipments picking up milk from the farm and a lock-out tag and RFEM system is installed on truck shipments from the milk plant to importing facilities. A mandatory test is applied when the truck arrives at the milk plant and at the importing facility. The optimal testing strategy for the lock-out tag and RFEM system is to test only when mandatory testing is required. Buyer risks average 1.83304E-07% with a 95% confidence of 1.54713E-07 to 2.01009E-07%. Seller risks average 1.66972E-09% with a 95% confidence interval of 2.30648E-17–7.47412E-09%. With the lock-out tag and RFEM system, buyer and seller risks, although still minimal, are larger than those in the base case. Average costs for testing, lock-out tags and RFEM, recleaning, and quality loss are \$0.009009742, \$0.000194221, \$6.70864E-11, and \$8.09505E-09/gal, respectively. The results indicate that the 95% confidence intervals are between \$0.00 and \$3.62357E-08/gal for quality loss costs and \$0.009180129 and \$0.009224166/gal for the total system. Installing a lock-out tag and RFEM system increases the certainty equivalent to \$0.009203971, which indicates that the decision maker would require a risk premium of \$0.000194228/gal to be indifferent between the lock-out tag and RFEM system and the base case.

In the next scenario, a lock-out tag system is installed on truck shipments picking up milk from the farm and a lock-out tag and RFEM system is installed on truck shipments to importing facilities. A mandatory test is applied when the truck arrives at the milk plant and testing at the importing facility is only mandatory when the RFEM system signals tampering. The optimal testing strategy for this system is to test only when mandatory testing is required. Buyer risks average 1.86531E-07% with a 95% confidence interval of 1.54713E-07–2.03577E-07%. Seller risks average 1.66972E-09% with a 95% confidence

| Seller risk | 2.22251E-23 | 1.66972E-09 | 1.66972E-09 | 7.6315E-07 |
| Costs ($/gal) | | | | |
| Cost of testing | 0.009009742 | 0.009009742 | 0.004545456 | 0.0422221 |
| Cost of tag/RFEM | 0 | 0.000194221 | 0.000194221 | 0 |
| Cost of recleaning | 6.70864E-11 | 6.70864E-11 | 6.70864E-11 | 6.7086E-11 |
| Cost of quality loss | 0 | 8.09505E-09 | 8.09505E-09 | 2.6285E-06 |
| Certainty equivalent ($/gal) | 0.009009743 | 0.009203971 | 0.004739686 | 0.04222474 |
| Comparison to base case | NA | 0.000194228 | −0.004270057 | 0.033215 |

interval of 2.30648E-17–7.47412E-09%. With the lock-out tag and RFEM system, buyer and seller risks, although still minimal, are larger than those in the base case. Average costs for testing, lock-out tags and RFEM, recleaning, and quality loss are $0.004545456, $0.000194221, $6.70864E-11, and $8.09505E-09/gal, respectively. The 95% confidence interval for total system costs ranges from $0.004705743 to $0.004740911/gal. The certainty equivalent is $0.004739686/gal with a risk premium of negative $0.004270057.

The third tracking strategy simulated is one where tests are applied and information stored OSF/OSB. This requires tests on all lots along the export milk supply chain in conformity with existing quality requirements. No lock-out tag or RFEM system is

installed and there are no optional testing locations. Average buyer and seller risks in the OSF/OSB system are 1.4908E-13 and 7.6315E-07 %, respectively. Costs for this system are the highest of the three export systems for testing and quality loss. Costs for testing, quality loss, and recleaning are $0.0422221, $2.6286E-06, and $6.7086E-11/gal, respectively. The OSF/OSB system has a certainty equivalent of $0.04222474/gal, and a risk premium of $0.033215/gal.

The buyer risks are the same in both the base case and OSF/OSB models and, although still minimal, higher in both lock-out tag and RFEM cases. The seller risks are lowest in the base case and highest in the OSF/OSB. The seller risks in both lock-out tag and RFEM cases are the same.

Decision makers would require a risk premium of $0.000194228/gal to be indifferent between a system that includes lock-out tags and RFEM units with mandatory testing at the milk plant and import facilities and a system that consists of mandatory testing at the milk plant and import facilities with random testing elsewhere. Decision makers would require a risk premium of $0.033020769/gal to be indifferent between the OSF/OSB case, and the lock-out tag and RFEM system with mandatory testing at the milk plant and import facilities. However, when comparing the base case to the lock-out tag and RFEM system with mandatory testing at the milk plant and at the import facility when the RFEM signaled tampering, the lock-out tag and RFEM system shows a negative risk premium. This means that this lock-out tag and RFEM system would actually cost less than the base case system due to the reduction in testing locations.

Sensitivities are conducted which show that varying the probability of contamination between 0.0001 and 0.1 does not change the optimal tracking strategy, but buyer and seller risks and certainty equivalents increase as the probability of contamination increases. By doubling or halving the cost of the lock-out tag and RFEM, the buyer and seller risks do not change and the certainty equivalent has minimal changes. When changing the reliability of the lock-out tag and RFEM, minimal changes occur in the buyer and seller risks, and the certainty equivalent does not change. When fixing the cost of recalls to the minimum, most likely, and maximum values instead of the triangular distribution, the buyer and seller risks and the certainty equivalent show minimal changes. In each of these sensitivities the optimal tracking strategy does not change.

## 5 REAL OPTIONS MODEL RESULTS

Real options results compare the cost and benefits or value of risk reduction over time and space. Recall that investment opportunities exist when adopting alternative tracking strategies. These opportunities enable firms to decrease variability of income or increase expected value of returns. From the NPV perspective, the increased expected values are compared with the systems costs of the alternative tracking technologies. Results are provided for both a firm that is vertically integrated in the supply chain and also a supply chain that has the major participants operating together but are not vertically integrated under the same company.

Simulated real options values for the vertically integrated domestic milk supply model indicate that the average NPV for a system with lock-out tags and RFEM is $1,591,745 when the probability of contamination of 0.01. The NPV/cost of the model is calculated to be 1.27 with a volatility of 0.0204 (Table 3). When the probability of contamination is altered to 0.0001, 0.001, and 0.1, average NPV equals $1,390,809, $1,590,364, and

**TABLE 3 Real Options Results**

| NPV | NPV | Cost | NPV/Cost | Volatility |
|---|---|---|---|---|
| | | Vertically integrated milk supplier | | |
| | | Domestic | | |
| Base case Pr. 0.01 | $1,591,745 | $1,252,671 | 1.27 | 0.0204 |
| Pr. 0.0001 | $1,390,809 | $1,252,671 | 1.11 | 0.0187 |
| Pr. 0.001 | $1,590,364 | $1,252,671 | 1.27 | 0.0249 |
| Pr. 0.1 | $822,298 | $1,252,671 | 0.66 | 0.0058 |
| | | Export with mandatory testing at milk | | |
| | | Plant and import facility | | |
| Base case Pr. 0.01 | $2,541,260 | $1,628,486 | 1.56 | 0.0023 |
| Pr. 0.0001 | $2,033,066 | $1,628,486 | 1.25 | 0.0028 |
| Pr. 0.001 | $2,371,304 | $1,628,486 | 1.46 | 0.0042 |
| Pr. 0.1 | $2,541,172 | $1,628,486 | 1.56 | 0.0024 |
| | | Export with mandatory testing when | | |
| | | RFEM signals tampering | | |
| Base Case Pr. 0.01 | $2,802,377 | $1,628,486 | 1.72 | 0.0047 |
| Pr. 0.0001 | $2,338,992 | $1,628,486 | 1.44 | 0.0024 |
| Pr. 0.001 | $2,938,368 | $1,628,486 | 1.80 | 0.0048 |
| Pr. 0.1 | $2,799,089 | $1,628,486 | 1.72 | 0.0047 |
| | | Nonvertically integrated milk supply chain | | |
| Producer | $107,067 | $29,820 | 3.59 | 85,571 |
| Milk plant/processor | $6,090,714 | $59,640 | 102.12 | 4,658,444 |
| Importer | $5,525,148 | $59,640 | 92.64 | 4,621,554 |

*Source:* NPV/Cost

$822,298, respectively. The corresponding NPV/cost ratios for these probabilities are 1.11, 1.27, and 0.66, respectively, whereas the corresponding volatility values are calculated to be 0.0187, 0.0249, and 0.0058, respectively. The system cost for the tracking strategy is $1,252,671.

For a vertically integrated milk supplier with RFEM installed and mandatory testing at the milk plant and import facility, the real options values indicate that the average NPV is $2,541,260, with a corresponding NPV/cost value of 1.56 and a volatility value of 0.0023, when the probability of contamination of 0.01. If testing is required only when RFEM signals tampering, the average NPV is $2,802,377, the NPV/cost ratio is 1.72, and the volatility value is 0.0047. The investment cost in both scenarios is $1,628,486. Table 3 shows that the NPV decreases when the probability of contamination drops.

The next step in the results process is to use the calculated NPV/cost and volatility values from the simulated real options results and graph them into the "tomato garden" framework to determine where and when investment in alternative tracking strategies will reduce most of the risks or be cost-effective. On examining the base case value of 0.01 for probability of contamination among all three scenarios for the vertically integrated milk supplier in the portfolio of options, the results indicate that in each of the scenarios the values fall into the area where the investment strategy will be beneficial to implement now (Fig. 2).

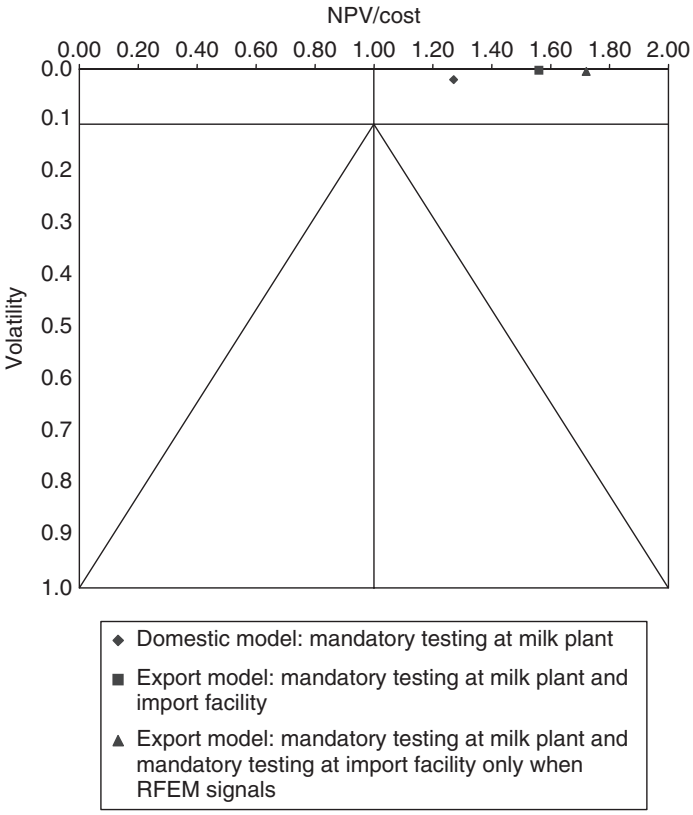

**FIGURE 2** "Tomato garden" option space framework: vertically integrated milk supply chain with probability of contamination of 0.01.

The sensitivity results graphed in the "tomato garden" framework for the probability of contamination of 0.0001 and 0.001 are similar to the base case. These results indicate that in each of the three scenarios for the vertically integrated milk supplier, the values fall into the area where the investment strategy would be beneficial to implement now. The sensitivity results for the probability of contamination of 0.1 show a change from the base case scenarios. In this sensitivity, the results for both export scenarios indicate that the values fall into the area where the investment strategy would be beneficial to implement now, but the domestic scenario results indicate that the values fall into the area where the investment strategy will never be beneficial if implemented.

Results may seem counter intuitive, suggesting that as a risk or probability of attack increases, a vertically integrated domestic firm will not invest in security measures. However, theory suggests that firms can afford to spend on security measures until the marginal benefits are equal to the marginal cost. When costs are greater than benefits from investments, this might suggest the need for external incentives. As the probability of attack increases significantly, public and private efforts may be required to mitigate

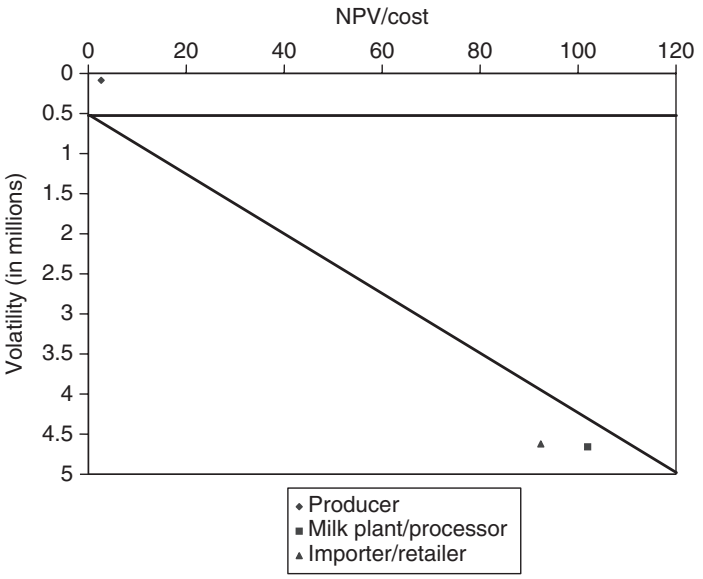

**FIGURE 3** "Tomato garden" option space framework: nonvertically integrated milk supply chain

food terrorism risks. This may be especially true to protect domestic consumers against food terrorism events. This also provides a justification for public sector spending to mitigate food terrorism events.

In the nonvertically integrated milk model, simulated real options values at the farm level indicate that the NPV is $107,067, the NPV/cost ratio is 3.59, and volatility is 85,571 (Table 3). NPV, NPV/cost, and volatility are $6,090,714, 102.12, and 4,658,444, respectively, for the processor and $5,525,148, 92.64, and 4,621,554, respectively, for the importer/retailer. The analysis indicates that for the farm level producer the values fall into the area where it would be beneficial to implement the investment strategy now, whereas the investment strategy would be beneficial probably later for the processor and importer/retailer (Fig. 3).

## 6 CONCLUSIONS

The findings show that as the probability of attack increases, the certainty equivalent and risk premium either do not change or change minimally, which could be due to the perception of the public that the different probabilities of an attack are not viewed as important as whether there is an attack or not. The buyer and seller risks also change minimally when the probability of attack changes, but do increase when the probability increases. However, the change in buyer and seller risks could lead to possible moral hazard issues. Findings also show that the RFEM technology is the more cost-effective tracking strategy compared to the alternative strategies used in mitigating agroterrorism

risks along the milk supply chain. The risk premium is lower for the RFEM tracking investment strategy than in the alternative tracking strategies. These results show a potential for real-time tracking and containment strategies.

The results of both the domestic and export supply chains indicate that no random testing is done. The buyer risks tend to be higher in the domestic model whereas the seller risks tend to be higher in the export model. The testing costs and certainty equivalents are lower in the domestic model due to the fewer number of testing locations and the reduced number of tags along the supply chain.

The real options results suggest that in the vertically integrated milk supply chain it would be beneficial for the domestic and export suppliers to invest in security measures now to reduce most of the risks, with the exception that the domestic suppliers should never invest when the probability of attack is 0.1. Since the results of the domestic supply chain indicate that an investment in food protection measures may not always be beneficial, policy implications may be derived. These policy implications may be that the costs to the domestic milk supply chain should be partly or completely subsidized. This results from the probability of contamination being increased to 0.1. The NPV/cost decreases to below one, which results in the region of never being beneficial in the "tomato garden" option space framework. This provides justification for public sector spending to mitigate food terrorism events. When analyzing the nonvertically integrated milk supply chain, the portfolio of options suggests that the investment strategy would be beneficial to implement now for the farm level entity and probably later for the milk plant/processor and retail/importer.

This study provides a framework for valuing investment strategies to mitigate possible agroterrorism occurrences in the supply chain and determining where these investments would reduce most risks. This framework is applied to the milk industry in this article, but it could also be applied to other food industries that are at risk. Other food products that could be at risk include various produce, honey, peanut butter, seafood, infant formula, baby food, fruit juice, soft drinks, bottled water, and products that use milk as an ingredient, such as yogurt and ice cream [25].

# MID-INFRARED SENSORS FOR THE RAPID ANALYSIS OF SELECT MICROBIAL FOOD BORNE PATHOGENS

LISA J. MAUER AND BRADLEY L. REUHS
*Department of Food Science, Purdue University, West Lafayette, Indiana*

## 1 INTRODUCTION

The goal of sensor research is to provide fast, accurate, and inexpensive methods for detecting chemical and biological contaminants. Sensors based on optical technologies have the advantages of sensor longevity and suitability for continuous monitoring. Optical methods are based on absorption, scattering, or fluorescence of light by the component of interest. Near-infrared (IR) and mid-IR spectroscopy are the most promising of the optical technologies available. IR spectroscopy, on which IR sensors are based, is a form of absorption spectroscopy that can provide both qualitative and quantitative information about the molecules being analyzed. With this method, it is possible to establish the presence of functional groups in a sample and the concentration of the sample components [1]. The measurement of concentration for IR sensors is a one-step relation between the concentration of the component of interest and the detector signal. In IR spectra, any deviation from the baseline (spectra of the control sample) shows the change in the concentration or structure of the component analyzed. Naumann et al. [2, 3] characterized the spectra of bacterial cell into five regions, which were associated with specific chemical groups of the different bacterial components, and concluded that selection of appropriate spectral regions and corresponding weights allowed for detection, identification, and discrimination of bacterial strains.

## 2 FUNDAMENTALS OF INFRARED (IR) SPECTROSCOPY

The fundamentals of IR spectroscopy are described in many references, such as [4], and a brief introduction is provided here to support the understanding needed for pathogen analysis applications. Mid-IR spectroscopy methods are based on studying the interaction of IR light (wavenumbers 4000–400 $cm^{-1}$) with samples. A general schematic for a mid-IR Fourier-transform infrared (FTIR) spectrometer is shown in Figure 1. The IR source in an FTIR emitting radiation is passed through an interferometer (usually a Michelson interferometer with a beamsplitter fixed mirror and moving mirror) that uses interference patterns to make accurate measurements of the wavelength of light. When IR radiation is passed through a sample, some radiation is absorbed and the rest is transmitted to the detector. The energy at which radiation is absorbed correlates to the frequency of

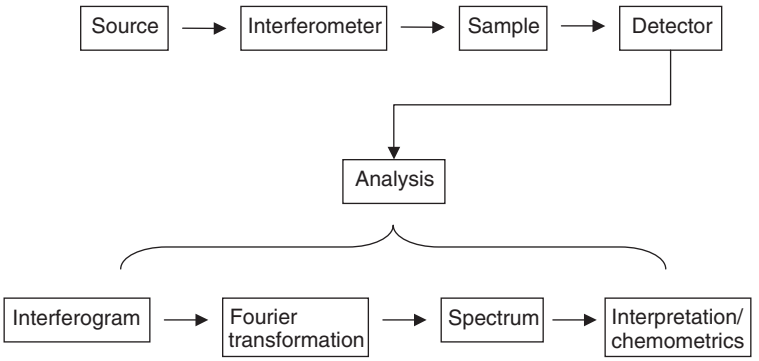

**FIGURE 1** General schematic of a Fourier-transform infrared (FTIR) spectrometer.

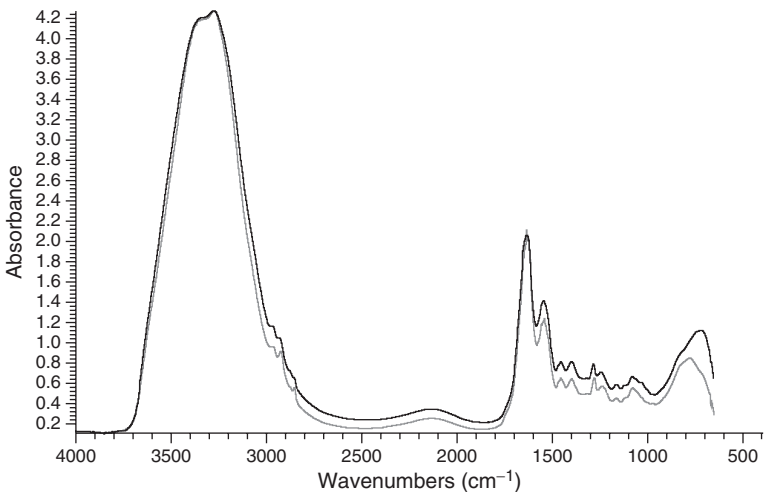

**FIGURE 2** Representative spectra (4000–600 $cm^{-1}$) of bacteria captured on a Metricel filter following the method described by Burgula et al. [5]. Black and gray lines represent the spectrum of *E. coli* O157:H7 and *Salmonella typhimurium*, respectively.

a specific chemical bond vibration in the sample. A functional group will absorb mid-IR radiation if the energy of the IR radiation equals a vibrational energy level difference in the molecule. For many molecules, the fundamental transition from the ground vibrational state to the first vibrational energy level occurs at an energy level, 4000–400 $cm^{-1}$, higher than the ground state. These fundamental transitions appear as peaks in an absorbance spectrum (a plot of the amount of radiation absorbed versus wavenumber, Fig. 2). Some functional groups will also have overtone transitions, excitation to higher energy levels, in the mid-IR range that appear as weak absorbance bands in spectra [4].

The wavenumber positions of absorbance peaks, peak intensities, and peak widths are useful for functional group, cell component, and sample identification. Wavenumber positions of absorbance bands are specific to the functional groups in a sample, thus each sample has a unique "fingerprint" absorbance spectrum. Group wavenumbers, or wavenumber regions in which functional groups absorb IR radiation regardless of other

**TABLE 1 Functional Groups of Major Mid-IR Peaks and Associated Absorbance Peak Wavenumbers**

| Approximate Wavenumber ($cm^{-1}$) | Functional Group Assignment |

(Adapted from Naumann et al. [3], Naumann et al. [7], and Burgula et al. [9]

molecular structures (Table 1), are useful for determining the presence or absence of specific functional groups in a sample [6], and were used by Naumann et al. [2, 3] to classify the spectra of bacteria. Although the general spectra of many bacteria appear similar (such as in Fig. 2), the differences in cell surface structures between bacteria enable differentiation and identification of individual bacterial strains on the basis of spectral differences [7, 8]. Specificity can be derived from spectra by focusing on specific absorbance regions related to those compounds that are diagnostic to a specific pathogen.

By using a library/database of spectra from different types of bacteria, the identification of an unknown bacterium is possible based on spectra matching algorithms (if a spectrum of that type of bacterium is present in the database). Peak intensity becomes important because IR spectra follow the Beer–Lambert law relationship where absorbance ($A_\lambda$) is proportional to pathlength ($l$), absorptivity ($\varepsilon_\lambda$), and concentration ($c$) (Eq. (1))

$$A_\lambda = 1\ \varepsilon_\lambda\ c \tag{1}$$

As the concentration of a molecule increases in the sample, the intensity/height of its absorbance band(s) will also increase (Fig. 3). This facilitates both functional group identification and quantitative assays. If spectra are collected for increasing

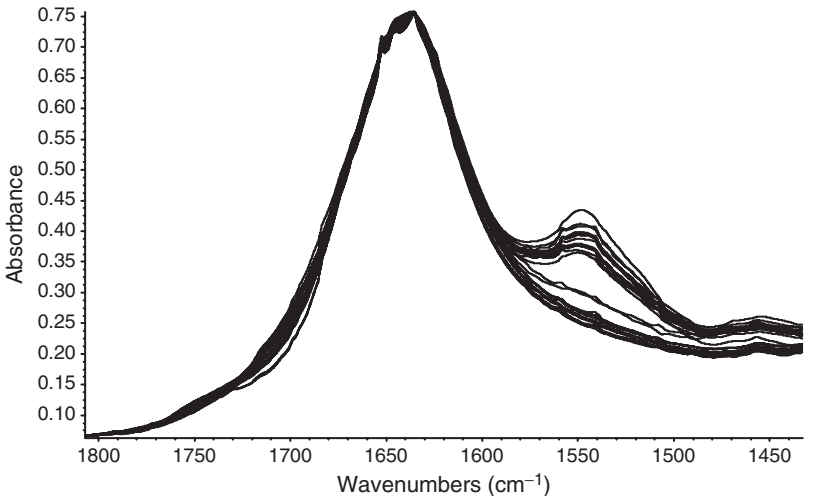

**FIGURE 3** Spectra (1800–1450 $cm^{-1}$) collected hourly from a 24 h growth curve of *E. coli* K12 grown in tryptic soy broth at 37 °C. The initial concentration was 4 CFU/ml at 0 h, the final concentration was 8.5 ± 0.3 log CFU/ml at 24h, and samples were prepared for FTIR analysis following the filtration method described by Burgula et al. [5].

concentrations of bacteria, there will be a corresponding increase in absorbance peak heights in regions characteristic to the cells, as shown in Figure 3. Absorbance peak widths are influenced by the number and strength of functional group interactions with the neighboring molecules, and the overlap of functional group absorbance peaks often occurs with increasing complexity of samples. To facilitate the interpretation of complex spectra, chemometrics approaches are commonly used. Chemometrics algorithms utilize statistical and mathematical techniques to analyze chemical data. Common chemometric approaches include pattern recognition (e.g. hierarchical cluster analysis, principal component analysis, and soft independent modeling of class analogies) and multivariate calibration and prediction (e.g. partial least squares and principal components regression) [10]. For IR sensors, chemometrics enable the interpretation of molecular structural information and correlation to bacterial composition and/or type for both qualitative and quantitative analyses [11–18].

## 3 ADVANTAGES AND DISADVANTAGES OF IR SENSORS

A summary of the advantages and disadvantages of FTIR spectroscopy methods for analyzing microorganisms described by Naumann et al. [7], Smith [4], Naumann [19], Mariey et al. [8], and Burgula et al. [9] is as follows:

### Advantages

1. Nondestructive: the sample remains intact during analysis.
2. Most molecules have IR bands in the mid-IR region (4000–400 $cm^{-1}$)
3. Spectra are unique molecular "fingerprints" that provide information related to functional groups and symmetry.

4. FTIR spectra have enough resolution that absorbances generated from specific pathogens can be differentiated.
5. Relatively fast and easy to use. Most samples can be scanned and spectra analyzed in less than 5 min.
6. Requires very little sample: nano- to microgram.
7. Software is widely available for spectral interpretation using multivariate statistical analysis.
8. May be applied to the field of microbiology for
   - providing information related to bacterial composition and cellular components;
   - screening/taxonomical classification and epidemiological studies;
   - quantification of microorganisms;
   - process control, microbial quality control, and hygienic checks.
9. It is not necessary to know the type of contaminant to successfully identify a potential problem. The advantage of quickly screening a sample for contamination using an IR sensor is balanced with the ability to specifically identify the contaminating substance from its spectra once a deviation from the baseline warrants further investigation.

**Disadvantages**

1. Spectral regions of various components often overlap, which may lead to misinterpretation of results. As samples become more complex, this problem increases.
2. A complete library of spectra for each type of bacteria is recommended to facilitate detection.
3. Surface method.
4. May require expertise in the analysis of spectra for chemotaxonomic classification (especially at the development stage).
5. Atmospheric conditions around the FTIR equipment during testing may affect spectral results.
6. Detection is facilitated by isolating or purifying the bacteria before analysis. Without an isolation step, the mixture of bacteria strains complicates the FTIR spectra.
7. Sample preparation procedures such as culture medium, growth time, and growth temperature may cause variations in spectra.

## 4 BACTERIAL CELL SURFACE COMPONENTS NEEDED FOR CELL IDENTIFICATION

The FTIR and chemometric discrimination of bacterial pathogens reflects many cell surface differences between bacterial species and strains. Although the differences in cell surface structures between Gram-positive and Gram-negative bacteria are considerable, there are sufficient variations in the surface structures between even closely related species, and also within a given species, for effective discrimination. This variation in the presence and abundance of various functional groups (Table 1) results in different spectral fingerprints for each pathogen.

The cell wall of a Gram-positive bacterium, such as *Listeria monocytogenes*, consists primarily of a relatively thick layer of peptidoglycan, a polymer of sugars and amino acids. The peptidoglycan forms a rigid, mesh-like layer over the cytoplasmic membrane that protects the cell protoplast from mechanical damage and osmotic rupture. The crystal lattice structure of the peptidoglycan is due to linear chains of alternating $\beta$-(1,4)-*N*-acetylglucosamine and a $\beta$-(1,4)-*N*-acetylmuramic acid, with each of the latter attached to a 4- to 5-residue peptide. The peptide usually contains L-alanine, D-alanine, D-glutamic acid, and diaminopimelic acid, although the exact structure may differ in different species. The latter three amino acids are not in proteins, and their presence in the peptidoglycan may help to protect the bacterial cell wall against peptidases. The high tensile strength and rigidity of the peptidoglycan yields the unique shape of a given bacterial cell (as opposed to spherical) and provides the protection against osmotic stress.

In Gram-positive bacteria, the thick cell wall (15–80 nm) consists of many layers of peptidoglycan, which are often associated with teichoic or teichuronic acids that are unique to Gram-positive bacteria. Teichoic acids are antigenic polymers of glycerol or ribitol phosphates, and teichuronic acids are chains of uronic acids and amino sugars or other sugar [20]. The variations in the presence and specific structure of various components yields the antigenic properties of the bacterial cell and gives each strain a chemical uniqueness. Also, these polymers are rich in functional groups, such as the carboxyl groups of uronic acids, which will be detected during FTIR analysis. Some strains produce other cell envelope components that are located outside of the cell wall [21], including capsule, such as hyaluronic acid capsule, and proteinaceous appendages. The impact of these components on bacterial identification by FTIR may not be significant, as there is not as much variation to the structures. However, the consistent production of a specific component by a given strain, and the lack of production by another strain would yield clear differences.

In contrast to Gram-positive bacteria, the cell wall of Gram-negative bacteria, such as *Escherichia coli* and *Salmonella* spp., is thin (approximately 10 nm); it consists of a single layer of peptidoglycan inside of a second membrane system, termed the *outer membrane*. The inner leaf of the outer membrane contains the common phospholipids found in the plasma membrane, but the outer leaf, which faces the environment, is unique: it almost entirely consists of lipopolysaccharide (LPS), a molecule found only in Gram-negative bacteria. In fact, LPS production is essential to Gram-negative cells, as mutations that completely block LPS biosynthesis are lethal. The LPS consists of three distinct domains: the lipid A membrane anchor; the nonrepeating core oligosaccharide; and the strain-specific O antigen or O polysaccharide [20, 22].

The lipid A and core are comparatively conserved within, and even among, bacterial species. In contrast, the O antigen, which dominates the surface chemistry of the cell wall, is highly variable among bacterial strains, to the extent that it is a primary source of serotype variation within a species. In addition to structural variation, O antigens are usually polymerized to different extents and demonstrate a range of degrees of polymerization, resulting in the "ladder pattern" that is common in polyacrylamide gel electrophoresis (PAGE) analyses of Gram-negative bacterial extracts [20, 23]. The specific structure of the O antigen yields the "O" designation for a given bacterial strain (such as O157), and hundreds of O antigens have been identified in numerous bacterial species. Although highly variable, O antigens generally display a common structural theme: they consist of relatively small repeats (three to five sugar residues is typical), and they are usually composed of a combination of common sugars (such as glucose,

mannose, fucose, and rhamnose) and unusual sugars. In addition, the O antigen repeat will often carry noncarbohydrate substitutions, such as phosphate, acetate, and pyruvate, on the hydroxyl or amino groups of the sugar residues. For example, in *E. coli* O157:H7 the O157 polysaccharide consists of tetrasaccharide repeats of *N*-acetylgalactosamine, fucose, glucose, and *N*-acetyl-4-amino-4,6-dideoxy-D-mannose. The hydrophobic character imparted by the deoxy sugars and acetyl groups is common in O antigens, and when acid groups are present on the O antigen, they are often esterified. Clearly, these features of bacterial LPS are beneficial in FTIR and chemometric analyses.

Gram-negative bacteria commonly produce a second class of antigens, termed *K antigens* [22, 24, 25]. In contrast to O antigens, the K antigens are highly acidic polysaccharides that form a hydrated, densely charged capsule over the cell wall, and only a fraction of the K antigens on the bacterial cell surface may be directly anchored onto the outer membrane. K antigens generally consist of monosaccharide, disaccharide, or trisaccharide repeating units, which include sialic acid-like sugars or uronic acids. For example, the K1 antigen of *E. coli* is a homopolymer of sialic acid, and the K5 antigen consists of equimolar amounts of glucuronic acid and *N*-acetylglucosamine. The thickness of the capsule varies, but in most strains that produce a capsule, the K antigen polysaccharides are present in abundance.

In summary, O and K antigens are strain specific and are responsible for much of the serotype specificity found within a species. In addition to the hydroxyl groups and glycosidic linkages that characterize polysaccharides, other common chemical features of O and K antigens include phosphate, acetyl, amide, carboxyl, methylene, and methyl groups, the latter of which may be C-linked, as in deoxysugars, or O-linked as a methyl ether or ester. The FTIR spectra of the cell walls will reflect the presence, abundance, and chemical environment of each unique group, resulting in a very specific spectral fingerprint for each strain. As with Gram-positive bacteria, Gram-negative cells also produce other cell surface components, such as flagella, pili, and membrane bound porin proteins, but the tremendous variation in O and K antigen structures yields the maximal discriminatory possibilities in chemometric analysis.

## 5 APPLICATIONS OF IR SENSORS FOR PATHOGEN DETECTION

FTIR methods that can accurately and rapidly identify, classify, quantify, and/or differentiate between many types of bacteria have been reported [2, 3, 8, 26–29]. FTIR is a physicochemical method that allows the chemically based discrimination of intact cells without their destruction and produces complex whole-organism biochemical fingerprints (spectra) that are reproducible and distinct for different bacteria [30]. Spectra can also be collected from cell components and used in pathogen detection and identification [31–33]. A reference library of spectra must be collected for each bacteria of interest, ideally spanning a range of concentrations, growth conditions, and spectral collection parameters. This spectral library is then used to develop chemometric analytical approaches for further sample analysis, such as pathogen detection, differentiation, and/or quantification. Commercial bacterial spectral libraries (e.g. Bruker optics) are available for different species and strains of *Staphylococcus*, *Pseudomonas*, *Bacillus*, *Clostridium*, yeasts, and other microorganisms; however, there is no standard FTIR spectral library for everything.

A wide range of FTIR techniques and scanning conditions have been used for collecting spectra of bacteria. Common techniques are

1. transmission FTIR [16, 26, 27, 29, 34–50],
2. diffuse reflectance FTIR [13, 30, 51],
3. attenuated total reflectance (ATR) FTIR [5, 30–33, 52–60].

Other FTIR techniques that have been used for bacterial analysis include specular reflectance spectroscopy (for study of surfaces), photoacoustic spectroscopy (PAS, for studying highly absorbing samples) [28], and IR microspectroscopy [46, 48].

Scanning conditions are often controlled by manipulating the number of scans, the resolution, and the wavenumber region. In the techniques referenced above, the number of scans ranged from 16 to 256, and the resolution varied from 2 to 16. The number of scans and resolution used should be based on optimizing the signal-to-noise ratio (SNR) for the analysis and available time; increasing the number of scans will increase the time for the analysis, although each scan generally takes less than one second to complete. The SNR can be increased by signal averaging over a number of scans ($n$), leading to an increase of SNR proportional to the square root of the number of scans as follows:

$$SNR \propto (n)^{1/2} \tag{2}$$

However, it is important to note that an increase in the number of scans will not necessarily improve the quality of the spectrum because of variations in the atmosphere over time. SNR can be altered by changing other instrumentation parameters as follows [4, 6]:

- SNR $\alpha$ (measurement time)$^{1/2}$
- SNR $\alpha$ resolution
- SNR $\alpha$ 1/(elapsed time between background and sample).

There is no advantage to decreasing the wavenumber region (4000–400 cm$^{-1}$) over which data is collected because spectral regions within the entire region can be selected and analyzed after complete spectra are collected. Many FTIR spectrometers have a wavenumber cutoff near 700–650 cm$^{-1}$, thereby shortening the useful wavenumber region to 4000–700 cm$^{-1}$.

### 5.1 FTIR Calibration Models

After a spectral library of foodborne pathogens is developed, spectral library searching can be done to compare an unknown spectrum to a collection of known foodborne pathogen spectra, with the resulting "hit quality index" providing a measure of similarity between two spectra [6]. Beyond the general library search, a calibration model can be developed in a two-step process (calibration and validation) to enable detection, differentiation, and quantification of foodborne pathogens. For calibration, spectra are collected from the samples of interest, which contain foodborne pathogens in parallel with standard plate count or other enumeration and identification procedures. This calibration spectra set (also called the *training set*) is used to relate the standard identification/quantification

results to the spectra. Chemometrics, multivariate techniques such as partial least squares and principal components regression, are recommended for analyzing food pathogen spectra that contain overlapping absorbance bands [11–18]. An important advantage of using multivariate methods is the ability to calibrate for foodborne pathogen types and concentrations when they correlate in a complicated, nonspecific way with multiple spectral regions. Validation of the calibration model is done using an independent set of spectra, called the *validation set*, collected from samples with known foodborne pathogen types and concentrations. If results from the validation set fall within acceptable accuracy limits using the calibration model (sometimes reported as root mean square error of prediction (RMSEP) or predicted residual error sums of squares (PRESS)), then the model can be used for analyzing new spectra. Note: it can take numerous samples, sometimes hundreds, to develop a robust calibration model; however, once developed, this model should be indefinitely useful for analyzing samples prepared following the same procedures used in developing the model [10].

## 5.2 Detection

Detecting pathogenic bacteria in a sample using FTIR spectra can be done by (i) identifying a spectral change from the baseline spectra of an uncontaminated sample (food, growth media, antibody-coated capture surface, etc.), and conducting a spectral library search to determine the presence of a known type of bacteria or (ii) identifying an increasing absorbance in the spectral regions characteristic to a bacteria (again verified through a library search) as samples are incubated and spectra recorded over time (Fig. 3). Using the first approach, a change from the baseline will indicate the presence of bacteria, but may not distinguish between living and dead cells (although there may be differences in the spectra of living and dead cells). Differences from a baseline can also be used to detect other bacteria or chemical agents in the sample as long as a spectrum of the "adulterant" is available. A likely more robust and feasible approach for using an IR sensor for differentiating between live and dead cells would be based on cell growth as described in the second approach. This approach would require more time than the first to allow for cell growth and repetitive sampling to establish the increasing absorbances due to increasing cell numbers, but an advantage gained is that these increases in absorbances can also be used to quantify the number of bacteria in the sample.

In the absence of a food matrix, the detection limit of an FTIR microscope is 100 bacterial cells, and differentiation studies are reliable using $10^3$ cells [2, 3, 61]. A benchtop FTIR system was able to detect bacteria when 40 cells were present in the IR beam area [9]; however, this approach required $\sim 10^6$ cells/ml to locate the needed cell number in the beam area due to the comparatively large ATR FTIR crystal surface area.

As samples become more complex than a single strain of cultured bacteria, the number of cells needed for detection (and differentiation and quantification) increases. Numerous spectral analytical approaches have been used to detect the presence of a specific bacteria in a mixture [5, 18, 44, 45, 57, 61, 62]. To reduce the complexity of a sample, traditional microbiological enrichment or selection techniques, or capture techniques, can be used to concentrate the desired bacteria before spectra collection. For example, an antibody capture system such as Dynabeads could be used to bind a target pathogen (such as the *E. coli* O157:H7 bound to Dynabeads; Fig. 4), and spectra of the bound bacteria could be collected to verify the presence of that pathogen. This approach could also

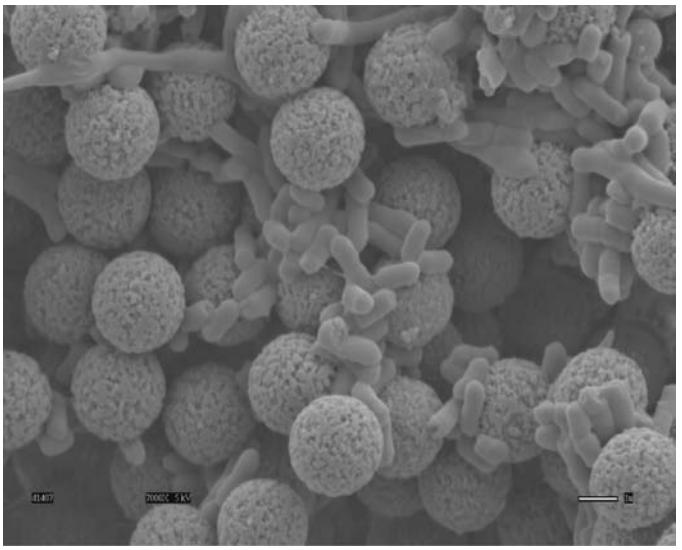

**FIGURE 4** Scanning electron micrograph image of *E. coli* O157:H7 captured on Dynabeads.

be used to determine if there is cross-reactivity of the capture antibody with nontarget microorganisms on the basis of spectral differences between different bacteria.

### 5.3 Differentiation

FTIR methods have been used for discrimination and classification of various microorganisms based on taxonomical classification, susceptibility to environmental stress, and type of growth medium. To enable differentiation, there must be structural differences between samples that appear as spectral differences (different spectral fingerprints based on absorbance peak differences, differing heights, and/or widths of peaks), and the differences must be consistent so that chemometric analyses developed for the spectral libraries and/or spectral-library-matching algorithms will be widely applicable to the samples of interest.

Examples of IR methods and approaches used for bacterial differentiation are listed here. Seven species of *Listeria* and five different serotypes of *L. monocytogenes* were successfully classified using FTIR in combination with discriminant analysis [27]. Discrimination of several distinct microorganisms (*Bacillus amyloliquifacens*, *Bacillus cereus*, *Bacillus subtilis*, *Citrobacter frendii*, *E. coli*, *Listeria innocua*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Staphylococcus epidermis*) was also successfully achieved with FTIR [63, 64]. A second derivative FTIR spectral method was used as a rapid screening technique for identifying *E. coli* susceptible to $\beta$-lactam and the transconjugants [53]. FTIR methods were also developed to differentiate and detect bacteria (including *E. coli* O157:H7), yeast, and fungi on the surface of food such as an apple or in an apple juice matrix [28, 58, 65]. FTIR analyses discriminated between intact and sonication-injured cells of *L. monocytogenes* [56]. Identification of foodborne bacteria such as *Bacillus*, *Vibrio*, *E. coli*, and others by profiling their fatty acid methyl esters (FAMEs) using ATR FTIR spectroscopy has been reported [66].

### 5.4 Quantification

Because IR spectra follow the Beer–Lambert law relationship (Eq. (1)), the intensities/heights of the absorbance bands are related to the concentrations of functional groups or cells in the sample. Controlled parallel experiments of spectra collection and traditional enumeration methods (such as plate counts) must be used to develop an FTIR spectral database of known concentrations/cell counts of the bacteria of interest and calibration curve based on absorbance levels. Using FTIR, calibration curves were successfully constructed for a two-component system of defined microorganisms to determine their concentrations [45]. Yang et al. [67] used ATR FTIR to enumerate bacteria in foods. In addition to quantifying bacteria, FTIR approaches have also been used to quantify polysaccharides in bacteria [68], for monitoring biofilms [69–71], and for quantifying dextrose uptake in *Candida albicans* microcolonies [40].

### 5.5 Cost Considerations

A major consideration for determining cost and usefulness of a pathogen detection technique is the amount of time required for detection. A summary of time required for pathogen detection by various methods is provided in Table 2. Data collection and analysis using FTIR require less than 30 min (as shown in the biosensors column in Table 2). Currently, the majority of time required for FTIR detection techniques is dependent on sample preparation, for example, enrichment, capture, and drying. A filtration approach used by Burgula et al. [5] reduced the time to detection by rapidly concentrating bacteria suspended in liquids onto a filter and then collecting spectra of the filter surface. Approximately, 100 bacterial cells are needed in the IR beam to enable detection [2, 3]; however, currently more than 100 cells are needed to rapidly concentrate 100 cells in the small area needed. Prices for FTIR spectrometers range from $10,000 to above $100,000 depending on detector types, manufacturer, crystal types (ZnSe crystals cost between $500 and $1000 while diamond crystals are closer to $10,000, but diamonds do not scratch and therefore have an indefinite use expectancy while ZnSe crystals last 6 months to 1 year), and so on. Some FTIR systems require a liquid nitrogen source for cooling. Beyond the initial equipment costs, the cost per sample can be quite low if standard growth media and filtration devices are used.

## 6 CRITICAL NEEDS ANALYSIS

Despite the potential of FTIR spectroscopy to detect and discriminate bacteria, there are limited spectral libraries available and limited studies on differentiation between stressed, dead, and live pathogens. The ability to discriminate between live and dead cells in a food matrix is critical for food safety applications and for making an effective estimate of the number of viable bacteria in foods. There is also a critical need to improve sample handling procedures before introducing the sample onto the FTIR for spectral analysis. Selective capture and concentration techniques are needed to rapidly isolate pathogens from foods; the isolates can be placed on a membrane, filter, crystal, or other surface, and then spectra of these isolates can be collected in a few minutes (again, an FTIR is capable of approximately one scan per second, so the number of scans influences the time needed to generate spectra).

**TABLE 2 Time Comparisons for Pathogen Detection by Various Methods**

| | Detection Time (h) | | | | |
|---|---|---|---|---|---|
| Steps | Conventional Culture | PCR | ELISA | IMS | Biosensors |
| Enrichment | 18–48 | 18–24 | 8–24 | 36–48 | 6–?? |
| Plating | 18–48 | — | — | 18–48 | — |
| DNA extraction | — | 0.5–1.5 | — | — | — |
| Bio- and chemical test | 5–24 | — | — | — | — |
| Serology | 4 | — | — | — | — |
| IMS bead extraction | — | — | — | 0.5 | — |
| Assay | — | 3–4 | 2–4 | — | 0.5 |
| Total time | 3–6 d | 21.5–29.5 h | 10–28 h | 2.5–4 d | 6.5 h–?? |

(Adapted from Dynal [72] and Rand et al. [73])
PCR = polymerase chain reaction
ELISA = enzyme-linked immunosorbent assay
IMS = immunomagnetic separation

## 7 RESEARCH DIRECTIONS

Although FTIR and spectral analysis methods have enabled identification and discrimination of bacteria, barriers to widespread use of this approach include sample preparation (such as 6–8 h culturing on agar media or broth), the sensitivity of the FTIR accessory and analysis used, interference from water absorbance, and the relative expense associated with crystal ATR FTIR surface materials. Research is needed to improve the sample preparation steps, thereby reducing the time for detection. Progress in rapidly concentrating and isolating pathogens from foods will reduce the overall time needed for pathogen detection. By improving sensitivity and specificity of spectral collection and analysis and reducing the time needed for sample preparation, FTIR methods have many potential applications for rapid detection of pathogens from foods.

# PULSENET: A PROGRAM TO DETECT AND TRACK FOOD CONTAMINATION EVENTS

KARA L. F. COOPER, DUNCAN R. MACCANNELL, AND EFRAIN M. RIBOT
*Centers for Disease Control and Prevention, Atlanta, Georgia*

## 1 INTRODUCTION

An estimated 76 million cases of foodborne illness occur each year in the United States [1], with many more that likely go unreported. The striking incidence of foodborne disease highlights the importance of effective surveillance for the rapid detection of outbreak clusters, and the role that these programs have in maintaining the safety of our food supply [2–5]. In recent years, a number of well-publicized outbreaks have been associated with widely distributed food products. Each outbreak underscores the potential vulnerability of our food supplies to microbial contamination, the threat to public health, and the potential impact to national and international security.

Contamination can occur at any stage of food production, from the originating farm or producer, through processing, packaging, shipping and storage, all the way to the consumer's table. Although changes in regulation, education, and technology over the course of the past century have resulted in an overall improvement in the safety of the foods we eat [2, 4], changing dietary habits and demand for increased variety and seasonality of many food products presents an important challenge to food safety, particularly when many foods are imported from abroad and/or consumed in an uncooked format. Today, many commercially prepared foods are produced or processed at centralized facilities and are widely distributed prior to consumption. Both of these factors facilitate the emergence of disseminated outbreaks, and foodborne contamination may impact multiple counties, states, or countries [6]. Furthermore, the complexity of these production and distribution networks can delay the recognition of foodborne outbreaks or hinder the identification and recall of contaminated products [2–4, 7]. The rapid detection of disease clusters is the critical function of PulseNet, and their association with outbreaks of foodborne disease combines traditional epidemiology with real-time, laboratory-based surveillance systems. In order to be effective, it also requires sufficient coverage, and the active participation of laboratorians and epidemiologists at both the state and federal levels [3, 8, 9].

PulseNet USA was established in 1996 to provide a unified infrastructure for the molecular surveillance of foodborne bacterial infections, and has significantly increased our ability to detect and act upon clusters of foodborne illness by standardizing and coordinating bacterial subtyping in public health laboratories nationwide [10, 11]. Participating laboratories compare DNA fingerprints from foodborne isolates across the country in near real time, and can compare these fingerprints to those from a suspected vehicle or source during the course of an investigation. This secondary capability is particularly

**TABLE 1 Examples of International Outbreaks of Bacterial Foodborne Outbreaks Recognized through PulseNet, 1995–2006**

| Year | Organism | Cases | Countries Involved | Implicated Vehicle | Reference |
|---|---|---|---|---|---|
| 1995 | *S.* Stanley | 250+ | Finland, USA | Alfalfa sprouts | Mahon [51] |
| 1998 | *Shigella sonnei* | 172 | Canada, USA | Parsley | MMWR [31] |
| 1999 | *S.* Muenchen | 207 | Canada, USA | Unpasteurized Orange Juice | MMWR [31] |
| 2000–2001 | *S.* Enteritidis | 168 | Canada, USA | Raw Almonds | Chan [28] |
| 2000–2002 | *S.* Poona | | Canada, Mexico, USA | Cantaloupe | MMWR [29] |
| 2001 | *S.* Oranienburg | 500+ | Austria, Belgium, Denmark Finland, Germany, Croatia Netherlands, Czech Repulic | Chocolate | Werber [27] |
| 2004 | *S.* Enteritidis | 29 | Canada, USA | Raw Almonds | MMWR [30] |
| 2004 | *E. coli* O157:H7 | 3 | Japan, USA | Ground Beef | MMWR [52] |
| 2006 | *E. coli* O157:H7 | 200+ | Canada, USA | Fresh spinach | MMWR [25] |

useful during traceback investigations, and is critical to both attribution and prevention/control efforts [9, 11, 12]. Hundreds of outbreak clusters are identified by PulseNet laboratories each year, prompting dozens of outbreak investigations. From the perspective of biosecurity and preparedness, many of the lessons learned from the investigation and follow up of these cases are equally applicable to scenarios involving intentional contamination. The PulseNet community is committed to improving the capacity and technology needed to respond rapidly to emerging threats and limit the scope of foodborne infections, both within the United States and abroad.

## 2 SCIENTIFIC OVERVIEW

Molecular epidemiology combines the principles of traditional epidemiologic investigation with tools derived from molecular biology to better understand and define the distribution of diseases or markers of interest within a given population [7]. As technology continues to improve, the molecular strain typing of bacteria has evolved significantly, particularly with the introduction and refinement of modern genomic and proteomic approaches [13]. Today, epidemiologic studies of foodborne bacteria rely predominantly upon genotypic methods for characterization and strain type assignment. Although the sensitivity, specificity, and appropriateness of these techniques varies according to both organism and context, pulsed-field gel electrophoresis (PFGE), which involves macrorestriction and fragment analysis of the entire genome, remains the predominant means or "gold standard" for subtyping many bacteria [13, 14].

The application of sophisticated molecular subtyping methods, coupled with informatic platforms that enable rapid comparison and communication of subtyping data, has greatly increased the sensitivity of surveillance systems to detect clusters of foodborne illness that are widely dispersed in space or time [3, 11]. However, detection of a cluster is only the first step, and a rapid but thorough investigation is critical to identify the source of infection and mediate an effective response before additional and preventable cases occur. Molecular subtyping data is often central to this process, helping to separate outbreak-related cases from sporadic infections that would otherwise confound the investigation. Once a contaminated product or vehicle has been identified, molecular data may also be used to provide definitive microbiological confirmation of the source of the infection [2, 4, 7, 9, 12]. Equally, these data may be used in a detailed investigation of affected food production and distribution chains, which may reveal how contamination occurred, and facilitate the development and implementation of measures to prevent similar events in future.

## 3 PULSENET USA

PulseNet USA was established in 1996 in collaboration with the Association of Public Health Laboratories, and has grown from an initial group of five interested public health laboratories to over 70 participants, including county, municipal and state public health departments, federal food regulatory agencies, agricultural, and veterinary laboratories [12]. Standardized PFGE protocols are at the core of PulseNet USA, allowing participating laboratories to rapidly generate PFGE patterns or "fingerprints" that are consistent between laboratories [13, 15, 16]. Once an isolate has been run, the PFGE pattern is compared to other local isolates and uploaded to a centralized and secure database system at the Centers for Disease Control (CDC) in Atlanta. These pattern data are actively curated, with ongoing real-time surveillance for unusual pattern frequencies or trends that may indicate the emergence of an outbreak. The participation of laboratories throughout the country enables the exquisitely sensitive and rapid identification of foodborne outbreak clusters, particularly those that are disseminated over a broad geographic area or protracted period of time.

An important key to the success of PulseNet USA has been the decentralization of subtyping activities to state and local public health laboratories. This decentralized approach has greatly extended the testing capacity of the network, with rapid subtyping occurring on a local level, and without the logistical problems of a centralized testing facility [11, 12]. Decentralization presents its own challenges, however: in particular, the allocation of infrastructure (i.e. equipment, supplies, and trained personnel) and funding, the development and maintenance of highly standardized subtyping and analysis protocols for pathogens of interest, and a means of effective, rapid, and secure communication for data and alerts between network members.

PulseNet relies on the ability to compare data generated by different laboratories in near-real time, and it is therefore necessary to ensure that protocols are standardized, and that data may be rapidly exchanged and compared. Within the PulseNet community, PFGE gel images are analyzed using highly customized image analysis software (BioNumerics, Applied Maths, Sint-Martens-Latem, Belgium), that operate using a basic client–server architecture. Through this software, PFGE patterns and related epidemiological information can be compared against both the local (client) database and against

all patterns that have been submitted to the National database (server) at the CDC. Currently, PulseNet has standardized PFGE protocols and networked databases in place for *Escherichia coli* O157, *Salmonella, Shigella* spp., *Campylobacter, Listeria monocytogenes*, *Vibrio cholerae*, *Yersinia pestis*, and *Vibrio parahaemolyticus* [16–21].

To provide rapid and secure messaging between PulseNet laboratories, a web-based forum has also been implemented to provide rapid alerts to laboratorians and epidemiologists throughout the country, and to provide timely information to the PulseNet community on patterns, tentative clusters, and important administrative or methodological updates. Together, the combination of highly standardized molecular protocols, database-driven curated analysis, and real-time secure communications has led to the discovery of many outbreaks that would likely not have been identified with traditional epidemiological methods [9, 22, 23].

Among its successes, PulseNet was instrumental in the recent identification and investigation of an outbreak of *E. coli* O157:H7 that involved 205 cases from across the United States and Canada [24, 25]. Epidemiologic follow-up of the PulseNet-identified cluster confirmed that 95% of the infected individuals had reported eating fresh, uncooked spinach during the 10 days prior to illness. The association of fresh spinach as a common source was subsequently confirmed by the isolation of the outbreak strain from three open bags of spinach that were recovered from patients' homes. The rapid and conclusive identification of the contaminated food product and implicated lot numbers resulted in faster and more specific consumer advisories, narrowed the recall of affected food products, and almost certainly limited the scope and severity of the outbreak. The origin of the contaminated spinach was traced to fields in several California counties. PFGE analysis of a cross section of environmental isolates from the San Benito area identified an exact match to the outbreak pattern, isolating the likely point of contamination to within a very narrow geographic margin and improving our understanding of predisposing events [24, 26].

With over a decade of successes such as these, PulseNet has proven to be an important tool for detection, investigation, control, and prevention of foodborne outbreaks within the United States (Table 1). Since its inception, national participation has grown to include all 50 states, as well as county and municipal public health laboratories and food regulatory agencies. In an increasingly globalized economy, the internationalization of PulseNet is a logical progression, but one which requires the ongoing cooperation and commitment of many international partners. The expansion of PulseNet coverage into global markets may also help to enhance food safety within the United States by expediting the identification of contaminated imports before or shortly after they enter the domestic food supply. More importantly, PulseNet International will build upon the successful foundations of PulseNet USA to help us better understand the epidemiology and prevention of foodborne infections on a global scale, and enhance food safety and public health throughout the industrialized and developing world.

## 4 PULSENET INTERNATIONAL

Over the past several decades, consumer demand has driven an explosive increase in both the scale and diversity of international food trades [12, 27]. In today's global market place, foods that are produced, processed, and packaged in one part of the world are more likely than ever to cross national borders, for consumption in countries many hundreds or even

thousands of miles away. Foodborne outbreaks may extend well beyond a single region or country, involve multiple imported/exported food products and include, inconsistent recordkeeping, and complex distributorships [6]. These factors can all greatly complicate the identification and investigation of international outbreaks, particularly when the scope of most existing foodborne surveillance systems is limited. In order to adapt to these changing parameters, surveillance programs must look beyond national borders to consider the role of economic globalization, and its impact on the safety of domestic food supplies. Internationalization of programs such as PulseNet will help to safeguard food safety within the United States, among our trade partners and within developing nations, where food and waterborne infections continue to represent a significant cause of morbidity and mortality [12].

### 4.1 Structure and Function

PulseNet International was established as an umbrella organization for independent regional PulseNet networks to provide a cooperative framework for enhanced foodborne disease surveillance on a global scale [12]. Governed by a steering committee that is chaired by the chief of PulseNet USA, PulseNet International currently includes six participating regional networks (USA, Canada, Latin America, Europe, Asia-Pacific, and Middle East) that represent 67 countries across 6 continents (Fig. 1). Expansion onto the global stage began with an informal collaboration between PulseNet USA and Canadian public health officials in 1999. This collaboration proved to be useful almost immediately, with the investigation of an outbreak of 91 cases of *Salmonella enterica* serotype Muenchen in 15 US states and 2 Canadian provinces [28]. Standardized molecular subtyping was able to rapidly identify cases, and suggested an association with the consumption of unpasteurized orange juice, which was later confirmed by epidemiologic follow-up. Cooperation between Canadian and US public health laboratories continued to provide concrete results over the next several years, reinforcing the value of the open and rapid exchange of molecular subtyping information, and its potential—both as an early warning system and as a tool for the investigation of transnational outbreaks [29–34].

The success of this first international collaboration promoted the foundation of PulseNet International. Over the past 5 years, regular organizational meetings have been held between the CDC and public health officials from Canada, Europe, Asia-Pacific, Latin America, and the Middle East to continue expanding the role of PulseNet in global surveillance for foodborne disease. At many of these meetings, the focus has been on establishing necessary infrastructure within each of the regional networks, and the integration of each regional network into PulseNet International. Extensive progress has been made with training in PulseNet Standardized PFGE Protocols, software-assisted gel analysis, and establishment of consistent laboratory and analytic QA/QC programs across each regional network [12]. PulseNet International has the added challenge of establishing effective surveillance networks between regional and national partners, whose public health interests may be overshadowed or complicated by important geopolitical differences. The composition and organizational structure within each of the PulseNet International regional networks is flexible, and may differ according to political, economic, and cultural structures within its membership. Despite these challenges, all regional networks have reached consensus on most core operational

**FIGURE 1** Delineation of the six PulseNet International regions including PulseNet USA, PulseNet Canada, PulseNet Europe, PulseNet Asia-Pacific, PulseNet Latin America, and PulseNet Middle East [35].

issues, and identified appropriate means by which to ensure effective, and equitable laboratory-based surveillance programs between their members.

The rapid exchange and comparison of PFGE pattern data are critical to surveillance functions, and consequently, information technology infrastructure for database access and communications is as necessary as the development of laboratory resources in the field. Data issues are similarly complex, and difficulties have emerged related to the implementation and maintenance of network infrastructure, and the establishment of multilateral agreements for information management and exchange. An ideal compromise might permit PulseNet members to log on to different PulseNet International servers with limited read-only or volatile access to conduct simple queries. If pattern matches are identified that extend beyond the user's home network, relevant epidemiological information, such as isolate source, relevant dates, serotype, and PFGE pattern information would be provided, and outbreak coordinators from all affected jurisdictions would be alerted or invited to participate in an investigation.

The first step in these processes came with the signature of a Memorandum of Understanding between PulseNet USA and PulseNet Canada in 2005, which formalized data-sharing arrangements between the two nations. This agreement granted limited access and cross-querying to public health investigators in both countries.and permitted the direct comparison of PFGE data from Shiga toxin-producing *E. coli* (STEC) and *Salmonella*. It is hoped that this memorandum will be the first of many agreements, both within and between the other regional networks that make up PulseNet International. In the meantime, a secure PulseNet International ListServ has been established to exchange pattern data and communicate related epidemiological information between networks. This approach is more time consuming, since international investigations currently require managers from each regional/national database to manually compare new patterns against their own local pattern database and notify the ListServ if relevant matches are identified.

### 4.2 Food Safety and Bioterrorism: Critical Need for PulseNet International

In recent years, an increase in worldwide terrorist activity has raised the profile of biosecurity, and with it, concerns over the vulnerability of international food supplies to acts of intentional biological or chemical contamination. Biological contamination is of particular concern, since pathogenic microorganisms are relatively easy to acquire, and in the case of bacteria, may be manufactured relatively quickly in significant quantities, with only limited budget and expertise [36–38]. Intentional contamination that occurs early in the supply chain, or before the food leaves its country of origin, may have broad international effects, since contaminated lots may be distributed to multiple countries and sold for consumption well before the contamination is detected. Although the importance of biosecurity has increased in many segments of the food production and trade industries, many aspects of international food supply chain remain vulnerable to attack, and naturally occurring outbreaks involving food imports highlight the feasibility and importance of this threat [38].

Historically, only a handful of cases of foodborne disease have been definitively linked to intentional contamination. A retrospective study of outbreak investigations revealed that 44 (4%) out of 1099 involved causative agents with bioterrorism potential, and of those, intentional contamination was considered as a potential explanation in only six [36]. Modern commercial food distribution systems provide an ideal delivery vehicle for widespread terrorist effect, and the threat, or even perceived threat of intentional contamination of the food supply, reinforces the importance of protection and surveillance as national security priorities [36–38].

It is likely that the intentional contamination of a widely distributed food product will initially resemble the emergence of a naturally occuring outbreak of foodborne disease, with a sudden increase in incident cases, and the implication of a well-known foodborne enteric pathogen [36, 38]. Unless the contaminant is of unusual type, character, or distribution, it is also likely that the emergence of an outbreak will first be detected by PulseNet laboratories as a cluster of identical PFGE patterns, and an outbreak investigation will be initiated. The certainty of intentional contamination may not emerge until well into the investigation of the outbreak, unless the event is publicized by complicit terrorist groups, strain(s) is/are of unusual subtype or character, or if the distribution of cases begins to support deliberate and multifocal contamination. PulseNet data will be crucial to determine the nature and extent of the outbreak, and to support criminal investigations by federal and international law enforcement, should they become necessary.

As with any foodborne outbreak, rapid detection and investigation are essential to mounting an effective response against a biological attack, expediting the traceback and removal of contaminated product(s) from the food supply and limiting the scope of the outbreak. Timely identification and response requires sophisticated laboratory-based real-time surveillance that functions at the level of the national population. Sensitivity and detection lag can both be greatly improved, particularly if frontline laboratories have sufficient capacity to complete and submit subtyping results immediately upon receipt. Ensuring that the public health system is ready to deal with intentional contamination events will require enhancement of preparedness and existing public health infrastructure, and as such, the maintenance of state and territory public health resources is critical [36, 37].

The ultimate purpose of any terrorist attack is to induce significant panic within the civilian population, undermine confidence in government, and threaten civil order [38, 39]. Attacks involving mass casualties and weapons of mass destruction are not necessary to achieve these goals. In fact, scenarios involving limited morbidity and

mortality, but which impact products and services that civilian populations use or are exposed to frequently during the course of daily life, can increase public anxiety and impose significant strain on public health and primary health care systems, even in the absence of an attack [38]. Among many foodborne outbreaks, unease and economic loss are typical with the identification and recall of a food product. Consumer confidence may be significantly eroded by an outbreak involving a particular food or brand, and the resulting aversion may affect individual producers or entire segments of the market. Thus, a biological attack or even a threat against consumer food supplies may incur significant financial cost, even if the direct impact on civilian populations is, or is expected to be low.

To date, the most significant example of intentional and malicious contamination of domestic food supplies occurred in the town of The Dalles, Oregon, in 1984, when followers of Bagwhan Shree Rajneesh contaminated 12 local restaurant salad bars with *Salmonella enterica* serotype Typhimurium in an effort to manipulate the outcome of local elections. Although there were no fatalities, the attack sickened 751 people, with 45 requiring hospitalization for acute salmonellosis. During the investigation of these cases, the possibility of intentional contamination was considered, but before the availability of molecular surveillance systems such as PulseNet, it took an exhaustive, year long study to link the commune to the outbreak [40]. The simplicity and efficacy of these attacks demonstrate the weaponized potential of foodborne bacteria, and their application to the subversion or manipulation of political processes. In the present day, where terrorist ideals extend beyond the Rajneeshee's desire to influence local politics, far faster action for response and investigation is required.

Among the potential biological agents that the CDC cited in a Strategic Planning Workgroup on Biological and Chemical Terrorism were *Clostridium botulinum*, *Salmonella* spp., *E. coli* O157, and *V. cholerae* [41]. In the United States, PulseNet standardized PFGE protocols and databases are already in place for all of these pathogens with the exception of *C. botulinum*, although a protocol is currently under development in collaboration with the Virginia Consolidated Laboratory Services. With an established sentinel network that extends throughout North America, and the cooperation of an increasing number of international partners, PulseNet is ideally positioned for the detection and investigation of foodborne bioterrorism, and is highly optimized for the bacterial agents most likely to be involved.

## 5 RESEARCH DIRECTIONS

Both the present and future success of PulseNet as a laboratory-based surveillance system depend upon its ability to accurately identify, transmit, and interpret bacterial subtyping data. This function must be accomplished rapidly and across a diverse network of national and international laboratories in order to provide timely and actionable information on the type and scope of an emergent outbreak. Although the concept of real-time bacterial subtyping is easy to understand, its implementation, particularly in the context of a broad geographical network, is neither simple nor straightforward.

For one, the process is technology-driven: as a technique, PFGE is highly robust and is amenable to implementation in laboratories with a wide range of resources and expertise. In practice, however, it is a labor intensive and meticulous procedure, and even with highly optimized and standardized protocols, PFGE subtyping of bacteria typically takes between 24 and 48 h from pure culture to a completed fingerprint. Furthermore,

because only a limited number of samples may be run in parallel, this throughput may be restrictive in time-sensitive outbreak situations [16, 18, 19].

More importantly, although PFGE affords a relatively high degree of discriminatory power and epidemiologic relevance [13, 15, 16], it is not always able to accurately resolve differences between outbreak and sporadic isolates, particularly among highly endemic strain types. As PulseNet databases have grown, database analysts have noticed a remarkably high degree of clonality among seemingly unrelated sporadic isolates (i.e. *S. almonella enterica* serotype Typhimurium DT104 complex [42], *S. enterica* serotype Enteritidis phage type 4, 8, and 13a [43], and *E. coli* O157:H7 [13]). When common patterns are encountered in an outbreak situation, it is often impossible to differentiate between potentially outbreak-related isolates and unrelated sporadic infections by PFGE alone, and the mis-identification of unrelated cases can greatly complicate epidemiologic follow-up.

With the increasing feasibility of routine genomic sequencing and high-throughput genetic analysis, the PulseNet methods development laboratory, in collaboration with state (MN, NC, and MA) and federal partners, has begun to develop and implement next-generation subtyping methods to enhance and complement existing PFGE-based protocols. The first of these new methods, multi-locus variable number tandem repeat analysis (MLVA), amplifies a series of short, tandem repeats within the bacterial genome and determines differences in copy number across all loci using capillary gel electrophoresis for high-resolution fragment analysis [44–46]. Interest in the evaluation of MLVA as a subtyping tool first arose after several studies demonstrated its ability to discriminate within highly clonal, PFGE-indistinguishable microorganisms [45, 47, 48], and MLVA has already proven useful in the investigation of outbreaks involving common PFGE patterns [44]. MLVA protocols for *E. coli* O157:H7, non-O157 STEC, *S. enterica* serotype *Typhimurium*, and *L. monocytogenes* are presently undergoing development or validation in our laboratory, and as of this writing, several protocols have been released for limited use by select PulseNet laboratories [7, 13].

The analysis of single nucleotide polymorphisms (SNPs) is also being evaluated as a next-generation subtyping approach, with active development of panels for rapid *E. coli* O157:H7 and non-O157 STEC subtyping/characterization [7, 13, 49]. A key advantage of SNP-based subtyping approaches lies in their genomic ubiquity, and their independence from fragment sizing, which negates the need for complex electrophoretic procedures, pattern normalization, and run times. However, selection and validation of SNP target panels are critical, and must combine sufficient coverage to detect genomic change, while retaining sufficient divergency to accurately discriminate between highly clonal bacterial lineages [49].

The development of meaningful interpretation and classification guidelines to describe and classify genetic changes in terms of strain type requires an extensive catalog of historical isolates, both sporadic- and outbreak associated. Occasionally, techniques prove to be too discriminatory: Several of the MLVA loci, for example, have a high degree of variability that may cause pattern instability even over a relatively short period of time [13, 50]. The continued evaluation of these protocols, in conjuction with PFGE and epidemiological data, should assist in the determination of the degree of variability that can be allowed during an outbreak investigation and the development of appropriate classification guidelines. Of greater concern is that many of the variable number tandem repeat (VNTR) sites that are useful for MLVA are highly specific to a given bacterial species or serotype (e.g. *E. coli* O157:H7 versus non-O157 STEC [13, 44]), and this

greatly limits the range of organisms that can be typed, with a corresponding increase in the number of protocols that must be developed, validated, and maintained.

An advantage of methodologies such as MVLA and SNP analysis is that many laboratories in the United States already have the necessary equipment available, although training and program funding continue to be problematic in many jurisdictions. These issues are accentuated in developing countries, and it is expected that new technologies will be initially integrated into PulseNet in a tiered approach and used primarily in situations where greater discriminatory power is required [12]. Laboratories that cannot justify an investment in new hardware, staff, and supplies would be encouraged to submit isolates to regional core laboratories, where resources for new technology could be centralized and more effectively supported or funded.

Future generations of bacterial subtyping have the potential to be more rapid and less technically demanding, while providing a higher level of epidemiological concordance than PFGE. However, the ultimate utility of these techniques is still being assessed, and their success will depend largely on their amenability to a diverse network of national and international partners. The introduction of any new subtyping technologies to the PulseNet program must be carefully weighed against instrumentation, infrastructural and staffing requirements, the compatibility and reliability of new data relative to existing methods, and by our own capacity to provide training and ongoing support to participating laboratories [12, 13].

With a rapidly expanding network of participating laboratories, PulseNet International is positioned at the forefront of global food safety and biosecurity initiatives. Building upon a history of successes in outbreak detection, response and prevention, it is our hope that the integration of new molecular and informatic technologies will further improve both the foundation and fabric of the PulseNet community, enhancing food safety and public health on a global scale.

# DEVELOPING RISK METRICS TO ESTIMATE RISKS OF CATASTROPHIC BIOLOGICAL AND BIOTERRORIST EVENTS: APPLICATIONS TO THE FOOD INDUSTRY

HAMID MOHTADI

*University of Wisconsin, Milwaukee, Wisconsin and University of Minnesota, Minneapolis, Minnesota*

## 1 INTRODUCTION

This article develops a data-based probabilistic algorithm for food vulnerabilities based on a statistical method known as *extreme value theory* that focuses on the distributional properties of the *maxima* or *minima* of a sequence of random variables. For the purposes of developing this probability metric, the focus is on intentional incidents for which food is a potential vehicle. Such incidents are broadly categorized in the literature as chemical biological and radionuclear (CBRN) events. While the food supply chain can be attacked in a number of different ways, the focus on CBRN-materials is warranted since their deliberate introduction into the civilian population is biased toward targeting the food sector's infrastructure, which provides reach across a wide region. The data are complied under a prior research project [1] funded by the Department of Homeland Security. While this data focuses on intentional CBRN events, there is a second project currently underway that aims at generalizes this data and the approach to accidental food events as well.

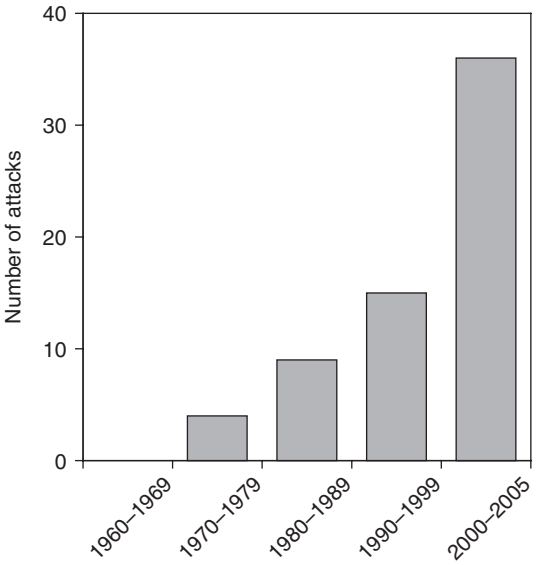

**FIGURE 1** Frequency of attacks on the food or water supply.Based on authors chronology of CBRN events and the sources cited therein

## 2 OVERVIEW

Since 2001, concern over intentional food contamination has been rising. Although the magnitude of health and human impacts or economic damage from intentional or accidental agents has not reached "catastrophic" levels, such a potential remains. For example, the World Health Organization (WHO) has been gravely concerned that food may be used as vehicle for terrorism.[1] Evidence does point to a recent rise in the severity of intentional food attacks (Figure 1). Evidence also suggests that many, if not all, food incidents have the *potential* to be intentionally caused and conversely, many known intentional food incidents may well be reported as accidental before true causes are discovered. The need to protect against such potential catastrophes requires an ability to assign risk to different events. This requires the knowledge of the likelihood of occurrence to each event. Yet, this seemingly simple task has not been possible thus far. The fact that such catastrophic events have fortunately not taken place yet, also implies the absence of hard data from which to build a probability-based risk metric framework. This poses a major stumbling block for a policy of protecting against catastrophic risk or for the developing of private risk markets for such extreme forms of risk.

The remainder of this article is organized as follows. First, data are discussed. Next, the statistical methodology is discussed. Following that, model estimation and statistical evidence on the likelihood of a catastrophic event that involves the use of CBRN material are provided. The final section contains the concluding remarks.

[1]In a (2002) report WHO states [2], "The malicious contamination of food for terrorist purposes is a real and current threat. . . The WHO and its Member States are concerned that chemical, biological or radionuclear agents might be used deliberately to harm civilian populations and that food might be a vehicle for the dissemination of such agents."

## 3 DATA AND THE OBSERVED TRENDS

### 3.1 Data

The data comprises of 448 observations complied from primary-source materials, internet postings, and the existing literature on CBRN-terrorist incidents.[2] The figure of 448 does not represent the universe of all CBRN events, rather it corresponds to the subset of the most publicized, and perhaps therefore, also the most serious incidents.[3] A separate data appendix, prepared by Mohtadi and Murshid [1] which is available online at the National Center for Food Protection and Defense (NCFPD) website provides a case-by-case description of incidents in the dataset (see the URL for Mohtadi and Murshid [1]).

The chronology provides a general description of each incident, along with details on the type of agent employed and the number of casualties that resulted. The data cover a 53-year period from 1952 to 2005. However, prior to 1975 the data on CBRN-activity is particularly sparse. Unlike the Monterey Institute's WMD database, which also focuses on CBRN events, but which also includes hundreds of hoaxes and pranks that do not necessarily relate to possession with intent or actual use some hoaxes, the CBRN data that we have complied also exclude *all* hoaxes. Excluded also are accidental releases of CBRN material such as, for instance, the explosion at Union Carbide's processing plant in Bhopal, India, or the meltdown of the nuclear reactor in Chernobyl, as well as the release of weaponzied anthrax in the Soviet Union in 1978. However, *attacks* that involved a threat to the containment of CBRN material such as acts of sabotage or direct acts of violence committed on CBRN facilities *are* included. Also, another large dataset, known as the *Terrorism Knowledge Base* [maintained at the National Memorial Institute for the Prevention of Terrorism (MIPT)], reported only 56 attacks involving CBRN material, hence the need to compile this data independently.

As in the case of WMD dataset, no attempt is made to distinguish terrorism from criminal activity for at least two reasons: First, because whatever the underlying motivation behind their use, these weapons have the *potential* to do significant harm or create an atmosphere of fear and panic. Thus for instance, on September 14, 2002, when Chen Zhengping tainted his competitor's water supply and pastry dough with rat poison, the underlying motive may have been purely financial, but the incident caused 41 deaths and over 400 hospitalizations.[4] Similarly the Tylenol murders in 1982, which though not linked to terrorist activity, nevertheless created an atmosphere of fear and panic, which by itself would satisfy the definition of terrorism. Second, the use of CBRN, even when they indicate petty crimes, indicate an acceptance amongst the criminally inclined to resort to what would previously have been exotic weaponry.

[2]The sources for the compilation of this data include reviews of recent terrorist incidents that were based on the weapons of mass destruction (WMD) database [3–6] as well as the open literature, such as Jenkins and Rubin [7], Livingstone and Arnold [8], Douglass and Livingstone [9], Hirsch [10], Mullen [11], Thornton [12], Kellen [13], Leventhal and Alexander [14], Kupperman and Woolsey [15], Kupperman and Kamen [16], Mullins [17], Purver [18], Tucker [19], Miller *et al*. [20] Carus [21], Mize [22].

[3]Mohtadi and Murshid [23, 24] provide a detailed survey of the existing terrorism dataset and explain why the need to collect our own data arose.

[4]"China Deaths Blamed On Rat Poison," *CNN*, September 16, 2002, "China Masks a Mass Poisoning," *The Guardian*, September 16, 2002.

### 3.2 Observed Trends

Evidence from the MIPT dataset indicates that there has been an increase in the severity of terrorist attacks over the past decade. For example, almost all of the incidents where mortality or injury exceeded one thousand occurred over the period from 1993 to 2006. Furthermore, it appears that the trend with respect to the choice of weaponry, targets and tactics, indicates a rise in "softer" targets such as attacks on private citizens or private property, and away from "high profile" targets such as the airlines or government and military facilities (Figure 2). To the extent that the food chain also constitutes a softer target, the same trend is observed here as well. Thus, while attacks on the food industry indicate a general rise since the 1960s, when there were no recorded attacks (Figure 2), the most dramatic increase has come since 1999, a trend which is hard to attribute to better reporting alone. Table 1 shows the CBRN attacks between 1950 and 2005 that led to at least 100 casualties.

While there have been attacks on our food and water supply that have involved the use of conventional weapons, there is no reason in particular why terrorists should favor the food supply chain over other potential targets when using such conventional means of attack. The real threat as far as the food chain is concerned is likely to come from chemical, biological or radionuclear contaminants, which can exploit an already present distribution network to maximize the potential for disruption. Of the 448 biological, chemical and radiological incidents that have been recorded, 75 involved either a direct attack or a plan to attack the food or water supply chains.[5]

[5]We define attacks on the food or water supply as any attack that involves tampering with food and beverages with the potential to create large scale casualties. Thus for instance, simple targeted poisonings that are directed at one or perhaps a few specific individuals are not considered an attack on the food chain. However, the incident where contaminated water was handed to Filipino soldiers that led to 19 fatalities and 140 injuries is considered an attack on the food chain. We also regard attacks on livestock or the animal population in a separate category. Attacks on drugs and medication were also considered separately.

**TABLE 1 A few CBRN Events with at Least 100 Injuries or Fatalities**

| Date | Agent | Target | Fatalities | Injuries | Description |
|---|---|---|---|---|---|
| 20-Sep-1984 | *Salmonella typhimurium* | Food or water supply | 0 | 751 | In September 1984, members of a religious cult known as the *Rajneeshees* contaminated salad dressing at 10 restaurants in The Dalles, a small town in Oregon, USA. |
| 6-Sep-1987 | Unknown | Police | 19 | 140 | Up to 19 members of the Philippine Constabulary died during a "fun run" in which an individual handed out bags of ice water contaminated with an unknown agent. |
| 27-Jun-1994 | Sarin | Private citizens and property | 7 | 500 | In June 1994, members of the *Aum Shinrikyo* released sarin gas in Matsumoto, Japan; 7 people died and approximately 500 more were hospitalized. |
| 20-Mar-1995 | Sarin | Private citizens and property/ transportation | 12 | 5500 | On March 20, 1995, one of the deadliest terrorist attacks in history was carried out on the Tokyo subway, by *Aum Shinrikyo*; 12 people died in the sarin-gas attack and over 5500 required treatment. |
| 8-Mar-1999 | Nitric acid | Food or water supply | 0 | 148 | In March 1999, 148 persons were poisoned by nitric acid placed in the food of a restaurant in Luoyang City, China. |
| 5-Apr-2001 | CS gas | Educational Institution | Unknown | 132 | An unknown group attacked schools using CS gas in the Central Highlands, Vietnam; 132 people were treated for ailments—headaches and breathing problems. |
