## 4 METHODOLOGY

Existing food protection efforts have ignored the role of probabilities and instead prioritized investments solely on severity. For example, data on health costs from food contaminations are estimated by the Economic Research Service, United States Department of Agriculture (USDA), and used by various agencies for public policy. This amounts to the implicit assumption that all catastrophic events are equally likely which is a gross error, leading to massive resource misallocation.

The method proposed here addresses this major gap. It does so by invoking the statistical properties of certain distributions, known as *extreme value distributions*, which allow us to use data on ordinary food poisoning events to deduce the probability of large catastrophic events. In effect, information about the "body" (modal part) of these distributions, allows us to extrapolate to the probabilities of catastrophic events that belong to the ***"tail"*** of these distributions.

The key insight explores the limiting behavior of the maxima, $M_n$, of a sequence$\{X_n\}$ of independent random variables with common distribution$F(x)$. At the heart of extreme value theory is the *extremal types theorem* [25, 26], which states if the maxima of sequences of observations converge to a nondegenerate law, $G(.)$, then$G(.)$ belongs to the class of generalized extreme value distributions (GEV):[6]

$$G_\xi(x) = \exp\left\{-\left[1+\xi\left(\frac{x-\mu}{\sigma}\right)\right]^{-1/\xi}\right\}; 1+\xi\left(\frac{x-\mu}{\sigma}\right) \geq 0 \tag{1}$$

where $\mu$ is a *location* parameter, $\sigma$ is a *scale* parameter and $\xi$ is the *shape* parameter that determines the sub-class of distribution from which our observations are drawn. Specifically, $\xi > 0$, $\xi < 0$, and $\xi = 0$ correspond to the Fréchet (heavy tailed), Weibull (bounded tailed), and Gumbel (light tailed) distributions, respectively. The GEV-representation is particularly useful, since it bypasses the need to identify the specific type of distribution to which the extreme value limit law belongs. Instead standard statistical methodology from parametric estimation can be applied to identify the parameters of interest. Other than the work by Mohtadi and Murshid [23], there has been one other study that uses this approach for terrorism data [28], but the authors use the MIPT data, not data based on CBRN events. A related article by Johnson et al. [29] studies the distribution of fatalities in two recent conflicts and show that these distributions follow a power law relationship that has a similar functional structure to the GEV distributions here.

Implicit in the approach adopted here is the assumption that the current experience with CBRN attacks is a good predictor of future CBRN terrorism. While the use of past data to forecast future trends is a common practice, the threat from CBRN weapons is likely to be dynamic as possibly unstable, as terrorists' actions are likely to be a function of an earlier counter-terrorist response by the government and *vice versa* [30]. Yet, it is difficult to imagine how the pattern of response and counter-response could change overnight. If, as is more likely, the dynamics of this process are gradual, an analysis of data can shed important light on the current capabilities of terrorists in addition to highlighting trends in their usage.

[6]See, for example, Coles [27].

## 5 MODEL ESTIMATION

The variation in CBRN dataset is rather limited as the overwhelming majority of attacks failed to cause death or injury. Nevertheless, there is some structure in the tails of the distribution coinciding with certain prominent cases, such as the *sarin* attacks in Japan and the *Rajneeshee* incident in Oregon. CBRN events, however, have apparently caused more injury than death. Following the *sarin* attack in Tokyo, for instance, roughly 5000 affected individuals needed medical treatment, whereas only 12 fatalities were reported. The largest CBRN-related fatalities occurred in Uganda, in which a cult was suspected of poisoning its members with sulfuric acid. Even here, the total number of deaths stood at 200, which pales when compared to the nearly 3000 deaths on September 11. Thus to maximize the variation in the dataset, casualties and injuries are added together. In addition, data prior to 1975 are omitted, since they are very sketchy.

The application of extreme value theory typically involves "blocking" the data into disjoint subperiods of equal length and fitting a GEV distribution to the block maxima. In setting the block size, researchers face a trade-off. "Blocking" too narrowly threatens the validity of the limiting argument, leading to a bias in estimation. Wider blocks, however, will generate fewer maxima, leading to greater variability in our estimates. This article opts for semiannual blocking as this choice seems to provide a reasonable trade-off between bias and variance.

The analysis detailed elsewhere [23, 24], allows for both time trends in the location parameter $\mu$ and the scale parameter $\sigma$, as well as breakpoints in the data. Dummy variables for the data breakpoints included 1980–1905 dummy, 1990–2005 dummy and post-1990 dummy. Based on a combination of the quantile–quantile (QQ) plots and maximum likelihood estimates, the best results are reported as shown in Table 2. These results indicate evidence of trend behavior in the severity of the attacks, as seen by the significance both in the location parameter $\mu$ and the scale parameters, $\sigma$. This is consistent with an increasing number of casualties resulting from the worst attacks each year. However, the fact that the value of the estimated shape parameter, $\xi$, is positive and significant in both models suggests that trend is not all that is at work and that at least some of the extreme variation in the data *must* be explained by the *heavy-tailed* nature of the underlying stochastic model.

***5.0.1 Forecasting Probability of Attacks.*** Based on our estimated two models reported in Table 2, one can calculate the probability of a CBRN attack of various magnitudes and time horizons. These estimates are provided in Table 3. The results suggest that the probability of a large CBRN attack, defined as an attack that inflicts between 1000 and 10,000 casualties (injury or death), is nonnegligible. Using the estimates for the second column of Table 2, which provided the best fit to the data, the likelihood that a CBRN attack (anywhere in the world) causes 1000 or more casualties is 0.40. As noted above, the distribution of CBRN events is characterized by pronounced tails. Consequently the current probability of a 10,000-casualty event is not much lower. Using the specification in Table 2, this value works out to be 0.28.

Obviously, these results are sensitive to how one models extreme variations in the data. Thus, if one believes that extreme observations, post-1990s, are better captured by a right shift of the location as opposed to scale parameter, then the current risk of an event leading to 10,000 casualties is relatively low—somewhere between 0.05 and 0.10 (not reported here). However by implication, a continuation of these trends would imply

**TABLE 2 GEV Parameter Estimates Fitted to CBRN Data**

| | | – | – |
|---|---|---|---|
| $\mu$ | Constant | 0.0096 | 0.0227 |

| $\xi$ | | 1.1979 | 0.5446 |
| | | (0.24) | (0.19) |
| Negative log likelihood | | 94.6 | 99.3 |

[a]Estimation was done in *R* using the **Introduction to Statistical Modeling of Extreme Values** (ISMEV) package. The ISMEV package is based on software written by Stewart Coles. Estimates are based on the log of the maximum number of fatalities and injuries over a six month period. Standard errors are reported in parentheses. The last row reports the negative log likelihoods for each model.

**TABLE 3 Probability of CBRN and non-CBRN Attacks of Various Severities**

| | | | |
|---|---|---|---|
| 1000 | Current risk | 0.31 | 0.40 |
| 5000 | | 0.27 | 0.31 |
| 10,000 | | 0.25 | 0.28 |
| 1000 | 5-year forecast | 0.34 | 0.47 |
| 5000 | | 0.30 | 0.38 |
| 10,000 | | 0.28 | 0.34 |
| 1000 | 10-year forecast | 0.37 | 0.54 |
| 5000 | | 0.32 | 0.44 |
| 10,000 | | 0.31 | 0.41 |
| 1000 | 20-year forecast | 0.42 | 0.67 |
| 5000 | | 0.37 | 0.56 |
| 10,000 | | 0.35 | 0.52 |

[a]The two columns report probabilities of CBRN events of various magnitudes within any given year, corresponding to the two parameter estimates of the two columns in Table 2, respectively.

that the future risk of a large event would be much higher. These values probably also overestimate the risk. In short, in whatever way, we choose to model the distribution of casualties from CBRN events, the presence of a nonstationary component is undeniable. As a result, the *recurrence* (return) period of these events is expected to decline with time.

## 6 CONCLUSION

This short article presents an overview of the ongoing research into the assessment of the risk of bioterrorism in the food sector. The analyses are based on nearly 450 observations from 1950 to 2005, but with a focus on the 1975–2005 period. The focus is on intentional and terrorist events at a global scale involving chemical, biological or radionuclear agents, agents that are especially likely to be associated with the food sector as the channel for their dissemination. The analytical method for assessing this risk derives from a statistical technique known as extreme value theory that is tailored to the estimation of "tail" probabilities for rare but catastrophic events. It has been applied to financial crisis, to earthquake predictions and to weather patterns. This study is one among the first efforts to also apply this to terrorism events. In our other articles, another data set (MIPT) consisting of over 25,000 observations were also used as a benchmark to compare the risk of terrorism in the food sector with terrorism at large.

The findings are somewhat alarming. For example, if we focus on catastrophic CBRN events, that is those with large numbers of casualties, we see a rise in their severity. Correspondingly, the average reoccurrence period for such attacks is on the decline, while their probability is on the rise as time goes by. Similar trends underline the findings with respect to terrorist attacks more generally that were documented elsewhere. Since food is a prime candidate for CBRN agents, the implication of this finding is self-evident. By quantifying such risks, this line of research has opened a path toward rationalizing the private and public sector decisions involving extreme risk forms, including both the public policy for ranking risk mitigating strategies and the also the development of private risk markets for catastrophic forms of risk.

## 1 OVERVIEW

As reported by the Environmental Protection Agency (EPA) [1], as recently as the mid-nineteenth century, drinking water supply and wastewater disposal focused on bringing drinking water to the population and carrying wastewater away, with minimal thought to treatment. Near the beginning of the twentieth century, health concerns started to force communities to address treatment. In 1872, Poughkeepsie, NY, introduced slow sand filtration to reduce turbidity in drinking water, which also removed the microbial contaminants that were responsible for typhoid, dysentery, and cholera epidemics. In 1908, Jersey City, NJ, introduced drinking water disinfection treatment using chlorination to further reduce disease outbreaks associated with drinking water. On the wastewater side, the EPA further pointed out that, if the wastewater received any treatment prior to 1900, it consisted of physically separating solids and floating debris from the water prior to a surface water discharge (e.g. primary treatment only). The nation's first wastewater filtration facility was built in 1907 in Gloversville, NY. In 1916, Chicago, IL, constructed an activated sludge treatment plant (secondary treatment).

The 1972 Clean Water Act required that all publicly owned treatment works provide secondary treatment of wastewater. By 1996, fewer than 200 systems, out of 16,204 nationwide, had not met this requirement. In 1974, the Safe Drinking Water Act established the current system of nationwide standards for drinking water contamination. Amendments to the SDWA have continued to improve drinking water quality by regulating contaminants that were not identified in 1974, or for which additional health data is not known. These amendments require the reduction of the allowable concentration in finished water. This vital infrastructure, however, is being threatened by an increasing gap between the funding needs to continue to provide the nation with safe drinking water and proper wastewater treatment and disposal and the amount being invested. Recent needs

surveys and gap analyses have noted that a significant increase in expenditures is needed to ensure continued national security in the clean water industry.

## 2 WATER USE BY SECTOR

The availability and use of water resources in the United States is strongly dependent on the distribution of the waters. Table 1 shows how water is distributed in the continental United States (distribution and replacement data from Ref. 2).

Even though the vast portion of all water in the United States is associated with groundwater, the annual turnover (replacement) of that water is relatively small.

Soil moisture and stream flow likely provide the greatest amount of annual replacement of this groundwater; however, in many areas, the replacement rate is less than the usage rate. Stream flows and other surface water bodies, though smaller in quantity than groundwater, are the most accessible forms that are readily available for development. Unfortunately, they are also most subject to large year-to-year variations owing to periods of drought and excessive rainfalls.

Figure 1 shows the size of the water withdrawals in the United States by source and Figure 2 shows how water withdrawals in the United States are used for various purposes [3]. In the 1960s, total withdrawals totaled about 320 billion gallons per day, or about $430 \times 10^9$ $m^3$ per year. Approximately 20% was from groundwater sources, while the remainder was from surface water sources (68% was from freshwater surface sources and 14% was from saline surface sources). Groundwater withdrawals are greater than the replenishment rates in a number of critical aquifers in the country, leading to deeper and deeper wells and more frequent abandonment of wells, plus concerns about land subsidence. In recent years, the total amount of withdrawals has continued to increase, especially for thermoelectric power cooling, irrigation, and for public water supplies. In 2000, the total withdrawal rate was estimated to be about 400 billion gallons per day, and groundwater still comprised about 20% of the total withdrawals. Most of these withdrawals are eventually discharged to surface waters as waste cooling waters, irrigation return flows, or treated industrial and domestic wastewaters.

**TABLE 1 Volume of Water in the Continental United States and Annual Flux**

| | Volume ($\times 10^9$ $m^3$) | Volume (%) | Replacement period (yr) | Flux ($\times 10^9$ $m^3$/yr) |
|---|---|---|---|---|
| Groundwater—shallow (<800 m deep) | 63,000 | 43.2 | >200 | <315 |
| Groundwater—deep (>800 m deep) | 63,000 | 43.2 | >10,000 | <6.3 |
| Freshwater lakes | 19,000 | 13.0 | 100 | 190 |
| Soil moisture (top 1 m of soil) | 630 | 0.43 | 0.2 | 3150 |
| Salt lakes | 58 | 0.04 | >10 | <5.8 |
| Average in stream channels | 50 | 0.03 | <0.03 (<11 days) | 1700 |
| Water vapor in atmosphere | 190 | 0.13 | >0.03 (>11 days) | <6300 |
| Frozen water in glaciers | 67 | 0.05 | >40 | <1.7 |

Data from Ref. 2.

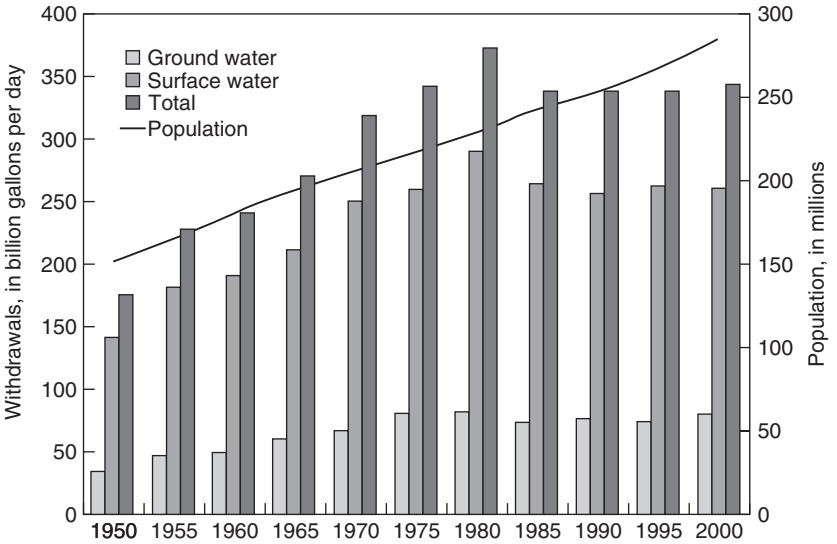

**FIGURE 1** Trends in population and freshwater withdrawals by source, 1950–2000 [3].

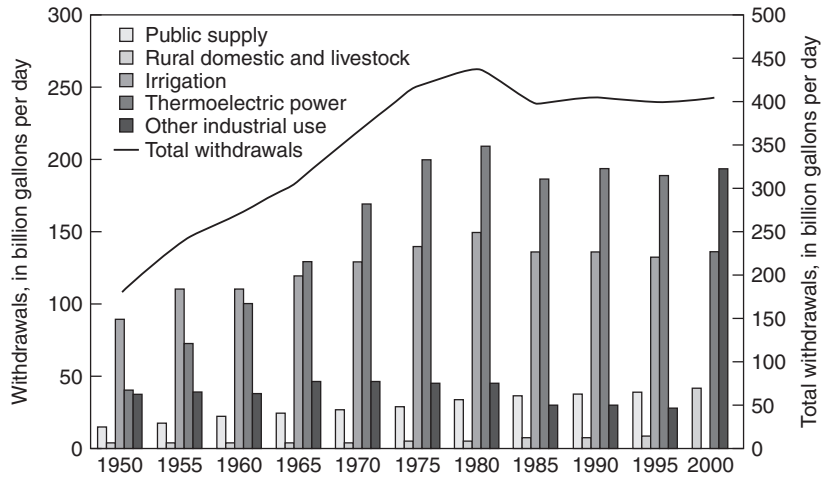

**FIGURE 2** Total water withdrawal for public supply, rural, irrigation, thermoelectric power, and other industries in the United States [3].

## 2.1 Agricultural Water Use

Figures 3 and 4 show how different crop use irrigation water in the eastern United States and in the western United States. Rice is the major irrigated crop in the east (in almost 5 million acre-ft per year), while alfalfa is the most irrigated western crop (using about 15 million acre-ft per year). Orchards also are irrigated with substantial amounts of water throughout the country. Total irrigated land in the United States has grown substantially and now comprises about 55,000 acres (relatively steady since the late 1970s), while it was only about 8000 acres in 1900 and 25,000 acres in 1949 [4].

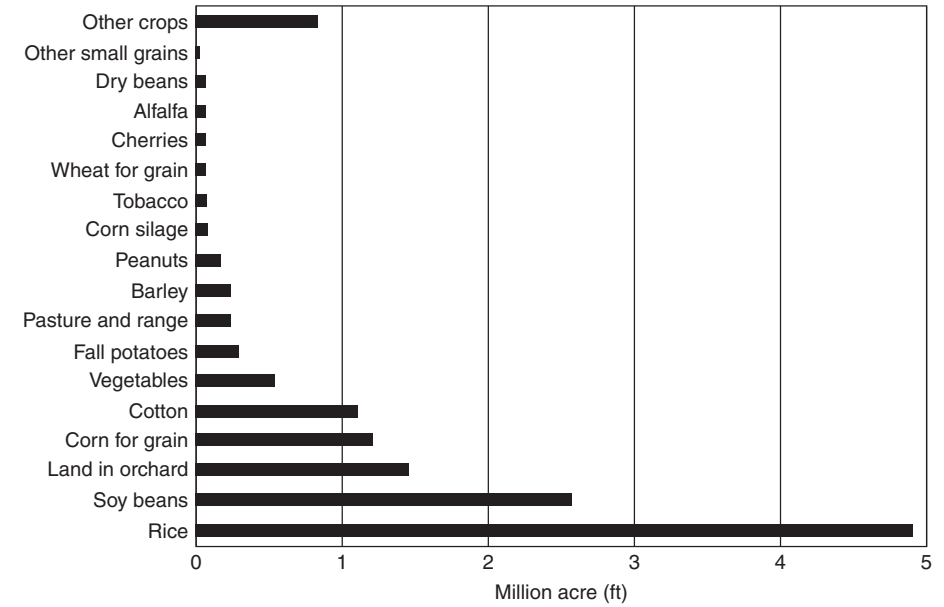

**FIGURE 3** Eastern water applications by crop, 1998 [5].

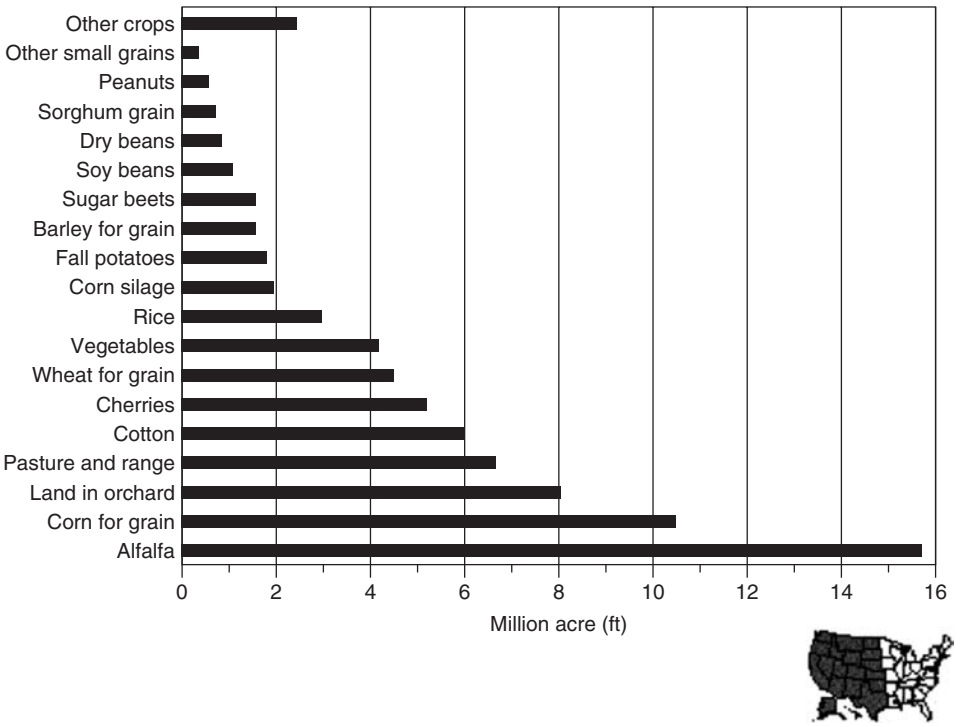

**FIGURE 4** Western water applications by crop, 1998 [5].

### 2.2 Domestic Water Use

Domestic water demand from public water supply utilities has increased faster than the general population growth over the past 50 years. Figure 2 shows that the per capita domestic water use has increased from about 117 gal/person/day in 1950 to more than 180 gal/person/day in 1995. During this time period, the US population has increased from about 150 to about 270 million people, resulting in a 2.8 times increase in domestic water withdrawals over this period. The water supplied by public water supplies also serves institutional, commercial, and some industrial uses, and is more than what is used in a household. These additional uses are included in the calculations for per capita (or per person) daily uses, such as those reported above. Table 2 shows the typical household water use alone, which is generally slightly less than half of the total water supplied by a public water utility on a per captia basis. It is interesting to note that only about 40% (34.5 gal/person/day) of this total needs to be supplied by highly treated water, associated with drinking, kitchen, dishwasher, bathing, and laundering uses. The other household waters can be supplied by poorer quality water, as it is not consumed and not associated with human contact. Most of this other water is simply used to carry wastes to the treatment plant where the wastes are then removed from the water (at great cost).

### 2.3 Public Water Supply Treatment

According to the EPA [7] there are approximately 158,000 public drinking water systems in the United States that serve at least 25 people or have at least 15 service connections (Table 3). These systems serve most people in the United States (282 million). Approximately 53,000 of these public drinking water systems are community water systems that supply water year-round to residents. However, just 8% of those 53,000 systems (4034) serve 81% of the population.

Besides the 53,000 community water systems noted in Table 3, there are about 19,000 nontransient noncommunity water systems (a public water system that regularly supplies water to at least 25 of the same people at least six months per year, but not year-round. Some examples are schools, factories, office buildings, and hospitals, which have their own water systems) and about 86,000 transient noncommunity water systems (a public water system that provides water at a location such as a gas station or campground where people do not remain for long periods of time). These other public water systems serve

**TABLE 2 Typical Personal Water Use by an Urban Family of Four**

| Activity | Per Capita Daily Use (gallons) | % of total |
|---|---|---|
| Drinking and kitchen water use | 2 | 2 |
| Dishwasher (3 loads per day) | 3.75 | 4 |
| Toilet (16 flushes per day) | 24 | 28 |
| Bathing (4 baths or showers per day) | 20 | 23 |
| Laundering (6 loads per week) | 8.5 | 10 |
| Automobile washing (2 car washes per month) | 2.5 | 3 |
| Lawn watering and swimming pools | 25 | 29 |
| Garbage disposal unit (1% of all other uses) | 0.75 | 1 |
| Total | 86.5 | 100 |

| % of population | 32 | 68 | 100 |

Ref. 7.

about an additional 20 million people. In terms of numbers of systems, most of the systems obtain their water from groundwater sources. In contrast, most of the population is served by surface water supplies (Table 4).

Traditional surface water treatment for drinking water includes sedimentation (often after chemical coagulation and flocculation), filtration, and disinfection. Groundwater treatment may skip the sedimentation and filtration steps, if the source water is sufficiently clean. Many modifications to these processes exist based on the quality of the source water used. Table 5 lists the types of treatment systems serving public water supplies. The 2435 treatment plants that were surveyed were a small sample of the total number of treatment plants in the country. The table also shows that most water treatment plants still use disinfection, with no additional treatment. This is likely because many systems have groundwater sources with low sediment loads that do not require sedimentation and filtration. There are few obvious trends in the treatment technologies used for the different sized systems. Ion exchange, membranes, and other chemical treatment methods are represented in all plant sizes. However, community water softening is more common with the smaller plants.

During the 2005 fiscal year, the EPA [7] reported health-based violations by states. These violations were either for treatment technique problems, or for exceeding the maximum contaminant level (MCL) numeric standards. From 2% (Alabama) to 33% (Washington, D.C.) of the systems had reported violations. These violations affected <1% (Delaware) to 98% (Washington, D.C.) of the population served in each state or

**TABLE 5 Types of Water Treatment Plants Serving Public Water Supplies (Percentage)**

| | 100 or less | 101–500 | 501–3300 | 3301–10,000 | 10,001–50,000 | 50,001–100,000 | 100,001–500,000 | Over 500,000 | All Sizes |
|---|---|---|---|---|---|---|---|---|---|
| Disinfection with no additional treatment | 67.0 | 52.9 | 47.5 | 31.8 | 33.5 | 37.3 | 43.9 | 68.5 | 49.4 |
| Other chemical treatment | 7.0 | 19.8 | 10.7 | 25.1 | 12.1 | 10.6 | 3.6 | 1.5 | 14.3 |

Data from Ref. 8.

district. Systems using groundwater supplies had a much greater number of violations than systems using surface water supplies. Between the years 2001 and 2005, the number of violations in the country has steadily increased from 82,655 to 118,420, although the population affected appears to have randomly varied from year to year (ranging from about 13 million to 26 million). Most of the violations were for microbial (about 45,000 violations) and for lead and copper violations (about 13,000) in the FY 2005. Of these violations, the most common problems were related to meeting the total coliform rule/turbidity criteria (about 35,000 violations). By far, most of the violations were associated with very small systems (e.g. they had about 10 times the violation rate per number of systems compared to the very large systems).

## 2.4 Wastewater Treatment

Traditional municipal biological wastewater treatment consists of the following steps: sedimentation, biological treatment (often through an activated sludge process), secondary clarification, filtration, and disinfection. Biosolids are generated from the waste activated sludge. Figure 5 shows the increasing percentage of the US population served by centralized wastewater treatment systems. Most of the remaining population is served by household septic tank systems. The first wastewater treatment plants in the United States were built in the late 1800s and used primary treatment with physical sedimentation of solids and floatation/skimmer removal of floating material before discharges to nearby receiving waters. Activated sludge treatment plants (secondary treatment) were built starting in 1916, although they were not required throughout the country until 1972. Almost 99% of all wastewater treatment plants provided secondary treatment by 1996.

Table 6 is from the *Clean Watersheds Needs Survey Report to Congress* [9] and indicates the number of facilities reporting in the survey as a function of facility size. Most of the plants are relatively small (the median size is $<1$ MGD), although most of the nation's wastewater is treated in much larger plants (median size in the 10–100 MGD range). The

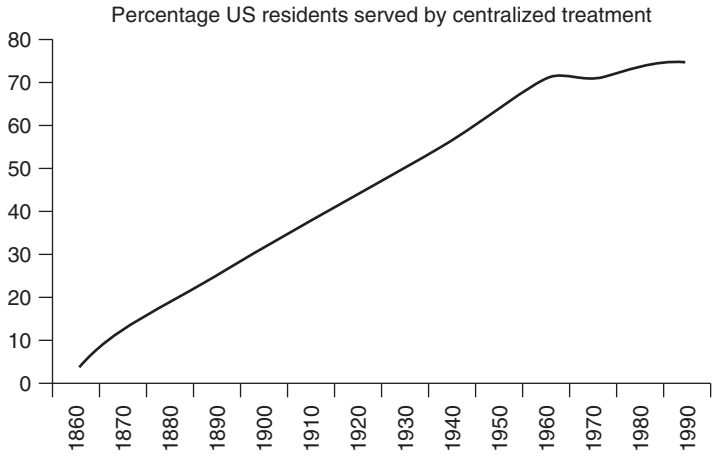

**FIGURE 5** Percentage of US residents served by centralized wastewater treatment plants [12].

**TABLE 6 Wastewater Treatment Facilities by Flow Capacity (not All States Reporting)**

| Design Flow Range (MGD) | Number of Facilities | Total Future Design Flow Capacity in Range (MGD) |
|---|---|---|
| 0.001–0.1 | 6112 | 298 |
| 0.1–1 | 7223 | 2750 |
| 1–10 | 3525 | 12,081 |
| 10–100 | 748 | 19,873 |
| 100 and greater | 64 | 15,040 |
| Total | 17,674 | 50,042 |

MGD = millions of gallons per day [9].

**TABLE 7 Technologies Used in Wastewater Treatment Facilities in the United States (2000 survey)**

| | Number of Facilities Reporting | Future Design Capacity (MGD) | Percent of US Population |
|---|---|---|---|
| Less than secondary | 27 | 481 | 1.2 |
| Secondary | 9463 | 20,008 | 31.9 |
| Greater than secondary | 5739 | 26,239 | 43.2 |
| No discharge | 2221 | 2,579 | 6.5 |
| Partial treatment | 224 | 734 | n/a |
| Total | 17,674 | 50,041 | 82.8 |

See Ref. 9.

different types of treatment technologies employed in the wastewater treatment facilities surveyed by the EPA are shown in Table 7. As previously noted, almost all of the US wastewater treatment facilities provide at least secondary treatment, with almost half of the population's sewage now receiving advanced treatment (e.g. filtration and/or biological nutrient removal). For example, within the next decade, many wastewater plants in the Chesapeake Bay watershed will be investigating and/or installing either biological nutrient removal (BNR) or enhanced nutrient removal (ENR) treatment strategies in response to the nutrient discharge caps enacted in several of the watershed's tributary states.

## 2.5 Distribution and Conveyance Systems

Limited information is available about the amount of additional infrastructure (piping, pumps, storage tanks, pump stations, etc.) in the drinking water distribution and waste water collection systems. One estimate, from the American Water Works Association database, states that there were approximately 1.43 million km (867,000 mi) of municipal water piping in the United States in 2000 [10]. One estimate of the amount of sanitary sewer pipe in the United States as of 1980, is approximately 1.2 million km (4 billion ft), up from an earlier estimated length of pipe in 1960 of 500,000 km (300,000 mi) [11].

## 3 WATER AND WASTEWATER INFRASTRUCTURE COMPONENT NEEDS

In 2002, the US EPA conducted an analysis of the infrastructure needs associated with the nation's clean water (wastewater and stormwater treatment and disposal) and drinking water (treatment and supply) systems for the 20-year period from 2000 to 2019. In the preface to the report, the Assistant Administrator for Water stated the following reasons for conducting this analysis:

> As our economy and population grow, we must periodically take a good look at the challenges ahead and reassess our nation's needs for infrastructure to ensure clean and safe water. By "infrastructure" we mean the pipes, treatment plants, and other critical components that deliver safe drinking water to our taps and remove waste water from our homes and other buildings. Recognizing the importance of having a common understanding of the challenges ahead, the US Environmental Protection Agency (EPA) undertook a "Gap Analysis" to review the historical patterns of infrastructure investment, compare it to projections of future needs, and provide a transparent assessment of the gap between needs and spending.

The report found that much of the current gap is associated with deferred maintenance, inadequate capital replacement, and a general aging of the infrastructure. In addition, population growth and increasing water consumption have also contributed to the critical needs facing the nation's water systems. Although this gap may be very large if not addressed (about $400 billion for clean water, which they define as treating wastewater, and about $300 billion for drinking water), they concluded that it would largely disappear if municipalities increased their clean water and drinking water spending at a modest real rate of growth of 3% per year over this 20-year period.

In the 20 years since the mid-1970s, communities spent about $1 trillion on drinking water treatment and supply and wastewater treatment and disposal works. However, future investments are needed to keep pace with growth in demand and to replace and repair deteriorating water infrastructure. Table 8 lists the typical expected service life for various water system components. Many of these components have long expected lives, but they also require substantial maintenance efforts to ensure continued high levels of service. Without continued maintenance, natural deterioration will significantly reduce the usefulness of the components.

The EPA [8] also reported an AWWA study that concluded that expenditures to repair and replace deteriorating infrastructure will increase steadily over the next 30 years. The 1996 Clean Water Needs Survey reported major categories of future expenditures, as shown in Table 9. The total costs were $225 billion dollars in 2001.

One indication of the recent growth in water system infrastructure is illustrated in Figure 6 [8] which shows the miles of sanitary sewer pipes installed per decade. Figure 7 is a plot showing the expected average age of this installed wastewater collection network. The expected average age is expected to increase to more than half of the service life estimate by 2050. Table 10 shows the classification of the condition of this pipe network

**TABLE 8 Useful Life of Drinking Water and Wastewater Components [8]**

| **Wastewater Components** | |
|---|---|
| **Useful Life** | **Component** |
| 80–100 | Collections |
| 50 | Treatment plants—concrete structures |
| 15–25 | Treatment plants—mechanical and electrical |
| 25 | Force mains |
| 50 | Pumping stations—concrete structures |
| 15 | Pumping stations—mechanical and electrical |
| 90–100 | Interceptors |
| **Drinking Water Components** | |
| **Useful Life** | **Component** |
| 50–80 | Reservoirs and dams |
| 60–70 | Treatment plants—concrete structures |
| 15–25 | Treatment plants—mechanical and electrical |
| 65–95 | Trunk mains |
| 60–70 | Pumping stations—concrete structures |
| 25 | Pumping stations—mechanical and electrical |
| 65–95 | Distribution systems |

**TABLE 9 1996 Clean Water Needs by Category [8]**

| | |
|---|---|
| New collectors and interceptors | 11% |
| Treatment works | 22% |
| Separate sanitary sewer overflow (SSO) corrections | 41% |
| Phase 1 stormwater | 4% |
| Combined sewer overflow (CSO) control | 22% |

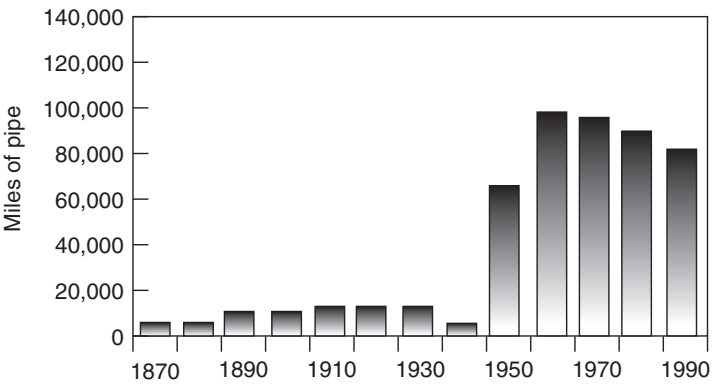

**FIGURE 6** Sanitary Sewer Pipe Installed per Decade [8].

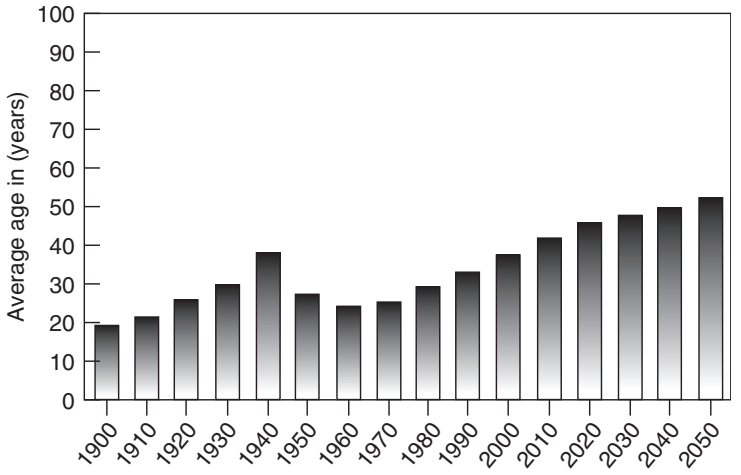

**FIGURE 7** Average Age of Wastewater Collection Pipe [8].

**TABLE 10 Deterioration of Sanitary Sewer Pipe Network with Time [8]**

| Year | Excellent | Good | Fair | Poor | Very Poor | Life Elapsed |
|---|---|---|---|---|---|---|
| 1980 | 69% | 19% | 3% | 3% | 2% | 5% |
| 2000 | 43 | 17 | 18 | 14 | 2 | 7 |
| 2020 | 33 | 11 | 12 | 13 | 23 | 9 |

from 1980 to expected 2020 conditions. The increased amount of poor, or worse, condition pipe is very obvious, and is likely to cause increasing failures (sanitary sewer overflows (SSOs), breakages, and flow capacity losses).

The needs survey and gap analysis is known to underestimate the gap for stormwater drainage and treatment systems. As indicated above, about 4% of the calculated gap is associated with Phase I stormwater communities. Locklear [13] notes that the need surveys recently conducted do not consider many documented stormwater issues. It is felt that the next needs survey, scheduled to be conducted in 2008, will be more comprehensive and accurate. As an example, the 2000 Needs Survey identified $5.5 billion over the next 20 years to address stormwater management needs, based on data from 19 states and the District of Columbia. However, a recent stormwater needs survey conducted by the California section of the ASCE (*the Infrastructure Report Card* [14]) identified this same amount just for their state.

The Water Infrastructure Network report released in 2001 states that if the water and wastewater infrastructure fails, the nation "risks reversing the public health, environmental, and economic gains of the last three decades [15]."

# PROTECTING WATER INFRASTRUCTURE IN THE UNITED STATES

JONATHAN G. HERRMANN, KATHLEEN A. NICKEL, AND AMELIA D. MCCALL
*National Homeland Security Research Center, U.S. Environmental Protection Agency, Cincinnati, Ohio*

## 1 INTRODUCTION

Ensuring clean and safe water has been the responsibility of the US Environmental Protection Agency (EPA) since it was formed in 1970. Water infrastructure was designated one of a number of critical infrastructures for the United States, and EPA was designated the lead federal agency responsible for protecting water systems by Presidential Decision Directive 63 (PDD-63) [1]. Following the terrorist attacks of September 11, 2001, water system protection became an even more important national public health and safety priority. Beginning with the *Public Health Security and Bioterrorism Preparedness and Response Act* (Bioterrorism Act) of 2002 and continuing with a series of Homeland Security Presidential Directives (HSPDs), both Congress and the White House have further recognized the water sector as a critical infrastructure deserving protection from threats and intentional attacks.

Federal agencies and water utilities have been directed by both the legislative and executive branches of government to take steps that heighten the security and protection of the water sector. Consistent with these legislative and executive requirements, EPA has taken many actions, in collaboration with partners from the water industry, academia, and other government agencies, to better protect the nation's water infrastructure. This article contains an overview of some of these actions as well as an appendix that describes contaminants of interest to the water sector.

## 2 WATER SECURITY

In the United States, water systems are vitally important to public health. These systems may be government owned or privately held facilities that draw water from underground aquifers or surface water sources (i.e. rivers, lakes, and reservoirs). Approximately, 90% of the United States' population is supplied by water from one of these systems [2]. A public water supply consists of a water source, conveyance systems (e.g. pipes and pumps), a treatment plant, and storage facilities. Wastewater systems are also part of the

water sector. These systems consist of sewer pipes, storm water drains and ditches, a treatment plant, and a body of water that receives the treated effluent and storm water runoff.

**BOX 1 HSPD SIDEBAR**

Shortly following the terrorist attacks of 2001, the Office of the President began issuing a series of HSPDs, which task federal departments and agencies with specific responsibilities and communicate presidential decisions concerning national homeland security policy.

- [*] *PDD 63: Critical Infrastructure Protection.* (1998) mandated that public and private organizations must be able to maintain the continuity of the US critical infrastructure in the event of a terrorist attack. Critical infrastructure includes the physical and cyber-based systems that are essential for the economy and the government to operate at a minimum level. Water systems were identified as a critical infrastructure.
- *HSPD-7: Critical Infrastructure Identification, Prioritization, and Protection.* (2003) established a national policy for federal departments and agencies to identify and prioritize critical infrastructure and key resources and to protect them from terrorist attacks. Water infrastructure protection is explicitly tasked to EPA, whose responsibilities include conducting or facilitating vulnerability assessments of the sector and encouraging risk management strategies to protect against and mitigate the effects of attacks against critical infrastructure and key resources.
- *HSPD-8: National Preparedness.* (2003) required the establishment of a national domestic all-hazards preparedness goal and described the way federal departments and agencies will prepare for a response to a national incident. It includes a system for assessing the nation's overall readiness to respond to major events, especially those involving acts of terrorism.
- *HSPD-9: Defense of United States Agriculture and Food.* (2004) established a national policy to defend agriculture and food systems against terrorist attacks, major disasters, and other emergencies. It required EPA to build upon/expand current drinking water monitoring and surveillance programs.
- *HSPD-10: BioDefense for the Twenty-first Century.* (2004) directed agencies to develop standards, protocols, and capabilities to address the risks of contamination following a biological weapons attack and to develop strategies, guidelines, and plans for decontamination of persons, equipment, and facilities—including water infrastructure.
- *HSPD-19: Combating Terrorist Use of Explosives in the United States.* (2007) established a national policy and called for the development of a national strategy and implementation plan on the prevention and detection of, protection against, and response to terrorist use of explosives in the United States.

[*]HSPD-7 specifically supersedes PDD 63.

The important role that the nation's water sector plays in providing the public with clean and safe water has made water security a national priority. The Bioterrorism Act of 2002 required water utilities serving more than 3300 people to complete vulnerability assessments of their facilities and then prepare emergency response plans. EPA provided guidance, computer-based tools, and, in some cases, funding to assist the utilities in conducting their vulnerability assessments. Understanding their facilities' vulnerabilities provides owners and operators with a means of prioritizing activities and investments to protect their utility's assets.

As the lead federal agency for ensuring the security of the water sector, EPA works closely with experts from the water industry to continually improve the ability of water and wastewater utility owners and operators to prevent, detect, respond to, and effectively recover from attacks on their systems. EPA has been guided in this effort by national organizations and associated experts, including the National Drinking Water Advisory Council (NDWAC), the American Water Works Association (AWWA), the Water Environment Federation (WEF), the National Research Council (NRC) of the National Academies, and EPA's Science Advisory Board (SAB). The expertise provided has helped EPA identify data needs and research gaps. The research needs and information gaps are being addressed either by EPA scientists and engineers or researchers in other organizations with a strong interest in water systems research and water sector protection.

## 2.1 Recommendations of the National Drinking Water Advisory Council

The Water Security Working Group (Work Group) was charged by the NDWAC with identifying security practices, incentives for improvements in security, and measures of security progress. In response to this charge, the Work Group reached consensus on 14 findings that (i) established the features of active and effective security programs, (ii) identified ways government personnel and others might encourage utilities to adopt and maintain active and effective programs, and (iii) suggested utility-specific and national measures of water sector security progress [3].

The Work Group suggested three aggregate performance measures that would provide an indication of progress with respect to securing the nation's drinking water:

1. Implementation of "active and effective" security programs as measured by the number of utilities implementing the 14 program features (Box 2).
2. Reduction in security risk as measured by the number of high security-risk assets lowered to medium- or low risk (based on the results of vulnerability assessments).
3. Reduction in the inherent risk potential of utility operations as measured by a reduction in the use of hazardous substances by utilities and specifically the number of utilities that convert from gaseous chlorine to other forms of chlorine or other treatment methods [3].

**BOX 2 FOURTEEN FEATURES OF AN ACTIVE AND EFFECTIVE WATER SECURITY PROGRAM**

1. Make a commitment to water security
2. Promote security awareness
3. Identify those in charge
4. Assess vulnerabilities—keep vulnerability assessments up to date
5. Identify security priorities and resources
6. Employ protocols to detect contamination
7. Monitor threat level information
8. Develop measures to assess security program
9. Incorporate security into emergency response plans
10. Establish controls to restrict access
11. Identify sensitive information and restrict access to sensitive communications
12. Incorporate security into construction designs
13. Implement strategies for communication with employees, response organizations and customers
14. Forge partnerships with community, infrastructures, and response organizations

## 2.2 Critical Infrastructure and Key Resource Sector-Specific Plan

As NDWAC's Work Group was evaluating the security practices of the water industry and contemplating its recommendations, EPA was conducting a complementary evaluation. As required by HSPD-7: Critical Infrastructure Identification, Prioritization, and Protection [4], the Department of Homeland Security prepared a National Infrastructure Protection Plan that mandated the development of and established the framework/guidelines for drafting sector-specific plans (SSPs). EPA, as the sector lead, prepared the SSP for water. The SSP specifically laid out a number of security goals and objectives for the sector:

**Goal 1: Sustain protection of public health and the environment**

- *Objective 1.* Encourage integration of security concepts into daily business operations at utilities.
- *Objective 2.* Evaluate and develop surveillance, monitoring, and warning capabilities to recognize risks, and develop response capabilities to respond to those warnings.
- *Objective 3.* Develop a nationwide laboratory network for water quality that integrates federal and state laboratory resources and uses standardized diagnostic

protocols and procedures, or develop a supporting laboratory network capable of analyzing water quality for security threat agents.

**Goal 2: Recognize and reduce risks in the water sector**

- *Objective 1.* Improve identification of vulnerabilities with the intent of increasing the sector's overall security posture.
- *Objective 2.* Improve identification of potential threats through information sharing between sector partners (water utilities; national associations; and federal, state, and local governments).
- *Objective 3.* Identify public health and economic impact consequences of man-made or natural incidents to improve utility risk assessments.

**Goal 3: Maintain a resilient infrastructure**

- *Objective 1.* Emphasize continuity of drinking water and wastewater services as they pertain to utility emergency preparedness, response, and recovery planning.
- *Objective 2.* Explore and expand implementation of mutual aid agreements/compacts in the water sector.
- *Objective 3.* Identify and implement key response and recovery strategies.
- *Objective 4.* Increase understanding of how the sector is interdependent with other critical infrastructure sectors.

**Goal 4: Increase communication, outreach, and public confidence**

- *Objective 1.* Communicate with the public about the level of security and resilience in the water sector, and provide outreach to ensure the public's ability to be prepared for and respond to a natural disaster or man-made incident.
- *Objective 2.* Enhance communication and coordination among utilities and federal, state, and local officials and agencies to provide information about threats.
- *Objective 3.* Improve relationships among all water sector security partners through a strong public–private partnership characterized by trusted relationships [5].

In addition to its own goals and objectives, the SPP acknowledged the performance measures offered by the Work Group and is aligning these measures with its own aforementioned goals [5].

## 3 RESEARCH ON WATER INFRASTRUCTURE

Science and technology are powerful tools being used to achieve the goal of securing our nation from terrorist threats and attacks. Internationally recognized experts in diverse fields of science and engineering are dedicated to this goal. Researchers at EPA and throughout the federal sector are developing strategies and techniques that help prevent, prepare for, and recover from public health and environmental emergencies arising from intentional attacks on our nation's infrastructure.

One of EPA's most ambitious research initiatives was the development of the *Water Security Research and Technical Support Action Plan* (herein referred to as the *action plan*) [6]. The action plan defines numerous projects that result in strategies and tools to protect water infrastructure. The plan was developed following multiple meetings, held in late 2002 through early 2003. These meetings involved stakeholders from the water sector, public health officials, emergency and remedial response personnel, and

representatives from other federal agencies. Following the meetings, and as part of its own evaluation of potential threats, EPA developed a plan to meet the water sector's security needs. The action plan identifies projects under way or planned by EPA. The action plan is written in such a way that other organizations can also conduct projects that are identified. The National Academy of Sciences reviewed the action plan in May and July of 2003, subsequently endorsing it. The action plan was implemented in October of 2003.

Research conducted under the action plan has resulted, and will continue to result, in products that support the water sector in several ways. These products are (i) strategies to prevent damage from attacks, (ii) tools to rapidly detect contamination, (iii) techniques to rapidly contain contamination and mitigate contamination impacts, and (iv) methods to support rapid recovery following an attack. The action plan reflects EPA's interests in physical and cyber attacks as well as contamination events involving chemical, biological, and radiological contaminants.

### 3.1 Protecting Drinking Water Systems from Physical and Cyber Attacks

Physical attacks range from minor acts of vandalism to major incidents that can result in damage to structures such as pumps, pipelines, and storage facilities. These attacks can disrupt service, resulting in loss of potable water to residences and industries, and loss of water for emergency services such as fire control. Disruption in service by the water sector can quickly result in a public health emergency not only due to shortages in drinking water but also due to failure to supply water to critical and interdependent facilities, such as medical facilities and energy plants. Cyber attacks, as they relate to the water sector, generally affect the supervisory controls and data acquisition (SCADA) equipment that is used to operate treatment plants and distribution systems. SCADA systems are used to automate plant operations such as the opening and closing of valves, addition of treatment chemicals, and operation of pumps. Plant operations could be impacted by hackers who disrupt these operations.

With support from EPA and the water industry, the American Society of Civil Engineers (ASCEs) has developed voluntary design standards for new construction, reconstruction, and retrofitting water facilities with a focus on security. The standards include minimum security standards for SCADA and other computer systems used by the water industry. The design standards are available on the ASCE website (http://www.asce.org/wise). In addition, EPA is developing recommendations for countermeasures, such as redundant systems to mitigate the impacts of attacks. The Agency has also issued information on establishing collaborations with other water utilities and sectors to share information and resources in preparation for and response to service disruptions.

Continually analyzing threats is important not only for protecting the water sector, but also for understanding the cascading effects on interdependent sectors. Recently, local, state, and federal officials and representatives from private industry met to review a case study involving a power outage in the Washington, DC, area and its impacts on various sectors. The analysis resulted in several lessons learned and functioned as a "wake-up call" to the participants. The incident evaluated was a Category 2 hurricane that resulted in an extensive, yet short-term power outage. Participants realized the need for additional planning to successfully manage a longer-term crisis. Lessons learned from the exercise are summarized in Box 3.

**BOX 3 LESSONS LEARNED FROM HURRICANE CASE STUDY**

- Staffing.
  - prepare contingency staffing plans;
  - cross-train employees and minimize multiple responsibilities for individuals;
  - prepare for long-term events (staff sustainability);
  - consider and plan for the needs of employees' families;
  - use Emergency Operations Center (EOC) and resources from other agencies and organizations (i.e. Parks and Recreation Department, trade associations, neighboring jurisdictions, and larger utilities).
- Communications.
  - provide redundant communication technologies (800 MHz radios, amateur radio, and cell phones)
  - develop protocols for regular interagency and interdisciplinary communication;
  - enhance timeliness and effectiveness of communication to the public, including alternative methods to communicate emergency measures when standard modes, such as television and radio, are not available due to power loss.
- Practice urban forestry planning and regular tree trimming to prevent downed trees and limbs that, in turn, can down power lines.
- Identify sources for rapid financial aid.
- Improve fuel supplies and stockpiles for response and recovery.
- Establish or improve upon mutual aid and assistance agreements [7].

### 3.2 Identification of Drinking Water Contamination Threats and Threat Scenarios

The combination of a contaminant and the circumstances of its use comprise a threat scenario. EPA has made significant progress in identifying priority contaminants and evaluating how they might be used to harm the water sector. Threat scenarios were identified and prioritized through an analysis of the potential health effects of the contaminant, the availability and quantity of the contaminant needed to cause harm, and the modes by which the contaminant could be introduced to a drinking water system. Because they provide information on water sector vulnerabilities, the threat scenarios are contained in classified documents.

EPA has initiated several projects to better understand the nature of contaminants of interest. These projects include compilation of information on the properties of these contaminants into a comprehensive, computer-based tool with links to information and databases maintained by multiple agencies. These sources provide information about toxicology, personal protective equipment, disposal guidance, and more that need to be easily and quickly accessed during an emergency.

Since many of these contaminants have not previously been considered for use in intentional attacks, additional study is needed to fully understand their impacts on human

health and the environment. Although some, such as the chemical warfare agents, have been studied by the military, their impacts on the general public health would in all likelihood be more protective. Exposure to levels of contaminants that would not result in health impacts to young, healthy individuals could have tragic results for sensitive populations such as the immune compromised and the elderly in the nation's general population.

Research is under way to supplement the current knowledge base on contaminants of interest. Because of the hazards posed by these contaminants, EPA and its partners are working to identify surrogates and simulants. Surrogates and simulants are chemical, radiological, or biological agents that behave in a manner similar to the contaminants of interest, but because they are not as toxic or pathogenic, they can be more safely used in research experiments. Researchers from government and industry worldwide are interested in the identification of these surrogates and simulants to support their research.

### 3.3 Improving Analytical Methodologies and Monitoring Systems for Drinking Water

A water utility's ability to rapidly contain contaminated water and manage the consequences of a contamination event is very important. It is dependent on the water utility's ability to quickly detect a change in water quality and identify the contaminant(s) responsible for that change. Experiments involving water quality sensors' responses to contamination in a water distribution system are being conducted by EPA. Contaminants are injected into distribution system simulators, and the responses of commercially available water quality sensors are evaluated. Common water quality sensors are being tested because many water utilities already use them to monitor general water quality and are knowledgeable about their operation and maintenance. It is anticipated that these same sensors will be successful in alerting a utility to intentional contamination events.

Experiments conducted to date involved challenging 20 water quality sensors to detect over 25 contaminants injected into the distribution system simulators.

Water utilities most commonly monitor free and total chlorine, total organic carbon (TOC), specific conductance, oxidation reduction potential (ORP), pH, and turbidity as indicators of general water quality. Of all the water quality sensors tested, those monitoring free chlorine and TOC detected the widest array of contaminants. Both free chlorine and TOC levels were changed by the presence of the contaminants in the water. For example, herbicides and pesticides produced a large decrease in free chlorine and an increase in TOC due to their organic content.

Compounds such as inorganic arsenite decreased free chlorine but did not affect TOC. Biological suspensions of nonpathogenic *Escherichia coli* and spore-forming bacteria (meant to simulate the bacteria that cause anthrax) were also tested. When tested in their growth media, free chlorine was consumed and TOC increased. It was not the bacteria themselves that were detected by the sensor, but the growth media. Military agents such as nerve, choking, blister, and blood agents were tested at an off-site facility capable of handling these contaminants of interest. Free/total chlorine and/or TOC detected all four of these types of contaminants. The laboratory experiments showed that the use of on-line water quality sensors as part of a contamination warning systems is feasible, and as a result, field testing is being piloted at water utilities around the United States.

Although the ability of water quality sensors to rapidly detect changes in water quality is encouraging, currently available sensors cannot define the specific contaminant responsible for the change. Laboratory analysis is necessary to identify the contaminant(s) in the water. Complicating the laboratories' task is a lack of validated analytical methods that can be used to confirm the identity of contaminants in water samples. Many of the contaminants of interest with respect to intentional contamination of water supplies have not previously been considered as terrorist threats. As such, methods to detect many of these contaminants in water have not been developed, or if developed, have not been tested with stringent quality controls and then validated through a multiple laboratory process.

To begin to address this issue, EPA compiled *Standard Analytical Methods for Use Following a Homeland Security Event (SAM)* [8]. This document was prepared to ensure that all laboratories use the same analytical methods following a homeland security incident so that results are comparable. SAM includes the best, currently available methods. Some of the methods are routinely used in nonenvironmental applications, such as medical diagnostics, but have not been applied to environmental matrices, such as water. Efforts are under way to adapt these methods for use with environmental samples that have interferences not experienced with clinical samples. Candidate methods will be put through a rigorous process of validation by multiple laboratories. It is only after successful completion of multilaboratory validation that a method will be considered acceptable as a standard method.

Successful analysis of biological agents in water involves a unique complication. The concentrations of microbes in water samples may be very low compared with those typically seen in clinical samples (e.g. blood). Detection of very low concentrations of microbes in water can be difficult: analogous to finding a needle in a haystack. Yet there are no agreed upon safe levels for many microbes in water. Thus, it is necessary to detect the proverbial needle. To do so, the sample must be concentrated; in other words, the amount of water in the sample must be reduced while retaining the microbes. EPA has developed an ultrafiltration apparatus and a tested protocol to concentrate microbes in water samples and increase the probability of detection. The apparatus uses nonreactive hollow fiber membranes (polysulfone or low protein binding membranes) as the preferred medium for filtering.

The system operates with 5–10 lb/in.$^2$ difference between the sample and concentrate reservoirs. This difference forces water through the membrane. Microbes cannot pass through the membrane, while some water is forced through the membrane by the pressure differential. The ultrafilter concentrates the microorganisms and sends them to the concentrate reservoir. The concentrate recirculates and mixes with more undiluted sample until the entire volume has been reduced to a target volume. A successful prototype of the apparatus has been built and tested. Preliminary test results indicate that water samples ranging in volume from 10 to 1000 l can be concentrated down to approximately 250 ml. Concentration reduces the risks associated with transporting large quantities of contaminated water samples in addition to aiding the analysis by increasing the probability of detection.

Effective sample collection, preparation, and analytical methods are imperative to rapid detection and containment of contamination. Equally critical is the establishment of a network of capable and well-equipped laboratories. EPA is working to establish a network of laboratories that can perform both presumptive and confirmatory analysis of environmental samples. The model for this network is Centers for Disease Control

and Prevention (CDC)'s laboratory response network (LRN) for clinical samples, which has been in operation for many years. Consistent with the CDC model, the environmental response laboratory network (ERLN) will consist of many laboratories capable of performing presumptive analyses using methods available in the open literature.

Fewer labs, employing rigorous quality assurance protocols, will have the capability for confirmatory analyses. Still fewer (reference) laboratories will have access to classified methods and these laboratories would be capable of detailed analysis and forensic investigations. In the case of environmental samples, presumptive analyses will be performed by water utility laboratories, hazardous materials teams, and contractor laboratories; confirmatory analysis will be reserved for state and federal government laboratories; and finally, federal government labs (i.e. EPA and Department of Energy) will maintain reference laboratory capabilities.

### 3.4 Containing, Treating, Decontaminating, and Disposing of Contaminated Water and Materials

Containing contaminated water in a distribution system is a challenge due to the quantity and velocity of the water moving through the system. By the time suspicious water quality is detected, the water may have reached an exposure point (i.e. household, manufacturing plan, and medical facility). There are financial, technical, and health implications associated with shutting down a distribution system. As such, it is imperative to not only rapidly detect changes in water quality in a distribution system, but also understand the significance of these changes such that responsible risk management decisions can be made. EPA has developed software to help utility managers understand the fate of contaminants in their distribution systems, to optimally place water quality sensors, and to interpret data collected by these sensors.

A computer model, EPANET, is commonly used by water utilities to understand flow and contaminant transport through distribution systems. Until recently, EPANET has been limited to tracking the dynamics of a single chemical transported through a network of pipes and storage tanks, such as a fluoride used in a tracer study or free chlorine used in a disinfection decay study. EPA has released an extension to EPANET called *EPANET-MSX* (MultiSpecies eXtension) that considers multiple interacting species in both the water flow and on the pipe walls. This capability has been incorporated into a stand-alone program as well as a toolkit library of functions that programmers can use to build customized applications. The software can be downloaded free of charge from the EPA website (http://www.epa.gov/nhsrc/news/news073007a.html). EPANET-MSX allows users the flexibility to model a wide range of chemical reactions of interest including free chlorine loss, the formation of disinfection by-products, nitrification dynamics, disinfectant residuals, and adsorption on pipe walls. Homeland security researchers are particularly interested in modeling the fate and transport of contaminants of interest in drinking water distribution systems.

In addition to models that predict contaminant fate in a distribution system, EPA has developed a computer-based sensor placement optimization tool (SPOT). Given the current state of sensor technology and the interest in better understanding water quality in distribution systems, many water utilities have been installing water quality sensors as part of a contamination warning system. As discussed in the previous section, research has shown that in the presence of contaminants, water quality sensors are able to detect changes in free chlorine, TOC, ORP, specific conductance, and other parameters. SPOT

allows users to select design objectives and compare and contrast the benefits of different sensor placements.

Water quality monitoring stations can provide information about general water quality conditions only at a specific location and time. If these monitoring stations are isolated from each other, detecting a contaminant and its movement is extremely difficult. This limitation is compounded by the fact that water quality at a given location can be highly variable, with several factors affecting it including pump and tank operations, system demand, and source water quality. To address these factors, EPA's research program has developed "Canary", an event detection system (EDS) named for the "canary in a coal mine" analogy. Canary is a software program that processes data from water quality sensors in real time and predicts whether the recorded water quality changes are the result of a contamination event or natural variations in water quality. Sophisticated algorithms incorporated into EDS tools like Canary can efficiently mine large amounts of water quality data produced by monitoring stations and detect anomalies that are indicative of contamination or other water quality problems. The early detection system tool implemented as part of a contamination warning system is critical to the performance and reliability of the system

The success of any computer modeling tool is dependent on the quality of its input data. The environmental fate of chemical, biological, and radiological contaminants needs to be better understood if models are to perform optimally. Of particular interest is what happens to contaminants when dispersed in source waters (e.g. rivers, lakes, and groundwater), water treatment plants, or distribution systems (e.g. pipelines and storage tanks).

Concentrations of chemical, biological, or radiological contaminants in source waters will, in many cases, be reduced to below levels of concern through dilution and routine treatment at a drinking water plant. In cases where even very low levels of contaminants produce toxicity or aesthetically unpleasant results, dilution may not provide adequate safety assurances. This is particularly true, posttreatment, in the distribution system. Also, some contaminants may attach themselves to pipe walls in a water distribution system, resulting in the slow release of contaminants back into the water. Attachment could be directly onto the pipe wall material, the biofilm layer, or corrosion-inhibiting layers intentionally deposited on the pipe walls.

A better understanding is needed regarding which contaminants may attach to the interior of the water distribution system and how they can best be removed. EPA is currently researching the fate and persistence of various contaminants in distribution systems and conducting experiments using a variety of decontamination and inactivation techniques to determine their effectiveness. Decontamination in this context refers to the removal of contamination; whereas, inactivation refers to the diminishment or elimination of a contaminant's toxicity or pathogenicity. Ultimately, a guide that documents the effectiveness of decontamination and inactivation techniques will be produced.

Although complete and rapid removal or inactivation of contamination is the goal following a terrorist attack on a water supply, this goal may not always be achievable. For some contaminants, flushing the pipes or treatment of the water by chlorination or other methods may be sufficient to remove them. However, for other chemicals, disposal of contaminated piping and treatment system components may be necessary. To assist utilities faced with the prospect of disposing of these materials, EPA developed a web-based decision support tool (DST). The DST assists in the disposal of residues from

the cleanup of contaminated water systems and other structures by providing information needed for selection of an appropriate disposal facility.

Included with this information is pertinent regulatory requirements and facility contact and permit information. The tool contains the ability to quickly estimate quantities and characteristics of residues produced during cleanup operations so that cost trade-offs between decontamination and disposal can be evaluated early in the process of restoring a contaminated facility. This information is then incorporated into the detailed waste profiles needed to negotiate contracts with disposal facilities and transportation companies. The DST provides information to assist in decision making relevant to decontamination and disposal of materials associated with drinking water treatment plants, distribution systems, water-using equipment and appliances, wastewater treatment plants, and a number of types of buildings. The disposal tool is available for use with permission and can be accessed through the EPA website (http://www.epa.gov/nhsrc/news/news083005d.html).

Whenever drinking water systems are incapacitated, alternative supplies of water must be provided. Plans must be in place to provide clean and safe drinking water to customers. Until recently, contingency plans most commonly addressed drought and short-term disruptions. In consideration of the potential for long-term disruptions resulting from intentional attacks on water systems, contingency approaches for providing drinking water need to be reevaluated. Innovative approaches such as transportable or modular units that can treat water at different locations must also be considered. In fact, the Bioterrorism Act required a review of methods for providing alternative water supplies.

EPA has begun an evaluation of water supplies and delivery system alternatives for systems of various sizes and geographical areas, and will consider types of water sources, adjacent systems and interconnection, system redundancies, pressure sources, and portable capabilities. Such an evaluation has benefits that go beyond a terrorist attack. These benefits include improved preparedness for natural hazards (e.g. earthquakes, floods, and tornadoes) or accidents (e.g. line breaks and chemical tank failures). Contingency planning is nothing new. The Safe Drinking Water Act of 1974 required all water utilities to prepare contingency plans that would be implemented during an emergency. These plans have, however, been reevaluated with increased vigor as utilities were required to perform vulnerability assessments as part of the Bioterrorism Act of 2002.

The vulnerability assessments focused on seven water system components that might incapacitate the system. These include the water source, treatment facilities, transmission and distribution lines, storage facilities, water system personnel, records (plans and operating manuals), and indirect components (electric power, supplies and materials, communications including telemetry and facility and personnel security). Using the results of their vulnerability assessments, water utilities have begun to implement additional contingencies. Many have added system redundancies such as backup pumps and extra storage, and have defined emergency water sources and negotiated mutual aid agreements with neighboring utilities.

### 3.5 Targeting Impacts on Human Health and Informing the Public of Risks

An important component of a contingency plan is communication with mutual aid providers, government, and the public. Although there are many formulas for effective communication during a crisis, all require careful planning, thoughtful message preparation, simplicity, and accuracy. Working with communication experts, EPA evaluated several approaches for communication during crises and adopted a process called

*message mapping*. A message map is developed taking into account a number of factors. Most important is the recognition that under stress most people can comprehend and retain only a very few pieces of critical information.

A successful message map focuses on only three points and presents these points at a level of simplicity understandable to people with an education four grades lower than the target audience. Other important factors for inclusion in a successful message map are statements of compassion and optimism, citation of credible third parties, and truthful and accurate information. EPA has prepared numerous message maps for its own use in preparation for crises and has provided training to many of its partners on the techniques [9]. A report and video tutorial on the process of message mapping and examples of message maps can be found on the EPA website (http://www.epa.gov/nhsrc/news/news040207.html).

Despite the importance of planning, much of the information that will need to be communicated during a crisis is situation specific. During the emergency, quick and easy access to accurate information will be necessary. Some of this information pertains to the properties of the contaminants and their impact on human health and the environment. work is under way to better understand the contaminants of interest with respect to terrorist events, including defining levels of exposure to the contaminants below which there are no health concerns or at which the use of protective equipment is required (i.e. advisory levels). This information is very important to determine when evacuation is needed and when safe occupancy can be resumed.

Biological agents pose the greatest challenge, compared with chemical and radiological agents, in predicting health outcomes. Developing a scientifically acceptable method of performing microbial risk assessments (MRAs) is an EPA priority. In the past, MRAs have been addressed mostly by risk assessors trained to perform chemical risk assessments. Most MRAs to date have focused on the hazardous characteristics of the microbial agent with little appreciation for the complex interactions involving host susceptibility or the factors governing environmental exposure. Consequently, there is no consensus methodology to assess risks associated with microbial agents intentionally released into the environment (e.g. water, indoors and outdoors).

The unique challenge of assessing risks associated with exposure to pathogens is that microbial agents are capable of replicating and changing after being released. Adding to that complexity, homeland security experts are concerned that microbial agents may be genetically modified to enhance virulence or promote dissemination. These modifications could increase the harm to those exposed or increase the number of those exposed. The delivery concentration of these modified agents may also be higher than the dose normally received through natural transmission pathways (i.e. person-to-person and animal-to-person).

Although MRA is a fledgling science, strides are being made. Studies are under way to advance the science in the following key areas:

1. understanding the key properties related to microbe detection;
2. developing protocols for the design of novel and advanced sampling and analytical methods;
3. identifying and testing highly efficient biological aerosol sampling devices;
4. understanding genomic reengineering of characteristics such as virulence, detection capability, and antibiotic resistance;

5. understanding physical modifications of biological agents in aerosols to increase their airborne dispersion;
6. recognizing physiological and biochemical processes involving pathogenic-induced infectivity and disease; and
7. understanding the fate and persistence properties of biological agents in order to design decontamination protocols for cleanup and reentry into buildings and outdoor areas (Tonya Nichols, Ph.D., Personal Communication, 2007).

EPA is involved in studies to advance MRA in several important ways, including (i) physiological models development, (ii) bioaerosol studies, and (iii) pathogenicity assessments.

***3.5.1 Physiological Models.*** A scientifically credible risk assessment is dependent on accurate data and knowledge of how the microbes impact the human body at varying exposure levels (i.e. dose–response).

Since experimentation using human and animal subjects is necessarily highly restricted, models must be developed that can reasonably predict health outcomes. EPA has been involved with two model development efforts that are advancing the field of MRA:

*Physiological Assessment of Microbial Effects (PhAME) Workgroup*. The PhAME Workgroup is a multiagency team formed to develop innovative approaches to defining the exposure–dose–response continuum for inhaled microbial pathogens. Developing a method to establish advisory levels requires examining the available toxicological, infectivity, and virulence information on each biological threat agent, followed by a statistical analysis of the data. A comprehensive knowledge base is needed to structure the available data from human and animal exposures in order to permit more rigorous statistical analysis via a variety of commercially available analytical tools. To address this need, the PhAME Workgroup has been responsible for developing the pathogen information catalogue (PI Cat), which is a comprehensive knowledge base on dose assessment.

The PhAME Workgroup has been using this knowledge base and other government resources to develop physiologically based infectivity models that extrapolate information on contaminant effects to humans based on animal dose–response data. Data on particular species (e.g. guinea pigs, rats, and monkeys), which are housed in the PI Cat, can be used to determine survival curves. Physiologic extrapolation models (PEMs) can be designed to extrapolate survival curves from animals to humans (Tonya Nichols, Ph.D., Personal Communication, 2007).

*Physiologically Based Biokinetic (PBBK) Models*. PBBK models are being developed using the rabbit model. The model evaluates the fate of inhalational anthrax in the rabbit, by assessing the deposition of spores in the lung, germination of the spores, the spread of bacteria during disease, and the effect of immunization. The data can then be extrapolated to predict low-dose infectivity of anthrax in humans. This information will contribute to health and exposure assessments needed to derive cleanup goals.

***3.5.2 Bioaerosol Studies.*** Relatively little is known about how everyday activities could influence human exposure to biological contaminants. EPA is conducting targeted research that advances the knowledge and understanding of the fate and transport of microorganisms in air and water, and the potential risk to humans from exposure to

organisms released by various modes of delivery. EPA has identified and engaged organizations to collaborate in this effort. Understanding the behavior of biological agents in water-based aerosols, which could be created if water distribution systems become contaminated, has been an area of great interest to EPA and public health organizations.

Most aerosol research to date involves evaluating biological agents as inert particles. EPA's key contribution to this area has been to design and conduct experiments to not only determine the extent of biological contamination, but also assess the survivability of the agent being delivered through the aerosolization pathway. For example, if the agent does not survive aerosolization or the decay rate is known to be rapid, a decontamination or cleanup effort may not be necessary. To test survival and dissemination, agents have been grouped into representative classes as follows:

- naturally occurring waterborne agents;
- spores that are extremely hardy and environmentally persistent;
- vegetative bacterial cells, which are not normally environmentally persistent.

Biological contaminants in tap water may become aerosolized in droplet or vaporized form during use, thus creating three routes of potential entry into a susceptible host: inhalation, ingestion, and dermal exposure. In order to more reliably assess the risk of exposure to pathogens in these situations, studies are being conducted to better understand the dynamics of exposure to contaminated aerosol droplets and vapor, and in particular, the behavior and viability of pathogenic microorganisms contained in water droplets and vapor generated at varying water temperatures under varying environmental conditions.

In addition to influencing public health advisories, the information generated from these studies will impact how cleanup activities are conducted. For example, contaminated water could be aerosolized by decontamination activities (water spray), as well as by showering performed during personnel decontamination upon exiting the contaminated environment. Modifications to these practices will be necessary if it is determined that through aerosolization, these pathways spread contamination or increase human exposure to pathogens.

***3.5.3 Pathogenicity Assessments.*** In MRA, not only survivability and transport of biological agents are to be considered but pathogenicity, or the ability of a microbe to cause disease, must also be evaluated. Pathogenicity assessments are analogous to the better-understood hazard assessments for chemicals; however, they consider the many complexities associated with disease processes. For example, there is much interplay between the disease agent (strain specificity), the host immune response (susceptibility), and the exposure pathway (route of entry). Figure 1 depicts how biological and chemical risks are equated. EPA is developing a methodology for conducting pathogenicity assessment that involves a novel application of the epidemiological disease triangle. The disease triangle describes the interplay of three critical factors in the infectious disease process: (i) susceptible host, (ii) pathogen, and (iii) favorable environmental conditions.

Understanding the characteristics of the pathogen, particularly its virulence (i.e. relative ability of a microbe to cause disease) is a major goal of hazard characterization. Virulence factors, ranging from membrane structures to excreted toxins, provide a

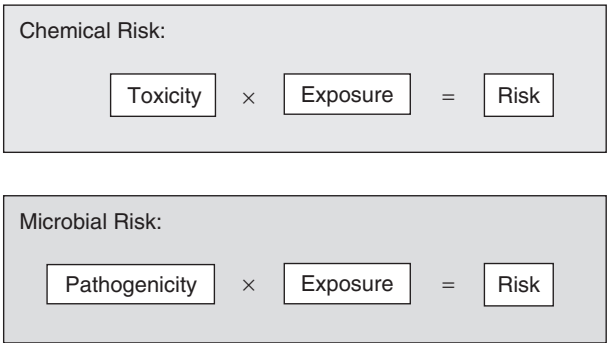

**FIGURE 1** Comparing biological and chemical risks from contaminants of interest.

biological agent with its pathogenic potential. EPA is compiling virulence factors for contaminants of interest. The data compilation effort includes

- associated microorganisms;
- genetic sequences;
- accessory factors (i.e. genes and/or proteins);
- environmental conditions for genetic expression;
- modes of action;
- structural analysis, when applicable;
- genetic recombination potentials;
- detection assays.

The pathogenicity assessment considers that virulence factors usually act in concert and that microbes exhibit adaptability to environmental pressures.

Accurate exposure pathway analysis is important to the pathogenicity assessment because microbial modes of action are dependent on the portal of entry into the host. For example, a traditional foodborne organism that causes a short-term gastrointestinal disease may be lethal if the organism gains entry to the bloodstream, via a break in the skin. It is also possible that an inhalational pathogen may not cause disease through an ingestion pathway. On the contrary, some pathogens cause disease no matter the portal of entry. *Bacillus anthracis*, for example, causes disease through all three exposure pathways: inhalational, gastrointestinal, and dermal anthrax. The pathogenicity assessment step evaluates the microbe's potential impact upon entry into each portal, which determines the significance of exposure pathways identified in the exposure assessment.

## 4 SHARING INFORMATION ON RESEARCH RESULTS

EPA's efforts to collaborate with its water sector partners means that frequent and effective communication is paramount to water sector security. Although easily accessible information must be available to sector partners, precautions must also be taken to ensure

that sensitive information on asset vulnerabilities and threat agents is not available for use by terrorists. There are many ways to share information on the results of data gathering and information development. Much of EPA's research results are provided using state-of-the-art information delivery techniques such as websites and electronic downloads. In some instances, the information developed is sensitive and can only be shared with a more limited set of customers or information users. The relatively small amount of information is shared in this fashion.

*The Water Information Sharing and Analysis Center (WaterISAC)* is a secure information system intended for use by drinking water and wastewater utilities. WaterISAC, managed by the Association of Metropolitan Water Agencies, was established to facilitate two-way communication between government agencies, law enforcement, research institutions, other ISACs, and the water utilities. It is specifically oriented to provide information on threat alerts and knowledge about threat agents and security systems. WaterISAC was established in response to PDD-63 and Executive Order 13231, which recommended that critical sectors establish information sharing and analysis centers. In addition to disseminating information, WaterISAC employs security analysts who scrutinize information for patterns, trends, and associations between seemingly unrelated events in order to provide early warning of potential dangers. This analysis provides a proactive and preventative element to water security [10].

Because WaterISAC is a privately established and operated venture, membership fees are required. Some smaller utilities experience difficulty in meeting the fee requirements of WaterISAC so, using a grant from EPA, WaterISAC established the Water Security Channel. Although password protected, the Security Channel does not have the highly sophisticated security of WaterISAC. It cannot provide all of the services and benefits of the ISAC, but it is free of charge and offers a library of federal advisories. WaterISAC and the Security Channel are instrumental in sharing information on a national level; however, more localized engagements are equally important. Regional, state, and local collaborations, consisting of organizations that will be required to work together during emergencies, can help promote an understanding of roles and responsibilities, and establish relationships that will help ensure effective response in times of emergency.

*Water Security Information Collaboratives* are groups of organizations and agencies formed to share information and address common issues regarding security. These collaboratives can take many forms, from ad hoc groups that meet only as needed to formal organizations complete with charters, mission statements, operating budgets, and regularly scheduled meetings. The principal benefit of a collaborative is enhanced drinking water and wastewater security and public health protection. Among the many other benefits, a collaborative provides is the opportunity for utility officials to develop working relationships with the people on whom they will rely during an emergency. Another benefit is the opportunity to share information from a variety of sources. For example, the water utility may subscribe to WaterISAC, from which it receives early warnings of potential threats, as well as information about security. State water regulatory agencies can provide expertise, resources, and information. Local law enforcement officials obtain updates from the Department of Homeland Security and regional offices of the Federal Bureau of Investigation (FBI). Public health agencies receive information from the CDC and are part of new disease surveillance programs being implemented around the country.

A focused effort to share information can ensure that utilities have a more comprehensive picture of the current security condition. Other benefits of collaboratives include the following:

- improved detection of, response to, and recovery from security crisis events;
- enhanced working knowledge and understanding of different professional disciplines;
- more effective use of different skills and resources;
- increased effectiveness in educating consumers and responding to questions from the media and public;
- improved intergovernmental communication;
- better understanding of various organizational perspectives and enhanced ability to resolve conflicts in a noncrisis environment;
- heightened sense of trust and community among organizations;
- identification and elimination of obstacles that prevent full cooperation;
- joint project development;
- increased efficiency through resource and information sharing;
- multiple communication links;
- enhanced problem-solving and team-building capabilities; and
- identification and coordination of interorganizational dependencies.

EPA has produced a guide to help the water sector establish security collaboratives. The guide includes case studies of three successful collaboratives [10].

## APPENDIX A: CONTAMINANTS OF INTEREST

A great deal can be done to prepare for intentional destructive acts against a drinking water or wastewater system without consideration of specific contaminants. Improved cyber and physical security and effective monitoring of general water quality all play a role in protecting water infrastructure. Following suspicion of tampering or an unexplained change in general water quality, a utility must quickly and confidently identify and characterize contaminants that may have entered the system. To successfully prepare for an intentional contamination event, utilities, researchers, responders, and public health professionals need to be knowledgeable of the range of contaminants that could be used to attack a drinking water or wastewater system.

Many organizations have compiled lists of the potential contaminants of interest that could damage drinking water or wastewater systems. These lists vary somewhat based on organizational responsibilities or interests, yet there are common contaminants among most of the lists. Contaminants of interest can be grouped into several categories: biological agents, chemical agents, toxic industrial chemicals, and radionuclides. This appendix provides a description of the contaminants of interest associated with water infrastructure.

## A.1 BIOLOGICAL CONTAMINANTS OF INTEREST

There are two primary types of biological agents that are contaminants of interest:

*Pathogens*, which may be bacteria, viruses, or protozoa, are replicating disease-causing organisms. Pathogens are infectious meaning that they will cause disease in a large number of exposed individuals. An example of a highly infectious pathogen is *B. anthracis*, the organism that causes the disease anthrax. Although highly infectious, *B. anthracis* is not communicable from human to human and is therefore not contagious. Pathogens capable of inflicting the greatest damage are both infectious and contagious. *Variola*, the pathogen that causes the disease smallpox, is both infectious and contagious.

*Biotoxins*, poisonous substances produced by living things, are common in nature. In many ways an attack using a biotoxin is more like a chemical attack than a biological attack, but because they are produced by living organisms, they are included in this section. Examples of biotoxins include venoms produced by insects and snakes. Biotoxins cause disease either on contact or by entering tissue and interacting with proteins. Reactions to biotoxins may be minor such as a bee sting or extremely lethal such as the reaction to ricin or botulism toxin.

A review by Burrows and Renner [11] discussed a variety of biological agents that might be used to intentionally contaminate water systems.

1. *Bacillus anthracis.* It is a spore-forming bacterium that causes the disease anthrax. The bacterium may occur in spore or vegetative form. Anthrax occurs in three forms: pulmonary, cutaneous, and intestinal. *B. anthracis* spores are very persistent and can survive in the environment for decades. While in its vegetative state *B. anthracis* is readily susceptible to inactivation by chlorine, the spore form requires exposure to 5–10% bleach or formaldehyde solution for inactivation. Although spores of *B. anthracis* may be physically removed from water through filtration systems capable of removing particles $<1\,\mu m$, significant hazards would be associated with handling of the contaminated filter components [11].
2. *Brucella melitensis and Brucella suis.* These are bacteria responsible for the disease brucellosis, which is highly infectious in cattle, pigs, and sheep. In humans, the infection is referred to as *Malta fever* or *undulant*. The illness is incapacitating, causing fever, aches, and pains, but the rate of fatality is relatively low. Brucellosis is known to have been contracted through the consumption of contaminated milk; thus, transmission through water is a concern. *B. suis* has been weaponized as an aerosol. *B. melitensis* is persistent in water for 20–72 days but can be inactivated by 1% sodium hypochlorite [11].
3. *Vibrio cholerae.* It is a bacterium, which causes acute, highly infectious cholera in humans and is transmitted through contaminated food or water. *V. cholerae* has been used throughout history to purposefully contaminate food and water. Symptoms of cholera are acute diarrhea resulting in dehydration. Without treatment, victims may die in a matter of hours of the onset of symptoms. *V. cholerae* may survive for weeks in water but is sensitive to heat, sunlight, and drying, and is easily killed by chlorine [11].
4. *Clostridium perfringens.* It is a common and highly persistent bacterium found in sewage. It causes food poisoning, which is associated with consumption of contaminated and undercooked meats. Symptoms include diarrhea, but unlike cholera, food poisoning is rarely fatal. *C. perfringens* is possibly transmissible through

water, which is of concern due to its insensitivity to chlorine. Aerosolization is another possible route of concern [11].

5. *Burkholderia mallei.* It is a bacterium that commonly results in the disease glanders in equines, although it can also occur in humans. The disease has not been seen in humans since 1945, but the bacteria are of concern for weaponization because it takes relatively few organisms to result in infection [12]. The symptoms of glanders depend upon the route of infection. The types of infection include localized, pus-forming cutaneous infections, pulmonary infections, bloodstream infections, and chronic suppurative infections of the skin. Generalized symptoms of glanders include fever, muscle aches, chest pain, muscle tightness, and headache. Additional symptoms have included excessive tearing of the eyes, light sensitivity, and diarrhea. Bloodstream infections can be fatal in a week to 10 days [12].
6. *Burkholderia pseudomallei.* This bacterium causes the disease melioidosis, which is clinically and pathologically similar to glanders, but the ecology and epidemiology of melioidosis are different. Melioidosis is predominately a disease of tropical climates, especially in Southeast Asia where it is endemic. The bacteria causing melioidosis are found in contaminated water and soil, and are spread to humans and animals through direct contact with the contaminated source. Glanders is contracted by humans from infected domestic animals [13].
7. *Yersinia pestis.* It is the bacterial cause of plague, a disease that has resulted in infamous devastation throughout history. Plague may occur in three forms: pneumonic plague, bubonic plague, and septicemic plague. Pneumonic plague can spread from person to person through the air. Bubonic plague is the most common form of plague. It occurs when an infected flea bites a person or when materials contaminated with *Y. pestis* enter through a break in a person's skin. Bubonic plague does not spread from person to person. Septicemic plague does not spread from person to person.[14]. *Y. pesitis* has been used in the intentional contamination of food and water sources. The bacteria can survive in water for several days. It is inactivated by heating to 55–72°C or by 1% sodium hypochlorite [11]. It could be killed after several hours of exposure to direct sunlight.
8. *Chlamydia psittaci.* It is a rickettsia bacterium that causes the disease psittacosis through inhalation of contaminated bird droppings. The disease results in pneumonia, with accompanying fever, chills, headache, muscle aches, and a dry cough [11]. Psittacosis is not transmissible from human to human. *C. psittaci* is stable in seawater up to 24 hours and thus may be able to survive in fresh water. It is inactivated by 1% sodium hypochlorite [11].
9. *Coxiella burnetii.* It is a rickettsia bacterium, which causes Q fever in humans. Q fever may be acute or chronic. Only about one-half of all people infected with *C. burnetii* have symptoms. Most acute cases of Q fever begin with sudden onset of one or more of the following: high fevers (up to 105°F), severe headache, fatigue, muscle pain, confusion, sore throat, chills, sweats, nonproductive cough, nausea, vomiting, diarrhea, abdominal pain, and chest pain. Fever usually lasts for one to two weeks. Weight loss can occur and persist for some time. Thirty to fifty percent of patients with a symptomatic infection will develop pneumonia. In addition, a majority of patients have abnormal results on liver function tests and some will develop hepatitis. In general, most patients will recover to good health

within several months without any treatment. Only 1–2% of people with acute Q fever die of the disease [15].

10. *Salmonella typhi.* This bacterium causes the life-threatening disease typhoid fever in humans. *S. typhi* infects only humans. Persons with typhoid fever carry the bacteria in their bloodstream and intestinal tract. In addition, a small number of persons, called *carriers*, recover from typhoid fever but continue to carry the bacteria. Both ill persons and carriers shed *S. typhi* in their feces [16].
11. *Shigella spp.* The Shigella bacterium causes dysentery, or shigellosis. It is characterized by diarrhea, abdominal pain, and bloody stools. The bacteria are transmitted through a fecal–oral route and are commonly seen in countries with poor sanitation. The disease is spread by those with active infections and by asymptomatic carriers. Shigellosis outbreaks are not uncommon, often associated with insufficiently treated recreational waters. *Shigella* are 99% inactivated by 0.05 mg/l chlorine and ultraviolet radiation [11].
12. *Francisella tularensis.* This bacterium causes the potentially serious disease tularemia. *F. tularensis* has been weaponized as an aerosol and is of concern as an agent for intentional contamination of water [11]. Symptoms may vary depending on the route of exposure but may include sudden fever, chills, headaches, diarrhea, muscle aches, joint pain, dry cough, pneumonia, ulcers, swollen glands, painful eyes, and progressive weakness. Tularemia is treatable with antibiotics [17]. *F. tularensis* is a hardy microbe that can thrive and multiply in water and mud. It is sensitive to heat but resistant to freezing. Studies on inactivation with chlorine have yielded mixed results [11].
13. *Rickettsia prowazekii.* It is a rickettsial bacterium, which causes epidemic typhus and Brill–Zinsser disease. Brill–Zinsser disease is a mild form of epidemic typhus. It occurs when the disease reactivates in a person who was previously infected. It is more common in the elderly [18]. *R. prowazekii* may be aerosolized, although there is no history of its use as a weapon or as an agent for intentional contamination of water supplies [11]. *R. prowazekii* is heat sensitive (50°C) and is inactivated by 1% sodium hypochlorite [11].
14. *Enteric viruses.* These are commonly transmitted by the fecal–oral route and although not documented as having been weaponized, they may be potable water threats. Symptoms of enteric viral infections include vomiting, abdominal distress, diarrhea, and dehydration. Fatality is rare among healthy adults. Enteric viruses may persist for 8–32 days in surface waters and >64 days in tap water. Enteric viruses are sensitive to chlorine and may be treatable through common municipal water treatment practices [11].
15. *Viral Hemorrhagic Fevers (VHF).* These result in a number of viral illnesses, including Ebola, Congo fever, Lassa fever, Marburg fever, and others that result from exposure to several different viral families. There is some evidence that these viruses have been weaponized, but no indication of intentional contamination of water sources has been documented [11]. Specific signs and symptoms vary by type of VHF, but initial signs and symptoms often include marked fever, fatigue, dizziness, muscle aches, loss of strength, and exhaustion. Patients with severe cases of VHF often show signs of bleeding under the skin, in internal organs, or from body orifices such as the mouth, eyes, or ears. Some types of VHF are associated

with renal (kidney) failure [19]. VHFs are sensitive to heat in excess of 56°C and are inactivated by UV light, 1–2% sodium hypochlorite, and/or 1% iodine [11].

16. *Variola major.* This is a viral disease more commonly known as *smallpox*. It is known to have been weaponized as an aerosol. Its use as an agent to contaminate water is not documented [11]. Before 1980, the smallpox vaccine was administered to the general public. Through the immunization program the disease was eradicated. Variola major virus supplies are now limited to research laboratories. It is unknown whether Variola virus is transmissible through water, but it can be inactivated by 1% sodium hypochlorite [11].
17. *Cryptosporidium parvum.* It is a protozoan, which is a common water contaminant associated with livestock waste. Although not previously used as a weapon, it is highly infectious, easily obtained, and readily transmissible in water and thus a concern for use as an agent of intentional contamination [11]. Crypto, as the illness is commonly called, is easily spread through the fecal–oral route. It is one of the most common waterborne illnesses associated with both contaminated drinking and recreational waters. The parasite lives in the host intestine and is discharged through the feces. A thick outer shell (oocyst) protects the protozoan and allows it to be persistent outside the host. Crypto can be transmitted by swallowing contaminated water or particles that have come into contact with contaminated surfaces. Crypto may be asymptomatic in some people, while others will suffer intestinal cramping, diarrhea, vomiting, fever, and aches. It is generally not fatal in healthy populations [20]. *C. parvum* oocysts are stable in water for days or more, but are heat sensitive and can be inactivated by boiling. The oocysts are highly resistant to chlorine-based disinfection and to chlorine dioxide. UV light systems of an advanced design have achieved $>4$ $\log_{10}$ inactivation of *C. parvum* oocysts. *Cryptosporidium* is an emerging pathogen for which disinfection regimens are still being developed [11].
18. *Aflatoxins.* These are naturally occurring biotoxins produced by many species of *Aspergillus*, a fungus, most notably *Aspergillus flavus* and *Aspergillus parasiticus*. Aflatoxins are toxic and carcinogenic. Aflatoxins have been weaponized although there is no documentation of their use as a water contaminant. Aflatoxins produce acute necrosis, cirrhosis, and carcinoma of the liver in a number of animal species. No animal species is resistant to the acute toxic effects of aflatoxins; hence, it is logical to assume that humans may be similarly affected. For most species, the lethal dose of aflatoxin ranges from 0.5 to 10 mg/kg body weight. The symptoms described are produced by an average intake of 2–6 mg/day of aflatoxins. Aflatoxins have limited water solubility and are probably heat stable. They are probably chlorine tolerant under normal disinfection conditions, but this needs to be determined [11].
19. *Cyanobacterial toxins (Microcystins, Anatoxin A).* These are powerful toxins produced during cyanobacterial blooms. Cyanobacteria have potential for weaponization through aerosolization but may also impact water supplies. The symptom of Anatoxin A poisoning is acute respiratory distress, whereas Microcystins are a liver toxin. These biotoxins are known, respectively, as the *fast* and *very fast death factors*. Alum flocculation, filtration, and chlorination are ineffective in the removal of cyanobacterial toxins, water purifiers containing carbon, ion exchange resin, and silver may be partially effective, whereas reverse osmosis was completely effective [11].

20. *Botulinum toxins.* These are produced by the bacteria *Clostridium botulinum*, which are commonly found in soils. Botulinium toxins have been weaponized as aerosols. Because of the quantities needed, it is unlikely that they would be used to contaminate a large water source, but they have potential to contaminated smaller supplies. The most common and lethal exposure route for botulinium toxin is ingestion, although dermal forms are on the rise due to intravenous drug use. Symptoms include double vision, blurred vision, drooping eyelids, slurred speech, difficult swallowing, dry mouth, and muscle weakness. If untreated, paralysis of the arms, legs, trunk, and respiratory muscles may occur. Death results from suffocation. Botulism toxins are inactivated by sunlight and exposure to air, heat, and chlorine. The toxins can be removed from water using reverse osmosis and possibly charcoal filtration [11].
21. *Ricin.* It is derived from castor beans and has been used throughout history as an assassin's poison. Ricin is easily produced in small quantities. Ricin poisoning can occur through inhalation, ingestion, or dermal contact, with inhalation and ingestion being the most serious. Inhalation results in severe respiratory distress, fever, and nausea. Ingestion results in vomiting, diarrhea, with possible liver, kidney, and spleen failure. There is no antitoxin for ricin [21]. Ricin can be inactivated by relatively high levels of chlorine (100 mg/l). It is removed from water by reverse osmosis and may possibly be removed by carbon filtration [11].
22. *Saxitoxin.* This toxin is the cause of paralytic shellfish poisoning and is produced by the marine dinoflagellate *Gonyaulax*, among others. Paralytic shellfish poisoning is typically encountered through ingestion of shellfish that have fed on *Gonyaula*, whose toxin accumulated in the fish. There is indication, however, that saxitoxins have also been isolated for use as an intentional poison. Saxitoxins are water soluble but can be inactivated by a strong chlorine solution (100 mg/l). Almost completely can be removed by reverse osmosis, whereas only partially removed by charcoal filtration [11].
23. *Staphylococcal enterotoxins.* These are toxins produced by bacteria such as *Staphylococcus aureus*. Staphylococcal enterotoxins have been weaponized and are of concern from both an ingestion and inhalation route. Ingestion results in gastrointestinal pain, vomiting, and diarrhea. Inhalation results in respiratory distress and fever. Poisoning is not fatal in healthy populations, but is incapacitating for a period of weeks. The toxin is heat sensitive and can be removed from water by carbon filtration [11].
24. *Mycotoxins: T-2.* It is isolated from cereal grains infected with the fungi *Fusarium*. Ingestion of mycotoxin could be life threatening. Unconfirmed and controversial findings suggest that mycotoxins were used as biological warfare agents in Laos, Cambodia, Afghanistan, and Iraq, thus weaponization is possible. Topical exposure causes blistering and skin necrosis. Sublethal effects of ingestion include lightheadedness, nausea, vomiting, and diarrhea.

    Mycotoxins are stable in water for a week, possibly longer, and are resistant to chlorine and iodine. The toxin is removed from water by reverse osmosis. Treatment by charcoal filtration should be effective [11].

## A.2 CHEMICAL AGENTS OF INTEREST

Included in this section is general information on chemical agents that have been used or considered for use in warfare. Chemical warfare agents are generally categorized into three groups: choking agents, nerve agents, and tissue-damaging (blistering) agents.

### A.2.1 Choking Agents

The most often considered choking agents are chlorine and phosgene. Exposure to these choking agents occurs most commonly through inhalation. The agents react with the water in the body to form hydrochloric acid: a strong acid that causes irritation and burning. Additional cell damage occurs through acylation of nucleophiles and lipid oxidation, by which free radicals "steal" electrons from the lipids (fats) in cell nucleus membranes. Chlorine reacts with water quickly, thus symptoms of chlorine exposure occur quickly. Phosgene reacts more slowly, thus symptoms could be delayed up to 48 hours. Symptoms of exposure to choking agents include

- coughing
- burning sensation in the throat and eyes
- watery eyes
- blurred vision
- difficulty breathing or shortness of breath
- nausea and vomiting.

Skin contact can result in lesions similar to those from frostbite or burns. Following exposure to high concentrations of phosgene, a person may develop fluid in the lungs (pulmonary edema) within 2–6 hours [22]. Phosgene has an odor similar to that of freshly mown hay and may be less noticeable or offensive, thus less likely to discourage consumption. Hydrolysis of phosgene, however, occurs quickly, thus it would not be a persistent contaminant in water [23].

### A.2.2 Nerve Agents

Nerve agents derive their name from their mode of action in the human body. They are organophosphorus compounds and are divided into two chemical families: the "G-agents" (e.g. tabun, sarin, and soman), named after the Germans who first created them, and the "V-agents", or venomous agents, (e.g. VA, VG, and VX). The V-agents were synthesized post-WWII, while the G-agents were manufactured during the war. Nerve agents can be dispersed as liquids or in aerosol form, allowing them to be inhaled, ingested, or absorbed through the skin. The most important chemical reactions involving nerve agents, particularly with respect to contaminated water treatment, take place directly at the phosphorus atom. The P–X bond is easily broken by nucleophilic reagents, such as water or hydroxyl ions (alkali). In aqueous solution at neutral pH, the nerve agents decompose slowly, whereas the reaction is greatly accelerated following the addition of alkali. The result is a nontoxic phosphoric acid.

The formation of the nontoxic phosphoric acid is also accelerated by a rise in temperature or by a catalyst (e.g. hypochlorite ions from bleaching powder). This hydrolysis forms the basis of most decontamination procedures using decomposition. In general, an area exposed to G-agents gets decontaminated through natural processes within a few days. However, V-agents may remain on the ground for several weeks because of their greater stability with respect to water and their much lower volatility. At pH levels between 7 and 10, VX is transformed into an extremely nonvolatile product of hydrolysis, which is incapable of penetrating skin [24].

### A.2.3 Blister Agents

Blister agents, or vesicants, are cytotoxic alkylating compounds. The most widely known of the blister agents is "mustard" or "mustard gas" (military designator: H). Other blister agents are sulfur mustard (HD), nitrogen mustard (HN), Lewisite (L), an arsenic containing vesicant, and phosgene oxime (CX). Phosgene oxime is a halogenated oxime with very different properties from those of the other agents.

**BOX A.1 EXAMPLES OF VESICANT OR BLISTER AGENTS WITH MILITARY DESIGNATORS IN PARENTHESES**

1. mustard or mustard gas (H);
2. sulfur mustard (HD), characterized by delayed action;
3. sulfur mustard with agent T (HT), the latter is bis-2-(2)-chloroethylthioethyl ether, similar to HD in structure;
4. nitrogen mustard (HN);
5. lewisite (L), similar to sulfur mustard in action, except immediate effects occur within minutes;
6. mixture of mustard and lewisite (HL), the combination of sulfur mustard (37%) with lewisite (63%) gives it a garlic odor;
7. phenyldichloroarsine (PD), like lewisite, is an organic dichloroarsine
8. phosgene oxime (CX), a pulmonary toxin with vesicant effects [25].

The mustard gases and lewisite are highly insoluble. Sulfur mustard quickly degrades to less toxic chemicals in agitated water [26], such as would occur in a distribution system. The rate of degradation of the mustard gases in water increases with heating. Similarly, degradation of nitrogen mustards in water with 90–95% hydrolysis is expected within 24 hours [27]. Although the persistence of lewisite in the environment is not well studied, it is known to lose its blistering properties in water. Phosgene oxime, unlike the other blister agents, is highly (70%) soluble in water. Although produced, it has never

been used in warfare, thus limited information is available. It is degraded by bacterial action in water over a few days [28].

## A.3 INDUSTRIAL CHEMICALS AND MATERIALS OF INTEREST

The following chemical information is from EPA's Planning for and Responding to Drinking Water Contamination Threats and Incidents [29]. The table includes information on chemical contaminants, both inorganic and organic, that potentially have an adverse impact if introduced into the drinking water supply. This is not an exhaustive list of chemicals, and there may be many others that could be used to contaminate a water supply. Additional information is provided for classes and/or constituents that may be of concern for terrorist use. These constituents are highlighted in Table A.1.

### A.3.1 Heavy Metals

Living organisms require trace amounts of some heavy metals, including iron, cobalt, copper, manganese, molybdenum, vanadium, strontium, and zinc, but excessive levels can be detrimental. Other heavy metals such as mercury, lead, and cadmium (with one exception for the latter) are toxic metals—they have no known vital or beneficial effect on organisms, and their accumulation over time in the bodies of mammals can cause serious illness. Toxic metals are metals that form poisonous soluble compounds and have no beneficial biological role. Often heavy metals are considered synonymous with toxic metals, but lighter metals also have toxicity. Toxic metals imitate the action of an essential element in the body, distorting the metabolic process to cause illness. The toxicity is a function of solubility, so that as insoluble salts or in the metallic form, toxic metals may have negligible toxicity [30]. Lead, osmium, and mercury are the toxic metals of greatest concern with respect to terrorist attacks. There are several methods for removing heavy metals from water:

- ion exchange
- specialized sorbents
- novel membranes
- precipitation
- electrokinetic processes
- phytoremediation [31].

### A.3.2 Arsenite Compounds

Arsenic (As) exists in the soil environment as arsenate, As(V), or as arsenite, As(III). Although arsenate is more common, arsenite is more toxic. Arsenite compounds are 4–10 times more soluble than arsenate compounds. Arsenic compounds occur in water as a result of both natural processes, such as weathering of arsenic minerals, and anthropogenic activities, including mining, industrial waste discharge, and application of arsenic herbicides and pesticides. Several treatment options are available for the removal of arsenic

**TABLE A.1 Chemical Contaminants, Their Availabilities, and Restrictions**

| Class | Examples (Not Exhaustive) | Sources | Limited Access? |
|---|---|---|---|
| | Inorganic chemical contaminants | | |
| Corrosives and caustics | Toilet bowl cleaners (hydrochloric acid), tree-root dissolvers (sulfuric acid), and drain cleaners (sodium hydroxide) | Retail and industry | No |
| Cyanide salts or cyanogenics | Sodium cyanide, potassium cyanide, amygdalin, cyanogen chloride, and ferricyanide salts | Supplier and industry (especially electroplating) | Yes |
| Metals | Mercury, lead, osmium, their salts, organic compounds, and complexes (even those of iron, cobalt, copper are toxic at high doses) | Industry, supplier, and laboratory | Yes[a] |
| Nonmetal oxyanions, organo-nonmetals | Arsenate, arsenite, selenite salts, organoarsenic, and organoselenium compounds | Some retail, industry, supplier, and laboratory | Yes[b] |
| | Organic chemical contaminants | | |
| Fluorinated organics | Sodium trifluoroacetate (a rat poison), fluoroalcohols, and fluorinated surfactants | Supplier, industry, and laboratory | Yes |
| Hydrocarbons and their oxygenated and/or halogenated derivatives | Paint thinners, gasoline, kerosene, ketones (e.g. methyl isobutyl ketone), alcohols (e.g. methanol), ethers (e.g. methyl *tert*-butyl ether, MTBE), and halohydrocarbons (e.g. dichloromethane, tetrachloroethene) | Retail, industry, laboratory, and supplier | No |
| Insecticides | Organophosphates (e.g. malathion), chlorinated organics (e.g. dichloro-diphenyl-trichloro-ethane (DDT)), carbamates (e.g. Aldicarb), and some alkaloids (e.g. nicotine) | Retail, industry, and supplier (varies with compound) | Yes |
| Malodorous, noxious, foul-tasting, and/or lachrymatory chemicals | Thiols (e.g. mercaptoacetic acid and mercaptoethanol), amines (e.g. cadaverine and putrescine), and inorganic esters (e.g. trimethylphosphite, dimethylsulfate, and acrolein) | Laboratory, supplier, police supply, and military depot | Yes |

| | | | |
|---|---|---|---|
| Organics, water-miscible | Acetone, methanol, ethylene glycol (antifreeze), phenols, and detergents | Retail, industry, supplier, and laboratory | No |
| Pesticides other than insecticides | Herbicides (e.g. chlorophenoxy or atrazine derivatives) and rodenticides (e.g. superwarfarins, zinc phosphide, $\alpha$-naphthyl thiourea) | Retail, industry, agriculture, and laboratory | Yes |
| Pharmaceuticals | Cardiac glycosides, some alkaloids (e.g. vincristine), antineoplastic chemotherapies (e.g. aminopterin), and anticoagulants (e.g. warfarin). Includes illicit drugs such as lysergic acid diethylamide (LSD), phencyclidine (PCP), and heroin | Laboratory, supplier, pharmacy, and some from a natural source | Yes |

[a]Availability may be commercially limited for the more toxic metals, especially the heavy metals, which can be quite expensive. Iron and copper are readily available, but not usually in soluble (bioavailable) forms.

[b]Availability of arsenicals and selenium compounds in the retail sector has been reduced owing to environmental regulations, but such products can occasionally be found as part of older inventories of merchandise, especially in small-town hardware stores. Supplies of such materials may generally be too small to cause concern.

from water: zero valent iron has been found to have the ability to simultaneously remove As(V) and As(III) compounds in water [32]. Dried water hyacinth plant roots prepared to a fine powder can remove more than 93% of As(III) and 95% of As(V) from a solution containing 200 μg of arsenic per litre within 60 minutes of exposure [33]. The use of titanium oxide ($TiO_2$) photocatalysis is attractive for the treatment of arsenic contaminated water [34].

### A.3.3 Carbamate and Organophosphate Pesticides

The word "organophosphates" (OPs) refers to a group of insecticides or nerve agents derived from phosphoric acid esters that act as inhibitors of the enzyme cholinesterase. The pesticide group carbamates (CMs) also act on this enzyme. CM and OP pesticides are widely used in homes, gardens, and agriculture. They are pesticides that can bind, or inhibit, acetylcholinesterase, making it unable to breakdown the neurotransmitter acetylcholine, resulting in paralysis and eventually death. Methods for removing OP and/or CM pesticides from water/ground water include the following:

- Bioremediation/biodegradation (live microbes—example carbofuran-metabolizing *Pseudomonas* sp.) [35].
- Enzymatic bioremediation (alternative to live microbes).
- Phytoremediation: for moderately water soluble organic contaminates, it may be possible to use plant species that can translocate and metabolize a contaminant within their shoots. For highly lipophilic compounds, a phytoremediation strategy would best focus on stimulation of biodegradation within the root zone of plants.
- Natural attenuation.
- Sulfuric acid treatment [36].
- High-performance liquid chromatography [37].

### A.3.4 Herbicides

Modern agriculture production practices rely heavily on the use of herbicides to control weed populations. Atrazine and simazine are widely used herbicides for the control of broadleaf weeds in corn, sorghum, sugarcane, and other crops. Because of their widespread use for over 50 years, these s-triazine herbicides are often detected in ground water, sediments, and soils at levels exceeding the maximal concentrations set by the EPA. Pesticides impact drinking water through leaching to ground water and discharge to surface water. Surface water discharge includes overland transport of storm water runoff and contributions from tile drains. Herbicides may be removed from water through the following treatment processes:

- bioremediation/biodegradation (live microbes/*in situ* treatment)
- carbon adsorption
- photodecomposition (sunlight breakdown) [38]

- air stripping
- reverse osmosis or ultrafiltration.

### A.3.5 Rodenticides

Rodenticides are a category of chemicals used in pest control intended to kill rodents. There are three common types of rodenticides: anticoagulants, metal phosphides, and hypercalcemia. Fatal internal bleeding is caused by doses of anticoagulants such as brodifacoum, coumatetralyl, and warfarin. Metal phosphides have been used as a means of killing rodents and are considered single-dose, fast-acting rodenticides (death occurs commonly within 1–3 days after single-bait ingestion). The acid in the digestive system of the rodent reacts with the phosphide to generate the toxic phosphine gas. Hypercalcemia such as calciferols (vitamins D), cholecalciferol (vitamin $D_3$), and ergocalciferol (vitamin $D_2$) are used as rodenticides. They are toxic to rodents and if the dose of the toxin is high enough, it leads to death. Treatment methods of rodenticides typically include

- bioremediation/biodegradation (live microbes/*in situ* treatment) [39]
- carbon adsorption
- air stripping
- reverse osmosis or ultrafiltration.

## A.4 RADIOACTIVE CONTAMINANTS OF INTEREST

Terrorist organizations may use radioactive substances in a number of ways, as part of radiological dispersion devices (RDD) and improvised nuclear devices (IND) radioactive substances may also be directly injected into a water supply. Of these modes of attack, the IND has the potential to result in the most destruction. An IND requires nuclear material such as highly enriched uranium or plutonium and through detonation causes an explosive chain reaction. An RDD, by contrast, does not result in the generation of radiation but disperses radiological particles. Most damage would result from the initial blast; however, radiological particles could contaminate buildings, outdoor areas, and water supplies. An RDD attack is considered more probable than an IND attack because little technical knowledge is needed to construct the devices and the materials are more readily available. The probability of direct injection of radionuclides into water supplies is low due to the relative difficulty in obtaining radiological agents compared with chemical or biological agents. There are, however, some radionuclides that are toxic in very low doses and are therefore discussed in this article.

### A.4.1 Cesium 137

It is produced when uranium or plutonium absorbs neutrons and undergoes fission. Examples of the uses of the fission process are nuclear reactors and nuclear weapons. The

splitting of uranium and plutonium atoms creates numerous fission products. Cesium-137 is one of the more well known of these products [40]. As cesium-137 undergoes radioactive decay, both $\beta$ particles and $\gamma$ rays are emitted. Cesium-137 decays to barium-137, a short-lived decay product, which in turn decays to a nonradioactive form of barium. The major radiation dose, which associates with cesium-137, is actually from the barium-137. The half-life of cesium-137 is 30.17 years. Cesium is soluble and moves easily through the environment. Its persistence and solubility makes the cleanup of cesium-137 difficult [40].

### A.4.2 Strontium 90

It is another radioactive product of nuclear fission. It has a half-life of 29 years and thus will persist in the environment. It is mobile in the environment and is therefore a potential threat in water. Strontium-90 decays to yttrium-90, emitting $\beta$ particles in the process. Unlike $\gamma$ rays, which can easily penetrate the body, $\beta$ particles are significantly blocked by the dermis and therefore present the greatest risk to health when ingested or inhaled. Ingestion is the most common route of exposure to Strontium-90. In the body, Strontium-90 behaves much like calcium, concentrating in bone and bone marrow. Bone tumors and tumors of the blood-cell forming organs are the main health concern. These tumors result from exposure to the $\beta$ particles emitted during the radioactive decay of strontium-90 and yttrium-90 [41].

KEN THOMPSON
*CH2M HILL, Englewood, Colorado*

## 1 RISK MITIGATION

To mitigate risks, United States (US) water systems typically use one or more of the following general approaches:

- adding physical protection systems (PPSs), equipment, or hardware;
- developing security policies/procedures;
- modifying management and staffing practices.

If utilities cannot mitigate risks through one or more of these means, then the other options they have used are to accept the risk as a cost of doing business or to reduce the risk by buying insurance.

## 2 PHYSICAL PROTECTION SYSTEMS

PPSs have included perimeter hardening improvements, such as fences or gates, and electronic security systems, such as card access or camera surveillance systems. However, not all security systems that have been installed have been effective. An effective PPS must include elements of deterrence, detection/assessment, delay, and response. These elements are described below.

*This article gives an overview of current security practices observed at public water systems in the United States. It covers risk mitigation, cyber security and contamination warning systems.

### 2.1 Deterrence

Deterrence is the capability to discourage an adversary from attempting to perform a malevolent act against a facility. Deterrence can be accomplished in one or more ways, including:

- well-maintained fencing or walls that present an imposing presence;
- presence of signage that indicates prosecution if trespassing occurs;
- good lighting;
- visual observation by persons or passing vehicles;
- high visibility of security guards.

Deterrence is difficult to quantify for high consequence, low frequency events such as a major bomb attack or large scale assault. It may be impossible to determine if the absence of a major attack is because of the deterrent effect of an effective PPS or whether no adversary would contemplate an attack even if a facility had been left completely unprotected.

### 2.2 Detection/Assessment

In the event that an adversary is not deterred and does attempt to enter a facility to carry out theft, sabotage, or other malicious activity, the next best option for the PPS is to defeat the adversary's attempt. This requires the detection of the intrusion attempt and holding back the intruder while there is still sufficient time to take an appropriate response. For high consequence events, an appropriate response requires the arrival of law enforcement personnel capable of stopping the adversary before the adversary has completed the malevolent act. In the case of low consequence events such as minor theft or vandalism, it may be adequate to allow the malevolent act to occur as long as the system obtains a video record of sufficient quality to allow subsequent identification and prosecution of the criminal.

*2.2.1 Detection/Assessment Systems.* The first line of defense is the discovery of an adversary attack. This involves the following events depicted in Figure 1:

- An abnormal occurrence is detected (through either a sensor or personnel) and an alarm is initiated.
- The sensor and assessment subsystems report and display information.
- Someone assesses this information and determines whether the alarm is valid.

An effective assessment system provides two types of information associated with detection: (i) whether the alarm is a valid or a nuisance alarm and (ii) the cause of the

**FIGURE 1** Detection sequence diagram.

alarm (that is, what, who, where, how many) so that the appropriate response may be initiated.

The effectiveness of the detection function is measured by the probability of sensing adversary action and the time required for reporting and assessing the alarm.

Examples of detection and assessment system components used by US water systems include the following:

- *Observation by personnel*, including neighbors, staff workforce, or security guards/law enforcement personnel.
- *Intrusion detection sensors*, such as fence disturbance, door position, glass-breakage, buried line, microwave, active-and-passive infrared, and video motion analytic systems.
- *Timely assessment*, preferably using closed-circuit television (CCTV) with instant playback of pre- and post-alarm images of the area associated with the intrusion alarm. Personnel may also be used for assessment, but that option is frequently much more expensive to provide reliable timely detection on par with CCTV.
- *Access control* using photo badges, card readers, personal identification numbers (PINs), and possibly biometrics such as a hand-geometry reading. The entry points used by the workforce represent places where an adversary could gain entry, bypassing the other elements of the PPS detection system; the ability of the access control system to identify unauthorized entry attempts is a component of the detection and assessment system.

***2.2.2 Delay Systems.*** Delay is the function of slowing the adversary on his or her way to the target. It is important to note that delay devices placed before any opportunity for detection are of little value. An intruder not faced with detection has all the time required to climb a fence or cut a lock. When the penetration has been detected and a response initiated, any delay facing the adversary gives the response force more time to successfully interrupt the threat.

Following are examples of delay system components used by US water systems:

- *Locks*, which must be shielded so that they cannot be easily defeated. This includes strengthening of door jambs to prevent mechanical spreading, and placement of metal guards to prevent prying of the latch.
- *Long distances* to be traversed, especially if traversing must be accomplished without a vehicle.
- *Barriers* of various types such as fences, walls, doors, and sturdy metal screens over windows.
- *Activated delays* such as pop-up vehicle barriers, automated lockdown of doors, and smoke or aqueous foam dispensers.

***2.2.3 Response Systems.*** Response is the time required by the security force (e.g., police or other law enforcement officers) to prevent adversarial success. Response includes both interrupting and stopping the adversary. The measure of response effectiveness is the time between receiving a communication of adversarial action and interrupting it with sufficient capability to stop the adversary. The effectiveness measures include the probability of accurate communication, the time required to communicate,

and the response force engagement effectiveness. An effective security system must be able to detect the adversary early enough that the adversary has not had time to cause the undesired event, delay the adversary long enough for the response to arrive, and stop the adversary before his or her mission is accomplished. If the design basis threat (DBT) includes a potential terrorist threat, any response force must be armed and have sufficient numbers to have a capability to stop the threat. DBT is defined as the adversary against which a utility must be protected. Determining the DBT requires consideration of the threat type, tactics, mode of operations, capabilities, threat level, and likelihood of occurrence. (*Source: ASCE/AWWA Draft American National Standard for Trial Use, Guidelines for the Physical Security of Water Utilities, December 2006).*

The PPS must perform the functions of detection, delay, and response in a period of time that is less than the time required for an adversary to complete his or her tasks. This relationship is shown in Figure 2. Security master plans developed for US utilities typically utilize the analysis described below.

As seen on this diagram, the adversary faces certain tasks (which equate to time) to get to the target area. In this example, the adversary must climb a fence, run to the transformers, open the drain valves, set the ignition sources, and leave before the fires occur. This total time is shown as the "adversary task time."

The "system delay" is the total delay time that the present security system provides from the time of first detection. "PPS time required" is the total time that the present system provides for detection, assessment, and response.

Because the system delay after detection time is greater than the time required to detect and respond to the intrusion, the PPS will be successful in interrupting the adversary.

Figure 3 shows what would happen if the first detection opportunity (perhaps a fence motion sensor) were moved to the transformer area. The adversary has a reduced remaining task time because he or she has already climbed the utility area fence before detection. Because the first alarm is now at the transformer area and the time required for detection and response will remain the same, the two boxes representing these functions must be

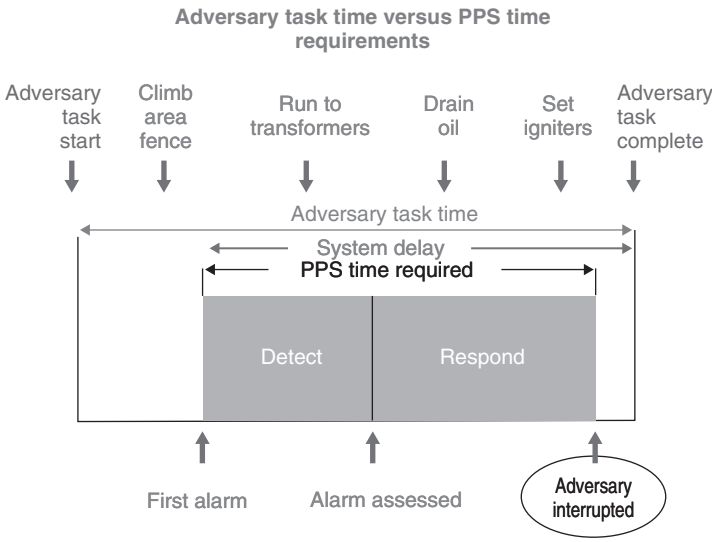

**FIGURE 2** Adversary task time versus PPS time requirements for a successful PPS.

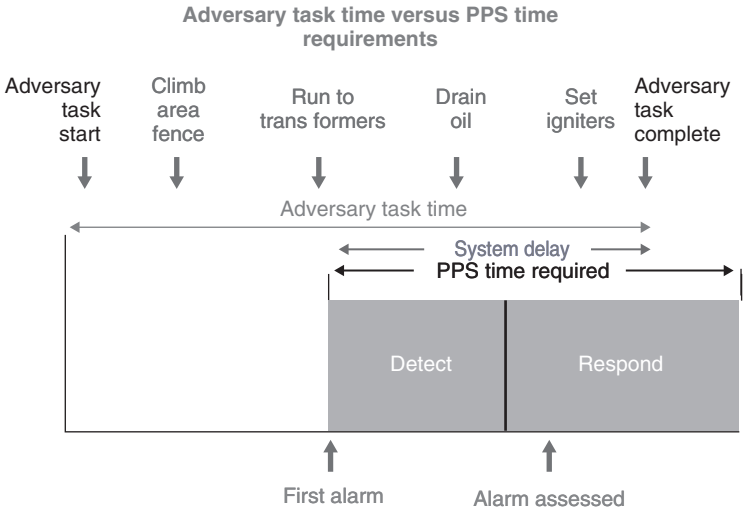

**FIGURE 3** Adversary task time versus PPS time requirements for an unsuccessful PPS.

shifted to the right on the timeline as shown. The PPS is now ineffective against the same adversary, because the adversary completes the effort before the response.

## 3 METHODOLOGIES FOR IDENTIFYING PHYSICAL PROTECTION SYSTEMS

To effectively identify appropriate physical protection measures and systems, a systematic methodology is necessary. Because it is rarely feasible to provide all assets or facilities with the same level of protection, it is necessary to identify those assets that are critical for the system to continue functioning and then prioritize security upgrades and/or modify policies and operational procedures to mitigate identified risks. This way, a balanced security program can be developed with the most appropriate resources allocated where they are most needed.

### 3.1 American Society for Industrial Security

The American Society of Industrial Security (ASIS) has developed the following methodology for identifying and evaluating PPSs, illustrated in Figure 4. This approach is used in security master plans developed for some US water utilities.

1. *Identify assets.* Determine the groups, core business organizations, equipment, buildings, vehicles, or other assets at risk.
2. *Specify loss events.* Identify loss events or vulnerabilities. These might include damage or destruction of equipment, harm or assault to employees, etc.
3. *Frequency of events.* Review and determine the probability of loss risk and frequency of events based upon consideration of prior incidents, trends, warnings, etc.

4. *Impact of events.* Evaluate the costs associated with the loss of tangible (direct costs, such as financial) or intangible (indirect costs, such as psychological) assets of an organization.
5. *Options to mitigate.* Identify options available to prevent or reduce losses through security improvements, such as hardware, procedures, and policies.
6. *Feasibility of options.* Study the feasibility of implementing mitigation options that do not interfere with the key operations or profits of the business.
7. *Cost/benefit analysis.* Identify costs associated with the suggested mitigation options.

## 3.2 Additional Recommendations

***3.2.1 Start from Inside and Work Out.*** In addition to the ASIS methodology presented in Figure 4, CH2M HILL recommends that, when identifying potential delay measures for physical protection, utilities should begin at the interior of the facility at the critical assets and work outwards. Delay measures such as hardened walls, locks and barriers can be enhanced protection at a reduced cost if they are close to the asset being protected. For example, if an asset such as a generator needs to be protected from damage, it is more cost effective to provide protective fencing around the asset (the generator) instead of fencing an entire site.

***3.2.2 Balanced Layered Security.*** The most critical assets should be identified, and if possible, located or moved to the center core of the facility, with concentric rings

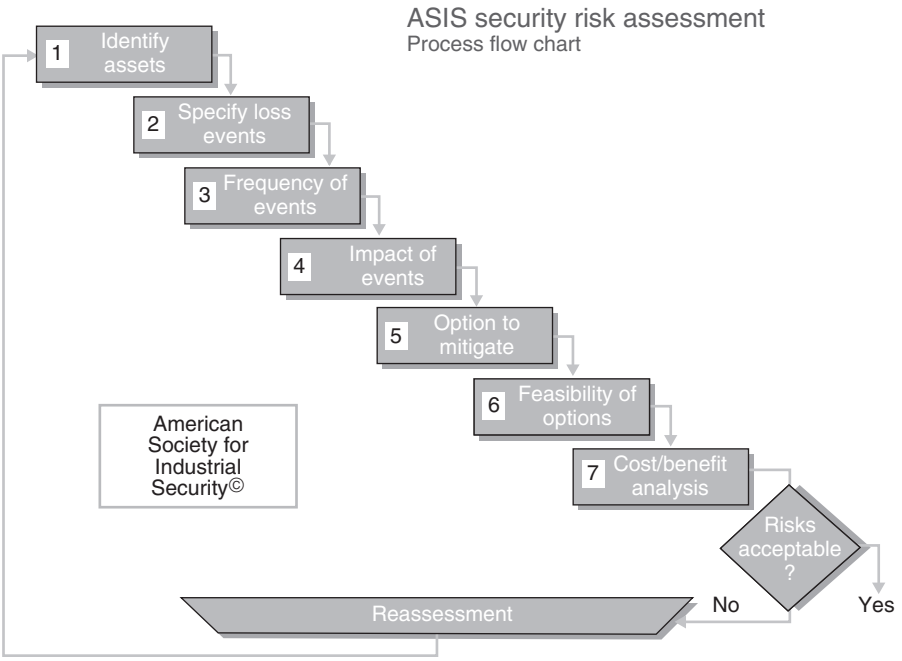

**FIGURE 4** ASIS general security risk assessment methodology. (Source: General Security Risk Assessment Guideline, 2003, American Society for Industrial Security.)

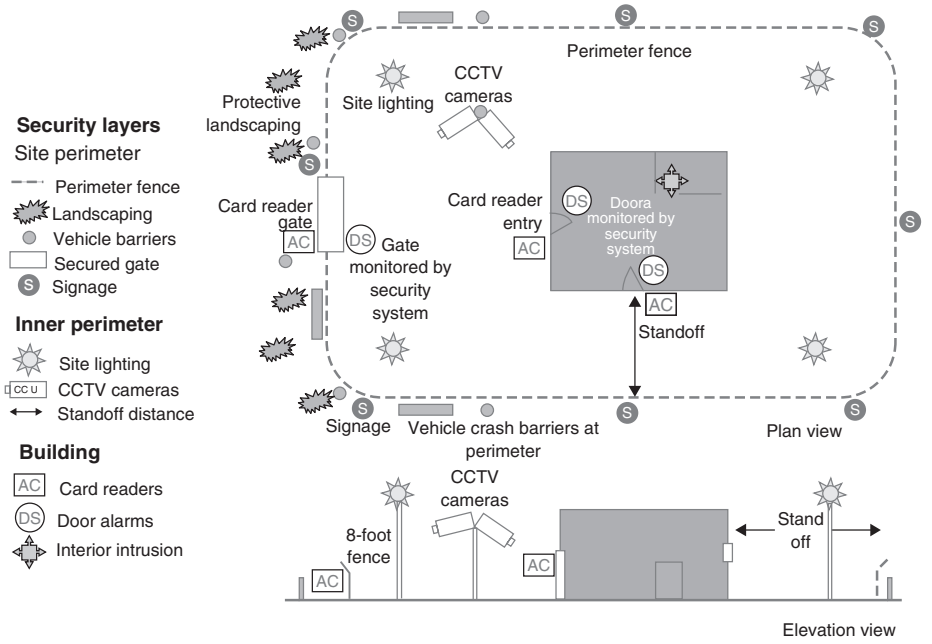

**FIGURE 5** Sample layered security recommendations for a facility.

of security protection provided around the asset as shown in Figure 5. Multiple layers of security will necessitate that the adversary must defeat each of these layers in order to carry out a successful attack. The use of multiple barriers requires more extensive preparation by the adversary and transportation of more breaching equipment, creates adversary uncertainty, and provides multiple opportunities for the adversary to fail in a successful breaching attempt.

### *3.2.3 Other Suggested Recommendations.*

- Utilities should implement a security procedure to identify when keys are not returned. This should include a policy to receive reports of lost keys on a regular basis and assess whether the locks should be re-keyed as a result of lost or stolen keys. Also, the work of security staff and lock technicians needs to be coordinated.
- In the case of an employee quitting or being terminated for cause, the vulnerability becomes higher and the utility should have a procedure in place to automatically secure facilities from access by this employee.
- Utility vehicles should be locked at all times, with keys removed from the vehicle and stored in a secure location. At service centers, the keys should be stored within the building and a sign-out procedure for vehicles should be implemented.
- Utilities should explore using shackle protection of their padlocks or consider hardening the padlock entry hinge. With time, an adversary could defeat the padlock system; hardening or protecting the padlock shackle will add more delay to the gate areas.

- Utilities should develop a policy for re-keying facilities on a regular periodic basis, such as every 5 years, or when a significant security breach or event occurs. To the broadest extent feasible, an electronic key system such as a card key or a pin-key product should be implemented.
- A corporate policy for dealing with temporary and contractor badges should be developed and adopted. The policy should include provisions for auto-expiration of visitor/contractor badges, limited access areas at facilities, limited available access time periods, and a requirement for mandatory two-person entry at critical areas. System auditing should be done on a periodic basis to identify outdated or missing temporary badges within the system.
- Utilities should develop a methodology for generating a variety of standard reports, including
  - card holders granted access through specified doors;
  - card holders attempting entry into unauthorized areas;
  - actions taken to acknowledge security alarms.
- Automatic reports should be defined and produced on a weekly basis for management review. Most card reader systems allow customized reports that can be automatically generated at scheduled intervals. These reports allow attempted breaches of security or other incidents be investigated properly and quickly.
- Some means of accurate intrusion detection, coupled with video assessment, should be provided at all critical facilities.
- It is critical that all perimeter doors be monitored for door forced-open alarm conditions. Balanced magnetic door contact switches interconnected to an intrusion alarm panel or to a monitoring system is a recommendation for all perimeter doors.

## 4 CYBER SECURITY

Cyber security is the protection of enterprise information systems from outside or inside attack. The reliance of a water utility on its automated systems can be substantial: the supervisory control and data acquisition (SCADA) system runs the plant, the financial system maintains fiscal equilibrium, and several other systems facilitate most business processes. In short, if the information systems do not work, the enterprise will not operate.

### 4.1 Cyber Security Vulnerabilities and Consequences

US water utilities have been vulnerable to cyber attacks from many points of entry. Gaining unauthorized entrance to an organization's information infrastructure is no longer the province of a small cadre of skilled intruders. The specific vulnerabilities of widely used platforms, like Microsoft Windows, are detailed on any number of websites. Inexpensive computers, anonymous Internet accessibility, and readily available hacking tools offer political and criminal organizations a potent tactical weapon.

The consequences of a compromised information system can have catastrophic repercussions to a utility. A penetrated financial system can result in lost revenue or stolen identity information from ratepayers, a sabotaged website has the potential to shake public trust, or interruption of the plant process because of SCADA malfunction can lead to service interruptions or water quality issues for the community. Effective cyber security

requires a balanced, planned approach that imposes standards across a broad range of technologies and personnel management.

### 4.2 Cyber Security Threats

There is no shortage of potential intruders to the enterprise from the Internet. For the purposes of the following cyber security discussions, intruders that have targeted water utility systems are as follows:

- *Outside attackers.* The primary goal of this group is unauthorized entry; their motivation is thrill-seeking, criminal opportunity, or political goals.
- *Inside attackers.* The primary goal of an inside attacker is to disrupt enterprise operations; their motivation is personal gain or vengeance.

The primary defense against outside attackers is both a robust anti-intrusion system, and security training for employees. A classic "low-tech" intrusion tactic called *social engineering*, where outsiders trick employees into revealing their user names and passwords over the telephone. The most effective deterrence against insider attack is a clearly articulated security policy, accompanying procedures, and noncompliance consequences.

### 4.3 Deterring Cyber Attack from the Outside

Cyber security addresses the need to ensure continuous functioning of the information systems serving the utility. Of special concern to water utilities is the SCADA system, whose distributed components autonomously maintain continuous operation of the various processes. Figure 6 gives an overview of the multiple vulnerability points of a typical SCADA system.

Cyber intruders have gained access to an enterprise network via one of three broad avenues:

- Internet
- Telephone system
- Wireless (including radio)

The following discussion outlines methods of preventing unauthorized entry from each avenue.

***4.3.1 Internet Intrusion.*** The outside hacker/attacker is most easily deterred at the firewall to the Internet. If no entry point is penetrable, the hacker will likely move on and choose an easier target. Internet access to the enterprise, however, is not always under the control of water utility Information Technology (IT) staff. In the cases of water departments in municipalities, it is common for the umbrella municipality to administer all security aspects of the Internet gateway.

No matter who administrates the Internet gateway, it is important for the utility to understand the standards that were used in developing security solutions. The Payment Card Industry (PCI) or Criminal Justice Information System (CJIS), for example, provide detailed configuration compliance requirements before allowing credit card payments or

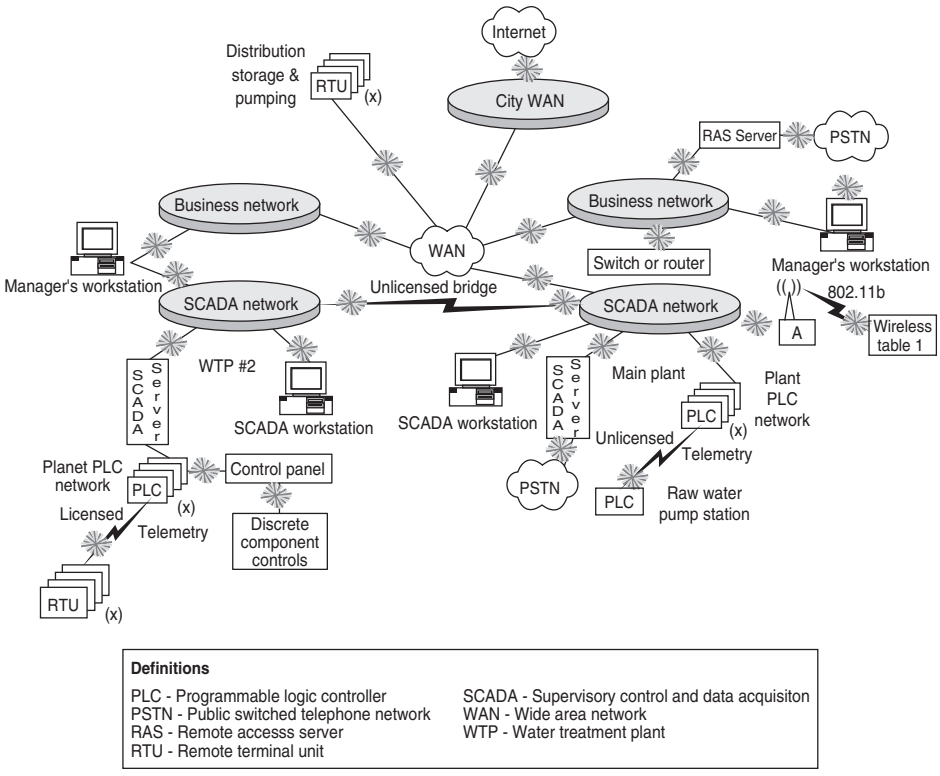

**FIGURE 6** Overview of SCADA system vulnerabilities.

storage of sensitive court documents. The National Institute of Standards and Technology (NIST) is currently the leading authority on providing SCADA system security guidelines (www.nist.gov); the SANS (SysAdmin, Audit, Network, Security) Institute (www.sans.org) provides similar guidelines for the business network.

Important internet intrusion prevention design elements include the following:

- *Intrusion prevention.* Install and monitor firewalls that employ "stateful packet inspection." For additional security, implement stateful packet inspection firewalls in combination with a "proxy server" firewall to provide a layered security approach. Conduct periodic penetration tests on the Internet firewall to uncover "open ports" commonly used by hackers.
- *Intrusion detection.* Install an Intrusion Detection System (IDS) at the Internet gateway and regularly audit IDS logs for evidence of unauthorized entry. An IDS can provide valuable information about intrusion attempts.
- *Access control.* Restrict general user access to critical applications via configuration of switches, routers, or internal firewalls. For example, segregate financial servers by locating them on a separate network segment with tightly restricted user access.

- *VPN access.* Employ a virtual private network (VPN) solution to ensure secure access to assets inside the enterprise from the Internet.
- *Hardened operating systems and applications.* Conduct server and workstation software audits to ensure the operating systems are "hardened" with the most current upgrades and security-related patches.

***4.3.2 Telephone System Intrusion.*** The most common method of telephone system intrusion is via dial-up modem. Many SCADA systems employ a modem to facilitate system maintenance by the vendor or utility IT staff. Traditionally, these modem connections have little or no security; they are an attractive target for "war-dialing," a common technique used by telephone hackers.

In addition, modems can be found attached to remote access servers (RAS) on the business network to facilitate employee dial-in. Finally, some employees occasionally install a personal modem to their workstation so they can access work from home. This last type of modem is difficult to track down and usually has no provisions for security. Design elements to reduce risk from the telephone system are as follows:

- *Modems.* Create policies designed to prevent the installation of unauthorized modems on enterprise equipment. Commercial phone-scanning software can usually identify modem connections not sanctioned by the utility. Turn off SCADA modems unless needed for remote troubleshooting or application updating by an authorized vendor representative. Configure modems to allow dial-up access from a restricted set of phone numbers. Use a timer to turn off modems after a preset period of time if not in use.
- *Telephone lines.* Telephone lines are sometimes used to connect to remote terminal units (RTUs) from the field. Consideration should be given to encrypting commands to prevent interference from attackers "tapping" into leased or owned phone lines.

***4.3.3 Wireless Intrusion.*** The explosion of wireless networking (or Wi-Fi) at home and in the workplace has created an enormous security risk for water utility network administrators. Many wireless installations in the workplace can exist without the knowledge of the IT group. These installations generally have little or no security and can be accessed by anyone within a large signal range.

- *Wi-Fi.* Configure authorized Wi-Fi access points to appropriate security and encryption levels. Minimize reception area by antenna type and placement. Use wireless detection software and hardware to identify unauthorized installations.

Many utilities rely on unlicensed radio transmission via 900 MHz radios to interact with remote SCADA components in the field. RTUs in the field exchange, monitor, and control information in "plain text." These unencrypted broadcasts can be intercepted and retransmitted with different—potentially harmful—information. Utilities should evaluate the following areas:

- *Unlicensed radio (900 MHz).* Encrypt radio traffic between RTUs (or programmable logic controllers (PLCs) with radio units) to master unit with scrambler/descrambler devices. As an alternative, modify or replace radios to take advance of more secure spread spectrum frequency-hopping transmissions.

- *Remote terminal units.* Provide hardened lockable enclosures for all remote control system units. Many of these units are in isolated areas with few protective measures to deter vandalism.

### 4.4 Deterring Cyber Attack from the Inside

The key to deterring inside attacks is a cyber security plan that seeks to minimize inadvertent or intentional damage to the SCADA system by employees and contractors. At the core of any security plan is an enforceable security policy and accompanying procedures that promote operational accountability and auditability. Several SCADA-specific security practices are as follows:

- *Separate the SCADA and business networks.* Isolate the SCADA network via firewalls or other networking devices that restrict network traffic to and from the business network. Figure 7 offers a simplified view of a SCADA network separated from the business network by a firewall.

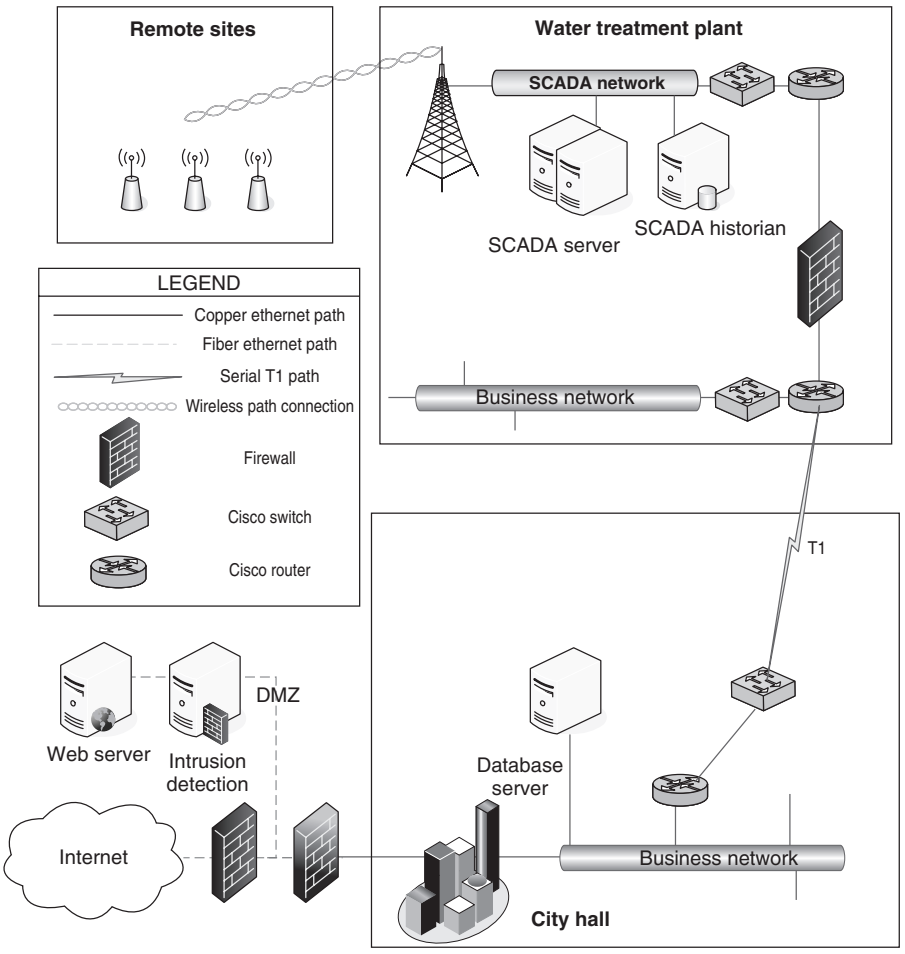

**FIGURE 7** Sample SCADA network separation diagram.

- *SCADA-specific policies.* Develop and post SCADA cyber security policies in control rooms. Immediately remove user accounts from the SCADA system upon termination of employees.
- *SCADA system passwords.* Require individual logon credentials to access the SCADA system. Enforce appropriate password-strength rules for user access (i.e., more "complex" passwords for administrators). Require a password to make software programming changes to RTUs/PLCs.
- *SCADA security guidelines.* Configure SCADA logon privileges to match responsibility levels. Maintain SCADA log files that associate user log-on credentials with actions and changes such as set points made to SCADA systems. Program set point ranges to reject potentially harmful out-of-range adjustments.
- *Physical security for SCADA.* Monitor access to the control room (and network/server room) with an entry system that stores information about who has entered and departed. Backup SCADA servers and programming workstations to tape every night and store appropriate tapes off site. Maintain SCADA infrastructure in environmentally appropriate facilities (with separate heating, ventilating, and air conditioning (HVAC), power redundancy, etc.).

## 5 CONTAMINATION WARNING SYSTEMS

After performing vulnerability assessments in 2002 and 2003, water utilities began to focus on the possible intentional or accidental contamination of their source and finished waters, a topic not addressed in the vulnerability assessments. Source waters can be easily contaminated due to unintended causes (agricultural runoff, accidental spills, etc.); however, treatment processes can reduce or eliminate the risk posed to consumers. On the other hand, the ease by which a distribution system can be contaminated accidentally (e.g. cross connections), or intentionally due to multiple points of access is of great concern to utilities. The large majority of utilities have realized that due to the novelty of the threat, the difficulty of detecting contamination, and the uncertainty of its consequences, they were not well prepared to cope with such incidents. To reduce the risks, significant work started in the area of contamination warning systems (CWSs) so that utilities can provide the appropriate response to protect the health and safety of the public and their employees. In addition to detecting contamination, the water quality monitoring also provides the dual benefit of operational insight, resulting in improved operations.

As a response to such industry concerns, various agencies (particularly the US Environmental Protection Agency (EPA)), professional associations, and utilities have undertaken various initiatives and projects on contamination detection. This interest has been reflected by the numerous conferences, seminars, and workshops given on the subject. Significant sources of information on the subject are the *Interim Voluntary Guidelines for Designing an Online Contaminant Monitoring System* (Pikus, 2004) published by the American Society of Civil Engineers (ASCE), and several publications released under EPA's Water Security Initiative (formerly WaterSentinel). These publications include *WaterSentinel System Architecture*, Draft, Version 1.0 (EPA December 2005), *Water Security Initiative; Interim Guidance on Planning for Contamination Warning System Deployment* (EPA 817-R-07-002, May 2007), *WaterSentinel Online Water Quality Monitoring as an Indicator of Drinking Water Contamination* (EPA December 2005), *WaterSentinel Consequence Management Strategy*, Draft Version 1.0

(EPA December 2005) and *Overview of Event Detection Systems for WaterSentinel* (EPA December 2005). Furthermore, EPA's Threat Ensemble Vulnerability Assessment (TEVA) Research Program has released several papers on evaluating the impact of contamination on distribution system customers and locating sensors on distribution systems (http://www.epa.gov/nhsrc/news/news073007.html#sensor, accessed October 19, 2007). The material presented here has been primarily based on these documents.

According to the *Water Sentinel System Architecture* document, a CWS is "a proactive approach to managing threat warnings that uses advanced monitoring technologies/strategies and enhanced surveillance activities to collect, integrate, analyze, and communicate information to provide a timely warning of potential water contamination incidents and initiate response actions to minimize public health and economic impacts." This definition of CWS also includes information sources such as public health agencies, consumer complaints, physical security alerts, and laboratory analyses. A representation of such a comprehensive CWS is illustrated in Figure 8. In this article, CWS is limited to identifying contaminants through the use of online water quality monitoring instruments.

Pikus lists the following objectives of a CWS:

- to provide a reliable early warning of a contamination event so that steps can be taken to reduce its effects by limiting exposure of the at-risk population;
- to indicate the location and travel of the contaminant to facilitate implementation of the appropriate responses;
- insofar as possible, to identify the contaminant and determine its concentration so that the most appropriate response can be mounted, and to alert and inform the medical community about the potential need for treatment;

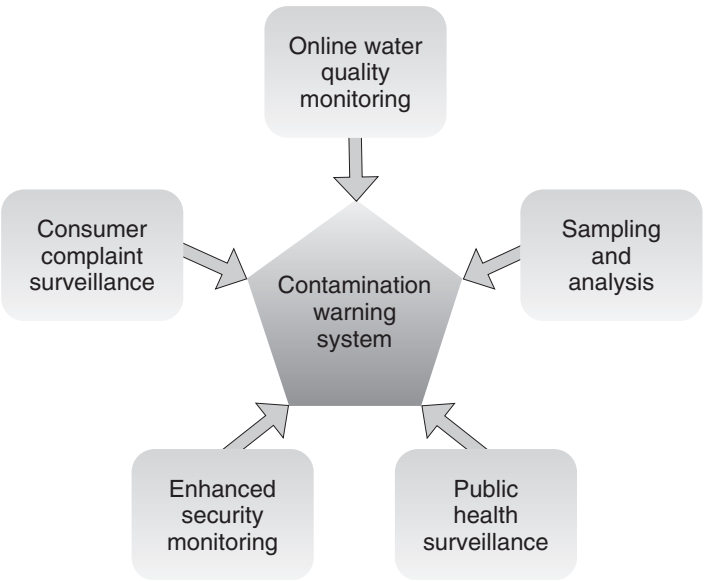

**FIGURE 8** Conceptual diagram of a comprehensive CWS. (Source: US EPA Water Security Initiative, Request for Applications for Contamination Warning System Demonstration Pilots Presentation, June 18, 2007.)

- to provide information on the "normal" operating characteristics of the water-supply or wastewater system;
- to support or supplement the existing regulatory surveillance activities.

To meet these objectives, the development of a CWS should include the following elements:

- types of contaminants to be monitored;
- online monitoring instruments and sensors (current industry practice assumes that monitoring should be continuous in order to spot any contamination events.);
- contaminant fate and transport models that are applicable under given hydraulic and water chemistry conditions;
- monitoring locations;
- communications links and protocols for the necessary collection, transfer, and analysis of data;
- integration with existing SCADA system;
- tools and guidance for the proper interpretation of data (that is, event detection systems).

### 5.1 Type of Contaminants

The need to know what the potential contaminants might be is to give utilities a sense of the potential threats to their systems, to provide the public health community a sense of the illnesses and medical emergencies that might occur, and to determine the monitoring instruments that might be better suited for each utility.

There are three major categories of contaminants:

- chemical (including biotoxins);
- biological (pathogens);
- radioactive materials.

Unfortunately, the number of potential contaminants is very large and unwieldy for the utilities to work with. EPA provided the following list of contaminant categories and identified which contaminant categories can be identified by which method (Table 1).

### 5.2 Monitoring Instruments

Given the extent of water distribution systems and the unlimited number of potential contamination insertion points, utilities might need a relatively large number of monitoring instruments in their systems to feel confident that they can detect any contamination on time. However, currently there are no affordable and practical continuous monitoring instruments that can identify all contaminants.

On the other hand, most known contaminants in water affect, to varying degrees, some measurable properties of the water, indicating their presence through changes in these properties. As a result these properties, or parameters, are called "surrogate" parameters, and they can be measured by commercially available and relatively affordable instruments. The effectiveness of these instruments, however, needs further scrutiny because

**TABLE 1 Contaminant Categories and Detection Strategies**

| Class | Description | Water Quality | Consumer Calls | 911 Calls/EMS | Hospital Data |
|---|---|---|---|---|---|
| 1 | Petroleum products | √ | √ | | |
| 2 | Pesticides (with odor or taste) | √ | √ | √ | |
| 3 | Inorganic compounds | √ | √ | √ | |
| 4 | Metals | √ | √ | √ | |
| 5 | Pesticides (odorless) | √ | √ | √ | |
| 6 | Chemical warfare agents | √ | | √ | |
| 7 | Radionuclides | √ | | √ | |
| 8 | Bacterial toxins | √ | | | √ |
| 9 | Plant toxins | √ | | | √ |
| 10 | Pathogens causing diseases with unique symptoms | √ | | | √ |
| 11 | Pathogens causing diseases with common symptoms | √ | | | √ |
| 12 | Persistent chlorinated organic compounds | √ | | | |

*Source: US EPA Water Security Initiative, Request for Applications for Contamination Warning System Demonstration Pilots Presentation, June 18, 2007*.

their sensitivity might not be sufficient to detect minor (but still real) changes in water quality due to contamination. Furthermore, changes in water quality also occur due to the dynamic nature of distribution systems (operational changes, source water blending, etc.).

Recommended surrogate parameters are:

- residual chlorine;
- turbidity;
- TOC;
- pH;
- conductivity;
- oxidation reduction potential (ORP);
- ammonia, chloride, and nitrate.

System pressure and temperature are also monitored.

Instruments that monitor these parameters are currently being employed in CWSs motelled at several US utilities. Once contamination is suspected, utilities need to collect additional samples and test them at a laboratory with specific contaminant detection capabilities for confirmation purposes.

### 5.3 Contaminant Fate and Transport Models

Contaminant fate and transport models are used to predict the change in the nature and concentration of the contaminants. These changes occur due to the various constituents in the water (e.g. chlorine residual), pipe characteristics (e.g., cement lining in iron

pipes, biofilm), the alkalinity of the water, and so on. Thus, these models support the interpretation of water quality changes, if they might be due to normal operational changes or due to contamination. In distribution systems, hydraulic/water quality network models are employed for this purpose.

### 5.4 Monitoring Locations

As mentioned above, a relatively large number of instruments might be needed to provide sufficient coverage to a distribution system. However, this is neither affordable nor practical. Thus, utilities must select an optimal number of locations that they can afford and sustain. There are some software packages that currently support the identification of sensor locations within distribution systems. EPA's TEVA program also supports this kind of applications. Pikus (2004) provides the following guidance in the selection of the instrument locations.

The local site conditions that a utility should consider include:

- easy access to the instrument site by authorized personnel;
- available space for the instruments and auxiliary equipment;
- suitability of candidate instruments for the sampling site and access to other utilities;
- physical security of the instrument site;
- hydraulic conditions at sampling sites;
- existing sampling sites for baseline or compliance monitoring.

System-wide and topological factors include:

- potential areas or points of entry of contamination;
- likely contaminants;
- contaminant transport time and concentration;
- proximity to vulnerable populations;
- relative water demand and associated flow characteristics.

### 5.5 Proper Interpretation of Data (Event Detection)

As discussed by Pikus, the purpose for analyzing the data obtained from monitoring instruments is to:

- identify the presence and location of significant contamination in the system;
- identify the contaminant or its class with sufficient specificity to allow appropriate responses;
- characterize the level of contamination at various parts of the system;
- determine time to consumption;
- eliminate false negatives and minimize false positives;
- assess public health risk;
- provide timely information to decision makers.

Data analysis, however, is a relatively complex task due to two primary sources of variability in the data:

1. Temporal variations, due to changing operational conditions in a water system, such as:
   - seasonal variations due to changes in the source water or demand (such as lawn irrigation in summers);
   - weekday variations due to changes in demands and operation practices (such as weekday vs. weekend use, utility maintenance activities, etc.);
   - diurnal variations due to changes in hourly demands by residential, commercial, or industrial customers.

   Typically, higher Cl residuals are observed when the water age is younger due to higher demand. In some cases, depending on the alkalinity of the water, cement-lined pipes affect the pH of the water in the distribution system, increasing pH with water age.
2. Instrument based variations which are introduced into the data due to the reliability of the instruments. Field instruments tend to require more maintenance and calibration than laboratory instruments and are less accurate. To increase the confidence in the sensors, it might be necessary to have duplicate instruments, but this is not a common practice due to increased maintenance needs and associated costs. More typical is taking duplicate samples for lab verification.

To address these issues, it is critical that a utility becomes very familiar with the quality of its water and its seasonal, weekday, diurnal and spatial variations. An illustration of temporal variations of chlorine residual at one utility is shown in Figure 9. This can be done by conducting a baseline water quality analysis, and then comparing monitoring instrument results with its baseline to determine whether there is potential contamination.

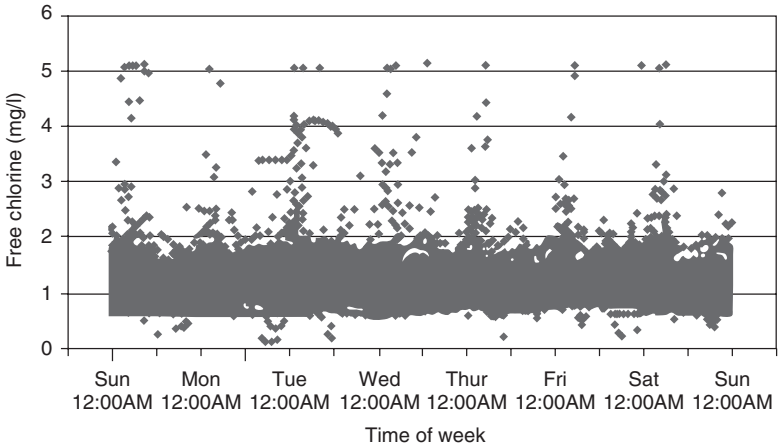

**FIGURE 9** Temporal variations in baseline Cl residual data.

## 1 INTRODUCTION

Wastewater results from mankind's use of water in all aspects of daily life, including personal hygiene, food preparation, commercial activity, industrial production, and recreation. Historically, increasing population density forced mankind to abandon localized disposal (cesspools, septic tanks, etc.) toward collection and conveyance of contaminated water away from population centers for the prevention of disease and protection of water supplies. The aggregate of these contaminated waters has over time come to be known as *wastewater* or *sewage*. Most commonly, this wastewater was directly discharged into local surface waters, such as streams, lakes, rivers, and oceans. Also, a limited amount of this water was used for irrigation.

Mankind's relationship to the environment has been documented as far back as 3750 BC in the form of archeological findings and ancient writings. The history of what we call "sewers" is most fascinating and is well documented in the literature. In the United States, the first sewerage system constructed in a major city is reported to have been in New York City in 1805 [1].

The long battle to separate mankind from its waste products has taken many turns owing to political decisions and cultural changes, but the agreement that the "great sewer construction period" in US cities occurred from the mid eighteenth century until 1915 when Baltimore completed its sewer system [1]. Most of these city sewer systems were

designed to dispose of both human wastes and stormwater to some distant point away from population centers.

Initially, the direct discharge of wastewater into local surface waters was not considered a serious human health or environmental concern [2]. This assessment was based solely on esthetic parameters such as color, odor, and clarity. As population density and per capita water use increased, combined with expanding industrial output, the impacts of these discharges became more pronounced, leading eventually to engineered wastewater management/treatment prior to discharge.

The practice of treating wastewater began with studies in London in the mid-nineteenth century and migrated to the United States soon after [1]. The number of municipalities and communities incorporating end-of-pipe treatment for their sewer systems grew phenomenally in the first half of the twentieth century. Initially, treatment approaches were primarily developed to reduce nuisance conditions (e.g. odors) in receiving waters and not for public health protection. Federal laws in the later part of the twentieth century were passed in response to the lack of state and local enforcement of pollution abatement laws and regulations. The results of passage and implementation of these federal laws have had a significant positive impact on the water quality of the majority of water bodies in the United States. The American Housing Survey of 2006 (US Census Bureau) estimated that nearly 80% of the US population is now served by municipal collection systems and treatment facilities.

The above historical scenario has evolved concurrently with newly developed scientific knowledge relating to the epidemiological basis of human exposure and disease. These advances in science served as the prelude to the passage of numerous federal and state laws that sought to minimize the now-quantifiable hazards to public health and, more recently, the environment.

## 2 DEVELOPMENT OF WASTEWATER SEWERAGE SYSTEMS

Stormwater conveyance has been documented as the major reason for the construction of most early sewers. Incorporation of human excretions into stormwater conveyance was initially strongly discouraged. The transition of combining the two wastes emanated primarily from England, which unfortunately passed this practice on to its colonies [1]. In the second half of the twentieth century, it became clear that "sanitary sewers" should be built to separate human wastes from stormwater; therefore, no new combined sewers have been installed in recent years. Separation of the two flows has become the norm in the United States. Conventional sewer design technology has not changed significantly for several decades and has often been applied inappropriately to smaller systems.

The governing principle of sanitary sewer design is that wastewater is conveyed from each service connection to the collector and then, it flows through the collector sewer by gravity. However, hydraulic design standards require that the pipe must slope sufficiently to maintain a velocity of 2 ft/s in order to convey the solids and prevent accumulations in the sewer that can lead to blockages. Thus, unless favorable ground slopes exist, the depth of cut to accommodate this requirement and, therefore, the cost per lineal foot become excessive. In the United States, this maximum depth is typically about 25 ft. In such cases, lift stations are required to pump the wastewater toward the ground surface in order to reestablish the necessary head for continued gravity flow. Design requirements

also dictate the insertion of manholes at regular (e.g. 250–300 ft) intervals to facilitate access to the sewer for inspection and cleaning.

After nearly 100 years, the above approach is still utilized in designing wastewater collection systems. For the past few decades, this type of system has been installed in suburbs outside of the densely populated urban areas for which they were originally conceived. This has resulted in increasingly expensive sewer systems that employ more sewer pipe length, manholes, and pump stations per service connection compared to strictly urban applications. This approach to sewer design, which can involve numerous connections below the groundwater table, tends to increase the infiltration of additional water requiring treatment. As a result, natural groundwater comingled with wastewater is treated and discharged into a surface water body that may be far removed from its original basin. Base flow in the surface waters of the original basin is thus reduced and wells in that basin can suffer reduced productivity. Examples of this effect can be found in Boston and other metropolitan areas [3].

Stormwater collection system designs are in a state of flux. In recent years, federal laws and regulations have forced cities to curtail unauthorized "non-point-source" (NPS) discharges into the waters of the United States. This has resulted in the emergence of numerous programs to minimize untreated discharges from combined and storm sewers. The impetus for these efforts has been the United States Environmental Protection Agency's (USEPA's) national surveys [4] that have determined that most of stream and lake water quality impairment in the United States is due to these and other NPS discharges, rather than from wastewater treatment plant (WWTP) effluents.

In recent years, considerable emphasis has been placed on prevention of runoff through on-site capture of rainwater and snowmelt. These efforts are aimed at reducing the volume and pollutant concentrations in conveyance systems. Although these sources are less concentrated in some pollutants than in municipal wastewater, they do contain most of the constituents displayed in Table 1 (from [5]) and are more concentrated in certain pollutants, such as metals and hydrocarbons. Best management practices are also being applied to provide end-of-pipe treatment for these formerly untreated contaminant sources.

## 3 DEVELOPMENT OF WASTEWATER TREATMENT SYSTEMS

### 3.1 Overview

Wastewater contains a number of physical, chemical, and microbiological pollutants. Some are objectionable only from an esthetic point of view, while others pose the potential for causing serious health problems and disease as well as damage to the environment. The major classes of contaminants found in residential or domestic wastewater are summarized in Table 1. Typical concentrations and per capita loadings of these contaminants for domestic wastewater are provided in Table 2 [5]. Industrial waste constituents of varying hazard potential and toxicity may receive some degree of pretreatment prior to being combined with the domestic wastewater component to form the mixed contaminated liquid flow known as *municipal wastewater*. Municipal WWTPs must contend with and treat all constituents present in the incoming flow, irrespective of the proportions and characteristics of the domestic and industrial contributions.

Table 2 clearly indicates that wastewater is laden with potential pathogens (bacterial and viral), putrescibles (organics that can result in oxygen deficiency and generation of odors), and nutrients (nitrogen and phosphorus that can stimulate nuisance organism

**TABLE 1 Wastewater Pollutants of Concern**

| Pollutant | Reason for Concern |
|---|---|
| Suspended solids | In surface waters, can result in the development of sludge deposits that smother benthic macroinvertebrates and fish eggs and may contribute to benthic enrichment, toxicity, and sediment oxygen demand. Excessive turbidity can block sunlight, harming aquatic life (e.g. block sunlight needed by plants) and contribute to decreased dissolved oxygen in the water column. In drinking water, turbidity is esthetically displeasing and interferes with disinfection |
| Biodegradable organics | Biological stabilization of organics in the water column can deplete dissolved oxygen in surface waters, creating anoxic conditions harmful to aquatic life. Oxygen-reducing conditions create taste and odor problems in drinking water and allow metals to leach from soil and rock in ground to surface waters |
| Pathogenic agents | Parasites, bacteria, and viruses can cause communicable diseases through direct/indirect body contact or ingestion of contaminated water or shellfish. A particular threat when partially treated sewage pools on ground surfaces or migrates to recreational waters. Transport distances of some pathogens in ground or surface waters can be significant |
| Nitrogen | An aquatic plant nutrient that can contribute to eutrophication and dissolved oxygen loss in surface waters, especially in lakes, estuaries, and coastal embayments. Algae and aquatic weeds can contribute trihalomethane (THM) precursors to the water column that may generate carcinogenic THMs in chlorinated drinking water. Excessive nitrate nitrogen in drinking water can cause methemoglobinemia in infants and pregnancy complications for humans. Livestock can also suffer health impacts from drinking water high in nitrogen |
| Phosphorus | An aquatic plant nutrient that can contribute to eutrophication of inland and coastal surface waters and reduction of dissolved oxygen |
| Toxic organics | Toxic organic compounds present in household chemicals and cleaning agents can interfere with certain biological processes in conventional and alternative on-site wastewater treatment systems (OWTSs) and can be persistent and bioaccumulative in the aquatic environment. They can cause damage to ecosystems and human health directly or through ingestion of contaminated aquatic organisms (e.g. fish and shellfish) |
| Heavy metals | Heavy metals (e.g. lead and mercury) in drinking water can cause human health problems. In the aquatic ecosystem, they can also be toxic to aquatic life and accumulate in fish that may be consumed by humans, resulting in metal toxicity health threats |

growth that degrade water quality). Thus, the practice of early sewer builders in separating urban populations from their waste products was based on factual elements that were not yet understood fully.

Early wastewater treatment practices concentrated on the removal of suspended materials, floatables, and garbage and debris [6]; [7]. The preliminary and primary treatment processes employed for achieving these limited objectives consisted of screening, sedimentation, and grease/oil removal [8]. This type of treatment removed visible objectionable materials without affecting the chemical and biological characteristics of the waste appreciably. However, the discharged wastewater still contained sufficient organic matter to cause significant adverse impacts on receiving waters. The remaining organic content of this wastewater was removed through aerobic biodegradation

**TABLE 2 Constituents of Typical Residential Wastewater**

| Constituent | Mass Loading (grams/person/day) | Concentration (mg/l) |
|---|---|---|
| Total solids (TS) | 115–200 | 500–880 |
| Volatile solids | 65–85 | 280–375 |
| Total suspended solids (TSS) | 35–75 | 155–330 |
| Volatile suspended solids | 25–60 | 110–265 |
| 5-day biochemical oxygen demand ($BOD_5$) | 35–65 | 155–286 |
| Chemical oxygen demand (COD) | 115–150 | 500–660 |
| Total nitrogen (TN) | 6–17 | 26–75 |
| Ammonia ($NH_4$) | 1–3 | 4–13 |
| Nitrites and nitrates ($NO_2$-N; $NO_3$-N) | <1 | <1 |
| Total phosphorus (TP) | 1–2 | 6–12 |
| Fats, oils, and grease | 12–18 | 70–105 |
| Volatile organic compounds (VOC) | 0.02–0.07 | 0.1–0.3 |
| Surfactants | 2–4 | 9–18 |
| Total coliforms (TC) | — | $10^8$–$10^{10}$ |
| Fecal coliforms (FC) | — | $10^6$–$10^8$ |

resulting in depletion of dissolved oxygen (DO) in the water body and concomitant fish kills and degradation of drinking water resources. Additionally, the recreational use of these water bodies became problematic due to increased incidence of water-borne diseases [9]. In retrospect, use of impacted surface waters for drinking water supply required more rigorous chlorination, which we now know results in the formation of carcinogenic chlorinated disinfection byproducts.

In the first half of the twentieth century, these observations and human health impacts underscored the need for more advanced wastewater treatment focused on reduction of dissolved organic matter. Biological oxidation rapidly emerged as the most viable technology to achieve this objective. Early biological treatment systems consisted of lagoons that afforded sufficient retention time for microorganisms to convert organic matter into carbon dioxide ($CO_2$), water, and new biomass [10]. Due to the large footprint required for lagoon-based treatment, its use was limited primarily to small flows and rural areas [10]. Application of biological treatment to large wastewater flows typical of high-density population centers led to the development of more efficiently engineered biological systems that emphasized the retention of large concentrations of biomass allowing more compact treatment systems. Numerous treatment processes, commonly referred to as *secondary treatment*, emerged. These secondary treatment processes were not only effective in reducing the dissolved organic content of wastewater, but were additionally capable of trapping a significant portion of suspended matter with the retained biomass. Prominent among these processes were the activated sludge (AS) and trickling filter systems. Typically, secondary treatment is used in conjunction with primary treatment where the two systems complement each other, yielding effluents low in suspended and dissolved organic matter. Wide application of these systems significantly improved the esthetic quality of the receiving waters of this country.

Primary settling is a separation process that results in the production of waste solids, while secondary treatment results in the production of excess biomass. These solids-bearing streams, commonly referred to as *primary and secondary sludge*,

respectively, require further treatment and disposal or reuse. Sludge handling and treatment generally consists of volume reduction, stabilization, dewatering, and final disposal via incineration or landfilling. Alternatively, treated sludge can be land applied for soil conditioning and nutrient enhancement.

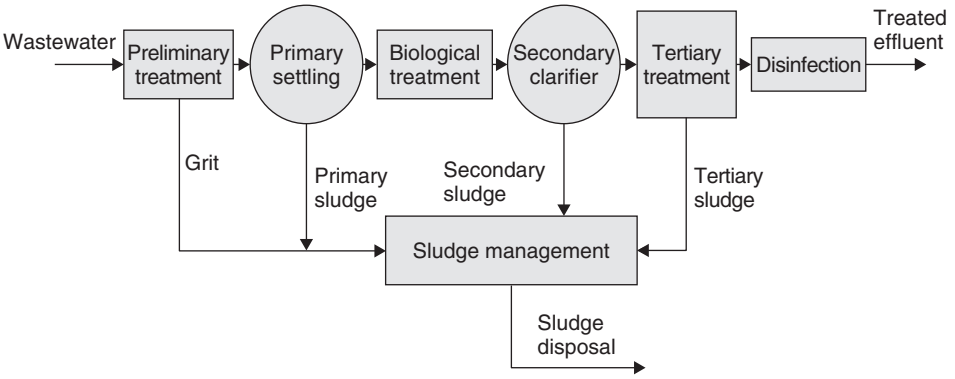
During the 1960s–1980s, USEPA instituted a Construction Grants Program to assist municipalities in upgrading existing primary treatment plants to secondary treatment. These upgraded treatment plants improved the receiving water quality across much of the United States with significant human health and environmental benefits as manifested in reduced enteric disease transmission, less fish kills and consumption advisories, less recreational contact hazards, more suitable water supply resources, and a general sense of environmental well being [8].

The significant improvements in receiving water quality realized as a result of widespread implementation of secondary treatment focused attention on remaining problems associated with the environmental impact of continued discharge of nutrients, such as nitrogen and phosphorus. The widespread use of soil-based wastewater systems in rural areas generally captured most of the phosphorus in the soil, but nitrogen was only partially removed (~20%) before incorporation into groundwater. Phosphorus (in freshwater) and nitrogen (in marine water) discharge continued to promote the excessive growth of algae (a process known as *eutrophication*), whereas the discharge of ammonia from most secondary plants resulted in oxygen depletion due to the oxidation of ammonia to nitrate in the receiving water. Excessive algal blooms are undesirable due to oxygen depletion in shallow waters and the production of esthetically displeasing taste and odor compounds in drinking water. As a result, additional treatment became necessary in many areas to manage the nutrients discharged in WWTP effluents [10].

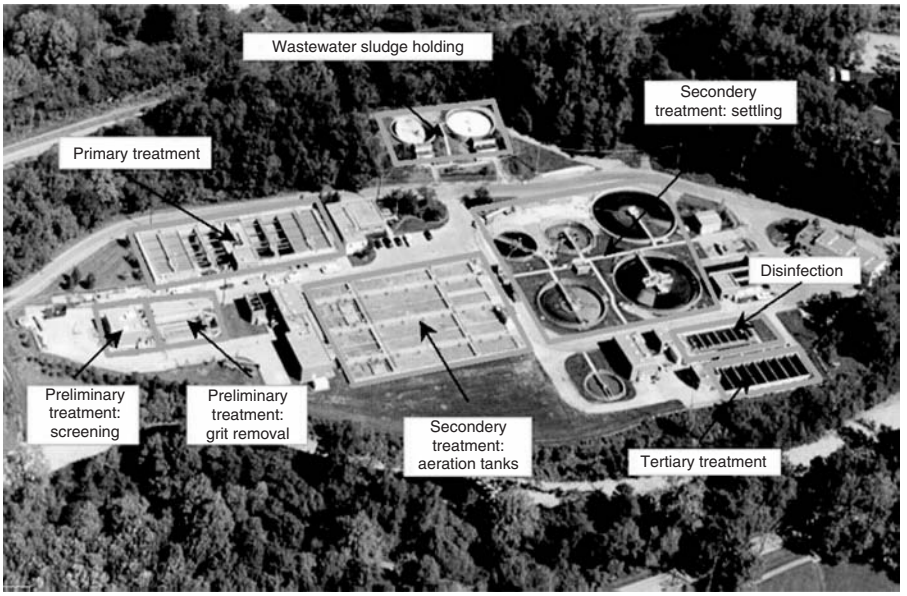
Collectively, the group of technologies designed to control nutrients and further reduce organics and solids in final effluents is referred to as *tertiary treatment*. Innovative treatment processes have been developed to further improve WWTP effluent quality. These include sand filtration for improved solid reduction, carbon adsorption for managing specific industrial pollutants and alternative disinfection processes, such as ozonation and ultraviolet (UV) inactivation, which do not form chlorinated byproducts, and some membrane separation technologies (e.g. reverse osmosis) facilitate more direct water reuse [11].

### 3.2 Description of Treatment Processes

Most of the modern large treatment plants are comprised of preliminary treatment units, primary settling or clarification, hereafter referred to as *primary clarification*, and secondary biological treatment consisting of a biological oxidation process followed by separation of solids, that is, secondary or final clarification. The liquid treatment sequence is sometimes followed by one or more tertiary treatment units needed to meet specific effluent discharge requirements or standards. The final step in the treatment sequence is usually effluent disinfection to reduce the pathogenic potential. Preliminary treatment, primary clarification, secondary biological treatment, and tertiary treatment processes (if used) result in a treated effluent and generate various waste sludge streams and debris that require subsequent treatment and/or disposal. A schematic diagram of a typical municipal WWTP is presented in Figure 1a. An aerial photograph of the Sycamore municipal WWTP, Cincinnati, Ohio is shown in Figure 1b. Following is a brief discussion of the treatment unit operations shown in Figure 1a.



(a)



(b)

**FIGURE 1** (a) Schematic diagram of a typical municipal wastewater treatment plant. (b) Aerial view of the Sycamore municipal WWTP, Cincinnati, Ohio.

***3.2.1 Preliminary Treatment.*** Depending on the topography and location of a WWTP, gravity flow collection systems commonly used for conveying wastewater to the plant normally result in the wastewater reaching the plant that is significantly below grade. This may necessitate the need for a lift pump to transfer the wastewater to the plant elevation. To protect the lift pump, screening devices are often employed to remove large objects from the wastewater. These may include dead animals, rags, tires, wood debris, and other large objects that may hamper proper functioning of the pumps [11].

Once at plant elevation, comminutors or grinders are often used to decrease the size of the remaining suspended materials in the wastewater. Comminution is typically followed by grit removal. Grit removal devices (grit chambers) are designed to separate high-density inert particles from low-density organic particles. This separation

is accomplished through the use of high superficial flow velocities that scour the high-surface area, low-density organic particles from the grit. Grit chambers are commonly of two designs, air lift vortex or high-velocity open channel design [10].

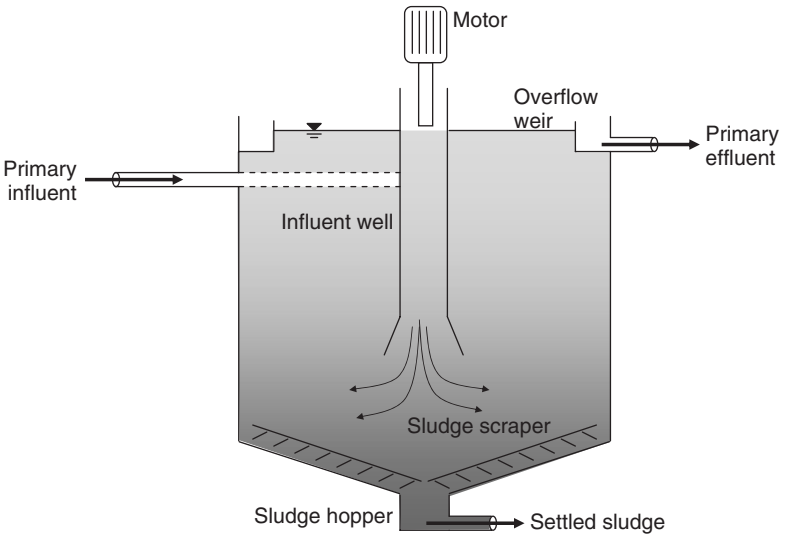
***3.2.2 Primary Clarification.*** The organic content remaining in wastewater after preliminary treatment is comprised of a suspended fraction and a dissolved fraction. Collectively, the organic content of wastewater is often quantified using surrogate measures such as biochemical oxidation demand (BOD) and/or chemical oxygen demand (COD). Both of these measurements represent an estimate of the oxygen required to mineralize the organic matter to $CO_2$ and water. Total suspended solids (TSS) refers to the *filterable portion* of the solids remaining in the wastewater. TSS comprises both organic and inorganic material. The ignitable fraction of the TSS is referred to as *volatile suspended solids* (VSS) and is used as a surrogate for solids of organic origin.

Primary clarification consists of a continuous flow tank that provides a quiescent zone and adequate retention time to remove 50–67% of TSS and 27–40% of BOD [10]. Solids thus removed are collected in a hopper at the bottom of the tank and can be withdrawn intermittently or continuously. The withdrawn material is referred to as *primary sludge*. Floatables present in the wastewater (i.e. grease, oil, and scum) are removed at the surface using skimming devices. Floatables are generally burned and primary sludge is routed to subsequent sludge management units. Primary clarifiers are commonly 10–16 ft deep and provide a hydraulic retention time (HRT) of 1.5–2.5 h [10]. A schematic diagram of a typical circular primary clarifier is portrayed in Figure 2a. A photograph of a rectangular primary clarifier at the Gest Street WWTP of the Metropolitan Sewage District of Greater Cincinnati, Ohio is shown in Figure 2b.

***3.2.3 Secondary Treatment.*** Secondary treatment is most often comprises two unit processes, a biological oxidation reactor followed by a solids separation unit (final clarifier). Within the biological reactor, most organic matter is transformed by biomass (bacteria and other microorganisms) to innocuous end products and new biomass. Excess biomass is commonly referred to as *waste secondary sludge*, and is managed either separately or in combination with primary sludge [11]. The most commonly employed secondary biological treatment processes are the AS and trickling filter (TF) systems.

*3.2.3.1 Activated Sludge.* AS systems rely on biomass sedimentation and recycle to maintain elevated levels of suspended biomass within a biological reactor called *aeration tank*. Mixing and oxygen transfer within the aeration tank are accomplished by either mechanical or diffused aeration devices. The sustained operation of AS systems requires the removal of excess biomass (waste AS) to maintain a manageable inventory of biomass (mixed liquor) within the secondary treatment system. The ratio of the biomass inventory within the AS system to the biomass wasted daily in the secondary sludge is referred to as the *solids residence time* (SRT). This parameter is typically maintained in the range of 5–15 days, whereas the aeration tank is usually designed to provide an HRT of 3–8 h [10]. Biomass recycle (return AS) and the concomitant decoupling of HRT and SRT in an AS system results in volume reduction in the biological reactor equivalent to the ratio of SRT/HRT.

The secondary clarifier in the AS system serves two functions, liquid–solid separation (clarification) and biomass concentration. Clarification takes place in the upper portion of the secondary clarifier, and its effectiveness depends on the nature of the biomass



(a)

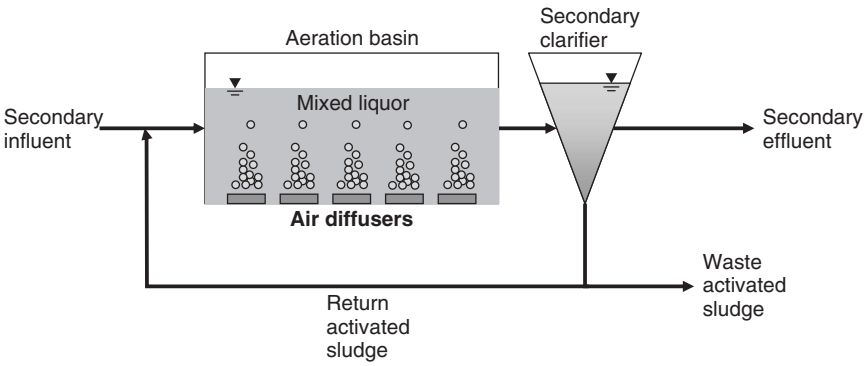
(b)

**FIGURE 2** (a) Schematic diagram of a typical circular primary clarifier. (b) Photograph of a rectangular primary clarifier in Gest Street WWTP at the Metropolitan Sewage District of Greater Cincinnati, Ohio.

solids and the discharge rate of the clarified wastewater flow per unit surface area of the tank (overflow rate). The lower portion of the secondary clarifier is devoted to the collection and thickening of settled biomass prior to its recycle to the aeration tank. The degree of thickening achieved in the clarifier hopper depends on the type of sludge collection and removal system utilized and biomass characteristics. Optimization of the thickening function of the clarifier allows a more compact aeration basin design. Excess

biomass produced in the aeration tank is commonly wasted from the secondary clarifier recycle stream. This wasting operation is necessary to maintain biomass SRT at levels that permit effective settling of these solids to the bottom of the clarifier. Skimming devices are used on the surface of these clarifiers to collect and transport floating particles to a waste trough. Secondary clarifiers for the AS system are typically 12–20 ft [10] in depth with an HRT of 2–3 h [11]. Successful operation of the AS treatment system is predicated on the ability of biomass to agglomerate into larger particles (flocs) that are amenable to settling and removal.

A schematic diagram of a typical diffused aeration AS system is shown in Figure 3a. A photograph showing the surface of AS aeration basins equipped with diffused aerators at the Gest Street plant of the Metropolitan Sewage District of Greater Cincinnati, Ohio is given in Figure 3b.



(a)

(b)

**FIGURE 3** (a) Schematic diagram of a typical diffused aeration activated sludge system. (b) Photograph of several activated sludge aeration basins (diffused aeration) in Gest Street WWTP at the Metropolitan Sewage District of Greater Cincinnati, Ohio.

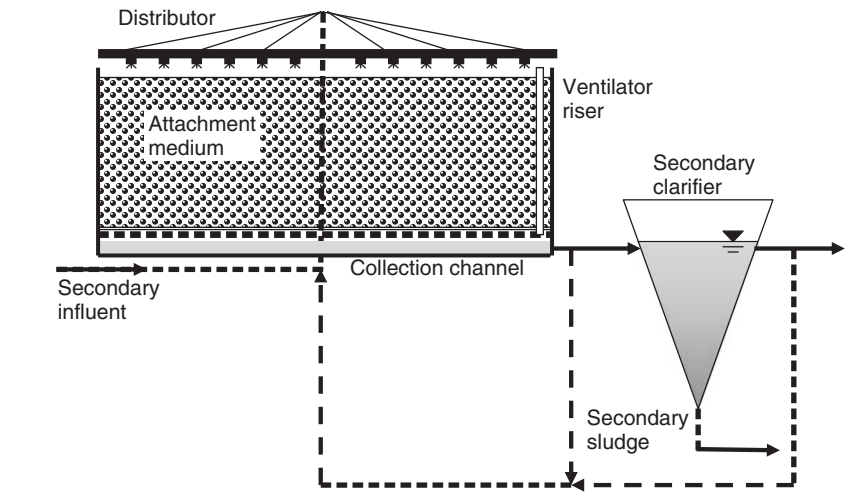
*3.2.3.2 Trickling Filtration.* TF systems are generally used as a simpler secondary treatment system for smaller municipalities. TF systems are comprised of two components, a TF bioreactor followed by a secondary clarifier. TFs rely on the application (or trickling) of a thin layer of primary effluent to the surface of a bed of artificial or natural inert filter media onto which attached biomass has developed (biofilm). The applied wastewater trickles by gravity flow down through the media for treatment. Successful operation of TF systems requires uniform distribution of wastewater across the filter surface and with depth. Application rates should not exceed the biofilm's soluble organic removal capacities for efficient treatment to occur. Attachment media options include natural materials (such as rock and redwood) and synthetic engineered materials (such as plastic and blast furnace slag) that optimize flow distribution and media porosity and maximize attachment surface area and oxygen transfer. Effluent recirculation is employed with rock media to effect more even flow distribution and media wetting and thereby promote improved removal efficiency. Effluent recirculation becomes less necessary when engineered or more open media are used [10].

The primary function of the secondary clarifier in a TF system is to clarify the treated wastewater for effluent discharge. In addition, biomass sloughed from the TF media, which represents the net biomass growth, settles to the bottom of the clarifier from where it is wasted for subsequent management. Secondary clarifiers following TF systems are designed with up to 15 ft depth [10] and an HRT of 1–1.5 h [11]. A schematic diagram of a typical TF system is presented in Figure 4a. Photographs of a typical rock media trickling filters are shown in Figure 4b.

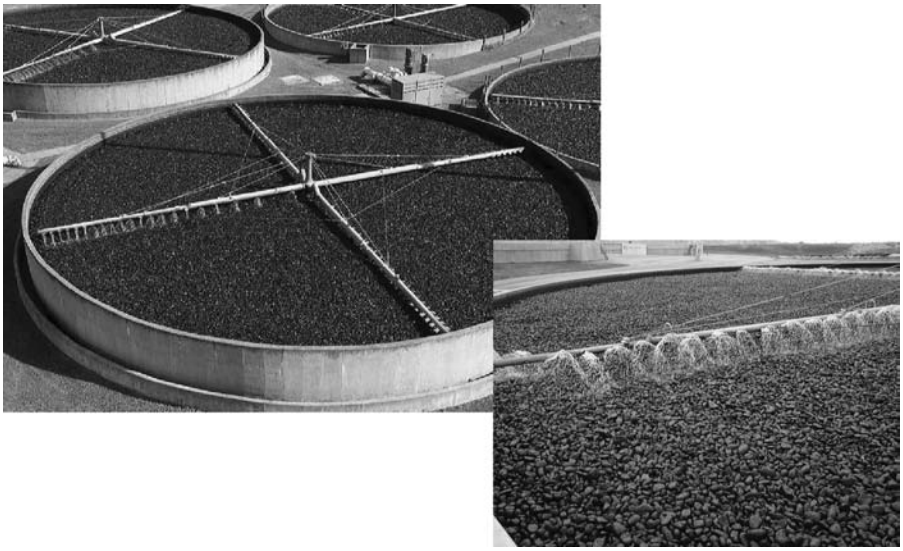
*3.2.3.3 Comparison of AS and TF Systems.* Although both AS and TF systems are regarded as secondary treatment processes, the two technologies differ significantly with respect to effluent quality, ease of operation, resiliency or susceptibility to upsets, and adaptability for nutrient control and tertiary treatment. In general, AS systems maximize soluble organic removal, while TF systems are well adapted to the removal of suspended particles and result in less turbid effluents [10]. With the interchange of biomass between aeration tank and clarifier, the secondary clarifier of an AS system requires considerable operator attention and staffing due to its sensitivity to varying wastewater characteristics and aeration basin operating conditions. Since biomass in a TF is retained within the bioreactor, management of the biomass inventory is less challenging than in AS systems. TFs operate at significantly higher SRTs than do AS systems, resulting in less biosolids production and, therefore, less biosolid disposal requirements. TFs are more resilient and less susceptible to chemical upsets (both natural and intentional) because the attached biomass, with its reduced impacted surface area and exposure time, is less vulnerable to toxic episodes. Furthermore, AS systems are more susceptible to extreme flow events that can lead to biomass washout from the final clarifier resulting in temporary process failure.

With their many possible flow and aeration configurations, AS systems can be designed to treat wastewater of differing characteristics. For example, selection of the sludge recycle reentry point can be tailored to optimize treatment of wastewater of differing organic contaminant strengths and distribution of organic matter between the suspended and soluble fractions.

***3.2.4 Nutrient Control.*** Many nutrients are found in municipal wastewater, those of most concern being ammonium nitrogen (ammonia) and phosphorus [10]. Ammonia



(a)



(b)

**FIGURE 4** (a) Schematic diagram of a typical trickling filter system. (b) Photographs of typical rock media trickling filters (adapted from http://industrial–landscape.com and www.centervilleut.net).

is a reduced form of nitrogen that can, with appropriate process control, be biologically oxidized to nitrate nitrogen (nitrate) in WWTPs. If not oxidized in the WWTP, ammonia will normally be oxidized over a longer period of time in receiving waters contributing to oxygen depletion. Single-stage secondary AS systems can under optimum operating conditions of organic loading, SRT, temperature, and DO achieve ammonia oxidation (nitrification). Alternately, nitrification can be achieved in specially designed second-stage AS or TF systems where the bulk of the organic content of the wastewater has been removed in a first-stage secondary treatment unit. Such second-stage units can

be designed for maximum nitrifying biomass retention to compensate for low oxidation rates associated with lower seasonal temperatures.

Effluent dominated receiving waters and health issues (i.e. blue baby syndrome) may require nitrate removal (denitrification) [6]. Denitrification is the process of reducing nitrate to nitrogen gas using either organic matter present in the wastewater or the addition of an organic substrate. When wastewater organic matter is to be used for denitrification, a portion of the aeration basin is reserved for this process, with the degree of nitrate removal achieved dictated by the wastewater recycle rate. Alternately, more complete denitrification is possible by passing the entire nitrified effluent through a dedicated biological unit process. Such a process can either be a variation of the AS system or one of several fixed film designs [10].

Phosphorus removal can be accomplished through biological or chemical control technologies, with chemical technologies being more prevalent at present. Chemical phosphorus control relies on the precipitation of orthophosphate as a metal salt (i.e. iron, aluminum, or calcium). Chemical precipitation agents can be added to the primary clarifier or the aeration basin or the recycle sludge flow of an AS system. For fixed film systems, precipitating chemicals are added to either the primary or secondary clarifiers, but not directly to the fixed film reactor in order to avoid coating of the biofilm.

***3.2.5 Tertiary Treatment.*** Depending on final effluent discharge standards and the possibility of water reuse (direct or indirect), many types of unit processes can be employed for the removal of trace residual organics and metals, dissolved salts, and residual particulate matter [11]. Such processes include, but are not limited to, ion exchange, reverse osmosis, carbon adsorption, chemical coagulation/flocculation, and various forms of filtration (e.g. sand filtration, dual media filters, and ultrafiltration) [11]; [10]. Of these processes, filtration is the most commonly practiced form of tertiary treatment. Filtration is primarily used to remove suspended and colloidal particles and associated organic matter. Such a polishing process enables municipal WWTPs to meet discharge standards of BOD and particulate matter that are not attainable using conventional biological treatment technologies alone.

***3.2.6 Disinfection.*** Prior to final discharge, treated wastewater is often subjected to one of several disinfection processes for pathogen control. This is particularly important when the effluent is discharged to receiving waters used for recreational purposes (swimming, skiing, fishing, etc.) or as a drinking water source. Disinfection process alternatives consist of chlorination, UV light, and ozonation, with chlorination being by far the most common choice. Typically, chlorination is followed by sulfur dioxide dechlorination to remove any free and combined chlorine residuals prior to discharge.

***3.2.7 Sludge Management.*** Wastewater treatment results in the production of several sludge streams requiring further handling, treatment, and final disposal. These sludges are comprised of suspended matter removed during primary treatment and excess biomass generated during secondary treatment. Additionally, smaller waste sludge streams can be produced if tertiary treatment is practiced.

The primary and secondary sludge streams are often treated biologically (either aerobic or anaerobic digestion) to destroy a portion of the organic matter and excess biomass. The purpose of sludge digestion is to stabilize organic matter, thus rendering it less

susceptible to rapid decomposition upon final disposal. Uncontrolled rapid decomposition is accompanied by noxious odors and may serve as a vector attractant promoting the spread of disease. Aerobic and anaerobic processes used for sludge digestion are single-pass systems requiring very long contact times (SRTs ranging from 40 to 60 days for aerobic digestion and 10–28 days for anaerobic digestion) [10]. Consequently, concentration of the sludge stream prior to the digestion unit operation is highly desirable to minimize digester volume. Primary sludge is more concentrated than waste secondary sludge and, therefore, may not require preconcentration (thickening) prior to digestion as may be necessary for waste secondary sludge.

Sludge thickening is often accomplished using separate gravity settling tanks optimized to generate sludges with solid contents in the 3–5% range. The thickening process generates a very turbid supernatant that is recycled to the head of the plant for treatment. Alternately, waste secondary sludge can be recycled to the primary clarifier for cothickening with the primary sludge.

Aerobic sludge digestion is carried out in aeration basins under oxidative and ambient temperature conditions and yields destruction of organic suspended solids in the range of 38–50%. Conversely, anaerobic digestion occurs under reductive (fermentative) conditions and often requires heating to elevated temperatures to achieve mesophilic conditions (37–42°C) as well as destruction of organic suspended solids by approximately 50% [11]. Some WWTPs utilize even higher temperatures for anaerobic digestion (into the thermophilic range of 50–57°C) [10] to promote even greaterdestruction of solids and sludge stabilization. Aerobic digestion converts organic carbon into $CO_2$, whereas under anaerobic conditions, organic carbon is converted into methane and $CO_2$. The methane is often used to partially satisfy the energy needs of the WWTP.

Prior to final disposal and to reduce handling costs, digested sludge is typically subjected to dewatering that can yield sludge solid contents ranging from 12 to 40% depending on the selected dewatering device [8]. Processes utilized for sludge dewatering include centrifuges, vacuum filters, belt presses, filter presses, and sand drying beds.

Sludges that have been subjected to biological stabilization and dewatering are known as *biosolids*. Biosolids can be disposed in sanitary landfills or applied for soil conditioning to agricultural fields or for land reclamation (land application) [8]. Despite its inherent reuse of nutrients and other constituents in soil, biosolids land application is currently being subjected to increased public scrutiny due to potential nuisance and health concerns arising from aerosols drift, contact hazards, runoff to surface waters, and groundwater contamination. Incineration, while practiced historically, is less common today due to increasing costs, increasing community resistance, and perceived health issues with stack emissions. A schematic diagram of a typical sludge management system is illustrated in Figure 5a. Photographs of heated and unheated anaerobic digesters at the Fairfield Ohio WWTP are presented in Figure 5b and c, respectively. Photographs of two belt filter presses used for sludge dewatering are depicted in Figure 5d, whereaswhile a centrifuge and vacuum filter are shown in Figure 5e.

***3.2.8 Wastewater Reuse.*** Wastewater reuse can be divided into two categories, potable and nonpotable uses. Typical nonpotable reuse includes agricultural, irrigation and industrial applications. Agricultural and irrigation applications involve the reuse of wastewater that has received varying degrees of treatment prior to its application to crop, forage, and recreational areas [10]. Treated wastewater is generally used by industries for process and cooling water applications.

**FIGURE 5** (*Continued*)

Direct potable water reuse involves treatment of WWTP effluents employing traditional or more advanced water treatment technologies to produce finished drinking water that meets all applicable quality standards. Indirect water reuse has been practiced historically, either inherently or by design. Water withdrawn from surface and groundwater sources for human consumption frequently contains a significant fraction of treated or untreated municipal wastewater or agricultural runoff. In the arid western and southwestern portions of the United States, population pressures are increasingly dictating the use

of effluent dominated flows as drinking water sources [11]. Such instances mandate the use of fail-safe, nontraditional technologies, such as membrane separation and advanced oxidation treatment. Membrane separation is often employed for the removal of dissolved inorganic species, while advanced oxidation targets dissolved refractory organic matter.

Direct potable water reuse is not normally allowed in the United States, but aquifer recharge combined with specific minimum aquifer retention times prior to use appears to be gaining in popularity as an indirect water reuse option. Extended residence of this recharged water in the aquifer can mitigate or dilute residual contaminants inherent to wastewater.

## 4 PUBLIC RISK AND WASTEWATER TREATMENT INFRASTRUCTURE

Public vulnerability to disruptions of wastewater collection and treatment systems is of a secondary nature and not as critical as disruptions to drinking water, power, communications, and public health systems. Nevertheless, there are severe implications associated with wastewater treatment disruption or reduced capacity. These impacts, which are proportional to wastewater flow, have both immediate human health and longer-term ecological and economic effects. For that reason, this chapter emphasizes treatment technologies more often associated with larger systems. If the disruption is of a physical nature, such as fire, explosion, or structural failure, disablement of collateral infrastructure, such as drinking water, communication, and power systems may also occur. Chemical disruption, whether intentional or inadvertent, would result in temporary loss of biological treatment capability with no resulting damage to the physical structure of the collection system or the plant.

The large number of manholes in conventional gravity sewer systems offers numerous access points where toxins can be introduced to sewers from where they can be spread to a larger segment of the population and/or upset WWTP processes, which will lead to contamination of receiving waters and downstream drinking water intakes. Pumping stations are less numerous than manholes, but they are vulnerable to explosives. Any destruction of such vital infrastructure can result in sewer backups and massive basement and surface contamination leading to high potential for disease, as witnessed by the after effects of Hurricane Katrina on the Gulf Coast.

Combined sewers are still found in many older US cities, although most are implementing sewer separation or overflow event minimization efforts. The vulnerabilities of these systems are somewhat different from those for sanitary sewers. Because these conveyance systems have so many more access points in the form of stormwater inlets, they are more easily contaminated by a large dose of toxins. However, during rainfall or snow melting events, they carry much more water and thus have a greater potential for dilution during wet weather periods.

All the sewers described above can also be vulnerable to deliberate contamination of groundwater when they are located in deep coarse-grained or karst subsoils that lie above unconfined aquifers. Under these conditions, exfiltration of sewer contents becomes a serious potential vulnerability when these aquifers supply drinking water for municipalities. Newer sewer designs that use pressure and vacuum as motive forces do not have manholes and greatly reduce exfiltration potential, and are thus less susceptible to the above man-made disruptions.

Cessation or reduction of effective treatment at a WWTP may render down-gradient water supplies unsuitable for processing with the existing water treatment facilities. This disruption could be short term or longer term in nature. Short-term disruption would have limited economic and health implications, while longer term disruption may render the receiving water unsuitable as a drinking water supply for the indefinite future. Disruption of or damage to the collection system, on the other hand, could have severe immediate health, economic, and esthetic ramifications to the community. The inability to convey wastewater away from the source can rapidly lead to flooding of homes and accumulation of wastewater on streets and low-lying areas, resulting in direct contact with water-borne pathogens and the spread of disease.

Since the primary removal mechanism for organic contaminants in wastewater is biological degradation, any materials added to the wastewater that can inactivate the biomass will lead to loss of effective treatment. If the introduced material is inhibitory but not toxic, the plant will recover after a relatively short disruption upon dilution and purging of the material. This plant disruption can be longer term if the introduced material is toxic to the biomass, resulting in plant washout and the need for microbial regrowth. This phenomenon can also occur in WWTPs that receive combined wastewater and stormwater and are not equipped to bypass or equalize excessive flow due to major storm events. In such instances, the increased stormwater flow can lead to failure of the final clarifiers and washout of biomass.

The proximity of the traditional collection system to the general population and its accessibility, especially in the case of combined sewer systems, makes it highly susceptible to intentional or accidental disruptions. These disruptions could include blockage with large objects with resultant sewer backup and flooding, structural failure, power failure at lift stations, and introduction of flammable or explosive materials. A fire or explosion could result in localized or widespread infrastructure damage of water supply, communication, power, and transportation systems. Whereas the collection system is dispersed throughout the community and not readily amenable to increased security, the WWTP itself can be more effectively protected from intentional disruption with increased security measures.

# WATER SUPPLY AND WASTEWATER MANAGEMENT REGULATIONS, STANDARDS, AND GUIDANCE

VANESSA M. LEIBY
*The Cadmus Group, Inc., Damascus, Maryland*

## 1 INTRODUCTION

A number of governing authorities pertain to drinking water and wastewater utilities, collectively known as the *Water Sector*. Most provide broad environmental authority that may support security-related activities and initiatives; some specifically address homeland security. Existing authorities provide for public health and environmental protection measures; identify and regulate hazardous chemical, radiological, and biological substances; provide for worker safety; and ensure that the public receives information about water quality and chemical hazards. These laws also provide enforcement authorities for the US Environmental Protection Agency (EPA) and state primacy agencies and permitting authorities that implement many of EPA's environmental laws. New security-related directives and authorities address collection of asset-specific information, further promote information sharing and protection, require vulnerability assessments and development of emergency response plans (ERPs) for certain sizes of community water systems (CWSs), and encourage or require identification of protective strategies and implementation of protective programs. Unless otherwise noted, the authorities identified in this article apply to drinking water and wastewater utilities. Pertinent authorities will be described in several broad categories: (i) presidential directives; (ii) general homeland security laws; (iii) drinking water and wastewater environmental laws; (iv) other environmental laws that may impact the Water Sector, and (v) laws that apply to access to information.

## 2 PRESIDENTIAL DIRECTIVES

The President of the United States has issued a series of Presidential Directives relating to matters pertaining to homeland security. The first directive, Presidential Decision Directive 63, was issued in May, 1998, and set the administration's policy on critical infrastructure protection. Since that time, the President has issued 15 additional Homeland

Security Presidential Directives (HSPDs), a number of which relate to the Water Sector. The Directives most pertinent to the Water Sector are discussed in more detail below. More information on all the Directives can be found at http://www.dhs.gov/xabout/laws/editorial_0607.shtm [1].

### 2.1 Presidential Decision Directive 63

In May, 1998, Presidential Decision Directive 63 (PDD-63) was signed. This directive set the administration's policy on critical infrastructure protection (CIP), identified key sectors, and assigned lead agencies for sector liaison. EPA was designated the lead for the Water Sector, working in cooperation with other federal agencies and the public and private sectors. PDD-63 also authorized the development of Information Sharing and Analysis Centers (ISACs) for each sector to serve as a mechanism for gathering, analyzing, and disseminating appropriate security-related information among the public and private sector and the government. The complete text of PDD-63 can be found at http://www.fas.org/irp/offdocs/pdd/pdd-63.htm [2].

### 2.2 Homeland Security Presidential Directive/HSPD-7 (Critical Infrastructure Identification, Prioritization, and Protection—December 17, 2003)

This directive establishes a national policy for federal departments and agencies to identify and prioritize U.S. critical infrastructure and key resources to protect them from terrorist attacks that could:

- cause catastrophic health effects of mass casualties comparable to weapons of mass destruction;
- impair the ability of federal departments and agencies to perform essential missions or ensure the protection of public health and safety;
- undermine state and local government capacities to maintain order and deliver minimum essential public services;
- damage the Water Sector's capability to ensure the orderly functioning of the economy and delivery of essential services;
- have a negative impact on the economy through the cascading disruption of other critical infrastructure or key resources;
- undermine public morale and confidence in our national economic and political institutions.

The Secretary of Department of Homeland Security (DHS) is charged with integrating and coordinating implementation efforts among federal departments and agencies, state and local governments, and the Water Sector. The Secretary is to establish uniform policies, approaches, guidelines, and methodologies for integrating infrastructure protection and risk management activities within and across sectors and developing metrics as part of a national plan for critical infrastructure and key resources protection. The Secretary also maintains an organization to serve as a focal point for the security of cyber space, and prepares an annual federal research and development plan to support this directive. Federal agencies are required to work with state and local governments and the Water Sector to accomplish these objectives, and are instructed to appropriately

protect information associated with carrying out this directive. The directive focuses on critical infrastructure and key resources that, if exploited, could cause catastrophic health impacts or mass casualties. It identifies EPA as the Sector-Specific Agency (SSA) for the Water Sector (drinking water and wastewater systems) and calls on SSAs to:

- identify, prioritize, and coordinate infrastructure protection activities within their sectors;
- collaborate with relevant federal departments and agencies, state and local governments, and the Water Sector, and conduct or facilitate vulnerability assessments of the sector;
- encourage development of risk management strategies to protect against and mitigate the effects of an attack;
- promote the continued development of information sharing and analysis mechanisms, in collaboration with the Water Sector.

To implement this directive, EPA, in coordination with its Water Sector partners, created the Water Sector-Specific Plan (Water SSP), a broad-based critical infrastructure protection implementation strategy that depicts the mission, protective efforts, research priorities, indicators of progress, and necessary actions to improve the protection of the Nation's drinking water and wastewater utilities. A copy of the Plan can be found at http://www.epa.gov/safewater/watersecurity/pubs/plan_security_watersectorspecificplan.pdf [3]. More information on HSPD-7 can be found at http://www.dhs.gov/xabout/laws/gc-1214597989952.shtm [4].

### 2.3 Homeland Security Presidential Directive/HSPD-8 (National Preparedness—December 17, 2003)

This directive establishes policies to strengthen the preparedness of the United States to prevent and respond to threatened or actual domestic terrorist attacks, major disasters, and other emergencies, through the development of a national domestic all-hazards preparedness goal. It provides for state grants to build—through planning, training, and exercises—the capacity of first responders to react to terrorist events. Funds can also be used to purchase equipment. States are required to develop state-specific plans. The directive also calls for the development of quantifiable performance measures. The text of this directive can be found at http://www.dhs.gov/xabout/laws/gc-121544427124.shtm [5].

### 2.4 Homeland Security Presidential Directive/HSPD-9 (Defense of United States Agriculture and Food—January 30, 2004)

This directive establishes a national policy to defend the agriculture, water, and food system against terrorist attacks, major disasters, and other emergencies. It calls on EPA and other federal agencies to:

- build upon and expand current monitoring and surveillance programs for public health and water quality, which provide early detection and awareness of disease, pest, or poisonous agents;

- develop nationwide laboratory networks for water quality, which integrate existing federal and state laboratory resources;
- develop and enhance intelligence capabilities to include collection and analysis of information concerning threats, delivery systems, and methods that could be directed against the Water Sector;
- accelerate and expand countermeasure research, and development of methods for detection, prevention technologies, agent characterization, and dose–response relationships for high-consequence agents.

To implement HSPD-9, EPA has created a Water Security Initiative to design, deploy, and evaluate a model contamination warning system for drinking water security; developed a Drinking Water Laboratory Response Preparedness Project to develop and implement regional laboratory response plans for each of EPA's 10 Regions; and created a Water Laboratory Alliance to provide drinking water utilities with an integrated nationwide network of laboratories with the analytical capabilities and capacity to support monitoring and surveillance, response, and remediation to intentional and unintentional drinking water contamination events involving chemical, biological, and radiological contaminants. More information on these initiatives can be found at http://cfpub.epa.gov/safewater/watersecurity/initiative.cfm [6], http://www.epa.gov/safewater/watersecurity/pubs/fs_watersecurity_dwlabresponseproject.pdf [7], and http://www.epa.gov/safewater/watersecurity/pubs/fs_watersecurity_waterlaballiance.pdf [8], respectively. More information on HSPD-9 can be found at http://www.dhs.gov/xabout/laws/gc-1217449547663.shtm [9].

### 2.5 Homeland Security Presidential Directive/HSPD-10 (Biodefense for the 21st Century—April 24, 2004)

This directive provides a comprehensive framework for the nation's biodefense. It builds on past accomplishments, specifies roles and responsibilities, and integrates the programs and efforts of various communities—national security, medical, public health, intelligence, diplomatic, agricultural, and law enforcement—into a sustained and focused national effort against threats from biological weapons. The directive focuses on threat awareness, prevention and protection, surveillance and detection, and response and recovery. Specific direction to departments and agencies to carry out this biodefense program is contained in a classified document. More information on this Directive can be found at http://www.dhs.gov/xabout/laws/gc-1217605824325.shtm [10].

## 3 GENERAL HOMELAND SECURITY LAWS

In addition to specific Presidential Directives, there are a number of general homeland security laws that provide for the necessary structure to support and implement these initiatives. The principal laws are discussed below.

### 3.1 Homeland Security Act of 2002, P.L. 107–296

This act created the DHS by bringing together a number of independent agencies to analyze intelligence and coordinate security research across government, academia, and the private sector.

Provisions encourage partnerships between Government and the Water Sector to better protect civilian infrastructure, and to create volunteer teams to help local communities respond to attacks on information systems and communication networks. Section 505 requires the Secretary of Homeland Security to provide funds to EPA for homeland security planning, exercises and training, and equipment. More information about the Law can be found at http://www.dhs.gov/xlibrary/assets/hr-5005-enr.pdf [11].

### 3.2 Critical Infrastructure Information (CII) Act of 2002

The Critical Infrastructure Information (CII) Act of 2002, defines critical infrastructure information, and provides for the development of programs to protect such information, particularly information submitted voluntarily. The act also defines information sharing and analysis organizations.

Under this act, DHS has created the Protected Critical Infrastructure Information (PCII) Program that is designed to encourage public and private industry, and others with knowledge about critical infrastructure, to share sensitive and proprietary business information with the Government. The focus of this program is: (i) analyzing and securing critical infrastructure and protected systems; (ii) identifying vulnerabilities and developing risk assessments; and (iii) enhancing recovery-preparedness measures. Information submitted, if it satisfies the requirements of the Critical Infrastructure Information Act of 2002, is protected from public disclosure under (i) the Freedom of Information Act; (ii) state and local disclosure laws, and; (iii) use in civil litigation.

More information about PCII can be found at http://www.dhs.gov/xinfoshare/programs/editorial_0404.shtm [12].

## 4 DRINKING WATER AND WASTEWATER ENVIRONMENTAL LAWS

The following laws govern the regulation of drinking water and wastewater systems in the U.S. While the discussion relates primarily to EPA, it is important to note that state governments most often have direct jurisdiction over drinking water and wastewater systems, and that state governments are most involved in fostering security at the local level through primacy agencies and permitting authorities. In order to obtain primacy, states and tribes must adopt regulations for contaminants that are no less stringent than the regulations promulgated by EPA.

### 4.1 Safe Drinking Water Act, 42 U.S.C. §§300F-300J-26 (Drinking Water)

The general provisions of the SDWA provide a basis for drinking water security by protecting the quality and underground sources of drinking water. To protect the quality of public drinking water, EPA establishes regulations for national primary and secondary drinking water standards. States may receive primacy from EPA to administer the safe drinking water program if they adopt regulations no less stringent than the federal government's, and meet other conditions, as described below.

- Have regulations for contaminants that are no less stringent than the regulations promulgated by EPA.
- Adopt, and implement procedures for the enforcement of state regulations;

- Maintain an inventory of public water systems in the state.
- Have a program to conduct sanitary surveys of the systems in the state.
- Have a program to certify laboratories that will analyze water samples required by the regulations, and identify a laboratory that is certified by EPA that will serve as the state's principal lab.
- Have a program to ensure that new or modified systems will be capable of complying with state primary drinking water regulations.
- Have adequate enforcement authority to compel water systems to comply with national primary drinking water regulations, including:
  - the authority to sue in court;
  - the right to enter and inspect water system facilities;
  - the authority to require systems to keep records and release them to the state;
  - the authority to require systems to notify the public of any system violation of the state requirements;
  - the authority to assess civil or criminal penalties for violations of the state primary drinking water regulations and public notification requirements.
- Have adequate record keeping and reporting requirements.
- Have variance and exemption requirements as stringent as EPA's, if the state chooses to allow variances or exemptions.
- Have an adequate plan to provide for safe drinking water in emergencies such as natural disasters.
- Adopted authority to assess administrative penalties for violations of their approved primacy program.

The statute applies to public water systems (PWSs)—systems for the provision of water to the public for human consumption through pipes and other constructed conveyances including federal facilities, such as military bases and hospitals, and other sites with their own drinking water systems. Drinking water programs most applicable to water security are as follows.

- *State wellhead protection.* This program provides that states establish programs to protect wellhead areas (i.e. the surface and subsurface areas surrounding water wells or well fields supplying a PWS) from contamination.
- *Source water protection.* The EPA must develop guidance for states to carry out source water assessment programs. States must delineate the source water areas of all PWSs, and identify actual or potential sources of contamination. Program elements include risk reduction (delineation and source inventories), risk ranking and screening (susceptibility analyses), risk management measures (prevention programs), and preparation for unexpected drinking water supply emergencies (contingency planning).
- *Protection of underground sources of drinking water.* The EPA must promulgate regulations for state underground injection control (UIC) programs to prevent underground injection that endangers drinking water sources.
- *Sanitary surveys.* States conduct regular sanitary surveys of PWSs. A sanitary survey entails a review of the water system's assets, distribution system plans and

maps, routine operation and maintenance (O&M) records, monitoring and sampling plans, and operator certification status.

- *Emergency powers.* The EPA is authorized to take necessary precautions upon receiving information that contamination of a PWS or underground water source may present an imminent and substantial danger to human health, and that appropriate state and local authorities have not acted to protect human health.
- *Maintaining records and monitoring.* Suppliers of potable water, and others subject to the requirements of the act, may be required by the EPA administrator to maintain records and conduct monitoring.
- *Public water system supervision grant program.* Helps states to implement drinking water programs to protect public health. These grants are used by state drinking water program administrators to monitor drinking water quality, conduct sanitary surveys, enforce drinking water standards, and provide technical assistance to local communities. Separate security grants have been provided to states to help focus and direct state-level security initiatives.
- *National drinking water standards.* As noted above, EPA is authorized to establish regulations for national primary and secondary drinking water standards, in order to protect the quality of public drinking water. Use of treatment techniques and technologies may be a requirement under some drinking water regulations, as well as monitoring requirements (see "Maintaining records and monitoring," above). In addition, EPA may establish an interim drinking water standard for a contaminant to address an urgent threat to public health, and may publish health advisories (which are not regulations) or take other appropriate actions for contaminants not subject to any national primary drinking water regulation.
- *Public Health Security and Bioterrorism Preparedness and Response Act, P.L. 107–188.* Also referred to as the *Bioterrorism Act of 2002* —see text below.

The text of the SDWA can be found at http://epw.senate.gov/sdwa.pdf [13].

### 4.2 Public Health Security and Bioterrorism Preparedness and Response Act of 2002, Public Law 107–188 (Drinking Water)

Among other provisions, this act amends the SDWA by inserting Title IV—*Drinking Water Security and Safety* into Title XIV of the Public Health Services Act as sections 1433, 1434, and 1435. It requires the following activities:

- The EPA must provide to community water systems (CWSs) baseline probable-threat information required to complete vulnerability assessments.
- Each CWS serving 3300 or more persons must conduct a vulnerability assessment, certify its completion, and submit a copy of the assessment to EPA, according to a specified schedule.
- Each CWS serving 3300 or more persons must prepare or revise an emergency response plan that incorporates the findings of the vulnerability assessments, and must certify to EPA that the system has completed such a plan within six months of completing a vulnerability assessment.
- The EPA must develop a protocol to protect this information.

- The EPA must develop vulnerability assessment guidance for systems serving fewer than 3300 persons.
- The EPA must conduct research studies in the following:
  - Prevention, detection, and response to the intentional introduction of contaminants into CWSs and their source water.
  - Methods and means by which terrorists could disrupt the supply of safe drinking water or act against drinking water infrastructure.
  - Methods and means by which alternative supplies of drinking water could be provided in the event of the destruction, impairment, or contamination of PWSs.

The EPA has supported the development of a suite of vulnerability (risk) assessment tools for drinking water and wastewater systems of all sizes that address unique and fundamental security concerns. All vulnerability assessments are currently conducted at the utility level. Identification of priority assets is dictated by local conditions, and the determination of threats is identified by the specific Water Sector utility conducting the assessment. As part of the vulnerability assessment, utilities develop an inventory of system assets, including, but not limited to, physical, cyber, information technology, and personnel components, and identify which assets are most critical to the system's mission. To further assist Water Sector utilities, EPA coordinates with DHS's National Cyber Security Division to assist with the development of DHS's national strategy to secure cyber space, and to engage the Water Sector in better protecting cyber-assets.

Important to note is that "vulnerability assessment" is the accepted terminology in the Water Sector due to the language of the Bioterrorism Act of 2002. The term is equivalent to the DHS's "risk assessment" since the methodologies developed for the Water Sector considers all the components of risk (consequence, threat, and vulnerability). More information on the Bioterrorism Act of 2002 can be found at http://www.epa.gov/safewater/watersecurity/pubs/security_act.pdf [14].

### 4.3 Federal Water Pollution Control Act (Clean Water Act), 33 U.S.C. §§1251–1387 (Wastewater)

The Clean Water Act (CWA) governs the quality of discharges to surface and ground water. It establishes national technology-based standards for municipal waste treatment, and numerous categories of industrial point-source discharges (discharges from fixed sources, such as pipes and ditches) requires states, and in some cases tribes, to enact and implement water quality standards to attain designated water-body uses; addresses toxic water pollutants; and regulates dredge-and-fill activities and wetlands. The act provides a number of enforcement authorities for EPA, and states that have accepted permitting authority. The statute also applies these requirements to federal facilities, such as military installations and Department of Energy sites. Programs most applicable to security include:

- *Prohibition of discharges into waters of the United States.* Except as permitted by the act, the discharge of any pollutant by any person is unlawful. These discharges include the discharge into navigable waters of any radiological, chemical, or biological warfare agent; high-level radioactive waste; and medical waste. This provision authorizes the National Pollutant Discharge and Elimination System (NPDES) program.

- *Toxic and pretreatment effluent standards.* The EPA must identify toxic pollutants for which the application of best available technology (BAT) is required. In addition, EPA must promulgate pretreatment standards for pollutants that are not susceptible to treatment by publicly owned treatment works (POTWs) but are introduced into POTWs, and for pollutants that would interfere with the operation of such treatment works. The national pretreatment program is authorized by this provision.
- *Oil and hazardous substance liability.* The EPA is required to develop a list of hazardous substances (other than oil) that present an imminent and substantial danger to the public health or welfare. Any person in charge of a vessel or facility must, as soon as that person has knowledge of any unlawful discharge of oil or hazardous substance, notify the Federal government.
- *Imminent and substantial endangerment.* When EPA receives notice that a pollution source presents imminent and substantial endangerment to human health or livelihood, it may sue for the immediate restraint of anyone causing or contributing to the pollution, or take any other action necessary.

Information on the CWA can be found at http://epw.senate.gov/water.pdf [15].

## 5 OTHER ENVIRONMENTAL LAWS THAT IMPACT THE WATER SECTOR

In addition to laws that regulate the Water Sector directly, other environmental laws give EPA authority to take various actions that impact water security. These laws are described below.

### 5.1 Toxic Substances Control Act (TSCA), 15 U.S.C. §§ 2601–2692

TSCA addresses risks to public health and the environment from existing and new chemical substances, any number of which could be used to contaminate a water supply. It establishes a framework for identifying potentially harmful chemical substances, and controlling their use through a variety of regulatory tools. These tools include, screening new chemical substances, testing existing substances, labeling and record keeping, and restricting activities involving substances that present unreasonable health or environmental risks. The act also gives EPA the authority to address imminent hazards.

### 5.2 Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), 7 U.S.C. §§ 136 et seq.

The primary focus of Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) is to provide federal control of pesticide distribution, sale, and use. Under FIFRA, EPA studies the consequences of pesticide use, and requires users (farmers, utilities, and others) to register when purchasing pesticides. Users must also take exams for certification as applicators of pesticides. All pesticides used in the United States must be registered (licensed) by EPA. Registration ensures that pesticides will be properly labeled and will not cause unreasonable harm to the environment if used according to specifications. This law provides authority for EPA to regulate the use of pesticides, including those that could be used to contaminate water supplies.

### 5.3 Comprehensive Environmental Response Compensation, and Liability Act (CERCLA), as amended (Superfund), 42 U.S.C. §§9601–9675

Comprehensive Environmental Response Compensation, and Liability Act (CERCLA) provides for the cleanup of sites where hazardous substances have been released into the environment, or where there is a substantial threat that they will be released. The statute authorizes EPA to clean up and take action to prevent releases of hazardous substances, and to recover costs from parties who may be responsible for a release or threatened release. It gives the President authority to remove hazardous substances, provide for long-term remedial action, and take any other action necessary to protect the public health or welfare, or the environment. It also creates the national contingency plan that establishes the minimum requirements of the hazardous substance response plan including methods of determining priorities among releases based on relative risk or danger to public health or welfare, or the environment.

### 5.4 Resource Conservation and Recovery Act (RCRA), 42 U.S.C. §§6901–6992K, Hazardous Waste Management (Subtitle C)

Resource Conservation and Recovery Act (RCRA) regulates the management and disposal of hazardous and nonhazardous solid waste. Subtitle C of the statute establishes a comprehensive system designed to manage hazardous waste from its creation, through its transportation, to its ultimate disposal. RCRA requires EPA to ban the disposal of certain wastes by injecting them deep under ground, if it may be reasonably determined that such disposal may not protect human health and the environment for as long as the waste remains hazardous.

### 5.5 Occupational Safety and Health Administration (OSHA) Process Safety Management Rule (29 CFR Part 1910.119)

Some water utilities that store or use more than 1500 pounds of gaseous chlorine (or other listed toxic chemicals) are required to comply with this rule. It is designed to prevent or minimize the consequences of catastrophic releases of highly toxic chemicals by requiring facilities to design and operate safe processes, and to plan for emergencies.

### 5.6 Other OSHA Safety Regulations

Several other important Occupational Safety and Health Administration (OSHA) safety regulations apply to work sites containing toxic chemicals such as chlorine gas. These regulations include the OSHA Hazard Communication Standard (29 CFR 1910.1200), Standard for Control of Hazardous Energy (lockout/tag out) (29 CFR 1910.147), Respiratory Protection Standard (29 CFR 1910.134), Personal Protective Equipment Standard (29 CFR 1910.132), and Hazardous Waste Operations and Emergency Response (HAZWOPER) Standard (29 CFR 1910.120).

### 5.7 Clean Air Act (CAA), Section 112(r), 42 U.S.C. §§ 7401–7671q, EPA Risk Management Plan Regulation, 40 CFR Part 68.150

Utility processes containing more than 2500 pounds of chlorine gas are required to implement an accident prevention program, conduct a hazard assessment, prepare and

implement an emergency response plan, and submit to EPA a summary report known as a *risk management plan* (RMP). The RMP must include an executive summary that provides a brief description of the facility's accidental release prevention and emergency response policies, the regulated substances handled at the facility, the worst-case release scenario(s) and alternative release scenario(s), the 5-year accident history of the facility, the facility emergency response program, and planned changes to improve safety at the facility (see 40 CFR Part 68). The full RMP also includes an Off-site Consequences Analysis (OCA), which provides the real extent of a worst-case scenario. Other chemicals that may be present at Water Sector utilities, including ammonia, sulfur dioxide, and chlorine dioxide, also trigger RMP regulatory requirements if they exceed certain threshold quantities.

## 6 LAWS RELATED TO ACCESS TO INFORMATION

The following acts affect the public's ability to obtain information pertaining to the critical infrastructure of drinking water and wastewater systems.

### 6.1 Emergency Planning and Community Right-To-Know Act (EPCRA), 42 U.S.C. §§11001–11050

Emergency Planning and Community Right-To-Know Act (EPCRA) requires states to establish State Emergency Response Commissions (SERCs) that, in turn, are required to establish Local Emergency Planning Committees (LEPCs). The LEPCs are to develop local emergency response plans for releases of extremely hazardous chemicals. Each facility handling extremely hazardous chemicals in excess of threshold quantities must notify the LEPC, and must report any releases over a threshold quantity to the LEPC. If the facility is required under the Occupational Health and Safety Act of 1970 (29 U.S.C. 651 et seq.) to maintain Material Safety Data Sheets (MSDSs), the facility must submit an MSDS for each extremely hazardous chemical on site above the threshold quantity, or a list of such chemicals, grouped by hazard (flammable, toxic, etc.), to the LEPC, the SERC, and the local fire department. The facilities must also submit annual inventories of toxic chemicals managed at the facility over the threshold quantity during the previous year.

### 6.2 Freedom of Information Act (FOIA), 5 U.S.C. §§552–552A

Freedom of Information Act (FOIA) provides a mechanism for members of the public to obtain documents and other information from federal government agencies. The act exempts from disclosure matters relating to national defense or foreign policy, matters specifically exempted by statute, trade secrets and privileged or confidential commercial matters, inter and intraagency memoranda not available by law outside of litigation, certain records or documents compiled for law enforcement purposes, and other categories of sensitive information. Vulnerability assessments provided to EPA under section 1433 of the SDWA, and any information derived from them, are exempt from disclosure under FOIA.

### 6.3 Federal Advisory Committee Act (FACA) 5 U.S.C. §§5—Appendix 01/02/01

The purpose of FACA is to ensure that advice rendered to the executive branch by the various advisory committees, task forces, boards, and commissions formed by Congress and the President is objective and accessible to the public. Committee memberships must be fairly balanced in terms of the points of view represented and the functions to be performed. Committee meetings must be open to the public, and their records must be publicly available.

# ROLES OF FEDERAL, STATE, AND LOCAL AUTHORITIES IN WATER INFRASTRUCTURE SECURITY

J. A. ROBERSON
*American Water Works Association, Washington, D.C.*

## 1 INTRODUCTION

Response and recovery from any incident always starts at the local level, but in many cases, when local resources are inadequate, state and/or federal assistance is needed. The Department of Homeland Security (DHS) is now playing a more prominent role in national security and preparedness, and the Environmental Protection Agency (EPA) still plays a significant role as the Sector-Specific Agency (SSA) for the water sector. The federal role is still evolving based on 9/11, and Katrina and other natural disasters, and is not always clear. Much progress has been in clearly defining everyone's roles and responsibilities, but more work is needed to ensure appropriate preparedness, response, and recovery capabilities at all levels.

## 2 BACKGROUND

Similar to all other critical infrastructure (CI), security took on a whole new meaning for water and wastewater utilities after 9/11. These utilities now have to balance security along with all of their other competing priorities such as water quality, finances, efficiency, customer service, infrastructure investment, and others. Utilities have now taken a hard look at the vulnerabilities of the different facilities within their systems, and began to make the investments to lessen those vulnerabilities and to instill a culture of security in the daily operations of the utility. In many instances, utilities developed their vulnerability assessment (VA) with the assistance from consultants, with tools developed to guide them through critical questions. Small utilities often applied a simple checklist method depending on the complexity of their operations.

The approximately 8000 water utilities serving greater than 3300 people were required under the Public Health and Safety Act of 2002 (The Bioterrorism Act, PL 107–188) to conduct VAs, and then revise their emergency response plans (ERPs) based on what they learned in conducting their VAs. The VAs were required to be submitted to the EPA, which had significant constraints placed on it by the Bioterrorism Act on how these VAs could be reviewed and used. The utilities only had to submit a certification of a revised ERP to EPA. Many wastewater utilities also voluntarily conducted similar VAs and revised their ERPs.

In most cases, only a small portion of a typical utility VA might include working with the local fire and police departments to improve response time to the different facilities scattered throughout the local community. Response and recovery from any incident (natural or manmade) always starts at the local level. Utilities and/or local authorities initiate the response as soon as possible, but in many cases, soon find that their own resources are inadequate. State and federal resources will then be brought in to assist the local authorities when local resources cannot handle larger and more significant incidents.

A new paradigm has emerged in the past few years. In essence, utilities need to go beyond internal analysis and internal discussions. Utilities need to go beyond minimal contact with the local fire and police departments and engage with a broad range of outside organizations. Making the time commitment and investing the resources necessary to cultivate working relationships with a variety of other organizations at the local, state, and federal level to develop appropriate response and recovery plans and to improve preparedness capabilities are critical. A utility manager should neither be exchanging business cards on the hood of a pickup truck during an emergency nor should that utility manager be the only utility representative forging such relationships. These relationships need to be established and cultivated before disaster strikes, or before the emergency hits, as part of the utility's preparedness activities. The need for these relationships with different authorities will likely vary based on local, state, and institutional frameworks, but would typically include first responders such as

1. fire, police, and emergency management;
2. public health officials such as city and county health officials and staff at the local hospitals;
3. local and state elected officials, public information staff within these authorities;
4. local and state homeland security staff; and
5. federal agencies such as the Federal Bureau of Investigation (FBI), the Centers for Disease Control and Prevention (CDC), and the DHS.

## 3 THE FEDERAL ROLE

The federal role in water infrastructure has evolved significantly since the initial designation of the water sector as one of the CI sectors in Presidential Decision Directive 63 (PDD-63). This designation occurred during President Clinton's Administration, and some might argue that this action was instigated by the Oklahoma City bombing in April 1995. However, it was more likely a combination of several other issues such as ongoing instability in the Middle East. Homeland security became a significant national priority after 9/11, and more federal resources were directed to this issue. The federal government had to respond to new threats to homeland security, and needed to restructure its preparedness and response functions. The Homeland Security Act of 2002 assigned the responsibility of protecting critical infrastructure/key resources (CI/KR) to the newly created DHS, which was established by Congress in the Homeland Security Act of 2002 (PL 107–296).

The first attempt at a national strategy for homeland security that focused on CI came soon after 9/11 with the Executive Order on Critical Infrastructure Protection issued by President Bush on October 16, 2001. This was followed by *The National Strategy*

*for Homeland Security* that was developed by the Office of Homeland Security in the White House in July 2002. This broad strategy defined homeland security, established a framework for organization, and identified critical mission areas. *The National Strategy for the Physical Protection of Critical Infrastructure and Key Assets* was more geared specifically toward infrastructure and was released in February 2003.

### 3.1 Homeland Security Presidential Directives

PDD-63 was replaced and supplanted by a series of Homeland Security Presidential Directives (HSPDs) during the Bush Administration. The federal role in infrastructure security is evolving due to these HSPDs, and this evolution clearly has impacts on the water sector. HSPDs typically require DHS and/or other federal agencies to develop some type of plan or take other specific actions. HSPDs do not have the force of law to require utilities (or other entities) to meet specific regulatory requirements—like the Bioterrorism Act. Although several HSPDs ultimately may impact the water sector, HSPD-5, HSPD-7, and HSPD-8 best define the federal role and the relationships between the federal, state, and local roles in water security and for all other CI/KR sectors.

### 3.2 HSPD-5 and the National Response Plan (NRP)

HSPD-5, released on February 28, 2003, addresses management of domestic incidents, such as the natural disasters such as hurricanes or floods, manmade accidents such as the derailment of chemical railcars, and acts of terrorism. In HSPD-5, DHS was directed to develop a new National Response Plan (NRP) to align federal capabilities and resources for an all-hazards approach for domestic incidents. An all-hazards approach refers to developing the capabilities to respond to natural disasters, manmade accidents, and acts of terrorism. For acts of terrorism, federal agencies will generally take the lead role from the homeland security perspective.

The first NRP [1] was released in December 2004. The NRP consists of several major elements, including a Base Plan that details the concept of operations, coordinating structures, and roles and several Emergency Support Function (ESF) Annexes. The ESF Annexes organize and merge capabilities and resources into functions, that is, transportation, and mass care, that are most likely needed during an incident. The water sector is listed under ESF-3, Public Works, and the United States Army Corps of Engineers (USACE) is the lead federal agency for ESF-3. There is an ongoing debate about whether a separate ESF is needed for the water sector because of its role in response and recovery and its potential economic effects within the community [2]. The USACE is typically more geared toward structural assessment and repair and debris removal. In some cases, the USACE has not completely understood that response for the water sector will need to go beyond delivery of bottled water to getting the water and wastewater system back to normal operations in order to restart the economic engine in a community.

Some issues with the initial NRP became apparent in the response to Hurricane Katrina, and some have severely criticized the federal response to that incident. The NRP is currently undergoing a significant revision to better spell out the federal, state, and local responsibilities and to incorporate lessons learned from Hurricane Katrina.

The NRP is a specific application of the National Incident Management System (NIMS). NIMS incorporates the use of the Incident Command System (ICS). ICS has traditionally been used by first responders such as fire and police, and to a degree, is a

new concept for the water sector. The use of an Incident Commander is one of the key ICS concepts. As an incident unfolds, the utility general manager or emergency manager will likely start off as the Incident Commander. But, this will likely change as the utility realizes that their resources are inadequate, and state and federal resources will be brought in to assist the local authorities. Utilities have to be prepared for transitioning the role of Incident Commander to the proper authorities, and that transition could vary from incident to incident. Understanding NIMS and ICS is critical now as any state or local entity receiving federal funding has to be NIMS-compliant.

### 3.3 HSPD-7 and the National Infrastructure Protection Plan (NIPP)

HSPD-7, released on December 17, 2003, addresses the identification, prioritization, and protection of CI for the purposes of preventing, deterring, and mitigating the effects of malevolent acts. Implementing this policy requires a substantial commitment to public–private partnership from both governmental agencies and the owner–operators of the actual infrastructure. Governmental agencies are not typically used to a partnership model, as agencies are typically regulators. Owner–operators are typically wary of the government due to its more traditional regulatory role.

In HSPD-7, the President directed the DHS Secretary to be the lead federal agency for the protection of 17 sectors of CI/KR through the development of a National Infrastructure Protection Plan (NIPP). Those 17 sectors are as follows:

1. Agriculture and Food;
2. Defense Industrial Base;
3. Energy;
4. Public Health and Healthcare;
5. National Monuments and Icons;
6. Banking and Finance;
7. Drinking Water and Water Treatment Systems;
8. Chemical;
9. Commercial Facilities;
10. Dams;
11. Emergency Services;
12. Nuclear;
13. Information Technology;
14. Telecommunications;
15. Postal and Shipping;
16. Transportation Systems; and
17. Government Facilities.

HSPD-7 assigned responsibility for each CI/KR sector to SSAs. DHS is the SSA for the 10 CI/KR sectors numbered 8–17 above. Other federal agencies have been designated as the SSA for sectors numbered 1–7 above on the basis of their expertise and experience with working that individual sector. EPA is the SSA for the water sector due to its expertise with water and wastewater systems and through its regulatory programs under the Safe Drinking Water Act (SDWA) and the Clean Water Act (CWA).

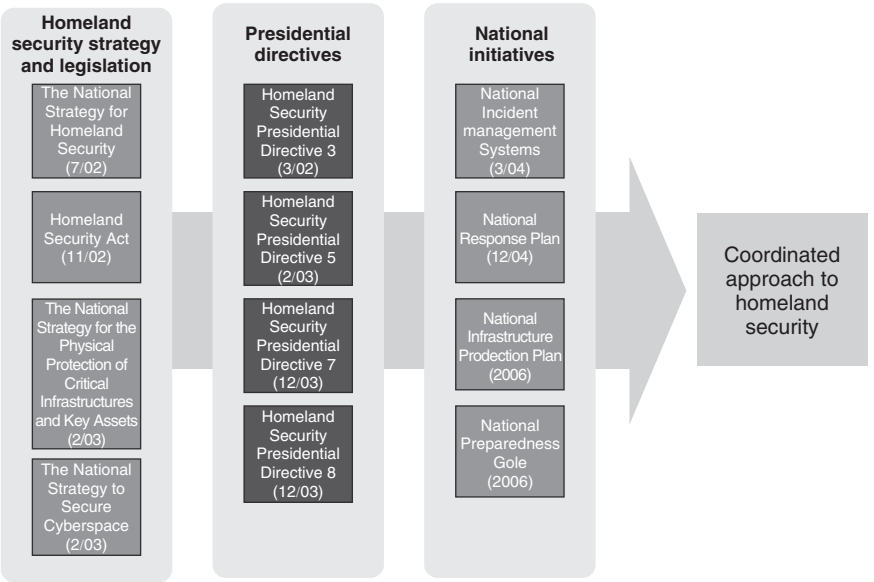

**FIGURE 1** Organization of Homeland Security: related authorities (from page 9, Water Sector-Specific Plan).

Figure 1 shows how the various bills, strategies, plans, and HSPDs fit together to achieve (or accomplish) a coordinated federal approach to homeland security. This is a high-level graphic of an extremely complex process, with multiple parts of multiple organizations moving concurrently toward the common goal of improving homeland security.

In June 2006, the NIPP [3] was completed by DHS. The NIPP is essentially the federal roadmap for the protection of all sectors of CI/KR. The NIPP provides the unifying structure for the integration of all efforts to "build a safer, more secure, and more resilient America". The cornerstone of the NIPP is its risk management framework that ultimately needs to be used by all CI/KR sectors. DHS wants to measure the effectiveness of CI/KR protection efforts to provide constant feedback, and development of those security metrics will be challenging for all of the 17 CI/KR sectors.

### 3.4 Sector Coordinating Councils and Sector-Specific Plans

As part of the implementation of HSPD-7 and as part of this new partnership model, DHS has encouraged each CI/KR sector to develop its own Sector Coordinating Council (SCC) to provide policy input to DHS and its SSA (if the SSA is not DHS). DHS wanted to hear a single voice from each CI/KR sector on the difficult security policy issues. Members of each SCC are selected by the owner–operators to represent the different subgroups of each sector, and each SCC develops its own governing documents. The Water SCC consists of two utility representatives from the following eight organizations:

- American Water Works Association (AWWA);
- American Water Works Research Foundation (AwwaRF);
- Association of Metropolitan Water Agencies (AWMA);

- National Association of Water Companies (NAWC);
- National Rural Water Association (NRWA);
- National Association of Clean Water Agencies (NACWA);
- Water Environment Federation (WEF); and
- Water Environment Research Foundation (WERF).

Staff from the each association serve as nonvoting representatives to the Water SCC and also provide logistical and technical support. These support functions include developing a vision and mission for each sectors and building a Sector-Specific Plan (SSP) and the associated metrics.

For the government side, that is, not the owner–operators, there is a corresponding Government Coordinating Council (GCC) for each CI/KR sector. Each SCC and GCC works with DHS and the appropriate SSA in a partnership, and sometimes that is easier said than done due to the number of parties involved.

After the release of the NIPP in June 2006, each of the 17 CI/KR sectors was required to develop its own SSP by the end of the 2006. All of the individual SSPs were reviewed by DHS and the White House in early 2007, and all of the SSPs were jointly released in May 2007.

The Water SSP has the following four goals:

1. sustain protection of public health and the environment;
2. recognize and reduce risk in the water sector;
3. maintain a resilient infrastructure; and
4. increase communication, outreach, and public confidence.

More detailed objectives have developed under each goal [4]. One of the challenges for the water sector today is the development of metrics that match up to the goals and objectives of the Water SSP. How do you really measure the effectiveness of specific water security and/or preparedness efforts? This question is being debated by all CI/KR sectors, as ultimately, DHS wants metrics from all sectors to be able to evaluate how well it is meeting its goal to "build a safer, more secure, and more resilient America". DHS would like all CI/KR sectors to develop these metrics and then voluntarily report data on meeting these metrics so it can evaluate not only how effective each sector is but also evaluate cross-sector, and then roll up all sectors into a national evaluation.

### 3.5 HSPD-8 and Water and Wastewater Agency Response Networks (WARNs)

HSPD-8, focusing on National preparedness, was also released on December 17, 2003. The purpose of HSPD-8 is to help entities at all levels of government develop and maintain the capabilities to prevent, respond to, and recover from major events or incidents of national significance. A key priority is the expansion of regional collaboration through mutual aid agreements and assistance compacts. A major initiative in the water sector is the expansion of the number of Water and Wastewater Agency Response Networks (WARNs), which is discussed in more detail later.

## 4 THE STATE ROLE

For most natural disasters, the State Emergency Management Agencies (EMAs) and Emergency Operations Centers (EOCs) will typically be the focal point for response and recovery efforts. As previously discussed, federal resources will be brought in to assist the state and local authorities when larger and more significant incidents require additional resources. Seats at the state EOCs are sometimes closely guarded, and utilities may or may not be able to get a seat. The EOC serves as a focal point for matching resources and requirements.

Since 9/11, most states have now established a Homeland Security Office that may or may not be separate from the State EMA, and this sometimes causes differences in priorities. However, these Security Offices are important as they serve as the conduit for federal funding.

The Emergency Management Assistance Compact (EMAC) provides a mechanism for crossing state lines for mutual aid and assistance. EMAC is a State-to-State Compact accessed through the State EMA. The request for equipment and/or personnel must be approved by both the requesting and assisting EMA before any assets can be deployed. EMAC addresses liability and other legal issues that may arise between states during the provision of assistance.

With recent hurricanes and other natural disasters proving that nature is the more likely threat than terrorists, utilities are debating how to balance physical security such as guns, guards, and gates with improved resiliency and response capabilities [5]. The AWWA has developed a white paper [6] to assist states in forming WARNs. This white paper details a 10-step program to form a WARN, and the water sector is holding workshops across the country to expand the number of state-level WARNs. The goal of these networks is "utilities helping utilities". In other words, what can utilities do to help each other in the first three days after an incident while the state and federal resources are being organized. Resources and requirements will be matched through these networks during an incident. The desire by water utilities to "do the right thing" is stimulating the growth in the number of WARNs. The next step in the evolution of WARNs is the formation of a national steering committee to address interstate issues.

## 5 THE LOCAL ROLE

As previously discussed, response and recovery from any incident (natural or manmade) always starts at the local level. Utilities started their effort with the VAs and ERPs required under the Bioterrorism Act. Many utilities are now evolving their ERPs into Business Continuity Plans (BCPs) to address new and emerging issues as potential reductions in workforce from pandemic influenza. In January 2007, DHS's NIMS Integration Center (NIC) recommended that state and local government adopt The National Fire Protection Association (NFPA) 1600: *Standard on Disaster/Emergency Management and Business Continuity Programs* (and other standards) as part of NIMS implementation [7].

Local and/or county EMAs and EOCs are typically the focal point for response and recovery efforts. If possible, utilities should have a seat at the local/county EOC. Utilities

should make the time commitment and invest the resources necessary to cultivate working relationships with the appropriate staff at the state and local EMAs.

## 6 SUMMARY AND CONCLUSIONS

Response and recovery from any incident (natural or manmade) always starts at the local level. Utilities and/or local authorities initiate the response as soon as possible, but in many cases, soon find that their resources are inadequate. State and federal resources will then be brought in to assist the local authorities when local resources cannot handle larger and more significant incidents.

The federal role is not always clear and that role is evolving as the various HSPDs are moving further in the implementation process. Much process has been made, but more work is needed to ensure appropriate preparedness, response, and recovery by the various local and state entities, and by the various federal agencies.

# POTENTIAL CONTAMINATION AGENTS OF INTEREST

ROBERT M. CLARK
*Cincinnati, Ohio*

## 1 INTRODUCTION

There are nearly 60,000 community water supplies in the United States serving over 226 million people. Over 63% of these systems supply water to less then 2.4% of the population and 5.4% supply water to 78.5% of the population. Most of these systems provide water to less then 500 people. In addition, there are 140,000 noncommunity systems that serve schools, recreational areas, trailer parks, etc. [1]. Some of the common elements associated with water supply systems in the United States are as follows:

- *Water source,* which may be a surface impoundment such as a lake, reservoir, river, or ground water from an aquifer;
- *Conventional treatment facilities,* including filtration, which removes particulates and potentially pathogenic organisms, followed by disinfection, primarily for surface supplies;
- *Transmissions systems,* which include tunnels, reservoirs, and/or pumping facilities, and storage facilities;
- *Distribution systems,* carrying finished water through a system of water mains and subsidiary pipes to consumers.

## 2 WATER SYSTEM VULNERABILITY

Water systems are spatially diverse and therefore, have an inherent potential to be vulnerable to a variety of physical, chemical and biological threats that might compromise a

systems' ability to reliably deliver safe water. Community water supplies are designed to deliver water under pressure and generally supply most of the water for firefighting purposes. Therefore a loss of water or a substantial loss of pressure could disable firefighting capability, interrupt service, and disrupt public confidence. This loss might result from sabotaging pumps that maintain flow and pressure, or disabling electric power sources that might lead to long term disruption. Many of the major pumps and power sources in water systems have custom-designed equipment and could take months or longer to repair and/or replace [2].

Major areas of vulnerability include the following:

- raw water source (surface or groundwater);
- raw water channels and pipelines;
- raw water reservoirs;
- treatment facilities;
- connections to the distribution systems;
- pump stations and valves;
- finished water tanks and reservoirs.

Each of these system elements present unique challenges to a water utility in safeguarding water supply [3].

## 2.1 Physical Disruption

The ability of a water supply to provide water to its customers can be compromised by destroying or disrupting key physical elements of the water system. These elements include raw water facilities (dams, reservoirs, pipes, and channels), treatment facilities, and distribution system elements (transmission lines and pump stations).

Physical disruption may result in significant economic cost, inconvenience, and loss of confidence by customers, but has a limited direct threat to human health. Exceptions to this generalization include (i) destruction of a dam that causes loss of life and property in the accompanying flood wave and (ii) an explosive release of chlorine gas at a treatment plant. Water utilities should examine their physical assets, determine areas of vulnerability, and increase security accordingly. An example of such an action might be to switch from chlorine gas to liquid hypochlorite, especially in less secure locations which decreases the risk of exposure to poisonous chlorine gas. Redundant system components would provide backup capability in case of accidental or purposeful damage to facilities.

## 2.2 Contamination

Contamination is generally viewed as the most serious potential terrorist threat to water systems. Chemical or biological agents could spread throughout a distribution system and result in sickness or death among the consumers, and for some agents the presence of the contaminant might not be known until emergency rooms report an increase in patients with a particular set of symptoms. Even without serious health impacts, just the knowledge that a group had breached a water system could seriously undermine consumer confidence in public water supplies [4].

Accidental contamination of water systems has resulted in many fatalities. Examples of such outbreaks include cholera contamination in Peru [5], *Cryptosporidium* contamination

in Milwaukee, Wisconsin (US) [6], and *Salmonella* contamination in Gideon Missouri (US). In Gideon the likely culprit was identified as pigeons infected with *Salmonella* that had entered a tank's corroded vents and hatches [7].

## 3 MICROBIAL THREATS

Waterborne pathogens have been recognized as a threat to human public health throughout history but the development of drinking water treatment techniques have controlled this threat since the beginning of the twentieth century. Although modern drinking water treatment has virtually eradicated waterborne disease from developed countries, drinking water treatment systems have been identified as a potential security vulnerability.

Water-related microbial pathogens can be categorized as water-based or waterborne pathogens. Water-based pathogens spend part of their life cycle in water to reach and infect a potential host. An excellent example of a water-based pathogen is malaria for which mosquitoes are a vector. Since water-based pathogens are not transmitted totally through water they are not potential agents of bioterrorism.

Waterborne pathogens, however, are those transmitted through ingestion of contaminated water primarily through the fecal-oral route. In this case water acts as a passive carrier of infectious agents. Some waterborne pathogens that can cause problems in drinking water include *Campylobacter jejuni*, pathogenic *Escherichia coli*, *Yersinia enterocolitica*, enteric viruses such as rotavirus, calicivirus, astrovirus, and parasites such as *Giardia lamblia*, *Cryptosporidium parvum* and *Microsporidia* sp. Table 1 provides useful summary information related to these organisms. Some species of environmental bacteria have demonstrated the ability to survive in drinking water biofilms and have been identified as opportunistic pathogens including *Legionella* spp., *Aeromonas* spp., *Mycobacterium* spp., and *Pseudomonas aeruginosa* [8–10].

Bacterial pathogens can cause gastroenteritis, including cramps, diarrhea, nausea, vomiting, chills, and mild fever. Bacterial pathogens are generally sensitive to disinfectants such as chlorine and include the following [2, 3, 8, 14]:

- *Salmonella;*
- *Shigella;*
- *Escherichia coli* O157:H7;
- *Yersinia;*
- *Vibrio;*
- *Campylobacter;*
- *Legionella*.

Viral pathogens can pose a 10- to 10,000-fold higher infection risk then bacteria. Important waterborne viral pathogens include the following:

- *Adenovirus;*
- *Astroviruses;*
- *Hepatitis A;*
- *Hepatitis E;*
- *Norovirus;*
- *Rotaviruses*.

**TABLE 1 Pathogens of Public Health Significance[a,b,c,d,e]**

| Pathogen | Disease | Incubation Period |
|---|---|---|
| *Salmonella bongori and Salmonella enterica* | Salmonellosis | 12–36 h |
| *Salmonella paratyphi A, B, and C* | Paratyphoid fever | 8–14 d |
| *Salmonella typhi* | Typhoid fever | 1–3 wk |
| *Shigella dysenteriae, S. flexneri, S. boydii, and S. sonnei* | Shigellosis (bacillary dysentery) | 1–7 d |
| *Vibrio cholerae* | Cholera | 2–3 d |
| *Vibrio parahaemolyticus* | Gastroenteritis | 8–48 h |
| *Yersinia enterocolitica* | Yersiniosis | 3–7 d |
| *Clostridium perfringens* | — | 10–12 h |
| *Bacillus cereus* | — | 6–24 h |
| *Escherichia coli enteropathogenic* | Endemic diarrhea | 9–12 h |
| Coxsackeivirus | Gastroenteritis | 3–5 d |
| Hepatitis A virus | Hepatitis | 28–30 d |
| Polio virus | Poliomyelitis | 7–14 d |
| *Cryptosporidium sp.* | Cryptosporidiosis | 7 d |
| *Entamoeba histolytica* | Amoebiasis | 2–4 wk |
| *Naegleria fowleri* | Naegleriasis and Acanthamebiasis | 3–7 d |

[d]American Public Health Association [13].
[e]http://www.bt.cdc.gov/agent/agentlist.asp.

Parasitic pathogens are a significant threat to drinking water supplies. Nearly 20,000 protozoan parasites have been identified of which 20 genera are known to cause diseases in humans some of which include the following:

- *Acanthamoeba*,
- *Cryptosporidium parvum*,
- *Entamoeba histolytica*,
- *Microsporidia*, and
- *Naegleria*.

In general, the most effective mechanism for controlling these pathogens is disinfection, especially with chlorine. Table 2 summarizes the capacity of chlorine for inactivating water-related pathogens based on *CT* values. In calculating *CT*, *C* is the concentration of disinfectant (chlorine) in mg/l and *T* time in minutes. Column 4 contains the *CT* value and the target reduction for a given *CT* is given in Table 5 [8, 15, 16]. However other disinfectants may also be effective. Table 3 summarizes *CT* times for a representative set of microorganisms based on the use of chlorine, chloramines, ozone and chlorine dioxide

**TABLE 2 Inactivation of Microbes using Chlorine[a,b]**

| Bacteria | Temperature (°C) | pH | C × T (mg/l × min) | Percentage Reduction |
|---|---|---|---|---|
| *Campylobacter jejuni* | 25 | 8.0 | 0.5 | 99.99 |
| *E. coli* | 25 | 7.0 | 3.0 | 99.99 |
| *Legionella pneumophila* | 21 | 7.6–8.0 | 17.5 | 99 |
| *Mycobacterium chelonei* | 25 | 7.0 | 42 | 99.95 |
| *Mycobacterium fortuitum* | — | 7.0 | 30 | 99.4 |
| *Mycobacterium intracellulare* | — | 7.0 | 9 | 70 |
| *Salmonella typhi* | 20 | — | 3 | 99 |
| *Shigella dysentriae* | 20–29 | 7.0 | 0.5 | 99.6–100 |
| *Vibrio cholerae S. strain* | 20 | 7.0 | 1 | 100 |
| *Vibrio cholerae R. strain* | 20 | 7.0 | 60 | >5 logs |
| *Yersinia enterocolitica* | 20 | 7.0 | 30 | 92 |
| Adenovirus | 25 | 8.8–9.0 | 0.132 | 99.8 |
| Hepatitis A | 25 | 6 | 0.42 | 99.99 |
| Norovirus | 25 | 7.4 | 22.5 | Not completely inactivated |
| Rotavirus | 25 | 7.4 | 22.5 | 100 |
| *Crytposporidium parvum* | 25 | 7.0 | 7200 | 90 |
| *Entamoeba histolytica* | 22–25 | 7.0 | 50 | 100 |
| *Giardia lamblia* | 25 | 6.0–8.0 | 15 | 100 |
| *Naegleria fowleri* | 25 | 7.3–7.4 | 45 | 99.99 |

[a]Abbaszadegan and Alum [8].
[b]http://www.bt.cdc.gov/agent/agentlist.asp.

[17]. As can be seen, ozone is the most effective disinfectant but it does not maintain a residual, and is therefore of only limited use in protecting a distribution system.

### 3.1 Biological Agents

In addition to general pathogens of concern in water supplies some pathogens can be categorized as biological warfare agents. Table 4 contains a basic listing of potential warfare agents and Table 5 contains potential warfare biotoxins. The biological agents listed in Tables 4 and 5 are not only deadly in their own right but also have the potential to be weaponized. Table 5 provides a general overview of the organisms that might be used in biological warfare.

Some of the organisms that have potential use in bioterrorism are discussed below [2, 3, 11, 12].

*Anthrax.* Anthrax, a highly infectious disease of hooved animals, is easily transmitted to humans. The three recognized forms of disease in humans are cutaneous,

**TABLE 3 Summary of *CT* Value Ranges Inactivation of Various Microorganisms by Chlorine, Preformed Chloramines, Chlorine Dioxide and Ozone [17][a]**

| Microorganism | Free Chlorine pH 6 to 7 | Preformed Chloramine pH 8 to 9 | Chlorine Dioxide pH 6 to 7 | Ozone pH 6 to 7 |
|---|---|---|---|---|
| *E. coli* | 0.34–0.05 | 95–180 | 0.4–0.75 | 0.02 |
| Polio virus-1 | 1.1–2.5 | 768–3740 | 0.2–6.7 | 0.1–0.2 |
| Rotavirus | 0.01–0.05 | 3806–6476 | 0.2–2.1 | 0.006–0.06 |
| Phage $f_2$ | 0.8–0.18 | ND | ND | ND |
| *G. lamblia* | 47–150 | 2200[b] | 26[b] | 0.5–0.6 |
| *G. muris* | 30–630 | 1400 | 7.2–18.5 | 1.8–2.0 |
| *Cryptosporidium parvum* | 7200[c] | 7200[d] | 78[d] | 5–10[c] |

[a]Note: All *CT* values are for 99% inactivation at 5°C except for *Giardia lamblia* and *Cryptosporidium parvum*.
[b]Values for 99.9 % inactivation at pH 6–9.
[c]99 % inactivation at pH 7 and 25°C.
[d]99 % inactivation at pH 7 and 25°C.
ND–no data.

pulmonary, and gastrointestinal. It is caused by a spore-forming bacterium, *Bacillus anthraces*, which has been weaponized for aerosol application and was used by the Japanese Army during World War II to contaminate food and water supplies of Chinese cities [12]. Abdominal pain, fever, vomiting, bloody diarrhea and shock are the principal manifestations of this form of the disease, which has an incubation period of 2–7 days. Anthrax spores are easily removed by any water treatment filter system with pore size $<1$ μm.

*Brucellosis.* Brucellosis is caused by *Brucella melitensis* and *Brucella suis* and because it is contracted through consumption of contaminated milk, water is a potential route of infection.

*Cholera.* Cholera is an acute infectious disease caused by the ingestion of food or water contaminated by the bacterium *Vibrio cholerae*. It was used by the Japanese Army during World War II to contaminate food and water supplies of Chinese cities [11] and is therefore a potential threat for contaminating potable water [3].

*Clostridium perfringens. C. perfringens* is a common organism found in secondary sewage effluent. Since it is commonly a cause of food poisoning it has potential for drinking water contamination.

*Melioidosis.* Melioidosis is caused by the bacillus *Burkholderia* (formerly *Pseudomonas*) *pseudomallei*. Since human disease can be caused by ingestion or by contact with contaminated water, it is a threat via the water route.

*Plague.* Plague is a disease of rodents, both wild and domestic, caused by the bacillus *Yersinia pestis* and transmissible to humans. It is generally considered to be a threat in water as well. Cultures were used by the Japanese Army during World War II to contaminate food and water supplies of Chinese cities [12].

*Coxiella (Q Fever). C. burnetii*, a rickettsial or rickettsia-like organism common among domestic farm animals, causes Q fever in humans and it has been noted that it is possibly transmitted from cattle through raw milk.

**TABLE 4 Biological Warfare Agents[a,b,c]**

| Agent/ Disease | Weaponized | Water Threat | Type of Organism | Infective Dose | Stable in Water | Chlorine Tolerance |
|---|---|---|---|---|---|---|
| Anthrax | Yes | Yes | Bacteria | $6 \times 10^3$ | 2 years | Resistant |
| Brucellocis | Yes | Probable | Bacteria | $10^4$ | 20–72 days | Unknown |
| Cholera | Unknown | Yes | Bacteria | $10^3$ | Survives well | Sensitive |
| *Clostridium perfringens* | Probable | Probable | Bacteria | $10^8$ | Common in sewage | Resistant |
| Glanders | Probable | Unlikely | Bacteria | $3.2 \times 10^6$ | 30 days | Unknown |
| Melioidosis | Possible | Unlikely | Bacteria | Unknown | Unknown | Unknown |
| Plague | Probable | Yes | Bacteria | 500 | 16 days | Unknown |
| Salmonella | Unknown | Yes | Bacteria | $10^4$ | 8 days | Inactivated |
| Shigellosis | Unknown | Yes | Bacteria | $10^4$ | 2–3 days | Inactivated |
| Tularemia | Yes | Yes | Bacteria | $10^8$ | 90 days | Inactivated |
| Fever | Yes | Possible | Rickettsia | 25 | Unknown | Unknown |
| Typhus | Probable | Unlikely | Rickettsia | 10 | Unknown | Unknown |
| Psittacosis | Possible | Possible | Bacteria-like | Unknown | — | Unknown |
| Encephalomyelitis | Probable | Unlikely | Virus | 25 | Unknown | Unknown |
| Enteric viruses | Unknown | Yes | Virus | 6 | 8–32 days | Inactivated |
| Hemorrhagic fever | Probable | Unlikely | | $10^5$ | Unknown | Unknown |
| Smallpox | Possible | Possible | Virus | 10 | Unknown | Unknown |
| Cryptosporidiosis | Unknown | Yes | Protozoa | 132 | Stable | Resistant |

**TABLE 5 Potential Warfare Biotoxins[a,b,c]**

| Biotoxin | Weaponized | Water Threat | NOAEL | Stable Water | Chlorine Tolerance |
|---|---|---|---|---|---|
| Aflatoxin | Yes | Yes | 75 μ | — | Probably tolerant |
| Anatoxin A | Unknown | Probable | Unknown | — | Probably tolerant |
| Botulinum toxins | Yes | Yes | 0.0004 μg/l | Stable | Inactivated 6 ppm at 20 min |
| Microcystins | Possible | Yes | 1.0 μ/l | Probably stable | Resistant at 100 ppm |
| Ricin | Yes | Yes | 15 μg/l | Stable | Resistant at 10 ppm |
| Saxitoxin | Possible | Yes | 0.4 μg/l | Stable | Resistant at 10 ppm |
| Staphlococcal endotoxins | Probable | Yes | 0.1 μg/l | Probably stable | Unknown |
| T–2 mycotoxin | Probable | Yes | 65 μg/l | Stable | Resistant |
| Tetrodotoxin | Possible | Yes | 1.0 μg/l | Probably stable | Inactivated 50 ppm |

*Note:* NOAEL—No Observed Adverse Effect Level.
[a]Burrows and Renner, 1989; Burrows and Renner [11, 12].
[b]Clark and Deininger [2, 3].
[c]http://www.bt.cdc.gov/agent/agentlist.asp.

*Salmonelloses.* The Salmonellae are pathogens belonging to the enteric bacilli. *Salmonella typhimurium* is often found in outbreaks of food poisoning. It was used by the Japanese Army during World War II to contaminate food and water supplies of Chinese cities [12], and there are reports suggesting that it has been used by terrorists to contaminate drinking water [3].

*Shigellosis.* Shigellosis is a bacillary dysentery caused by the ingestion of various *Shigella* species, in particular *S. dysenteriae*. *Shigella* spp. are most commonly disseminated under conditions of poor hygiene through "direct or indirect fecal-oral transmission." *Shigella* cultures were used by the Japanese Army during World War II to contaminate food and water supplies of Chinese cities [12]. *S. dysenteriae* has been implicated in intentional food contamination and should be considered a threat to potable water supplies.

*Tularemia.* Tularemia is an epizootic disease of animals (especially rabbits and rodents), transmissible to humans, and caused by the bacillus *Francisella tularensis* (formerly *Pasteurella tularensis*). *F. tularensis* has been weaponized in the aerosol form; contaminated water is also a potential source of disease.

*Enteric viruses.* The enteric viruses, commonly transmitted by the fecal-oral route in infants, should be considered potable water threats. Iraq has researched enterovirus 17 (Picornaviridae) and human rotavirus (Reoviridae), both of which cause gastrointestinal disorders, but have apparently not been weaponized.

*Cryptosporidiosis.* Cryptosporidiosis is a gastrointestinal infection resulting from ingestion of the oocysts of a protozoan, *Cryptosporidium parvum*. It is commonly contracted from drinking water contaminated with cattle wastes. Although *C. parvum* has not been weaponized it has been suggested as a potential agent for sabotaging potable water supplies by reason of its infectivity and ready availability [3, 6].

*Anatoxin A.* Anatoxin A, also known as the very fast death factor, is an alkaloid neurotoxin produced by the filamentous freshwater cyanobacteria *Anabaena flos-aquae*. Wild and domestic animals poisoned by anatoxin through ingestion have been observed in the field to be staggering, gasping, and suffering convulsions. Death by respiratory arrest occurs in minutes to hours.

*Botulinum toxins.* Botulinum toxins are derived from protein toxins produced by *Clostridium botulinum* and exist in seven neurotoxic forms. They have been weaponized by Iraq and other countries for aerosol application [3, 18]. To successfully contaminate a potable water supply, a biotoxin even as lethal as the botulinum toxins must be introduced downstream from treatment facilities and be able to survive contact with chlorine. The quantities involved make it impractical to poison large reservoirs.

*Microcystins.* The microcystins are hepatotoxic products of freshwater blooms of cyanobacteria of the *Microcystis* spp., *M. aeruginosa* in particular. Microcystin-LR, also known as the fast death factor, is the most common of the microcystins and presumably the toxin of choice to be weaponized. Although the aerosolized form of microcystin is the most likely threat, ingestion—even from natural sources—must be considered a significant hazard.

*Saxitoxin.* Saxitoxin, the cause of paralytic shellfish poisoning, is produced by the marine dinoflagellate *Gonyaulax*, among others. Saxitoxin is highly toxic by ingestion, more toxic still by injection, and perhaps most toxic by aerosol administration. It has been weaponized for covert purposes. Saxitoxin is water soluble, acid stable, alkaline labile, and stable at normal atmospheric conditions.

*Staphylococcal enterotoxins.* Staphylococcal enterotoxin B (SEB), which has been weaponized, is one of a number of protein toxins produced by bacteria such as *Staphylococcus aureus*. SEB can be either inhaled (aerosolization) or ingested from contaminated water or food, and could be used to sabotage food or low volume water supplies.

*Mycotoxins, T–2.* The T–2 toxin is one of several trichothecene mycotoxins isolated from cereal grains infected with *Fusarium* and some other genera of fungi. Russian experience with infected agricultural products indicates that ingested trichothecenes could impose a deadly threat [12]. Unconfirmed and controversial findings suggest the use of trichothecenes as biological warfare agents in Laos, Cambodia, and Afghanistan. Iraq has investigated the weaponization of trichothecenes. Other trichothecenes, viz., nivalenol, 4-deoxynivalenol, and diacetoxyscirpenol may be present in crude preparations; their toxicities are probably similar to but no greater than that of T–2.

*Tetrodotoxin.* Tetrodotoxin is a potent neurotoxin that has caused the deaths of many humans as a result of consumption of improperly prepared pufferfish. It was investigated as a potential biological warfare weapon and may be sufficiently soluble to present a threat to drinking water.

## 4 CHEMICAL AGENTS

All water supplies are vulnerable to chemical spills. For example, the FMC Corp located in South Charleston, West Virginia caused one of the largest industrial spills in recorded history. The spill consisted of carbon tetrachloride that has serious human health effects. Exposure to very low levels of carbon tetrachloride increases the risk of liver damage and the spill caused the intakes of several water treatment plants on the Ohio River to be closed for several days.

In January 1988, a 4-million gallon oil storage tank owned by the Ashland Oil Company, Inc., split apart and collapsed at an Ashland oil storage facility located in Floreffe, Pennsylvania, near the Monongahela River. The spill released diesel oil into an uncapped storm drain that emptied directly into the river. The oil was carried by the Monongahela River into the Ohio River, temporarily contaminating drinking water sources for an estimated one million people in Pennsylvania, West Virginia, and Ohio, contaminating river ecosystems; killing wildlife; damaging private property; and adversely affecting businesses in the area [19].

### 4.1 Chemical Categories

Hazardous chemicals are categorized by the type of chemical or by the effects a chemical would have on people exposed to it. The categories used by Centers for Disease Control (CDC) are as follows:

- biotoxins;
- blister agents/vesicants;
- blood agents;
- caustics (acids);
- choking/lung/pulmonary agents;
- incapacitating agents;
- long-acting anticoagulants;
- metals;
- nerve agents;
- organic solvents;
- riot control agents/tear gas;
- toxic alcohols;
- vomiting agents.

Biotoxins are discussed under the section on microbial agents and are summarized in Table 5.

*3.1.1 Chemical Non-Warfare Agent*. Several chemical non-warfare agents pose a significant threat to public health if released in drinking water supplies. Some of these compounds are listed in Table 6 and some of them such as sodium cyanide are highly toxic. Column 3 of Table 6 contains $LD_{50}$ values for some of the compounds, which represents a dose at which 50% of a test population experiences lethality. Column 5 contains NOAELs for some of these compounds.

*3.1.2 Chemical Warfare Agents*. There is a broad range of chemical agents that might be utilized in an attack against a drinking water distribution system. Several chemicals

**TABLE 6 Summary of Some Potential Chemical Contaminants[a,b]**

| Common Name | Chemical Name | $LD_{50}$ ($mg \times kg^{-1}$) | NOAEL ($mg \times kg^{-1 \times d-1}$) |
|---|---|---|---|
| Compound 1080 | Sodium fluroacetate | 2–5 | 0.005 |
| Sodium cyanide | NaCN | 2.2 | 20.4 |
| Potassium cyanide | KCN | — | 27 |
| Cyanogen bromide | Cyanogens bromide (CNBr) | 20 | 44 |
| Aldicarb | 2-methyl-2(methylthio) propionaldehyde o-(methylcarbamoyl)oxime | — | — |
| Strychnine | — | 2.35 | — |
| Sodium azide | Sodium azide ($NaN_3$) | — | 3.57 |
| Potassium silver cyanide | Potassium silver cyanide ($KAg(CN)_2$) | 21 | 82.7 |
| Paris green | Copper acetoarsenite | 22 | — |

[a]Field [14].
[b]http:www.bt.cdc.gov/agent/agentlistchem.asp.

agents originally developed for aerosol dispersal during warfare may also be effective through direct ingestion, dermal adsorption, and inhalation during showering. The categories of chemical warfare agents that have potential for contaminating water systems are as follows:

- Incapacitating agents: Incapacitating agents are drugs that make people unable to think clearly or that cause an altered state of consciousness (or unconsciousness).
- Nerve agents: Nerve agent or organophosphate toxicity might result from multiple routes of exposure. These agents cause excess respiratory and oral secretions, diarrhea and vomiting, diaphoresis, convulsions, altered mental status, miosis, bradycardia, and generalized weakness that can progress to paralysis and respiratory arrest.
- Vesicants: The most common clinical effects after exposure to blistering agents or vesicants include dermal, respiratory, ocular and gastrointestinal signs and symptoms. These symptoms are normally manifested within minutes.
- Lung irritants: Lung or pulmonary agents are chemicals that cause severe irritation or swelling of the lining of the nose, throat and lungs.
- Blood agents: Blood agents are poisons that affect the body by being absorbed into the blood.

Table 7 lists some of these agents by type, along with the chemical name, $LD_{50}$ values and NOAELs.

## 5 CHEMICAL OR BIOLOGICAL RELEASE EXAMPLES

Consider two possible toxic releases into a water supply. A pathogenic organism might be *Vibrio cholerae* while a potential deadly chemical that could be released might include sodium cyanide. Possible attack scenarios involving these two agents are discussed in the following sections.

**TABLE 7 Summary of Potential of Chemical Warfare Agents[a,b]**

| Common Name | Chemical Name | Type of Agent | $LD_{50}$ (mg $kg^{-1}$) | NOAEL (μg $kg^{-1}$ $d^{-1}$) |
|---|---|---|---|---|
| Agent BZ | 3-Quinuclidinyl benzilate | Incapacitant | 18–25 | 0.5 |
| Lysergide | 9,10-Didehydro-*N*,*N*-diethyl-6-methylergoline-8$\beta$-carboxamide | Incapacitant | 46 | 0.5–2.0 |
| LSD-based BZ | — | Incapacitant | — | — |
| Mescaline | 3,4,5-Trimethoxy-$\beta$-phenethylamine | Incapacitant | — | — |
| Benzilates | — | Incapacitant | — | — |
| Agent GA (tabun) | Ethyl *N*,*N*-dimethylphosphoramido-cyanidate | Nerve agent | 9.3 | — |
| Agent GB (sarin) | Isopropyl methylphosphonofluoridate | Nerve agent | 43–158 | — |

*Vibrio cholerae*: Some systems are very vulnerable to microbiological contamination but chlorine residuals are assumed to be protective. There are, however, natural microorganisms that are highly resistant to chlorine as illustrated in Table 5. In March 1991, the US EPA was requested by the Peruvian Ministry of Health to send a team of water supply experts to Peru. The team provided technical support to the field epidemiology staff of the US CDC, which had been in Peru for some time studying a major cholera outbreak.

During the course of the investigation, the EPA team began a series of disinfection experiments on several cholera strains [20–22]. One strain was an isolate recovered from a patient during the Peruvian epidemic. This isolate exhibited both a "rugose" variant as well as a "smooth" type of culture. The smooth culture which is normally associated with cholera exhibits a round smooth colonial morphology. The rugose variant represents an extremely rough form of *V. cholerae* and receives its name from the corrugated appearance of colonies on nonselective agar media. The EPA investigators found that the rugose variant was more resistant to disinfection than the smooth culture.

Chlorine inactivation experiments were conducted in triplicate for each condition as previously described. Both the Gulf Coast and Peruvian smooth strains were readily inactivated by free chlorine. The smooth cultures exhibited classical first order inactivation. At 1 mg/l free chlorine, the smooth strains were inactivated by greater than 4 orders of magnitude in less then 20 s. Rates of inactivation did not differ significantly between the two strains.

Disinfection of the rugose culture displayed a deviation from first order kinetics. After 80 s of exposure to free chlorine in samples containing both smooth and rugose organisms, the smooth strain was inactivated by approximately 3 orders of magnitude. The rate of inactivation of the rugose variant portion of the sample was significantly lower then that of the smooth culture and showed only limited inactivation. These results suggest that there are naturally occurring pathogens that are resistant to chlorination. Such organisms can be cultured and grown in a laboratory with ease and the normal chlorination practices can thus be defeated.

*Cyanide*: On February 2, 2002, four Moroccans were arrested for plotting an attack against the US Embassy in Rome [23]. Their plan was to contaminate the embassy water supply using 10 pounds of powdered potassium ferricyanide. Cyanide is one of the most lethal and rapidly acting poisons known to man. Clinical symptoms can occur within minutes of exposure and exposure can be fatal.

Cyanic compounds can be found in simple or complex forms and simple cyanic forms are more toxic than those in complex forms. The two most notable simple cyanide species are hydrogen cyanide and hydrocyanic acid and cyanogen chloride. Cyanide affects the central nervous system, cardiovascular system, thyroid, and blood.

Drinking water exposure includes the potential for inhalation, dermal absorption and ingestion. Ingestion of drinking water is the most important exposure route. The USEPA's Maximum Contaminant Level (MCL) for cyanide in drinking water is 0.2 mg/l. There are several analytical techniques that detect cyanide in water.

Free chlorine can be used to destroy cyanide and the resulting byproducts are bicarbonate ions and nitrogen gas.

## 6 PUBLIC HEALTH IMPACTS

If a biological or chemical attack should occur in a drinking water distribution system and if no other information is available, it would most likely be identified through the public

health system. Illness would be reported by hospitals, clinics, individual physician's offices, and there might be reports from pharmacies of increased demand for antidiarrhea medications. In addition sudden increases in absentees in schools or a spike in illness in nursing homes might be reported. However, a major challenge would be to differentiate between background illness in the system and the increases associated with an attack. To illustrate this effect data is presented in Figure 1 from a *Salmonella* outbreak identified in Gideon in early December 1993, which affected around 486 of the 1104 residents. Investigators concluded that all the affected residents had consumed municipal water [24].

During November 1993, the residents of Gideon reported objectionable tastes and odors in the residential water supply. The utility superintendent initiated an aggressive and comprehensive flushing program beginning at 8 a.m. on Wednesday, November 10, 1993, flushing all 50 hydrants in the system for 15 minutes each. Unfortunately, the largest municipal tank had apparently been severely contaminated with *Salmonella serovar typhimurium (S. typhimurium)* and the flushing caused the contaminant from the elevated tank to be dispersed throughout the network. This action led to a major waterborne disease outbreak.

On November 12, two days after the flushing event, 44 students from the elementary and the high school combined, were taken ill in Gideon, which was the largest number ill during the outbreak. This sudden spike in illness two days after the flushing was a response to the contaminant outbreak. However, there are only two cases of reported illness from the general population as early as November 12 as can be seen from Figure 1a. The Gideon school also shows a high percent disease incidence value of 70.1%. These observations suggest that some sensitive subpopulations such as school children are more susceptible than adults to illness caused by waterborne contaminants.

Although the nursing home had a lower percent disease incidence of 41.2% as compared to the school, eventually seven nursing home residents died of Salmonellosis. This could be indicative of water usage patterns that are different or it may be that once the nursing home residents contract disease, they are more likely to die.

Nilsson et al. [25] simulated a deliberate biochemical assault of a soluble conservative contaminant to a single node on the main line of a well-calibrated municipal drinking water distribution system. Migration of the contaminant plume was tracked for 55 h throughout the pipe network, and the cumulative mass loading was computed at four target nodes strategically located on looping links and deadend branches. This exercise was repeated for 1000 independent trials to establish a baseline distribution of consumer dose exposures at the target nodes. A battery of simulation experiments was then performed to examine the sensitivity of the nodal load distributions to various system characteristics and water-use patterns. Results from the simulation experiment show that variability in the total mass load received at a node can be apportioned between the variability in the water-use volume and variability in the mean delivered concentration. Overall, however, the operation of the network storage tank had the greatest influence on the nodal mass loadings.

## 7 SUMMARY AND CONCLUSIONS

There are nearly 60,000 community water supplies in the United States including a larger number of noncommunity systems that serve recreational areas, schools and other facilities. All of these systems represent some level of vulnerability. Drinking water

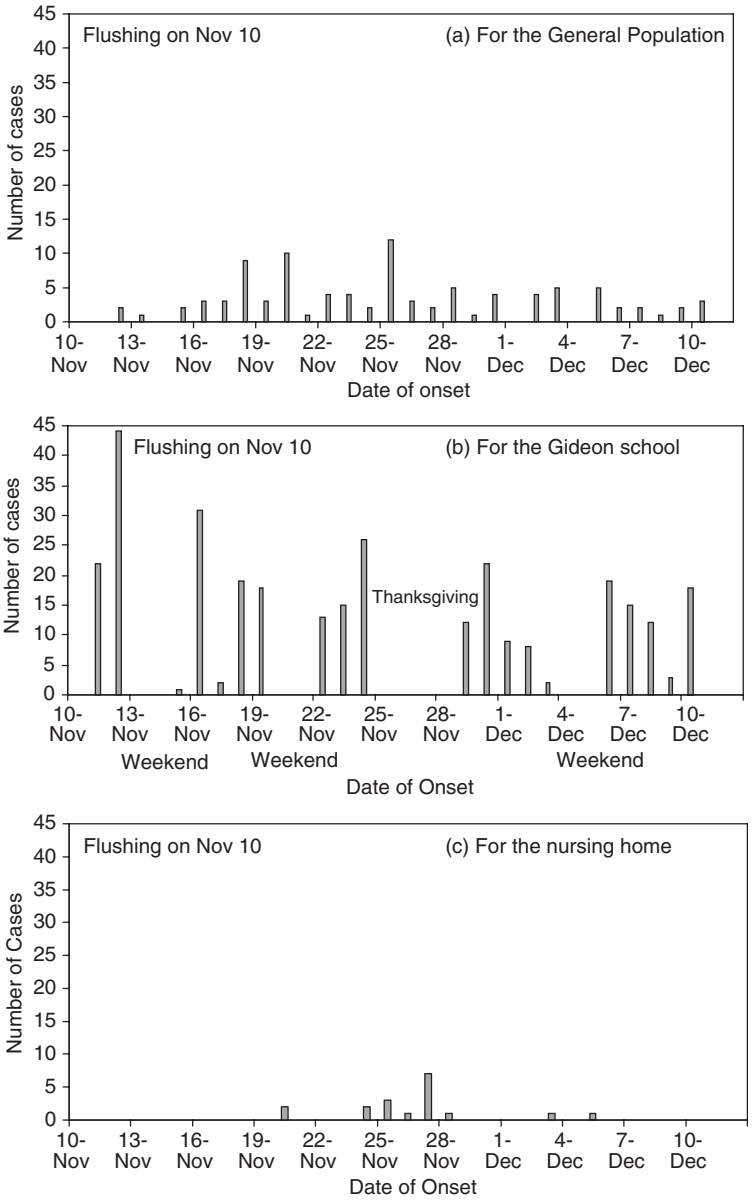

**FIGURE 1** (a)–(c) Disease onset in the Gideon network.

distribution systems are especially vulnerable to both microbial and chemical contamination and there are a number of organisms and chemicals (including biotoxins) that have this potential. In addition there are naturally or easily modified agents that could be a very serious problem should they enter a drinking water distribution system.

Identifying an attack once it has occurred may be difficult and it would most likely be identified through the public health system. Increases in illness especially among sensitive subpopulations might be the only manifestation of a waterborne attack.

It is clear that drinking water systems must be sensitive to the potential for deliberate attacks.

# UNDERSTANDING THE IMPLICATIONS OF CRITICAL INFRASTRUCTURE INTERDEPENDENCIES FOR WATER

RAE ZIMMERMAN

*Institute for Civil Infrastructure Systems (ICIS), New York University, Wagner Graduate School of Public Service, New York, New York*

## 1 INTRODUCTION

Water systems are dependent on and interdependent with many other infrastructures. This is an outcome of functional necessities, spatial proximity to other infrastructures, and economies of scale that have arisen over time. These relationships are growing with the size of the population, generally increased demand for water resources [1, p. 10] particularly for public supplies [2, p. 39], population distribution that has promoted the transmission of water over long distances, the geographic concentration of water-related infrastructure components, and changes in technology for water control and delivery

systems. This article begins by introducing the concept of dependence and interdependence, characteristics of water systems (covering water supply and wastewater treatment) essential to understanding the nature and impact of these relationships, and the relevance of this area of inquiry for security policy, including the allocation of resources for risk management and needs of emergency response. Finally, existing research organized by the major infrastructure sectors to which water is interrelated, how interdependencies can be measured, and recommendations for future research directions are discussed.

Dependence and interdependence as they pertain to infrastructure are usually considered distinct concepts. Rinaldi et al. [3, p. 14] define dependency as a relationship between two infrastructures in a single direction, that is, one infrastructure influences the state of another, whereas interdependency is bidirectional (and implicitly multidirectional) with two (and implicitly more) infrastructures influencing each other. Spatial and functional concentration is a key element associated with interdependence.

Although interdependencies are often beneficial, they may also be disadvantageous if they potentially increase the vulnerability of water systems and the systems that depend on water to threats posed by natural hazards and terrorism. Disruptions in systems upon which water is dependent, whether from natural hazards, terrorism, or accidents, necessarily magnify the effects on water systems. Security strategies now emphasize an all-hazards approach encompassing natural hazards, terrorism, and other intentional attacks given that outcomes or consequences of these different events are often similar. Natural hazards that often drive infrastructure disruptions have been increasing, with the annual rise in federally declared major US disasters estimated at 2.7% per year from 1953 to 2005 [4, p. 382]. Similarly, terrorist attacks disrupting the interdependent infrastructure can magnify the consequences. Although terrorist attacks directly on water infrastructure (as distinct from vandalism or acts of sabotage) are rare in the United States, the threat for water is real enough to prompt the US government to include it in the list of critical infrastructures slated for protection under federal homeland security programs. In the United States, water systems have been compromised in a manner analogous to a terrorist attack, and internationally, terrorist attacks on water have been quite prevalent [5, p. 528].

Interdependencies between the water sector and many other kinds of infrastructure and especially those that comprise emergency services have been identified as a critical element of federal security policy, including resource allocation for risk management. Interdependencies are a centerpiece of the National Infrastructure Protection Plan (NIPP), and are a component of assessing risk to the water sector. For energy and water interdependencies alone, the House and Senate Subcommittees on Energy and Water Development Appropriations requested "a report on energy and water interdependencies, focusing on threats to national energy production that might result from limited water supplies" [6, p. 9]. The US Department of Homeland Security (DHS) issued sector-specific plans (SSPs) to implement the NIPP with input from other agencies. The water sector is one of 17 critical infrastructure sectors to which the plan applies. The water SSP is the longest of the SSPs issued by the US DHS [7]. The water SSP defines dependency and interdependencies in the following way: "Reliance on another asset or sector for the functioning of certain assets is called a dependency; if two assets depend on one another, they are called interdependent" [7, p. 50]. Interdependencies between the communications sector and the water sector are included as an important element in the Communications SSP [8]. The water sector is mentioned in and regulated by over a dozen security and environmental laws combined and addressed in a half dozen federal directives and executive orders [7].

## 2 WATER SYSTEM COMPONENTS AND INTERDEPENDENCY

Water usage patterns provide a context for understanding water infrastructure and its relationship with other sectors. Figures 1 and 2 show the distribution of water use for total water and freshwater, respectively, in the United States (not including return flows, i.e. water consumption).

The type, extent, and impact of dependencies and interdependencies associated with water and other infrastructure vary depending on the water component and the type of technology used for each. Technologies for the provision of water and size of facilities are likely to dramatically alter the way in which other infrastructures are used to provide services for water infrastructure; for example, the Electric Power Research Institute (EPRI) [9, p. 3–5] estimates that unit electricity consumption for surface water treatment and wastewater treatment declines with the size of plant and for a given plant size, the variation in energy consumption for wastewater treatment can vary depending on the type of technology by one and a half to three times. The water-supply sector consists of a very complex system of interconnected resources, facilities, and services. Water sources exist both above and below ground. Large transmission systems, called *aqueducts*, primarily bring surface water supplies to the points of consumption connecting to the holding or storage reservoirs and extensive distribution lines. O'Rourke [10, p. 23] identifies water distribution lines as a type of "lifeline system" interdependent with other infrastructure lifelines noting that during the 2001 World Trade Center (WTC) catastrophe, water line breakages affected other infrastructure lifelines, flooding transit arteries and fiber-optic lines [10, p. 24; 11]. Underground water resources, accounting for about one-third of the

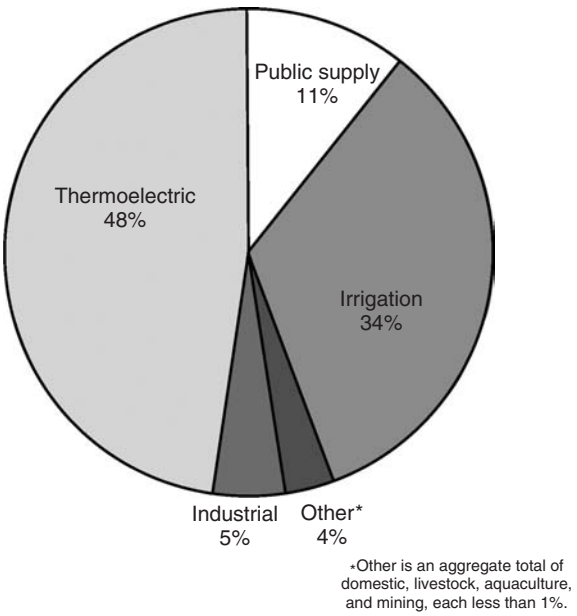

**FIGURE 1** Total water use by type of user, US, 2000. Note: This reflects total water use, and does not take into account return flow. (Source: diagrammed from US Geological Survey Estimated Use of Water in the United States in 2000, Figure 1, May 2004. http://pubs.usgs.gov/circ/2004/circ1268/htdocs/figure01.html.)

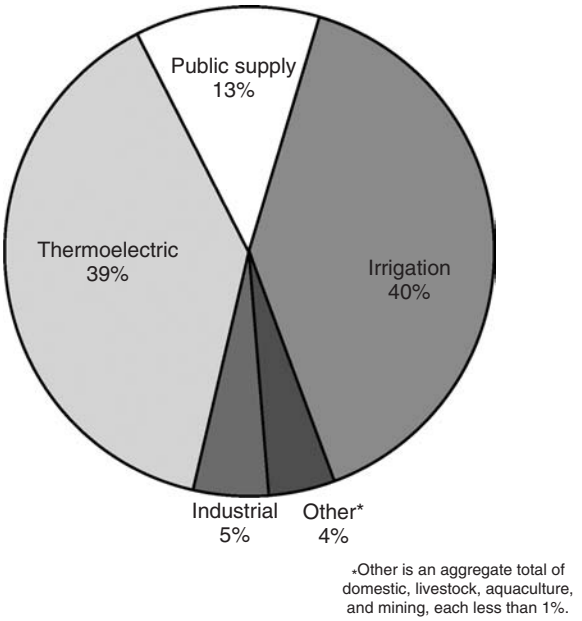

**FIGURE 2** Freshwater use by type of user, US, 2000. Note: This reflects total fresh water use, and does not take into account return flow. (Source: diagrammed from US Geological Survey, Estimated Use of Water in the United States in 2000, Table 2, May 2004. http://pubs.usgs.gov/circ/2004/circ1268/htdocs/table02.html.)

US public water supply [2], serve both large systems and individual users relying on wells usually associated with electricity-driven pumps for supply. Water storage represents another set of infrastructure facilities that interface with and are usually connected with the transmission and distribution systems.

Attributes of a couple of the key components—water and wastewater treatment plants and dams—are highlighted here because of their special significance for interdependencies and their consequences.

### 2.1 Water and Wastewater Treatment Plants

Water-supply plants are extensively distributed or localized throughout the US water supplies or community water supplies, defined under the Safe Drinking Water Act as serving 25 persons or more or having 15 service connections, as of 2004 numbered approximately 161,201 [7, p. 16] and serve 84% of the US population [7, p. 1]. In spite of the extensive geographic coverage of community water-supply facilities in the United States, they are concentrated, reflecting the fact that 45% of the US population is served by only 6.8% of the water-supply facilities [5, p. 531]. Wastewater utilities, regulated under the Clean Water Act, are far more concentrated than water systems, given their generally larger size and urban orientation, and the number of wastewater facilities is about one-tenth the number of water supplies. There are 16,255 regulated publicly owned treatment works [7, p. 19], serving 75% of the US population [7, p. 1]. The relatively greater degree of concentration of wastewater facilities is not accounted for by the lower percentage of people served, and has to do with economies of scale

in treatment technology. The degree of concentration is even greater in both the sectors when one considers that relatively few of these utilities serve the bulk of the population. These characteristics do not take into account private bottled water providers, organized and regulated differently, and is beyond the scope of this article.

## 2.2 Dams

Dams are another area where interdependencies can occur, since the provision of water (excluding individual water systems) usually begins with the use of dams, and the operation and control of dams depends on many other infrastructures. The National Inventory of Dams (NID) records close to 80,000 dams in the United States. The spatial distribution of dams is potentially significant for interdependencies and the vulnerabilities they may pose. At the state level, the number of dams and to a greater extent capacity (total maximum capacity) is highly concentrated: about half of all dams is located in only eight states, and about half of the total maximum dam capacity is located in only five states. The results of an initial analysis of the distribution of the number of dams and total maximum dam capacity as distributed by state in the United States are shown in Figures 3 and 4 [12]. People's dependency on storage of water by dams can in a gross way be portrayed in terms of where dams are located relative to population. The location of dams relative to population and population density is portrayed in Figure 5, indicating a modest relationship with a low, even though not significant, correlation. Numerous activities depend on the water supply that dams provide, reflecting the purpose that these dams serve (Fig. 6). Many dams serve multiple purposes. Analysis of data on the number of dams by primary purpose from the NID indicates that the following activities are dependent upon dams: recreation (33.4%), flood protection including storm water management (15.5%), and fire protection including stock and small pond farms (13.6%). In addition, 9.3% of the dams are used for water supply (as the primary purpose).

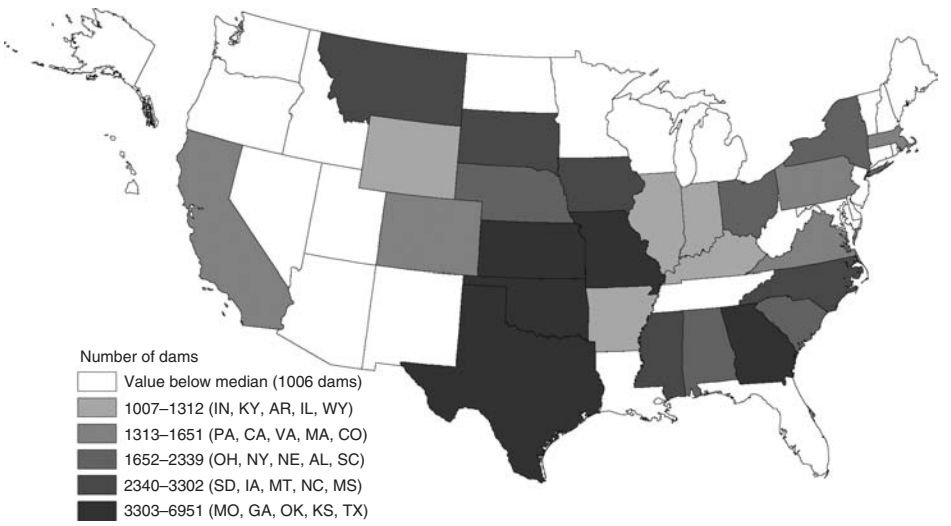

**FIGURE 3** Number of dams by state in the United States, 2006. (Source: mapped from The Stanford National Program on Dam Performance Database as of 2007 By Sara A. Clark, Graduate Research Assistant, NYU-Wagner, Institute for Civil Infrastructure Systems.)

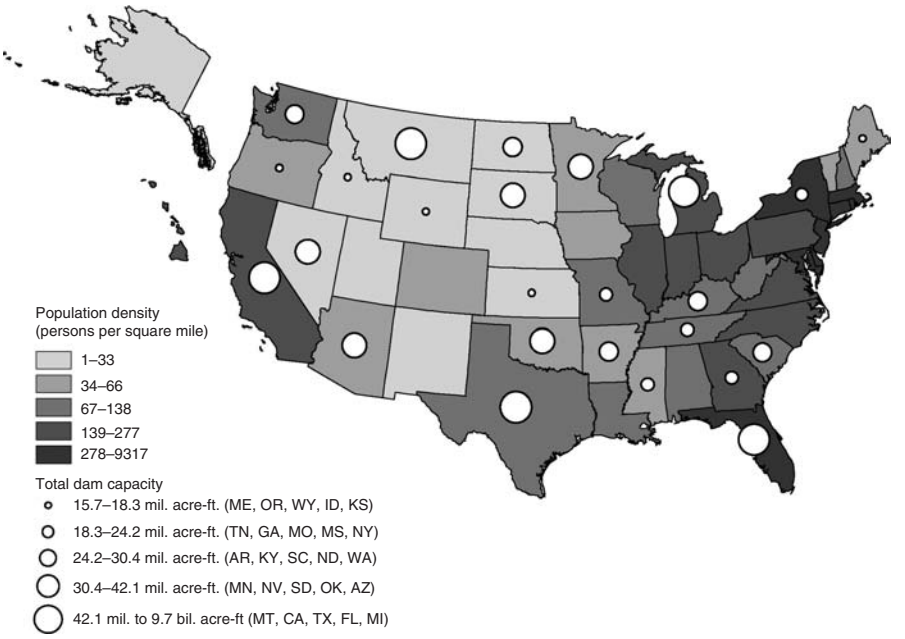

**FIGURE 4** Total dam capacity and state population density in the United States, 2006. (Source: mapped from The Stanford National Program on Dam Performance Database as of 2007; 2000 US Census; US UASI, DHS, 2006 By Sara A. Clark, Graduate Research Assistant, NYU-Wagner, Institute for Civil Infrastructure Systems.)

## 3 TYPES OF INTERDEPENDENCY

Conceptual literature in the infrastructure interdependency area emphasizes functional and geographic interdependencies as major types of interdependency, though other typologies have expanded or refined the number of categories [3, 13].

### 3.1 Geographic Interdependencies: Co-location

Physical interconnections often called *utility bundling* or *utilidors* [14] are enhanced in utility distribution systems by economies of co-location. Transportation is one infrastructure that has important physical linkages to water distribution systems. The water supply for the city of Paris, France, uses bridges to link water from the Left Bank to the Right Bank. A town in New Jersey shares wastewater treatment services with a town in Pennsylvania which involves transporting wastewater across a bridge. During a drought period, New York City constructed a temporary water-supply line, which traveled across the George Washington Bridge to supply water to New Jersey if required. Spatial linkages between water distribution systems and electric power and telecommunication lines are also common. Although these interdependencies provide many advantages and innovations, the proximity of water distribution lines to other infrastructures potentially magnifies vulnerabilities to disruption.

Large cities routinely experience water distribution disruptions, and causes vary. In New York City, environmental factors are a major factor contributing to the average

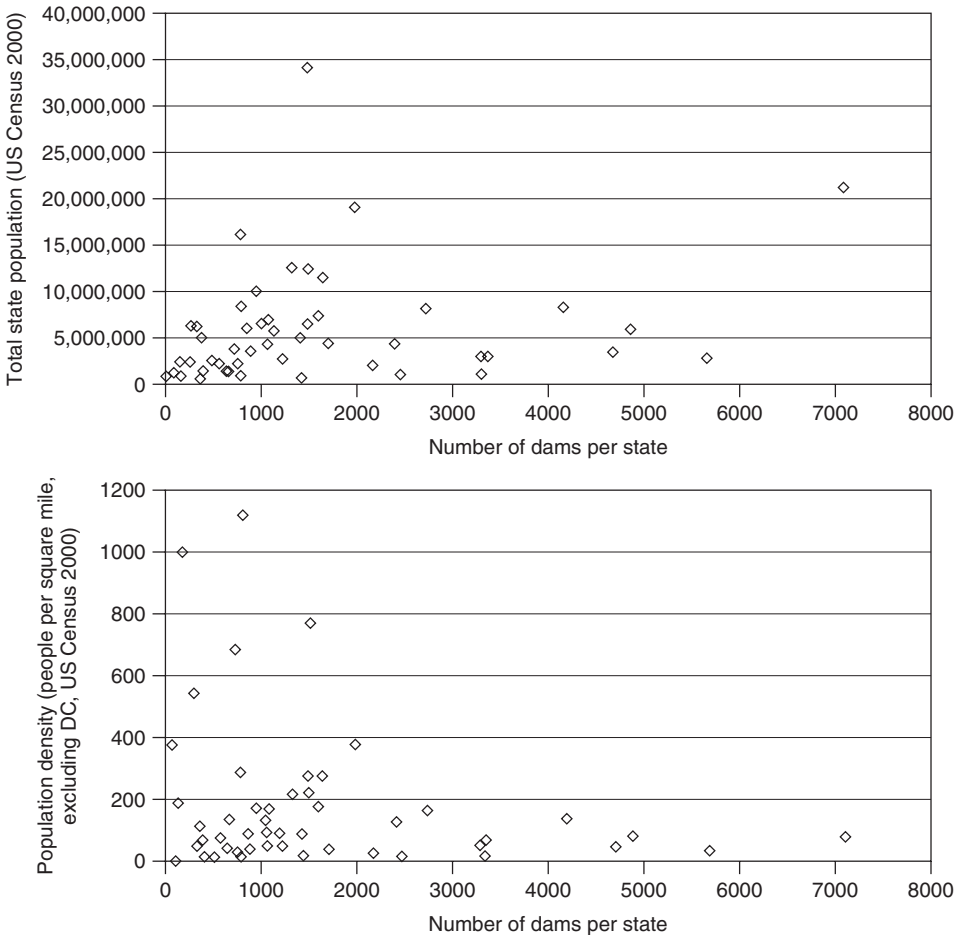

**FIGURE 5** Relationship of number of dams to state population and state population density in the United States, 2006. (Source: graphed from the national inventory of dams as of fall 2006 by Sara A. Clark, Graduate Research Assistant, NYU-Wagner, Institute for Civil Infrastructure Systems.)

of 500–600 water main breakages annually. Water main breakages can disrupt other infrastructure and vice versa. Ways that water disruptions affect other infrastructures include undermining or washing out of street surfaces by water releases, shorting out of electrical lines, and undermining support of gas lines. Ways that water disruptions are caused by other infrastructures include proximity to roads and transit systems [15], vibration, weakening of lines from the undermining of soil support due to construction, being hit by construction equipment, and electrical conductance created by proximity to electrical lines and voltages from trains. An analysis of about 100 cases of multiple infrastructure failures involving water main and other infrastructure breakages found that water main breakages are more commonly initiators of outages in other nearby infrastructures, such as gas main breaks and roadway washouts, than vice versa, but these findings are sensitive to the types of cases in the database [16].

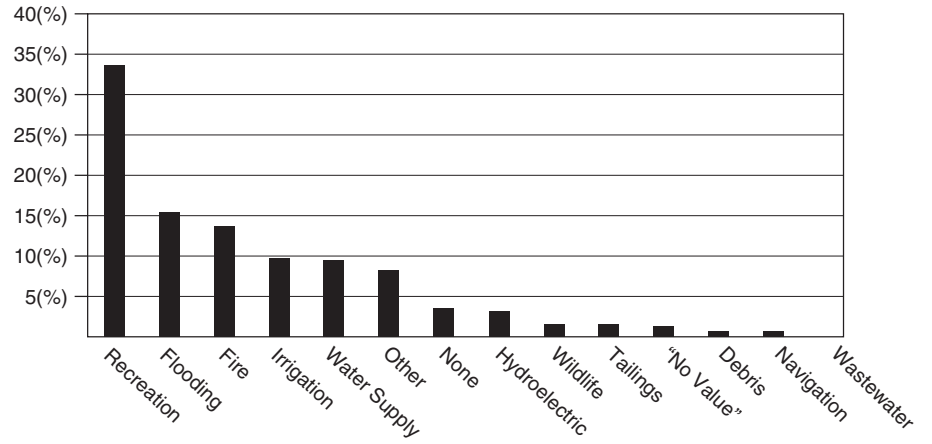

**FIGURE 6** Distribution of dams by purpose in the United States, 2006. (Source: graphed from The Stanford National Program on Dam Performance Database as of 2007.)

### 3.2 Functional Interdependencies by Infrastructure Sector

***3.2.1 The Energy Sector: Water and Energy Interdependencies.*** *Water for energy production*. As shown in Figures 1 and 2, 48% of total water usage and 39% of freshwater withdrawals in the United States in 2000 were accounted for by thermoelectric power [2, p. 35], though when consumption is considered, most of that water is returned and thermoelectric power production in 1995 accounted for 3.3% of consumption [6]. The U.S. Department of Energy (DOE) notes that "of the 132 billion gallons per day of freshwater withdrawn for thermoelectric power plants in 1995, all but about 3.3 billion gallons per day (3%) was returned to the source. While this water was returned at a higher temperature and with other changes in water quality, it was available for further use" [6, p. 17]. Thermoelectric generating plants using open-loop cooling in turn produce 31% of US energy generation [6, p. 18].

*Energy for water production and wastewater treatment*. The dependency of water on electric power has been underscored by a number of very large power outages that threatened water services or actually did bring water production and wastewater treatment to a halt. Electric power outages in California in 2001 nearly stopped major water pumps [3, p. 11; 17]. The August 2003 US and Canada electric power outage stopped wastewater pumps in New York City resulting in untreated water discharges to New York waterways. The same outage disrupted water-supply plants in major cities such as Cleveland and Detroit, and it took those two cities over two times as long to restore their water systems as relative to the amount of time it took to restore electricity (see Section 3). Electric power outages have been increasing at the rate of 7.2% in the United States between 1990 and 2004 [18]. Weather-related events have been dominating other conditions as causes of electric power outages, contributing to an increasing overall outage duration rate of 14% between 1990 and 2004 in the United States and higher rates since the late 1990s [19]. Both these trends are likely to affect water systems. Although water production and movement (for both treatment and supply) account for a small portion of energy produced in the United States, estimated at 4% across all functions [6, p. 25; 9, pp. 1–2], from the perspective of the individual water company, energy figures prominently in water

production, accounting for an estimated 80% of the costs for processing and distribution of municipal water supplies [9, pp. 1–2]. The estimated electricity consumption for fresh water supply in 2000 provided by public water-supply agencies was 30.6 billion kWh per year, and this was estimated to increase up to 45.7 billion kWh per year by 2050, an increase of about 50%, largely driven by population growth [9, p. A-3]. In the water production process, most of the energy is used for pumping and treatment. For example, the East Bay Municipal Utilities District, a water company that provides both water supply and wastewater treatment, uses half of its energy for pumping and treatment (Fig. 7). Its use of energy to acquire raw water is lowered by the fact that it obtains its water resources via gravity.

The transportation of water itself is dependent upon energy in most cases unless transport occurs via gravity. Although no comprehensive information exists on changes in the acquisition of water, it is often cited that water is being accessed from longer and longer distances to meet water needs, especially for urban areas, which will inevitably involve increases in the use of electricity.

***3.2.2 The Transportation Sector: Water, the Chemical Industry, and Transportation.*** The reliance of the water industry on transportation for the provision of chemicals to treat water is a potential vulnerability point, and has contributed to changes in the choice of chemicals. The viability of providing water services by centralized water utilities to dense urban areas is dependent on quality controls, which, in turn, is dependent on chemicals, in particular, chlorine gas for disinfection. Potential attacks on chlorine storage tanks and transport vehicles and accidents involving the transport of chlorine by truck or rail have underscored this as a distinct vulnerability. The water industry performs conversions from chlorine gas to the less vulnerable sodium hypochlorite and ultraviolet disinfection, and this conversion has been estimated to be $647,000 to $13.1 million per plant at about two dozen selected larger plants [20]. An analysis of the conversion cost data reveals a moderate but positive correlation between the cost of conversion and plant size as shown in Figure 8 [12].

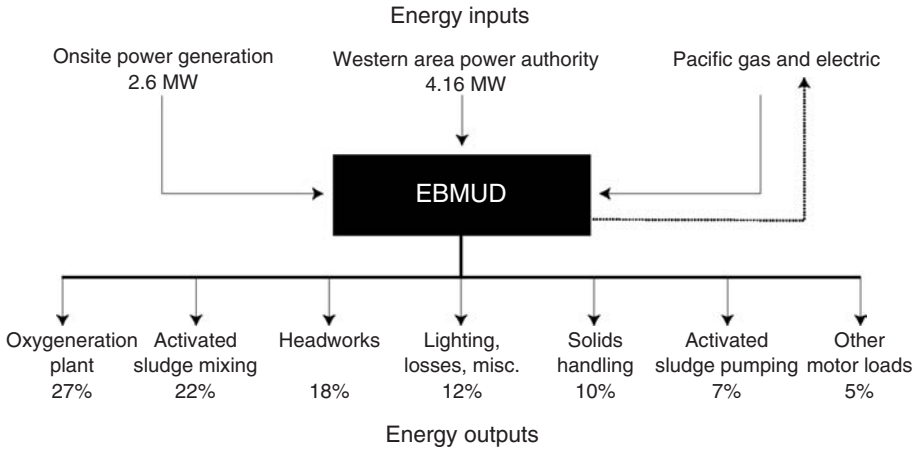

**FIGURE 7** Example of energy use in a water supply and wastewater treatment plant: East Bay Municipal Utility District, California, 2004. (Source: diagrammed from information in Hake, J. M., Gray, D. M. D., and Kallal, S. (2004). Power Diet. California's energy crisis prompts one treatment plant to reevaluate its power intake. *Water Environ. Technol*., May, 37–40.)

Report to the Chairman, Committee on Environment and Public Works, US Senate, GAO-07-480, March, Table 1, p. 14.)

***3.2.3 Water, Communications, and Information Technology.*** In the water sector, communication and information technologies increasingly control water quality, distribution, and customer interfaces. Information technologies are not only linked to water systems but also provide connections between water and other systems. The dependency of water on communications and information technology is identified in the Communications SSP [8, p. 41]. The effect of disruptions of computerized control systems, such as supervisory control and data acquisition (SCADA), on water systems is noteworthy. For example, in 2001, a hacker disabled the SCADA system operating the wastewater treatment system, Queensland, Australia, causing extensive discharge of sewage [21, p. 9].

Information technology, particularly as used in water applications, has been revolutionized by nanotechnology enabling detection of water chemicals to achieve extraordinary sensitivity. Wireless communication technologies further revolutionized water measurement. In the mid twentieth century, water-supply and wastewater quality standards were largely based on qualitative measures of chemical and biological material, for example, appearance, and by the late twentieth century quantitative standards gradually emerged, for example, expressed in parts per thousand and parts per million. In the twenty-first century those measures often went into the parts per trillion levels. These increasingly more stringent standards were made possible by newer detection technologies [22, p. 80]. As a result of the increase in the quantification of and limits of detection for water quality measures, the water industry has become more dependent on information technologies that are usually very specialized [22, 23]. In 2006, American Society of Civil Engineers (ASCE) and American Water Works Association (AWWA) draft guidelines for water utility security outlined an extensive set of criteria for sensor-based detection, which reflect the greater use of, and hence dependency upon information technologies for water infrastructure [24, Section 9].

## 4 MEASURING FUNCTIONAL INTERDEPENDENCY

When attention was first drawn to the importance and centrality of infrastructure interdependency, it was at a more conceptual and scenario-based level. Over the past decade or more, quantified measures of interdependence have emerged, potentially providing inputs for some of the modeling efforts underway in the area of infrastructure interdependencies. For example, Zimmerman and Restrepo [25, p. 223] applied the ratio of the amount of time it took for electric power to be restored and the time it took for water services to be restored after the August 2003 blackout, finding that the restoration time for the Cleveland water supply and Detroit system was at least two three times, respectively, as long as the time it took for electric power to be restored in those cities, assuming an average electricity outage of 24 h. Dependency on electricity-driven pumps (rather than reliance on gravity systems) accounted for most of the delay in these areas. In other cases, backup power enables water systems to be restored more quickly than relying on the restoration of the general electric power systems [25, p. 226].

## 5 GLOBAL CONSIDERATIONS

Considerable attention has been paid to the dependence of population growth and economic development on resource capacity, and water and the infrastructure that supports it is a key component of the resource base. A concept capturing the resource capacity and usage relationship is the "ecological footprint", defined as utilization of resources by a population or economy relative to the availability or production of that resource [26]. The footprint or imbalance cited by the World Wildlife Fund (WWF) is that the use of resources globally by 2006 has exceeded the ability to regenerate those resources by approximately 25% and the footprint has increased more than three times what it was in 1961 [26, p. 1]. Globally, water withdrawal per capita and the ratio of withdrawals to resources (water stress) vary dramatically from country to country. Globally, the correlation between water stress and the ecological footprint (defined at the country level) is positive at 0.4 and statistically significant; however, if the four countries (in the Middle East and Africa) with extreme values of water stress are eliminated, the correlation between these two factors approaches zero [12]. The ecological footprint appears unrelated to water consumption, however, it seems to be qualified by two factors that are likely to influence water consumption: a country's income and availability of water. With respect to income, the WWF [26, Table 2], for example, notes that high-income countries withdraw almost double the amount of water per capita (957,000 $m^3$ per year) than middle- or low-income communities do (552,000 and 550,000 $m^3$ per year, respectively). However, "water stress" is the same in high- and low-income countries (10% of total resources), whereas it is half of that (5% of total resources) in middle-income countries.

## 6 RESEARCH DIRECTIONS

Water systems depend upon other infrastructures, in particular, electric power, information technologies, and transportation, and indications are that this dependency is likely to increase with technological changes in water production and delivery. Other infrastructures in turn require water to function. These relationships imply that a disruption

in water systems or the infrastructures upon which water is interdependent creates a far more complex system of impacts than is typically portrayed by a direct or single disruption of one infrastructure, and in some cases can magnify the costs to human life, health, and welfare. Thus, a deeper understanding of the ramifications of these interdependencies and their consequences should disruptions occur is needed. A means to quantify these interdependencies and their consequences is a necessary prerequisite to comparing the nature and magnitude of consequences across different types of interdependencies.

Vulnerabilities from interdependencies exist on top of vulnerabilities posed by any condition or performance problems that water infrastructure may experience. Water and wastewater infrastructures nationwide were rated D–, the lowest grade given to any infrastructure area, by the ASCE in its 2005 infrastructure scorecard on the basis of condition alone from noncatastrophic sources [27]. Research is needed on how such ratings and other assessments can incorporate interdependencies and the natural hazard and terrorism context. This will ultimately affect the performance and viability of infrastructures dependent on water.

Global perspectives on water usage are important in addressing a new set of dimensions about dependency and interdependency that impact infrastructure and the people who depend on these systems. Water usage is a key component of the global resource base. An understanding of how patterns of water usage by different kinds of infrastructures influences resource capacity as measured by such concepts as the ecological footprint is critical to linking security with sustainability.

Interdependencies among infrastructures have a special significance in times of emergencies, since emergency response is heavily dependent upon infrastructure. In fact, it is likely that the impact of such interdependencies may become magnified given the compressed time frame necessary for emergency response.

Thus, the scope of the concept of infrastructure interdependencies is expanding and undergoing a transformation to adapt to the needs of security. The water sector represents a key part of that picture.

# SURVEILLANCE METHODS AND TECHNOLOGIES FOR WATER AND WASTEWATER SYSTEMS

STANLEY STATES

*Pittsburgh Water and Sewer Authority, Pittsburgh, Pennsylvania*

## 1 INTRODUCTION

Drinking water utilities are potentially vulnerable to a variety of intentional malevolent acts. These include physical assaults with explosive or incendiary devices, intentional release of harmful treatment chemicals such as gaseous chlorine or ammonia, cyber attacks on utility SCADA (supervisory control and data acquisition) systems or information systems, and intentional contamination of the drinking water. Intentional

contamination is generally considered to be the scenario of greatest concern because this is the one that could potentially affect and could have significant effects on the greatest number of people. Furthermore, if a contamination attack is conducted clandestinely, officials may not become aware of the event until people become ill.

Wastewater utilities are also subject to physical and cyber attacks, as well as the intentional release of dangerous treatment chemicals to the environment. Although wastewater is not ingested, contamination of wastewater collection or treatment systems with flammable substances such as gasoline could result in serious explosions. The intentional addition of volatile toxic chemicals or pathogens could impact the health of wastewater workers and the public. Wastewater systems are also indirectly vulnerable to contamination events in that if the drinking water system becomes contaminated, it is likely that at least some of the contaminated water would end up in the sanitary collection system. Additionally, water used to decontaminate buildings and equipment that had been intentionally contaminated by chemical, biological, or radiological agents could also find its way into the municipal wastewater system. An example situation is the concern expressed over the disposal of contaminated water following the intentional contamination of post offices and government buildings during the mailborne anthrax attacks in 2001.

Contamination warning system (CWS) is an important tool for improving the security of drinking water or wastewater utilities, directly or indirectly, susceptible to intentional contamination events. A key component of CWS is the continuous, on-line network of monitoring equipment strategically located at various sites in the treatment plant and drinking water distribution or wastewater collection systems. The purpose of the monitors is to detect chemical, biological, or radiological contaminants that could pose a threat to the public or utility. The monitors might also be able to detect the carrier matrix within which a contaminant is injected, such as the growth medium supporting a bacterial culture. Ideally, the monitoring network would provide multiple benefits in that it might detect contaminants accidentally injected into a water or wastewater system as well as those injected intentionally. Monitoring devices such as chlorine analyzers may also be useful for utility process control or for ensuring regulatory compliance.

There are currently five approaches being taken for on-line, real-time monitoring for contaminants in drinking water:

- monitoring routine chemical parameters as surrogates or indicators for chemical, and perhaps even biological, contaminants (detecting a “chemical change of state”);
- real-time toxicity biomonitoring;
- monitoring for radiation to detect the presence of radionuclides;
- detecting, identifying, and quantifying specific chemical contaminants; and
- detecting, identifying, and quantifying specific pathogens.

Currently, there are few remote monitoring networks being installed in wastewater systems to detect intentional or accidental contamination events. However, wastewater monitoring networks follow the same five approaches.

The following is a description of some of the commercially available equipment, which is currently being used in CWS, and some of the emerging technologies that could be used in these five monitoring approaches.

## 2 MONITORING ROUTINE CHEMICAL INDICATORS OF CONTAMINATION

Currently, there are several practical obstacles for on-line detection of contamination in water systems. One of those is that a large number of chemical, biological, and radiological agents, accidentally or as a result of a malevolent act, contaminate drinking water or wastewater systems. It would be very difficult, and prohibitively expensive, to develop and deploy analytical devices that could qualitatively and quantitatively monitor, on a continuous on-line basis, for each of these specific agents. Currently, the technology for this type of specific monitoring exists at a fairly basic level. Furthermore, chemicals that have not previously been considered to be candidates for use as intentional contaminants could be used, or combinations of contaminants could be utilized, which would confuse analytical efforts to identify specific agents.

One of the approaches to deal with these obstacles is to utilize basic chemical parameters (such as pH, chlorine concentration, total organic carbon [TOC], and conductivity) as surrogates or indicators for many of the contaminants that could potentially appear in water. Changes in the values for these basic parameters could signal a significant chemical "change of state" in the water, thereby suggesting the presence of an unknown contaminant. This is similar to the use of coliform bacteria as indicators for the possible presence of waterborne pathogens; a practical approach that has been utilized for the past 100 years in the water industry. Monitoring for basic parameters is feasible because on-line monitoring equipment for these parameters has already been developed, and in some cases has been deployed in water systems for years. Additionally, the instrumentation is relatively inexpensive, especially when compared to the analytical instruments that would be needed to detect, identify, and quantify specific contaminants.

Several studies have been published supporting the feasibility of monitoring for contamination by measuring surrogate parameters. Byer and Carlson [1] conducted a series of both batch and pilot scale distribution system studies to test whether four credible contaminants for intentional contamination of drinking water could be detected using the routine parameters, such as chlorine concentration, pH, turbidity, conductivity, and TOC. The contaminants included pesticides, rodenticides, and industrial inorganic compounds. Their results showed that three of the four contaminants were detected below a concentration that would cause significant health effects, and the fourth was detected near the concentration for acute health effects. Hall et al. [2] utilizing both bench studies and recirculating plumbing loops with on-line sensors, investigated the extent to which changes in standard water quality parameters may indicate the presence of contaminants. The sensors were challenged with secondary effluent from a wastewater treatment plant, potassium ferricyanide, a malathion insecticide formulation, a glyphosate herbicide formulation, nicotine, arsenic trioxide, aldicarb, and *Escherichia coli* with growth media. The results of the study indicated that, while no single water quality parameter responded to all of the contaminants used, all of the contaminants caused at least one parameter to change significantly.

Some of the equipment currently being used for surrogate monitoring is described below.

### 2.1 On-line Chlorine Measurement

Residual chlorine is one of the most widely measured on-line chemical parameters in the water industry. Free and total chlorine concentrations can be measured on a continuous basis for regulatory compliance purposes to ensure adequate disinfection at the treatment plant and the maintenance of a protective residual in the drinking water distribution system. For process control purposes, chlorine can be measured on a continuous basis, and the results linked with an alarm system that notifies the operator of low chlorine concentrations and the need for increased dosage. Chlorine readings can also be tied into a feedback loop to automatically pace the dosage of chlorine applied at the treatment plant or at chlorine booster stations in the distribution system. Additionally, continuous measurement of chlorine concentration can be utilized to help ensure water system security. A significant decline in chlorine residual can signal an unexpected increase in disinfectant demand and suggest the presence of a contaminant in the water. The study published by Hall et al. [2], described above, indicated that a change in chlorine level is one of the most sensitive chemical indicators for a number of contaminants.

A variety of chlorine measurement devices are available from a number of manufacturers. These devices utilize amperometric, DPD, or polarographic membrane methods for free and total chlorine measurement.

### 2.2 General Organic Chemical Load

There are several analytical instruments that can be utilized to provide a gross measurement of the organic content of water. These include TOC analyzers and UV–visible spectrometers.

TOC analysis is a commonly used technique to measure the carbon content of dissolved and particulate organic matter present in water. Many drinking water utilities monitor TOC to evaluate raw water quality or to gauge the effectiveness of treatment processes designed to remove organic carbon. Some wastewater utilities also employ TOC analysis to monitor the efficiency of treatment processes. In addition to these applications, changes in TOC concentration can be used as a surrogate for contamination from organic compounds (e.g. petroleum products, industrial solvents, and pesticides). Although TOC analysis can not identify specific contaminants, gross deviations from normal TOC concentrations can be an indication of a chemical contamination in a system. On-line TOC analyzers could be placed at critical locations within a drinking water distribution system, either at the intake of a drinking water treatment plant or at a wastewater influent wet well to detect potential chemical threats. TOC analysis has been shown to be an especially sensitive method for detecting changes caused by a variety of contaminants that could potentially be introduced accidentally or intentionally into a public water supply [2]. The response time for TOC analyzers varies with manufacturers' specifications. However, 5–15 min is generally required to obtain stable readings. Detection limits vary from 0.2 to 1 mg/l carbon. A TOC monitor currently deployed within the Pittsburgh drinking water distribution system is the Sievers 900 On-Line TOC Analyzer[1] utilizing UV/persulfate oxidation and membrane conductometric detection.

Another surrogate parameter for general organic content of water is UV–visible absorbance. A UV–vis spectrometer will react with any organic contaminant that absorbs

[1] Ionics Instruments, Boulder, CO.

in the UV range. The alarm sensitivity for many organic contaminants is between 1 and 500 ppb. The types of organic compounds detected include phenol, toluene, xylene, many pesticides, some nerve gases, crude oils, and naphthalene, among others. The types of compounds not detected include short-chained aliphatics. Response time can be less than 1 min. Potential advantages of UV–vis spectrometry, compared with TOC measurement, are quicker response time, greater sensitivity, less maintenance, and lower initial cost. A commercially available product, which is deployed in the drinking water distribution system of Vienna, Austria, and some other European cities is the spectrolyser spectrometer with the ana::larm software package manufactured by scan Messtechnik.[2]

## 2.3 Oil and Petroleum Detection

Monitors are available for detecting the presence of oil and petroleum products in water. Light scattering devices are employed on commercial offshore oil rigs to detect surface sheens on the water. However, these are too insensitive for practical use in drinking water. On the other hand, fluorometry has been used for years to detect the presence of hydrocarbons in source waters at drinking water treatment plant intakes, and to help characterize the progress of petroleum product plumes in lakes and rivers following industrial spills. Commercially available fluorometers such as the Turner TD 4100[3] can detect dissolved gasoline, diesel, jet fuel, and oil components such as the BTEX compounds (benzene, toluene, ethylbenzene, and xylenes). These instruments continually measure the fluorescence of aromatic hydrocarbons in a flowing stream of water ranging from low parts per billion to high parts per million. Fluorescence occurs when a molecule absorbs light energy of a specific wavelength and emits light energy of a longer wavelength.

## 2.4 On-line Analytical Probes and Multiparameter Panels

On-line analytical probes are the most commonly used devices for early warning security systems. They are relatively inexpensive, simple to use, provide continuous monitoring with remote access to data, and are commercially available from a number of vendors. Many of these devices are already in place for process control both in treatment plants and in distribution systems. These include electrodes that measure a variety of chemical parameters (e.g. fluoride, dissolved oxygen, ammonia, nitrate), thermistors for temperature, potentiometric devices for oxidation–reduction potential, conductivity cells for specific conductance, and nephelometric units for turbidity.

Several manufacturers have combined a number of already available individual sensors into panels of sensors that track multiple water quality parameters. These multiparameter panels detect physical/chemical changes in one or more water quality parameters (change in chemical state), which suggest that a contaminant has been intentionally or accidentally added to the water. The idea is for the multiparameter monitor to provide an early warning for an unspecified contaminant. Some commercially available devices include the Clarion-Sentinal 500 Series,[4] the Rosemount Analytical WQS,[5] and the YSI 600 D.[6]

[2] s::can Messtechnik, Vienna, Austria.
[3] Turner Designs, Inc., Sunnyvale, CA.
[4] Clarion Sensing System, Inc., Indianapolis, IN.
[5] Rosemount Analytical, Irvine, CA.
[6] YSI Inc., Yellow Springs, OH.

A more advanced application of the multiparameter panels is the attempt to establish a characteristic pattern of changes in multiple parameters (a signature or fingerprint) that might be used to presumptively identify the contaminant. Several commercial entities and research groups are currently working to develop this approach. For example, the Hach Corporation[7] is marketing the GuardianBlue system. This unit consists of sensors, which the company has previously sold individually, that they have now combined into a preconfigured system, "water panel", for more comprehensive monitoring. The panel includes analyzers for TOC, chlorine, pH, turbidity, and conductivity. The system also includes an "event monitor" that facilitates real-time analysis of data from the monitoring panel. The event monitor integrates the readings for all the chemical parameters into a composite value or vector. If the composite value differs substantially from normal background level, and from routinely encountered deviations from the norm caused by utility operational changes such as turning on distribution system pumps, the event monitor triggers an alarm. Additionally, Hach has developed an agent library that contains a signature or fingerprint of the changes expected to occur in composite parameters when one of 80 different contaminants is introduced into the water. The 80 contaminants (which include arsenic, herbicides, ricin, and *VX*) are believed by the manufacturer to be potential candidates for used in an intentional contamination incident. The entire monitoring device can be set up remotely to communicate directly with a utility's SCADA system.

### 2.5 Multiarray Sensors

In addition to analytical probes, there are on-line sensors that measure a similar set of chemical parameters by utilizing electrochemical technology, rather than through the use of reagents. These sensors can be configured as a multiarray sensor to monitor for a number of chemical parameters. As with the on-line analytical probes, the multiarray sensors can be operated remotely with data reported to a SCADA system.

Censar Technologies Inc.[8] (formerly Dascore Six-Cense) manufactures a multiarray sensor called the *multiparameter water quality/security sensor*. This sensor, designed as a 1 in.$^2$ ceramic chip layered with gold, can be permanently inserted into a pressurized main stream or a side stream of water. It can monitor simultaneously for pH, dissolved oxygen, temperature, oxidation–reduction potential, conductivity, and either chlorine or monochloramine concentration. The sensor chip is field replaceable with a typical 6-month life according to the manufacturer.

## 3 REAL-TIME TOXICITY BIOMONITORING

Ultimately, the drinking water contaminants of most immediate significance are those that are acutely toxic to the people using the water. No analytical chemistry technique can directly measure toxicity. Specific analytes can be monitored for, but toxicity can only be inferred by comparing measured chemical concentrations with published toxicity values. However, it is possible to utilize living organisms, or biological systems, as biomonitors or sentinels to detect the presence of toxic substances. Some biomonitors measure changes

[7]Hach, Loveland, CO.
[8]Censar Technologies Inc., Wimborne Dorset, UK.

in the behavior or physiology of living organisms resulting from stresses induced by toxicity. Others detect toxic substances through cellular responses of prokaryotic cells (bacteria) or eukaryotic cells (from higher level organisms).

The use of biomonitors as toxicity screening devices is advantageous since the spectrum of contaminants potentially detected is much broader than that of analyte-specific determinations. The disadvantage of biomonitors is that they do not identify the specific chemicals causing a response. In this sense they are like biological smoke detectors. Additionally, biosensors can sometimes respond to water quality changes that are not harmful to people. These could include sudden shifts in temperature, pH, turbidity, and so on.

The classic example of a toxicity biomonitor is that of coal miners, years ago, bringing canaries into the mine with them to detect the presence of noxious gases such as methane. Although the concept seems simplistic for modern application, in reality there is no better broad spectrum indicator of potential toxicity for people than observing the toxic reactions among other organisms exposed to the environment in question.

A number of biosensors are commercially available for on-line monitoring of both source waters and finished drinking waters. These include organisms as diverse as bacteria, algae, mollusks, daphnia, and fish. Also available are biological sensors utilizing biological systems, such as enzyme systems, rather than whole living organisms.

The use of biomonitors in finished drinking water requires the removal of chlorine residuals since chlorine is toxic to most aquatic organisms. While this was a stumbling block several years ago, there are now commercially available dechlorinating units that continually remove chlorine through the addition of chemicals such as sodium thiosulfate. Reducing agents are typically not harmful to aquatic organisms at the concentrations needed to neutralize chlorine. However, there is always a concern that these chemicals could neutralize certain potential toxicants thus interfering with their detection. An example of a dechlorinating system currently on the market is the "portable dechlorinator" manufactured by Geo-Centers, Inc.[9]

The following is a description of some of the types of biomonitors that are currently available for use in source waters and finished waters.

### 3.1 Bacteria-Based Toxicity Sensors

Several bacteria-based sensors are being used by water utilities and response teams for rapid toxicity testing of grab samples of water collected during the investigation of contamination threats. These sensors are effective because the metabolism and/or cellular structure of bacteria can react rapidly to the presence of toxicants. Certain bacteria exhibit natural or genetically engineered bioluminescence that emits measurable light when the bacterial cells are healthy. Since the bioluminescence is closely tied to respiration, changes in the metabolism or cellular structure of the bacteria decreases bioluminescence. A reduction in bioluminescence, which can be measured with a photometer, suggests the presence of a toxic substance. Still other toxicity detectors monitor bacterial metabolism via changes in parameters such as bacterial oxygen demand.

A bacteria-based toxicity sensor that is commercially available for continuous on-line use in water is the TOXcontrol system manufactured by microLAN.[10] This automated

[9]Geo-Centers, Inc., Newton, MA.
[10]microLAN, Netherlands.

biomonitoring system utilizes freshly cultivated fluorescent bacteria, *Vibrio fischeri*, as the biological sensor. The natural luminescence of the bacteria is measured before and after exposure to 4.5 ml of the suspect water to estimate the amount of toxicity. This estimate is calculated using a computer software package that is part of the biomonitoring system. Toxicity standards are run at preset time intervals for system calibration. The bacteria are cultivated in a separate bioreactor for automatic and controlled cultivation. The manufacturer claims that only weekly maintenance of the system is required. A thiosulfate dechlorination system can be included with the system to permit operation within a chlorinated municipal water system.

### 3.2 Daphnia Toximeters

Daphnia (water fleas) are small free-swimming crustaceans that are visible to the naked eye and are very sensitive to toxicants. In fact, *Daphnia magna* has been utilized for over 100 years for toxicity testing of raw and treated waters, as well as industrial effluent. In on-line Daphnia toximeters, several daphnids are housed in a glass chamber through which the water being monitored continuously flows. The swimming behavior of the daphnids is monitored by closed circuit TV and the data are analyzed by computer. Changes in swimming behavior by several daphnids suggest the possible presence of a toxic substance in the water. This surveillance device has been used in Europe and was employed during the 2002 Winter Olympics in Salt Lake City, UT.

A Daphnia Toximeter manufactured by bbe moldanke[11] is deployed on-line with a measuring cycle of 30 min. Toxicity is monitored by observing swimming speed, swimming altitude, and turning and circling movements, as well as the number of live daphnia.

### 3.3 Mussel Monitors

Mussels are filter feeders that acquire their food by sifting through large volumes of water. If toxic substances appear in the water, mussels avoid exposure by closing their shells. The frequency of valve opening and closing can be monitored to indicate toxin avoidance behavior.

In commercially available mussel monitors, a number of mussels are glued to the top of a flow-through unit. Valve opening and closing is monitored by high-frequency induction sensors attached to the shells. A variety of mussels including clams, oysters, blue mussels, and even the nuisance organism, zebra mussels have been utilized for monitoring. Delta Consult[12] sells the MosselMonitor, which can be used to monitor chlorinated drinking waters since it utilizes a continuous thiosulfate pretreatment to remove chlorine. According to the manufacturer, the MosselMonitor can be operated on-line continuously for a 2–3-month period before replacement of mussels is required.

### 3.4 Algae Toximeters

In this toxicity monitoring device, chlorophyll fluorescence is utilized as the indicator of water quality. If water quality is good, algae photosynthesize and fluoresce. However, if substances are present in the water that negatively affect the algae, both photosynthesis and fluorescence are suppressed. A measured reduction in fluorescence indicates

[11] bbe moldanke, Kiel-Kronshagen, Germany.
[12] Delta Consult, Netherlands.

a decrease in the concentration of active chlorophyll and suggests the presence of a substance injurious to the algae. The commercially available systems utilize either algae already present in the water being tested or algae continually cultured in a fermenter and automatically injected in precisely defined amounts, into the measurement chamber. The algal fluorescence sensor is normally interfaced with a personal computer to facilitate interpretation of results.

A commercially available algae toximeter is manufactured by bbe moldanke, in which algae are continually cultured in a fermenter that regulates the concentration and activity of the algae. A raw water sample is automatically injected with a preset concentration of algae, at specified time intervals, and algal fluorescence is measured. Activity and fluorescence of the algae should be constant if no toxic substances are present.

### 3.5 Fish

Currently, several types of fish biosensors are in use. The simplest is the avoidance behavior sensor, which is based on the fact that fish tend to swim away from water containing poisonous or irritating substances. Such a system typically involves housing fish in a series of connected tanks through which the water being monitored continuously flows. The sentinel fish are fed in the first tank that initially receives the test water, and tend to spend most of their time there. However, if the quality of the incoming water deteriorates, the fish swim into the tanks located farther downstream and ultimately into an "escape tank" that is plumbed so that the water does not turn over as frequently as in the upstream tanks. This avoidance behavior suggests the possible presence of toxic substances in the water. Potentially, this type of system could be automated by using closed circuit TV or movement sensors in the pipes interconnecting the various tanks.

A more sophisticated approach to utilizing fish as biomonitors is employed by several commercial manufactures who sell systems that detect toxicants or degradation in water quality by observing changes in the ventilatory pattern or swimming behavior of fish. In these systems, a number of fish are held in individual chambers under continuous flow-through conditions. Electrical signals generated by muscle movements of individual fish are monitored, amplified, and sent to a personal computer for analysis. Ventilatory rate, ventilatory depth, gill purge (cough), and whole body movements are observed and measured. The stress caused by the sudden appearance of a toxic substance in the water will cause changes in ventilation and body movement and can trigger an alarm. Commercially available systems include the Bio-Sensor Fish Monitor,[13] Intelligent Aquatic Biomonitoring Systems IAC 1090,[14] and Medaka Sensor.[15]

Mikol et al. [3] described the New York City Department of Environmental Protection's experiences using ventilatory changes in fish, to protect the source waters for the New York City drinking water system. They found that the biomonitors could be operated for extended periods of time with minimal maintenance and downtime. They described several instances in which the biomonitors successfully detected the presence of accidentally discharged surface water contaminants in the source water. They also reported concentration ranges of some contaminants that elicited a response among bluegills in

[13]Bio-Sensors Inc., Blacksburg, VA.
[14]Intelligent Aquatic Biomonitoring System (iABS), Intelligent Automation Corp., Poway, CA.
[15]Seiko Corp., Japan.

laboratory studies that they and their associates had conducted previously. These included a positive response to cyanide at 0.01–0.10 mg/l, mercury and zinc at >0.1–1.0 mg/l, malathion at >1.0–10.0 mg/l, phenol at >10.0–100.0 mg/l, and acetone at >100 mg/l.

## 4 MONITORING FOR RADIATION TO DETECT RADIONUCLIDES

Radiation monitoring equipment is designed to measure either the total amount of radiation emitted from a source (gross radiation) or the specific types and energy levels of radiation emitted from a source. Responders trying to determine whether there is an elevated level of radiation in the water from accidental releases or intentional introductions do not necessarily require that the specific radionuclides causing the contamination be immediately identified. They would rather most likely be interested in utilizing some type of continuous, on-line screening equipment to measure gross radiation. The common types of gross radiation are $\alpha$, $\beta$, and $\gamma$.

On-line instruments for monitoring $\alpha$, $\beta$, and $\gamma$ radiation in water have been developed. However, there are a limited number of models available, and they can be expensive. Technical Associates[16] offers the SSS-33-5FT for approximately $58,000. This is a flow-through scintillation detection system for $\alpha$-, $\beta$-, and $\gamma$-radiation monitoring. The detector can be preset to measure one type of radiation, or all three combined, and can be equipped with a system that sends an alert if unusual counts are detected. Canberra[17] sells the OLM-100 on-line liquid monitoring system, which is attached to the exterior of a pipe and continuously measures the radiation in a liquid stream. The cost of this device is between $35,000 and $70,000 [4].

## 5 SCREENING FOR SPECIFIC CHEMICAL CONTAMINANTS

Unlike the general organic chemical load monitors (TOC and UV–vis spectrometry), gas chromatography (GC) and gas chromatography–mass spectrometry (GC–MS) can detect, identify, and measure the concentration of a wide variety of specific organic compounds. In fact, of all of the on-line physical/chemical monitors described above, GC and GC–MS are the only analytical techniques, currently being deployed in a continuous on-line mode, which can actually identify a specific chemical contaminant. Both these techniques can detect and identify a large number of volatile organic compounds in the low parts per billion (ppb) to parts per million (ppm) range, and can operate automatically and unattended. In the case of GC, the components of a complex mixture are separated, their retention times are compared to known standards, and then the concentrations are quantified. In GC–MS, the organic components are separated by GC, and a more definitive identification of contaminants is provided by mass spectrometry using mass to charge ratio of chemical compound fragments and comparing the mass spectrum with internal libraries that contain thousands of chemical fingerprints of known organic compounds.

Some of the on-line devices collect and concentrate volatile organic compounds (VOCs) from water using standard purge and trap technology. In the continuous on-line

[16]Technical Associates, Los Angeles, CA.
[17]Canberra, Meriden, CT.

mode, sample collection is automated and analysis occurs at regular programmable intervals throughout a 24-h period. INFICON[18] manufactures both GC and GC–MS instruments that utilize purge and trap, and can be operated as on-line monitors for either natural waters or finished drinking waters.

A highly specialized mass spectrometer is being utilized to screen water samples, in an on-line mode, at the Phoenix Arizona Water Services Department [5]. This photoionization and quadrupole ion trap, time-of-flight mass spectrometer provides high-speed screening and molecular identification for weaponized chemicals and other hazardous compounds. The commercially available mass spectrometer is used in an automated mode as an early warning system screening device. The advantage of this particular mass spectrometry approach is that it can be operated on-line and, unlike most mass spectrometers, can analyze mixtures of compounds without preliminary separation by GC. With its integrated autosampler, the instrument provides a high throughput monitor capable of analyzing samples every 45 s.

## 6 SCREENING FOR SPECIFIC PATHOGENS

While a number of devices are currently employed for real-time monitoring of the general chemical characteristics of water (e.g. chlorine concentration and TOC), and for screening for specific chemical contaminants (e.g. on-line GC–MS), the ability to continually screen drinking water for the presence of microorganisms is still quite limited.

A microbial sensor must include a recognition device (bioreceptor), which can react with a target microbe. One approach is to utilize immunoassay-based sensors that recognize specific proteins on the surface of a microbe. Another approach is to employ a bioreceptor that recognizes nucleic acid, either DNA (deoxyribonucleic acid) or RNA (ribonucleic acid), uniquely characteristic of a specific microorganism. When the target protein or nucleic acid is present in the sample, a biological reaction takes place between it and the bioreceptor, creating a physical or chemical change that is converted into an electrical signal proportional to the target microorganism's concentration in the solution. The signal is then amplified, processed, and displayed as a measurable piece of data [6].

In the case of immunoassay-based sensors, antibodies that have an affinity for specific antigens associated with a particular species are utilized. Antibody-based biosensors incorporate antibodies onto a sensor surface and utilize the hybridization between antigen and antibody as the recognition factor [7].

Nucleic acid-based bioreceptors contain on their surface an oligonucleotide that is complimentary to the nucleic acid sequence of the target organism. Recognition consists of hybridization between the bioreceptor's complimentary oligonucleotide and the target microbe's single stranded DNA or RNA. The hybridization reaction generates either an amperometric, optical, thermal, or mass differential signal that is amplified for quantification. The major technical problem associated with nucleic acid biosensing, unlike immunoassay biosensing, is that the DNA or RNA must first be extracted from the target cell. The extraction process requires reagents and incubation steps. Furthermore, following extraction, the double stranded DNA must be denatured into single stranded

[18]INFICON Corp., East Syracuse, NY.

DNA through a heating process. The challenge lies in fully automating the pretreatment extraction and denaturation steps.

An advantage of both immunoassay- and nucleic acid-based sensors is that they can be highly specific and, therefore, able to identify a specific target microbe with certainty. However, since there is such a variety of microbes that could accidentally or intentionally contaminate a water system, these approaches would require the deployment of a complicated array of bioreceptors to provide broad spectrum coverage. An additional disadvantage of both nucleic acid- and antibody-based biosensors is the lifespan and fragility of the recognition system. Nucleic acids and antibodies are biological macromolecules that can be damaged by conditions typical of water and wastewater systems.

Another biosensor approach for on-line biomonitoring of water systems utilizes amperometric detection of the $\beta$-galactosidase enzyme for detection of *E. coli* [8]. $\beta$-Galactosidase is an enzyme involved in lactose fermentation in *E. coli*. In this biosensor system, reagents are added to induce production of $\beta$-galactosidase in *E. coli* present in the sample, which, in turn, hydrolyzes the reagent phenyl $\beta$-D-galactopyranoside to produce phenol, which is detected by an amperometric sensor. Using this system, sensitivity of detection has been observed at a level of 10 CFU/ml of *E. coli* after a 5-h incubation period. Although the sensitivity of this system is generally greater than that of nucleic acid or immunoassay systems, the obvious disadvantages of its application as a real-time microbial sensor are the requirements for reagents, the 5-h incubation time, and the biosensors's specificity for a single bacterial species.

Still another biosensor approach for continuous monitoring is based on optical recognition of microbes [9]. Multiangle light scattering (MALS) is a reagent-less optical approach. MALS technology involves continual irradiation of a flowing column of water with a laser beam. Particles in the column of water scatter the laser beam producing a pattern that is detected by a number of detectors on the opposite side of the water column. Since a variety of angles are monitored simultaneously, a three-dimensional pattern is generated that represents the structure and size of the particle in the laser's path. The goal of MALS is to differentiate between waterborne microorganisms and inorganic particles based on the pattern of scattered light. An additional objective is to identify microbes by comparing the pattern of scattered light with a library of unique "bio-optical signatures" that have been developed by analyzing known microorganisms. The light pattern resembles a fingerprint since it is unique to the internal and surface features of the particles, including size, shape, morphology, and material composition. The current limitations of MALS for on-line monitoring include interferences from organic and inorganic particulate matter in the water sample stream, and difficulty achieving low detection limits. However, developmental efforts are being taken to address these issues.

## 7 PATHOGEN DETECTION SYSTEMS CURRENTLY UNDER DEVELOPMENT

Several continuous monitoring systems for pathogens have been designed, based on the biosensor approaches described above, and are deployed in several drinking water utilities in the United States. Two of these are described below.

JMAR Technologies[19] manufactures the Biosentry System which is a commercial application of the MALS technology optical approach [10]. This technique has been commercially applied in the beverage industry and is now being adapted for use in drinking water utilities [11]. Biosentry is a laser-based system that continuously monitors water for microbes of interest, including pathogens, and attempts to classify them. The system can be used simply as a monitoring device recording microbe counts against time. Alternatively, the system can provide a real-time warning when a predetermined threshold for a particular pathogenic microbe is reached. The device can operate remotely and transmit data into a SCADA network via an encrypted internet connection. The system can send an alert via a number of means, including e-mail and encrypted internet, or directly into a linked information system. Information is refreshed at 1-min intervals and microbial counts are displayed for the species being monitored as well as for unclassified microorganisms.

The system typically monitors a water stream of about 35 ml/min. Sensitivity, and the ability to discriminate between various particles and microbes, is optimal with water containing fewer background particles (i.e. $<1000$ particles/ml). Limits of detection, as reported by the manufacturer, are approximately 150 organisms per milliliter over a 5-min period of surveillance. The commercially available system is currently programmed to detect the protozoans, *Giardia* and *Cryptosporidium*, as well as rod-shaped bacteria. Future developments are aimed at reducing detection limits and identifying a variety of other microbes including the salmonellosis, shigellosis, and anthrax bacteria, as well as various algae and molds.

Another on-line pathogen monitoring device, whose prototype is currently being tested at a large California Bay Area water utility and at a municipal water station in Arizona, is the unattended water sensor (UWS) for water distribution systems [12]. Tenix and Sandia National Laboratories are refining an innovative technology for the near real-time detection of pathogens and biotoxins in drinking water and wastewater. This system is intended to provide rapid automated and unattended contaminant detection and identification at remote locations. The signal could then be sent to a SCADA system within minutes. This system identifies contaminants using a signature based on physical constants of proteins (such as molecular weight or charge to mass ratio).

The UWS is, based on the microChemLab technology, a handheld manually operated instrument originally developed by Sandia Labs. The sample enters the automated sampling device and a 100 nl sample of water is collected. This sample is pH buffered and reacted with a UV fluorogenic label. The sample then enters the detection system in which electrophoresis is used to separate components of the sample and a laser-induced fluorescent protein signature is recorded. The migration times are compared with a database of separations of threat agents and, if a specified matching threshold is reached, the system communicates the results.

The goal is to refine this system so that it can operate without operator intervention for up to 30 days. Ideally, a sample would be analyzed every 30 min. The system currently recognizes protein signatures for the biotoxins ricin and SEB. The next developmental targets include nitrifying bacteria, algal toxins, and *E. coli*. Ultimately, it is hoped that the system will be able to detect and identify a variety of bacteria, viruses, protozoans, and biotoxins.

[19]JMAR Technologies, San Diego, CA.

## 8 CONCLUSIONS

As indicated above, there are five basic approaches currently being utilized for on-line security monitoring of water. To date, most of the applications focus on drinking water. However, many of the same devices could probably be used effectively in wastewater collection and treatment systems.

Although a significant amount of research and development is being devoted to developing new equipment, current technical capabilities are still rather basic. Unfortunately, development of innovative continuous monitoring technology for drinking water and wastewater applications is probably limited due to the relatively small commercial market represented by the water industry. It is hoped that the current US government emphasis on establishment of CWSs for drinking water supplies, typified by the US Environmental Protection Agency's Security Initiative [13], will encourage additional technological advances.

# DESIGNING AN OPTIMUM WATER MONITORING SYSTEM

WALTER M. GRAYMAN
*W.M. Grayman Consulting Engineer, Cincinnati, Ohio*

## 1 INTRODUCTION

Monitoring can serve as a window for observing the quality of water in a water-supply system at a location and at an instant in time. Water quality monitoring can serve several purposes including the following:

1. detect contaminants introduced intentionally or accidentally into the water supply;
2. assist in routine water quality operations of the water system;
3. fulfill regulatory requirements.

The monitoring system should be designed and operated to meet the specific designated objectives. Monitoring can be characterized by the frequency of sampling and the handling methods. With automated sampling/monitoring procedures, the water quality sample is collected and analyzed without human intervention. Continuous on-line monitors collect and analyze samples at a specified interval. Grab sampling involves the manual collection of a sample and analysis of the sample in the field or in the laboratory. Both automated and manual sampling procedures serve a role in most well-designed monitoring programs.

## 2 ROLE OF MONITORING IN WATER SECURITY

Within the context of water security, monitoring is typically performed in order to detect the presence of a contaminant within the water. When combined with a mechanism for communicating and using the information in a timely manner, the information can serve as an early warning that allows the water utility to modify operation or treatment, or to issue notifications to reduce the potential impacts of the contaminated water on customers. In the past, such early warning systems (EWSs) were used primarily to monitor the quality of surface water systems that served as sources for water supplies [1, 2]. The EWS for the Ohio River Basin implemented and managed by the Ohio River Valley Water Sanitation Commission (ORSANCO) over the past quarter of a century is the foremost example of this type of system in the United States [3]. This system is composed of 15 gas chromatographs (GC) located at key locations on the river that monitor for 22 volatile organic compounds and report and track the contaminants as they move downstream. In Europe, the Rhine River has the most comprehensive monitoring and EWS, which were constructed in response to a major chemical spill that occurred in 1987 [4].

In the twenty-first century, the emphasis within the water industry has evolved from source water monitoring to detect accidental contaminant spills to include monitoring in distribution systems to detect intentional contamination events. The focus on distribution systems as the most likely target can be attributed to the following factors: there is less dilution water than in surface water bodies; other than disinfectant residual, there is minimal treatment affecting a contaminant added within the distribution system, and the relatively short travel time from likely point of contamination to the customer. This has led to considerable research and development on the implementation of contamination (or early) warning systems within distribution systems.

## 3 CONTAMINATION WARNING SYSTEM

A contamination warning system (CWS) or EWS is a combination of monitors, institutional arrangements, analysis tools, emergency protocols, and response mechanisms designed to provide early warning of contaminants in order to minimize customer exposure. Formerly referred to as *early warning systems*, the term *contamination warning systems* is now used more frequently when referring to distribution systems because of the general acceptance that it is unlikely that a warning could be issued early enough that no customers would be impacted by the contamination.

The characteristics of the potential threat are an important issue in the design of a CWS. A threat is defined as the specific contamination (agent) that is introduced into the system, the quantity that is introduced and the location where it is introduced. The impacts of the contamination event will depend upon both the characteristics of the threat and the effectiveness of the CWS (and associated response process) in thwarting or mitigating the effects of the threat.

Monitoring and sampling are important elements in the CWS as a mechanism for detecting, characterizing, and confirming the threat. These three roles for monitoring/sampling within the context of an emergency response are shown in Figure 1. Initial detection generally requires the use of on-line monitors that continuously or frequently sample the water to determine the presence of an unusual constituent in the water. Manual rapid field assessment sampling is then used as a mechanism to confirm that there is a credible threat and potentially to characterize and identify the nature of the threat. Final confirmation and characterization of the actual constituent in the water generally requires the use of laboratory analytical analysis. In an actual system, final confirmation may not occur until after full-scale emergency response has been initiated. Additional information on this topic is presented in Environmental Protection Agency (EPA)'s Response Protocol Tool Box [5].

## 4 IDEAL CONTAMINATION WARNING TECHNOLOGY

It is useful to identify the characteristics of the ideal monitoring technology used in the detection phase of a CWS. These characteristics are enumerated below.

- fully automated (operates on-line and remotely);
- frequent sampling rate (continuous or frequent sampling);
- rapid response time;
- high sensitivity;

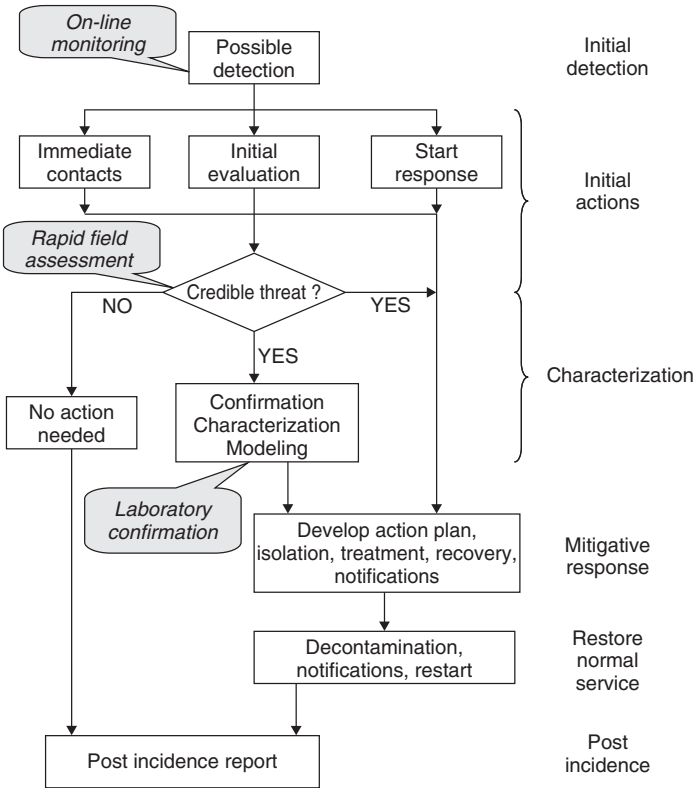

**FIGURE 1** Role of monitoring in an emergency contaminant response system.

- high specificity (low cross reactivity);
- high reproducibility;
- can detect many contaminants (broad spectrum);
- qualitative and quantitative;
- low rate of false positives/false negatives;
- rugged and minimal maintenance required;
- easy to use (little technical expertise required);
- inexpensive;
- communicates results to off-site responders.

Although many of the currently available on-line monitoring technologies that are being considered for use as part of CWSs display some of these characteristics, none of the available technologies currently meets all of the objectives stated above.

## 5 MULTIOBJECTIVE MONITORING PROGRAMS

As previously discussed, monitoring programs can serve many purposes in a water-supply system. Design of a single purpose monitoring system to address water security issues is

costly and frequently water utilities are unable or unwilling to make sufficient expenditures to develop a robust water security monitoring system. However, if the monitoring program can also serve additional purposes such as water quality characterization and process control, then the expenditures may be more easily justified. The primary issues in the design of a multiobjective monitoring program are the clear definition of the monitoring objectives and the design of a system that will adequately serve all desired objectives.

## 6 REVIEW OF MONITORING METHODS

Monitoring can be broadly characterized as (i) on-line continuous monitors and (ii) manual field level or laboratory analysis. As previously described, on-line monitors are typically used as a broad-scale method for detection of aberrations that may be contaminants in source or finished water while manual methods (either in the field or laboratory) serve as a means of confirming or characterizing the nature of the contamination.

On-line monitors may be further classified as physical/chemical sensors and biosensors. In most cases, on-line physical/chemical sensors measure changes in indicator parameters, such as chlorine, color, pH, conductivity, total organic carbon (TOC), and so on, individually or in a multiparameter analysis in order to detect a "change of state" of the water as a method of inferring the presence of a contaminant. In a few cases, on-line monitors may actually measure the concentration of one or more parameters. Table 1 summarizes the characteristics of on-line physical and chemical sensors.

On-line biosensors utilize biological species (e.g. fish, algae, mollusks, Daphnia, and bacteria) as sentinels for toxic contaminants. These are considered to be whole-organism sentinels that measure changes in physiology or behavior of living organisms resulting from stresses induced by toxins. This is similar to the "canary in the coal mine" that was used to determine the presence of carbon monoxide in the mine prior to entry by miners. Biosensors may suggest that there is something unusual in the water but do not identify the specific toxin. They monitor various characteristics of the biospecies to determine if they are stressed or responding to the potential presence of a contaminant. Biosensors indicate actual toxicity and can detect combined or synergistic effects of multiple toxins. Historically, biosensors have been used as part of source water EWSs for well over a quarter of a century. They are currently being applied in experimental cases to distribution systems. The primary needed change is that the water must be dechlorinated prior to use in the biosensor. Table 2 summarizes the characteristics of biosensors.

For both physical/chemical and biosensor approaches, prior to the actual use of the sensors as part of a CWS, a parameter baseline must be established. In this phase, the monitor is applied over a period (typically several months to a year) to establish the normal range and pattern of parameter values that would be expected. Additionally, the relationship between changes in parameters and the presence of specific contaminants must be understood. Computerized data systems may be used to analyze and report on significant changes in parameters indicating the potential presence of a contaminant [6, 7].

There is considerable recent and ongoing research in physical/chemical and biosensors in both the water industry and in other areas, such as the chemical, food processing, and medical industries. As a result, many technologies are emerging and being tested and can be expected to become commercial products within the 1–10 year horizon.

**TABLE 1 Summary of On-line Physical and Chemical Sensors**

| Category | Characteristics | Example Technologies |
|---|---|---|
| On-line analytical probes | Relatively inexpensive<br>Easy to use<br>Can provide continuous monitoring with remote access to data<br>Available from a variety of manufacturers | Ion-selective electrodes<br>pH<br>Elemental anions (e.g. Cl, Br)<br>Ammonium<br>Nitrate/Nitrite<br>Certain metals (e.g. Pb, Cn)<br>Surfactants<br>Hardness<br>dissolved oxygen (DO) probes<br>Multiple probe systems |
| Multiarray sensor | Replaceable ceramic chip<br>In-pipe or side stream | pH, $Cl_2$, DO, oxygen-reduction potential (ORP), temperature, conductivity |
| General organic chemical parameters | Provide gross measure of organic content<br>Analysis can be performed in batch mode or on-line<br>TOC or UV254 | TOC analyzers<br>Multi-wavelength spectrometer |
| Oil and petroleum | Light scattering detects floating oil<br>Fluorometry detects dissolved gasoline, diesel, jet fuel, BTEX, and so on | |
| Specific organic chemicals | GC detects volatile organic compounds (VOCs), fuel oil components<br>Mass spectrometry | Continuous on-line GC monitor for VOCs in water<br>On-line photo ionization (PI)/mass spectrometry–PI and quadrupole ion trap, time of flight mass spectrometry<br>GC/MS: in situ probe purge and trap GC/MS system |
| Radioactivity | Need to measure alpha, beta, and/or gamma radiation<br>Limited number of models currently available<br>Relatively expensive | |

Criteria for the selection of monitoring technology should reflect local objectives and include the following:

- cost (capital and operational);
- spectrum (broad spectrum or specific constituent);
- sensitivity;
- operational and maintenance requirements;
- environmental requirements (power, shelter);
- sampling frequency;
- communications requirements.

**TABLE 2 Summary of Biosensors**

| | |
|---|---|
| Daphnia toximeter | Several daphnids (water fleas) housed in a glass chamber through which sample water continuously flows |
| | Swimming behavior (speed, altitude, etc.) monitored by closed circuit TV and analyzed via integrated PC |
| | Extensively used in Europe and during Salt Lake City Olympics |
| Mussel monitors | Mussels avoid toxins in water by closing shells |
| | Mussel shells are glued to top of the flow-through unit. Valve opening and closing are monitored by high-frequency induction sensors attached to shells |
| | Mussels utilized include clams, oysters, blue mussels, and zebra mussels |
| Algae toximeter | Algae are cultured continually in a fermentor |
| | Test water flowing continually through the toximeter and algae is automatically injected into the measurement chamber |
| | Amount of living chlorophyll is measured by fluorescence technique |
| | Algae sensor is interfaced with a PC |
| Fish sentinel system | Utilize fish swimming in chambers |
| | Computer-linked (noncontact) electronic sensors monitor physiological responses (ventilatory frequency, ventilatory depth, etc.) and whole-body movement |
| | Changes in activity or physiological responses can signal toxic contamination |
| Bacterial monitoring system | Utilize either freeze-dried or customer-activated bioluminescent bacteria |
| | Reduction in luminescence suggests toxicity in water |

A detailed review of monitoring technology is available in *Technologies and Techniques for Early Warning Systems to Monitor and Evaluate Drinking Water Quality: A State-of-the-Art* [8] and *Interim Voluntary Guidelines for Designing an Online Contaminant Monitoring System* [9]. Independent reviews of selected monitoring technologies have been conducted by EPA as part of their Environmental Technology Verification (ETV) program and Technology Testing and Evaluation Program (TTEP). Under the WaterSentinel (formerly called *WaterSentinel*) initiative, EPA is establishing a critical early warning detection capability in selected cities as a means of encouraging other cities to adopt monitoring and surveillance programs [10].

## 7 OPTIMAL MONITORING LOCATIONS

Roberson and Morley [11] state that "once a utility has determined the potential contaminants that need to be monitored and what monitoring technologies are appropriate, the utility must determine where to locate the sensors and how often to monitor. Monitoring could be conducted in the raw water sources, in the treatment plant, or in the distribution system. Many consider the distribution system to be the most vulnerable, so a significant portion of contamination monitoring research has focused on that portion of the water system."

Historically, monitoring sites have been selected primarily on the basis of informal selection criteria that reflect the representativeness and accessibility of the sites and

the specific purpose(s) of the monitoring system. However, with the increasing costs associated with more sophisticated monitors and the perceived need for greater coverage, attention has turned to more quantitative assessment tools. Optimization techniques that formally define specific objectives for the monitoring system and search for and evaluate alternative systems have been the subject of research and development.

In the pre-9/11 era, primary emphasis in the design of water quality monitoring systems was on systems that addressed regulatory requirements, process control, and identification of contamination associated with accidental spills. In water distribution networks, the initial use of models to select water quality sampling locations is attributed to Lee et al. [12] using the concept of coverage of a network by tracing flow pathways and evaluating the effectiveness of monitors to "cover" the network. Although other papers built upon the concept of coverage to select optimal monitor locations using alternative solution methods, such as mixed-integer programming and genetic algorithms, the primary emphasis was still upon identifying problems in the distribution system of water quality that gradually deteriorated [13–15]. Other applications addressed the case of rapid deterioration of water quality due to an external source of contamination of the distribution system. Kessler et al. [16] applied an "all-shortest-path" algorithm to determine the least time that it will take for the contaminant to travel from the pollution source to any other node and a minimum set covering algorithm (equivalent to a minimum cost) to select the optimal set of monitors. Grayman and Males [17] used Monte Carlo simulation to evaluate alternative water quality monitoring systems used as part of a source water EWS for detecting accidental spills in the Ohio River.

The context for selection of monitoring locations changed dramatically following the events of September 2001. Whereas previously, the objective of the monitoring stations was to identify rapid deterioration of water quality within a distribution system or due to accidental external contamination of the distribution system, after 2001, the emphasis changed to identification of intentional contamination of the distribution system. Within this context, monitors (sensors) were assumed to be part of an EWS.

Berry et al. [18] provide a succinct description of the sensor placement problem in the post-2001 era. "For EWS design, the goal of a sensor placement optimization formulation is simple: to place a limited number of sensors in a water distribution network such that the impact of an accidental or intentional injection of contaminant to public health is minimized. However, no specific, concrete formulation for sensor placement has emerged that is widely accepted by the water community. There are a wide range of alternative objectives that are also important when considering sensor placements, such as minimizing the cost of installing and maintaining the sensors, minimizing the response time to a contamination event, and minimizing the extent of contamination (which impacts the recovery costs). Additionally, it is difficult to quantify the health impact of a contamination event because human water usage is often poorly characterized, both in terms of water consumption patterns as well as how the water consumption impacts health effects. Consequently, surrogate measures like the total volume of water consumed at all sites have been used to model health impacts; this measure assumes that human water consumption is proportional to water consumption at all junctions within the network."

Since 2001, there has been extensive research in the development of algorithms for the optimal monitor location in order to detect an intentional contamination event. These

algorithms can be categorized as static models and dynamic models [18]. Static models simply consider whether an attack can reach a downstream population, whereas dynamic models use the temporal dynamics of contaminant flow to determine whether a downstream population is affected before the contaminant is detected. Since dynamic models represent the actual temporal variation in flow conditions in a distribution system, they are considered to be more realistic and are the subject of most ongoing research. The algorithms and solution methodologies have included various optimization techniques and heuristics to select monitor locations including mixed-integer programming [19], greedy heuristics [20], and genetic algorithms [21]. Other studies have considered the multiobjective analysis [22] and incorporated the effect of stochastic processes on selection of sensor locations [23].

Optimization and heuristic algorithms have been used to determine the best location of monitors in several real and hypothetical distribution systems. The largest application of such algorithms is EPA's Threat Ensemble Vulnerability Assessment (TEVA) program. Alternative sensor location algorithms have been used to identify the optimal sensor placement in large- and medium-sized water distribution systems [24]. The Monte Carlo simulation approach is used to evaluate alternative sensor locations, number of sensors, sensor characteristics, sampling frequency, response time, and the type and duration of the contamination events. The sensors are assumed to be part of a contaminant warning system and the performance assessed on the basis of minimizing the average number of persons who become ill from exposure to a contaminant. The average number of people who become ill is determined by examining nearly all possible contamination intrusion points. As part of the TEVA program, EPA and Sandia National Laboratories have developed the Sensor Placement Optimization Tool (SPOT) [25]. At this time, the availability and distribution of this tool has not been established by EPA.

Several methodologies for selecting sensor locations were tested as part of the Battle of the Water Sensor Networks with the results presented at the 2006 Water Distribution Systems Analysis Symposium [26]. This exercise objectively compared the performance of contributed sensor network designs, consisting of a set of sensor locations. Independent research teams and practicing engineers contributed their designs for two different water distribution networks (small 100-node system and large 12,000-node system). Each team was asked to develop designs according to a precise set of rules to facilitate design comparisons. These rules specify the design performance metrics, the characteristics of contamination events, and the detection technology used to raise an alarm. Contributed sensor network designs were evaluated using four quantitative design objectives: expected time of detection, expected population affected prior to detection, expected contaminated water demand prior to detection, and expected likelihood of detection. In another study, application of water distribution modeling in selecting sensor locations was demonstrated in a "red team–blue team" exercise designed for educational purposes [27].

An alternative ranking procedure for locating monitors in a distribution system was developed as part of the PipelineNet project developed by Science Applications International Corporation (SAIC) in conjunction with EPA, AwwaRF, Federal Emergency Management Agency (FEMA), and the interagency Technical Support Working Group [28]. In this approach, "initially, all the elements of the water distribution system are

available for monitoring. This universe is reduced to a smaller set based on priorities set by a water utility. These priorities may include physically accessible nodes, definition of priority areas based on flow, velocity, pressure and water quality, and proximity to critical facilities (i.e. schools and hospitals). Among the specific issues to be addressed are: (i) location of monitoring points in the distribution system, (ii) timing and frequency of monitoring, and (iii) monitoring techniques and water quality parameters." Though this methodology does not ensure an optimal solution, it can help a water utility to define the specific objectives of a monitoring plan and to design a monitoring system that is tailored to those objectives.

## 8 CASE STUDY

In order to demonstrate the design process for an on-line water quality monitoring program, a case study for Ann Arbor, Michigan is presented [29]. The Ann Arbor city's water system provides drinking water to about 130,000 customers and operates a distribution system that provides service to approximately 40 square miles of the city and surrounding customer communities. Increasing concerns about the water quality within this distribution system as well as concerns about potential contamination events within the distribution system led to the development of a comprehensive monitoring plan. To understand the issues and develop solutions, the city's water utility undertook an evaluation of how to select and locate water quality monitoring equipment most effectively to meet these multiple goals. The study was conducted as a joint effort between utility personnel and an interdisciplinary team assembled by the Camp Dresser Mckee (CDM) consulting engineering firm. The following activities were pursued as part of the Ann Arbor project:

1. *Define mission and objectives.* A representative group of utility managers and staff met in a facilitated setting to develop a mission statement for the project, establish a project schedule, and to define specific objectives to monitor design. The overall objective was defined as, "creating an optimized distribution system detection and monitoring network with respect to both contamination events and normal variation in system quality".
2. *Survey current industry practices in on-line monitoring.* A 1-day expert workshop on on-line monitoring was conducted for the utility. A questionnaire on current monitoring practices was developed and sent to key progressive water utilities based on the review of the literature and the workshop. Follow-up phone calls and site visits to selected utilities, research laboratories, and monitoring manufacturers provided information for the preparation of a project report on the state of the art of on-line monitoring.
3. *Identify and rank potential monitoring sites.* Utility personnel developed a list of 179 potential monitoring sites. This listing included current monitoring/sampling locations, utility facilities, public buildings including fire stations, and university and public school buildings in the city. The list of sites was subsequently reduced to 30 locations based primarily on accessibility. Each of these 30 field locations was visited, data were collected, and the sites were numerically ranked based on

the ownership of the site, availability of a connection to the distribution system, availability of power, communications, and existing heating, ventilating, and air conditioning (HVAC), and accessibility.

4. *Identify and test candidate monitors.* Based on the project objectives and the review of the state of the art of on-line monitoring, key parameters of interest were identified. Parameters were selected to serve either as water security indicators or water quality indicators or, as in the case of total chlorine, as indicators for both objectives. One or two candidate monitors were identified for each of these parameters and test instruments obtained from manufacturers. These instruments were each challenged with four different water sources (raw river water and groundwater, finished drinking water and one distribution system location). Pilot testing on each water type was performed for 1–3 weeks. Results were compared to the approved bench testing methods normally employed by the utility.
5. *Adapt and test water system hydraulic model.* A key element in the quantitative design of the optimum monitoring network was a hydraulic model of the Ann Arbor distribution system. An all pipes, extended period simulation model was available at the start of the project. Some adaptation was required in order to update the model to current conditions and to represent different seasonal/water usage periods. Further changes were made during a validation period that identified some inaccurate valve positions that resulted in improper prediction of the movement of water through the system.
6. *Apply modeling tools.* The monitoring design phase resulted in the development of a phased program for implementing different types of monitors at different locations within the distribution system. The primary tools that were used in this task were the TEVA and PipelineNet software products. The study team worked with EPA using the TEVA models and SAIC, developer of the PipelineNet model, in application of these tools. Both models require a significant policy-related input to guide their usage. The TEVA model was used to select the most effective locations for monitors that would be part of a CWS for intentional events. Input to this model included expected response times, critical seasonal cases, and the duration of contamination events, and was determined through facilitated sessions with utility staff. Figure 2 shows an example graphical output with the reduction in health effects plotted as a function of the number of monitors and the expected response time. As illustrated, the results are very sensitive to response time. The graphs also show that the benefits increase significantly for up to five monitors and then level off beyond that number. The models were applied for both the case where all locations in the distribution system were candidates for monitors and for the case where only the 30 top ranked sites were considered. A “regret analysis” showed that the loss in benefits associated with consideration of only these 30 sites, as compared to all locations, was relatively small indicating that the increased accessibility and lower costs associated with this subset of candidates was justified. PipelineNet was used to identify locations for monitors for real-time assessment of water quality. In a facilitated group meeting, Ann Arbor personnel identified surrogate parameters that would be indicative of potential water quality problems and provided weights for prioritizing these parameters. These included velocity, water age, and pipe roughness. PipelineNet was then used to rank water

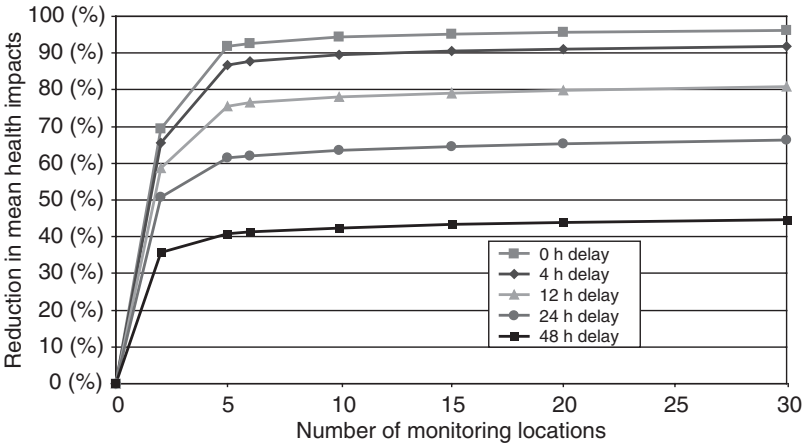

**FIGURE 2** Impact of response delay.

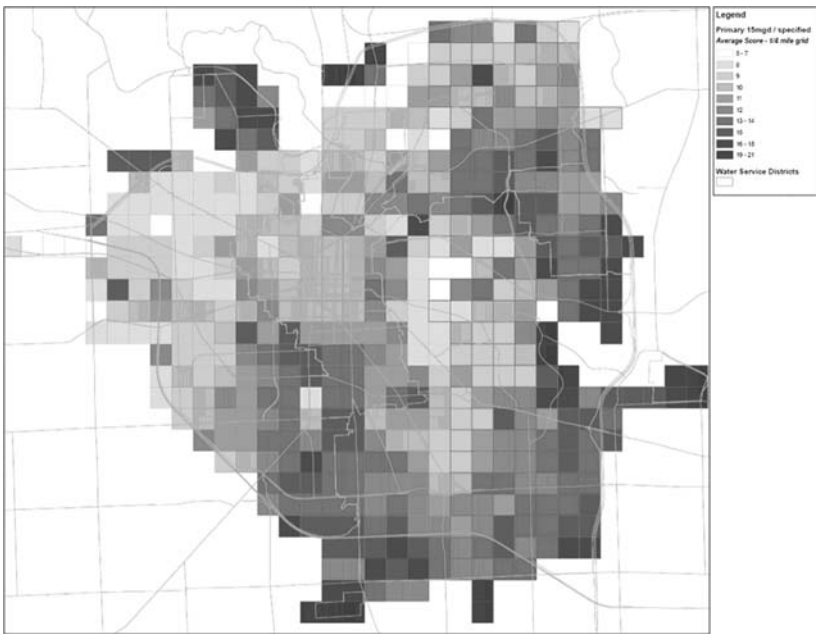

**FIGURE 3** Water quality ranking for alternative monitoring locations.

mains in the system based on these factors. This data was used to assess general water quality conditions in each one quarter square mile using a grid-based output shown in Figure 3.

7. *Select monitoring locations.* The results of the application of the TEVA and PipelineNet models were used to develop a prioritized list of monitoring locations. In general, there was no significant overlap in the location of monitors selected for water security as opposed to those selected for detection of water quality

problems. This lack of co-occurring sites was caused by the different drivers for security monitoring (protect as much population as possible) versus water quality monitoring (find the areas of deteriorating water quality, typically associated with high water age and, therefore, in more remote or isolated parts of the distribution system). Based on these results, several sites were selected for security monitoring and several locations were selected for water quality monitoring. One of the sites selected for security was the same as a site selected for water quality.

8. *Phased implementation plan.* A phased implementation plan has been developed for the monitoring program. In the first phase, two monitoring systems will be implemented at high-priority sites. During this phase, the CANARY event detection software developed by EPA/Sandia [30] will be tested. In a second phase, based on the results of the first phase, additional monitoring stations will be established at the remaining high-priority sites.

## 9 SUMMARY AND CONCLUSIONS

A contaminant warning system using on-line monitors for detection, linked with a coordinated emergency response plan, can serve as a mechanism for responding to intentional contamination events. With proper design, such systems can serve other purposes such as identification of more routine water quality problems. There has been a large surge in research in the area of design of optimum monitoring systems. However, significant research is still needed in the development of economical, robust on-line monitors and of software to evaluate rapidly the output from on-line monitors to identify the onset of contamination events.

## ACKNOWLEDGMENTS

The author would like to express his appreciation to the following individuals for their many helpful suggestions and contributions to the case study: Sumadh Bahl, Mark Ten-Broek, Janice Skadsen, Rob Janke, and William Samuels. He would also like to thank Stanley States and Alan Roberson for their insight and knowledge in the joint development of AWWA's contamination monitoring technologies workshop.

## 1 INTRODUCTION

Emergency response planning is designed to support operations during any type of emergency, and is built on the principles set forth in the National Incident Management System (NIMS) and the National Response Framework (NRF). Emergency Response Plans (ERPs), also known as *emergency operations plans*, serve as guidances for agencies and staff, should an incident occur. The ERP documents are required for water agencies by the Bioterrorism Act, and are suggested for any agency. A basic ERP should provide staff with procedures and contact information for use during potential emergency events for which the agency should prepare [particularly events identified as threats in the vulnerability assessment (VA)]. ERPs should be one part of an overall preparedness program that includes staff training, emergency exercises, business continuity planning, and yearly revisions. Such a program has the goal of utility resiliency. Any ERP should be consistent with other agency plans, as well as local ERPs, and should be developed in coordination with stakeholders.

### 1.1 Return on Investment for a Utility Preparedness Program

Preparedness planning and exercises can make even a major emergency more manageable and help speed recovery efforts. Utility emergency plans have been used to help save lives and property after a disaster. Emergency protective measures require capital; the return on investment of preparedness planning comes from the results of being prepared when a potentially costly or dangerous event occurs. This can be measured in lives saved, uninterrupted service/quickly restored service, and lower insurance rates on account of having an ERP.

The time and cost to develop a plan is well worth the reputation of dependability that is gained with customers by having an ERP. Although a utility's reputation with customers and local decision-makers is not an obvious operational issue, no utility can function properly without customer confidence and local support. A properly developed

and publicized ERP can go a long way toward consumer confidence, bringing consumer use and support to help secure funding for all utility programs.

## 2 LEGISLATION AND DIRECTIVES

There are several Homeland Security Presidential Directives (HSPDs) and federal laws that affect emergency planning for water and wastewater utilities. These are often evolving, and utilities can find the latest HSPD information at the Department of Homeland Security (DHS) web site: http://www.dhs.gov/xabout/laws/editorial_0607.shtm.

Emergency planning should address relevant and applicable water and wastewater utility emergency planning and response requirements, including, but not limited to, the following.

The *Public Health Security and Bioterrorism Preparedness and Response Act of 2002* (PL 107-188) requires community water systems to conduct VAs under the authority of the US Environmental Protection Agency (USEPA). The law requires water utilities that serve more than 10,000 customers to develop or revise an ERP.

***HSPDs*** establish nationwide policies and approaches for federal, state, and local governments to work effectively and efficiently together to prepare for, respond to, and recover from domestic incidents, regardless of cause, size, or complexity, using a NIMS and Incident Command System (ICS). The National Integration Center (NIC) Incident Management Systems Division has been established as the lead federal entity to coordinate NIMS compliance. Specific HSPDs relevant to ERPs include, but are not limited to, the following (http://www.dhs.gov/xabout/laws/editorial_0607.shtm):

*HSPD 3—Homeland Security Advisory System.* HSPD 3 creates a Homeland Security Advisory System to inform all levels of government and local authority, as well as the public, about the current risk of terrorist acts. The system involves a five-level, color-coded Threat Condition indicator to correspond to the current situation. Agency-specific protective measures associated with each Threat Condition allow a flexible, graduated, and appropriate response to a change in the nation's level of risk [1].

*HSPD 5—Management of Domestic Incidents.* HSPD 5 serves to enhance the ability of the United States to manage domestic incidents by establishing a single, comprehensive NIMS. NIMS is designed to cover the prevention, preparation, response, and recovery from terrorist attacks, major disasters, and other emergencies. The implementation of such a system would allow all levels of government throughout the nation to work efficiently and effectively together. The directive gives further detail on which government officials oversee and have authority for various parts of the NIMS. HSPD 5 also establishes that utility staff are first responders and must be trained as such [2].

*HSPD 7—Critical Infrastructure Identification, Prioritization, and Protection.* HSPD 7 establishes a national policy for federal departments and agencies to identify and prioritize critical infrastructure and to protect them from terrorist attacks. The directive defines relevant terms and delivers 31 policy statements. These policy statements define what the directive covers and the roles various federal, state, and local agencies will play in carrying it out [3].

*HSPD 8—National Preparedness and Annex 1, National Planning.* HSPD 8 establishes policies to strengthen the United States' preparedness in order to prevent and respond to threatened or actual domestic terrorist attacks, major disasters, and other emergencies. The directive requires a national domestic all-hazards preparedness goal, with established mechanisms for improved delivery of federal preparedness assistance to state and local governments. It also outlines actions to strengthen preparedness capabilities of federal, state, and local entities. This is a companion directive to HSPD 5. Most utilities are one of the local entities that can receive federal assistance [4].

*HSPD 21—Public Health and Medical Preparedness.* It is the policy of the United States to plan and enable provision for the public health and medical needs of the American people in the case of a catastrophic health event through continual and timely flow of information during such an event, and rapid public health and medical response that marshals all available national capabilities and capacities in a rapid and coordinated manner. Utility staff, as first responders, are among those with priority for flu vaccines [5].

*Robert T. Stafford Disaster Relief and Emergency Assistance Act, as amended by Public Law 106-390, October 30, 2000* (the Stafford Act), authorizes the President to issue major disaster or emergency declarations in response to catastrophes that overwhelm state and local governments. Such declarations result in the distribution of a wide range of federal aid to individuals and families, certain nonprofit organizations, and public agencies. The forms of assistance authorized by the Stafford Act include temporary housing, grants for personal uninsured needs of families and individuals, repair of public infrastructure, emergency communications systems, and other forms of assistance. Congress appropriates money for activities authorized by the Stafford Act to the Disaster Relief Fund (DRF), which is administered by the Federal Emergency Management Agency (FEMA) within the DHS. Appropriations to the DRF remain available until expended. Utilities are able to apply for disaster mitigation funding [6].

## 3 EMERGENCY RESPONSE PLANNING WITHIN THE BUSINESS CONTINUITY PLANNING UMBRELLA

Unlike ERPs, which focus on disaster response activities, a business continuity plan (BCP) defines how a utility continues its everyday business functions in a not-so-everyday environment. This includes the financial effects of a crisis, as well as adapting policies to meet the changing needs of employees and the utility, resuming normal operations, keeping and paying employees, keeping and billing customers, and staying in business. A utility may choose to organize its resiliency program under the BCP umbrella, and include the ERP as one of the plans within that umbrella (Fig. 1).

An enterprise business continuity plan (EBCP) serves as an umbrella plan for emergency preparedness, response, and recovery. The resultant plan for a utility will facilitate federal and state compliance efforts by streamlining the organization of numerous disparate plans and documents, some that are required by law.

A utility must review its plans to determine which plans or parts of plans can be combined to help form the overall EBCP, and which plans should remain stand-alone documents. While doing this, the utility should also develop an outline for the EBCP, and basic principles to adhere to during its development.

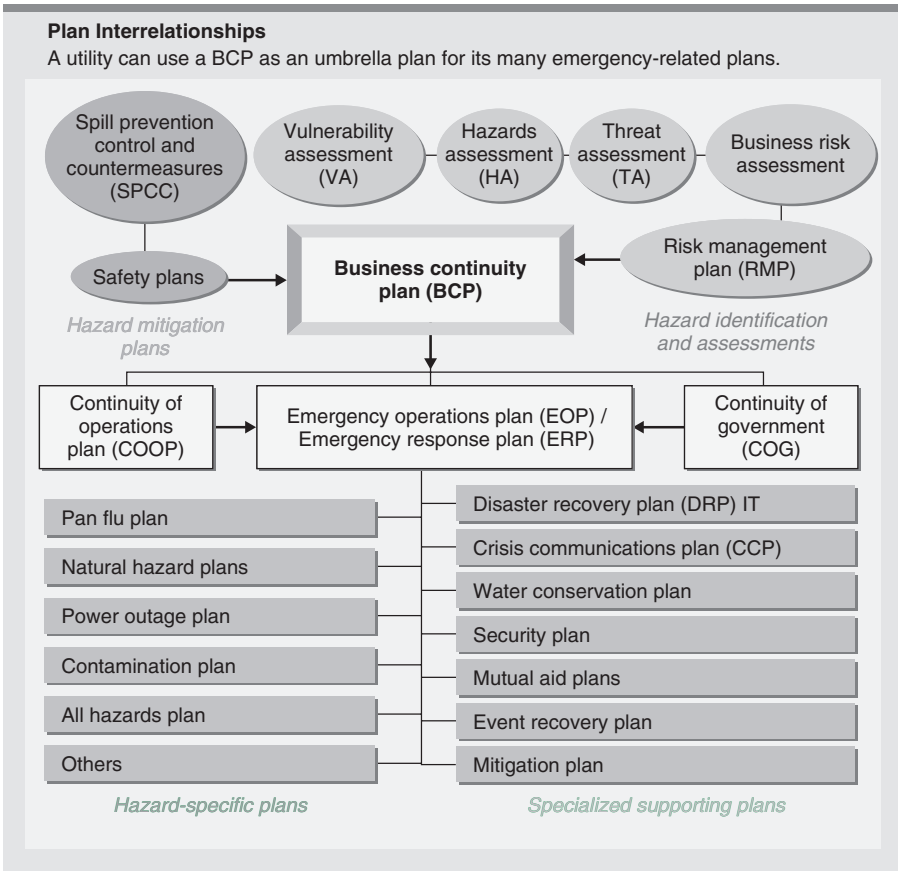

**FIGURE 1** Plan interrelationships (courtesy of AWWA [7]).

The utility may consider converting existing paper and electronic files into a common electronic format, like Microsoft Word, Excel, and Visio. This can be done using optical character recognition (OCR) software for any paper-only documents. Next, assemble the content of the electronic documents within a table of contents (TOC) according to the outline developed during the document review. Some content will be combined, revised, or discarded and the remaining content should undergo technical editing to catch any errors from the scanning and revising. Any plans that are required legally or contractually should be maintained in their full form within the EBCP or as an annex, but will still fall under the umbrella of the EBCP.

The restructured plan will designate how the content will be divided into discreet files and where cross-referencing the different plans (e.g. hyperlinks) can be used.

## 4 PHASES OF EMERGENCY MANAGEMENT

Emergency management involves five phases characterized in Figure 2: assessment, mitigation, preparation, response, and recovery. These phases occur based on an ongoing

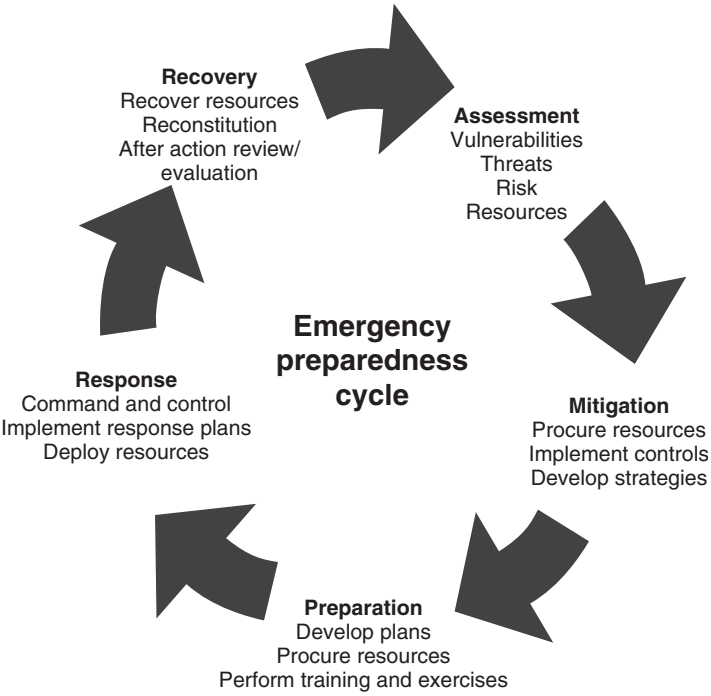

**FIGURE 2** Emergency preparedness cycle.

cycle that accounts for changes in operations, threats, vulnerabilities, and risks and builds upon lessons learned from exercises and actual incidents. This continuous cycle facilitates continuous improvement in emergency preparedness.

### 4.1 Assessment

The assessment phase comprises activities that increase the organization's understanding of the potential threats, vulnerabilities, and risks associated with facilities, operations, and personnel. The basic parameters of threat assessment include probability of occurrence and level of impact of a particular incident. Threats may include acts of terrorism, workplace violence, natural disasters, pathogenic outbreaks, chemical or radiological releases, explosions, and critical service interruptions. Applying potential threats to a specific facility allows assessment of vulnerability, which is the determination of specific factors that may increase or decrease the probability of occurrence. Information compiled via threat and VAs allows a general determination of risk for a particular facility or operation. Resource assessment identifies the pre- and postincident measures, equipment, personnel, and other resources in place to avert or minimize the impact of an incident.

### 4.2 Mitigation

Understanding threats, vulnerabilities, and risks, and the resources in place for incidents of concern allows mitigation planning. The mitigation phase comprises activities undertaken to lessen the occurrence of known and unknown hazards, and/or reduce the severity of

their potential impacts. During this phase, utility management will procure resources, implement controls, and develop strategies that serve to avert and/or minimize the impact of potential hazards in a prioritized manner based on the assessment phase. Examples of mitigation activities include relocating facilities and assets from flood-prone areas and enhancing physical and cyber-security measures against attack. Successful mitigation activities can greatly reduce the number of emergency event scenarios for which a utility would otherwise have to respond.

### 4.3 Preparation

The preparation phase involves developing overarching plans and hazard-specific plans, procuring preparedness resources, and training and exercising of response personnel. An ERP serves as the overarching response plan for all incidents occurring within a utility. Additional support annexes and procedures will augment an ERP for specific incidents, such as tornado response operations and chemical spills. Response planning also includes coordinating with response partners through joint training and exercises and mutual aid agreements; and procuring and prepositioning emergency resources and assets to where they will be most effective during a response.

### 4.4 Response

The response phase involves those actions taken to respond to and stabilize the impact of an emergency event. For events that are predictable to some extent, such as weather-related events, this can also include mobilization and preparatory actions taken immediately prior to the event (like positioning generators at pump stations). The primary objective of the response phase is to stabilize the situation and prevent loss of life and property and damage to the environment. The response phase will likely include the following tasks:

- activation of a utility's ICS and county, state, regional, and federal command and control systems;
- implementation of response, communications, operational, and other procedures contained in the ERP;
- deployment of resources and, as necessary, resource acquisition through the local Emergency Operations Center (EOC) that coordinates and accesses other local, state, and federal agencies.

The response phase can last from hours to days to weeks and may require 24/7 staff scheduling and emergency contractor support. The response phase will last until the Incident Commander determines that the event has terminated and demobilizes the Incident Command Team.

## 5 NATIONAL INCIDENT MANAGEMENT SYSTEM (NIMS) AND INCIDENT COMMAND SYSTEM (ICS)

Utility personnel, in addition to response partners, will implement the ICS when responding to an emergency event as set forth in the NIMS and the NRF. Emergency plans will go

into effect when an emergency event has occurred or a credible threat has been identified; employees may need to take on roles different from their everyday job during a disaster.

## 5.1 Incident Command System

ICS is a standardized on-scene emergency management system that provides for the adoption of an integrated organizational structure. ICS is the combination of facilities, equipment, personnel, procedures, and communications operating within a common organizational structure, designed to aid in the management of resources during incidents. It is used for all kinds of emergencies, and is applicable to small as well as large and complex incidents [8]. All utility staff must be trained in the basics of ICS to comply with federal laws; if a locality is not compliant then it may not receive federal funding/reimbursements from FEMA.

## 5.2 National Incident Management System

NIMS is a system mandated by HSPD-5 that provides a consistent nationwide approach for state, local, and tribal governments; the private sector; and nongovernmental organizations (NGOs) to work effectively and efficiently together to prepare for, respond to, and recover from domestic incidents, regardless of cause, size, or complexity. To provide for interoperability and compatibility among state, local, and tribal capabilities, NIMS includes a core set of concepts, principles, and terminology. HSPD-5 identifies these as ICS; multiagency coordination systems (MACSs); training; identification and management of resources (including systems for classifying types of resources); qualification and certification; and the collection, tracking, and reporting of incident information and incident resources.

## 5.3 NIMS Compliance

NIMS compliance is a requirement to receive federal emergency response and preparedness funding. All grant funding dealing with disaster mitigation, preparedness, and response requires compliance. The FEMA encourages utilities to take the following actions regarding NIMS compliance [9].

### *5.3.1 Adoption*

- Adopt NIMS for all departments/agencies; as well as promote and encourage NIMS adoption by associations, utilities, NGOs, and private sector emergency management and incident response organizations.
- Designate and maintain a single point of contact within government to serve as principal coordinator for NIMS implementation jurisdiction-wide (to include a principal coordinator for NIMS implementation within each department/agency).
- Ensure that Federal Preparedness Awards [to include, but not limited to DHS Homeland Security Grant Program and Urban Area Security Initiative (UASI) Funds] to state/territorial departments/agencies, as well as local governments, support all required NIMS compliance objectives.
- Audit agencies and review organizations should routinely include NIMS compliance requirements in all audits associated with Federal Preparedness Awards.

### *5.3.2 Planning*

- Revise and update emergency response/operations plans, standard operating procedures (SOPs), and standard operating guidelines (SOGs) to incorporate NIMS and NRF components, principles, and policies, to include planning, training, response, exercises, equipment, evaluation, and corrective actions.
- Promote and/or develop intrastate and interagency mutual aid agreements and assistance agreements (to include agreements with the private sector and NGOs).
- Include preparedness organizations and elected and appointed officials in the development of emergency response/operations plans.
- Plan for special needs populations in the development of ERPs (to include, but not limited to, individuals with limited English language proficiency, individuals with disabilities, children, the aged, etc.).
- Include preparedness organizations and elected and appointed officials in the development of ERPs.
- Plan for special needs populations in the development of ERPs (to include, but not limited to, individuals with limited English language proficiency, individuals with disabilities, children, the aged, etc.).

### *5.3.3 Training*

- Use existing resources such as programs, personnel, and training facilities to coordinate and deliver NIMS training requirements.
- Promote and encourage delivery of NIMS training (as identified in the Five-Year NIMS Training Plan Schedule, December 2007).
- Complete ICS-400 Advanced ICS training or equivalent by appropriate personnel (as identified in the Five-Year NIMS Training Plan, February 2008).
- Complete Emergency Management Framework Course—Awareness Training (as identified in the Five-Year NIMS Training Plan, February 2008)

### *5.3.4 Exercise*

- Incorporate NIMS concepts and principles into all appropriate state/territorial training and exercises.
- Plan for and/or participate in an all-hazards exercise program (e.g. Homeland Security Exercise and Evaluation Program) that involves emergency management/response personnel from multiple disciplines and/or multiple jurisdictions.
- Incorporate corrective actions into preparedness and response plans and procedures.
- Include NGOs and the private sector in an all-hazards exercise program, when appropriate.
- Promote the integration of ICS, MACS, and Public Information into appropriate exercises and evaluate against associated target capabilities [refer to Homeland Security Exercise Evaluation Program (HSEEP) Volume III and the Exercise Evaluation Guides].

### *5.3.5 Communications and Information Management*

- Apply common and consistent terminology as used in NIMS, including the establishment of plain language (clear text) communications standards.
- Utilize systems, tools, and processes to present consistent and accurate information (e.g. common operating picture) during an incident/planned event.
- Institute procedures and protocols for operational and information security during an incident/planned event.
- Institute multidisciplinary and/or multijurisdictional procedures and protocols for standardization of data collection and analysis to utilize or share information during an incident/planned event.
- Develop procedures and protocols for communications (to include voice, data, access to geospatial information, Internet/Web use, and data encryption), where applicable, to utilize or share information during an incident/planned event.

### *5.3.6 Resource Management*

- Inventory response assets to conform to NIMS National Resource Typing Definitions, as defined by FEMA Incident Management Systems Division.
- Ensure that equipment, communications, and data systems acquired through state/territorial and local acquisition programs are interoperable.
- Utilize response asset inventory for intrastate and interstate mutual aid requests [such as Emergency Management Assistance Compact (EMAC)], training, exercises, and incidents/planned events.
- Initiate state/territory-wide system to credential emergency management/response personnel to ensure proper authorization and access to an incident including those involving mutual aid agreements and/or assistance agreements.
- Inventory and type specific emergency management/response resources and assets to address unique needs beyond current "Tier One" NIMS National Resource Typing Definitions.
- Institute policies, plans, procedures, and protocols to prevent spontaneous deployment of resources/personnel and/or responding to a request that bypassed official resource coordination processes (i.e. resources requested through improper channels).
- Institute mechanisms to deploy, track, recover, demobilize, and to provide reimbursement for resources utilized during response and recovery.

### *5.3.7 Command Management*

- *ICS.* Manage all incidents/planned events in accordance with ICS organizational structures, doctrine, and procedures. ICS implementation must include the consistent application of Incident Action Planning (IAP), common communications plans, implementation of Area Command (AC) to oversee multiple incidents that are handled by separate ICS organizations or to oversee the management of a very large or evolving incident that has multiple incident management teams engaged, and implementation of unified command (UC) in multijurisdictional or multiagency incident management, as appropriate.

- *MACS.* Coordinate and support emergency management and incident response objectives through the development and use of integrated MACSs, that is, develop and maintain connectivity capability between local Incident Command Posts (ICPs), local 911 Centers, local EOCs, the state/territorial EOC and regional and/federal EOCs, and NRF organizational elements.
- *Public Information.* Institutionalize, within the framework of ICS, Public Information, [e.g. Joint Information System (JIS) and a Joint Information Center (JIC)] during an incident/planned event.
- Ensure that Public Information procedures and processes can gather, verify, coordinate, and disseminate information during an incident/planned event.
- Utilize access control measures during an incident, as appropriate.

### 5.4 NIMS Training

The FEMA has free on-line courses in emergency preparedness (www.fema.gov/prepared/train.shtm). The courses described in this section provide utilities with guidance as to how each Homeland Security Region collaboratively uses the NIMS and the ICS during emergency events.

*ICS 100: Introduction to Incident Command System.* ICS 100, introduces the ICS and provides the foundation for higher level ICS training. This course describes the history, features and principles, and organizational structure of the ICS. It also explains the relationship between ICS and the NIMS.

*ICS 200: ICS for Single Resources and Initial Action Incidents.* This course is designed to enable personnel to operate efficiently during an incident or event within the ICS. ICS-200 provides training on and resources for personnel who are likely to assume a supervisory position within the ICS.

*ICS 300: Intermediate ICS for Expanding Incidents.* This course provides training on and resources for personnel who require advanced application of the ICS. The target audience for this course is for individuals who may assume a supervisory role in expanding incidents or Type 3 incidents. These incidents may extend into multiple operational periods.

*ICS 400: Advanced ICS.* This course provides training on and resources for personnel who require advanced application of the ICS. The target audience for this course is senior personnel who are expected to perform in a management capacity in an AC or multiagency coordination entity.

*IS 700: National Incident Management System, An Introduction.* This course introduces and overviews the NIMS. NIMS provides a consistent nationwide template to enable all government, private sector, and NGOs to work together during domestic incidents.

*IS 800: National Response Framework, An Introduction.* The course introduces participants to the concepts and principles of the NRF [10].

### 5.5 NIMS/ICS Training for Utility Personnel

Utility upper management, middle managers, first-line supervisors, and certain entry level positions require appropriate NIMS compliance training. NIMS compliance for these units

will be based on FEMA recommendations for "predesignated first responders who are operationally driven during an emergency." This includes personnel who will be fulfilling responsibilities either in the Unified/ICP or in the field.

*Entry level.* FEMA IS-700: NIMS, An Introduction
ICS-100: Introduction to ICS
*First line, single resource, field supervisors.* IS-700, ICS-100 and ICS-200: Basic ICS or its equivalent
*Mid-level management: strike team leaders, division supervisors, EOC staff, and so on.* IS-700, IS-800.A NRP, ICS-100, ICS-200 and ICS-300*
*Command and general staff; area, emergency and EOC managers.* IS-700, IS-800.A, ICS-100, ICS-200, ICS-300* and ICS-400*

The courses above (with the exception of ICS-300 and ICS-400) are available for on-line training at http://training.fema.gov/IS/crslist.asp.

## 6 PROMOTING RESOURCE AND INFORMATION EXCHANGE AMONG STAKEHOLDERS

### 6.1 WARN

The Water and Wastewater Alert Response Network (WARN) is a voluntary agreement for utility mutual aid assistance in the event of an emergency within a network. All states have established a network or steering committee for a network to provide and receive emergency aid and assistance. The assistance may arrive in the form of personnel, equipment, materials, and other associated services as necessary from other water/wastewater utilities. Participation in a network is voluntary; there is no obligation to respond, and there is no direct cost to become a member of the network. For more about the WARN networks, see http://www.awwa.org/government/content.cfm?ItemNumber=30229.

### 6.2 Emergency Exercises

Emergency exercise programs include regular training of personnel; testing of systems and equipment to be used during implementation of the plan; and exercises to assess, validate, and identify problems with the plan, procedures, systems, and facilities. Consistent with the HSEEP guidance (https://hseep.dhs.gov/support/HSEEP_101.pdf), the objectives of an exercise program are as follows:

- assess and validate plans, policies, and procedures
- ensure personnel are familiar with emergency procedures
- ensure that personnel are sufficiently trained to carry out essential functions in an emergency situation
- test and validate equipment to ensure both internal and external interoperability
- discover planning weaknesses

- reveal resource gaps
- improve coordination
- practice using the communication network
- clarify roles and responsibilities
- improve individual performance
- improve readiness for an actual emergency.

## 7 HOW TO DEVELOP AN EMERGENCY PLAN

### 7.1 Types of Threats

The emergencies that may affect utility operations or services include natural, technological, and human-caused disasters. Natural disasters include severe thunderstorms, lightning, flooding, tornadoes, and earthquakes. Technological disasters result from accidents or other unintentional acts, and may include fire, power failure, and chemical release. Human-caused disasters are the result of an intentional malevolent act; examples of human-caused disasters are bomb threats, unauthorized entry, and terrorist attacks.

The hazards and emergency events that may be typically applicable to utility facilities and/or services are listed below:

- power failure
- severe weather
- earthquake
- medical emergency
- fire/explosion
- chemical release
- destruction/failure of any part of the water system
- bomb threat/suspected explosive device
- unauthorized entry
- workplace violence
- civil disorder/terrorism
- contamination threat to the water system
- identified contamination in water system
- SCADA (Supervisory Control and Data Acquisition system) attack/electronic
- SCADA attack/physical
- volcanic eruption (ash fall).

### 7.2 Plan Approval

Representatives of the water/wastewater system who are ultimately responsible, such as the system manager, owner, board members, commissioners, and council members,

should review, approve, and sign the ERP. This demonstrates support for the plan, acknowledges the effort put into its preparation, and puts it officially into effect.

Be sure to secure and protect the ERP as it may contain sensitive information about facilities and response activities that you may not want others to know in order to safeguard the water/wastewater system.

## 8 CONTENTS OF AN EMERGENCY PLAN

The purpose of an ERP is to provide written procedures for response actions associated with potential water and/or wastewater utility emergencies, including human-caused/intentionally-caused (e.g. terrorist event), natural (e.g. hurricane, tornado), and/or technological (e.g. process safety failure) emergencies and disasters.

The primary objective of an ERP is to provide clear and concise information to utility management to facilitate response actions and mitigate adverse impacts, in the event of emergency incidents involving water and/or wastewater utility personnel, assets, and/or services to the community.

There are many ERP examples for utilities. The following is a sample outline of an ERP that is specific for the planning needs of a water and wastewater utility. Each utility has unique needs and may require a simpler or more expansive ERP than suggested by this article. Any utility ERP should be NIMS compliant.

**Executive Summary**
**Introduction to the ERP**
- **Purpose of the Plan**
- **Goals**
- **Plan Organization**
- **Situation, Limitations and Planning Assumptions**
- **Plan Ownership and Requirements**
- **Authorities and References**
- Definition of Type of Emergency by Level
- **Overview of Facilities**
- Water Facilities
- Wastewater Facilities
- Solid Waste Facilities
- Natural Gas Facilities
- **Event Specific Response**
- Utility Critical Assets
- **Emergency Systems and Equipment**
- Backup Power
- Emergency Equipment Inventory

**Concept of Operations**
- **Phases of Emergency Management**

- Assessment
- Mitigation
- Preparation
- Response
  - Initial Response Operations
  - Sustained Response Operations
  - Recovery
- **Emergency Response Team and Emergency Operations**
- **Emergency Direction and Control**
- Incident Command
- Unified Command
- Initial Operations
- Sustained Operations
- **Incident Command and the Incident Management Team**
- Utility Incident Command Organization
- Incident Management Team
- **Technical Command Center Operations–General**
- **Mutual Aid Agreements**
- **Employee Care and Support**
- **Balancing Crime Scene Investigation and Emergency Response**

**Tactical Communication/Public Information Policy and Procedures**

- **Tactical Communications**
- Communication Resources
- Backup Telephone Service
- Mobile Radios for Incident Management Team
- Emergency Alert System
- **Responsibility and Authority for Communications**
- Chain of Command
- Contact Lists
- Communications with Elected Officials
- **External Communications (Public and Media)**
- Public Information
  - Hotline for External Communications to Public and Employees
  - Call Center for Two-way Communication with the Public and Employees
- Media Relations
  - Public Information Officer (PIO)
  - Spokesperson
  - Media Access Privileges
  - Information to be Reported and Released to the Media/Stakeholders
  - Initial Media Release
  - Follow-up Media Release
  - Tools/Technology Used to Contact Media

Media Contacts
**Items for Media and Public Information Distribution**

**Emergency Facilities and Equipment**
**Purpose**
**Emergency Operations Center Locations**
Location Maps
Suggested Supplies to be Stored at the EOC
**Transportation Resources**
**Procurement of Equipment and Supplies**

**Plan Activation**
**Triggers**
**Emergency Action Levels**
Internal Notification
External Notification

**Termination, Recovery, and Follow-Up**
**Recovery Organization**
**Recovery Operations**
**FEMA Documentation**
**Utility Operations Centers**
Financial
Electronic Records
Communications, Control and Coordination
**Resumption of Normal Operations**
**Evaluation of Response Effectiveness**
Document Lessons Learned
**Restock and Replenish Equipment and Supplies**

**Training, Exercises, and Documentation**
**Overview and Requirements**
**Training Requirements Matrix**
**Employee Awareness and Proficiency Training**
**Training**
**Emergency Exercises**
Discussion-Based Exercises
Operations-Based Exercises
**Documentation**
Formal Training
Exercise Participation

Exercise Control and Evaluation
After-Action Reports and Improvement Planning

**Administration and Logistics**
**Medical Needs of Responders/Support of Response Personnel**
**Site Security**
**Records Preservation and Document Control**
**Emergency Planning Activities**

**Emergency Response Plan Maintenance**
**Program Maintenance Team**
**Plan Review Responsibility**
Responsibility for Changes
**Plan Distribution**

## 9 CONSIDERATIONS FOR EMERGENCY RESPONSE PLAN CONTENT

Tips to consider when developing common sections of an ERP are discussed below.

### 9.1 Mutual Aid Agreements

Mutual aid and assistance agreements establish a Mutual Aid Assistance Program among its signatories and contain procedures and standards for a water and wastewater utility Mutual Aid and Assistance Program.

Before an emergency occurs, mutual aid agreements should be established with nearby water providers, emergency suppliers, and other agencies that can assist during an emergency.

The utility should coordinate with the fire department and Hazardous Materials (HAZMAT) teams to be certain that these groups have the utility dispatch contact information and will call the dispatch if a chemical spill occurs near a raw water source.

### 9.2 Intertie Connections and Agreements with Other Systems

An intertie to the other local water utilities serves to establish a link to most water systems in the state and allows the utility much greater flexibility in purchasing water from other water agencies or exchanging supplies following a disaster.

### 9.3 System Information

Basic information should be gathered on the locations of system components such as the well fields, distribution system, collection system, and so on. It must be ensured that system information is not available to unauthorized persons. This basic information must be kept easily accessible to authorized staff for emergency responders, repair people, and the news media. System information should include names, locations, and population served.

## 9.4 Response Actions for Specific Events

***9.4.1 Job Action Sheets.*** A Job Action Sheet (JAS) is a tool for defining and performing a specific emergency response functional role. The tasks on the JAS can be amended to fit the situation by adding or deleting tasks. The unit leader, branch director, or section chief issuing the JAS should review it for applicability and add in writing any incident-specific instructions or changes.

Developing good JASs, appropriate for specific personnel and emergency response roles, allows planners and responders to understand responsibilities and to identify gaps or duplicity. They also serve as guides for the development of training curricula. While regular planning, training, exercises, and evaluation are necessary to ensure that personnel are competent to perform assigned emergency response roles, JASs ensure that each responder understands and performs assigned duties according to plan. Each person assigned to serve in a response role serves a critical function and must become familiar with their JAS. JASs provide instructional information and serve as a good illustration of the division of labor that occurs in the other sections. While a single person might be competent to carry out all of the associated tasks, in a large emergency no one person can carry out all these tasks simultaneously.

***9.4.2 Situation Checklists.*** Utilities should establish an emergency response checklist to immediately guide employees through the essential actions they must undertake to ensure the protection of the organization's assets and human resources in the event of an emergency.

Utilities should research which emergencies could affect operations or their ability to provide services. Most of these specific hazards can be found in the utility's VA or Hazard Mitigation Plan. Checklists of procedure should be developed for each emergency event and added as an appendix to the ERP. The appendix can also contain checklists for general emergency response actions, such as evacuation and sheltering-in-place, which may be required during multiple types of emergencies. The checklists serve as a guideline only; as not every step on this list is appropriate for every organization or emergency.

## 9.5 Roles and Responsibilities

For disaster response to be successful, it is critical for the utility to have good, communicative relationships within each of their departments and with other city and county agencies. An ERP will support the utility's ability to respond to an emergency rapidly and to better integrate with other involved agencies. Rapid and efficient response to emergencies should minimize the impacts of the event, including reducing the impact to customers, and limiting the cost of recovery for the utility.

An important part of any emergency response is the familiarity of the responders with the ICS and the role of the Incident Commander at the site of the emergency situation. The Incident Commander is responsible for coordinating activities and calling in support from the utility and other agencies in order to properly respond to the situation at hand.

Many types of incidents will be handled by utility personnel. However, for those emergencies that require response by a fire department or police personnel, the Fire Chief or senior police officer on-scene may act in the role of the Incident Commander, as appropriate. This role may change from one person to another if the situation changes or requires the presence of outside agencies. The utility must recognize that its role may change as an emergency situation changes.

### 9.6 Succession Planning

Succession planning provides for an orderly and predefined assumption of senior official's duties in the event that an official is unavailable to execute their legal obligations. Orders of succession should include the conditions under which succession will occur, methods of notification, and any limitations of authority for the successors.

## 10 COMMUNICATIONS

### 10.1 Emergency Notification of Personnel

Upon notification of an incident, the incident is logged internally and information is communicated to the director of security and emergency management, public/media relations, and the emergency operation/control center (when applicable). As appropriate, notification would also be provided to commissioners, the mayor or county administrator, directors, managers, supervisors, and the mayor's office of communications.

### 10.2 Internal Communication

During an emergency managed primarily by the utility, the public information officer (PIO) can be responsible for providing information to on-site staff. Many utilities set up employee hotlines, which can be updated with current information and instructions. In the event of injuries or casualties, an employee's supervisor and human resources department will share responsibility for any notifications that may be required.

During an emergency managed by others, the local emergency response agency generally takes the lead in disseminating information to on-site staff and their emergency contacts. Assistance will be provided by the PIO, supervisors, and other utility staff as needed.

### 10.3 External Communication

Public information is critical as a means to support emergency response operations and to facilitate public safety during a major incident. Effective risk communication programs are particularly important in the initial phase of a crisis to ensure that the general public understands the risk, proper procedures, help center locations, and other crucial information. Communication strategies must focus on both pre- and postincident communications. Preincident communications provide the public with general information regarding evacuation and other preplanned strategies. Postincident communications provide information to facilitate safety among stakeholders and the general public following an incident. A structure to facilitate both pre- and postincident communications is described below in Figure 3.

### 10.4 Communication with the Public

Because public information is critical to incident management, it is imperative to establish Public Information Systems and protocols for communicating timely and accurate information to the public during emergency situations. Effective risk communication programs are particularly important in the initial phase of an incident to ensure that the

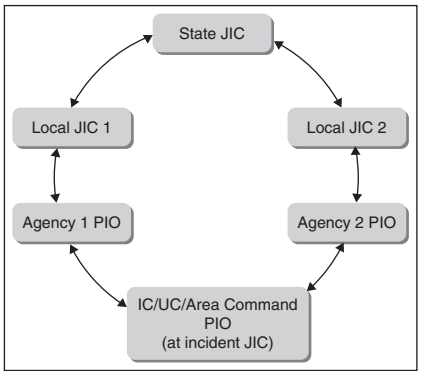

**FIGURE 3** Structure for Communications.

general public understands the risk, proper procedures, where to report for assistance, and other crucial information. Principles to support effective emergency Public Information Systems required by NIMS are addressed below.

***10.4.1 Public Information during Incidents.*** Under ICS, the PIO is a key member of the command staff. The PIO advises Incident Command on all public information matters related to management of the incident, media and public inquiries, emergency public information and warnings, rumor monitoring and control, media monitoring, and other functions required to coordinate and disseminate accurate and timely information related to the incident.

The PIO establishes and operates within the parameters established for the JIS. The JIS provides an organized, integrated, and coordinated mechanism for providing information to the public during an emergency and includes plans, protocols, and structures used to provide information to the public. It encompasses all public information related to the incident. Key elements of a JIS include interagency coordination and integration, developing and delivering coordinated messages, and support for decision-makers. The PIO, using the JIS, ensures that decision-makers and the public are fully informed throughout an incident response.

***10.4.2 Coordination of Public Information.*** During emergencies, the public may receive information from a variety of sources. Part of the PIO's job is to ensure that information received by the public is accurate, coordinated, timely, and easy to understand. One way to ensure coordination of public information is by establishing a JIC. Using the JIC as a central location, information can be coordinated and integrated across jurisdictions and agencies and among all government partners, the private sector, and nongovernmental agencies. The JIC is the physical location where public information staff involved in incident management activities can colocate to perform critical emergency information, crisis communications, and public affairs functions. JICs provide the organizational structure for coordinating and disseminating official information.

## 10.5 Communication with Critical Customers

Critical customers are the at-risk members of the community that resides within a utility's service area. Examples of critical customers include:

- hospitals
- schools
- elderly housing.

The utility's PIO is responsible for notifying priority water customers of changes in water quantity and/or quality that may seriously affect their operations. The resources available to make multiple notifications may be limited during an emergency. Therefore, the 911 Call Center, special call center or other city departments may provide assistance as needed.

## 11 PERSONNEL SAFETY

During any incident, particularly one requiring a lengthy response, it is important to provide for the health, security, and comfort of employees. The following list presents important elements to consider when supporting emergency response personnel.

- replacement clothing, additional protective clothing, replacement footwear and gloves, and other personal protective equipment (PPE);
- shift schedules and rest periods designed to avoid exhaustion;
- meals and safe support areas for removal of personnel from a site; and
- means for personnel to ensure the safety of their families.

Medical surveillance of emergency responders is required for those personnel who may come in contact with hazardous materials. According to 29 CFR 1910.120 (http://www.osha.gov/pls/oshaweb/owadisp.show_document?p_table=standards&p_id=9765), hazardous material workers and technicians must undergo periodic medical exams. Medical certification for hazardous material work is maintained in personnel records maintained by organizational human resource offices. Additionally, appropriate Health Information Privacy Protection Act (HIPPA) requirements must be followed in collecting, storing, and using this data.

The Safety Officer is responsible for monitoring and assessing hazardous and unsafe situations and developing measures for assuring personal safety. Depending upon the nature and extent of the emergency, the Safety Officer may activate Assistant Safety Officers, additional staff from other disciplines, and/or specialized technical support.

Responsibilities associated with this position may include, but are not limited to:

- obtaining a briefing from the Incident Commander;
- identifying hazardous situations associated with the incident, and ensuring that adequate levels of protective equipment are available and are being properly used;
- identifying potentially unsafe acts, and ensuring implementation of corrective actions. Ensuring safety of on-scene operations, and immediately correcting any unsafe practices;
- reviewing proposed emergency response actions for safety. If an action is or may be unsafe, assist in identifying protective measures or alternative options;
- establishing and maintaining the proper level of security at the EOC and incident scene;

- if applicable, ensuring adequate sanitation and safety in food and beverage preparation;
- tracking accidents and/or injuries to response personnel. Developing and implementing recommendations for preventative and corrective actions;
- investigating any accidents that occur within the incident area. Ensuring that the scene is preserved for investigation and that the incident is properly documented; and
- documenting all significant actions and information in the event log.

### 11.1 Emergency Equipment

***11.1.1 Personnel Protective Equipment.*** *Personal protective equipment* (PPE) refers to protective clothing, hard hats, goggles, or other garments designed to protect utility personnel from job-related occupational safety and health hazards.

***11.1.2 Emergency Communications Equipment.*** Two-way radios, land-line telephones, and cellular telephones are examples of equipment that are most often used to maintain communication among the EOC, field personnel, and external agencies.

Radios should be distributed to management personnel such as the: Utility Director, Incident Commander, Chief Plant Operator, Engineering Manager, or designees for these positions.

## 12 ERP ACTIVATION

A utility must determine when to activate their ERP. Threat warnings and other triggers may be used as notifications for staff to begin their emergency actions.

### 12.1 Threat Warning System

A threat warning is defined as an unusual event, observation, or discovery that indicates the potential for contamination and initiates actions to address the concern. Threat warnings may come from multiple sources, including:

- security breach, which is an unauthorized intrusion into a secured facility that may be discovered through direct observation, an alarm trigger, or signs of intrusion;
- witness account of suspicious activity, such as trespassing, breaking and entering, or other forms of tampering;
- direct notification by perpetrator, either verbally or in writing;
- notification by law enforcement, including local, county, state, or federal agencies;
- notification by news media;
- unusual water quality parameters, when evaluated in the context of the established baseline and the performance characteristics of monitoring and detection equipment;

- unexplained or unusually high incidence of consumer complaints about the aesthetic qualities of drinking water, or minor health problems resulting from exposure to water; and
- notification by public health agencies regarding an increase in the incident of disease or death in a given population.

ERPs should be activated in the event of incidents that pose an unreasonable risk to human health, safety, and/or the environment and/or has the potential for catastrophic impact on utility operations (e.g. terrorist attack, fire and/or explosion, hazardous material spill or release, natural disasters). As such, an ERP provides a standard, yet flexible, framework for incident mitigation, preparedness, response, and recovery. Implementation of ERP procedures must be flexible to accommodate differing circumstances of critical events and changing conditions.

Incidental events (e.g. spills) that can be controlled without threat to human health or the environment by using appropriate engineering controls, work practices, PPE and/or can be contained within the immediate area of the event with NO potential to extend beyond the immediate area, do not require implementation of an ERP.

## 12.2 Triggers

Triggers are events that require activation of an ERP. When activated, utilities switch from normal operations to a operations designed to support activation, response, and recovery relative to a particular hazard or event. The specialized concept of operations supports resource acquisition and deployment to support mitigation and recovery efforts in a safe and effective manner. In addition to national or regional disaster declaration, triggers may include the following:

- notification from the health department that there may be a water quality problem
- medical illnesses or injuries preventing staff from working
- natural disasters (e.g. flooding)
- radiation release
- terrorist or criminal activity.

These ERP triggers require tiered levels of response. A small event may require only a small activation, while a larger incident may require full activation and outside support. Events which trigger activation of the ERP will dictate both the scope of the logistical response and the breadth of affected personnel and facilities. Foreseeable natural disasters such as tornadoes may require complete evacuation of certain facilities, while other events may only impact noninhabited structures.

In addition to utility-specific emergency action levels for response during an emergency event, the Office of Homeland Security has developed the Homeland Security Advisory System for the general public [11].

If the DHS threat level changes, the American Water Works Association (AWWA) will alert water systems via e-mail about the change and recommended emergency

preparations. AWWA's system is known as the *Water Information Sharing and Analysis Center* (WaterISAC) [12].

## 13 PLAN MAINTENANCE

An ERP is a valuable tool to prevent and minimize the impact of emergency incidents. It is critical that an ERP be maintained to reflect current conditions and that agency personnel are well trained and able to respond as planned. The contact list in an ERP should be checked and updated regularly (at least twice a year, and more frequently for some utilities). Updates to the entire plan should be made at least once a year, and should be timed to include lessons learned from emergency exercises.

# TREATABILITY OF CONTAMINANTS IN CONVENTIONAL SYSTEMS

KIM R. FOX

*National Homeland Security Research Center, U.S. Environmental Protection Agency, Cincinnati, Ohio*

## 1 INTRODUCTION

Earlier articles in this book have pointed out the need for information on how to protect, detect, and respond to a terrorist attack on a water system. Those attacks may happen in many ways and this article focuses on the response to a contamination attack. The information presented here is to be used to help plan for and to respond to contamination of a water system. Other articles focus on the decontamination of the hard surfaces whereas this article focuses on the treatment of the contaminated water.

The treatment of the contaminated water depends on many factors and these factors include class of contaminant, water quality parameters, volume of water to be treated, location of the water to be treated, and more. Many of the factors above are site specific, and so are not addressed in this article. This article presents general treatment techniques that could be used based on various classes of contaminants. These treatment techniques are not solely for treatment of intentionally contaminated water, but are the same ones that would be used to remove contaminants from any water that contain these contaminants.

The US Environmental Protection Agency (EPA) has proposed a system to help communities detect an intentional contamination of distribution system as early as possible. That system is called the *water security initiative*. The architecture of this system describes the classes of contaminants that the EPA is concerned about [1]. The list of contaminant classes is shown in Table 1.

## 2 WATER TREATMENT

The various types of water treatment technologies available (or applicable) depend on the type of contaminant and the extent of the contamination. For example, if a storage tank was contaminated with a microbial contaminant that could be inactivated by disinfectant, then proper levels of the disinfectant could be added to the storage tank for the proper length of time and no additional treatment would be necessary. In the case where an inorganic chemical contaminant was introduced into an aquifer, a granular activated carbon (GAC) water treatment plant might need to be constructed in order to treat the water for very long periods of time. The various typical water treatment

**TABLE 1 Classes of Contaminants**

| Contaminant Class | Description |
|---|---|
| 1 | Petroleum products |
| 2 | Pesticides (chlorine reactive) |
| 3 | Inorganic compounds |
| 4 | Metals |
| 5 | Pesticides (chlorine resistant) |
| 6 | Chemical warfare agents |
| 7 | Radionuclides |
| 8 | Bacterial toxins |
| 9 | Plant toxins |
| 10 | Pathogens causing disease with unique symptoms |
| 11 | Pathogens causing diseases with common symptoms |
| 12 | Persistent chlorinated organic compounds |

practices are described below along with a summary of their capabilities and where they could be used. A full description of the following techniques can be found in the literature [2].

Conventional coagulation/settling/filtration water treatment uses chemical pretreatment to cause particulate material in a water system to form floc that would then be settled out in a sedimentation basin and/or be removed by filters. The typical pretreatment chemicals include aluminum or iron coagulants and lime or polymers, and the type and amount of chemical depends on the quality of water. This type of treatment is very good at removing particulate matter (including microorganisms), small amounts of various chemical contaminants, and to some extent various radionuclide contaminants. Although this process is very good at removing many contaminants, the process would be difficult to install during an emergency situation. There are some mobile water treatment units that utilize this technology, but these mobile units could not treat large quantities of water. This technology would be (and is) very useful in treating the drinking water for communities that use surface waters as their source water. As an added advantage, this process provides a measure of protection in case their source water becomes contaminated.

One modification to the conventional process is known as *direct filtration*. In direct filtration, the sedimentation step is eliminated. Source waters that contain low levels of particulate material may be suitable for direct filtration. The types of contaminants removed by direct filtration and the limitations of direct filtration are similar to conventional treatment.

GAC is an adsorption and absorption media that can be used to remove many organic contaminants from water. GAC is also effective in removal of low amounts of inorganic contaminants and radionuclides. The GAC is typically placed into a contactor and the water passes over and through the carbon. The contaminants attach themselves to the carbon and are removed from the carbon during reactivation or remain on the carbon for disposal (depending on the contaminant). GAC contactors can be installed

quickly, and the carbon can be replaced when the carbon is spent rather than trying to reactivate the carbon. GAC systems are also readily available for smaller applications, such as apartment buildings, homes, or even small enough for single faucets. Thus, during an emergency situation, GAC units could be utilized to treat only the water that was to be used for consumption or to treat all of the water that was being distributed.

One modification to GAC is known as *powdered activated carbon (PAC)*, where instead of the water flowing through a carbon contactor, the PAC is added to the water and then removed by other processes. The types of contaminants removed by PAC are similar to those listed under GAC. PAC is typically used in situations where seasonal (or occasional) contamination occurs and the activated carbon is only needed for relatively short times.

Aeration is a process where high volumes of air are passed through the water in an effort to transfer the contaminant from the water to the air and thus remove the contaminant from the water. There are several types of aeration systems utilized in drinking water treatment and they range from pipes that bubble air into a pool of water, to pressurized, diffused bubble systems, to tower aeration processes. In all cases, the treatment process is to pass air through the water to strip out the contaminant. Aeration techniques are typically used to remove volatile organic contaminants, but there are a few radionuclides that can be stripped from water by this process. Aeration systems can be installed in relatively short periods of time and they are adaptable to various sizes of systems. For example, aeration systems have been placed into open-air reservoirs, down the single wells or to centrally treat water in a community. One drawback to aeration systems is that the water will have to be repumped after aeration to pressurize the system.

Several treatment technologies, described under the category of membrane treatment, include reverse osmosis, nanofiltration, and microfiltration. In all three cases, the idea is to pass water through a membrane by applying pressure while leaving the contaminants on the other side of the membrane and removing from the system in a concentrated waste stream. In drinking water treatment, these three technologies are differentiated by the size of the contaminant that will go through the membrane. Reverse osmosis system is capable of removing chemicals (inorganic or organic), microorganisms, and radionuclides. Nanofiltration would typically be capable of removing inorganic chemicals, some large organic compounds, and microorganisms. Microfiltration is used only to remove the microorganisms.

All of the membrane technologies are such that they can be installed easily and range in size from single faucet application (home reverse osmosis units) to large-scale applications for treating water for large communities. There are mobile water treatment systems utilized by the military and some of these use membrane technologies to remove as many contaminants as possible.

Ion exchange technology is one where water passes over a bed of ion exchange media (typically resin beads). The resin beads have sacrificial chemical groups attached to them, such as sulfate, sodium, potassium, hydrogen, and others. The chemicals in the water exchange themselves for the chemical group on the resin. Currently, ion exchange systems are utilized for inorganic chemical, radionuclides, and some organic chemicals. Ion exchange system can be installed easily and readily available in cartridge systems

for small applications, whole house systems (home water softener), commercial size for industrial uses, and full-scale water treatment systems.

Activated alumina treatment is not a common practice in drinking water treatment, but is being used to remove specific inorganic chemicals from some water supplies. The removal process is by both adsorption and ion exchange within the activated alumina. Activated alumina has not been used to remove organics or microorganisms from drinking water.

One of the most common forms of water treatment that would be used during and intentional attack of a water system is the use of a disinfectant. Currently, the most common drinking water disinfectants used are chlorine, chloramines, and ozone. Ultraviolet light is also used to disinfect drinking water. Typically, the drinking water disinfection processes are utilized to inactivate microorganisms, oxidize inorganic chemicals, or destroy some organic compounds. The amount and type of disinfectant required depends on the water quality, type and number of organisms, and chemical to be oxidized. Disinfectant technologies are probably the easiest technology to implement in an emergency situation. Quantities of disinfectant could be added manually to a storage tank if necessary, the water utility could increase the disinfectant addition at the treatment plant, or disinfection equipment could be added in desired locations.

Heat inactivation is the final process to be discussed. During drinking water emergencies, boil water orders are often implemented. Notices are given for individuals to

**TABLE 2 Treatment Techniques for Individual Contaminant Class**

| Contaminant Class | Treatment Techniques |
|---|---|
| 1 | Aeration, membrane, carbon [3] |
| 2 | Granular activated carbon, powdered activated carbon, reverse osmosis, aeration, and disinfection [4] |
| 3 | Ion exchange, membrane, granular activated carbon, disinfection, and coagulation/filtration [2] |

| 10 | Membrane, disinfection, coagulation/filtration, lime softening, and boiling [2, 10] |
| 11 | Membrane, disinfection, coagulation/filtration, lime softening, and boiling [2, 10] |
| 12 | Ion exchange, membrane, granular activated carbon, and coagulation/filtration [2] |

boil their water prior to consumption. This process is suggested only for microbial problems and recommended only when boiling is thought to be the desired treatment (Table 2).

## 3 FUTURE RESEARCH

At present, the US EPA's National Homeland Security Research Center (NHSRC) is evaluating specific water treatment and decontamination technologies for various drinking water contaminants. The list of contaminants includes those not normally found in drinking water system and those that could be used in an intentional attack. The information gathered in these projects will be made available to water utilities and those that assist water utilities during an emergency. The data that are considered nonsensitive will be published in peer journals or on EPA's website. For data that are considered sensitive, secure publications and access will be available.

Future research will also be necessary on newly created chemicals and mutated or genetically altered microorganisms. Much of that work will be long-term research projects as the specific contaminant is identified.

## 1 INTRODUCTION

Returning a water system to complete operation after a contamination event requires *ex situ* treatment of the contaminated water and *in situ* decontamination of the water system equipment and distribution system piping. The technologies and actions implemented will be a function of a large number of variables. Current research is discussed in the next section. Subsequently, applicable treatment/decontamination technologies are presented in a tabular form. That table includes technologies currently employed by water systems as well as applicable decontamination technologies employed in the nuclear industry.

## 2 SCIENTIFIC OVERVIEW

This article presents an assessment of developing and developed technologies for decontaminating municipal water system equipment, the distribution system itself, and contaminated water after a contamination event. The technology assessment is qualified by recognition of the substantial unpredictability of a purposeful contamination and the complexities surrounding returning the system to safe operation. Those complexities and uncertainties are discussed in the following Problem Definition section and reflected in the later Research Direction recommendations.

### 2.1 Problem Definition

The range of potential contaminants found in a purposeful or inadvertent contamination of a water system includes biological, chemical and radiological agents. This range is only one of the uncertainties to be addressed in dealing with and responding to such an event. Some of the needed information includes:

- *Nature of the contaminants.* The classification of the chemical/biological contaminants (inorganic chemicals, organic chemicals, microorganisms) is one of the parameters that dictate the decontamination approach to be employed for decontamination. For instance, disinfection agents are powerful decontamination approaches for microbial contaminants and some organic contaminants. However, they have little or no effect on removal of inorganic contaminants. The potential for agents to adsorb/absorb (generically described as adherence in this article) on distribution system materials, scale, or sediment vastly complicates decontamination. Radiological contaminants, generally a subset of inorganic contaminants, present unique decontamination issues. Radiological contaminants also present a unique biological and public response problem. Radiological hazards are likely to be present in very small mass quantities. These small mass quantities will be difficult to decontaminate and completely remove from the system.
- *Extent of the contamination.* Isolation of the contamination to a pressure zone or distribution system area is highly desirable, as it limits the subsequent decontamination and treatment effort. If isolation is not possible, then decontamination of a major portion of the system will be a costly and very time-consuming operation.
- *Materials of construction and age of the water distribution system.* Aggressive decontamination approaches can expedite return to normal operations, but these approaches may be limited by the robustness of the system itself. Older highly scaled distribution systems, in which agent adherence is likely, may require more aggressive treatment to remove the contaminants, but these systems are also susceptible to structural failure under aggressive treatment.
- *Cleanup standard.* Whether the system must be decontaminated to meet drinking water standards [1] or less stringent requirements, such as the US Department of Homeland Security's proposed Protective Action Guides [2], would significantly impact the decontamination approach. With some contaminants, compliance with drinking water standards will require implementation of multiple technologies.

Simply stated, the decontamination approach will be dictated by the characteristics of the contaminant and the system to be decontaminated. An additional factor for consideration is the public acceptance of any decontamination approach and the resulting "end state" or cleanup standard. The environmental remediation industry has experienced stakeholder rejection of cleanup approaches that meet all technical requirements.

## 2.2 Research and Development Status

The American Water Works Association Research Foundation (AwwaRF) sponsored a bench-scale study for decontamination of drinking water system infrastructure, during the period 2004–2006 [3]. The objective of this research program was "to provide a basis for developing standard operating procedures (SOPs) that can be adopted for use by water utilities for remediation of contaminated water infrastructure in the event of a major contamination incident" [3]. The study investigated various decontamination methods for their effectiveness in removal of particular types of contaminants from drinking water distribution system pipe surfaces.

The contaminants examined in the study included the following:

- *Inorganic chemicals.* Cyanide, arsenic, mercury, and surrogates of radioactive isotopes (cesium, strontium, cobalt, and thallium).
- *Organic chemicals.* Chlordane and para dichlorobenzene (p-DCB).
- *Microbial contaminants. Bacillus thuringiensis* and MS2 bacteriophage.

In these bench-scale experiments, AwwaRF used 12-in. lengths of pipe sections of various materials. The diameter of the pipe sections varied from 0.75 to 3 in. During the water matrix testing and contaminant adherence tests, the pipe sections were filled with the contaminant mixtures and the pipe surfaces were exposed to contaminants for a period of 7 days.

***2.2.1 Phase 1a: Water Matrix Test.*** The objective of the water matrix test was to determine whether the water matrix had a substantial impact on the adherence of contaminants to the pipe surface. The following water matrix parameters were examined: temperature, pH, alkalinity, and total organic carbon (TOC). Only two types of pipes were tested in the water matrix test: chlorinated polyvinyl chloride (cPVC) and iron pipes. There was no significant or consistent impact of water matrix variables (i.e. temperature, pH, alkalinity, and total organic carbon) on the attachment of microbes, inorganic metals, or organic contaminants to cPVC or iron pipe surfaces.

***2.2.2 Phase 1b: Contaminant Adherence Tests.*** Contaminant adherence tests were performed on various pipe materials, including the combinations of biofilm on cPVC and iron pipe, polyethylene, new and heavily tuberculated (used) galvanized pipe surfaces, epoxy-coated steel pipe, and cement-lined ductile iron pipe with and without the asphalt seal coat. Following were the results:

- Greater than 5% of cesium, strontium, cobalt, and thallium were attached to iron, new galvanized, or iron/used galvanized biofilm pipes.
- Chlordane adsorbed to all pipe surfaces, except the cement-lined ductile iron and polyethylene pipes.
- The adsorption of p-DCB was not as strong as chlordane; however, greater than 5% of p-DCB adsorbed to iron-biofilm, new galvanized, used galvanized, cement-lined ductile iron (with asphalt seal coat), and epoxy-coated steel pipe.
- Bacillus spores attached best to iron-biofilm pipe. No substantial adsorption (less than 5%) of cyanide, arsenic, mercury, or MS2 bacteriophage was observed on any of the pipe materials tested.

***2.2.3 Phase 2: Examination of Decontamination Procedures.*** AwwaRF's bench-scale decontamination test was focused on the contaminants that showed adsorption capacity of greater than 5% on various pipe materials. For the examination of decontamination procedures, decontamination agents were applied to the contaminated pipe sections for 24 h. The pipe surfaces were then rinsed with one-water wash and a final "getter-wash". The effectiveness of the decontamination procedures was calculated by determining the amount of contaminant in the final "getter-wash" compared to the final "getter-wash" from nondecontaminated pipes. The decontamination agents tested included common

surfactants, chelating agents, pure industrial surfactants, commercial surfactant combinations, and chlorine/hypochlorite.

***2.2.4 Decontamination of Bacillus Spores.*** Decontamination tests with Bacillus spores were conducted using chlorine as the decontamination agent at different levels of concentration–time (CT) values (ranging from 300 to 30,000 mg/l/min) to remove Bacillus spores from heavily tuberculated galvanized pipe and iron-biofilm pipe surfaces. Inactivation of Bacillus spores attached to tuberculated galvanized pipe was not pronounced for various chlorine contact times tested. The highest removal efficiency obtained was 84% with a CT application of 30,000 mg/l/min. Results from the Bacillus spores on iron-biofilm pipe were not conclusive due to the very low level of attached spores. The significantly high CT value with lower removal of Bacillus species in the AwwaRF study demonstrates the challenge associated with decontamination of microbial contaminants from the pipe surfaces as compared to removal from bulk water [4].

***2.2.5 Decontamination of Inorganic Contaminants.*** Decontamination techniques tested for inorganic contaminants, cesium, and strontium (radionuclide surrogates) included chlorination, treatment using Simple Green, a commercial decontamination agent (1 and 10%), NaEDTA disodium ethylenediaminetetraacetic acid (1%), and sodium citrate (1%) on two types of pipe surfaces: heavily tuberculated (bulb-like scale adhering to pipe walls) galvanized pipe and cement-lined ductile iron pipe (without asphalt seal coat). Decontamination tests of cobalt and thallium, also radionuclide surrogates, on new iron or galvanized pipes were conducted with chlorination and treatment using Simple Green (1 and 10%). The decontamination results were as follows:

- Chlorination resulted in the removal of cesium on used galvanized and cement-lined ductile iron pipes at 23% and 26%, respectively.
- Strontium was minimally removed by chlorination on cement-lined ductile iron pipe.
- The 10% Simple Green resulted in removal of cesium and strontium with efficiencies ranging between 18 and 56%.
- None of the decontamination agents successfully removed cobalt and thallium from new iron pipes or galvanized pipes.

***2.2.6 Decontamination of Organic Contaminants.*** Three commercial surfactants, Surfonic N-60, Surfonic TDA-6, and Empicol LZV, were evaluated as decontamination reagents at three concentration levels (0.05, 0.5, and 5%) for organic contaminants (chlordane and p-DCB) on cPVC, used galvanized, and epoxy-coated steel pipe surfaces. The results, tabulated in Table 1, were highly variable depending on the contaminant and pipe material.

In 2004, Battelle Science and Technologies initiated a bench-scale drinking water pipe decontamination study under the funding of EPA's National Homeland Security Research Center [5]. The objective of this study was to understand adherence/attachment of various contaminants on pipes commonly used for drinking water distribution.

This study examined several kinds of chemical contaminants, including three kinds of organophosphates (mevinphos, dichlorvos, and dicrotophos), diacetylmorphine (heroin), gasoline, mercuric chloride, strychnine, sodium fluoroacetate, and sodium cyanide. The

**TABLE 1 AwwaRF's Decontamination Study Results**

| Pipe Type | Contaminant[a] | Surfactant | | |
|---|---|---|---|---|
| | | Surfonic N-60 | Surfonic TDA-6 | Empicol LZV |
| cPVC | Chlordane | Good removal | Good removal | Average removal |
| | p-DCB | Poor removal | Poor removal | Poor removal |
| Used galvanized | Chlordane | Good Removal | Good Removal | Average removal |
| | p-DCB | Average removal | Average removal | Poor removal |
| Epoxy-coated steel | Chlordane | Average removal | Average removal | Average removal |
| | p-DCB | Poor removal | Poor removal | Poor removal |

[a]The qualitative performance ratings are defined in terms of percent as follows:

| | |
|---|---|
| <20% | poor removal |
| 20–50% | average removal |
| 50–80% | good removal |
| >80% | excellent removal |

bacterial contaminants examined included *Bacillus anthracis* Sterne (anthrax), *Burkholderia thailandensis* ATCC 700388 (glanders), *Vibrio cholerae* ATCC 25870 (cholera), and *Salmonella choleraesuis* typhi ATCC 6539 (typhoid). Two neurotoxins (Brevetoxin PbTx-3 and botulinum type A) and one mycotoxin (aflatoxin B1 [sigma]) were also studied.

In this study, the pipe housings were filled with contaminated water to maximize the surface area contacted, with very little oxygen present. Test pipe segments were sealed by covering the liquid with a Teflon sheet at both ends. The pipe materials evaluated included the following:

- Polyvinyl chloride (PVC) Schedule 40
- Aged black iron
- Copper
- High density polyethylene (HDPE)
- Cement-lined ductile iron with or without seal coat
- Steel pipe with high solids epoxy.

Contaminants were sealed in the test pipe materials for 1-day and 7-day hold tests at room temperature as well as at 2–8 °C for 7-day hold tests. Battelle subsequently evaluated decontaminant effectiveness, but those results are not available.

Primary results of the adherence results are qualitatively described in Table 2. Note that not all contaminants were evaluated in all pipe types. Related observations include the following:

- Most of the chemical contaminants adsorbed on cement-lined ductile iron pipes.
- Copper and mercury formed an amalgam on the pipe surface, and this type of mercury slowly leached back into the distribution systems.
- There was no difference between contaminant adherence to various types of iron pipes, whether they were cement-lined or not.

**TABLE 2 Battelle Adherence Study Results**

| Contaminant | Pipe Type | | | | | |
|---|---|---|---|---|---|---|
| | PVC | Aged Black Iron | Copper | HDPE | Cement-lined Ductile Iron | Epoxy- Lined Steel |
| Mevinphos | Adsorbed | | Adsorbed | | | |

| Gasoline | Adsorbed | | | | | |
| Mercury chloride | | | Adsorbed | | | |
| Strychnine | Adsorbed | | | | | |
| Sodium fluoroacetate | | | | | Significant Adherence | |
| Anthrax | High adherence | Moderate adherence | High adherence | High adherence | Moderate adherence | High adherence |
| Glanders | High adherence | | | High adherence | | Moderate adherence |
| Typhoid | Moderate adherence | Moderate adherence | Bactericidal action | Low adherence | Bactericidal action | Moderate adherence |
| Aflatoxin B1 | Adheres | | Less adherence | Adheres | | |

- Fluoroacetate showed significant adherence to ductile iron pipe surfaces, though it was found to be very soluble in water.
- Strychnine and diacetylmorphine dissociated into morphine within a few minutes.
- Botulinum toxin was found to be unstable in water.

A pilot-scale experimental test program was conducted during the period 2005–2007 by Shaw Environmental, Inc. under the sponsorship of EPA's National Homeland Security Research Center [6]. The primary objectives of this decontamination research were to quantitatively determine the potential of target contaminants for persistence in dynamic drinking water distribution systems and to perform quantitative determination of the efficacy of various decontamination methods for removing contaminants from drinking water distribution systems. This effort differs from the AwwaRF and Battelle studies in that this project examined a pilot-scale dynamic system rather than a bench-scale static unit.

A pilot-scale drinking water distribution system simulator (DSS) was constructed from a 6-in. diameter clear PVC pipe. To quantify the extent of adherence of the contaminants to the surface of real-world pipe materials, 10 small rings (coupons) from real-world pipe sections were integrated into the PVC DSS. The real-world pipe coupons used for the study were made of used cement-lined ductile iron pipe sections taken from a pipe that had been in service for 5 years. A set of PVC coupons was included to serve as "control" coupons. Each coupon measures 1 in. in width. At the end of each run, the coupons were removed from the system and analyzed for specific contaminants. An accelerated biofilm cultivation protocol was developed and applied in the DSS for 2–3 weeks prior to the injection of contaminants. A heterotrophic plate count (HPC) of $10^4$ colony forming units (CFU)per square centimeter or higher was considered to adequately represent a viable biofilm population in the pipe-loop system.

A complete decontamination test included evaluation of the contaminant adherence to the pipe surface followed by an evaluation of a specific decontamination procedure. During the adherence test, contaminants were injected into the pilot-scale pipe-loop system. For these contaminants, appropriate decontamination technologies were selected and their effectiveness was determined. Table 3 presents a list of primary experimental design parameters for conducting the pilot-scale adherence/decontamination studies.

Results from experiments studying the effects of flow rates on the adherence of contaminants to the pipe surfaces are tabulated in Table 4. In summary, all tested contaminants have a strong tendency to adhere to cement-lined ductile iron pipe surfaces, and the adherence capacity of target contaminants to the clear PVC pipe surfaces varied significantly.

Table 5 presents a summary of the performance of various decontamination techniques for the target contaminants tested in this study. The variability in the decontamination effectiveness was assessed by the different coupons employed within the pipe-loop system. Therefore, only qualitative ratings of the various decontamination methods are indicated in Table 5.

## 3 CURRENT DECONTAMINATION AND TREATMENT PRACTICES

The previous subsection presented research results from ongoing adherence and decontamination studies. This section describes available decontamination technologies and

**TABLE 3 Experimental Design Parameters for EPA/Shaw Pilot-Scale Decontamination Study**

| Parameters | Selected Materials/Conditions |
|---|---|
| Target contaminants | Sodium arsenite, mercuric chloride, *Bacillus subtilis*, diesel fuel (No. 2), chlordane |
| Pipe material evaluated | Cement-lined ductile iron (from 5-year-old T&E facility pipe-loop system), clear PVC |
| Biofilm | Biofilm cultivated on pipe wall (target HPC: $10^4$ CFU/cm$^2$) |
| Distribution system simulator operating parameters | Flow mode: recirculation |
| | Flow rates: 1, 15, 60 ga/min |
| | Temperature: ambient high bay temperature |
| | pH: pH of Cincinnati tap water ~8.5 |
| | Free chlorine at start of study: ~1.0 mg/l |
| Contact time for contaminant adherence study | 2 d after injection of contaminant into pipe-loop system |
| Concentration of target contaminant | 10 mg/l of mercury, arsenic, and diesel fuel (No. 2), chlordane (as alpha+gamma chlordane, 40 mg/l as technical chlordane) |
| | $10^4$ cells/ml of *B. subtilis* |
| Decontamination approaches evaluated | **Arsenic**: Baseline water flushing |
| | Low pH (i.e. pH 4) flushing |
| | Phosphate buffer flushing |
| | Acidified potassium permanganate flushing |
| | NSF Standard 60 Products flushing: |
| | *NW-310/NW-400 flushing* |
| | *Floran Biogrowth Remover/Catalyst flushing* |
| | *Floran Top Ultra/Catalyst flushing* |
| | **Mercury:** Baseline water flushing |
| | Low pH (i.e. pH 4) flushing |
| | Acidified potassium permanganate flushing |
| | ***B. subtilis***: Baseline water flushing |
| | Shock chlorination |
| | **Diesel fuel:** Baseline water flushing |
| | Surfonic TDA-6 flushing |
| | **Chlordane**: Surfonic TDA-6 flushing |

provides a brief description of these technologies. Note that many of these technologies are considered "available", but have not necessarily been deployed in real municipal water systems. They are included here for consideration in responding to an unpredictable contamination event.

### 3.1 Available Decontamination Technologies

Table 6 is a compilation of decontamination technologies applicable to removal of microbial, organic, and inorganic (including radiological) contaminants. Table 6 also includes a qualitative assessment of the applicability, the effectiveness, and limitations of the decontamination technologies. Table 6 is divided into three sections. The first section lists

**TABLE 4 Shaw Adherence Study Results**

| Contaminant | Pipe Type | |
|---|---|---|
| | Cement-lined Ductile Iron | Clear PVC |
| Arsenic | Strongly adheres | Adheres |
| Mercury | Very strongly adheres | Adheres |
| Bacillus subtilis | Strongly adheres | Strongly adheres |
| Diesel, No. 2 | Strongly adheres | Adheres |
| Chlordane | Strongly adheres | Adheres |

**TABLE 5 Performance of Decontamination Techniques for Various Target Contaminants from EPA/Shaw Pilot-Scale Decontamination Study**

| Contaminants | Decontamination Method | Qualitative Performance Rating[a] |
|---|---|---|
| | Water flushing | Average |
| | Low pH | Average |
| | Phosphate buffer | Poor |
| Arsenic | Acidified potassium permanganate | Good |
| | NW-310/NW-400 | Good |
| | Floran Biogrowth Remover/Catalyst | Good |
| | Floran Top Ultra / Catalyst | Average |
| | Water flushing | Average |
| | Low pH | Average |
| Mercury | Acidified potassium permanganate | Excellent |
| *Bacillus subtilis* | Water flushing | Poor |
| | Shock chlorination | Average |
| Diesel fuel, No. 2 | Water flushing | Average |
| | | Good |
| | Surfonic TDA-6 | Excellent |
| | | Good |
| Chlordane | Surfonic TDA-6 | Excellent |
| | | Excellent |

[a]The qualitative performance ratings are defined in terms of percent/log removal are as follows:

| For chemical contaminants | | For microbiological contaminants |
|---|---|---|
| <20% | Poor | <1 log removal* Poor |
| 20–50% | Average | 1–2 log removal Average |
| 50–80% | Good | 2–3 log removal Good |
| <80% | Excellent | <3 log removal Excellent |

$$^{*}\text{Log removal} = \text{Log}\left[\frac{\text{count of microbes adhered on coupon before decontamination}}{\text{count of microbes remained on coupon after decontamination}}\right]$$

**TABLE 6 Decontamination Technologies Applicable to Contamination of Municipal Water Systems**

| Decontamination Technology | Applicability | Effectiveness | Limitations |
|---|---|---|---|
| | | **Water Treatment System/Equipment Decontamination Technologies** | |
| Grit/Shot Blasting (also dry ice blasting and other potential blast media) [7–9] | Applicable to all contaminants in tanks, very large diameter piping, and accessible equipment | Removes scale and controllable quantities of base material. Therefore, very effective at removing contaminants | Generally a manual access. Some remote systems can be applied. Blast media must be removed as the contaminants will be contained in the media |
| High pressure spray [7] | Applicable to all contaminants in tanks, very large diameter piping and accessible equipment | Depending on the pressures used, some as high as 20,000 psi, scale can be removed very effectively. Lower pressure sprays may not remove tightly adhered scale | Generally requires manual access. Some remote systems can be applied. Safety considerations must be addressed |
| Chemical treatment [10] | Applicable to all contaminants in tanks, piping, pumps and accessible equipment. Chemicals are selected to address particular contaminants and materials of construction. | Aggressive chemical systems can be very effective in removing scale and some base metal. Foams may be used to apply chemicals to improve effectiveness | Aggressive chemical systems must be carefully monitored to avoid equipment damage. Captured treatment chemicals may require management as hazardous waste. Chemicals must be effectively neutralized prior to reuse of the equipment; only ingestion-safe chemicals may be used. Safe handling of the chemicals must be addressed |
| | | **Distribution System Decontamination Technologies** | |
| Flushing/unidirectional flushing/back flushing [11] | Applicable to microbial, organic and inorganic contamination. Current method of choice by utilities to deal with water distribution system contamination | Flushing can remove loose sediments deposited in the pipe and scouring some biofilm from the surface | Typically not effective in pipes larger than 12 in. in diameter. Limited effectiveness in microbial contamination due to biofilm attachment. Large volumes of flushings must be treated |

(*continued overleaf*)

**TABLE 6** (*Continued*)

| Decontamination Technology | Applicability | Effectiveness | Limitations |
|---|---|---|---|
| Air scouring [11] | Applicable to microbial, organic and inorganic contamination. Current method of choice by utilities for water distribution system contamination | Air scouring can remove sediments in the pipe, soft scales, biofilm, and other adhered materials. Very effective for sediment removal. Fairly effective in removal of biofilm | Typically not effective in pipes larger than 12 in. in diameter. Flushings must be treated |
| Pigging/swabbing [11] | Applicable to microbial, organic, and inorganic contamination. Current method of choice by utilities to deal with water distribution system contamination | Effective at removing sediments, biofilm, and friable scales in larger pipe diameters | More effective in larger pipes. Can be used in smaller 4–6 in. diameter pipes by introducing and recovery through fire hydrants. Flushings must be treated |
| Chlorination/shock chlorination [11] | Applicable to microbial contamination. Chlorination is the most frequently used form of halogen disinfection for drinking water in the United States. Chlorine can be applied for the deactivation of most microorganisms and it is relatively cheap | Chlorination is effective for removal of *Escherichia coli*, spores, and other bacteria from water. The effectiveness depends on the proper dose and contact time of the disinfection agent. Chlorination is not very effective for crypto and Giardia removal<br>Chlorination can remove part of bacteria from pipe surfaces, but the effectiveness is not as promising as that for water. High CT value is required for removal of bacteria from pipe surfaces and tuberculated pipes | Formation of disinfection by-products (DBP); odor and taste [12] |

| | | | |
|---|---|---|---|
| Chloramination [11] | Applicable to microbial contamination. Chloramines are the second most commonly used final disinfectant in drinking water treatment next to free chlorine. Chloramines are applied more and more often in the United States as an alternative for chlorine during secondary disinfection of drinking water | Chloramines are effective for the deactivation of bacteria, spores, and other microorganisms; however, the reaction mechanism is slower than chlorine. Monochloramine is the most effective disinfectant. Little to no trihalo methanes (THM) and other DBPs are formed during chloramine disinfection. Chloramines remain actively within the plumbing much longer, because it takes long for chloramines to be broken down | Less reactive than chlorine<br>The efficacy of chloramine disinfection is pH dependent and increases with decreasing pH values |
| Chlorine dioxide [13] | Applicable to microbial contamination. Chlorine dioxide has been used for years in potable water disinfection (United States since 1944) | Chlorine dioxide is superior to chlorine in the destruction of spores, bacteria, viruses, and other pathogen organisms on an equal residual base (even Cryptosporidium and Giardia), at lower concentrations. The required contact time for $ClO_2$ is lower. It destroys THM precursors, and little to no THM and other DBPs are formed during chlorine dioxide disinfection. Relatively stable and in less likely to react with oxidant demand substances than free chlorine. Chlorine dioxide removes biofilm from water systems and prevents it from forming when dosed at a continuous low level. Chlorination, on the other hand, has been proved to have little effect on biofilms | Disadvantage is the presence of chlorite and chlorate resulting from chlorine dioxide treatment. Chlorine dioxide exists as an undissociated gas dissolved in water in the pH range from 6 to 9. The disinfection efficiency increases within this range with increasing pH. It is more vulnerable to volatilization than free chlorine or monochloramine |

(*continued overleaf*)

**TABLE 6** (*Continued*)

| Decontamination Technology | Applicability | Effectiveness | Limitations |
|---|---|---|---|
| Ozonation [13] | Applicable to microbial contamination. Ozone is widely used for drinking water treatment, because of its excellent disinfection and oxidation qualities. Ozone has been used for disinfection of drinking water in the municipal water industry in Europe for over 100 y | Ozone is a more effective disinfectant than chlorine, chloramines, and even chlorine dioxide. No DBP formation. Ozone, unlike chlorine products, can deactivate resistant microorganisms such Cryptosporidium and Giardia. Ozone is relatively unaffected by pH within the range normally encountered in water treatment. | Ozone results in the formation of biodegradable organic matter. Ozone rapidly decomposes in water; its life span in aqueous solutions is very short (less than one hour). Therefore ozone is less suitable for residual disinfection, but can be used in short distribution systems. |
| UV disinfection [13] | Applicable to microbial contamination. It is one of alternative methods to conventional chlorine disinfection | UV can deactivate resistant microorganisms such as Crypto and Giardia. It can be combined with ozonation to improve the disinfection effectiveness | UV cannot provide residual disinfection. This technology has been deployed in groundwater treatment, but would have to be adapted to large volumes of drinking water |
| Surfactant treatment | Applicable to organic and inorganic contamination. Currently, it's not a common practice used by water utilities in the United States. | Surfactants are effective in removal of organics and inorganics from pipe surfaces. The removal efficiency depends on the types of contaminants and surfactants used. Pilot-scale tests indicate that some commercial products are effective in removal of highly adsorptive organic contaminants, such as diesel fuel and chlordane from various pipe surfaces | After removing target contaminants from distribution systems, the cleaning agents (i.e. surfactants) must be flushed from the distribution systems |

| | | | |
|---|---|---|---|
| Hydrochloric acid and other strong acids (low pH flushing) [11] | Applicable to inorganic contaminants. Although readily applied, the danger to decontamination workers and inadvertent contact by users make it undesirable in anything by restricted areas of the distribution system | Effective in removing scale and deposits following flushing | Does not remove all deposits. Flushings must be captured and treated. Requires neutralization after treatment. Distribution system damage can result from residual acids |
| Phosphoric acid (low pH flushing) [11] | Applicable to inorganic contaminants. Sequesters some inorganics. Easily applied in the distribution system | Somewhat effective to very effective, depending on the contaminant and the distribution system materials. The phosphate radical may be particularly effective for some contaminants | As a weak acid, it would require long-term exposure to dissolve scale. The acceptability of food-grade phosphoric acid will require approval in the distribution system |
| Acetic acid (low pH flushing) | Applicable to inorganic contaminants. Sequesters some inorganics. Easily applied in the distribution system | Somewhat effective to very effective, depending on the contaminant and the distribution system materials. The acetate radical may be particularly effective for some contaminants | As a weak acid, it would require long-term exposure to dissolve scale. The acceptability of food-grade acetic acid will require approval in the distribution system |
| Citric acid/Na Citrate (low pH flushing) | Applicable to organic contaminants. Easily applied in the distribution system | Somewhat effective to very effective, depending on the contaminant and the distribution system materials. The citrate radical may be particularly effective in removing some contaminants | As a weak acid, it would require long-term exposure to dissolve scale |
| Acidified potassium permanganate [14] | Applicable to inorganic and some biological contaminants. This is a low pH flush supplemented with permanganate, which oxidizes the inorganics into a soluble form | Some effectiveness as a disinfectant. Effective in dissolution of some metals (iron and manganese) | Brown precipitate must be removed |
| NaEDTA and other chemical sequesterants [14] | Applicable to inorganic contaminants. Sequesterants selected to address contaminants | Selectively effective for contaminants targeted | Questionable acceptability in public water systems due to toxicity |
| Relining [15] | Applicable for all contaminants as a last resort. Applicability is limited by the age, materials, and configuration of the system | Highly effective if applicable | Slow to implement and generally limited to simple configurations |

(*continued overleaf*)

**TABLE 6** (*Continued*)

| Decontamination Technology | Applicability | Effectiveness | Limitations |
|---|---|---|---|
| System replacement | Applicable for all contaminants as a last resort. Very expensive, but for some highly toxic contaminants, may be applicable | Totally effective | Very slow to implement, particularly if large areas of the distribution system are involved |
| **Water Treatment Technologies (Addressing Cleanup of Water Flushings)** | | | |
| Precipitation/coagulation /filtration [13] | Applicable to microbial, organic, and inorganic contaminants. Precipitation, coagulation, and filtration are common steps of water treatment process used in water treatment plants in the United States | Filtration process is effective in removing some microorganisms, but the removal efficiency depends on the operation of the process<br><br>Crypto causes larger problems than Giardia, because of the size. Crypto is 4–5 μm in size, which makes it difficult to remove by conventional filtration [6]. Giardia is 8–14 $\mu$m in size, which makes it easier to remove by conventional filtration than crypto [30]. Effectiveness of direction filtration ranges from 90 to 99% for virus removal, and from 10–99.99% for Giardia removal. The most effective direct filtration configurations for Giardia removal muse include coagulation | Direct filtration is only applicable for systems with high quality and seasonally consistent influent supplies. The removal efficiency depends on the filtration operation. Temperature is another factor that affects the removal |

| | | | |
|---|---|---|---|
| | | | Although coagulation reduces the concentrations of DBP precursors from organic contamination, coagulation shifts the distribution of the DBPs formed by chlorination toward the more brominated species |
| | | Coagulation/filtration can remove some of organics including pesticides, herbicides, and insecticides, volatile organic carbons (VOCs), DBP precursors, and other organics | |
| | | | For inorganic contaminants, the effectiveness is limited by solubility of precipitated species |
| | | Coagulation/filtration (assisted by pH adjustment) can remove many inorganic contaminants | |
| Sand filtration [13] | Applicable to microbial contamination. Low cost, simple operation, and reliable water filtration process. | Sand filtration effectively removes microorganisms, including *Giardia lamblia* that cannot be killed by traditional chlorination. Able to achieve greater than 99.9% Giardia removal | Not suitable for water with high turbidity. Extensive land is required. Filters in cold climates freeze, which reduce cleaning efficiency during cold weather |
| Cartridge filtration [13] | Applicable to microbial contamination. Emerging technology suitable for removing microbes and turbidity in small systems | *Cartridge filtration is effective for removal of some microorganisms* | Cartridge filtration systems require raw water with low turbidity. Polypropylene cartridges become fouled relatively quickly and must be replaced with new units. Although these filter systems are operationally simple, they are not automated and can require relatively large operating budgets |

(*continued overleaf*)

**TABLE 6** (*Continued*)

| Decontamination Technology | Applicability | Effectiveness | Limitations |
|---|---|---|---|
| Adsorption/ion exchange [13, 16] | Applicable to organic and inorganic contaminant removal. Activated carbon treatment is one of the common practices of water treatment in the United States | Activated carbon is an effective process for removing organics including pesticides, herbicides, insecticides, volatile organic carbons (VOCs), DBPs precursors, and other organics | Organics that are poorly adsorbed by activated carbon include: alcohols; low molecular weight ketones, acids, and aldehydes sugars and starches; very high molecular weight or colloidal organics; and low molecular weight aliphatics. Activated carbon is not effective in removing vinyl chloride from water. Bacterial growth on the carbon is another potential problem. Excessive bacterial growth may cause clogging and higher bacterial counts in the treated water |
| | | For inorganic contaminants ion-specific adsorbents can be utilized | Ion exchange can be a polishing step in removing low concentration residuals from treated water |
| Evaporation/ distillation | Typically a polishing step following primary treatment | Highly effective | Energy intensive and requires specialized equipment |
| Membrane filtration [13] | Applicable to organic and inorganic contaminants. Membrane filtration can be an attractive option for small systems because of its small size and automated operation. Membrane processes are increasingly employed for removal of bacteria and other microorganisms, particulate material, and natural organic material, which can impart color, taste, and odor to water | Membrane technologies are effective processes for removing pesticides, herbicides, insecticides, VOCs, DBP precursors, and other organics | Requires specialized equipment and pretreatment to avoid fouling of the membranes. Potentially a large "rejects" stream to be managed with a secondary treatment technology |

| | | | |
|---|---|---|---|
| | | Residual concentrations are a function of membrane effectiveness and quantity of "rejects" (concentrated waste) stream | |
| Oxidation technologies [13] | Applicable to organic and microbial contamination. Advanced oxidation processes have limited applications in the area of drinking water | Advanced oxidation processes can remove both organic and oxidizable inorganic components. The processes can completely oxidize organic materials to carbon dioxide and water. | Advanced oxidation processes often have higher capital and operating costs compared with biological treatment. This method requires the addition of chemicals, such as ozone, hydrogen peroxide, hypochlorite, permanganate, etc. |
| Air stripping [13] | Applicable to high volatility organics contaminants | Effective in removing volatile organics including volatile pesticides and fuels | Low volatility organics such as polychlorinated biphenyls (PCB) are not separated. Stripping columns can be fouled by organism growth |

technologies that can be applied to contaminated large equipment, representing equipment that can be manually entered and physically treated. Tanks and large distribution system piping are some examples. The second section of Table 6 tabulates technologies applicable to the distribution system piping. There are some physical decontamination options such as pigging, but most of the distribution system options are chemical in nature. Note that the applicability of these technologies is constrained by the materials of construction of the distribution system, its age, and complexity. A previously mentioned decontamination issue mentioned previously is scaling and biofilm in the distribution system. Adherence of contaminants on the distribution system may at first minimize the impact of a contamination event by removing the contaminant from the water stream, but will make ultimate cleanup very difficult due to slow leaching (desorption) of adhering species. The last section of Table 6 includes technologies applicable to *ex situ* treatment of the contaminated water flushings. These flushings could result from a straightforward system flush, or they could contain materials scraped outby pigging, or residual chemicals from the chemical treatment. In a large-scale contamination event, capture and storage of these flushings could be difficult.

## 3.2 Technology Descriptions

***3.2.1 Decontamination Methods Appropriate for Tanks and Equipment with Access.*** Decontamination for tanks and equipment accessible to personnel with tools pose an addressable decontamination challenge. Structures can be cleaned by conventional cleaning techniques as listed below and then rinsed before being returned to service:

- *Grit/shot blasting.* Grit/shot blasting uses sand or metal shot propelled against a contaminated surface using compressed air. It is a common industrial process with inexpensive equipment readily available. It is effective in the decontamination of all surfaces [7–9]. Variations of grit/shot blasting include dry ice blasting and soft media (abrasive impregnated sponge) blasting.
- *High pressure spray.* Ultra-high-pressure wash uses a pressure booster to produce a very high pressure stream of water capable of cutting through hard materials [7]. It is used in the nuclear decontamination industry to spall a layer of concrete and is capable of removing corrosion products.
- *Chemical cleaning.* Some decontamination surfactants were cited in the ongoing research discussions. Chemical decontamination methods used by the nuclear industry use very aggressive chemicals that can remove radionuclides tightly bonded to contaminated surfaces [7, 10]. Foam can be used to increase chemical contact time with the contaminated surface.

***3.2.2 Decontamination Methods Appropriate for Distribution System.*** Pipe cleaning systems of municipal water system are capable of decontamination of some agents and in some configurations. The decontamination system must be able to address contamination in sediment, biofilm, friable scale, and hard scale.

- *Flushing/unidirectional flushing.* Conventional flushing is widely used in water systems to respond to water quality issues. It involves simply opening one or more

fire hydrants and allowing water to flow until sediment or other contaminants are removed [11]. Unidirectional flushing is an improvement on conventional flushing in that valves are closed and hydrants opened in a systematic fashion that maximizes water velocities.

- *Air scouring.* Air scouring is currently deployed and uses pulses of water and air to clean pipelines [11]. It may be combined with decontamination agents to enhance decontamination. Alternatively, it may reduce contact time of the decontamination agent and limit effectiveness.
- *Pigging/swabbing.* Pigging is also a currently used technology where water pressure is used to push a swab or polyurethane cylinder, or a bullet-shaped or dumb bell-shaped pig through the line [11]. Pigging removes layers of sediments, biofilm, soft scale and hard scale. Abrasive pigging uses a pig with abrasive materials such as Velcro, carbide straps, plastic brushes, or wire brushes embedded in the shell of the pig to more aggressively remove harder scales.
- *Chemical decontamination.* Chemical decontamination removes contaminants from the pipe wall, sediment, biofilm, friable scale, and hard scale by dissolution or desorption. Numerous chemical decontaminants are identified in Table 6. The decontamination agent is injected into an isolated part of the system and recycled through that portion until the objectives are reached. The decontamination is typically followed by neutralization agents and flushing of the system to remove last traces. Common chemical decontamination agents include oxidizers for organics (i.e. hypochlorite, acidified potassium permanganate), strong acids, weak acids, sequestering agents, and surfactants. Commercial cleaning agents are available and frequently include combination of chemical agents [14].
- *Pipeline relining options.* Cleaning or upgrading distribution system piping has been described as *Trenchless Technology* [15]. Trenchless technologies include relining by spray-on concrete linings and insertion of linings. Although this is not a "decontamination" process per se, it is listed here as an option for consideration. This option may be particularly interesting in the case of low levels of nuclear contamination or as a final assurance that contaminant desorption is precluded in the system.

***3.2.3 Decontamination Methods (Treatment Methods) Appropriate for Contaminated Water (Flushings).*** Although it is expected that a portion of the contaminant residual will remain adsorbed or adhered to the distribution system piping and equipment, contaminated water remains a problem to address. In addition, contamination removed from the system through decontamination processes needs to be isolated and treated prior to discharge. There are several water treatment technologies as shown below that could be employed post event to remove contaminants from the flushed water or decontamination flushings.

- *Chlorination/chloramination.* Chlorine gas or hypochlorites are added to water as a gas or liquid [17]. They are strong oxidizers and destroy bacteria and other organisms. Chloramination supplements the chlorine additive with ammonia and extends the stability of the active chlorine oxidizer.

- *Precipitation/coagulation/filtration.* Water treatment facilities commonly use combinations of precipitation, coagulation, and filtration for water purification. Contaminant-specific chemicals chosen to precipitate (floc) the contaminant allow for contaminant removal as settled solids or in a filter. The clarified liquid is commonly filtered in sand filters or mechanical systems to remove residual solids.
- *Adsorption/ion exchange.* Adsorbents are materials whose makeup and internal pore surfaces physically trap or bond with the contaminants. Ion exchange media (water softeners) are a common application of adsorbents. Typical adsorbent materials include granular activated carbon (GAC), zeolite, bentonite clay, activated alumina, silica gel, porous polymer, and ferric media. Zeolite media have been proved to be highly selective scavengers for metal cations. GAC is primarily used for removal of organic substances [18].
- *Evaporation/distillation.* Contaminants are separated from water by vaporization and subsequent condensation of the purified water. Solids and nonvolatiles are left behind and concentrated, separating the solid contaminants from the water vapor. The capital and operating costs to construct an evaporation system is significant.
- *Membrane processes.* Membrane processes apply pressure on one side of a semipermeable membrane that forces a separation of the solute from the solvent. The membrane rejects ions on the basis of their size and charge. Variations of membrane processes "reject" smaller and smaller contaminants. The ranking of these processes from coarsest to finest separation is microfiltration, nanofiltration, ultrafiltration, and reverse osmosis (RO). RO is the tightest possible membrane process in liquid–liquid separation. Essentially, all dissolved and suspended solids are rejected. RO systems can be configured in "cascades" or series systems that minimize reject volumes or raise permeate quality, or both [18].
- *Oxidation technologies.* Oxidation technologies destroy organic contaminants by attacking carbonaceous compounds (chemical or pathogens) and converting them to simple oxidation products. Typical oxidation technologies employ hydrogen peroxide or ozone, sometimes supplemented by ultraviolet (UV) light.
- *Air stripping.* Air stripping separates volatile organics from water by vaporizing the organic in air that is bubbled through the water or via contact in countercurrent stripping columns.

## 4 HOW TO SELECT A DECONTAMINATION/TREATMENT TECHNOLOGY

The issues to be addressed by the decontamination technology were introduced in a prior subsection. The decontamination approach must be selected from a number of technology options, each with their own applicability and effectiveness. The EPA's water system toolbox outlines the steps involved in technology selection and implementation [13]. The steps are as follows:

1. *Determine the cleanup goal.* The cleanup goal must be established to complete engineering of the decontamination and treatment system.
2. *Select evaluation criteria; effectiveness, implementability, and cost.* EPA recommends that the selection criteria follow the same general approach as those used

in selecting cleanup methods for environmental remediation. Effectiveness is a measure of the technology's ability to meet the cleanup/treatment goals including short-term and long-term protection of the public health and environment, compliance with regulations, and residual generation. Implementability includes the requirements of safety of the involved workers as well as cleanup schedule issues. Lastly, cost is included as a criterion in addition to the other criteria.

3. *Do treatability testing, if required.* Treatability testing involves either bench-scale or pilot-scale confirmation that the selected decontamination technology meets cleanup criteria. Even more importantly, secondary waste treatment/disposal approaches should be evaluated to ensure that the decontamination is not impeded by secondary issues.
4. *Cost the cleanup.* Having selected the decontamination approach, the complete decontamination and recovery to normal operation can be estimated with some accuracy for either the selected approach, or multiple approaches, as required.
5. *Downselect.* Completion of the testing procedures and costing efforts will facilitate a final selection of the decontamination approach. It is also noted that abbreviation of this ordered recovery procedure may well be considered in a significant event. However, recognition of these steps is warranted.

## 5 RESEARCH DIRECTIONS

The EPA's Water Security and Research Action Plan identified the needed research in 2004 [19]. Recovery from any contamination event, intentional or unintentional, requires knowledge of the contaminated system and the specific contaminant, but identification of the fate and transport potential of the contaminant in the system is a significant need. Three general research needs can be as listed below:

- Methods to quickly identify a contamination event and the extent of contamination.
- Determination of the fate and transport of contaminants in the distribution system. This modeling must include the effects of adsorption/desorption characteristics of organic chemicals, inorganic chemicals, and microbes on various materials and biofilm in the contaminated system.
- Continued evaluation of existing and emerging decontamination agents for their effectiveness and ability to reach the "cleanup" goal.

## 1 CONTAMINATION AND DECONTAMINATION OVERVIEW

This article focuses on the decontamination of the internal workings (e.g. pipes, pumps, and tanks) of wastewater and stormwater systems contaminated as a result of a terrorist event involving chemical, biological, or radioactive agents. The decontamination of the external aspects of these systems (e.g. the interior walls and floors of a wastewater treatment plant that may be contaminated from open tanks or ponds) would be similar to that conducted for industrial operations.

### 1.1 System Contamination

Stormwater systems can be contaminated during precipitation events following a chemical, biological, or radioactive release or if contaminated runoff from decontamination activities is not collected. Contaminants can attach to the internal pipe walls of a stormwater system as well as follow any stormwater through leaks into the surrounding soil. If the stormwater system is not part of a combined sewer system, in which stormwater and sanitary wastes are collected and conveyed in the same pipe to a wastewater treatment plant, the contamination would be discharged directly into the environment, such as into streams, unlined detention/retention ponds, or other open waters.

The distribution of contamination is affected by the condition of a water pipeline system prior to an event. Pipe roughness, corrosion, sediment, and biofilms in a pipeline

*John MacKinney currently works for the US Department of Homeland Security

system serve to chemically and/or physically trap material. Similar traps also exist in drinking water systems. Even pipes that are not corroded and have no sediment or biofilm buildup can become contaminated, depending on the chemical and physical nature of the contaminant and the pipe itself. Solid waste and debris also serve as "sinks" (reservoirs) for any contaminant material in a combined sewer or a separate sewer system. In the latter case, infiltration into the system through pipe leaks could lead to contamination in the system. Restoration of such pipelines might require only routine cleaning (with the methods discussed in the following section), with any fixed contamination allowed to remain unless residual concentrations in the water were above acceptable levels.

Depending on the nature of the contaminant, it could become isolated, removed, or attached to the internal walls of a wastewater treatment plant (within piping, pumps, tanks, and equipment) as it moves through the treatment train. The contamination could also become isolated in sediments (sludges) collected in the primary settling tanks and generated during secondary treatment or adsorbed to dirt or biofilm on internal system walls. Advanced (tertiary) treatment methods, if used, might lead to precipitation of dissolved agents (within the sludge) or filter out agents, depending on the agent and the methods used.

Contamination of external surfaces within a treatment plant could occur from contact with material that has had previous contact with contaminated water and possibly from deposition of nonvolatile aerosolized agents. Aerosolization of contaminants may occur where the water surface in tanks is agitated, possibly during treatment processes such as aeration and skimming operations. Volatile agents, if still present in the water, may be released to the air by these types of operations and pose an immediate hazard in confined areas.

## 1.2 Decontamination

Decontamination is the removal of the potential hazard posed by radioactive, chemical, or biological agents, either through actual removal or rendering such agents inactive. In general, decontamination of an affected stormwater or sewer system consists of first removing any contaminated water, debris, and sludge from the system followed by treatment of residual contamination on the interior surfaces of the system. The greatest challenge in such systems is the delivery of an effective treatment to interior pipe walls deep within the system, especially where access is limited. This article focuses on removal of contamination from the system and treatment of residual contamination within the system itself.

For all threats (radioactive, chemical, and biological), physical removal of the hazardous material or agent ensures a reduction in the hazard. Unlike radioactive material, chemical and biological agents can be rendered harmless to humans (neutralized) through chemical and/or physical means. Thus, the discussion of decontamination options is presented separately for radioactive material and chemical and biological agents. Figure 1 presents a decision tree with decontamination options that may be used for cleanup of contaminated systems.

## 1.3 Radioactive Decontamination

Because radioactivity is an inherent property of radioactive isotopes, such contamination cannot be neutralized; decontamination of affected systems requires removal of the radioactive material. For pipelines, standard cleaning technologies can be used to

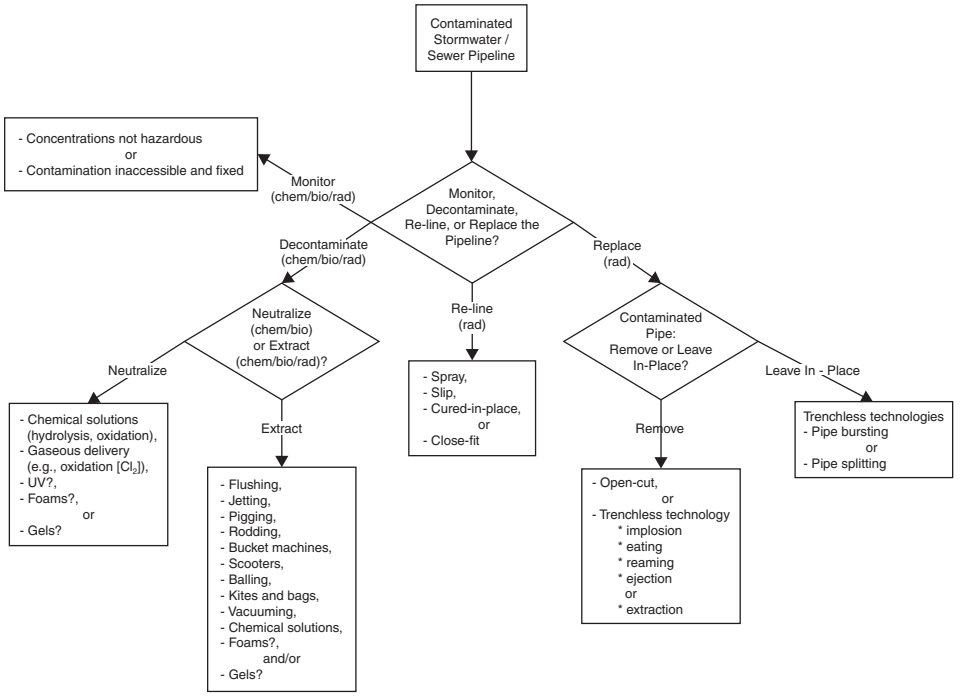

**FIGURE 1** Cleanup technology options for contaminated pipelines.

remove the contamination along with the detritus and debris normally found in sewer and stormwater systems. Such technologies are mostly physical removal processes. Because these technologies were not designed for radioactive decontamination, a pipeline that is cleaned in this way may have residual contamination on or within cracks and crevices in the pipe walls. The effectiveness of standard methods at radioactive decontamination will depend on particular site conditions and need to be tested. Care must be taken to properly protect workers and equipment from any removed material. A proper worker health and safety plan and disposition path for this radioactive waste material must also be in place.

Although sewer and stormwater systems are not pressurized (with the exception of force mains) as are drinking water systems, the operations used for cleaning and maintaining stormwater and sewer pipelines are similar in many respects to those used with water distribution systems. Cleaning operations in stormwater and wastewater systems, however, must also address solid wastes, grease, oils, detergents, roots, debris, rodents, and insects, in addition to a larger sediment buildup problem. Thus, mechanical cleaning methods, such as rodding and the use of bucket machines, are used as well as hydraulic methods, such as scooters or balling, kites and bags, flushing, jetting, and pigging methods [1, 2]. However, the use of hydraulic methods for cleaning sewers should be used only where the potential for backup into connected buildings can be averted.

Chemicals are often used to control a variety of problems such as roots, grease, odors, concrete corrosion, rodents, and insects. The generation of hydrogen sulfide by bacteria found in biofilms under anaerobic conditions in sewer systems creates two major problems: odor and the destruction of sewer pipes and other wastewater system components

[3]. While such applications of chemicals are preventative and not intended to remove material from these systems, chemicals can be used to aid removal (as discussed later in the section on potential technologies).

Radioactive contamination that is tightly bound (fixed) to pipe walls through processes such as chemical reaction or diffusion into the wall would not usually pose an immediate threat to human safety or the environment for smaller diameter pipelines because of its isolation within the system. That is, direct human exposure is unlikely because the pipelines are too small for humans to physically access. It is also possible, although usually not desirable, to fix in-place or isolate radioactive contaminants if contaminant removal is particularly difficult. If it is determined that any later release of this contamination would be insignificant (i.e. contaminant concentrations in effluent wastewater or stormwater would be below acceptable levels), cleanup may not be warranted. In such a case, cleanup might not be justified because of disruption (may be collocated with or in close proximity to utilities or under major thoroughfares and buildings), cost (removal, replacement, and disposal), and the risks of human exposure. Finally, it is reasonable, in cases where the half-life is short, to make use of radioactive decay in a decontamination strategy, but this may not be the case in terrorism incidents.

### 1.4 Chemical and Biological Decontamination

Chemical agents are toxic chemical compounds that may be of common industrial origin, or they may be engineered military chemical weapons. Chemical agents can be neutralized (also referred to as *detoxified*) through destruction of the compound through bond-breaking reactions or they may degrade naturally or volatilize. Biological agents are living bacteria and viruses (naturally occurring or engineered military biological weapons) that can be neutralized through processes such as sterilization and disinfection. Sterilization results in the elimination of all living microorganisms and viruses, while disinfection is a less complete elimination of such entities, especially those in the form of spores.

For chemical agents, of particular concern in stormwater and wastewater systems is those agents that are not readily hydrolyzed (subject to bond-breaking reactions with water) to harmless degradation by-products when in contact with water (e.g. hydrogen cyanide) or those that have hazardous degradation products that do not readily hydrolyze (e.g. Agent VX [4]). An excellent review of chemical agent persistence and degradation in the environment is provided in Munro et al. [5]. A number of biological agents that may persist in water include *Bacillus anthracis* (anthrax) and *Cryptosporidium* [6].

Chemical and biological agents can be removed from contaminated systems with standard cleaning technologies as discussed in the previous section for radioactive contamination. However, disposition of residual wastes from standard cleaning technologies would still require neutralization of the agents once removed. The most efficient process overall would be one that neutralizes the agents while they are within a system.

Most agents can be neutralized in alkaline solutions. For example, VX and the G agents can be hydrolyzed by alkaline hypochlorite solutions [7]. Thus, a standard chemical cleaning method using such a solution could theoretically be used to decontaminate a system. Detoxification of VX can also be achieved through acidic oxidation [8].

Oxidation remains one of the most effective methods of both chemical and biological agent neutralization. Chemical oxidation is already used for a variety of purposes throughout water treatment plants. It is often used to control biological growth such

as algae and other microorganisms that can hinder plant operations; remove inorganic and organic compounds; remove color; decrease odors, primarily from certain organic and sulfur compounds; improve coagulation and filtration processes; and disinfect. Many reactions involving oxidation result in precipitates that settle out of solution or can be filtered out [9].

The principal oxidants used in water treatment plants are chlorine ($Cl_2$), chloramines, chlorine dioxide ($ClO_2$), potassium permanganate ($KMnO_4$), and ozone ($O_3$). A final treatment stage in a number of wastewater treatment plants before discharge to the environment is disinfection with an oxidant such as chlorine. Chloramines are weak oxidants. Their primary role in drinking water treatment is for disinfection of water in distribution systems [10, 11].

## 2 POTENTIAL DECONTAMINATION TECHNOLOGIES

Stormwater and wastewater systems must be physically robust to handle the pressures exerted by running water on various scales and pressures. As discussed previously, cleaning methods range from physical, abrasive methods (e.g. scraping) for scale and root problems to chemical methods for odor and biofilm problems. With the exception of the large, open tanks in a wastewater treatment system, the major problem faced in decontamination as well as in cleaning is one of access. Access is required for monitoring, problem assessment, and problem resolution. Some newer emerging technologies combine methods for enhanced cleaning performance. Other industries face similar challenges with pipeline systems; their technical solutions may have potential application to stormwater and wastewater system decontamination (crossover technologies). If contamination cleanup is not feasible, methods to immobilize the contamination, where it is (pipe rehabilitation, e.g. pipe lining or in-place pipe replacement), may be an option.

### 2.1 Emerging Technologies

In culverts, which are used in some stormwater systems, silt often accumulates, providing a sink for contamination. A recent technological development allows for the removal of large amounts of soil and debris without structural damage [12]. The method employs a barrel reamer attachment, a round tool with fins and water jets, which rotates through the pipe, mixing water with dirt and debris. It is capable of cutting through roots and moving large rocks. Push or pull buckets may then be used to remove the debris from the pipe. Rotating wire brush and directional drilling attachments are also available. A controlled environment is maintained for optimum performance and handling of debris, especially if it is contaminated.

Another technology in the development stage uses dual rotating nozzles and variably sized cleaning tools as part of a vacuum unit that is extended into a pipe [12]. Debris is sucked into a holding tank as cleaning progresses.

Systems designed for sewer flushing are under constant development. Different systems that cause a flushing wave to pass through a sewer pipeline have been developed and used in France, Germany, and Switzerland [2].

### 2.2 Crossover Technologies

Chemicals are already used to control a variety of problems in wastewater systems. Expertise in the use of chemical solutions to clean pipe systems in other industries can

be brought to bear on the decontamination of stormwater and wastewater systems. The technology behind chemical cleaning to remove scale buildup in pipelines has been developed over time in a number of areas. Chemical cleaning of boilers and heat exchangers has been used for decades. Pipe cleaning has also evolved based on experience with marine vessels (waste pipelines, evaporators, and other equipment) and fire protection systems (stagnant water breeds biofilm and scale; many elbows, tees, and valves make other processes difficult) [13]. The chemical solution used is custom-tailored to the specific problem on the basis of the chemical nature of the scale and the type of pipe material. The solution is designed to penetrate, disperse, and dissolve the scale, while minimizing damage to the metallic components of a system.

In the closely allied area of drinking water systems, where compatibility with potable water is required, hydrochloric acid is typically used with weaker organic acids to bind dissolved metals. It is used with inhibitors to protect any base metal. The process involves a hydrant-to-hydrant recirculation system based on trailer-mounted equipment [13]. The length of pipe to be cleaned at one time is determined by the pipe's diameter, because the trailer-mounted holding tank must be large enough to contain the requisite volume of cleaning solution. Likewise, in the food industry, processing and delivery systems (e.g. equipment, pipes, tanks, and valves) must be periodically cleaned to eliminate chemical and biological contamination. Depending on the scenario, such methods and techniques may be translated for use in stormwater and wastewater systems.

In the nuclear industry, the use of chemical solvents for radioactive contamination of equipment and facilities is widespread. However, the primary application of these solutions is for metal surfaces. The use of chemical solvents on porous surfaces such as concrete is generally ineffective [14, 15]. Chemical decontamination is often a multistep process that involves either or both dilute and concentrated chemical reagents. Mild reagents are used primarily in an attempt to remove the contaminant material without attacking the base material. Such reagents require longer contact times with the contaminated material, but cause fewer problems with the treatment of secondary waste than do more-concentrated reagents [16].

## 2.3 Pipe Refurbishment or Replacement

Contamination firmly adhered to the inner wall of a pipeline, far removed from human contact, may not pose an immediate human health risk. In the case of biological or chemical agents, rinsing the pipeline with a neutralizing chemical solution may be the most expedient decontamination process. This option is not available for radioactive contamination. However, if effluent contamination levels are low and there is no concern about accumulation of higher concentrations in hot spots easily accessible to humans, no further action may be required.

Where cleaning methods are not effective (e.g. a heavily corroded sewer pipeline), pipe relining or replacement may be necessary if contaminant accumulation has occurred and/or the release of contaminants is likely in the future. Relining will not remove the contamination, but it will isolate the contamination in place between the inner wall of the pipe and the outer side of the new lining. Pipe cleaning and scraping will be necessary in order to reline a pipe, dislodging and removing some of the remaining radioactive material. Different relining methods include spray, slip, cured-in-place, and close-fit [12, 17].

Traditional pipe replacement (open cut [i.e. excavation]) is costly and disruptive to above-ground features and activities. Newer, less costly alternatives have been developed. Trenchless technologies such as pipe implosion, eating, reaming, ejection, and extraction result in pipe removal with concurrent installation of new pipe [18]. In such cases, any contamination could be removed with the old pipe and would have to be handled, treated, and disposed of properly. The most popular form of trenchless pipe replacement is pipe bursting in which the old pipe is fractured and the resulting pipe fragments are pushed outward as the new pipe is pulled in. This method works well with brittle materials such as cast iron, concrete, or clay. A newer method gaining popularity for use with more flexible pipe materials such as steel, ductile iron, and plastic is pipe splitting. In this case, the old pipe is slit with a series of cutting wheels and slightly expanded as the new pipe is pulled through. As a result, the new pipe is encased by the old pipe, providing some additional physical protection [19]. With pipe bursting or splitting, the old pipe is not removed, which means soil and groundwater may be exposed to any contamination. Thus, these methods should be used only if the contamination is expected to remain immobile.

## 3 CRITICAL NEEDS ANALYSIS

Wastewater and stormwater systems provide an infrastructure for carrying water away from most areas within an urban setting. Thus, they provide a readily available avenue for contaminated runoff and water-based decontamination activities. To best leverage this resource, reliable operational procedures (emergency options) and decontamination measures must be available to enable the use of these systems to full advantage.

### 3.1 Emergency Options

The location, nature, timing, and extent of a terrorist attack will determine what emergency response options are possible and reasonable. Depending on the circumstances, one approach could be to quickly contain the contamination in as small an area as possible, with the primary objective of keeping contaminated water out of the stormwater or wastewater systems (e.g. to keep contamination from reaching critical areas near stormwater drains). In this case, capture/management technologies and temporary, local water storage would need to be available to handle runoff from precipitation or decontamination water, if either is likely. The disposition of this contaminated water would require prior planning.

On the other hand, decontamination water may be directed to the stormwater system if contamination of the stormwater system is a minor concern. For example, the objective may be to clear the area of as much contamination as possible in the shortest amount of time to reduce human exposure or to remediate the contaminated area as soon as possible to restore public utilities or for economic reasons. However, once contaminated water is in the system pipeline, another set of options must be considered.

Whether the pipeline system contains stormwater or wastewater, the contaminated water may be allowed to take its regular course, diverted along an alternate path, and/or be sent to a temporary storage area. For stormwater systems, the sensitivity of the

normal outfall locations to the contaminant and the level of contamination must be weighed against potential diversion options, if any. For wastewater systems, it may be possible to remove the contamination in the treatment plant through standard or slightly modified treatment processes with little impact on continued operation, including decontamination of equipment if necessary. If time is needed to modify treatment processes or contamination of the treatment plant is a concern, contaminated water could be diverted to temporary storage, if available, or diverted directly to the environment.

### 3.2 Decontamination Measures

The selected option for handling contaminated water should come from an informed decision based on knowledge of the ramifications of a given choice versus its alternatives. Informed decision making requires that, for each option, an understanding of the contamination pathway, potential impacts, and the ensuing costs (health, environmental, and socioeconomic) be considered.

The widespread presence of stormwater and wastewater systems in urban areas makes them a useful asset in an emergency if low-cost, easily implemented decontamination methods for their remediation are available. Appropriate methods and their efficiencies will depend on the location of the contamination within the system, its adherence or incorporation into debris or pipe material, and its concentrations. Contamination levels in a pipeline and at the final destination of the pipeline will depend on a number of factors, including length of pipe traveled, pipe condition (material composition, extent of corrosion, and debris content), water flow, and contaminant properties (physical and chemical). Successful decontamination depends on the desired residual concentration levels and the effectiveness of the selected decontamination method. Complications that may arise include concentration of the contaminant in hot spots (before and during decontamination efforts) and methods for capture and treatment of the solid and liquid wastes.

Pipelines may be treated on a section-by-section basis while other sections remain operational. However, decontamination of a portion of a wastewater treatment plant, if not conducted properly, may lead to shutdown of the entire treatment system. Thus, work is needed to assess the effects of potential decontamination methods and their applicability to contamination at various locations along the treatment train. For example, if chlorine is used at the pretreatment stage to kill a biological agent or neutralize a chemical agent in the route of the incoming wastewater, it can be carried further along and eventually kill beneficial organisms in the secondary treatment stage.

The ability to successfully decontaminate a wastewater treatment plant also gives emergency planners and managers the option to treat any contaminated water at the plant, halting the spread of further contamination, if a viable water treatment methodology can be implemented.

## 4 RESEARCH DIRECTIONS

For effective decontamination of wastewater and stormwater systems, solutions that are compatible with existing equipment and that can be deployed rapidly and cost effectively

are required. Simple technologies minimize the need for highly specialized training and large capital investments for dedicated equipment with limited or no use beyond their designed purpose. For many agents, some treatment methods are available. However, understanding the complex interactions of terrorist's agents of concern with the urban environment and the real-world efficacy of proposed decontamination technologies is necessary to support decisions and actions involving the various options discussed in the previous section.

Future work is necessary in a number of areas. A potential threat must be understood within the environment in which it could be pursued before an effective countermeasure can be applied. Thus, conceptual system models need to be developed and exercised under a range of attack scenarios to determine the key aspects of contaminant fate and transport as well as potential mitigative measures (a system sensitivity analysis). The agents that pose the greatest threat and where they are likely to be found must be identified. The effectiveness of decontamination or mitigation technologies needs to be known for each type of threat (chemical, biological, or radioactive), crossover technologies should be exploited, and common treatment technologies need to be identified.

### 4.1 System Threat

To properly prepare for system decontamination prior to an unknown terrorist attack, it is necessary to identify which agents pose the greatest threat in wastewater and stormwater systems and where the greatest threat will be. A number of chemical and biological agents are readily hydrolyzed, and thereby neutralized, when they come into contact with water. Thus, carried by water flow, they pose little or no threat as they enter the system (see hhs192). Work is needed to identify those agents that remain a hazard once they are in the system.

Once contaminants are in a system, it is necessary to know where they are likely to distribute themselves so that decontamination efforts will focus on the high-concentration areas and response workers can take the proper precautions against exposure. Transport within the system will depend on the chemical and physical properties of the contaminants. Questions that need to be answered include how water is distributed within the system, how much contamination is expected to be trapped in the pipeline system, and how much is expected to enter wastewater treatment plants or the environment (e.g. retention/detention ponds). Common hot spots may be where debris collects at irregularities in the pipelines, such as catch basins in stormwater systems and manhole locations in wastewater systems. Such hot spots may act as an initial sink for contamination immediately following a release and act as a source as time passes.

Individual systems will need to be independently studied for consideration of system extent (e.g. length of pipe in use, cross-connections, and number and location of collection and discharge points), age (e.g. extent of biofilm, corrosion, and silt buildup), pipe characteristics (material, shape, and diameter), pipe elevations, and typical water flows. Initial work in this area would be served by system flow model development and could involve case studies of representative systems using tracers to help identify hot spots in individual systems from which some generalizations may be made for different contaminant types in wastewater and stormwater systems.

### 4.2 Decontamination Technology Effectiveness

A number of effective methods to clean wastewater and stormwater systems are available. Because contaminants were in a form that allowed them to enter the system as did dirt (particulates), hazardous chemical, biological, and radioactive materials are likely to be removed with standard cleaning methods. However, some fixed contamination may remain. For full-scale testing of traditional wastewater and stormwater system cleaning procedures, tracers or harmless contaminant surrogates could be used to determine if desired decontamination levels can be achieved.

The effectiveness of decontamination technologies will also depend on pipe or tank material (e.g. cast iron, concrete, and plastic). As aging systems are replaced, decontamination research should focus on the materials being used in replacement hardware and new construction. Finally, decontamination technology development must consider the potential for hazardous by-products, treatability of liquid and solid wastes, waste disposal implications, and the time and cost constraints for employing a technology.

### 4.3 Crosswalk between Disciplines and Industries

The neutralization and destruction of biological agents have been extensively studied and used in medical research, the health care industry (e.g. hospitals), and military programs. Likewise, the neutralization and destruction of chemical agents have been extensively studied in military programs [7, 20]. For radioactive contamination, a large amount of information has been generated by the nuclear industry from operations involving routine maintenance and decontamination and decommissioning activities during site cleanup [14, 15, 21]. Information is also available from the oil and gas industry, which contends with naturally occurring radioactive material buildup in pipes. In addition, data on the maintenance and cleaning of other pipeline systems (e.g. boiler and heat exchangers, marine vessels, fire protection, and food processing) can be exploited. This wealth of information can be combined with some traditional wastewater and stormwater cleaning methods to deliver chemical cleaning solutions to contamination within pipelines.

If the pipelines are not completely pressurized (to minimize secondary decontamination waste streams), sufficient solution-pipe contact time may be difficult to achieve. Increased contact times can be enhanced by the use of foams or gels, but delivery systems for interior pipe walls would need to be developed for this application. Spray lining larger-diameter pipes with epoxies or cementitious materials is an established pipeline rehabilitation method [12]. Modification of equipment for the handling of foams or gels may be a reasonable option. Ultraviolet (UV) radiation is a common neutralization technology used for the destruction of chemical and biological agents. Again, this technology may be viable for inside pipelines if a delivery system could be developed, perhaps coupled with remote technologies already used by contractors who specialize in stormwater or wastewater pipeline cleaning and maintenance.

Technologies in development to neutralize chemical and biological agents within a building environment may be applicable to pipelines. The use of gaseous hydrogen peroxide or chlorine dioxide as fumigants has been studied for use in contaminated rooms and ductwork [22]. Gas-phase delivery would enable contact with the entire internal wall of the contaminated pipe.

### 4.4 Common Treatment Technologies

The ideal decontamination technology for wastewater and stormwater systems would handle most potential threats from all three types of contamination—chemical, biological, and radiological. Many current cleaning methods for pipelines hold the promise as universal cleaning technologies because they are designed to physically remove all contamination. Research in this area is important to minimize the infrastructure necessary to support readiness and to respond to combined attacks (e.g. chemical and radiological).

Many oxidation methods have widespread application for a range of chemical and biological agents. Incorporation of these methods into a decontamination technology could leverage existing processes used in the drinking water and wastewater industries, relying on existing institutional knowledge and technology (e.g. the use of chlorine as a disinfectant). For example, hypochlorite solutions (at different strengths) have been recommended for use against both chemical and biological agents in military applications in the field [7, 20].

## 5 GENERAL CONSIDERATIONS AND SUMMARY

Although methods for the decontamination of wastewater and stormwater systems are available, they may not remove or neutralize agents to acceptable levels. Cost and time considerations may also drive better technology development. Table 1 summarizes available and potential technologies. Research is necessary to determine the most expedient methods for different situations and to develop a reliable suite of decontamination technologies ready to deploy in any metropolitan area. New or enhanced decontamination technologies should

- leverage existing methods;
- minimize exposure to response workers;
- minimize impact to the system and the environment; and
- minimize cost.

One way to reduce impacts is to focus on technologies that minimize the amount of secondary contaminated wastes generated. Less secondary waste reduces the amount of subsequent waste treatment and disposal. In two studies of radioactive contamination at sewage treatment plants, proper disposal of contaminated sludge was a significant cost incurred for those sites where cleanup was conducted [23, 24].

Decontamination of wastewater and stormwater systems is complicated by the inaccessibility of interior pipe walls. Flushing operations are simple, but will generate large amounts of secondary waste, especially for larger pipes. Methods such as jetting reduce the amount of water needed, but still require significant amounts of water compared to technologies that use foams or gels. Delivery of UV radiation or gaseous neutralization compounds to chemical or biological contamination is a possibility. Delivery systems for large-diameter pipes should be an important area of research.

**TABLE 1 Summary of Available and Potential Technologies for Pipeline Decontamination**

| Technology | Applicability[a] | | | | Comments |
|---|---|---|---|---|---|
| | Rad | Chem | Bio | Available[b] | |
| Contaminant Removal | | | | | |
| Physical processes | Y | Y | Y | Y | Includes traditional mechanical pipe cleaning methods that are designed for removal of dirt and debris; some residual contamination may be left on interior pipe walls |
| Chemical solutions | Y | Y | Y | Y | Solutions need to be tailored to contaminant and pipe material |
| Foams and gels | Y | Y | Y | N | Technology and delivery systems need improvement |
| Pipe removal | Y | NR | NR | Y | Recommended only for extreme case of radiological contamination |
| Agent Neutralization | | | | | |
| Chemical solutions | N | Y | Y | Y | Solutions need to be tailored to contaminant and pipe material |
| UV radiation | N | Y | Y | N | Development of delivery systems required |
| Chemical gases | N | Y | Y | N | Development of delivery systems required |
| Leave in-Place | | | | | |
| Fix in-place (pipe rehab) | Y | NR | NR | Y | Recommended only for extreme case of radiological contamination |
| Pipe bursting or splitting (pipe replacement) | Y | NR | NR | Y | Recommended only for extreme case of radiological contamination |

Y, yes; N, no; NR, not recommended, other methods are more cost effective.
[a]Applicability indicates a technology's suitability for decontamination of stormwater and wastewater system pipelines (e.g. cost and efficiency).
[b]Indicates if the technology is currently available for use. Further development may be required to reach its full potential as a decontamination technology.

## 1 INTRODUCTION

According to an article in the Engineering News-Record [1]:

> "simple measures that can protect the inhabitants of a building or users of critical infrastructure from chemical and biological attack are becoming routine since the September 11 terrorist attacks and the subsequent anthrax outbreaks. Many building owners and developers are demanding that design criteria for their projects include security master plans. And those in charge of protecting infrastructure are working out protocols to protect water, wastewater, and other systems. These include risk assessments to determine how much security is truly needed."

As quoted in the article [1], Keith Henson, director of security services for Lockwood Greene, Spartanburg, South Carolina reported on "four basic methods of protecting assets: modifying daily routines of building facilities and maintenance personnel; changing the security force; installing physical barriers; and adding electronic surveillance systems. Often, the simplest protection from any threat is distance."

Lessons can be learned from the experience of the US military in protecting buildings. As reported in the Engineering News-Record [1]:

> the US Army Corps of Engineers is charged with protecting the armed forces, including civilian employees, from chemical, biological and nuclear attacks in military buildings. Each military installation is responsible for designing its own buildings. The Corps' Construction and Engineering Research Laboratory in Champaign, Illionois, is developing a software tool to ensure that architects can understand the threats and design buildings to a certain threshold of protection. The Corps expects the software to familiarize designers with various materials as well. Some building materials are almost impossible to clean while others only need to be wiped down. Other high tech materials, such as carpet that can neutralize contaminants,

are under investigation. The laboratory is participating in a program run by the Defense Advanced Research Program Agency to develop buildings that are immune to chemical, biological, and radiological attacks.

City building codes typically require the owner or agent of a dwelling building to supply potable, safe, drinking water to the occupants. In addition, water supply systems need to be designed and installed so as to provide at all times, a supply of water to plumbing fixtures, devices and appurtenances in sufficient volumes and at adequate pressures to enable them to function satisfactorily under normal conditions of use. In addition, building codes typically require all users of a public water system to prevent cross-connections between the potable water piping system and any other piping system within the premises. This means that there must be a procedure or protocol in place at these buildings that is acceptable to a municipality, and that fully describes how these venues plan to manage their building in protecting and securing the drinking water system for the building and all appurtenances associated with the water system. In addition, the facility management must be aware of all employees, maintenance personnel, and contractors that come in contact directly or indirectly with the water system for the buildings under their control or portion therein.

An unscrupulous person using very simple tools or equipment, could compromise the drinking water system for any building or potentially, for a full city block or more. This could potentially result in the illness or death of the occupants of the affected building or area. Appropriate steps must be taken by building management to prevent such potentially problematic actions from occurring.

There must be a reassurance that the occupants of "high profile" buildings, either permanent or temporary, have a protected, safe, and secure drinking water system, and the employees or contractors working within these buildings are screened to reduce the potential to tamper or compromise the buildings' water supply system, or other critical mechanical systems (heating, ventilating, and air conditioning [HVAC], sprinklers) in these buildings. Also, that the drinking water in adjacent buildings is not affected by any terrorist act. There is a general attitude in the water industry that dilution keeps chemical contamination from being much of a threat to water systems; however, according to Ed Wetzel (Montgomery Watson Harza), as quoted in the Engineering News-Record [1] "there is no way to guarantee that a water system is 100% safe. As with buildings, the beginning point for protection is assessing the vulnerability of the system."

## 2 BUILDING AND PLUMBING ASSESSMENT

This assessment identified equipment and components of typical domestic water distribution systems in large buildings and venues such as in low rise and in high rise, commercial and residential buildings. Components of these systems include typical water service connections, associated piping, valves, tanks, pumps, water flow, and pressure characteristics. This information is essential in analyzing the vulnerability of such domestic water distribution systems to possible injection of contaminants.

### 2.1 Typical High Rise Configuration

Although exact configurations and designs of internal plumbing systems may vary from building to building, the potable water systems in high rise buildings are typically divided

into vertical zones. The zones are designed so that they can be served by a gravity or booster pump system while ensuring adequate (but not too high) pressure throughout the zone. Building codes vary from city to city; however, each zone typically encompasses about 25 floors but may not exceed 370 ft. For buildings larger than 370 ft, additional zones must be constructed. Furthermore, zones supplied by pumps may not exceed 300 ft.

Figure 1 shows an example of a schematic diagram of a domestic water distribution scheme in a 43-story high rise building, using a gravity tank supplying the upper zone of the building and a pump system supplying the lower zone of the building. This scheme is used when space for an intermediate gravity house tank is not available. Frequently, a tank is located above the bottom zone and water is pumped to that tank and then fed by gravity to the bottom zone.

### 2.2 Typical Low Rise Configuration

Similar to high rise buildings, the domestic water distribution system in a low rise may vary slightly in design from building to building, but they are typically one-zone systems supplied directly from the street main or via a booster pump system. A booster pump system normally supplies the higher portion of the building to achieve the minimum pressure required to operate a plumbing fixture or equipment. The lower portion of the building, like the ground and sublevels, are normally fed using the available street pressure. A suction tank may be required in a booster pump system.

Figure 2 shows an example of a schematic diagram of a low rise domestic water distribution system represented by a 10-story low rise building. In this example, a booster pump system combined with two large hydropneumatic tanks is being utilized. The hydropneumatic tanks primarily provide a constant boosted pressure in the distribution system and secondarily serve as storage.

Generic computer models of the water supply systems of a two-zone high rise and a low rise building have been constructed based on the general diagrams shown in Figures 1 and 2 respectively and on information gained from site visits to various buildings. These models were used to study, assess, and visualize various contamination scenarios. These modeling results are discussed further on in this article.

## 3 WATER SYSTEM COMPONENTS ASSOCIATED WITH LARGE VENUES

Water systems in large venue buildings typically include the following types of components: piping, pumps, storage tanks, backflow prevention devices and valves. Each of these components can serve a role in the potential introduction of a contaminant into the water system. In the following sections, a range of each type of component is described.

### 3.1 Piping Systems

Internal piping within commercial buildings generally range from 6-in. diameter for transmission pipes serving zones, down to 3/4-in. diameter or less for pipes serving individual fixtures. Typical pipe materials for service connections and domestic water distribution systems are cement-lined ductile iron for piping 4 in. and larger, and copper or red brass for piping smaller then 4 in. Pressure in pipes can range from around 28 psi at fixtures to 200 psi in some transmission piping within a building.

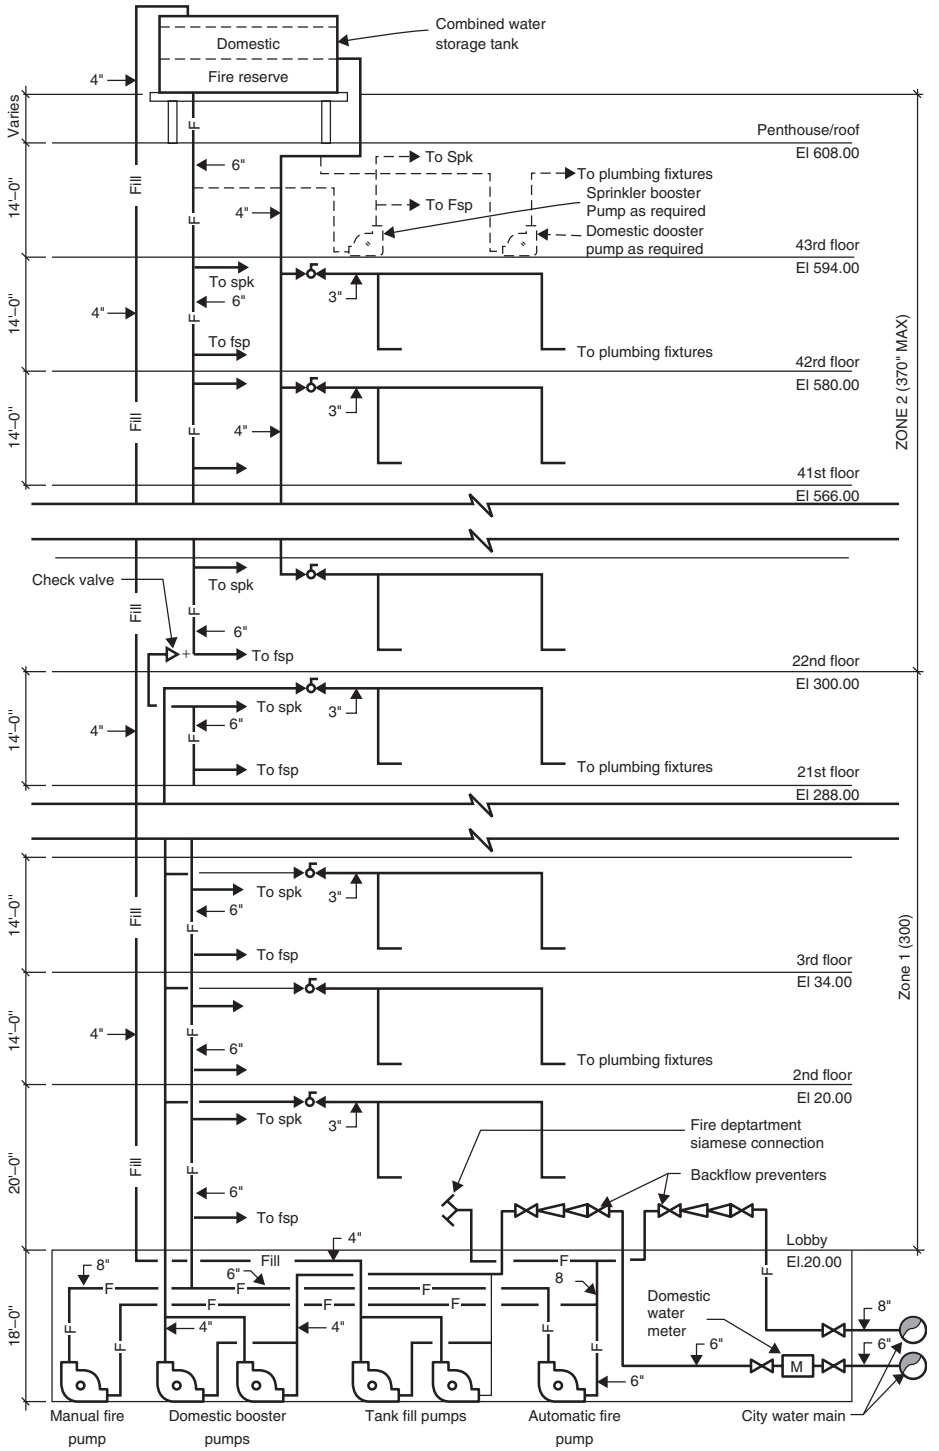

**FIGURE 1** Typical high rise building with gravity tank and pump zones.

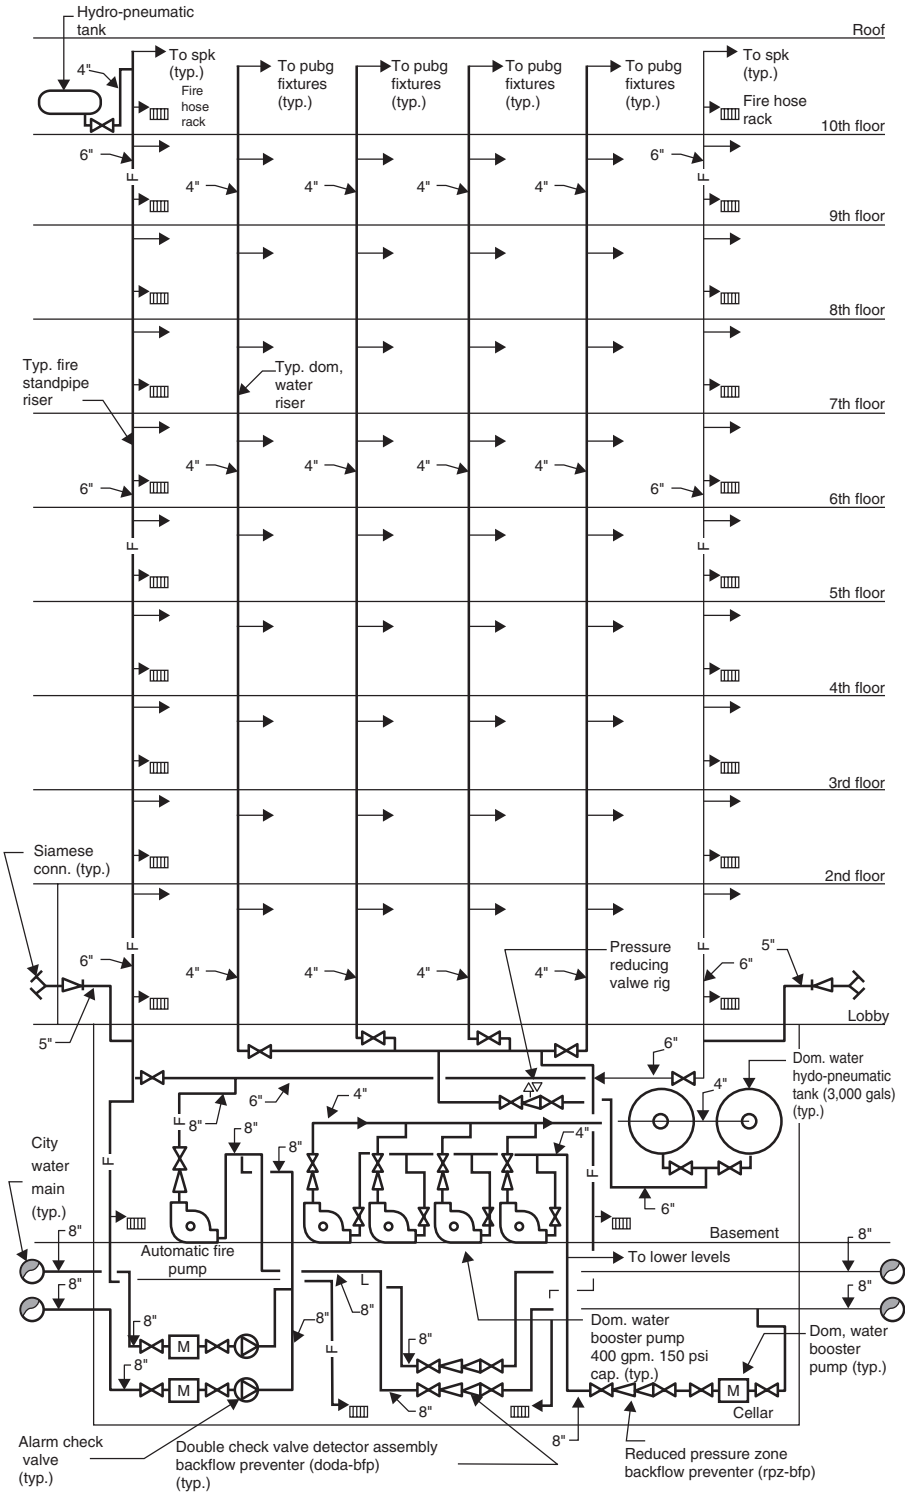

**FIGURE 2** Typical low rise building with a booster pump system.

### 3.2 Pumps

In most buildings, large, electrically driven, positive displacement pumps located in the basement are used to pump water to elevated tanks and/or to directly pump water for use throughout the building. A contaminant injected on the suction side of such pumps would be spread throughout the zone or area served by the pump. Additionally, there are numerous types of temporary pumps that are widely used in buildings for pressure testing of sprinkler and plumbing piping systems.

### 3.3 Storage Tanks

There are several water storage tank designs associated with a typical domestic water distribution system in large venue buildings. All are potentially quite susceptible to injection of contamination. Hot-water storage tanks and thermal expansion tanks are normally sealed and provided with backflow prevention devices at the water connection to protect the domestic water system from potential contamination. Therefore they are considered low risk for such contamination. The various types of storage tanks are described below.

Gravity house tanks serve as the main water supply of typical high-rise buildings. Due to excessive heights of high rise buildings, it became a disadvantage to use a pump to supply and maintain the pressure and flow required for domestic water distribution. This is especially true in very tall buildings, where the use of gravity storage tanks started and has become very popular. Gravity tanks are atmospheric type tanks and are normally built of wood, steel, or equivalent materials. Except for wooden tanks, they are lined with food grade rubber linings or other approved nontoxic coatings. Wooden tanks are always cylindrical in shape while steel and other tanks can be rectangular or cylindrical. The most popular and widely used gravity tanks in high rise buildings are wooden tanks because they are very reliable, easy to maintain and replace. The two types of wood used for wooden tanks are yellow cedar and redwood. Durability-wise, these tanks can last for 20 to 30 years and can withstand most harsh weather conditions. In a typical high rise application, gravity house tanks are used for combined service, in which the domestic water and fire water reserve are stored in the same tank. Typical capacities for gravity house tanks are from 10,000 to 16,000 gal per zone. Gravity tanks are susceptible to contamination because they are atmospheric tanks and have accessible openings for servicing and open-ended pipe trim such as the overflow pipe and drain pipe.

Suction tanks are atmospheric type tanks and have similar trim and components to gravity house tanks except for the discharge piping, which is directly connected to a pump or series of pumps. These tanks are auxiliary equipment to the domestic water system and that may be required if any power pump or booster pump supplying the domestic water system or portion of the system cannot be directly connected to the city water main. These tanks are mostly made of steel, and come in rectangular or cylindrical shapes. Typical capacities for these tanks are 7500 gal with pump capacity of 400–500 gpm and 10,000 gal with pump capacity of 501 gpm or more.

Hydropneumatic tanks are closed, pressure type tanks and are used with water booster pump systems to boost and maintain a constant pressure in a water distribution system. Although the sole purpose of a hydropneumatic tank is to boost inadequate pressure and properly cycle pumps, it has also been widely used as a storage tank until the early 1970s. This resulted in oversized tanks that require large mechanical spaces in a building. The erroneous idea that a reserve water capacity is available, similar to a gravity tank system, has been a major contributing factor to the misapplication of these systems. The design

is flawed because when the low pressure limit is reached, the remaining water in the tank is absolutely useless to satisfy any system demand. Nowadays, hydropneumatic tanks are smaller and are being used solely to boost inadequate pressure in a water system. These tanks although closed and pressurized, are also susceptible to intentional contamination because they are provided with drain valves and air charging fittings, where a pump can be connected easily to inject contamination.

### 3.4 Backflow Prevention Devices

Backflow preventers are devices designed to prevent back-siphoning and back-pressure from adding contaminated fluids into a potable water supply due to cross-connection in building plumbing systems. Cross-connections are actual or potential connections between a potable and nonpotable water supply that constitute a serious public health hazard. The backflow preventer device described below is used in typical service connections of high rise buildings or large venues to protect the city water supply.

A reduced pressure zone (RPZ) Backflow preventer device provides the maximum protection against back-siphoning and back-pressure condition, and is normally used in high hazard applications. It consists of two check valves and a differential zone with a relief valve between the two checks. The relief valve normally stays closed due to the pressure exerted by the zone. The zone is always maintained at least 2 lb less than the supply pressure. When the supply pressure drops, the pressure in the zone will also drop and cause the relief valve to open and discharge the water from the system side of the water system to the atmosphere. This device is furnished with test cocks and gate valves to enable testing.

### 3.5 Valves

System valves include meter test tees, drain valves, and strainers. A meter test tee consists of a shut-off valve (normally a gate valve) joined with a piece of pipe or nipple that has a cap at the outlet. This test tee is connected to the main pipe downstream of a water meter and used to test and calibrate the flow of water through a meter. Drain valves are used to remove water, partially or totally from the lowest portion of tanks or piping system. These valves are normally gate or ball valves. Other types such as electronic or mechanical automatic drain valves can also be used, depending on the type of application. Strainers are used to separate and collect debris, such as sands, stones, and other foreign materials from water flowing through a piping or tank systems. The two most commonly used strainers in a water distribution system are the basket and “wye-pattern” strainers. These strainers have accessible retainer caps and basket covers that can be easily opened by hand or a simple hand tool for maintenance.

### 3.6 Wall Hydrants

Wall hydrants are devices used for cleaning of building exteriors and miscellaneous irrigation purposes. These valve assemblies are mounted on exterior walls of buildings and equipped with hose end connections. The two most popular types used in buildings are the exposed type, where the valve outlet and key operator are mounted exposed from the exterior wall and the enclosed type, where the valve is in a box, locked and flushed with the exterior wall. These valves are directly connected to the domestic water distribution piping.

### 3.7 Service Connections

Typical design flows for large commercial buildings can range from 65 to 400 gpm per service connection depending on the number of house tanks, booster pumps, and fill pumps in a building. The length of the connection and the presence of appurtenances such as valves and fittings vary depending upon the specific local requirements and conditions. A service connection to a building is typically designed to a maximum working pressure of 200 psi. However, internal plumbing fixtures and equipment are generally designed to a lower working pressure, thus requiring pressure reducing valves (PRVs) to reduce the incoming pressure before supplying plumbing fixtures and equipment. Typical pipe materials for service connections and domestic water distribution system are cement-lined ductile iron for piping 4 in., and larger and copper or red brass for piping smaller then 4 in.

In order to pump a contaminant from within a building into the external water system, the pump must overcome the pressure in the receiving main in addition to losses associated with moving the water from the building to the main. For pipes, the friction losses are based on the pipe diameter, the flow or velocity, and the roughness of the pipe. Additional losses are associated with appurtenances such as bends, valves, meters, and so on. Typical roughness coefficients (C-factor used in the Hazen-Williams equation) for new pipes are in the range of 120–150 depending upon the material. As the pipe ages, a pipe can become pitted or corroded leading to lower roughness factors. More typical C-factors for older, small diameter pipes used as connections would be in the range of 100–120. Minor losses associated with bends, valves, and so on are generally in the range of 0.2–2.

## 4 WATER SUPPLY VULNERABILITY

Under the headline, "Water Utility Officials Fear 'Backflow' From Terrorists - Reservoirs May Be Safe, but House Pipes Can Be Used to Push Toxins Into a Neighborhood," the Wall Street Journal [2] published an article on the vulnerability of households and other buildings to the introduction of contaminants into the water system. Although the article also sensationalized the issue by stating that "the flow of water into a house or business ... can be accomplished with a vacuum cleaner or bicycle pump," it did correctly identify this vulnerability. A Department of Defense Report [3] correctly stated that, "All faucets are vulnerable to an internal release, depending on physical accessibility and line pressure. Agents can be introduced into a building's water distribution system if the water line pressure in its piping, pressure tanks, or water softener treatment system is overcome." Without adequate and secure backflow devices, a contaminant introduced into a building could also be pumped into the distribution system, effectively contaminating parts of the public water system.

Recognizing the potential vulnerability of water distribution systems to intentional contamination, there has been a significant body of work addressing this issue [4]. However, there has been very little published on the subject of the impacts within a building that has been contaminated through the direct introduction of contaminants into the plumbing system. For large buildings, such contamination could potentially impact hundreds or even thousands of people.

### 4.1 Potential Soft Targets in Large Venues

Based on examination of plumbing plans for large venue buildings, and professional experience, the following soft targets were identified as potential entry points for intentional contamination. Although any direct connection to the water system (e.g. sinks, hose bibs, etc.) could serve as an entry point, the following are specific identified targets within most buildings.

1. In a combined system (fire protection and domestic service served from the same system), a pump could be hooked up to the Siamese connection and contaminant pumped directly into the building system or building tank. The Siamese connection is used as an auxiliary water supply designed so that the fire department can hook up their pumper truck and supply water to the internal fire system (e.g. sprinklers). This would not be effective if there is a separate fire and domestic system. Wall hydrants could serve as a similar entry point for a contaminant.
2. A contaminant could be directly introduced into a tank within the building without a pump.
3. From a utility closet (or other fixture), a pump could be hooked up and pumped directly into the water system. If there is a check valve on the tank then the contaminant could not be pumped into the tank in this manner.
4. An RPZ backflow preventer is a port that a pump could be attached to, at a relatively low pressure. There is usually a test connection that is readily available and could be used.
5. There is frequently a test connection (outlet) on the downstream side of a meter. This provides access to the entire system served by that meter.
6. Many large venue buildings have tanks located on their roofs (see Table 1 below). Typically, doors leading to the roof are not locked from the inside since they are used as fire exits (though they may be alarm-fitted). This could allow entry to a tank on the roof.
7. Direct injection into a hydropneumatic tank.

**TABLE 1 Potential Scope for Contamination through Alternative Entry Points**

| Entry Point | Contamination Potential |
|---|---|
| Siamese connection/ wall hydrant | Entire building |
| Tank | Zone |
| Fixture | Part of zone or building |
| RPZ port | Entire building |
| Meter connection | Entire building |
| Roof access | Zone |
| Hydropneumatic tank | Zone or entire building |

The entry points for potential contamination in buildings can be grouped as follows:

1. Entry points that have the potential to contaminate the entire building
2. Entry points that have the potential to contaminate a single zone (in a multizone building) or the entire building in a single zone building
3. Entry points that have the potential to contaminate a part of the building or a zone.

Table 1 describes the potential spatial scope of contamination for the seven entry points previously described.

### 4.2 Hydraulic Models and Contamination Scenarios

In order to test the potential impacts of a contamination event in a building, hydraulic models representing two generic large buildings were constructed. The models are used to investigate the movement and spread of contamination for alternative contamination scenarios. Scenarios investigated include different locations for the injection, different injection quantities, durations, and times.

The first set of model scenarios corresponded to the addition of a contaminant at or near the connection point to a city water system. As indicated in the Table above, this could be achieved through a Siamese connection, wall hydrant or through a tap located in the vicinity of the water meter, RPZ or a pipe on the suction side of the interior pumps. This scenario could also represent the impacts of a contamination event in the city water system. Impacts of the event are greatest when the contaminant is added during the period of highest water usage. For the case of a contaminant injected from midnight to 3 a.m., there are no impacts because the pumps were not operating in this scenario. The greatest impacts occur with the 3-h injection starting at 6 a.m. because of the large amount of water used at the start of the work day.

A second potential pathway for contamination of the water system is the direct injection of a contaminant into one or both of the tanks. Since the tanks are not pressurized, a contaminant can be added by direct insertion into the tank (i.e. pouring a liquid or powder into a hatch or other entry on the top of the tank), rather than through pumping. When a contaminant enters a tank, it is diluted with the clean water that already exists in the tank. In the present example, it is assumed that the tanks are completely and instantly mixed. This is generally a reasonable assumption for a small tank with a small diameter feed line [5]. As water is consumed in the upper half of the building, the contaminated water is drawn from the roof tank and delivered to the fixtures on the effected floors. The progression of floors impacted by the contamination and the resulting concentrations are shown in Figure 3. This figure shows snapshots of the building at 1 p.m., 2 p.m., and 5 p.m. representing 1 h, 2 h, and 5 h after the start of the contamination event. As expected, no contaminated water is delivered to the lower floors served by the mid-level tank. A series of model runs were made in order to study the effect of the time that the tank is contaminated, on the resulting exposure. The same amount of contaminant was added in separate model runs at midnight, 6 a.m., noon, and 6 p.m. and the exposures calculated over the next 24 h. The results are very insensitive to the time of day when the tank is contaminated.

The final set of model runs with the high-rise model looked at the impacts associated with injection of contaminants at various fixtures within the system. In the first scenario, a low head pump is used to inject the contents of the 55-gal drum over a period of 2 h

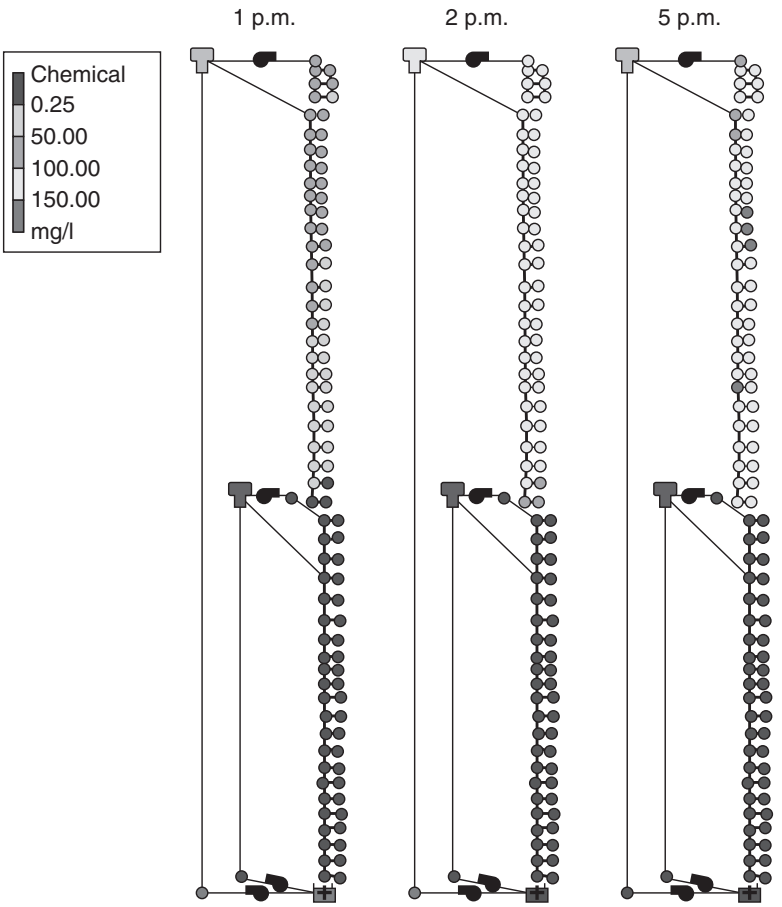

**FIGURE 3** Snapshots of building water system showing contaminant concentration.

starting at noon. The moveable tank/pump is attached to a fixture such as a utility sink on the 27th floor. The pump is capable of overcoming the pressure on the downstream side of the PRV (70 psi) but cannot overcome the pressure on the upstream side (137 psi). As shown in Figure 4, as a result, all of the contamination affects water usage on floors 25, 26, and 27 served by the PRV on floor 27. In the next scenario, a higher head pump is used that is capable of overcoming the pressure on the upstream side of the PRV. However, as long as the demand on the downstream side of the PRV (associated with usage on floors 25, 26, and 27) exceeds the rate at which the contaminant is injected into the fixture, the contaminant will stay within the three-floor zone and not affect other floors. When the water usage on floors 25, 26, and 27 is set to zero, only then will the contaminant move through the PRV in the main riser. As shown in Figure 5, when the contaminant enters the riser, it will mix with the water that is coming from the tank and move with the flow (i.e. toward the lower floors), resulting in contaminated water feeding those floors. Viewing this issue from a building safety perspective, the above analysis suggests that the most vulnerable component of the system is fixtures on high floors (or on a floor near the top of a zone in a multizone building).

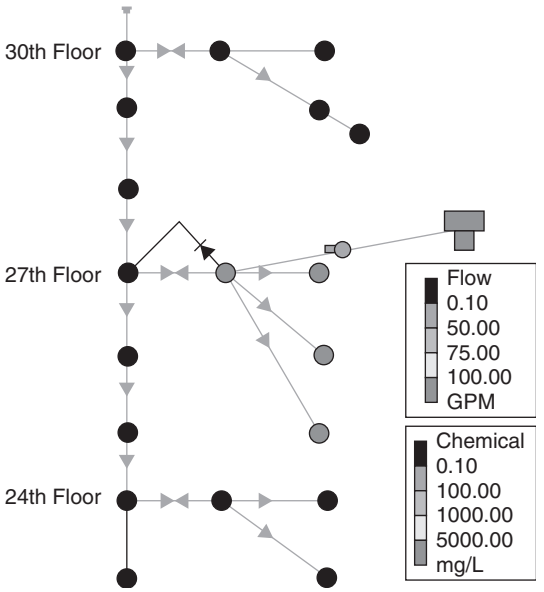

**FIGURE 4** Movement of contaminant introduced by low head pump.

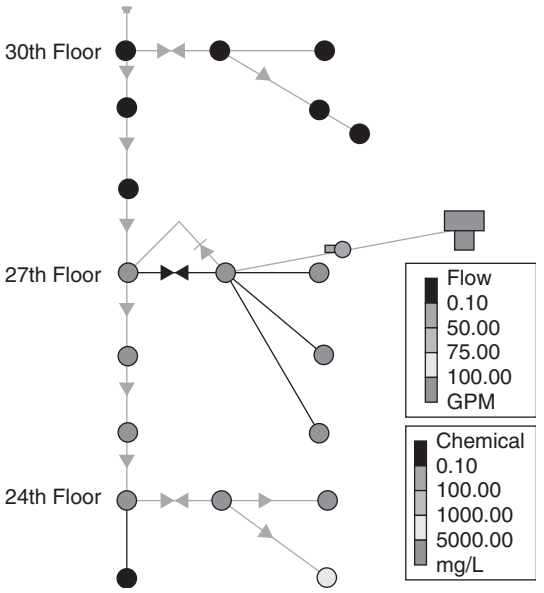

**FIGURE 5** Movement of contaminant introduced by high head pump.

## 5 CONCLUSIONS

This article provides information on the potential threat to a building's domestic and potable water supplies from chemical and biological agents that could potentially be used by terrorists. Distribution systems and piping systems within buildings are potentially susceptible to intentional contamination. In order to introduce a contaminant into a pressurized system, one must only overcome the internal pressure using an appropriate pump. Typically pressures within a system can range from a minimum of about 30 psi to 200 psi. Some components, such as most storage tanks, are not pressurized so material can be added by direct entry without a pump. The quantity of material that would need to be added to a water system in order to result in health or other impacts depends upon the specific contaminant and the flow rate in the entry pipe, or the water volume in the tank.

Based on an examination of plans for typical large venue, high rise and low rise buildings several potential points of vulnerability were identified. Typically these vulnerable points included access points near the entry point for pipes connecting to the city water system and storage tanks within the building. Access to these points could lead to contamination of the entire building or, in the case of multizone buildings, contamination of an entire vertical zone. Tanks are especially vulnerable because typically, they are not pressurized so that a contaminant could be introduced directly without the need of a pump. Although any fixture within the building could serve as a point of contamination by use of a pump capable of overcoming the system pressure, for most cases only that part of the building that is "downstream" of the entry point would be impacted, thus limiting the extent of the contamination.

Hydraulic models proved to be a useful tool for estimating the spread of the contaminant and the resulting human exposures. Several different scenarios were modeled for high-rise and low-rise buildings to demonstrate the likely consequences of various contamination schemes. Impacts depended upon the location of the entry point, duration of the event, time of day of the event, quantity of contaminant introduced into the system, and lethality of the agent. Based on the analysis of a typical high-rise building and a low-rise entertainment venue, it was found that a significant number of people could be impacted by the introduction of a contaminant into the water system.

The primary mechanisms for protecting a building from widespread contamination events are to limit access to key locations within the building. These key locations include: (i) the area in the vicinity of the connection or entry point of water from the city system into the building, (ii) internal tanks, and (iii) potential contamination points such as fixtures on high floors.

# COMMUNICATIONS AND INFORMATION INFRASTRUCTURE

# CRITICAL INFRASTRUCTURE PROTECTION: TELECOMMUNICATION

TED G. LEWIS

*Center for Homeland Defense and Security, Naval Postgraduate School, Monterey, California*

## 1 INTRODUCTION

The telecommunications sector is a complex adaptive system exhibiting *self-organized criticality* (SOC) suggesting its vulnerability to systemic failure. Over its 100-year history, the architecture of the telecommunications sector in the United States has evolved into a scale-free network with critical nodes located in a small number of major *telecom hotels*, that is, buildings containing a high concentration of switching equipment, storage, and interdependent connections. These *hubs* were formed by economic, regulatory, and technical forces operating over four historical periods: an *unregulated beginning*, the *telecom war* years, the *regulated vertical monopoly* period, and the current deregulated *competitive era*. This article briefly traces the evolution of telecommunications in general and telephony in particular. Using network science theory, we show that hubs and *betweener* nodes are the most critical components in the national system. Furthermore, these critical nodes are the direct result of regulatory forces shaping the industry, which have had major impact on telecommunications. Because of economic, regulatory, and technical forces ever-present in the industry, the telecom sector has evolved into a state of SOC. Although the industry has not experienced a calamity on a scale similar to the 2003 Eastern Power Grid Blackout, I believe that the two networks have evolved to a similar state.

## 2 OVERVIEW

Telecommunications infrastructure became the first *critical infrastructure sector* in the United States following the Cuban Missile Crisis of 1962. The confrontation between President Kennedy and Premier Khrushchev of the former Soviet Union, eventually led to the NCS (National Communications System) and the formation of the NSTAC—*National Security Telecommunications Advisory Committee*—created

by President Reagan (EO12382–1982) to advise the President of the United States on matters pertaining to the security and well-being of telecommunications. The first critical infrastructure sector was renamed the *Communications Sector* by the Department of Homeland Security in 2009 [1]. Regardless of its name, telecommunications security has always been on the forefront of homeland security even before the creation of the US Department of Homeland Security in 2003.

The communications sector, like many other fundamental infrastructure sectors, has a long and rich history of evolutionary change. Generally speaking, power, energy, telecommunications, and other interstate commerce sectors such as transportation have emerged as *complex adaptive systems*, becoming very large, complex, and malleable networks with both strengths and weaknesses. These strengths and weaknesses are a by-product of technical, economic, social, and regulatory policies of the United States, which have shaped these industries for over 100 years. Generally, it is believed that these forces are responsible for the current state of SOC for this sector.

This article develops a framework for understanding this complex adaptive system. Note that it is a *system*, which is more than merely a collection of components. Network modeling is a natural way to simplify and understand the rudiments of complex systems, and in particular the *architecture* of such systems. A network represents a system as a collection of *nodes* connected by *links*. For example, a social network is a collection of people, represented by nodes, and their associations, represented by links. A telecommunications network may be modeled at several levels: the physical level model uses nodes to represent switches and links to represent wires. A telecommunications network model might also equate nodes with buildings containing thousands of switches, and links with thousands of fiber optical cables. Networks are abstract mathematical objects that serve only to represent what is of most interest to the study of a system.

Determination of *individual* asset security has very little payoff for homeland security. For one thing, it is too expensive to protect every asset, and for another thing, it is not necessary. Knowing that a transformer in a power grid or a telephone pole in a telecommunication system is vulnerable to a terrorist attack or natural disaster such as a hurricane, tells us very little about the vulnerability of the larger system. Because of the complexity, interdependencies, and varying criticalities of large and complex systems that span the entire nation—or major portions of it—we must understand the system's architecture. Network models allow us to study large and complex system architectures as *evolving systems* so we can understand *system vulnerabilities* and derive strategies to deal with them. The immediate objective, then, is to protect the entire telecommunications infrastructure by judicious selection of critical components. A longer term, more ambitious objective is to suggest measures that cause wholesale restructuring of the telecommunications sector such that it is intrinsically more secure.

## 3 EVOLUTIONARY FORCES THAT SHAPE THE SECTOR

In some sense the communications sector has come full circle: from digital to analog, and then back to digital. Its creators envisioned a system somewhat like today's Internet, that is, a global broadcast network that connected everyone to everyone else. But their vision was limited by available technology going back over 200 years ago. Samuel Morse (1791–1872) perfected the first commercially successful digital system called the *Telegraph*, and demonstrated it in 1844 by transmitting *Morse Code* (dots and dashes are

equivalent to the binary 1s and 0s of today) from Washington D.C. to Baltimore. Western Union transmitted digital messages much like today's e-mail from coast to coast in 1861. Thus was born the first electronic communication network for transmitting disembodied messages between a pair of humans. Technology was the limiting factor, but profitability would soon motivate rapid advances in technology, obsolescing digital telephony almost immediately.

Western Union enjoyed a brief monopoly of the electronic communication business until 1876 when Alexander Graham Bell (1847–1922) successfully transmitted his voice over an analog channel to Mr. Watson, his assistant. Bell filed his "telephone patent" only a few hours ahead of Elisha Gray (1835–1901) of Western Electric. (Western Electric made the telephones and switching equipment for exchanges.) He founded the *Bell Telephone Company* and quickly built the first telephone exchange network in Hartford, Connecticut in 1877. Bell later purchased Western Electric from Elisha Gray in 1882, and proceeded to create one of the largest of many *vertical monopolies* of the twentieth century. Bell Telephone linked two cities (New York and Boston) together in 1883, but it would take the company nearly another 60 years to subscribe 50% of the population. The first mobile telephone did not appear until 1946! Compare this to the rate of adoption of the video tape recorder in the 1980s (12 years to reach 50%), and the rapid adoption of most new technologies today, such as the iPod, Internet e-mail, and cellular handsets.

Historically and politically, it is important to note that the first cellular telephone network (1979) was built in Japan rather than the United States. Through most of the twentieth century, communications in the United States consisted mainly of the *public switched telephone network* (PSTN) owned and operated by AT&T. This slow pace of technology innovation by a vertical monopoly led to radical changes in the industry, primarily to stimulate innovation and rapid adoption of new technologies. Slow adoption of new technology would become one of the factors leading to deregulation of the communications industry in 1996.

Patent litigation in 1879 separated voice and data: Justice allowed Bell Telephone to operate voice networks and Western Union to operate data networks (basically stock market quotes). This artificial separation between voice and data would become a barrier to advancement of telephony until invention of the Internet in 1969, and its commercialization in 1998. Even today, the *network neutrality* movement is about content, that is, whether voices, dates, pictures, etc. should be priced separately or not. The network neutrality advocates rightly claim that all information is digital, so how can telephone and telecommunications companies charge separate rates for different encodings of ones and zeros? So far, the network neutrality advocates have won, and this has not become a force shaping the sector.

### 3.1 Unregulated Beginnings

Table 1 lists major events in the evolution and shaping of the telecommunications sector. This timeline has four distinct periods: *Unregulated*, *Telecom War*, *Regulated*, and *Deregulated*. From 1877 to 1898, the industry was mainly unregulated. During this period, a large number of local companies emerged to serve local customers. This produced a large number of isolated and heavily connected networks characterized by dense wiring clustered around a small number of central switching offices. Even after consolidation set in, the resulting networks were clustered and highly focused on local calls. (Highly

clustered networks are more resilient and less vulnerable to failures and attacks than today's national-scale communication networks).

### 3.2 The Telecom War

A "telecom war" broke out among competitors after Bell's patents expired, prompting the U.S. Department of Justice to step in and enforce the Sherman Antitrust Act of 1890. While the case against AT&T was very similar to the Sherman Antitrust Act case against Microsoft, the action against AT&T was much more severe. The government forced AT&T to stop buying independent telephone companies without their permission; it required AT&T to interoperate with its competitors [the local exchange carriers (LECs), in today's language]; and required AT&T to divest its control of the Western Electric Manufacturing Company whereas Microsoft was merely fined and allowed to remain intact after being found guilty of violating the 1890 Act.

While the action against AT&T may have seemed severe, AT&T owned 223 of the 224 independent companies within a decade of the 1913 ruling! This illustrates one of the primary factors affecting and shaping many infrastructure systems: *increasing returns*. Increasing returns in economics says the more a certain commodity exists, the more valuable it becomes. In this case, increasing returns drove AT&T toward a monopoly: the more customers connected by the AT&T network, the more valuable the network became. The more valuable it became, the more customers wanted to subscribe. This spiral ended up with AT&T in the monopoly catbird seat.

Increasing returns accelerates the adoption of one technology and service over another, because it standardizes the user interface, exhibits the compounding network effect of being able to communicate with more people over a large network versus a small network, and motivates the owner operator to amortize fixed costs over an ever larger customer base.

In network terms, increasing returns is a kind of *preferential attachment* effect. It works like this: as customers randomly select one of many vendors to provide telephone service, they eventually realize that more people are subscribing to one service than another. The benefits of the "more popular" service may be intangible, but if only a few customers decide to switch to the more popular service, this begins a process of preferential attachment. Think of the vendor (competitor) as a node in a network, and the links as subscriptions. The more heavily connected node is preferred over the less connected nodes, which accelerates adoption of the heavily connected node. As more consumers subscribe to the preferred vendor node, more decide to also subscribe, which snowballs into an avalanche of connections. Thus, the popular node becomes a major hub of the network.

Fundamental infrastructure systems such as electric power, water and sewer, and telecommunications systems all exhibit the network effect known as preferential attachment. In the end, the preferred node becomes a monopoly, as Microsoft did in the 1990s. Emergence of a monopoly has little to do with the performance of a certain company or leader, but instead it is a fundamental property of fundamental infrastructure systems. Increasing returns sets in, and the infrastructure becomes the *only* player in the field, that is, a monopoly.

Although the theory of preferential attachment, increasing returns, and network effects were not well-understood in the 1930s, the results were clear: as a consequence of monopolies like AT&T, most customers were happy with their service, but not all. In particular, people living in rural or thinly populated areas were without service. The network effect was inaccessible to them because it was not cost-effective for the owner or operator of the telephone company to serve an isolated customer.

The Congress, in its wisdom, bartered *universal access* for *natural monopoly* of the major means of long-distance communication when it passed the 1934 Telecommunications Act. Universal access means that everyone gains access at a (somewhat) flat fee, regardless of his or her geographical location. Instead of nationalizing AT&T, the Congress provided monopolistic protections for the private enterprise in exchange for universal access. AT&T was required to amortize connection charges across all customers. But this privilege came at a price because innovation would slow to a halt without the incentives provided by competition.

### 3.3 Regulatory Period

The 1934 Telecommunications Act initiated the *regulatory period* of evolution. It provided for the regulation of telecom through the FCC (Federal Communications Commission), which answers only to the Congress. It declared the electromagnetic spectrum within the United States as public property and only the Congress had the right to regulate its use. A license and huge licensing fee was imposed on commercial broadcasts. Finally, the Congress required broadcasters to operate in the best interest of the public.

The 1934 Act had a huge impact on shaping the communications network of the United States. For example, the so-called "long lines" established by AT&T during this period remains a major component of the communications infrastructure today. The protocols and standards of operation established by AT&T remain as legacy systems. Specifically, the SS (switching system) computers designed and built by AT&T/Bell Labs established a global standard for how telecommunications systems operate. (They are legacy systems in the sense that the old analog protocols no longer work with the new digital protocols

of the Internet, and in some cases, the digital protocols have to be made to interoperate with newer digital protocols).

Because AT&T was a closely regulated vertical monopoly, the system operated seamlessly from end-to-end. Equipment interoperated, networks interfaced with one another, and universal access guaranteed safe and secure operation. In many ways the old AT&T system was more resilient and rugged than the cobbled together networks of today. According to Richard Kuhn, "For several decades AT&T has expected its switches to experience not more than two hours of failure in 40 years, a failure rate of $5.7 \times 10^{-6}$." The old regulated system was extremely reliable!

### 3.4 Deregulated Oligopolies

The deregulated period began in 1974 and continues, today. It took 10 years for the US Department of Justice to break up AT&T this time. Breakup led to the "Baby Bells", or LECs which are regional telephone companies licensed to operate as monopolies within geographical areas of the United States. A total of 22 companies were granted seven operating regions, but the infrastructure remained much the same as during the regulated period. The Congress also sought to establish pricing, which was challenged by the LECs, leading to the states having the right to set prices for their citizens, in 1996. Nonetheless, pricing restrictions on both the wholesaler (LEC and, IEC or Interexchange Carrier) as well as the retailer (consumers) had a major impact on performance and reliability of the network. Why build out newer, faster, and more reliable networks when profitability is constrained by regulation?

The Baby Bells continued to be slow adopters of new technology and providers of better service. This period of telecom evolution may have persisted for some time if the Congress and the NTIA had not commercialized the Internet in 1993–1998 (National Telecommunications and Information Administration within the Department of Commerce, created in 1978 EO 12046). The commissioner of the FCC and the Congress justified its major revision of the 1934 Telecommunications Act mainly based on the concept that competition would spur innovation. One goal of the 1996 Telecommunications Act was to encourage universal Internet access for everyone's home and office. The Baby Bells, saddled with their legacy analog systems and voice-only mentality were taking too long to transition to the new digital age. This theme continues to resonate today.

The 1996 Act unbundled services, in other words, no more extra fees for extra services like digital data transmission (VoIP or voice over Internet protocol). It motivated the deployment of faster networks (xDSL), and limited ownership of Cable TV, TV, and radio stations. But most importantly, the 1996 Telecom Act established *peering* as a way of life for competitors. This has led to the number one vulnerability in the communications sector.

Peering is the practice of sharing networks with competitors. Company A may need Company B's network to provide long-distance connections for local customers. Conversely, Company B needs Company A's local connections to gain access to the "last mile" or household/office consumer. LECs typically own and operate local exchanges, while IECs ("long-haul" carriers) typically own and operate long lines (Fig. 1). In today's market both, local access to get onto the long lines and long lines to make long-distance calls, are required.

Peering radically restructured the industry, because it not only allowed, but motivated competitors to co-locate their switching equipment in close proximity to one another.

The consequences were dramatic and unanticipated: a small number (30–40) major switching hubs emerged as the preferred nodes. That is, the law of increasing returns appeared again. Only this time the result was creation of the *number one vulnerability* of the telecommunications sector: the carrier or *telecom hotel*. This phenomenon is explored later.

The telecommunications sector contains more than the wired-only network left over from the days of vertical monopolies and regulation. Even so, all communication networks depend on it. Satellite communication (with small exceptions), cellular telephony, Internet, and to a lesser degree, broadcast TV, Cable TV, and GPS navigation depend on the core capabilities of the wired network. Therefore, a potential threat to the wired network is also a potential threat to the wireless and associated networks. These systems are interdependent as shown in Figure 1.

## 4 MAJOR COMPONENTS OF THE SECTOR

A full discourse on the U.S. telecommunications system could easily fill an entire book, so the discussion here focuses on the top level. Figure 1 is a gross simplification of telecommunications in the United States. It consists of three major layers: the LECs and their customers; the long-distance interexchange carriers (IECs), and the various devices and services feeding into the points-of-presence (POP) gateways provided by the IECs. IECs operate long lines that connect cities and countries to one another.

Figure 1—reading from left to right—shows how a telephone call or e-mail transmission makes its way from one person to another. Suppose an e-mail sender is transmitting from one of the houses shown under the LEC column. The message travels to a *headend switch*, typically located in the neighborhood to serve up to 1,000 homes. The headend

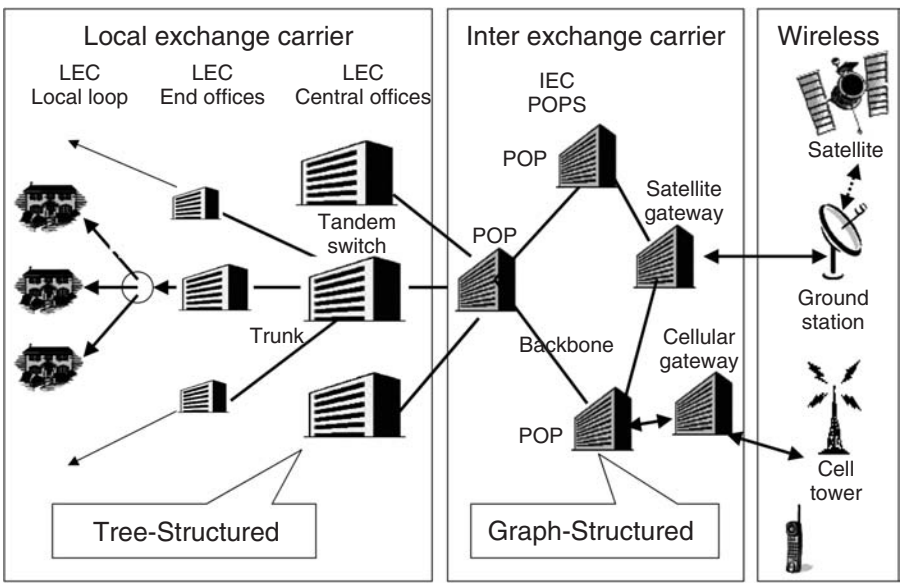

**FIGURE 1** Structure of the communications sector [2].

connects to a central office in the LEC, which forwards the message, locally or through the long-haul IEC network. If the recipient is located within the same network, the message is routed back through the tandem switches to a headend switch and then into the recipient's home. If the recipient is at a long distance, the message travels through a POP or gateway to the IEC network.

Suppose the recipient uses a cell phone from 1,200 miles away. The LEC must forward the message to a POP switch within an IEC network, as shown in the middle column of Figure 1. The IEC's gateway also acts as a bridge across networks that operate at different speeds and protocols (rules for exchanging messages). The sender's message may make its way across several IECs before finding a gateway that connects the sender with the receiver.

When the recipient answers his or her cell phone call the nearest cellular tower transmits the "connection signal" to a gateway within the wired IEC network. A roaming cell phone registers with local towers, so the IEC and LEC switches can find the cell phone regardless of where it is. Eventually, the network makes a connection between the sender and the recipient's local tower. This all happens at nearly the speed of light, so the consumer does not notice a long delay.

The most interesting feature of Figure 1 is this: to work as one integrated communications system, cellular, satellite, and other means of communication depend entirely on the *wired landlines*. The old AT&T long-haul lines (and others) are the backbone of the national system. Cellular transmission has a range of about 3 miles, so cell phones actually connect to land lines via a nearby tower. Transcontinental cell phone calls are not possible without the long lines maintained by the wired IECs. Even satellites depend on the terrestrial wired lines. Ground stations often provide feeds to television and other broadcast media, but they need a stable and reliable wired landline network to operate. These systems are interdependent and together they form a very large and complex system.

The logical structure of Figure 1 shows that the telecommunications sector is a *system*, rather than a loose collection of local components and unrelated assets. As such, this system's resiliency is dependent on its "architecture" more than the resiliency of individual components. For example, the highly redundant IEC layer has many POP and gateway switches, so that the failure of one has minor implications for the reliability of the overall system. It begs the question, however, of which components are most *critical*, where criticality means failure of a critical component can lead to failure of the *entire* system.

Security analysts often overlook system analysis of infrastructure, preferring to perform asset analysis because it is easier. Analysts tend to pay more attention to local incidents involving a single asset such as a bridge, building, or computer, because it is easy. In reality, simple components frequently fail without bringing down an entire system. It is well-known that natural disasters are distributed according to a *power law*, whereby inconsequential failures occur with high frequency and high consequence failures occur with much less frequency [3]. However, the telecommunication system is a product of human engineering and Congressional regulation and these forces that have shaped the sector have also made it more vulnerable to targeted attacks than it would be if it were a product of nature. Therefore, it is important to ask, "What is critical in critical infrastructure protection, and in particular, telecom infrastructure?" Criticality is at the core of system analysis.

The answer to this question is found by investigating the architecture of the system, which in turn leads to understanding critical components whose failure might bring down the entire system. Because we cannot afford to protect everything, we opt to protect the

most critical components. This is the strategy called *network analysis* and it borrows heavily from the network science literature [4].

## 5 RESILIENCY OF NETWORKS

To understand the criticality of telecommunication system components we need to understand the fundamentals of network theory, because the structure of large and complex networks has a major impact on their survivability under stress. Ideally we want networks to continue to operate under less-than-perfect conditions. A plausible goal is to operate any infrastructure system as a robust network that is difficult to bring down even when purposely attacked. This analysis is limited to single-node attacks.

The telecommunications network is a bidirectional network because messages flow in both directions. A failure of one switch may or may not halt bidirectional flow because of redundant or alternate paths. However, failure of a switch may reduce the overall network capacity or speed. Resilience can have several definitions: as a measure of the impact of an attack on overall structural integrity of the network, or as a measure of the decline of output from the network (in terms of number of messages per unit time). We study both: the structural integrity of the telecom network due to cascade failure which is a single node outage that ripples through the network taking down affected nodes; and the decrease of output flow from a network in which messages flow from source to sink node. *Cascade failure analysis* determines resilience of the static structure (architecture) of the network, while *flow failure analysis* determines resilience of commodity flow through a network.

More formally, cascade failure resilience is defined as the fraction of nodes that continue to operate following the failure of a single node:

$$R_c = 1 - (I_c/n);$$

where
$R_c$ = cascade resilience,
$I_c$ = "infected" or damages nodes,
$n$ = number of nodes in the network.

Flow resilience, in contrast, is defined as the fraction of commodity flowing into sink nodes after a single node is attacked, compared to beforehand:

$$R_f = F_1/F_0;$$

where
$R_f$ = flow resilience
$F_1$ = flow after an attack
$F_0$ = flow before an attack

We can express both measures as a percentage in the interval (0, 100%). Cascade resilience parameter $I_c$ is estimated by simulating an *epidemic* or a contagion that spreads from the attacked node to adjacent nodes with probability $\gamma$, the infection rate, and repaired in $\tau$ time steps following failure. Once repaired, a node stays repaired, simulating

an SIR (Susceptible-Infected-Recovered) epidemic. $I_c$ is obtained by merely counting the *total* number of nodes infected from onset to recovery of all nodes. (We could also use the peak number infected, but this is left as an exercise for the reader). Flow resilience parameters $F_1$ and $F_2$ are estimated by simulating flows emanating from a single source node to a single sink node. A single source is constructed by aggregating all nodes with zero inputs; similarly, a single sink is constructed by aggregating all nodes with zero outputs. In simulations conducted by the author, link capacities are all the same and flows out of a given node are evenly divided among the outgoing links. Flows into a node are summed; it is possible for nodes to overflow or underflow. We ignore overflows and limit the amount of message flow through a link to the link's maximum capacity. In a telecommunication network, capacity is equivalent to bandwidth.

### 5.1 Hubs, Clusters, and Betweeners

We compare resiliency of three fundamental network structures: random, clustered, and scale-free. A random network is one in which nodes are connected to one another by randomly selecting pairs of nodes and linking them. Clustered networks contain highly connected neighborhoods of nodes that are connected to other nodes in the cluster. That is, if node A is connected to nodes B and C, then connecting nodes B and C forms a triangle. A, B, and C form the simplest possible fully connected network. The cluster coefficient of a single node is the number of triangles it is a part of, relative to the maximum number possible. A metric called the *cluster coefficient* quantifies the amount of clustering in a network, by taking the average of node cluster coefficient across all nodes. Figure 2 illustrates hubs, clusters, and betweenness: Figure 2a shows an unclustered random network. Figure 2b shows a highly clustered network. The central node of Figure 2b has $k = 4$ links connecting it to 4 neighbors. Thus, there are potentially $k(k-1)/2 = 4(3)/2 = 6$ triangular networks that can be formed out of its four neighbors. The central node belongs to 4 triangular networks, so its cluster coefficient is $4/6 = 0.67$.

A scale-free network has a very definite structure: most nodes have only a few link connections, while one or two nodes have a very large number of connections. A node with five connections (and therefore five links) has a *degree* of five. A network's hub is the node with the highest degree. Figure 2c illustrates a scale-free network containing a hub with degree of five.

### 5.2 Betweenness

Figure 2d illustrates another metric that will become useful later in the discussion of networks. *Betweenness* is a measure of *intermediary power* in a network. It is simple, but laborious to calculate. Betweenness is a measure of how many paths go through a node (or link) from all other nodes. To compute it, tally the number of shortest paths passing through a node or link, from and to all other nodes, for all nodes and links. Then scale the tallies to the unit interval (0, 1) by dividing them by the largest tally. The normalized number is the node or link *betweenness*. Figure 2d shows three of the nine paths passing through node 3, from and to all other nodes. Node 3 is a kind of gatekeeper because it indirectly connects other nodes to each other.

A network's *betweener* is the node or link with the highest betweenness value. In a sense, the betweener is a critical traffic node, because more messages can pass through the betweener node or link than any other node or link. This measure is useful in modeling

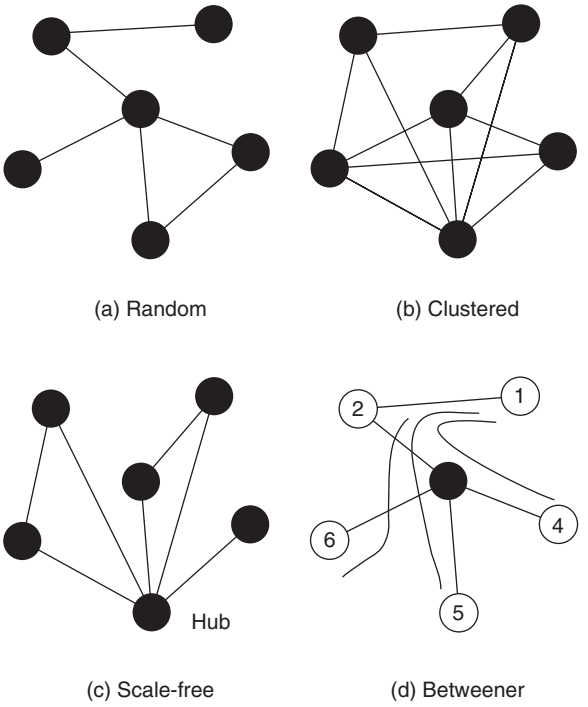

**FIGURE 2** Illustration of network topologies and the betweenness metric.

network flows, because the betweener can control the majority of flow through a network. Therefore, betweenness is an important metric for measuring resilience in flow networks such as a pipeline, transmission, or traffic networks. We want to simulate the impact of taking out the betweener on the flow resiliency of a telecom network.

## 6 RESILIENCE RESULTS

Now we turn to the subject of resiliency of a network. What constitutes "failure" in a network? If a single node or link fails, does it mean the entire network fails? If a "critical node or link" fails, does this equate to network failure? The 2003 Blackout of the Eastern Power Grid, triggered by a single link failure, propagated across the entire network disabling a large portion of it. The 2003 *cascade failure* acted much like an epidemic sweeping through a population. Therefore, experience tells us that epidemics are one form of failure that can bring down an entire network. Are telecommunication networks subject to epidemics? Yes. The spread of computer viruses and worms behaves very much like the spread of a virus in human populations. On a physical level, outage of one node affects adjacent nodes, because continuity depends on predecessor and successor nodes.

### 6.1 Cascade Resiliency

Network epidemics or *network storms* are observed in many infrastructures such as traffic jams, floods, power outages, communication outages, and e-mail congestion. In social

network theory, well-known contagions such as the H1N1 flu spread through human contact (links), and either persist (never go away) or die out. Similarly, an important question for homeland security is, "Do infrastructure epidemics live forever or eventually die out, once initiated within a network?"

Simulation of attacks on random, cluster, and scale-free networks shows how vulnerable networks are to targeted attacks. We generated networks with 50 nodes and 100 links, and randomly connected node-pairs to obtain a random network. Similarly, we generated cluster networks from random networks by repeatedly rewiring links such that the cluster coefficient of the entire network increased. This emergent process terminated when the overall network cluster coefficient reached 50% [4]. Finally, starting with a random network, we repeatedly rewired links chosen at random, but linked by preferential attachment to a randomly chosen node, until the largest node has degree at least four times the average. This produces a scale-free network with a degree sequence distribution that obeys a *power law*.

In each case, an attack on a single node initiates an epidemic which spreads to its neighbors with an infection rate of $\gamma = 25\%$. Infected nodes are repaired in $\tau = 5$ time steps, and once repaired, remain immune to subsequent infection. This simulates a susceptible-infected-susceptible (SIS) epidemic, producing epidemics that follow a very simple Kermack-McKendrick model [5] of logistic growth of the infection followed by a rapid decline as nodes mend and return to an operative state. As it turns out, the number of nodes infected over the life of the SIS epidemic is a measure of resiliency. Moreover, this number is different for random, clustered, and scale-free networks.

Figure 3 summarizes the results. Attacks on hubs are the most consequential (89% of the nodes are "infected"), while attacks on high cluster coefficient nodes are the least consequential (minimum of 17% for cluster attacks, and only 23% for hub attacks on cluster networks!). Clearly, attack strategy and network topology both bear on resiliency. Cluster networks are more resilient than scale-free or random networks!

A number of investigators have shown that scale-free networks are more tolerant of random attacks, but highly vulnerable to targeted attacks on the network's hub [6]. This

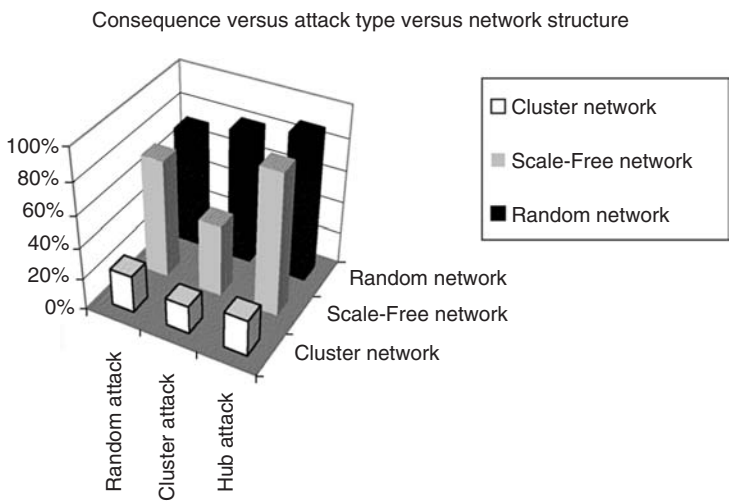

**FIGURE 3** Cascade failure in random, cluster, and scale-Free networks.

makes sense, because hub removal also removes the maximum number of links. It has also been shown that scale-free networks are more likely to sustain persistent epidemics, which is an important result for the telecommunication sector because computer viruses spread like epidemics. In fact, Wang and others confirmed this finding in an elegant and convincing network model that relates topology to persistence [7]. The Wang et al. model says network connectivity, as defined by the *spectral radius* of the network, relates to persistence as follows: $\rho\gamma - \Delta ?0$. If this relation exceeds zero, the contagion persists forever! Otherwise, it eventually dies out. Here $\rho$ is spectral radius, $\gamma$ is infection rate, and $\Delta$ is repair rate. The higher $\rho$, the more likely the epidemic never disappears from the network. And, scale-free networks have higher $\rho$ than equivalent random and cluster networks.

The opposite is true for cluster networks: they are tolerant of random and targeted attacks (because they have no hubs), and they are less likely to sustain recurring epidemics. Telecommunication networks are never clustered; rather they tend to be scale-free, so they are more susceptible to persistent epidemics. Figure 3 suggests that clustering improves resiliency against cascade failures by a factor of 3–4 over targeted attacks on scale-free networks.

Cluster networks are tolerant of both random and targeted attacks because they have more link redundancy than either scale-free or random networks. Interestingly, the Western US Electric Power Grid is a high cluster coefficient network, which means it should be more resilient than the Eastern power grid. According to Kendall [8], the reverse is true: Western grid outages exceeded Eastern and ERCOT outages during the period 1993–1999. This unexpected result is perhaps due to SOC, a topic that is described in more detail below.

Hubs attacks are more consequential than any other kind of attacks. The lesson is clear: protect the most critical nodes and links as defined by degree. An economical strategy with maximal return is to protect hubs and perhaps a few other high-degreed nodes within the telecom sector.

### 6.2 Flow Resiliency

Another form of "failure" in networks has to do with networks that supply some sort of commodity. A supply chain network such as a gas and oil pipeline network, water supply system, or airplane supply chain provide a commodity that flows from source to sink. It is important for sink nodes to keep up with demand, and to do so, flow must be continuous and not interrupted by a failure of a node or link along the way. In a telecommunication network, the commodity is voice, data, e-mail, etc.

Another kind of failure is *denial of service* due to reduction or termination of flow of messages through a network. An arbitrary network likely has many alternative paths from source to sink, along which a commodity can flow. Removal of a single node or link may or may not have much impact. This begs the question, "Does network structure matter to networks that supply a commodity such as e-mail messages or voice streams?" If we treat the telecommunications sector as a flow network, where e-mail, voice mail, and other digital information such as photographs flow from sender to receiver, what constitutes a threat to continuity of flow?

Simulation of attacks on directional random, cluster, and scale-free networks with a single source and single destination node produces much the same results as shown in Figure 3, except the consequences are measured in terms of flow resiliency, $R_f = F_1/F_0$.

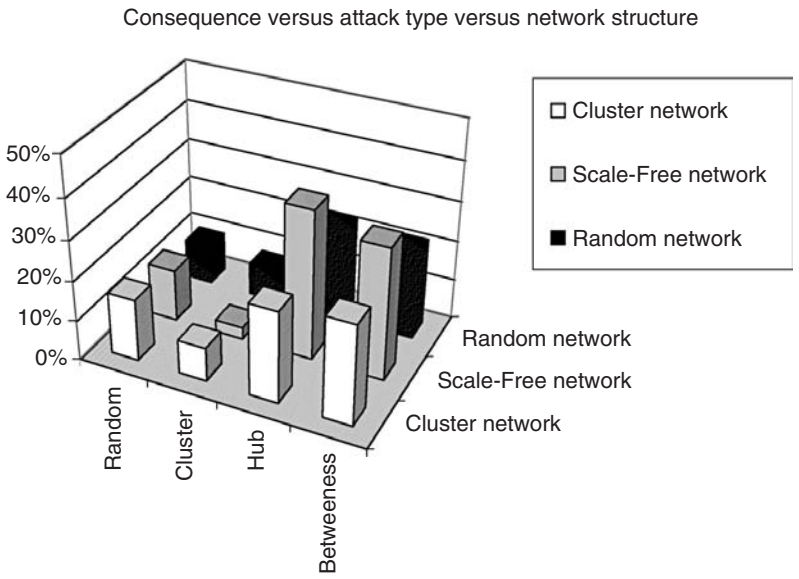

**FIGURE 4** Simulation results for flow networks.

Given an input of say 100 units, and demand of 100 units, what fraction actually reaches the destination node? If a node failure reduces output from 100 to 70 units, then $R_f = 70/100 = 0.7 = 70\%$.

Simulation results confirm that hubs are more critical than all other nodes except for high betweenness nodes (Fig. 4). Random and cluster networks are more resilient, but still suffer relatively high consequences when their hubs and betweeners are attacked. Scale-free networks suffer even more consequences because their hubs are larger. In many cases, the hub is also the betweener. This is why consequences are similar. Betweenness is a measure of the number of paths running through a node. Therefore, telecommunication networks are more vulnerable to hub and betweener attack than random or cluster attacks.

## 7 TELECOMMUNICATIONS CRITICALITY

Has the telecommunications sector reached a state of resilience, or the opposite? After 100 years of evolution, do we have a more or less secure and resilient communication network? This author claims that the sector has become *less resilient* and therefore, more likely to fail than ever before. The argument for loss of resiliency is based on two main observations: (i) after one hundred years of economic, regulatory, and technical pressure to be efficient, profitable, and politically acceptable to the Congress, the system has evolved into a weakened state, culminating with the 1996 Telecommunications Act; (ii) like many massively large and complex infrastructure networks with a long history of evolution, the telecom industry has reached a state of SOC. This claim is supported by the existence of critical nodes in the scale-free shaped sector. These two ideas are partners: evolution from randomness to a state of SOC, resulting in a network with hubs and betweeners.

### 7.1 The Hubs: Telecom Hotels

NSTAC identified *telecom hotels* as the number one vulnerability in the communications sector in 2003 [9] and recommended their protection as the top priority of homeland security. The report defines a telecom hotel:

"*Telecom Hotel*: Conditioned floor space owned and operated by a commercial Landlord for the purpose of hosting multiple service providers. Tenants may include the incumbent ILEC, competitive local exchange carriers (CLEC), Internet service providers (ISP), competitive access providers (CAP), Web hosting operations, or any other non-telecommunications commercial enterprises in need of floor space to support their electronic equipment" [9].

For example, *One Wilshire Boulevard*, a 30-story, 656,000 square foot building in downtown Los Angeles, is the single-most important point of connectivity in the Western United States. It houses over 240 telecommunications companies, provides up to 75 watts of power per square foot, and connects the United States with most of Asia. Backup power of 8 megawatts and 11,000 gallons of diesel provide resilience in case of power outages.

Details of telecom hotels are openly advertised over the Web along with security and resiliency provisions ( www.carrierhotels.com). Thus they are not only critical, but in the open. Their vulnerability, however, is perhaps low, because their importance to the entire sector is widely known, leading to exceptional security measures. Nonetheless, the high concentration of LEC and IEC switching equipment in one location raises concern. The first line of the NSTAC report says, "The Administration has expressed concern that the concentration of multiple entities' telecommunications assets in specific locations may have implications for the security and reliability of the telecommunications infrastructure" [9].

### 7.2 Self-Organized Criticality

The mere existence of telecom hotels is no accident. In fact, these highly concentrated assets are a direct consequence of evolutionary forces described above, leading up to and including the 1996 Telecommunications Act, which created telecom hotels in its wake. Specifically, the 1996 Act promotes peering and allows for sharing of facilities among competitors. Technically, it is better to peer with one's competitors by co-locating switches and routers in the same building, because it reduces time delays in transmission. Economically, the costs of housing, powering, and servicing an aggregated collection of equipment is lower, because they can be amortized over many companies. Politically, the Congress sought to increase innovation by encouraging collaboration between competitors. These forces set into motion the famous *preferential attachment*, leading to highly connected nodes housed under one roof. Telecom hotels are the most connected hubs of the communications sector.

Regulation leads to increasing returns, which leads to hubs, which in turn leads to SOC. SOC is a property of a complex adaptive system that operates near or at its *tipping point* [10]. Originally studied by Turcotte and colleagues [11, 12], definitions of SOC vary across fields of study. More formally, SOC is a property of a system that operates at or near a critical point dividing chaos and stability. Consequently, a slight change in system state tips the system in either direction, from stability into instability or the reverse.

Asset concentration in the telecommunications sector has been building for over 100 years. Initially, telephone companies were local and isolated. The telecom wars produced consolidation under AT&T. The breakup of AT&T into Baby Bells had little

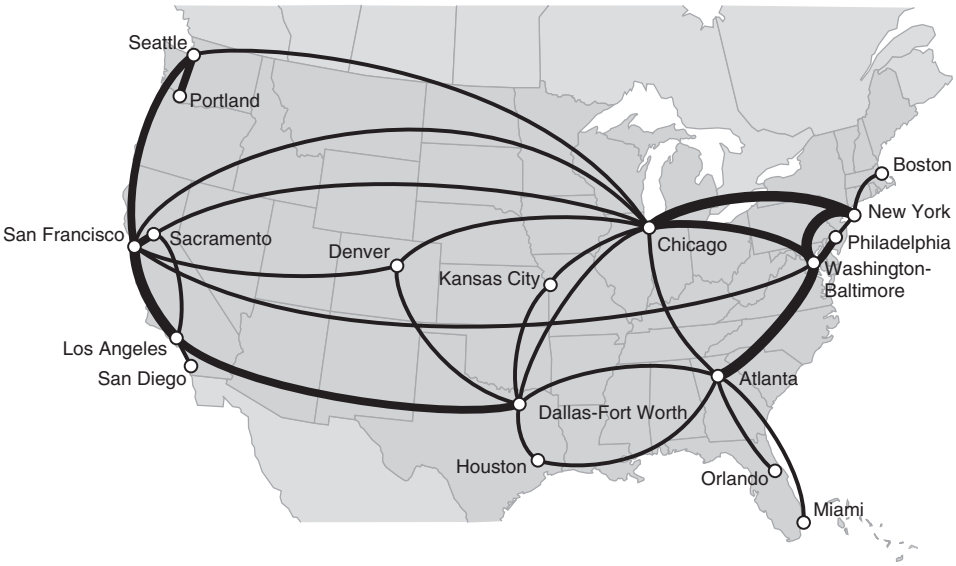

**FIGURE 5** Network of the top 30 telecom routes. [2002 Telegeography Research, www.telegeography.com].

effect on the communications network, because the separate companies used the same telephone lines and switches. During this period of asset consolidation the communication sector was perhaps a cluster network, rather resilient against hub and betweener attacks. Then the 1996 Telecom Act accelerated increasing returns; leading to fewer than 20 major hubs among the top 30 routes (Fig.5). Note that Chicago is both the hub and the betweener of this network.

A similar analysis (not shown here) confirms this theory for the top dozen AS-level Internet service providers, the *Tier-1 ISP network*. These major hubs handle e-mail, web, and voice-over-IP traffic and inevitably process everyone's Internet transactions. Their Autonomous System number identifies them, such as AS#1234. The large ISP located in Reston, VA. (AS#1239) is both betweener and hub of the top-level peers. Montreal (AS#6453) and Broomfield, CO (AS#3356) rank second. No one has studied in detail the system-wide consequences of a targeted attack on these ASs, so it is unknown how vulnerable the Internet is to removal of these critical nodes.

For a variety of reasons, the national telecommunications sector is optimized for high performance and low cost. Peering and the 1996 Telecom Act have moved the sector closer to its SOC, as evidenced by a few heavily connected hubs, highly concentrated in a handful of large telecom hotels, connected by thousands of links. As a result, vulnerability to cascade and perhaps flow attacks has increased since deregulation. Removal of a small proportion of highly connected nodes could result in major telecommunication outages.

While the conclusion drawn here has not been verified in practice, because we have no historical precedent for such a calamity, a similar SOC state exists for the electric power grid [13]. Dobson et al. extensively analyzed electrical power grids from around the world and made a strong case for SOC. Historical data supports Dobson's results, but such data is lacking in the telecommunications sector. Clearly, the power grid is different from

the telecommunications network, but it suffers from similar regulatory forces. Without similar analysis, SOC of the communications infrastructure remains speculative.

## 8 FINAL ANALYSIS

The telecommunications sector is an example of a scale-free network containing hubs (telecom hotels). This topography is a direct result of economic, regulatory, and technical forces that have shaped the sector over a period of 100 years. Perhaps the most dramatic step toward SOC occurred after the 1996 Telecommunications Act, which created the telecom hotels. Whether or not these will turn out to be the Achilles Heel of the sector remains to be seen. Currently, there is no historical data to support the conjecture that telecom hotel failure will lead to a telecommunications Pearl Harbor.

The components of the telecommunications sector in need of protection are the telecom hotels, major POP, network access points (NAP), and root servers. This adds up to perhaps 100–200 sites at the high end, and as few as 26 sites at the lower end. While the 13 root servers of the Internet have gone into hiding, there are 26 widely known NAP servers around the world that are critical to the security of the Internet. A full simulation of the effects of a cascade failure caused by a virus or physical attack on one of these critical nodes has yet to be carried out. This remains an open research question.

On a longer time scale, the telecommunications sector may evolve even closer to its SOC, unless policies are changed. Congressional regulation and economic forces have shaped the sector, so they can also be employed to reshape it. If Congress were to enact legislation that resulted in the dissipation of telecom hotels, increased redundancy, fewer betweeners, and perhaps increased path redundancy, the sector would remove its tipping point. Under this scenario, the network architecture would revert to a clustered or random network. In other words, an alternative strategy is to restructure the network instead of hardening critical nodes.

# STRATEGIES FOR PROTECTING THE TELECOMMUNICATIONS SECTOR

JOHN SULLIVANT

*$S^3E$–Sisters Three Entrepreneurs Security Consultants Company, West Hollywood, California and Magallanes Associates International (MAI), Thousand Oaks, California*

## 1 INTRODUCTION

To provide for the economic and national security of America, it is essential that we establish and maintain a telecommunications capability adequate to satisfy the needs of the nation during and after any national emergency. We now live in a world that is increasingly more dependent on information and the technology that allows us to communicate and do business globally, at the speed of light. Information has always been time-dependent but is more so today than ever. The composition of the telecommunications sector evolves continuously due to technology advances, business and competitive pressures, and changes in the marketplace and regulatory environment. Despite its dynamic nature, the sector has consistently provided robust and reliable communications and processes to meet the needs of businesses and governments [1].

## 2 BACKGROUND

### 2.1 A Historical Perspective

The Telecommunications Sector has evolved from a predominantly closed and secure wire-line telecommunications network focused on providing equipment and voice services, into a diverse, open, technologically sophisticated, highly interconnected, and complex industry with a wide array of infrastructure that spans critical aspects of the US government, economy, and society.

Three distinct policy events have shaped the course of the modern-day telecommunications industry. The first event was the 1984 court-ordered breakup of AT&T [2], a company that controlled the majority of the local and long distance markets. The second event was the passage of the Telecommunications Act of 1996 [3], which opened local PSTN (public switched telephone network) service to competition. It required incumbent carriers to allow their competitors to have open access to their networks. As a result, carriers began to concentrate their assets in collection facilities and other buildings known as telecom hotels, collection sites, or peering points instead of laying down new cable. Internet Service Providers (ISPs) also gravitated to these facilities to reduce the costs of exchanging traffic with other ISPs. Open competition has caused the operation of the PSTN and the Internet to become increasingly interconnected, software-driven, and remotely managed, while the industry's physical assets are increasingly concentrated in shared facilities. The third event was the horrific attacks of 2001, which led to sweeping changes in the reorganization of the US government with the creation of the US Department of Homeland Security (DHS), the realignment of security responsibilities of several government agencies under this new entity, and a wave of laws and national actions aimed at redefining the importance of the telecommunications and other sectors, and their threat environment. Homeland security is a concerted national effort to prevent terrorist attacks within the United States, reduce America's vulnerability to terrorism, and minimize the damage and recover from attacks that do occur [4].

In response to the attacks of 2001, the DHS issued a National Infrastructure Protection Plan (NIPP) in June 2006. This plan establishes a bold, comprehensive unifying structure and overall framework for the integration of national critical infrastructures and key resources protection efforts, into a single National Security Program. It requires designated lead federal agencies to work with the private sectors to address how sector stakeholders should implement the national strategy and protection measures, and how they can improve the security of their assets, systems, networks and functions [5].

The telecommunications sector, the theme of this article, is one of the 18 major industries identified in the NIPP as a National Critical Infrastructure. These sectors are diverse, operate in every State and affect every citizen, private and public entity, and the government at every level. The National Telecommunications Sector-Specific Plan augments the NIPP and describes the collaborate efforts between state, local, and tribal governments; nongovernmental organizations; and the federal government to secure the sector from a terrorist attack or other disaster. The plan offers a road map to prioritizing protection initiatives within and across the sector to ensure risk mitigation by lowering vulnerabilities, deterring threats, and minimizing the consequences of attacks and other incidents [1].

## 2.2 What Makes Up The Telecommunications Sector?

The Communications Sector is integrally linked with the Information Technology (IT) Sector. In general usage they are often referred to and incorporated under the common name "Telecommunications Sector." Driven by twenty-first century technology transformation and convergence, the Communications and the IT Sectors are becoming more closely aligned with telecommunications and eventually will merge into one entity. For the purposes of this article we will consider that merging to have taken place. The Telecommunications Infrastructure Sector [6] is a complex system of systems that incorporates multiple technologies and services with diverse ownership. More than 85 percent of telecommunications-related assets, systems, and networks are owned and operated by the private sector. Some owners and operators are government or quasi-government entities.

The infrastructure includes wire-line, wireless, satellite, cable and broadcasting, and the transport networks that support the Internet and other information systems. The sector provides voice and data service to public and private users through a complex and diverse public network infrastructure encompassing the PSTN, the Internet, and private enterprise networks. The PSTN provides switched circuits for telephone, data, and leased point-to-point services. It consists of physical facilities, access tandems and other equipment. The physical PSTN remains the backbone of the infrastructure with cellular, microwave, and satellite technologies providing extended gateways to the wireline network for mobile users. The Internet and private enterprise networks are key resources, comprising the domestic and international assets within both the IT and Communications Sectors, and are used by all other sectors to varying degrees.

## 2.3 How Do We Secure the Telecommunications Sector?

Much of the expertise required for planning and taking action to protect telecommunications assets lies outside the federal government, including precise knowledge of what needs to be protected [7]. The sector has historically factored natural disasters and accidental disruptions into network resiliency architecture, business continuity, and emergency preparedness planning strategies. The interconnected and interdependent nature of these service provider networks has fostered information sharing, cooperative response, and recovery relationships for decades. Since one service provider network problem nearly always impacts the networks owned and operated by other network providers, the community has a long-standing tradition of cooperation and trust, even in today's highly competitive business environment. Owners and operators have always been responsible for protecting their physical assets against unauthorized intruders. These measures, however conventionally effective in the past, generally have not been designed to cope with significant military or terrorist threats or the cascading economic and psychological impacts they may entail [8]. Such planning to defend against a terrorist attack is a relatively new phenomenon for the industry. With the wide range of operators and owners, companies, technologies, and government interests that make up the telecommunications community, it is important to find common ground in establishing sector security goals. Despite any initial variances in agreeing on a single strategic security vision, much headway has been made and new security enhancement initiatives continue to emerge as new technologies are developed and employed. Moreover, the telecommunications sector recognizes that other critical infrastructures are highly dependent on its services for basic operations. In this respect, interconnection, interoperability, and security are achieved

through technology standards, regulations, carrier agreements, and inter-carrier cooperation, enabling the infrastructure to operate effectively and rapidly restore networks after a disaster. Resiliency is achieved through the technology, redundancy, and diversity employed in the network design and by customers who plan for and employ diverse and resilient primary and backup communications capabilities [9]. Although industry partners maintain and protect the core backbone of the network and share assets and systems, and the facilities connecting these assets to the customer premises, customers are largely responsible for developing and employing mitigation strategies for access to their portion of the network through continuity of operations planning [10].

### 2.4 What are Critical Telecommunications Infrastructure Systems and Assets?

The U. S. Patriot Act defines *critical infrastructure* as "systems and assets, physical or virtual, so vital to the U.S. that the incapacity or destruction of such systems and assets would have a debilitating impact on national security, national economic security, national public health and safety, or any combination of these matters." Telecommunications, IT, and cyber space systems, functions and assets fall under this definition [11].

### 2.5 What is the U.S. Policy on Protecting National Critical Telecommunications Services and Computer-Driven Systems?

The Telecommunication Infrastructure and its computer-driven systems are essential to the nation's security, public health and safety, economic vitality, and way of life. Within the government these systems process and communicate classified national security information concerning the vital interests of the United States. This is necessary to gather intelligence, conduct diplomacy, command and control military forces, provide continuity of essential functions of government, and to reconstitute the political, economic, and social structure of the nation. A survivable communications system is a vital component of our deterrent posture for national defense. Within the private sector these systems process and communicate sensitive business, financial, and other competitive information vital to the interests of specific enterprises. Computer-driven systems monitor, operate, and maintain prime systems in all commerce activity: Banking and Finance; Busing and Ocean Liners; Chemical; Civil Aviation; Commercial Real Estate; Defense Industrial Base; Drinking Water and Water Treatment; Education and Research; Emergency Services; Energy (electric, oil, gas, and nuclear); Food and Agriculture; Manufacturing and Construction; Postal and Shipping; Public Health and Healthcare; Seaports and Staging Areas; and Trucking and Distribution Terminals. These services provide for the economic stability and survivability of the nation.

The national policy [12] to protect telecommunications has evolved from experiences and events stemming from previous national security incidents, natural disasters, and industrial mishaps. A family of policy directives and federal laws now formulate the policy of the United States to protect these systems. The overarching goals [13] of the US policy are as follows:

1. Build a safer, more secure, and more resilient America by enhancing the protection of telecommunication assets, operations, functions, and systems.
2. Prevent, deter, neutralize, or mitigate the effects of deliberate efforts by terrorists to destroy, incapacitate, or exploit them.

3. Ensure that disruption, interruption, or manipulation of critical functions that do occur are brief, infrequent, manageable, geographically isolated, and minimally detrimental to the welfare of the United States.
4. Strengthen national preparedness, timely response, and rapid recovery in the event of an attack, natural disaster, or industrial mishap.

The national policy to secure cyberspace [14] further articulates five national priorities: (i) the establishment of a security response system, (ii) a threat and vulnerability reduction program, (iii) an awareness and training program, (iv) efforts to secure government cyberspace, and (v) international cooperation. The policy emphasizes that cyber elements should have the following characteristics:

- Be robust enough to withstand attacks without incurring catastrophic damage;
- Be resilient enough to sustain nationally critical operations;
- Be responsive enough to recover from attacks in a timely manner.

The US policy focuses on protection measures that ensure essential government operations, public services, and economic functions are maintained in the event of a terrorist attack, natural disaster or other type of incident, and that elements of the telecommunication sector are not exploited for use as weapons of mass destruction.

## 3 THREATS, CHALLENGES, AND CONTINUOUS IMPROVEMENT

### 3.1 The General Threat Assessment

The threat to the telecommunications sector did not emerge on September 11, 2001. Long before that day, the nation's electronic systems had been targets of interception and disruption during times of war and armed conflicts, and from those who engaged in economic espionage and other criminal activity.

In less than one generation, the information revolution and the introduction of the computer into virtually every dimension of our society has changed how our economy works, how we provide for our national security, and how we structure our everyday lives. In the future, computer-related technologies will continue to open new vistas of opportunity for the American people. Yet this new age of promise carries within it peril. All computer-driven systems are vulnerable to intrusion and destruction. A concerted attack on the computers of any one of our critical infrastructures could have catastrophic affects on the economy [15].

The telecommunications sector faces both natural and man-made threats. It is susceptible to cyber threats such as interception, unauthorized electronic access, related forms of technical exploitation, as well as the hostile intelligence threat. The technology to exploit these electronic systems is widespread and used extensively by foreign nations, terrorist groups, and criminal elements. Other threats confronting the sector include: natural threats; cyber threats; workforce threats; explosive, chemical, and biological terrorist threats; and supply chain threats. The sector also is vulnerable to unintentional human error because of its high reliance on human interaction. It is important to mention that the threat assessment performed by the Homeland Infrastructure Threat and Risk Analysis

Center (HITRAC) on the Telecommunication Sector identified only a few direct threats, giving the sector a *low* threat rating. However, the risk for the sector as a residual target is *moderate to high* due to its interdependencies on other critical infrastructure and the significant consequences of loss that could materialize from collateral damaged sustained to sector assets and services, resulting from a direct attack upon the assets of another sector [16].

### 3.2 The Threat to America's Telecommunications Components

Attacks on telecommunications assets can produce cascading collateral damage for other sectors, far beyond the targeted asset and physical location of the incident. Natural, man-made or technological hazards could produce catastrophic losses in terms of human casualties, property destruction, and economic effects, as well as profound damage to public morale and confidence. Conversely, an attack on another sector could affect telecommunications assets. During the 2001 attacks, the telecommunications sector was not a direct target but nonetheless, significant damage impaired telecommunications facilities, lines, and equipment in the northeastern part of the nation. Much of the disruption to voice and data communications services throughout lower Manhattan occurred when a building at the World Trade Center complex collapsed into an adjacent Verizon communications center, which served as a major local communications hub within the public network. Approximately 34,000 businesses and residences in the surrounding area lost services for extended periods. Several critical government operations, among them the Federal Aviation Administration, NY City services, NY/NJ Port Authority, US Customs, FBI and US Secret Service activities were affected. Disruptions to other government and private customers in other service areas also occurred, as various carriers had equipment collocated at the site that linked their networks to Verizon. In addition, a considerable amount of telecommunications traffic that originated and terminated in other areas also passed through this location and was disrupted. AT&T's local network service in lower Manhattan was significantly disrupted following the attacks, which directly affected the operations of the World Financial District, the Stock Exchange, and international banking operations. Conversely, the electric system [17] in New York City remained operational for the island of Manhattan outside of the World Trade Center complex. Furthermore, needed electric service at Ground Zero was quickly and efficiently restored to support rescue and recovery operations.

Although not directly targeted, the telecommunications sector became a victim of significant cascading collateral damage. The loss of telecommunications service, as well as the damage sustained to the energy, water, banking and financial, public health, and transportation infrastructures created significant management challenges for the city of New York during the crisis. Despite this, the telecommunications sector demonstrated remarkable resiliency as the direct damage to its assets and operations was offset by diverse, redundant, and multifaceted communications capabilities—*a key aspect of security for this infrastructure* [18].

### 3.3 The Threat to America's Internet Networks

The Internet threat is not only physical damage to its assets but also stems from an intruder's ability to hack into the system from the outside and be capable of causing

disruption or destruction from within. The most widely reported Internet security problems of the past few years are "denial-of-service", which are designed to "crash" systems. With the explosive growth in broadband services, high-speed Internet access for home users makes it likely that future denial-of-service attacks on home computers will emerge. The misuse of the on-line environment through spam, identity theft, fake websites, and other means threaten to undermine the potential economic and social benefits of the on-line environment by eroding the trust and confidence in its safety and security [19].

Another concern is the potential for an intruder to hijack a user's computer, establishing a "backdoor" that can be activated anytime the computer is on-line, giving the intruder control over the user's system. Ironically, as government and corporate organizations have hardened their networks and become more sophisticated at protecting their systems, they have driven adversaries to pursue other targets of opportunity. Home-users with broadband connections are these new targets of opportunity both for their own computing resources and as an alternative method for attacking and gaining access to government and corporate networks [14].

Every day, in America, thousands of unauthorized attempts are made to intrude into the computer systems that control key defense facilities, power grids, banks, government agencies, telephone systems, nuclear power plants, water treatment plans, and public health and transportation systems. Some attacks are the equivalent of car thief "joy riders," committing a felony as a thrill. Others are committed for industrial espionage, theft, revenge-seeking vandalism, or extortion. Still others are committed for intelligence collection, reconnaissance, or the creation of a future attack capability. The perpetrators range from juveniles to thieves, from organized crime groups to terrorists, and from hostile militaries to intelligence services of foreign governments [20]. What has emerged in the last several years is an increase in the seriousness of the threat and a broadening of infrastructure sector targeting. Cyber crime costs have reached $100 billion a year in business disruptions and damage to systems. As a result, the Justice Department's Computer Crime and Intellectual Property Section, the FBI's Cyber Division, and the US Secret Service Electronic Crimes Task Force all play a central role in tracking crime and offenders, apprehending, and bringing to justice the responsible individuals and organizations [21].

## 4 TELECOMMUNICATIONS CHALLENGES AND CONTINUOUS IMPROVEMENT

Managing threat and reducing vulnerability in the telecommunications sector is a particularly complex challenge. While industry partners have been successful in protecting the core backbone of the telecommunications network, gaps exist in customer user responsibility. Not all customer critical systems and operations are supported by diverse primary and backup telecommunications capabilities or address the issue of single point failure consequences. Developing and employing mitigation strategies for their portion of the network, and mitigating their own risk through continuity of operations planning requires strengthening [22].

Table 1 summarizes a sampling of some of these challenges and potential solutions. The listing by no means is all-inclusive. My goal is to provide a top-level overview of some of the most significant complexities facing the telecommunications sector and what is being done, or should be considered, to narrow the vulnerability gap.

**TABLE 1 Telecommunications Sector Challenges and Continuous Improvements**

| Significant Challenges | Continuous Improvement |
|---|---|
| **1**. *Vagueness and ambiguity of planning*. In 2005, the Government Accountability Office (GAO) [23] reported that sector-specific plans varied significantly in addressing security protection measures. None of the 18 sector-specific plans fully addressed all 30 cyber security-related criteria. The Telecommunications and Information Technology Sector plans fully addressed many of the criteria, but the remaining 16 sector plans were less comprehensive. | • Enterprises that fell short of achieving expectations must adapt to the changing threat and hazard environment to address weaknesses and gaps in protection.<br>• Enterprises must continuously evaluate program weaknesses to reduce risk and introduce reasonable and prudent mitigation solutions.<br>• The emerging terrorist threat requires new approaches focused on intelligence-driven analyses, information sharing, and unprecedented partnership between the government and the private sector. |
| **2**. *Identifying and prioritizing critical assets*. The national security strategy for protecting critical resources recognizes that it is not practical or feasible to protect all assets, systems, and networks against every possible terrorist attack all the time [24]. | • Protection planning must address the full range of plausible threats and hazards, not just those most frequently reported or considered to be the most likely to occur.<br>• A proactive performance-based approach is required to enhance the decision-making processes, provide advance warning to potentially targeted assets and assist owners and operators in taking steps to protect assets in an all-hazards environment.<br>• The approach requires a coordinated and focused effort from our entire society. |
| **3**. *Protecting privacy and civil liberties*. Technologies designed to protect information and systems, if not carefully utilized, could inadvertently undermine civil liberties. Even with the best of intentions, technology that protects against intrusions, when cast too broadly, might profile innocent activity [25]. | • The U.S. Government must continue to do the following:<br>◦ protect the private information of its citizens that resides on its computer systems;<br>◦ partner with the private sector to protect personal information within their systems;<br>◦ consult with communities to define acceptable solutions; conduct legal reviews; and commit to comply with statutory and privacy solutions;<br>◦ develop robust intelligence and law enforcement capabilities to protect information systems, consistent with the law.<br>• Ensure the protection of American citizens' civil liberties, their rights to privacy, and to the protection of proprietary data. |

(*continued overleaf*)

**TABLE 1 (*Continued*)**

| Significant Challenges | Continuous Improvement |
|---|---|
| **4**. *Internet architecture and working remotely*. With many corporations allowing employees to work at home, computer systems used for business purposes outside the official work environment create a challenge for enterprises to safeguard such systems from attack. As organizations increasingly demand remote connectivity to corporate and government networks, the security of these remote endpoints becomes increasingly critical to the overall protection of the network. This increase in interconnectivity exposes the on-line environment to a growing number, and a wider variety, of threats and vulnerabilities [26]. | • A need exists to redesign the national information infrastructure. Initially it was built quickly and without concern for security, without thought that a sophisticated enemy might attack it. Now we must fix it to protect, guard against, or reduce the existing vulnerabilities.<br>• Government and industry must continue to work together to understand vulnerabilities, develop countermeasures, establish policies and procedures, and raise awareness necessary to mitigate risks. This includes the following:<br>◦ defining an appropriate threshold for security;<br>◦ expanding infrastructure diverse-routing capability;<br>◦ understanding the risks associated with vulnerabilities of the telecommunications infrastructure. |
| **5**. *Improving system performance, reliability and efficiency*. Significant challenges are to ensure the diversity of telecommunications services; to improve the reliability and efficiency of networks, telecommunications carriers, and the physical network facilities they use to route circuits; and to support critical government and industry operations to withstand the effects of wide-scale network disruptions [27]. | • Promote collaboration to advance performance, technology, and security. Partnerships and organizations currently available to address security include the Presidents National Critical Infrastructure Board, the Government Network Security Information Exchanges, the Telecommunications Information Sharing Analysis Centers (ISAC), and the National Reliability and Interoperability Council of the Federal Communications Commission (FCC). Other programs include the National Security Telecommunications Advisory Committee, Government Emergency Telecommunications Service, Telecommunications Service Priority and Wireless Priority Service, Special Routing Arrangement Service, Next Generation Priority Service, and the Hotline System. The continued success of these partnerships and programs assures the reliability and interoperability of the government's owned or commercially provided national security and emergency preparedness communications resources. |

- Redundancy within the infrastructure is also critical to ensure that single points of failure in one location will not adversely impact connecting others. Security assessment teams need to characterize this state of diversity and collaborate to understand the topography of the physical components of the architecture in order to establish a foundation for defining a strategy that ensures physical and logical protection diversity.
- Improving business protocols, hardening facilities, building resiliency, incorporating hazard resistance into facility designs, initiating countermeasures, installing security systems, leveraging "self-healing" technologies, promoting workforce surety programs, and implementing cyber security measures will enhance program performance effectiveness.

6. *Consistency in applying evaluation measurement standards*. Although stakeholders share similar objectives, they have different perspectives on what constitutes acceptable risk and how to achieve security and reliability. Therefore, an agreement on a sustainable security threshold and corresponding security requirements remains elusive [28].

- Adapting the measurement and evaluation criteria described in the NIPP will provide uniformity to the analysis process.

7. *Government and private sector cooperation*. There is a growing awareness that confidence and security in the use of the on-line environment cannot be addressed solely as a technology matter, but requires that all users be aware of the security risks and preventive measures, assume responsibility, and take steps to strengthen the security and reliability of information and the networks it travels on [29].

- There is a need for strong leadership between government and the private sector, for outreach to users, and for cooperation across borders.
- Reducing risk requires an unprecedented partnership between our country and our global partners. This includes agency involvement by the:
  - National Coordinating Center for Telecommunications
  - National Counterterrorist Center
  - National Joint Terrorist Task Force
  - US Coast Guard Intelligence Coordination Center
  - National Maritime Intelligence Center
  - International Maritime Intelligence Center

(*continued overleaf*)

**TABLE 1 (*Continued*)**

| Significant Challenges | Continuous Improvement |
|---|---|
| | • No single strategy can eliminate cyberspace vulnerabilities and their associated threats. The nation must continue to work with industry to manage risk and to enhance its ability to minimize the damage that results from attacks that do occur. This includes the following strategies:<br>◦ develop cohesive domestic strategies to ensure a trusted, secure, and sustainable on-line environment;<br>◦ address the threat posed by the misuse, malicious use, and criminal use of the on-line environment;<br>◦ develop watch, warning, and incident response and recovery capabilities to prevent cyber attacks and minimize damage and recovery time;<br>◦ encourage the establishment of mutual assistance programs for cyber security emergencies;<br>◦ raise awareness about the removal of impediments to information sharing about cyber security vulnerabilities between the public and private sectors;<br>◦ encourage software industry to consider promoting more secure "out-of-the-box" installation and implementation of their products;<br>◦ facilitate a national effort to promulgate best practices and methodologies that promote integrity and reliability in software code development, and processes and procedures that diminish the possibilities of erroneous code, malicious code, or trapdoors that could be introduced during development. |

**8**. *International protection*. Telecommunications networks are global in scope and extend beyond US borders. The federal government and private sector corporations also have a significant number of critical facilities located outside the United States. Providing adequate protection measures for these assets and services presents unique challenges [11].

- Industry and the US State Department should continue their involvement in international organizations such as those listed below:
  - G8
  - United Nations
  - NATO
  - European Union
  - Organization of American States
  - Asia-Pacific Economic Cooperation
  - Organization for Economic Cooperation and Development
  - International Maritime Organization
  - International Watch and Warning
- The US State Department should continue to collaborate with other federal agencies and international partners to do the following:
  - identify and prioritize the nation's critical foreign telecommunications dependencies;
  - build and strengthen international partnerships;
  - implement a comprehensive, integrated, international risk management program;
  - implement protection programs and resiliency strategies;
  - share information with international entities;
  - perform outreach to enhance information exchange and management of international agreements.
  - protect assets, systems, and networks that operate across or near the borders of foreign countries or rely on international aspects to enable critical functionality, require continuing coordination, and planning with all stakeholders;

(*continued overleaf*)

**TABLE 1** (*Continued*)

| Significant Challenges | Continuous Improvement |
|---|---|
| | ◦ interact with foreign governments and international organizations to enhance the confidentiality, integrity, and availability of cyber-based infrastructure having an international or global dimension;<br>◦ coordinate the protection of physical assets located on, near, or extending across the borders with Canada and Mexico or those with important economic supply chain implications;<br>◦ coordinate protection needs where the service originates from outside the United States to include US government and corporate facilities located overseas; |
| **9**. *The Technology Revolution and its impact on law enforcement activities*. Rapid changes in the telecommunications and computer industries have blurred the traditional gaps that separated these technologies. While the result of these changes improved our capability, many improvements make it difficult for law enforcement agencies to detect and prevent terrorist acts and inhibit lawfully authorized electronic surveillance. Some advanced technologies that form the backbone of the information superhighway also nullify the effectiveness of traditional methods of carrying out court-authorized wiretaps. Encryption technologies used to protect data are now available lawbreakers, preventing the government from obtaining contents of information it is authorized to intercept [30]. | • Adapt legislation and appropriations to support lawful programs.<br>• Encourage and fund research and development to create capabilities to respond to lawful searches.<br>• Develop new encryption technologies to counter the capabilities of lawbreakers.<br>• Continue to improve surveillance, monitoring, and detection capabilities to discover threats in the making rather than responding to an attack after the fact. |
| **10**. *Trained people*. America is short on training the IT specialists it needs to operate, improve, and secure its new IT-based economy. | • A nationwide initiative to recruit, employ, train, and retain adequate numbers of information security specialists to meet the demands of the industry is in order. |

## 5 CONCLUSIONS

### 5.1 Performance, Reliability and Efficiency

Three national program elements contribute to the stability and survivability of the telecommunications sector. The first is the advancement in micro-electronics technology, which has stimulated an unprecedented growth in the supply of telecommunications and information processing services. The second is the resiliency built into the telecommunications infrastructure that has increased the availability of services to its customers and reduced the impact of outages. The third is the priority service programs that have contributed to the continuance of critical telecommunications services and functions during an emergency [31]. Collectively, these initiatives have directly advanced the US policy on protecting national critical telecommunications services and computer-driven systems.

### 5.2 The Threat to America's Telecommunications Sector

The pace of the technological drive to install computer controls in every one of our nation's critical infrastructures far outstrips our potential to design computer security software, train IT security personnel, or develop and promulgate computer security practices and standards. We have created a gaping vulnerability in our national security and economic stability that affects not only computer-controlled systems, but also the vital databases maintained by public health centers, law enforcement, legal and judicial institutions, educational and research institutions, and proprietary data managed and operated by other sector functions and systems. We are vulnerable to mischief-making hackers, hardware and software failures, cyber criminals and, most alarmingly, to deliberate attack from nation states and terrorists. To complicate matters further, most critical infrastructures interconnect and therefore, depend on the continued availability and operation of other systems and functions. This interconnectivity is provided by the IT and telecommunications sectors, which increasingly control the operations and productivity of the other critical infrastructures. Given the dynamic nature of these interdependent infrastructures and the extent to which our daily lives rely on them, a successful terrorist attack to disrupt or destroy IT and telecommunications critical assets could have a tremendous impact beyond the immediate target and continue to reverberate long after the immediate damage is done [7].

### 5.3 Future Research Direction

The unique characteristics of the telecommunications infrastructure sector, the rapid change in technology, and the significant impediments complicating their protection requires an unprecedented level of public and private sector cooperation and government coordination. The challenge ahead is to develop a coordinated and complementary system that reinforces protection efforts rather than duplicates them, and that meets mutually identified essential requirements. In addition, many telecommunications assets, systems, and functions span national borders and, therefore, must be protected within the context of international cooperation [32].

Several government initiatives [33] have helped keep America safe since the 2001 attacks. The first initiative is the development of partnerships among government,

industry, academics, and others to ensure a trusted, secure, and sustainable telecommunications environment through the development, implementation, and review of guidelines and best practices. These federal programs augment the extensive state, local, tribal, territorial, and private sector protection programs that constitute important efforts already being implemented. The second initiative is the creation of Homeland Security Centers of Expertise, which challenges us to marshal our nation's advantages in the sciences and technology. These Centers are combating terrorism across a wide range of research and development activity and are studying the following:

- the interactions of networks and the need to use models and simulations;
- risk analysis related to the economic consequences of terrorist threats and events;
- potential threats to animals and agriculture and agro-security issues related to postharvest food protection;
- improvement and promotion of the design, development, and implementation of usable security measures in existing and new technologies.

The third initiative is the removal of structural and legal impediments that prevented the collection and sharing of information by our law enforcement and intelligence agencies. The fourth initiative concerns the government's diplomatic outreach and operational capabilities to build global partnerships to combat cyber crime whenever it originates.

### 5.4 The Prospects for the Future

Despite all the hard work accomplished to create new laws and the means to combat telecommunications terrorism, our work is far from complete in both planning and execution. We can expect to see more frequent and escalated planning activity by adversarial groups to attack our critical assets. Future attempts to disrupt or damage our communications capabilities is almost evident and probably a matter of time. The threat is that in a future crisis a criminal cartel, terrorist group, or hostile nation could seek to inflict economic damage, debilitating disruption and death, and degradation of our national response by attacking critical networks. Terrorists are relentless and patient. They are also opportunistic and flexible. Terrorists are inventive and resourceful in terms of target selection, as well as in the selection and use of specific instruments of violence, and intimidation at the time and location of their choosing [34].

In focusing our protection efforts, we must acknowledge three key factors [35]: (i) Given the immense size and scope of potential target sets within the telecommunications sector we cannot protect completely all things, at all times, against all conceivable threats. (ii) The assets, systems and functions that comprise the telecommunications infrastructure are not uniformly "critical" in nature, particularly in a national or regional context. (iii) Given the dynamics of the sector's size and scope, and diversity of mission, we must prioritize protection strategies to reduce vulnerability and threat condition; to maximize program effectiveness, efficiency, resources, and funding allocations; and to maximize returns on our investment.

Despite the tremendous effort we are putting into our planning, no protection strategy can succeed in isolation. It must be a part of a larger strategy that is responsive to economic and national security considerations [36]. We must move forward with the understanding that there are enemies who seek to inflict damage on our way of life.

They have attacked us on our own soil, and they have shown a willingness to use unconventional means to execute those attacks. The attack tools and methodologies they are employing are becoming widely available and, the technical capability and sophistication of users bent on causing havoc or disruption is improving. We now have an opportunity and an obligation to take action to prevent, deter, neutralize, or mitigate the effects of deliberate efforts to disrupt, interrupt, manipulate, destroy, incapacitate, or exploit telecommunications assets. We must renew our resolve to embark upon a program of self-assessment to identify program weaknesses; mitigation analysis and problem-solving to strengthen our security status; advanced research and development to improve technology performance and survivability; and enhance practices whereby we can objectively reduce the risk to telecommunications resources, assets, facilities, systems, and functions.

# WIRELESS SECURITY

MATTHEW SEXTON, EDWARD SMITH, AND BERNIE EYDT
*Booz Allen Hamilton, McLean, Virginia*

## 1 SCIENTIFIC OVERVIEW

Wireless networks have undoubtedly proliferated into many aspects of daily life, both personal and professional. Although many wireless networks exist, ranging from cellular networks to Wireless Fidelity (Wi-Fi), they can be divided into two primary categories: data-centric and voice-centric. Data-centric wireless networks primarily provide extensions of the existing Internet Protocol (IP)-centric networks and evolved from wired IP-centric networks providing security similar to that of wired networks. Voice-centric wireless networks evolved as extensions of the legacy wireline telephony networks and focus security on end user issues, such as cloning, billing fraud, and other forms of subscriber-based attacks. This end user fraud protection focus, although valid for an extension of the wireline voice network, offers weaker security architecture for data services added to the voice network as enhancements to user services.

### 1.1 Voice-Centric Networks

Security within today's voice-centric networks has advanced well beyond the rudimentary security provided by first-generation mobile phone services that were mere extensions of the public service telephone network (PSTN). User authentication, voice and data privacy, and assurance of transmitted data are becoming the norm in wireless voice services. Security technologies have evolved as voice and data networks have converged with modern cellular networks, which have a mixture of security technologies. Third-generation (3G) cellular networks are poised to enhance security based on lessons learned from current networks and the application of technologies from data-centric networks. The following is a brief summary of the advances and issues with current and future voice-centric wireless networks.

***1.1.1 Network Evolution Path.*** Cellular security is the result of two evolutionary paths taken from first-generation cellular services, which were simple extensions of the PSTN. In the United States, wireless security evolved from the first-generation Advanced Mobile Phone Service (AMPS), which provided limited security. The United States deployment of second-generation cellular (time division multiple access technology and code division multiple access [CDMA] technology) took a more limited approach to security and focused on addressing issues identified with the AMPS service, such as billing fraud resulting from the ability to clone phones and off-air voice intercept.

The first cellular enhancement addressed in the United States was billing fraud resulting from thieves collecting user information from off-air signaling and using that

information to clone phones. The solution was to employ more robust user authentication through a challenge-response method known as the *cellular authentication and voice encryption* (CAVE) algorithm. The CAVE algorithm is a challenge-response method that uses network and user parameters to develop shared secret data (SSD) to form the basis of over-the-air parameter exchanges. The method uses cryptography to create a dynamic authentication response used to verify the identity of the user, thus greatly reducing the possibility of successful phone cloning and fraudulent access.

Another US enhancement was increased voice privacy. This enhancement was made possible by increasing the complexity of the signal modulation and voice coding techniques employed in the digital transmissions, and by adding the optional application of a voice privacy mask to the digital voice. The digital modulation made the possibility of publicly available radiofrequency (RF) intercept systems, such as police scanners, intercepting and decoding the voice extremely unlikely. The application of a voice privacy mask added security from unwanted intercept if the data was intercepted.

Today, 3G cellular communications face many of the same design challenges and constraints as its 2G/2.5G ancestors. Two standards bodies govern the cellular industry; the Universal Mobile Telecommunications System (UMTS) is specified by the Third Generation Partnership Project (3GPP) and the CDMA2000 architecture is specified by 3GPP2 [1]. Both systems face many of the same risks and threats, and therefore share a number of common security elements or traits [2].

Subscriber authentication, session confidentiality, and signaling integrity are the primary goals of secure communications. UMTS and CDMA2000 security protocols such as the authentication and key agreement (AKA) protocol are more robust mechanisms designed to limit the vulnerability of and improve the security stance of cellular communications. A central concept for all wireless communications is access security. Restricting subscriber access to authenticated and authorized devices, coupled with voice and data encryption will reduce an organization's network vulnerability.

The Internet Protocol Multimedia Subsystem (IMS), originally designed by the 3GPP, is a widely accepted open standard effort to define an all IP-based wireless network. Its adoption has been slow, but the technology may help promote a convergent future that will bring cellular networks together with other wireless technologies. IMS promotes the use of employing established, open protocols and commodity equipment. This approach facilitates application access and promotes interoperability between disparate networks by bridging the gap for access technology, that is, IMS networks operate with any endpoint that supports IP capabilities. However, since IMS requires new network infrastructure, many carriers have been slow to implement their rollout plans because of costs and complexity.

***1.1.2 Project 25 Digital Radio.*** Project 25 (P25) is a standard for the manufacturing of interoperable digital two-way wireless communication products. Formed in 1989, P25 began as a joint effort between the National Association of State Telecommunications Directors (NASTD), the Association of Public-Safety Communications Officials-International (APCO), and a group of federal agencies to develop a series of standards to define a digital radio system (conventional and trunked) [3]. The Telecommunications Industry Association (TIA)-102.AAAB standard provides an overview of the security services available in land mobile radio (LMR) [4]. It generalizes security requirements into three categories: (i) confidentiality, (ii) authentication and integrity, and (iii) key

management. Two additional security-related TIA standard documents detail block encryption [5] and over-the-air-rekeying (OTAR) [6].

Either the Data Encryption Standard (DES) or Advanced Encryption Standard (AES) can provide confidentiality. Currently, AES support is required for compliance with the P25 block encryption standard, and DES is optional. Although DES was officially withdrawn (i.e. Federal Information Processing Standards [FIPS] 46-3) by the Secretary of Commerce, many governmental organizations including state and local governments still implement this algorithm. Encryption, chronological message numbers, and message authentication codes provide integrity, as does a device's electronic serial number (ESN). A key management facility (KMF) or a key variable loader (KVL) provides key management. A KMF uses OTAR and is therefore much more scalable than the manual use of KVLs to load subscriber device encryption keys. OTAR distributes traffic encryption keys (TEK) using key encryption keys (KEK) (also known as *shadow keys*) to ensure confidentiality of cryptographic secrets. A critical challenge to today's public safety personnel is secure and interoperable communications. There are many challenges to implement a KMF to KMF interface standard, that is, a shared interoperability key environment. Key generation/distribution between multiple agencies remains a challenge for a number of reasons. For example, agencies that employ OTAR may have the same interop keys, but subscriber unit storage location numbers may not map to the proper key identifier required for voice communications. This has been a problem for many years and is discussed in greater depth later in this technical article. It is also important to note that the key rotation schedule for P25 devices usually exceeds 30 days, compared to other wireless technologies that may rotate their communication key each session. While P25 devices can connect to laptops or other data networks [7], their transmission rates are limited and they cannot support broadband data applications.

## 1.2 Data-Centric Networks

***1.2.1 Radio Frequency Identification Technologies.*** Radio Frequency Identification (RFID) technologies are a form of automatic identification and data capture technology that uses electric or magnetic fields at radio frequencies to transmit information [8]. RFID tags are tiny microchip transponders that constantly listen for a radio signal sent by transceivers. The majority of RFIDs are "passive" or do not require a power source, they get their power from the radio signals themselves. Several common uses of RFID are: asset tracking, manufacturing, retailing, payment systems, security and access control, and even health care patient tracking. RFID has two groups of technical controls: controls to protect the tag, and controls to protect RF communications. Security controls vary by tag generation, and by the power supply and processing capability of the tag. Security is focused on the system as a whole, rather than the RFID tag alone. A comprehensive review of RFID technical, managerial, and operational controls are detailed in National Institute of Standards and Technology (NIST) SP 800-98: Guidance for Securing RFID Systems [8].

***1.2.2 IEEE 802.11 Wireless Local Area Networks.*** Wireless local area network (WLAN) communications offer organizations and users many benefits, such as portability, flexibility, increased productivity, and lower installation costs. The IEEE 802.11 standards working group developed the medium access control (MAC) and physical layer (PHY) specifications for wireless connectivity for fixed and mobile

devices within a local area. The original confidentiality protocol—Wired Equivalent Privacy (WEP)—was intended to provide security comparable to that of wired local area networks (LANs) [9]. Unfortunately, WEP turned out to be susceptible to a variety of attacks [10], and it suffered even more from poor vendor implementations, such as the reuse of initialization vectors [11] and the use of initialization vector of all zeros [12]. To address WEP's problems, IEEE established an IEEE 802.11 security enhancements working group that published the 802.11i specification. The Wi-Fi Alliance, an industry group, also promoted this effort through interoperability testing of equipment designed to the IEEE 802.11i specification. The Wi-Fi Alliance refers to the IEEE 802.11i enhancements as Wireless-Fidelity Protected Access (WPA).

The initial WPA specification addressed only a subset of IEEE 802.11i, the IEEE security amendment to the MAC layer, because the standard was not yet complete when WPA testing began. WPA employs the Temporal Key Integrity Protocol (TKIP) for data encryption which uses the same RC4 algorithm as WEP, but adds improved key management and message integrity checking. Of WEP, TKIP, and Counter Mode cipher block chaining-message authentication code (CBC-MAC) Protocol (CCMP), only CCMP uses the AES [13], which is FIPS-validated [14]. Both WEP and TKIP are based on Rivest's Cipher (RC4), which is not FIPS-validated. Following ratification of IEEE 802.11i, the Wi-Fi Alliance introduced WPA2, which identifies equipment capable of supporting all 802.11i requirements. In addition, two wired standards were implemented to provide network access control: 802.1x [15] and the Extensible Authentication Protocol (EAP) [16]. A comparison of the IEEE 802.11 security protocols is provided in Table 1.

***1.2.3 IEEE 802.16 Wireless Metropolitan Area Networks.*** As cellular services race toward 3G deployments, Mobile Worldwide Interoperability for Microwave Access (WiMAX) is emerging as a complementary technology to existing telecommunication and fixed-data technologies. The industry trade group WiMAX Forum trademarked the WiMAX name and promotes the interoperability of broadband wireless products based on the IEEE 802.16 standard. WiMAX technology provides yet another wireless service and more drive to develop seamless interoperability standards, such as IMS, among other wireless services, such as cellular and Wi-Fi. WiMAX technology was initially envisioned as a fixed wireless point-to-multipoint service that would provide backhaul services from homes and small businesses. It has evolved beyond this concept into a

technology that can provide not only last-mile access to homes and businesses but also mobile user access to broadband services.

Not only does the technology support coverage of a large number of users in a geographical area from a single Base Station, but also, with the addition of technologies to address mobility, the system is frequency efficient. A frequency reuse of one to one can be employed, resulting in a single carrier frequency used throughout an entire system. In addition, WiMAX provides high quality of service (QoS) for time-critical services, such as Voice over Internet Protocol (VoIP).

***1.2.4 WiMAX Security.*** The end-to-end WiMAX network architecture is based on a security framework that is service-application agnostic and gives users a strong suite of security tools. In particular, the framework supports the following: strong mutual device authentication between a mobile subscriber (MS) and the WiMAX network; all commonly deployed authentication mechanisms and authentication in homes and visited operator network scenarios based on a consistent and extensible authentication framework; data integrity, replay protection, confidentiality, and nonrepudiation using applicable key lengths; use of MS-initiated and terminated security mechanisms, such as Virtual Private Networks (VPN); and standard secure IP address management mechanisms between the MS/subscriber station (SS) and its home or visited network service provider (NSP). Mobile WiMAX supports current security features by adopting the best technologies available today. Support exists for mutual device and user authentication, flexible key management protocol, strong traffic encryption, control and management plane message protection, and security protocol optimizations for fast handovers. Table 2 details the usage aspects of WiMAX's security features.

**TABLE 2 Usage Aspects of WiMAX Security Features**

| WiMAX Security Feature | Description |
|---|---|
| Key Management Protocol | Privacy and Key Management Protocol Version 2 (PKMv2) is the basis of Mobile WiMAX security as defined in 802.16e-2005. |
| Device/User Authentication | Mobile WiMAX supports device and user authentication using RSA or IETF EAP protocol by providing support for credentials that are SIM based, Universal SIM (USIM) based, or digital certificate or username/password based. |
| Traffic Encryption | AES-Counter with CBC-MAC (CCM) is the cipher used for protecting all user data over the Mobile WiMAX MAC interface. The keys used for driving the cipher are generated from the EAP authentication. A traffic encryption state machine that has a periodic key (TEK) refresh mechanism enables sustained transition of keys to further improve protection. |
| Control Message Protection/ Secure Key Exchange | Control data is protected using AES-based Cipher-based message authentication code (CMAC), or MD5-based hash message authentication code (HMAC) schemes. |
| Fast Handover Support | Mobile WiMAX supports a three-way handshake scheme to optimize the reauthentication mechanisms for supporting fast handovers. This mechanism is also useful to prevent any man-in-the-middle attacks. |

RSA, Rivest-Shamir-Adleman; SIM, Subscriber Identity Module.

## 2 MOBILE AND WIRELESS SECURITY LANDSCAPE

Today, the wireless landscape continues to evolve. Security continues to remain a concern in the commercial or public space and for the handling of sensitive or classified information in government or private organizations. Federal data handling requirements are much more complex and restrictive than those in the commercial market; therefore, wireless systems in the government tend to remain independent of one another and commonly fail to implement an enterprise or holistic approach to information security.

The commercial market's security stance is easier to understand than the government market's stance; as a result, the standards bodies that define and develop future technologies are working to address commercial issues without addressing the added security needs of the federal government. To help close this gap, the federal government has become a greater participant in wireless standards development and therefore, interacts directly with industry standards bodies.

Standards bodies promote regulatory compliance by providing the reference model for layered security. The International Organization for Standardization (ISO) Open System Interconnection (OSI) standard is a worldwide communications framework for implementing protocols in seven layers. Wireless security technologies operate at Layer 1 (physical) and Layer 2 (data link) of the OSI model and may be tightly integrated with higher layer (Layers 3–7) security mechanisms to provide to a robust security solution.

### 2.1 Federal Legislation and Regulation

Although wireless security is not specifically addressed in the federal laws, the requirement to protect information affects the implementation of wireless technologies. Title III of the E-Government Act (Public Law 107-347)—the Federal Information Security Management Act (FISMA)—requires each federal agency to develop, document, and implement an agency-wide information security program. The government has also passed legislations to better regulate commercial industry and protect the privacy of American citizens. These laws include the Health Insurance Portability and Accountability Act of 1996, Gramm-Leach-Bliley Act of 1999, and Sarbanes-Oxley Act of 2002. The 9/11 Commission Act of 2007 also mandates an Federal Communications Commission (FCC) vulnerability assessment of the nation's critical communications and systems infrastructure and to create a backup emergency communications system which includes next generation and advanced communications technologies [17]. In April 2007, the FCC chartered the Communications Security, Reliability, and Interoperability Council (CSRIC) to recommend best practices to ensure the security, reliability, operability, and interoperability of public safety communications systems [18].

Legislation focused on the lawful intercept of confidential communications also includes the Communications Assistance for Law Enforcement Act (CALEA). CALEA is a US wiretapping law passed in 1994 that amends Title 18 of the United States Code to make clear a telecommunications carrier's duty to cooperate in the interception of communications for law enforcement and other purposes. CALEA aids law enforcement in its effort to conduct surveillance of citizens via digital telephone networks within the United States.

### 2.2 Federal Standards and Guidance Publications

This category of information security guidance is primarily provided by NIST [19] publications in accordance with the NIST's statutory responsibilities under FISMA. Federal agencies are required to use FIPS-validated cryptographic algorithms verified by the Cryptographic Module Validation Program (CVMP). Products validated as conforming to FIPS 140-2 [20] are accepted by federal agencies for the protection of sensitive information. Table 3 presents a list of NIST publications whose topics touch on wireless technologies.

### 2.3 Industry Standards and Guidance Organizations

Standards and guidance organizations play an important role in information security and interoperability. Industry plays an important role by promoting technical progress within a standard, but it can also pose a barrier to interoperable communications. Fortunately, there are non-profit groups that help drive the adoption of wireless communications standards. The major worldwide communications standards organizations periodically meet at an event called *Global Standards Collaboration* [21]. These organizations address many of industry's technical and operational issues to promote interoperable end-to-end communication solutions. The global standards organizations include the International Telecommunications Union (ITU), Telecommunications Industry Association (TIA), Internet Engineering Task Force (ITEF), Institute of Electrical and Electronic Engineers (IEEE), Alliance for Public Technology (APT), International Organization for Standardization (ISO), and the International Electrotechnical Commission (IEC).

Whereas the Department of Defense (DOD) may have departments focused on development of standards and their associated testing to ensure interoperability (e.g. the Joint Interoperability Test Command), civilian agencies lack such standards and verification groups for tactical or mission-critical communications. Fortunately, there are several standards organizations focused on developing this work. The Telecommunications Industry Association, Project 25 Technology Interest Group, Association of Public-Safety Communications Officials International and its subsidiaries promote the development of public safety communications, that is, the Project 25 communications standard. The IEEE 802 LAN/Metropolitan Area Networks (MAN) Standards Committee has also been instrumental in the development of data-centric wireless standards, including IEEE 802.11 (Wi-Fi), 802.15.1-2005[1] (Bluetooth), and 802.16-2004/802.16e-2005 (WiMAX). IEEE is focused on standards development, not interoperability; however, several industry organizations have formed groups (e.g. the WiMAX Forum and Wi-Fi Alliance) to promote the interoperability of several prevalent wireless technologies based on the IEEE 802 family of standards. In addition, perhaps the most widely used wireless technology, cellular communications, is governed through two international partnership projects. The Third Generation Partnership Project (3GPP) focuses on the evolution of the GSM family of technologies to Wideband Code Division Multiple Access (W-CDMA) technologies; whereas, a parallel partnership project, 3GPP2 was established as a collaborative 3G telecommunications specification-setting project for 3G technologies derived from North American Code Division Multiple Access (CDMA) systems (IS-95).

To facilitate the convergence of wireless technologies, the IEEE 802.21 standards body and the 3GPP Unlicensed Mobile Access (UMA) [25] partnerships formed a working group to standardize subscriber access to mobile circuit, packet, and IMS-based services over IP-based access networks, including the Internet.

## 2.4 Governmental Wireless Communications Initiatives

The American National Standards Institute (ANSI) Homeland Security Standards Panel (HSSP) helps identify existing consensus standards. If no standard exists, HSSP assists the U.S. Department of Homeland Security (DHS) and those entities requesting assistance to accelerate development and adoption of consensus standards critical to homeland security [21]. To date, two workshop meetings have been held. Their focus was to identify existing standards, standards under development, and gap areas in standardization for emergency communications. However, government-to-government communications were not addressed by HSSP, as public safety interoperability still remains the responsibility of several Federal agencies and working groups, which include the Federal Communications Commission (FCC), National Public Safety Telecommunications Council (NPSTC), DHS, National Telecommunications and Information Administration (NTIA), Institute for Telecommunication Sciences (ITS), and the National Security Telecommunications Advisory Committee (NSTAC). These organizations promote the advancement of governmental P25 technology and serve as a resource for addressing the telecommunications challenges of Federal agencies, state and local governments.

[1]Following the publication of 802.15.1-2005, the HYPERLINK ”http://en.wikipedia.org/wiki/IEEE” \o ”IEEE” IEEE Study Group 1b voted 90-0 to discontinue their relationship with the HYPERLINK ”http://en.wikipedia.org/wiki/Bluetooth_SIG” \o ”Bluetooth SIG” Bluetooth SIG, effectively meaning that the later versions of Bluetooth will not become future IEEE standards. Bluetooth standards are developed through the Bluetooth Special Interest Group (SIG) http://www.bluetooth.com/Bluetooth/SIG/

DHS relies heavily on wireless communications for mission success. The DHS Science and Technology Directorate is the primary research and development component of DHS, which pilots and evaluates emerging wireless technologies in support of homeland security. The Office of Emergency Communications (OEC) works across Federal, state and local entities to ensure, accelerate, and attain interoperable and operable emergency communications nationwide. OEC has engaged the Federal Partnership for Interoperable Communications Committee to actively address technical and operational interoperable activities with the federal wireless communications community [22]. In addition, DHS has other committees, working groups, subcomponents, and agencies focused on wireless communications and emergency response communications including the Federal Emergency Management Agency (FEMA), National Protection and Programs Directorate (NPPD), Office of Cybersecurity and Communications, Emergency Communications Preparedness Center (ECPC), and the National Communications System (NCS).

Federal government partnerships have also been launched to help facilitate the development of secure and interoperable communications Originally developed by a DoD/National Security Agency (NSA) program, the Secure Mobile Environment Portable Electronic Device (SME PED) is a Type-1 capable mobile and wireless device designed to enhance cross communication and support the mission of the US military, intelligence, and homeland security organizations. The SME PED offers converged secure Type 1 and Non-Type 1 wireless voice and data capabilities and is the first portable device to offer multiple independent levels of secure communication in both unclassified and classified modes.

## 3 CRITICAL NEEDS ANALYSIS

The protection, response, and recovery capabilities among federal, state, and local authorities rely on guaranteed secure wireless communications to extend their disparate wired infrastructures to the first responder. DHS dynamic business requirements and distributed wired infrastructure require complex solutions that are more difficult to secure. All connections to the wireless network must be authenticated, authorized, and protected. Guaranteed communications also require that wireless communications infrastructure provide a high level of availability.

Wireless security must address the areas where the wireless network is vulnerable: the device level and the network level (wireless and wireline). Wireless devices represent the edge of the extended infrastructure and should to be thoroughly secured in case of loss or theft. Unfortunately, a negative trade-off in performance exists when implementing device security. Mobile or portable devices have limited processing and power; therefore, implementing additional device security controls will adversely affect responsiveness and battery life.

Wireless access points are the gateways to an organization's trusted wired network. Although the air interface may be properly secured, a common shortfall of wireless architectures is their infrastructure. Generally, attacks fall into one of two categories: active or passive attacks. Active attacks require actions on the part of the attacker to penetrate or disrupt the network; passive attacks are used primarily for information gathering and surveillance. intrusion prevention systems (IPSs) provide a layer of defense and help protect a wireless system against threat consequences, including unauthorized disclosure, disruption, deception, and corruption [21].

### 3.1 Intrusion Prevention Systems

Wireless IPSs operate at Layer 2 of the OSI model, compared to Layer 3 and higher for wireline systems. IPSs are used to detect the presence of rogue and misconfigured devices, scan the air medium for denial of service (DoS) and other forms of attacks, and take defensive actions to protect the network. A key characteristic of wireless IPS systems is their responsibility to ensure that only authorized devices participate in an enterprise's wireless network. In addition, wireless IPSs address a variety of wireless-only attacks and respond with predefined steps that usually involve the wireless infrastructure. For example, an IPS must be able to identify and respond to known vendor implementation weaknesses, such as the EAP-Lightweight Extensible Authentication Protocol (LEAP) vulnerability to dictionary attacks.

### 3.2 Internet-Based Security Protocols

Wireless technologies must leverage the security capabilities of Internet-based standards. Wireless technologies that implement their own unique security protocols hinder secure and interoperable communications. Security should not be a barrier to communications but rather a catalyst for interoperability.

Federal government-level wireless communications require encryption, authentication, and authorization-related activities. These symmetric and asymmetric keys are required for the generation, distribution, storage, and destruction of cryptographic key material. Public safety technologies should employ key management solutions that are standards-based and promote interoperability.

Wireless technologies can leverage the mature security protocols implemented at higher layers in the protocol stack. For example, Secure Socket Layer (SSL) or Transport Layer Security (TLS) are Layer 4, certificate-based security protocols used extensively over the Internet; Internet Protocol Security (IPSec) is a Layer 3 security protocol that secures Layer 4 and higher. It is important to note that encryption only protects the layer above its implementation. For example, masking an Internet address requires Layer 1 or 2 security, which is where wireless security resides. Secure Multipurpose Internet Mail Extensions (S/MIME) is a security protocol that adds asymmetric encryption for secure text messaging, which is most commonly used for Internet e-mail. Table 4 details some common OSI layer security protocols.

There would be benefit to federal agencies leveraging DoD best practices and technology research. For example, the NIST and NSA established National Information Assurance Partnership (NIAP) to evaluate Information Technology (IT) product conformance to international standards. The program, officially known as the *NIAP Common Criteria Evaluation and Validation Scheme* (CCEVS) for IT Security, is a partnership between the public and private sectors to help organizations select commercial off-the-shelf IT products that meet international security requirements and to help manufacturers of those products gain acceptance in the global marketplace. Twenty countries now recognize the Common Criteria as the official third-party evaluation criteria for IT security products. Civilian agencies may wish to explore NIAP in its product selection to promote security and interoperability throughout the federal government.

First responders and other federal, state, and local personnel will increasingly need to carry radios with multiple air interfaces to interoperate with other agents and civilians in need. The ideal DHS handset would support public safety communication using P25;

**TABLE 4 OSI Layers and Corresponding Security Protocols**

| Layer | Security Considerations |
|---|---|
| Application | Detect and prevent malicious code, viruses, and other malware applications. Mitigation tools include firewalls, antivirus application, and intrusion detection applications. |
| Presentation | Protect data files by cryptography (e.g. file password encryption). |
| Session | Protect system from port exploits and validate digital certificates. SSL operates between the session and transport layers. |
| Transport | Provide authentication and secure end-to-end communications. Encryption protocols include Secure Shell (SSH-2) and Simple Key Management for Internet Protocols (SKIP). |
| Network | Protect the routing and the forwarding protocols. The IPSec standard provides multiple and simultaneous tunnels versus the single connection limit of the lower layer encryption standards. |
| Data Link (Wireless Security) | Protect the MAC layer from masquerade, DoS, impersonation, and Address Resolution Protocol (ARP) threats. Common encryption protocols include the Point-to-Point Tunneling Protocol (PPTP) and the Layer 2 Tunneling Protocol (L2TP). |
| Physical (Wireless Security) | Prevent jamming and DoS attacks in the air medium through frequency hopping and similar techniques. |

cellular telecommunications using CDMA, GSM, and evolving 3G protocols; and personal area communication using Bluetooth, ZigBee, or ultra-wideband techniques. The future will inevitably bring even more capabilities and IP-based services.

First responders need enhanced mobile devices that leverage industry standards to provide secure, scalable, and interoperable communication architectures. In addition, devices need to have a small form factor and be upgradeable, preferably over the air. Approaches that rely on hardware alone do not meet these requirements because adding hardware-based interfaces increases size and weight. Moreover, hardware cannot be modified over the air. Consequently, radio systems will rely increasingly on software. An ideal software radio will be able to switch between all of the air interface protocols discussed on a single platform. The devices might also employ adaptive or cognitive radio technology that senses the spectrum environment and automatically makes choices for the user to optimize the user's communications objectives (e.g. associating with a local Wi-Fi access point when a WiMAX connection is no longer available).

The flexibility of Software Defined Radios (SDRs) also introduces a significant security risk. In particular, when radio systems are software defined, they are vulnerable to software virus attacks. To modify a hardware radio, the attacker must physically touch each device and must have some level of radio expertise. In SDR systems, the potential exists for an attacker to disable thousands of radios over the air using automated tools acquired on publicly accessible web sites.

To counter this threat, SDRs can be designed to authenticate mobile code using digital signature technology. DHS personnel, for example, might only download and execute radio software that has been digitally signed by a DHS authority that vouches for its reliability. SDR platforms can also benefit from isolation kernels and operating systems that can partition computing resources to limit the impact of malicious code. Finally, trusted computing technologies, such as platform attestation and sealed storage, allow network

managers to ensure that only terminals with approved software loads are operating on the network.

## 4 RESEARCH DIRECTIONS

The Internet is the largest system ever built by, and leveraging the Internet's security protocols not only improves interoperability but also improves the public's ability to react and protect against new threats. If a transport medium employs its own unique security protocols, adversaries will quickly adapt and attack a network where it is most vulnerable. Strong physical security or wired encryption is ineffective if the extended wireless network employs untested or weak security controls. Research and development is ongoing and advancing in the wireless security industry. Grants and loans by federal agencies encourage technological advances, help promote economic growth, and encourage international trade.

### 4.1 Intrusion Prevention Systems

As vendors continue to offer all-in-one security solutions, the gap between wired and wireless IPS solutions should narrow. Monitoring the wireless medium alone will not properly safeguard an infrastructure from threats. One current trend is that wireless hardware vendors are partnering with wireless IPS software providers to help meet NIAP Common Criteria Certification as required by the DoD.

### 4.2 Internet-Based Security Protocols

Wireless standards that do not support IP hinder progress and may not provide holistic security or interoperability. Even the well-entrenched LMR (P25) market has started to embrace IP communications. Key and identity management will not be ubiquitous until wireless technologies agree on a common approach or leverage an existing solution, such as Internet public key infrastructure (PKI) or DoD PKI infrastructure. Key generation/distribution dissemination between multiple organizations remains a challenge for a number of reasons, that is, constrained by both technology and bureaucracy.

In addition, an addressing scheme (i.e. a subscriber number) may better enable first responders and law enforcement personnel (federal, state, local, and tribal) to intercommunicate. For example, an IP (or VoIP) Private Branch Exchange (PBX) can incorporate cellular and other IP-enabled devices into a department's in-house telephone switching system, that is, increasing information sharing.

### 4.3 Overlaying Security Services over IP-based Access Networks

When Transmission Control Protocol (TCP)/IP is used as the ubiquitous transport medium, wired and wireless devices can securely communicate if all devices employ the same effective security protocol. For example, personal digital assistants (PDAs) loaded with a secure application on one device can automatically detect and communicate securely with instances of the same application on other devices in network.

IMS is a standardized networking architecture that provides IP-based services through mobile and fixed networks. Mentioned earlier, IMS is agnostic to access technology and

can therefore operate with any endpoint that supports IP capabilities. The service-oriented architecture of IMS facilitates the development of new services while supporting legacy systems. IMS uses open standard IP protocols, defined by the Internet Engineering Task Force (IETF). Therefore, sessions between two IMS users, between an IMS user and a user on the Internet, and between two users on the Internet are established using exactly the same protocol. IMS bridges the interoperability gap of disparate wireless networks by operating with any endpoint that supports IP capabilities.

### 4.4 Mobile Device Security

Improvements in PED processing power coupled with decreased power requirements should be exploited to provide more advanced device security. Mobile devices have four general categories of risk: device access, data storage, data transmission, and data access. Technological advances should be leveraged to comply with Homeland Security Presidential Directive (HSPD-12), and personal identity verification (PIV) solutions that already exist should be explored and implemented where appropriate, such as, the DoD's PKI for the common access cards program. Greater cooperation and information sharing between civilian and defense agencies can help facilitate many legislative requirements focused on information security and empower our country to react better to natural and man-made disasters.

# ENERGY SYSTEMS

# COMPARATIVE RISK ASSESSMENT FOR ENERGY SYSTEMS: A TOOL FOR COMPREHENSIVE ASSESSMENT OF ENERGY SECURITY

PETER BURGHERR AND STEFAN HIRSCHBERG
*Paul Scherrer Institut (PSI), Laboratory for Energy Systems Analysis, Villigen PSI, Switzerland*

## 1 INTRODUCTION

Disasters and accidents occur as a consequence of the exposure of people and their socioeconomic activities to natural and man-made hazards [1–4]. The increase in the numbers and associated consequences of natural disasters and man-made accidents in the last three decades as well as the recurring occurrence of single devastating catastrophes in recent years [5–7] have made the issues of disaster and risk management a top priority at national and international levels. Large loss events cannot be addressed as isolated events anymore because they provide a potential threat to people's health and property, the supply of economic goods and services, and the degradation of ecosystem functions, fauna, and flora. Also, societal vulnerability has further increased because of the steady growth of industrialization, continuing rapid urbanization, the disproportionately high development of coastal and other risk-prone areas, and strong dependency on complex, interrelated infrastructures, constituting a serious challenge to society and its sustainable development [8–12].

Disasters are generally assigned to two principal categories, that is, natural or man-made (anthropogenic or human induced). Natural disasters can be further classified into several distinct groups, including geological (e.g. earthquake and volcano), hydrometeorological (e.g. flood and wind storm), and other (e.g. heat wave, drought, forest fire, and avalanche) disasters. For a more detailed overview, see, for example, the classification schemes used by the Center for Research on the Epidemiology of Disasters (CRED) [13] or international reinsurance companies [6, 7]. Man-made disasters are the result of accidental or intentional human action. Accidental events include transportation accidents, major fires and explosions, releases of chemical and toxic substances, and the

collapse of technical structures (e.g. buildings, bridges, and dams). Purposed malicious action ranges from vandalism and sabotage to terrorism and war.

In the literature, a large variety of more or less precise definitions of the term *risk* can be found, depending on the field of application, and the specific scope, objective, and boundary conditions of the object under study. In engineering and natural sciences, risk is frequently defined in a quantitative way: *risk (R) = probability (p) × consequence (C)*. This definition does not include subjective factors of risk perception and aversion, which can also influence the decision-making process, that is, stakeholders may make trade-offs between quantitative and qualitative risk factors [14]. Quantitative risk assessment is of critical importance in several risk-sensitive industries. Concerning the energy sector, a comprehensive and objective risk evaluation is essential [5] because its complex and interdependent technical systems and facilities comprise critical infrastructure elements to today's information society [11, 15]. Potential accidental events could result in highly undesirable outcomes, calling for an accurate risk assessment and management [16].

In the context of security, risk is often defined as a function of the three variables threat ($T$), vulnerability ($V$), and consequence ($C$): $R = T \times V \times C$. Threat is the measure that a specific accidental or intentional event will take place. Vulnerability is the measure of likelihood that various types of safeguards fail. Consequence is the magnitude of negative effects in the case of an accident or successful attack. This approach allows the identification of areas where high threat levels, extreme vulnerabilities, and high consequences overlap. It is this intersection that causes security concerns. Figure 1 provides an overview of the different aspects of each of the three elements.

Although accidents in the energy sector have been shown to form the second largest group (after transportation) of man-made accidents, their level of coverage and completeness is not satisfactory because they are commonly not surveyed and analyzed separately; rather they are implicitly included as one subgroup of technological accidents. In the early 1990s, the Paul Scherrer Institut (PSI) has developed and established the database ENSAD (*en*ergy-related *s*evere *a*ccident *d*atabase) to close this gap [17]. The focus was on severe accidents because they are viewed controversially by the public and in the energy policy debate, although the sum of smaller accidents is substantial. Furthermore, in relative terms, scarce major accidents have a higher probability of being reported and scrutinized than the much more frequent smaller accidents with minor damages [18, 19]. Since its first publication [17], ENSAD has been continuously maintained, updated, and extended in its content, coverage, and scope [5, 20]. Major progress has been achieved within the "China Energy Technology Program (CETP)" [21–23], the European Union (EU) research project on "New Elements for the Assessment of External Costs from Energy Technologies" (NewExt) [5], and a study of natural gas accident risks for the Swiss Gas and Water Industry Association (SVGW) [24]. Most recently, the database was updated and further extended within the Integrated Project "New Energy Externalities Developments for Sustainability" (NEEDS) of the EU 6th Framework Programme.

The comparative assessment of energy-related accident risks has received increased attention in the past few years for several reasons. The general increase in the annual number of accidents and accompanying damages has triggered public awareness. In addition, a number of extremely devastating disasters have amplified this trend, and at the same time the world-leading reinsurance companies have published damage claims that are one of a kind. Furthermore, there are indications that global climate change may lead to future changes in the intensity and frequency of some hazards. In summary, mankind is facing a tremendous challenge to prevent large-scale disasters and/or to mitigate their

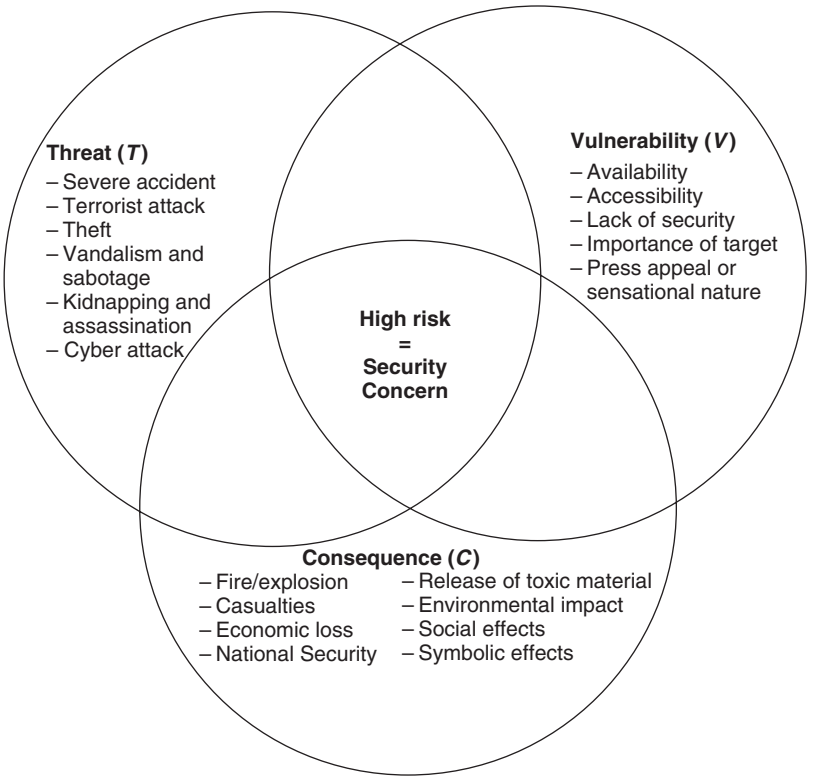

**FIGURE 1** The Venn diagram for security risk shows the various aspects of the three elements threat, vulnerability, and consequence.

impacts because they form a potential threat to the cohesion of society and its sustainable development goals.

However, recent experience has shown that it is not sufficient to direct our efforts only to the energy sector itself. On the one hand, energy provides critical inputs in the production of most goods and services, making them a key driver for all kinds of activities in modern society. On the other hand, the functioning of the energy infrastructure is likewise strongly dependent on supporting infrastructures, including availability and replacement of components, transportation, information and telecommunication systems, fuel and water supply, financial services, and so on. In this context, critical infrastructures denote vital systems that are characterized by mutual interdependencies essential for the provision of minimal services of the economy and government [11, 25, 26]. Parallel to the development of concepts for critical infrastructure protection (CIP), the concept of resilience has been applied to accident prevention, disaster management, and sustainable development [27–29]. Finally, the growing threat of international terrorism since the second half of the 1990s has led to the incorporation of CIP and civil emergency planning (CEP) issues into the broader context of homeland security, addressing a number of key aspects of the above-described methodological approaches and concepts [30–33].

This article provides a comprehensive, state-of-the-art analysis of severe accident risks in the energy sector. The methodological framework for the comparative assessment is presented, followed by an overview of the historical experience as represented in

ENSAD. Finally, comparisons of energy chains are based on aggregated indicators and frequency–consequence ($F-N$) curves, two well-established analytical methods.

## 2 ANALYTICAL APPROACH AND METHODOLOGY

### 2.1 Severe Accident Database

In the initial development phase of ENSAD, the requirements and time exposure were examined to build up a severe accident database for the energy sector. These preliminary investigations clearly showed that such a database should not be set up from the scratch, but rather by using existing information sources, because none of the available individual databases offers a fully satisfactory coverage to form alone a basis for the evaluation of severe energy-related accidents. Databases also differ in their scope, information coverage, level of detail, and quality. Therefore, the combination of information from a large variety of sources allows for the most complete compilation of accident records in terms of available information, level of detail, data quality, time period, and geographical coverage. Additionally, commercial databases should also be included to gain access to proprietary data that are not fully contained in publicly available information sources.

Figure 2 shows the information sources used to document energy-related accidents included in ENSAD for the years 1969–2000. The four most common sources summed up to 48.5%, followed by seven other sources that cumulatively contributed 22.6%. The remaining more than 170 sources amounted to about 29%. However, many of the sources with small shares were of critical importance because they covered specific energy

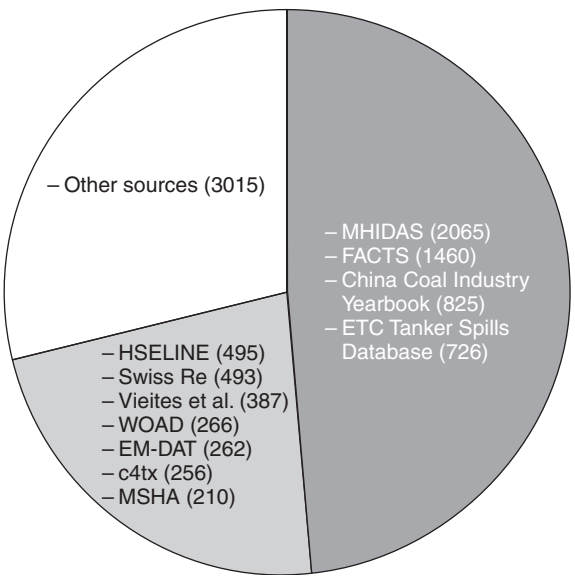

**FIGURE 2** Contributions of major sources to the total number of energy-related accidents stored in ENSAD for the years 1969–2000. Note that the total number of accidents sums up to more than the 6227 accidents documented in ENSAD because a specific accident may be reported by several sources.

chains and/or countries, were useful to resolve contradicting statements, and provided supplementary information that would otherwise not be available.

A database of the purpose such as ENSAD has to be based on relational database software to keep the amount of redundant information at a minimum level, which is not possible with a traditional spreadsheet approach. In our case, Microsoft Access was chosen because it meets our objectives and needs, and allows flexible programming based on SQL or Visual Basic applications. Its abounding export options facilitate data exchange with statistical software packages, the coupling with geographic information systems (GIS), and integration with other office software, internet, or intranet applications. The complete process of database building and implementation has been described in detail elsewhere [5, 17]; therefore, only an overview of the essential steps is provided here:

1. Selection and survey of relevant information sources. Criteria for acquisition include that retrieved data are of sufficient quality in terms of detail and accuracy.
2. Raw information is merged, harmonized, checked for inconsistencies, and verified before records are included in ENSAD.
3. Energy-related accidents are assigned to a specific energy chain and to a specific step within the selected chain. Information on date of occurrence, geographic location and site specification, country-specific attributes, accident type classification, technological characteristics, damage assessment, accident analysis, and verbal description is then collected and entered in ENSAD.
4. The database content of ENSAD is once more cross-checked to keep data errors at the lowest feasible level.
5. Comparative evaluations are then carried out on the basis of customized ENSAD queries.

### 2.2 Severe Accident Definition

In the literature, no unambiguous definition of the term *severe accident* can be found. Differences concern the actual damage types considered (e.g. fatalities, injured persons, evacuees, or economic costs), use of loose categories such as "people affected", and differences in damage thresholds to distinguish severe from smaller accidents.

This can be illustrated by the following examples. The "Worldwide Offshore Accident Database (WOAD)" of the Det Norske Veritas [34] considers an accident as severe or major, if more than one fatality occurred or if the damaged unit (e.g. oil platform, drill ship, or drill barge) experienced total loss. Glickman and Terry [35] define a significant accident for technological hazard, if it resulted in at least five fatalities or if it involved the release of a chemical, petroleum product, hazardous waste, or other hazardous material. The SIGMA publication series of Swiss Re Company [7] does not use the term *severe accidents*, but rather refers to catastrophic events.

The database of ENSAD uses seven criteria to distinguish between severe and smaller accidents. Whenever an accident is characterized by one or more of the following consequences, it is considered to be severe:

1. at least five fatalities;
2. at least 10 injured;
3. at least 200 evacuees;

4. extensive ban on consumption of food;
5. releases of hydrocarbons exceeding 10,000 (metric) tones (t);
6. enforced clean-up of land and water over an area of at least 25 $km^2$; or
7. economic loss of at least 5 million USD (2000).[1]

Generally, fatality data is most reliable, accurate, and complete, whereas in the case of injured or evacuated persons, details on the severity of an injury or the duration of an evacuation are frequently not clearly indicated. The estimation of precise values for economic loss is often difficult because different sources of information report various types of economic damages (e.g. insured vs. total loss), depending on their specific scope (e.g. insurance company vs. disaster recovery organizations). The other consequence indicators are either only relevant for specific energy chains or ENSAD contains very few entries with sufficiently detailed information. Therefore, ENSAD-based results presented here are focused on the number of fatalities.

### 2.3 Consideration of Full Energy Chains

The ENSAD database allows carrying out comprehensive analyses of accident risks that are not limited to power plants but cover full energy chains. Such a broader perspective is essential because for the fossil chains, accidents at power plants play a minor role compared to the other chain stages, that is analyses based on only power plants would radically underestimate the real situation [17].

In general, an energy chain may comprise the following stages: exploration, extraction, transports, storage, power and/or heat generation, waste treatment, and disposal. However, one should be aware that not all these stages are applicable to every energy chain. Table 1 gives an overview of distinct stages for the major fossil (coal, oil, natural gas, and liquefied petroleum gas (LPG)), hydro, and nuclear chains.

### 2.4 Normalization and Allocation of Damages

Comparisons of the various energy chains were based on data normalized to the unit of electricity production. For fossil energy chains, the thermal energy was converted to an equivalent electrical output using a generic efficiency factor of 0.35. For nuclear- and hydropower, the normalization is straightforward since in both cases the generated product is electrical energy. The gigawatt-electric-year ($GW_e$yr) was chosen because large individual plants have capacities in the neighborhood of 1 GW of electrical output ($GW_e$). This makes the $GW_e$yr a natural unit to use in discussions of total electricity production.

Results are provided separately for OECD (Organization for Economic Co-operation and Development) and non-OECD countries because of large differences in levels of technological development and safety performance. This distinction is also meaningful because of the substantial differences in management, regulatory frameworks, and general safety culture between these two groups of countries [5, 17, 36, 37]. Analyses were complemented by separate calculations for the Chinese coal chain. In the case of China, coal chain data were analyzed only for the years 1994–1999 when data from the China

[1]Different currencies were all converted to USD values. To take account of inflation, specific amounts were extrapolated using the US Consumer Price Index (CPI) to obtain year 2000 values.

| Waste Disposal | Waste Disposal | | | | Waste Disposal | |

Coal Industry Yearbook were available, indicating that previous years were subject to substantial underreporting [21–23].

A difficulty that arises in comparative studies with aggregated normalized severe accident records is that a large number of severe accidents occur in non-OECD countries at stages in the energy chain relevant for the export to OECD countries. This can be incorporated in the calculations by adding the appropriate share of the consequences of accidents that occurred at such energy chain stages in non-OECD countries to the damages that physically occurred in OECD countries, that is, OECD countries "import" fatalities. The net amounts of energy carriers imported to OECD countries from non-OECD countries form the basis for this allocation procedure, which has been described in detail in Hirschberg et al. [17]. It has been shown that OECD countries import from non-OECD countries a large fraction of their total consumption of crude oil and LPG, a small fraction of natural gas, and a negligible fraction of coal [5]. Aggregated indicators with allocation are particularly useful within a sustainable development perspective because they assume that the industrial OECD countries should bear a certain share of these damages.

## 2.5 Simplified Probabilistic Safety Assessment for Nuclear Power Plants

The simplified approach used by us in comparative risk studies is described in detail in [22, 23]. It builds on adapting plant-specific source terms from publicly available Level II probabilistic safety assessment (PSA) and combining them with a simplified assessment of off-site consequences resulting from hypothetical nuclear accidents. The basis for the methodology is calculations carried out using MACCS2 consequence code for the same light water reactor (LWR) plant and for two hypothetical accidents, one with early containment rupture and the other with a late vented release. Data for two different sites are used for the dispersion and dose calculations, the first a European continental site with relatively large population density in the vicinity of the plant, and the other a US site with relatively low population density within the first 10 km.

Early fatalities can be extrapolated from one site to another from the ratio of population within 8–10 km. This is because the radioactive content in a passing cloud is effectively dispersed over a very large volume very quickly (the MACCS2 code uses a Gaussian dispersion model), and the MACCS2 calculations show that mortality distance does not exceed 20 km under the worst possible weather conditions (i.e. with very small probability).

Delayed cancer deaths are found to be strongly correlated with the total population within 80–120 km. The MACCS2 calculations show that only a small background of delayed fatalities may occur beyond this distance. This is due to cloud dispersion and dilution of activities, since the dose must be incurred via inhalation or submersion in the passing cloud. Cancer deaths occurring from ingestion (late deaths) are found to be correlated with the total population around the site considered. For both the sites, a maximum distance of 800 km was considered; therefore, late deaths are considered proportional to the ratio of populations within 800 km.

Finally, land contamination is assumed to be correlated with the ratio of land fractions to 120 km, even though the correlation was found to be weaker than the ones found for health effects. A distance of 120 km is assumed for this type of calculations, because the MACCS2 results show that the maximum distance where land can be severely contaminated does not exceed 120 km for any of the radionuclide groups.

In conclusion, off-site consequences may be calculated approximately using activity of releases, as provided by Level II PSAs for the relevant source terms and the ratios discussed above.

## 3 OVERVIEW AND CONTENTS OF ENSAD

Currently, 18,706 accident records are stored in the ENSAD database, of which 88.4% fall in the period between 1969 and 2000. Within this period, 6995 accidents were considered severe because they resulted in at least five fatalities. Of these accidents, 39.5% were natural disasters and the other 4233 were man-made accidents. The latter can be further divided into energy-related accidents (1870 or 44.2%) and other man-made accidents (2363 or 55.8%). Figure 3 shows fatalities in all categories of severe (≥5 fatalities) man-made accidents and natural disasters from 1969 to 2000, totaling to about 3.4 million fatalities. Of these victims, more than 90% were due to natural catastrophes and about 10% were due to severe man-made accidents; 37% of the latter were killed in energy-related accidents.

The largest natural disasters were a storm and flood catastrophe in Bangladesh in 1970 (300,000 fatalities), the Tangshan earthquake in China in 1976 (290,000), and a drought and civil strife in Sudan in 1983 (250,000). In contrast, the largest man-made accidents resulted in fatalities one to two orders of magnitude lower. The top-ranked energy-related accidents include the Banqiao/Shimantan dam failure in China in 1975 (26,000 fatalities), the collision of the tanker "Victor" with the Ferry "Dona Paz" off the Philippines in 1987 (4386), and a tank truck collision with another vehicle in the Salang

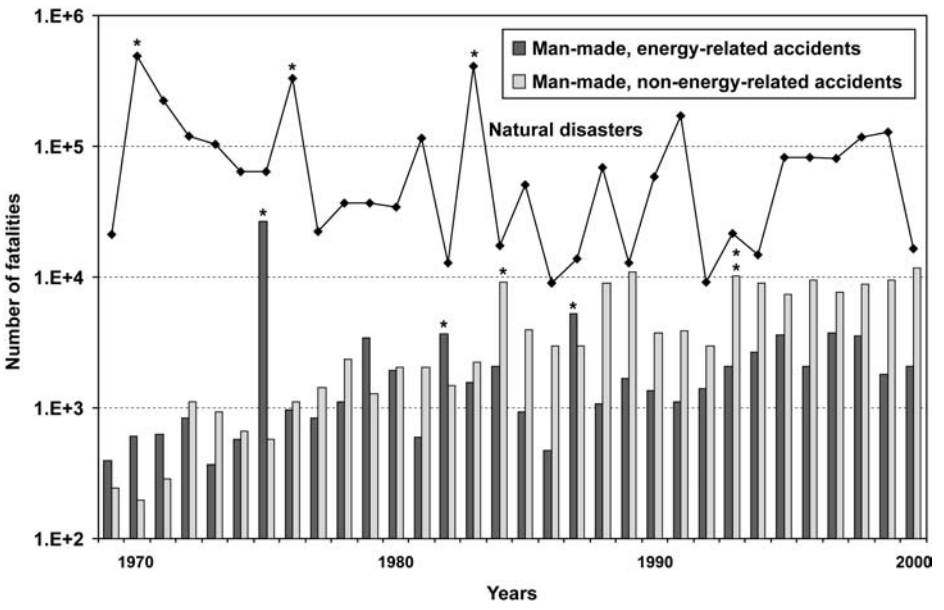

**FIGURE 3** Number of fatalities for severe (≥5 fatalities) accidents that occurred due to natural disasters and man-made accidents in the period 1969–2000. Years marked by an asterisk indicate the three most deadly accidents per category, which are also described in the text.

tunnel in Afghanistan's Parvan province in 1982 (2700). Furthermore, 9 out of the 10 most deadly accidents in the energy sector occurred in non-OECD countries, and were attributable to oil and hydro chains. Large nonenergy-related severe accidents include the accident at a pesticide plant in Bhopal in India in 1984 (5000 fatalities), the sinking of the ferry "Neptune" near the coast of Haiti in 1993 (1800), and the failure of the Gouhou dam (primary purpose: irrigation and water supply) in China in 1993 (1250).

For the period 1969–2000, the ENSAD database comprises 1870 severe accidents attributable to the energy sector, with a corresponding total of 81,258 fatalities (Table 2). The coal chain accounted for 65.3% of all accidents, with oil a distant second at 21.2%. Contributions by the natural gas (7.2%) and LPG (5.6%) chains were much less, while both hydro and nuclear account for less than 1% each. This dominance of coal chain accidents is fully attributable to the release of detailed accident statistics by China's coal industry, data that were not previously publicly available [21–23]. Altogether, 819 of the 1044 accidents collected for the Chinese coal chain occurred in the years 1994–1999, implying substantial underreporting prior to the release of the annual editions of the China Coal Industry Yearbook. Fatalities were clearly dominated by the Banqiao/Shimantan dam failures, which together resulted in 26,000 deaths. As a consequence, the hydro chain accounts for 36.8% of all fatalities. Among the fossil chains, coal accounted for the most fatalities, followed by oil, LPG, and natural gas.

Cumulated numbers of accidents for the different fossil energy chains were plotted on a world map for each country to visualize spatial distribution patterns and to identify accident hotspots (Figure 4). Additionally, total fatalities and chain contributions are shown for the top 10 countries in terms of fatalities, and for each energy chain the most deadly accident is indicated. Among the countries with highest death tolls, seven of them were non-OECD countries and only three belonged to the OECD countries. However, Mexico and South Korea gained OECD membership only in the mid 1990s (1994 and 1996, respectively), whereas United States has been a member since OECD's foundation in 1961. China was the most accident-prone country with 19,141 fatalities, of which

**TABLE 2 Summary of Numbers (acc) and Fatalities (fat) of Severe (≥5 fatalities) Accidents for the Different Energy Chains and Country Groups for the Years 1969–2000**

| | OECD | | Non-OECD | | Worldwide | |
|---|---|---|---|---|---|---|
| Energy chain | Acc | Fat | Acc | Fat | Acc | Fat |
| Coal | 75 | 2259 | 102 | 4831 | 1221 | 25,107 |
| | | | 1044 | 18,017 | | |
| | | | 819[a] | 11,334[a] | | |
| Oil | 165 | 3713 | 232 | 16,505 | 397 | 20,218 |
| Natural gas | 90 | 1043 | 45 | 1000 | 135 | 2043 |
| LPG | 59 | 1905 | 46 | 2016 | 105 | 3921 |

| Total | 390 | 8934 | 1480 | 72,324 | 1870 | 81,258 |

[a]Three values (first to third line) are given for the coal chain in non-OECD countries: non-OECD without China, China 1969–2000, and China 1994–1999 (see text).
[b]Banqiao/Shimantan dam failures together caused 26,000 fatalities.
[c]Only immediate fatalities, see text for latent fatalities.

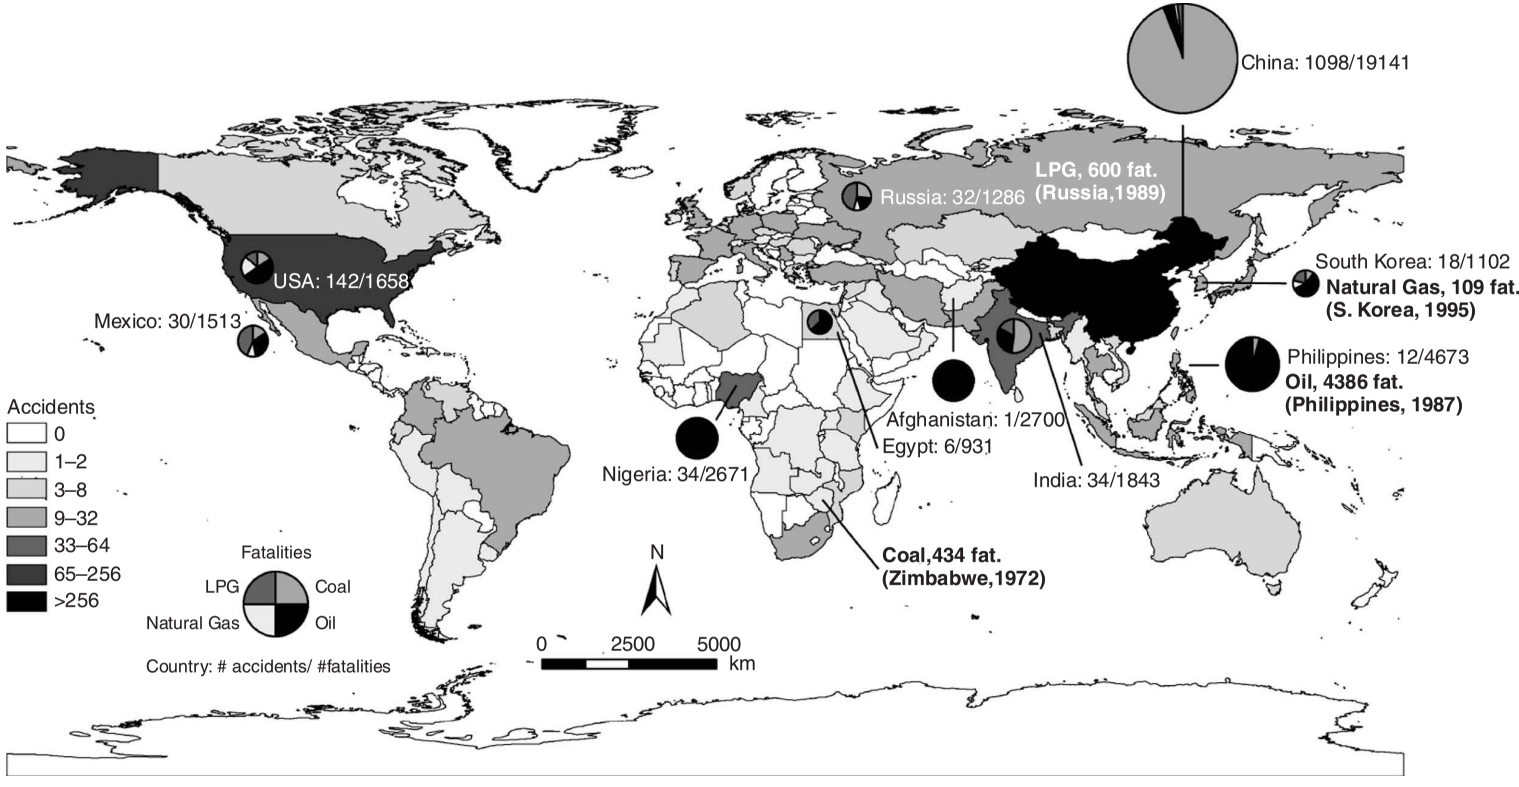

**FIGURE 4** Individual countries are shaded according to their total number of severe accidents in fossil energy chains (coal, oil, natural gas, and LPG) for the period 1969–2000. Pie charts show the contributions per chain for the top 10 countries in terms of fatalities. The most deadly accident for each chain is also indicated.

18,017 fatalities occurred in 1044 accidents attributable to the coal chain, but only nine of these resulted in 100 or more fatalities (Table 2). In contrast, the cumulated fatalities of the Philippines, Afghanistan, Nigeria, India, Mexico, Russia, South Korea, and Egypt were strongly influenced by a few very large accidents that contributed a substantial share of the total [36, 37]. United States exhibited a distinctly different pattern compared to the other countries with no extremely large accidents (only 3 out of 142 with more than 50 fatalities), and over 70% of accidents and associated fatalities taking place in the oil and gas chains.

## 4 COMPARATIVE ANALYSIS OF ENERGY CHAINS

The majority of accidents in fossil energy chains do not occur in power plants, but rather in other stages in the energy chains (Table 3). Over 95% of the victims in the coal chain lose their lives in mines, primarily due to gas explosions. With oil, the transportation to the refinery and regional distribution is the most accident-prone stage; most frequent are tanker accidents at sea and road accidents involving tank trucks. Transportation

**TABLE 3 Relative Share of Accidental Fatalities in the Stages of Different Energy Chains**

| | Coal | Oil | NaturalGas | LPG | Hydro | Nuclear |
|---|---|---|---|---|---|---|
| **Exploration / Extraction** | Explosions and fires in mines | Well blowouts, accidents on drilling platforms at sea | Well blowouts, accidents on drilling platforms at sea | | | |
| **Long Distance Transport** | | Tanker accidents at sea | Pipeline accidents | Pipeline accidents, LPG tankers at sea | | |
| **Processing / Storage** | | Process accidents in refineries and tank farms | | Accidents at refinery / natural gas processing plants | | |
| **Regional / Local Distribution** | | Overturning and collisions of tank trucks | Pipeline accidents | Overturning and collisions of tank trucks | | |
| **Power / Heat Generation** | | | Process accidents | Process accidents | Overflow or failure of storage dam | Core meltdown with large release of radioactivity |
| **Waste Treatment / Disposal** | | | | | | |

| 0 – 5% | 6 – 15% | 16 –30% | 31 – 60% | 61 – 100% |
|---|---|---|---|---|

is also a weak stage in the natural gas chain, which is dominated by pipeline accidents in transmission (long distance) and distribution (regional/local) networks. In the LPG chain, transportation accidents are most prominent too, particularly in regional and local distribution. In contrast, hydropower and nuclear power accidents occur only near the area of the storage dam or reservoir and the plant site, respectively. While coal chain victims are almost exclusively work related, gas and oil accidents involve a significant number of innocent bystanders as victims. If a storage dam breaks, then the general populace is almost exclusively affected, with the exception of the dam operators. Nuclear plant accidents may also lead to immediate fatalities, but here the deaths are dominated by latent fatalities (compare Sections 3.1 and 3.2) due to eventual cases of cancer.

### 4.1 Aggregated Indicators

Aggregated fatality rates of severe ($\geq$5 fatalities) accidents are reported only for immediate fatalities, whereas the significance of latent fatalities in the case of the nuclear chain is discussed in Section 3.2. Damage rates differed substantially among energy chains and country groups, with OECD countries generally showing significantly lower fatality rates than non-OECD countries (Table 4). Among the fossil chains, natural gas has the best performance, followed by oil and coal, whereas the value for LPG is one order of magnitude worse. The lowest fatality values occur for western style nuclear and hydropower plants, whereas dam failures in non-OECD countries may lead to thousands of victims in the downstream population. Additionally, Table 4 also displays a full allocation of damages for fossil energy chains on the basis of imports and exports (Section 1.4) because a large number of severe accidents in non-OECD countries are related to energy exports to the OECD countries. Severe fatality rates for the oil and LPG chains exhibited the most distinct increase for OECD countries and decrease for non-OECD countries compared to the rates without allocation, whereas differences for coal and natural gas chains were

**TABLE 4 Aggregated Fatality Rates for Full Energy Chains Based on Historical Experience of Severe Accidents ($\geq$5 immediate fatalities) in OECD and Non-OECD Countries for the Period 1969–2000, Except for China 1994–1999 (compare text). Allocated Values Incorporate Imports and Exports between OECD and Non-OECD**

| | No Allocation/With Allocation [fatalities/$GW_e$yr] | |
|---|---|---|
| | OECD | Non-OECD |
| Coal | 0.157/0.163 | 0.597/0.589 |
| | | 6.169[a] |
| Oil | 0.132/0.390 | 0.897/0.502 |
| Natural gas | 0.085/0.097 | 0.111/0.096 |
| LPG | 1.957/3.317 | 14.896/5.112 |
| Hydro | 0.003 | 10.285 |
| | | 1.349[b] |
| Nuclear | — | 0.048[c] |

[a]First line: OECD without China; second line: China for the period 1994–1999.
[b]Chinese dam failures of Banqiao/Shimantan with a total of 26,000 fatalities are excluded.
[c]Only immediate fatalities of Chernobyl accident; see text for latent fatalities.

distinctly less. Within the framework of sustainable development, it could be argued that the highly industrialized OECD countries should assume a certain share of these damages.

### 4.2 Frequency–Consequence Curves

Figure 5 provides $F-N$ curves for severe ($\geq$5 fatalities) accidents in OECD and non-OECD countries, including allocated curves. For fossil chains in OECD countries, natural gas has the lowest frequency, coal and oil are intermediate, and LPG has the highest frequency, whereas hydro and nuclear chains perform significantly better. Maximum consequences are negligible for hydro, followed distantly by natural gas (109 fatalities), and the other fossil chains have maxima between 2.5 and 4.5 times greater than natural gas. Concerning allocated $F-N$ curves, those for natural gas are practically identical (not shown in figure), the allocated curve for LPG exhibits higher frequencies at corresponding numbers of fatalities, whereas for the oil chain maximum consequences increase by a factor of about 3.8. This is fully attributable to the extremely deadly accident in the Philippines with 4386 fatalities already discussed before.

Non-OECD countries showed a comparable ranking as for OECD countries, except for the Chinese coal chain that performed significantly worse. However, the frequencies at corresponding numbers of fatalities were generally higher for non-OECD countries compared to OECD countries. Additionally, values for maximum consequences were one order of magnitude higher for the oil chain (4386 fatalities) compared to OECD countries, and the Chinese dam failure of Banqiao/Shimantan with 26,000 fatalities is by far the most deadly accident in terms of immediate fatalities. Concerning allocated $F-N$ curves, the oil and LPG chains have clearly lower maxima, whereas curves for natural gas are again almost identical.

For nuclear energy, immediate fatalities play a minor role, whereas latent fatalities clearly dominate. Therefore, total fatalities are split into the following categories: early (immediate) fatalities that occur shortly after exposure and latent fatalities that include all potential deaths occurring within 70 years from the radioactive release. For details see Burgherr et al. [5] and Hirschberg et al. [17]. Accident frequencies causing actual damage external to the plant associated with the nuclear chain (Chernobyl) are relatively low, but the maximum credible consequences may be very large due to the dominance of latent fatalities. According to Hirschberg et al. [17], estimated latent fatalities due to delayed cancers range from about 9000 (based on dose cutoff) to 33,000 (entire northern hemisphere with no dose cutoff) over the next 70 years. In 2005, a study by the "Chernobyl Forum"—a consortium of several United Nations organizations, the World Bank and the Russian, Belarus and Ukrainian governments—estimated that in the areas with high contamination, up to 4000 people could eventually die due to radiation doses from the Chernobyl accident, most of them among the so called liquidators [38]. Because of the more limited area considered, this value is substantially lower than the PSI values previously mentioned. The upper range in PSI's estimate is conservative (as intended) because it was not limited to the most contaminated areas. Finally, one should be aware that no dependable statistics can be determined from this single, severe accident. The Chernobyl accident data also cannot be transferred to Western plants, because they use a very different technology. For realistic calculations, it is necessary to use PSA (Figure 5).

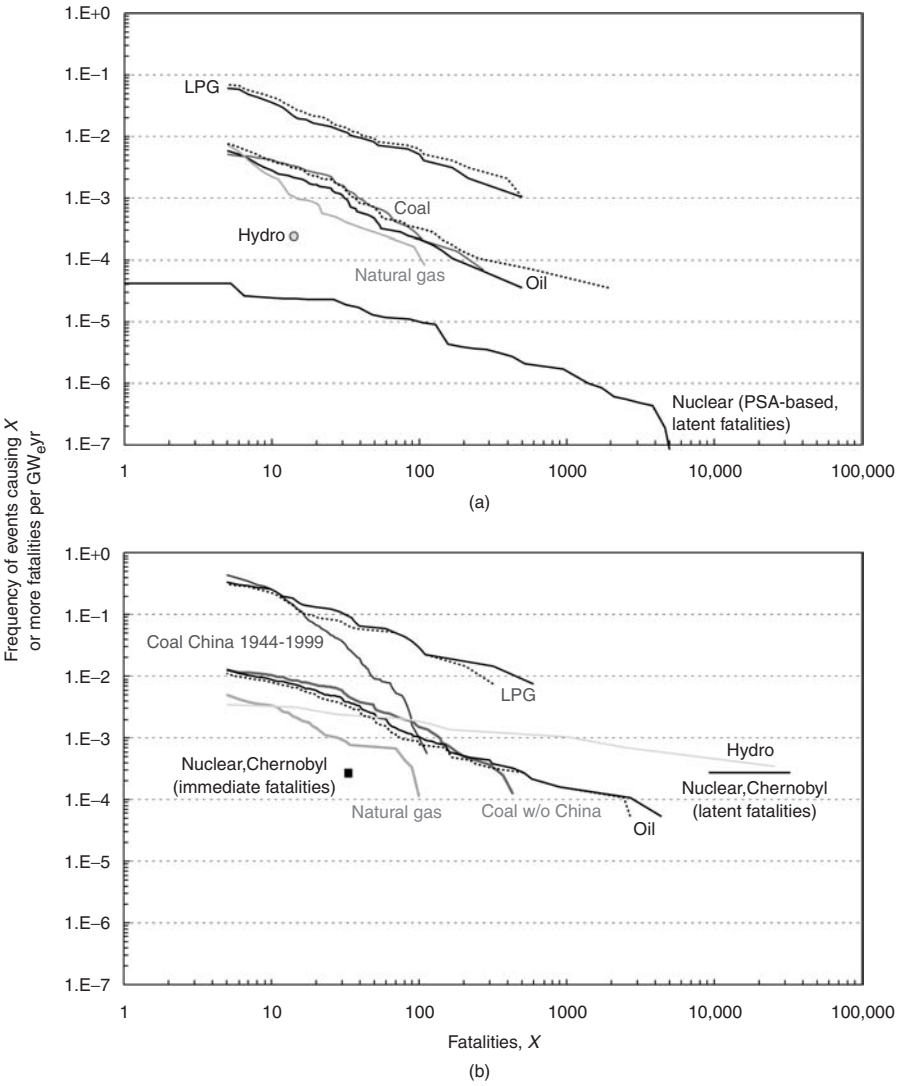

**FIGURE 5** Comparison of frequency–consequence curves for full energy chains based on historical experience of severe accidents in (a) OECD and (b) non-OECD countries for the period 1969–2000, except for China 1994–1999 (compare text). Dashed lines denote $F-N$ curves based on allocated values, that is, taking into account imports and exports between OECD and non-OECD countries. For natural gas, allocated curves are not shown as they are almost identical to nonallocated ones.

## 5 CONCLUSIONS AND RECOMMENDATIONS

### 5.1 Comparative Aspects

– The ENSAD database provides comprehensive accident data for the objective and quantitative analysis of specific technical aspects and the comparative assessment

of severe accident risks in the energy sector. However, it is in the nature of the topic that new accidents continuously occur; therefore, the ENSAD database needs to be maintained, updated, and extended to keep up with the growing historical experience and to provide state-of-the-art estimates of risk indicators.

– Energy-related accident risks in non-OECD countries are distinctly higher than in OECD countries; reflected by aggregated indicators as well as $F-N$ curves.
– The most accident-prone energy chain stages are upstream stages (i.e. extraction, refining, and transportation) in fossil energy chains, and hydropower in the less developed (non-OECD) countries.
– Expected fatality rates are lowest for Western hydropower and nuclear power plants. However, the maximum consequences can be very high. The associated risk valuation is subject to stakeholder value judgments and can be pursued in multicriteria decision analysis [39, 40].
– PSA perspective on severe accident risks is particularly important for energy chains whose risks are dominated by power plants, the historical experience of accidents is scarce, or its applicability is highly restricted. These conditions are valid for most Western hydro- and nuclear power plants.

## 5.2 Selected Future Developments

– Estimation of risk indicators for *future technologies* based on extrapolations of currently operating systems. This type of analysis has been introduced in the NEEDS Project of the EU 6th Framework Programme, and is further developed, systematized, and extended in several upcoming projects.
– Further advancement of the *simplified PSA approach* to establish a broader reference database for site-specific risk indicators for advanced nuclear designs has been initiated.
– Broader and *systematic evaluation of smaller accidents* in the fossil chains, as it has already been undertaken for natural gas [24]. Such an effort, however, requires access to the relevant raw data that are often subject to proprietary use.
– Qualitative analysis of *indirect impacts of accidents* on the energy sector. Besides the purely physical effects of severe accidents, a variety of indirect effects can occur, including environmental concerns (e.g. oil spills), acceptance problems of specific technologies due to extremely large maximum credible consequences or high accident frequencies, potential social conflicts among stakeholders (e.g. oil companies and local tribe communities in developing countries), and so on.
– Enhanced coupling of the ENSAD database with *Geographic Information System* (ArcGIS) together with multivariate statistical analyses to analyze spatial patterns across hierarchical scales.

LEO SCHRATTENHOLZER

*Visiting Professor of the Royal Institute of Technology, Sweden, (deceased)*

## 1 INTRODUCTION

One major thrust for the production of this volume on Science and Technology for Homeland Security was the "need for a coordinated scientific and technological response to terrorism" [1]. As a political response to terrorism, the Homeland Security Presidential Directive/HSPD-7 established a national policy for federal departments and agencies to identify and prioritize United States critical infrastructure and key resources and to protect them from terrorist attacks [2]. Voeller [1], (*op. cit*.) argues that the Presidential Directive

does not emphasize the "need to mobilize the nation's skills in science and technology" as strongly as the operational concerns. This apparent lack of emphasis was the stimulus for the study by the National Research Council (NRC) *Making the Nation Safer: The Role of Science and Technology in Countering Terrorism* [3]. In response to the research priorities identified by the NRC report, the present volume was proposed to create a major new reference resource. Picking up one of the aims proposed for this handbook, this overview article addresses "the international dimensions of homeland security."

## 1.1 Background

The background of the authors of this article is in the field of systems analysis. Together, they gathered some 40 years of work experience at the International Institute for Applied Systems Analysis (IIASA), a nongovernmental global institute for scientific research [4]. Adhering to the scientific method requires working with terms and concepts that are rigorously defined. In this regard, it appears unfortunate that the term "terrorism" has not been unambiguously defined (that is, in absolute rather than relative terms) even politically, let alone scientifically. We therefore refrain from using this term in the description of our analysis following below. In our opinion, the term "deliberate attacks" is a more precise—and therefore better—descriptor of what is commonly referred to as "terrorist attacks."

***1.1.1 Systems analysis.*** There appears to be no universally accepted single definition of systems analysis. One of the reasons is that the term has a specific meaning in some fields. Even IIASA itself does not promote a unique interpretation of its name on its website, but it is obvious that interdisciplinary research of interactions of systems is a key characteristic of systems analysis. A particularly important aspect of studying interaction is to avoid the pitfall of neglecting crucial interdependencies between systems. For the general question of national security, any systems analytical approach must therefore consider relevant international aspects in the form of outside reactions to national policies.

The second major pillar on which we want to base our concept is a general and fundamental tenet of systems analysis, according to which systems vulnerability is proportional to systems efficiency.[1] To the extent that increasing efficiency of a system goes along with decreasing redundancy, the assertion appears immediately plausible because in a system with many redundancies, the possibilities for substitution (of a malfunctioning subsystem) are greater than in a system with fewer redundancies. Furthermore, if we understand resilience as the opposite of vulnerability, we see that an important systems analytical issue to study is the interplay (trade-off) between resilience and efficiency, that is, to find a joint optimum (maximum) of the conflicting objectives, resilience and efficiency.[2]

As to energy systems, vulnerability and resilience are related to security in an obvious way. Energy security can be enhanced by increasing the resilience of the energy (infrastructure) system. For the purpose of analysis, we believe that it is useful to also distinguish between resilience in the short term and resilience in the long term. While short-term

[1]This general insight has been formulated and substantiated in many specific cases. See, for instance, [14], who analyzed different efficiency, vulnerability and cost functions and found "that these magnitudes display strong correlations."

[2]Accordingly, one of the first major themes of research undertaken at IIASA was a collaborative effort on resilience by IIASA's Ecology and Energy Projects [5, 6].

resilience is related to natural disasters and deliberate attacks, long-term resilience is more a fundamental structural feature of any system.

As a sequel, we cover two topics. The first section deals with basic design features of secure energy systems, and the next addresses the modeling of energy security and competition by presenting the design and some illustrative results of a model of gas-market competition. We also discuss policy implications of the analysis presented here.

## 2 COOPERATIVE ENERGY SECURITY

### 2.1 Resilient Energy Systems

In systems analytical terms, one important manifestation of resilience is the stable equilibrium of a system [6]. To illustrate this mathematically for the case of a one-dimensional dynamic system,

$$Y = \dot{x}(t),$$

a stationary state $x_0$ defined by

$$\dot{x}(t_0) = 0$$

is a stable equilibrium of the system if and only if

$$\ddot{x} < 0$$

In an interval around $x_0$, the dynamics of the system move it toward the equilibrium point.

Applying the concept to an energy system means that the system can be called resilient if it is designed in a way that the dynamic forces determining the evolvement of the system lead it back to the original equilibrium state after a minor (accidental) shock has displaced it away from the equilibrium point.[3] "An example of such a shock would be a deliberate hostile attack on a particular part of energy infrastructure. Addressing such a shock would be addressing the short-term resilience of an energy supply system.

Let us now turn to long-term energy system resilience and, consequently, on resilience as a fundamental structural feature of the energy system.

Doing so requires looking at the long-term vulnerabilities of a national energy system. One important—maybe the most important—long-term security threat to any national energy system is the failure of international suppliers of energy to deliver according to signed agreements or established market principles. Looking at examples of the past, we find that supply disruptions often were justified with disagreements among the partners (consuming, producing, and transit countries) and thus political rather than technical. From this we conclude that long-term resilience of energy supply requires energy importers, exporters, and transit countries to share a strong common interest,

[3]Perhaps one of the most well-known applications of the equilibrium concept is the model of equilibrium price, which results from the intersection of the demand curve and the supply curve. According to this model, for instance, a downward movement ("shock") of the demand curve is followed by an adjustment (reduction) of supply of the item in question. The shock and the adjustment together lead to a new price equilibrium. Alas, recent experiences (in particular in the years 2007 and 2008) have shown that in practice, and contrary to what the model suggests, prices can "run away" from levels that were considered stable.

which stabilizes any equilibrium and which treats "shocks" as a stability problem that must be solved jointly.

A prerequisite of such a system design is therefore symmetry, in the sense that the system must serve the interests of all parties involved. Thus if security of supply is the main criterion for the long-term resilience of an energy system from the importer's perspective, security of demand must be seen as the symmetric criterion from the perspective of an exporter. Both criteria taken together gave rise to cooperative energy security. We cover the two criteria, one by one, in the following two subsections.

Recent work in this area [7] generalizes the concept of resiliency in relation to critical infrastructures (e.g. energy infrastructures) by introducing cooperative systems models for quantitative vulnerability assessment for interdependent complex structures. They describe the resiliency of systems by highlighting the coexistence of two meta-indicator sets defined as tangibles (investments, available resources, and so on), and intangibles (geopolitics, cultural aspects, and so on).

## 2.2 Security of Supply

For a long time, energy security was more or less tacitly assumed to refer to the security of supply only. Accordingly, national energy security was defined as "adequate and reliable energy supply by reasonable prices to avoid damages of fundamental national goals and principles". Even the World Energy Council had only supply in mind when it defined energy security as the "Security of citizens, economics, society and nations against damages and for sustainable fuels and energy supply". Similarly, the International Energy Agency (IEA) sees energy security as the "availability of energy, sufficient (by volume) and available (by price)." In the case of the IEA, the lack of consideration of energy demand security is of course understandable on the grounds that its mission is defined as "energy policy advisor to 27 member countries in their effort to ensure reliable, affordable and clean energy for their citizens" [9].

Recently, energy supply security was analyzed also from the perspective of strategic goals that enhance the long-term resilience of the global energy system in terms amenable to energy modeling. Schrattenholzer [10] identified two indicators that are argued to measure long-term energy security. These are the resource-to-production (R/P) ratio of mineral primary-energy resources and equity, which are defined as follows:

The R/P ratio is defined, for any given year and any given resource, as the amount of the resource left for consumption ("in the ground"), divided by the annual consumption in that given year. Equity was defined as the ratio of average GDP per capita in today's developing regions and today's industrialized world regions.[4] Most global long-term scenarios include the data that allow these indicators to be calculated. Important examples are the scenarios published by IPCC's Special Report on Emission Scenarios [11].

## 2.3 Security of Demand

As we have argued above, symmetry is a necessary requirement for stable equilibria. Since the notion of energy demand security is a comparatively recent concept, we begin this discussion by deriving specific aspects of demand security from their "mirror images" on the supply side.

[4]In 1990, this ratio was approximately six per cent.

*Vulnerability of supply to natural disasters and deliberate attacks.* Natural disasters and deliberate attacks on energy supply infrastructure are hazards to suppliers as well as to consumers and thus symmetric in principle. Recognizing this suggests that producers and consumers have a natural interest in jointly addressing the risks posed by these hazards.

*Use of energy as a weapon by suppliers.* This demand-side hazard figures strongly in the public coverage of the issue of energy security. Often the symmetric hazard of consumers using the same situation as a weapon against suppliers is not included in the discussion. Considering the fact, however, that energy deliveries, for instance, those of natural gas, require sizable up-front investments, the possibility that consumers use sunk cost as leverage is an obvious hazard for suppliers.

*Energy prices.* Energy prices so high as to be felt as threatening the security of energy supply has, for suppliers, the mirror hazard of energy prices so low as to fail covering costs.

### 2.4 Conclusions

So far, we have mainly argued that a systems analytical approach suggests that the security of energy supply and the security of energy demand should be considered together. Now we turn to the question: *To which degree are security of supply and security of demand different concepts?*

To the extent that security is the absence of risk and risk is "*the probability of an unwanted event*" (Oxford University), the concepts are the same—only the unwanted events are different! If consumers and producers follow identical concepts, it is easier for them to practice active energy security in an institutionalized dialogue. Moreover, as our analysis suggests, disruptions (of supply or demand) can be avoided by timely planning. This is another argument for embarking on a comprehensive dialogue, supported by analysis and research, between consumer, producer, and transit countries. Following this argument, one would, for example, aim at minimizing the joint probabilities of all sides' unwanted events.

Also, the actors in such a global energy security management are likely to orient their assessment of the (subjective) probabilities involved in this exercise, according to scenarios of future developments. Thus, energy projections have always played a major role in long-term national security considerations but also in short- and medium-term policy decisions of governments and international organizations such as the IEA and the European Union.

## 3 MODELING ENERGY SECURITY

### 3.1 An Illustrative Example: Natural Gas

In order to illustrate how the concept described above can be applied to the formal modeling of real-world issues, we turn to one of the most interesting examples in the wider area of energy security, the international natural gas markets.

Before summarizing the model, we want to note that in our opinion, what is usually referred to as the natural-gas market lacks important features of more conventional markets. The main reason for this opinion is the lack of a global referencing point for the

price formation (as in case of oil), and the undeveloped trade on well-established markets. Due to its environmental friendliness—relative to the other fossil energy carriers, coal and oil—the share of natural gas in the primary-energy mix is on the increase, with some countries supplying 40 to 60% of their primary-energy needs with the "blue fuel." Although this "success story" began as early as in the 1970s, not much has been done in terms of establishing an institutional framework for efficient and reliable gas trade.

In pursuit of a suitable arrangement, in the beginning of the "gas era," consumers and producers tried to hedge the risks of both parties by negotiating long-term contracts (LTCs) which—as a rule—serve to protect producers' interests by introducing a minimum price and an indexing scheme (in some cases there is an additional condition called "take-or-pay," which increases the security of demand, but compromises the flexibility of the consumer) and consumers' interests by guaranteeing a certain delivery pattern throughout each year at predictable prices. The equivalent of *market clearance* occurs during re-negotiation phases, which can take years. These re-negotiations lead to contract amendments regulating the pricing mechanism. By adjusting the coefficients in the "formula," round by round, each party approaches an equilibrium price.

Today global gas trade is still following the formula "if there are no good relations between supplier and consumer, there is no gas trade." This condition immediately extends the matter from an economic layer to a political, if not—given the strategic interests of each party—geopolitical layer. The quoted formula wants to express that in most cases, physical gas deliveries under import-export deals require good bilateral relations between two or three countries. LNG (liquefied natural gas) imports into the USA[5] are a minor counterexample at best as only some 50% of these imports were delivered under short-term LNG contracts.[6] Likewise, regional and local distribution especially in Eurasia is also characterized by nonmarket price formation for end users.

These peculiarities of gas trade can be explained—among others—by the facts that (i) consumption and production centers are concentrated, (ii) the infrastructure for natural-gas production, transportation, and distribution and is very inflexible (due to the long economic service life of the equipment involved) and cost-intensive, (iii) there are few alternative means of gas delivery, which are, again, inflexible, and, finally, (iv) there are few major gas producers, and these are geographically scattered.

In any case, these types of international relations have an obvious bearing on national energy security. Our formal analysis of these relations builds on the notion of equilibrium in the form of agreed-upon prices and volumes.

In practice, such equilibrium suffers several drawbacks. First, the negotiation position of a consumer depends on a set of geopolitical factors and the state of bilateral relations. Second, there is very little or no competition between sellers at all (primarily due to inflexibility of the import infrastructure), which provides more leverage to the supplier. Thus, the equilibrium is defined on a very narrow optimization interval, which is sensitive to externalities and influenced by many intangible factors.

On the other hand, such long-term arrangement provides two very important ingredients to cooperative energy security: it guarantees the long-term demand for the supplier, which is a key condition to invest into natural-gas production and transmission infrastructure; and it allows the consumer to do national energy planning at given volumes and prices.

[5]The USA is often believed to be a pioneer in the liberalization of natural-gas trade, and LNG has been attributed the role of a "dissolver" of long-term trading agreements.

[6]Moreover, the share of LNG imports in the US consumption is very small—only 3.7% in 2007.

In public discussions in (Western) consuming countries, this mutual dependence of a producer and a consumer is often mistakenly perceived as a burden of the consumer alone. It is obvious, however, that both parties should be interested to act and plan jointly, thus improving energy security of both.[7] Although we recognize at the same time that such long-term interdependence, which extends to the energy sectors of both parties, can also reduce the flexibility of each of them and therefore can be associated with the disadvantages of long-term form of gas contracts.

Responding to the perceived shortcomings of long-term markets, the established up-to-date practice of short-term gas deals had the primary goal of reducing the burden of mutual dependence—the heritage of LTCs. Whereas past local gas markets were formed from scratch, new spot-markets were formed by analogy to oil markets. The main instruments in this spot-market trade are financial derivatives, covered by physical deliveries under long- or short-term contracts. Among the advantages of such a scheme one could highlight the room for competition, transparency (prices and quantities are reported publicly) and indifference with regard to suppliers.

However, while resolving almost all the supply-related drawbacks of the LTCs, markets (in their pure form) bring one big disadvantage with respect to security of demand, which is near zero. We can characterize such markets as *delivering energy security to consumer and supplier at the cost of efficiency and mutual dependence*, and we have encountered another manifestation of the tenet of systems analysis mentioned in the introduction, according to which efficiency (market efficiency from the perspective of suppliers) is proportional to vulnerability (of suppliers). Following the logic of cooperative energy security, it is thus natural to expect that the deterioration of suppliers' security will eventually reflect on consumers.

The arguments for the latter consideration go back to the issue of high investment intensity of gas infrastructure. Payback times, usually equivalent to between 10 and 15 years of a pipeline operating at maximum capacity, pose rather strict necessary conditions even for consideration of an export project.

We summarize main characteristics of the two market types (Table 1).

This comparison makes it obvious that both market models have advantages and disadvantages. Therefore a harmonious solution of cooperative energy security should include features of both of them.

### 3.2 Economic Aspects and Rationality

In previous sections, we identified that competition can help mitigating a number of unwanted features of gas trade; not to mention that fostering competitive energy markets is one of the key elements in modern energy policies of almost all countries. Competition and energy security are thus the key ingredients of the model that we shall summarize here.

The model is named GASCOM (*Gas* Market *Com*petition) and belongs to the family of gaming models. The key idea behind the model was to combine competition with existing methods of evaluating the economic efficiency of energy export projects. GASCOM covers gas trade from an evaluation of a transport corridor on a national level, to precise supply schedules and corresponding cash flows.

[7]The interests of transit countries will be discussed in the section on "Expanding the Scope: Geopolitics and the Inclusion of Transit Countries into the Analysis."

**TABLE 1 Main Characteristics of International Gas Trade Models**

| Long-term, Bilateral | Free-market |
|---|---|
| • Few producers, few consumers | • More producers, more consumers |
| • Price is indexed by alternative fuels | • Competitive short-term price formation (seasonality pattern) |
| • "Shock-absorbing" price formation | • High price volatility |
| • Two-way reliability (prices and quantities) | • Infrastructure development: mostly operational (storage), risky for transmission lines |
| • Infrastructure development: small risk | • Less dependable because more erratic |
| • Foreseeable thus dependable for consumers, producers, investors | • Indifferent with regard to suppliers or consumers |
| • Requires maintaining "good" long-term political relations; creates mutual dependence | |

One of the key characteristics of the gaming approach is that it provides an insight to all admissible strategies (in this particular example: of supply volumes and the timing of market penetration) of all agents. The model thus confirms with our understanding of systems analysis as described in the introduction because it includes all relevant feedbacks and interactions. The result is, for *all* agents,[8] an optimized supply schedule and an optimized time for entering the market.

Here are two interpretations of this model solution:

– In the case of LTCs the model replicates rounds of negotiations between the agents[9] who iteratively update their knowledge about their competitors and adjust their own strategy accordingly. Thus, having collected all information about responses of others to their strategy, agents are capable of defining an "optimal" time of entering the market, optimality being defined by the minimum time passed from the point of decision-making to payback (this option of optimality criterion is closer to maximization of internal rate of return, IRR, of the project rather than traditionally applied maximization of the net present value, NPV). Having determined the time of market entry, agents engage in the second, distinct phase of negotiations, because naturally, this represents another game, when agents control their supply to the market. Eventually (in most cases) all agents will reach a point (the Nash Equilibrium), where varying the timing or supply schedule will not improve their own benefit.

[8]This feature is in contrast to models in which the NPV of *one* (and only one) is maximized.
[9]In the example discussed here, the agents are one importer and many exporters.

Thus, for a LTCs case, a gaming model such as GASCOM, permits each agent to reveal the potential demand of the importer as well as the potential supply —a strategic advantage.

– In case of mid- and short-term contracts, the model imitates the market price formation (in our example, with regard to the future with the delivery in one year), where market fundamentals and the project's economical characteristics identify its competitive advantage. Technically, the solution is similar to the case of LTCs, but the essence of results is different. First, the equilibrium solution involves much higher market risks due to additional impact on price caused by agents' supply strategies. Second, the solution also presumes coordination between agents: no long-term plans will be valid in case there is some irrational behavior for one of the agents (i.e. deviation from equilibrium in pursuit of strategic interests).

Before presenting illustrative results, we would like to mention that most arguments in this section apply to cases when there is a need for the construction of new upstream infrastructure. With growing world demand for natural gas and a trend for diversification of supply sources, this issue is most relevant. Another consideration is that once a gas transmission pipeline has paid back, the risk profile of this infrastructure changes. This, in fact, defines the turning point with regard to providing cooperative energy security: it is most crucial for the payback period; after return of investments, the supplier might gradually engage in free trade.

The three figures below illustrate the processes described above. They illustrate results from a recent case study in which GASCOM was used to analyze the perspectives and the potential of the emerging gas market in China as well as of a set of proposed export projects from Russia, Kazakhstan, Turkmenistan, and LNG in the Pacific Basin [12]. In Fig. 1 we present the discounted cash flows before optimization, that is, the cash flows

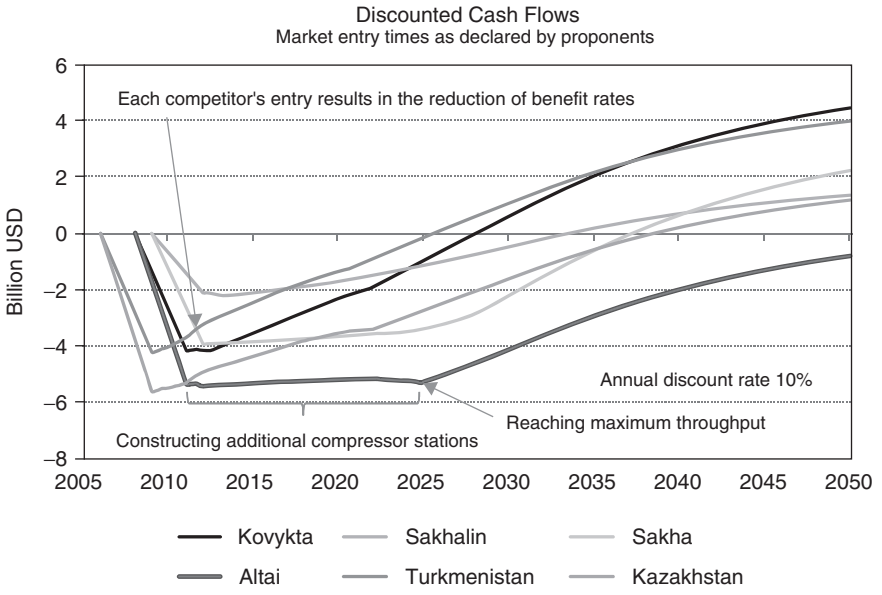

**FIGURE 1** Discounted cash flow with timing as announced by the promoters.

as a consequence of realizing the projects as announced by the representative companies. Explanations inserted into the graphics and the shapes of the curves demonstrate that the model reflects all important peculiarities of a transmission project. Not only that, without optimization one of the projects does not pay off before 2050; most of them also have a relatively low IRR. The underlying reason for this is that all agents endeavor to take a strategic position on a newly emerging market and therefore all of them enter it as quickly as they can. Since demand is limited, achievable prices are insufficient for the candidate projects to be economically attractive.

Figure 2 displays the cash flows for the same set of candidate projects after GASCOM optimization. Now all the projects pay off in a shorter time frame, and they have a higher IRR.

To give a broader picture, Fig. 3 presents the supply schedule by the agents and how it compares to total demand in the market after optimization with the GASCOM model.

From the past studies with the GASCOM model we would like to highlight two—as we believe—important conclusions.

In case of traditional gas trade, based on long-term contractual agreements, the suppliers have an incentive to cooperate with each other with the aim to mitigate market risks and to achieve the best financial results for all parties.

In the case of market trade, we have observed that the suppliers acting in a market with limited representation (i.e. not so many suppliers and even less consumers, which is the case of today's natural-gas markets) tend to keep it in deficit, thus increasing instantaneous profits which, given no possibility to build on long-term planning, is a more profitable strategy for them.

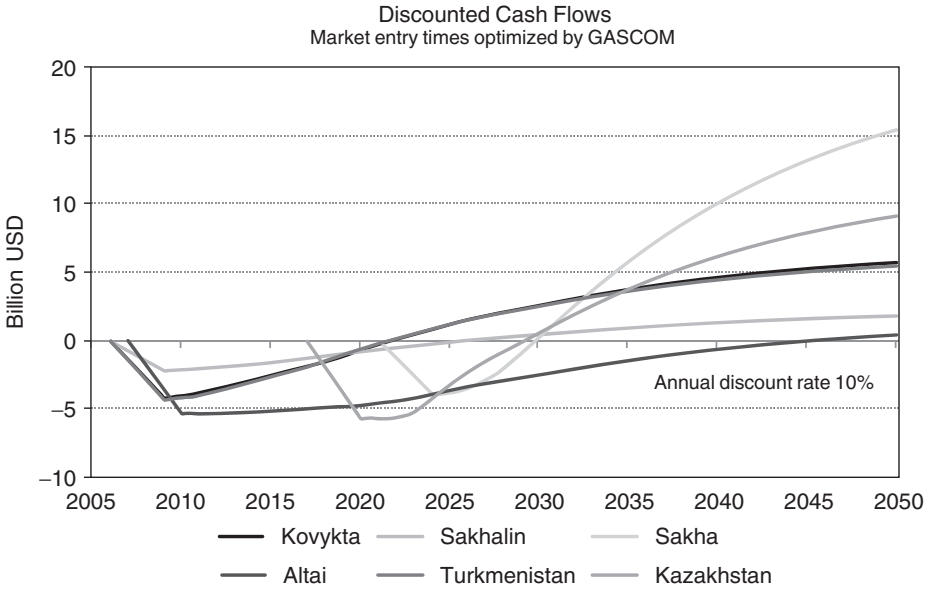

**FIGURE 2** Discounted cash flow with timing optimized by GASCOM.

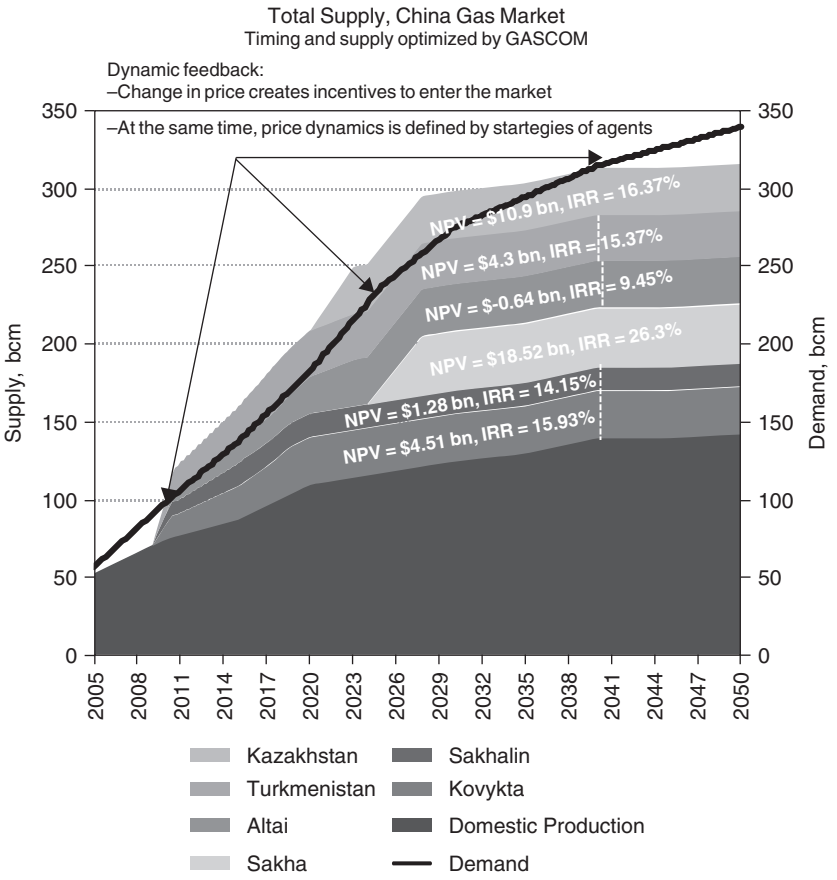

**FIGURE 3** Total supply in the market, timing and supply schedule optimized by GASCOM.

### 3.3 Expanding the Scope: Geopolitics and the Inclusion of Transit Countries into the Analysis

So far we based our discussion of energy security on price and volume factors. However, there are a number of concerns, which make it necessary to enhance the existing analysis tools so as to be closely related to the real world.

1. There has been a growing number of instances in which strategic aspects have dominated over traditionally considered technical and economical feasibility in the process of decision-making in the field of international energy deals.
2. Additional concerns are being raised by the growing complexity of the world energy infrastructure, which strongly exposes interdependability of its layers and sensitivity to short and long-term threats.
3. The interruption of the export flows of Russian gas in January 2009 suggest that role of transit regions in providing the security of supply had been underestimated by research. It is also important that bypassing traditional transit regions will have

a significant socioeconomic impact on them, which, in turn, will affect cooperative energy security.

GASCOM is being enhanced to take these concerns into account.

By monitoring the unwanted events (e.g. a supply disruption for a critical period of time) the new system will be capable of answering questions such as the following:

- Which setup and evolution of the import-export network guarantees the minimum vulnerability in case the given unwanted event occurs?
- How will alternative supply routes impact the cooperative security, that is, to which degree will it serve the suppliers' demand security, the consumers' supply security and the socioeconomic objectives of the transmitters?

In our opinion, these examples of modeling energy security are distinct from previous approaches to energy systems and capable of dealing with the nexus of energy system and its economic-environmental solutions in a dynamic geopolitical global perspective.

## 4 POLICY IMPLICATIONS

Viewing the resilience of a national energy system as a problem of homeland security can go a long way, but as we have argued in this article, going the whole way to international long-term energy security requires a systems analytical approach. One of the most important ingredients of such an approach is to include symmetry, most importantly the symmetry of demand security and supply security. We have illustrated this conviction with examples of popular arguments, which we analyzed from the perspective of symmetry. The resulting recommended strategy we call cooperative energy security.

The second major focus of this article was the presentation of GASCOM, a concrete model of gas trade, which is one of the most important issues in long-term international energy supply and demand. At the core of that model is the notion of Nash Equilibrium, which is completely symmetric by its very formulation.

Applying the model we analyzed two trade modes, a long-term, bilateral mode and a free-market mode. From our analysis of the advantages and disadvantages of the two modes we conclude that the "optimal" mode of the model is fully consistent with the strategy of cooperative security: LTCs until the end of the payback period, free trade afterwards. In addition to its security aspect, we think that cooperation is needed in any gas trade model due to the limited nature of gas "markets."

But how can we implement symmetry of global energy security in the real world? Generally speaking, consumer-producer dialogues that recognize this kind of symmetry and that enter the dialogue in a spirit of joint problem-solving, would appear as a prerequisite. Modest steps in this direction were undertaken jointly by IIASA's Dynamic Systems (DYN) and Environmentally Compatible Energy (ECS) Programs in 2004–2006. In the spirit of systems analysis, a forum was created, on which academia, industry, and policy-making from consumer and producer countries regularly exchanged their views about energy security—in this case of natural gas in particular—in a scientific and neutral environment.

Activities of this forum were the basis of contributions, by the authors of this chapter and their colleagues, to the Energy Modeling Forum's study on "Prices and Trade in a

Globalizing Natural Gas Market" (EMF-23), to the Civil G-8 activities preparing for the St. Petersburg G8 Summit, and to industrial applications.

In order to better understand the phenomena illustrated in this chapter, IIASA's DYN Program has embarked on the Fragility of Critical Infrastructures (FCI) initiative. The purpose of FCI is to view critical infrastructures in the context of systems analysis, that is assessing not only physical properties but also operational, regulatory and behavioral aspects of network nodes and agents involved.

In the meanwhile, the forum has been transformed into the so-called WIEN (***W***orld ***I***ndependent ***E***nergy***N***etwork) Group, moderated by the Institute of Energy and Finance, Moscow [13]. WIEN is an informal network of independent experts and acts as an assembly of individuals with academic, governmental, and industrial backgrounds who are interested in specific issues which are being addressed by the Network.

Also the thoughts presented in this article were inspired by the discussions on that forum and in the WIEN Group. Nonetheless, the authors are solely responsible for the contents presented here.

# LARGE-SCALE ELECTRICITY TRANSMISSION GRIDS: LESSONS LEARNED FROM THE EUROPEAN ELECTRICITY BLACKOUTS

HANS GLAVITSCH

*Swiss Federal Institute of Technology, Zurich, Switzerland*

## 1 INTRODUCTION

Electricity as the most versatile form of energy is the commodity of civilization, which has become something without which modern life is unthinkable. It is not a primary

form of energy, but rather a secondary one, which has to be converted from various primary forms. The locations where these are available may be at distances to those where they are consumed; for example, hydraulic sources or technical constraints may require distant placements of generating stations, although primary sources would allow their site anywhere. Further, electricity requires a transport by conductors or better by transmission lines. Thus, transmission is a basic means for providing electricity to consumers. Since the transportation loss is a function of the current, the transportation over long distances is done at high voltages as high voltages allow low currents, which produce low losses. Single transmission lines are not enough as they do not guarantee enough reserves. Hence, the practice has led to the formation of interconnected transmission networks, which provide reserves, contribute to the economy of the operation and equalize between deficiencies and surplus.

The interconnection, however, implies the propagation of disturbances over wide areas. Hence, deficiencies or surplus of power are felt in the overall system. In extreme condition, a disturbance with all possible internal corrections may evolve to a blackout or near blackout as experienced in recent years in the European interconnected system. There are various causes for blackouts, such as technical, conceptual, due to misunderstanding of phenomena, or simply due to human error.

## 2 BASIC MECHANISM OF ELECTRIC POWER TRANSMISSION IN A LARGE GRID

Electric power transmission is predominantly realized by the system of alternating currents (AC system), in particular by three-phase currents. The alternating mode allows transformation of voltages by the relatively simple transformer. A single-phase system generates a stream of pulsating power. However, if three single-phase systems—as a three-phase system consists of three single phase systems—are combined in such a way that the three single phase systems are shifted one third time period each the shifted pulsating powers result in one constant power stream. Alternating voltages and currents create synchronizing forces between generators such that all machines rotate at the same speed yielding one unique frequency in the system.

The sum of the input powers, thus the generated output, is balanced by the total of the consumed load. The level is adjusted such that the speed that is directly proportional to the frequency of the voltage stays at the nominal level, in terms of frequency 60 or 50 Hz. Any disturbance in the power balance causes a change in frequency. Thus, a drop in frequency is a signal that there is not enough primary power or an excess of load. The Union for the Co-ordination of Transmission of Electricity (UCTE) has established rules [1] for the contribution of generators in subsystems (areas) to the correction or maintenance of frequency. Should there be a major drop in frequency, each subsystem has to be adjusted such that it contributes in terms of the so-called primary control an amount of power proportional to its annual consumption. The amount is derived from an assumed maximum loss of generation of 3000 MW, which does not cause more than 180 mHz of frequency deviation. Besides global changes in frequency, there are local changes on transmission circuits, which may cause overloads.

Another important phenomenon is the change in system voltage. The transport of large amounts of power over long distances leads to a decrease in voltage, which may cause instabilities. Generally, the whole system is an oscillatory system that breaks up if the

amplitudes of the swings exceed a limit, and then there is a loss of generation, which could cause a chain reaction, that is, further losses. In order to counteract undesired oscillations, damping measures are installed in generators, explicitly in voltage regulators. The magnetic field in the generators is mainly responsible for the voltage, and the excitation system controlled by the voltage regulator reacts to any change in the voltage.

## 3 POWER FLOWS IN INTERCONNECTED GRIDS

Power flows in the grid are determined by the injected nodal powers, that is generation and consumption, and by the laws of the network acting on meshes and nodes, which consist of balances of voltages generated by currents times impedances in a loop or by balances of nodal currents. Impedances are characteristics of transmission lines. Because of mechanical properties, transmission lines can carry flows up to a predetermined thermal limit (conductor temperature determining the sag of conductors). Since the flows from one location to a distant one is fixed by the injected powers, the loss of a transmission circuit causes a redistribution of local flows. In extreme condition, the loss of one of the several parallel circuits causes a shift of the flow to the remaining ones, which can lead to overloads. A numerical example of a flow situation is given in Figure 1.

The total of flows is given by the injections at nodes A and B equaling the output at nodes C and D, that is 490 MW. In the normal operation, the flows in the circuits A–C, A–D, and B–D are also 490 MW. When the line A–C is lost, the loading on A–D reaches 279.4 MW and on B–D 210.6 MW without any change in the total of input/output at the nodes.

## 4 THE EUROPEAN INTERCONNECTED SYSTEM—THE UCTE SYSTEM

The European interconnected system consists of three major parts that are connected by high voltage direct current (HVDC), namely, the central UCTE system, the Scandinavian

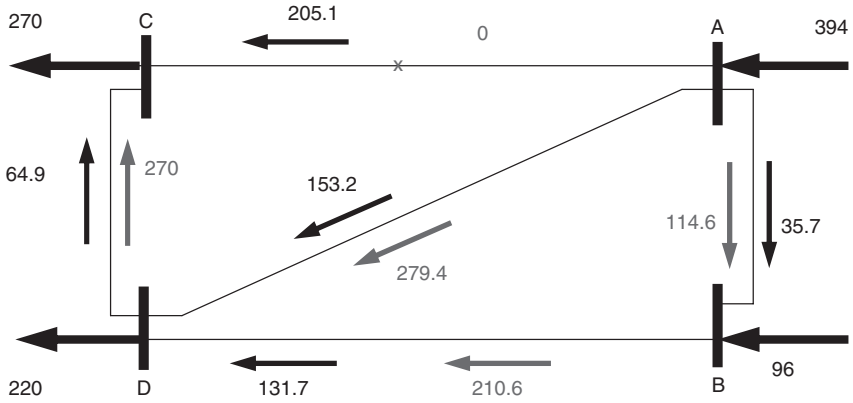

**FIGURE 1** Effect of outage of one circuit (A–C): black figures flow in nondisturbed network and grey figures flow when circuit A–C is tripped.

network, and the network on the British Islands. Here, the interconnected synchronous AC system, the UCTE system, is of interest. It extends from Denmark to Spain and from France to Greece and the East European countries. It consists of 380- and 220-kV-transmission lines operated to a maximum of 420 and 245 kV, respectively. The structure of the grid is characterized by substations where a large number of transmission lines terminate and a larger number of substations where just three or four lines are connected. Typical line lengths for 380 kV are in the range of 100–150 km, sometimes 200 km. For 220 kV, they are considerably shorter (50 km). In France, the line lengths are above 200 km for 380 kV. In Germany, Switzerland, and Northern Italy, the grid is highly interconnected. Tie-lines (circuits crossing borders) are not numerous, except in Germany and Switzerland. The number of tie-lines to East European countries is relatively less.

Originally, the UCTE system had the function to provide the security of supply in continental Europe. For this purpose, the system has been developed over the last 50 years with a view of assuring mutual assistance between national subsystems. However, there has been a fundamental change of paradigms over the past one or two decades. The transmission infrastructure is no longer just a tool for mutual assistance, but has become a platform for shifting ever growing power volumes all across the continent. On the other hand, the development of the system is more and more affected by stricter constraints and limitations in terms of licensing procedures and construction times.

In the UCTE system, the annual production in the year 2006 amounted to 2584.6 TWh, the maximum load 390.6 GW (third Wednesday in December) and the annual load reached 2530.1 TWh. Electricity is produced in nuclear stations (37%), conventional thermal stations (47%), and in hydro stations (16%, figures of 1999).

Within a country, one or more control areas operated by independent transmission system operators (TSOs) and a large number of market participants (traders) are in existence. Today there are 29 TSOs in 24 countries. Energy is exchanged for various reasons, hydro to thermal, day to night and vice versa, as well as for economic benefits. The annual exchange 2006 among UCTE countries reached 296,822 GWh, that is 11.7% of the consumption. This is an increase over the time before the opening of the market as the exchanged energy is typically in the order of 9–10%.

## 5 MANAGEMENT OF THE SYSTEM

### 5.1 Before Opening of the Market

The vertically organized utilities were focused on their system and consumers. Tariffs for the exchange between voltage levels were fixed and state controlled. On the transmission level, an exchange of energy and power took place for the benefit of reducing reserves, peaking power, system regulation, better control of frequency, area control, and coordinated scheduling. The TSOs were the traders and the actors. The operation was coordinated by the rules of UCTE, which comprised the reserve management, primary, secondary, and tertiary frequency control, as well as security management.

### 5.2 In the Open Market

The Directives of the European Community introduced the liberalization of the electricity market [2], which was implemented step by step and is now nearly complete. The aim is

a fully liberalized electricity market for all consumers whereby generation, transmission, and distribution are unbundled. The market participants are the traders and the TSOs are responsible for the technical aspects of operation. Explicitly, traders are utilities, power producers, and consumers, whereas TSOs are organizations for system control. In the open market, the exchange is governed by short-term economic objectives and trading takes place in a bilateral way and on central exchanges. However, there are also long-term contracts among partners being apart for short and long distances. As compared to the modes of operation, before liberalization flow patterns change markedly from hour to hour. There are countries that mainly export and import, that is France, Switzerland, and Germany export and Italy and Netherlands import. Some are net importers/exporters, others show changing patterns, and still other traders sell energy not originating in the own area.

As mentioned, TSOs are responsible for congestion management and system security; however, quite often they are not in command of controlling flows in their own area since the cause and origin of the problem lie outside the area, that is corresponding generation and consumption. The UCTE rules as laid down in the handbook [1] supplemented by the multilateral agreement (MLA [3]) are still in effect, the latter in particular focused on maintaining security. Congestion management is predominantly implemented in terms of auctions on cross-border transmission circuits. The methodology is market conform, but has limited effects as the TSOs lack information from neighboring areas and congestions within the areas are not handled. This is not satisfactory, as the annual exchange is increasing particularly in local zones such as in countries like Switzerland, France, Germany, Netherlands, and Italy.

## 6 THE ITALIAN BLACKOUT 2003

### 6.1 Introduction

The Italian transmission system is in a particular situation as the connection to the European network is geographically concentrated on the North only. The cross-border lines consist of not too many 380 kV circuits concentrated toward France and Switzerland. There is a 380 kV connection to Slovenia, but the network behind, that is, through Austria, consists of 220 kV lines only. The 380 kV loop through Hungary is not very effective because of high impedances, see Figure 2.

Because Italy does not generate nuclear energy and is with high energy costs due to fossil fired units, energy is imported from France, Germany, and Switzerland (for economic reasons) and the energy is stored in pump storage units during nights and weekends. The power flows predominantly over the circuits from France and Switzerland. As the flows are substantial and when it has been realized that the loadings of the tie-lines are critical, the countries involved established reference flows for the summer and the winter period, which were derived from power injections in the zone north of the Alps. According to these reference flows, the maximum import to Italy may reach 6500 MW in winter and 5500 MW in summer. These imports when appropriately distributed over the cross-border zones and circuits have been designed to guarantee an $(n-1)$-secure system. (The concept of $(n-1)$-security is discussed below.)

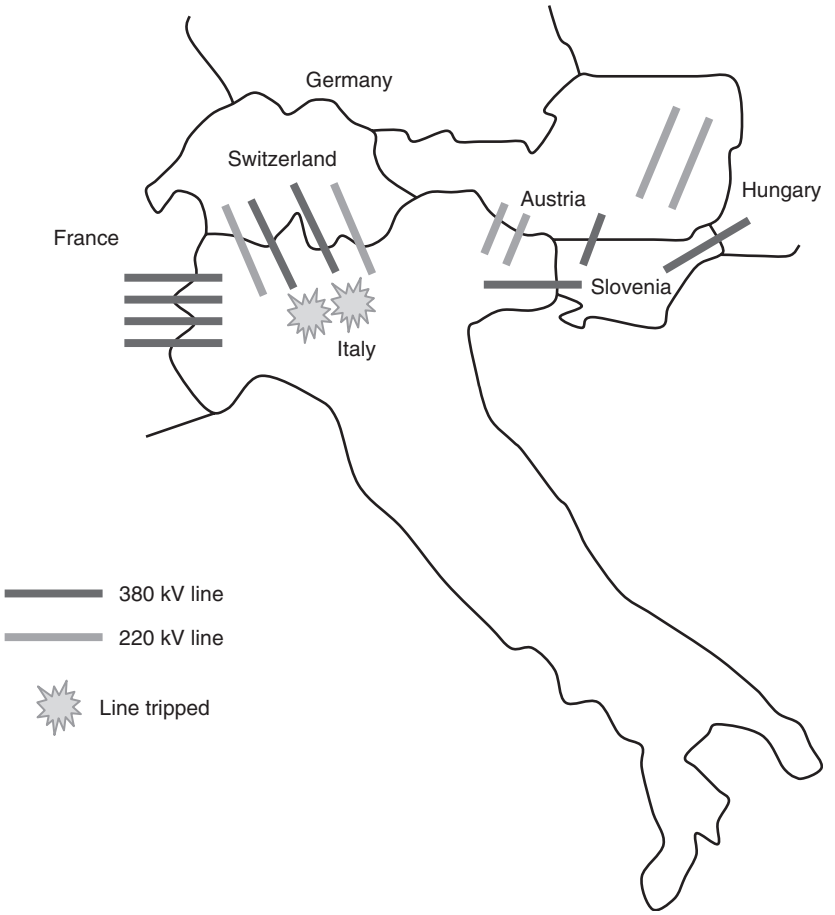

**FIGURE 2** Italy—tie-lines to the north.

### 6.2 Factual Sequence of Events—Blackout September 28, 2003

On September 28, 2003, a Sunday, at 03:00 a.m., a typical situation existed where 6651 MW was imported and apparently used for pumping (pump load 3638 MW). At this time, the total consumption in Italy was 27,702 MW. The tie-line flows and the scheduled flows are as follows [4, 5]:

| | Physical flows (MW) | Scheduled flows (MW) |
|---|---|---|
| Switzerland–Italy | 3610 | 3068 |
| France–Italy | 2212 | 2650 |
| Slovenia–Italy | 638 | 467 |
| Austria–Italy | 191 | 223 |

The physical flows are those actually measured and the scheduled flows are those set on the load—frequency controllers.

The cross-border circuits between Switzerland and Italy consisted, at that time, of two 380 kV circuits (single lines) and several 220 kV circuits. The 380 kV circuits run from Mettlen to Lavorgo (Lukmanier line) and Sils to Soazza (San Bernardino line), both cross the Alpes. The latter substations are still in Switzerland, but are connected via 380 kV lines to stations in Italy.

In the following paragraph, the exact sequence of events is discussed as reported in Refs. [4, 5].

At 03:01:42 a.m., the 380 kV circuit Mettlen–Lavorgo tripped due to a tree flashover. The automatic reclosure was unsuccessful because of a phase angle difference of 42° across the open breaker (the setting on the breaker was 30°). A subsequent manual trial was just as unsuccessful. As a consequence, the 380 kV circuit Sils–Soazza overloaded and reached 110% of its thermal rating. At this point, the state of $(n-1)$-security was lost. The operator at the control center in Laufenburg (at that time ETRANS, now Swissgrid) was unaware of the urgency of the situation. The Swiss operator noticed that the actual flows to Italy were roughly 300 MW above the scheduled value and requested a reduction of the imports from the Italian TSO (GRTN–Gestore della Rete di Trasmissione Nationale) by telephone at 03:11 a.m. The tolerable time for the reduction of the current was 15 min.

The reduction was performed and the imports reached the scheduled value after 10 min. However, the reduction was not sufficient and at 03:25:11 a.m., the circuit Sils–Soazza tripped due to a tree flashover (probably because of a high sag caused by the overload). Immediately afterwards further 220 kV circuits tripped, and at 03:25:28 a.m. the Italian network lost synchronism with the rest of the UCTE system. The Italian system has lost about 6500 MW, the frequency dropped causing the shutdown of generating stations, which led to the blackout (definite at 03:27:58 a.m. when the frequency dropped below 47.5 Hz). The rest of the UCTE system experienced a rise in frequency to 50.25 Hz with swings to 50.3 Hz. In the immediate vicinity of the Italian border in Switzerland (Ticino and Valais), the systems were lost (blackout). Otherwise the UCTE system was not affected, although it experienced the frequency changes.

The report [4] mentions four main reasons for the blackout:

1. Unsuccessful reclosing of the line Mettlen–Lavorgo (Lukmanier) because of a too high phase angle difference.
2. Lacking sense of urgency regarding the Sils–Soazza (San Bernardino) line overload, and call for inadequate countermeasures in Italy.
3. Angle instability and voltage collapse in Italy.
4. Right-of-way maintenance practices.

However, the principle of $(n-1)$-rule in chapter "Security and reliability standards—safety of the system" states that a single incident must not jeopardize the system, which implies that after a loss of the (n–1)-state the system is supposed to return to the $(n-1)$-state as soon as possible. This means identifying countermeasures which would enable the system to be brought back to a secure state. The report states that the appropriate countermeasure after the loss of the Mettlen–Lavorgo circuit would have been the shutting down of the pumps in the storage plants in Italy having a load of about 3500 MW.

### 6.3 Comments on and Interpretations of the Events/Findings

The reasons given in Ref. 4 are certainly true and correct, but do not give the complete picture. In particular, the first two points need further explanations. As far as point 1 is concerned it has to be realized that there was a substantial flow across the Swiss network where the circuit Mettlen–Lavorgo is imbedded. This flow caused the phase angle difference of 42°, which should have been below 30°. The Swiss Federal Office of Energy (SFOE) investigated the situation and came to the conclusion that the flow situation has been far away from the reference flow [6]. The reference flow would have produced a phase angle difference of 20° and there would have been no overload on the circuit in the first place. A simplified network illustrates the effect of flows on the phase angle difference at an open breaker, see Figure 3.

The phase angle difference is proportional to the sum of the flows C + D + E or to the flow A or B. A phasor diagram is shown on the right-hand side where phasors are the terminal voltages. The tree flashover is probably due to excessive sag of the conductors, which was caused by the overload. Hence, the flow situation is the primary cause of the tripping and the unsuccessful reclosing. The report states that the system was still $(n-1)$-secure at 03:00 a.m., which would have been correct if the countermeasures had been identified and implemented. This is one of the basic flaws in the whole process that must be further criticized by the following.

A quite similar disturbance happened in the critical zone of the Swiss network in the year 2000, which is documented in the annual report 2000 of UCTE [7]. On September 8, 2000, the San Bernardino (Sils–Soazza) 380 kV circuit tripped at 9:46 p.m. and at 10:11 p.m. the Mettlen–Lavorgo (Lukmanier) 380 kV circuit tripped, followed by trippings of 220 kV circuits between Switzerland and Italy as well as between Austria and Italy. These line trips led to load displacements on France to Italy line resulting in a flow of 3900 MW on 380 kV and 220 kV lines. As a result of this overloading, these transfrontier lines together with five other 380 kV lines in France reached their 20 min overload protection threshold, others even their 10 min overload protection threshold.

Italy was required to produce an additional 1800 MW, in order to ensure operational security without network separation. It was not possible to implement a sufficiently rapid reduction of nearly 1500 MW in exchange programs between Italy and Switzerland. For these reasons, the UCTE network frequency rose to 50.15 Hz.

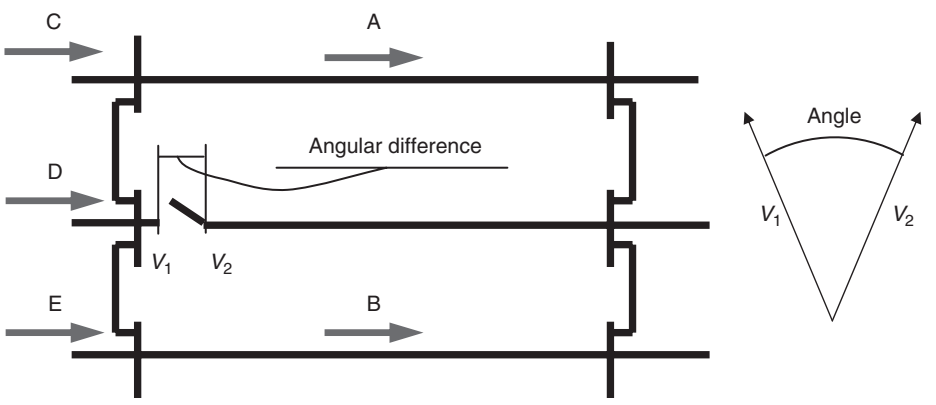

**FIGURE 3** Flows generating phase angle difference at open breaker.

The report mentions numerous problems that took place in the following hours and on September 9, 2000. However, no disturbances in the distribution were recorded. What is important is the concluding statement in the report:

> As a result of the events described above, TSOs in Italy, France, Switzerland have agreed to a joint procedure for the improvement of communications and the implementation of arrangements for the modifications of exchange programs in case of emergency.

The events after 03:00 a.m. on September 28, 2003, do not indicate that such a joint procedure has been established. Further, it is an open question what the countermeasures would have been if the outages had taken place during the week around 11:00 a.m. when no pumps were in operation.

Unless one would resort to substantial load shedding in Italy (the remedial measure to point 3 above), the solution to the problem is careful congestion management whereby flow patterns close to the reference flow are maintained and the security is monitored whenever the load changes. Swissgrid, the Swiss TSO, has implemented a security monitoring scheme [8], which generates security information within half a minute whereby the Swiss network plus the surrounding network comprising 6000 nodes is modeled. Today this is the only realistic and practical procedure to master the problem.

## 7 THE SYSTEM DISTURBANCE NOVEMBER 4, 2006

### 7.1 Situation and Actions before the Disturbance

On November 4, 2006, at 10:10 p.m., the European network was split into three parts caused by a planned outage of a double circuit 380 kV line in northern Germany where the consequences were meant to have been orderly estimated and considered secure, but finally evolved to a cascading process. The process separated the UCTE and caused low-frequency load sheddings, but did not lead to a complete blackout. A precondition to the disturbance was the heavy cross-border flow situation between East and West Germany on the one hand and Eastern Europe and South Eastern Europe on the other hand. Since this is essential to the understanding of the disturbance of the network areas, the generation and cross-border flows are shown in Figure 4 [9].

The East–West flow of 9260 MW was caused by a heavy load in the Netherlands, which was supplied by wind generation in the northeast. The double circuit line that was switched was the Conneforde–Diele line shown in Figure 5 located in the far northwest corner of Germany.

The line belongs to the network of E.ON, the important German utility and the taking-out-of-service was planned for November 5 and prepared the days before. The operation was requested by a shipyard for passing of ship on a canal that is crossed by the line. It was also coordinated with Tenne T, the TSO of the Netherlands. E.ON Netz, the TSO of E.ON, carried out an analysis of the impact of the operation using standard planning data. As no violation of the $(n-1)$-criterion was detected, E.ON Netz provisionally approved the switching off. On November 3, around 12:00, the shipyard requested E.ON Netz to advance the disconnection of the line by 3 h, to November 4 at 10:00 p.m. A provisional agreement was given by E.ON Netz after a new analysis did not reveal a violation of the $(n-1)$-criterion. At this point, the TSO of Rheinisch-Westfaelisches-Elektrizitaetswerk (RWE) of the adjacent German network

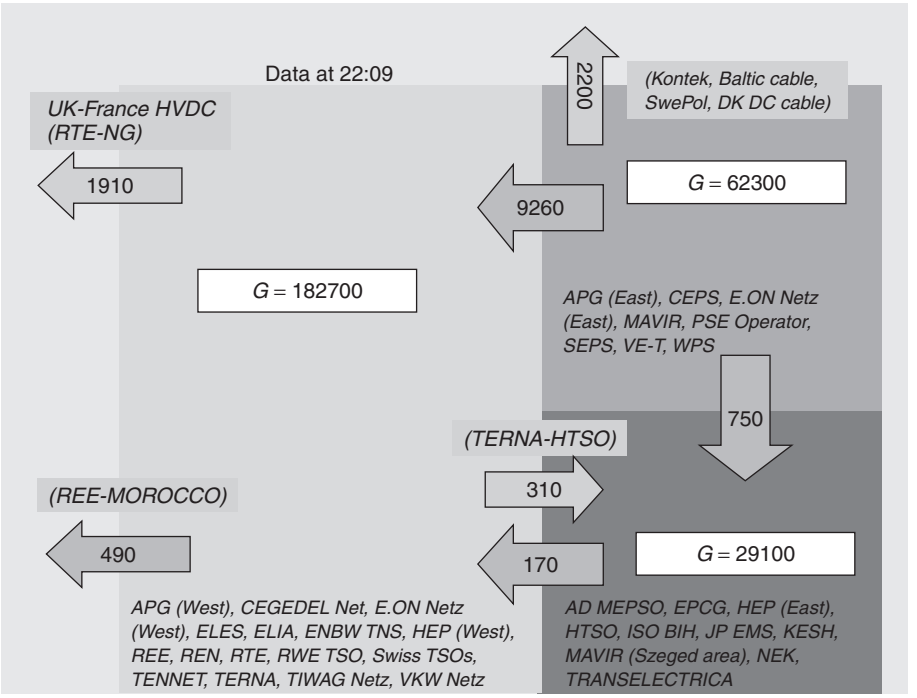

**FIGURE 4** Schematic of UCTE system: three areas before separation at 9:09 p.m. and generation and cross-border flows.

and the TSO of Tenne T were not informed about this procedure, so no special security analyses were made.

For the new situation, it was not possible to reduce the exchange program between Germany and the Netherlands including the outage of the Conneforde–Diele line (agreed timing, setting of capacities, and auctions). Further, there was no indication of the switching operation in the planning tools and data, such as day ahead congestion forecast (DACF), by E.ON Netz to all UCTE TSOs on November 3 with the forecast for November 4 at 10:00 p.m. and beyond.

As late as 6:00 p.m., E.ON Netz informed Tenne T and RWE TSO about the new time for the disconnection of the line.

At 9:29 p.m., a load flow calculation by E.ON Netz did not indicate any violation of limit values. On the basis of an empirical evaluation of the grid situation, E.ON staff assumed, without numerical computations, that, after the disconnection of the line, the security of the system would be met.

RWE TSO also made a load flow calculation and an $(n-1)$-analysis at 09:30 p.m. just before the opening of the line, which confirmed that the RWE grid would be highly loaded but secure.

### 7.2 Evolvement of the Disturbance

The two circuits of the Conneforde–Diele line were switched off at 9:38 p.m. and 9:39 p.m. Shortly afterwards, E.ON Netz received warning messages about the high loading

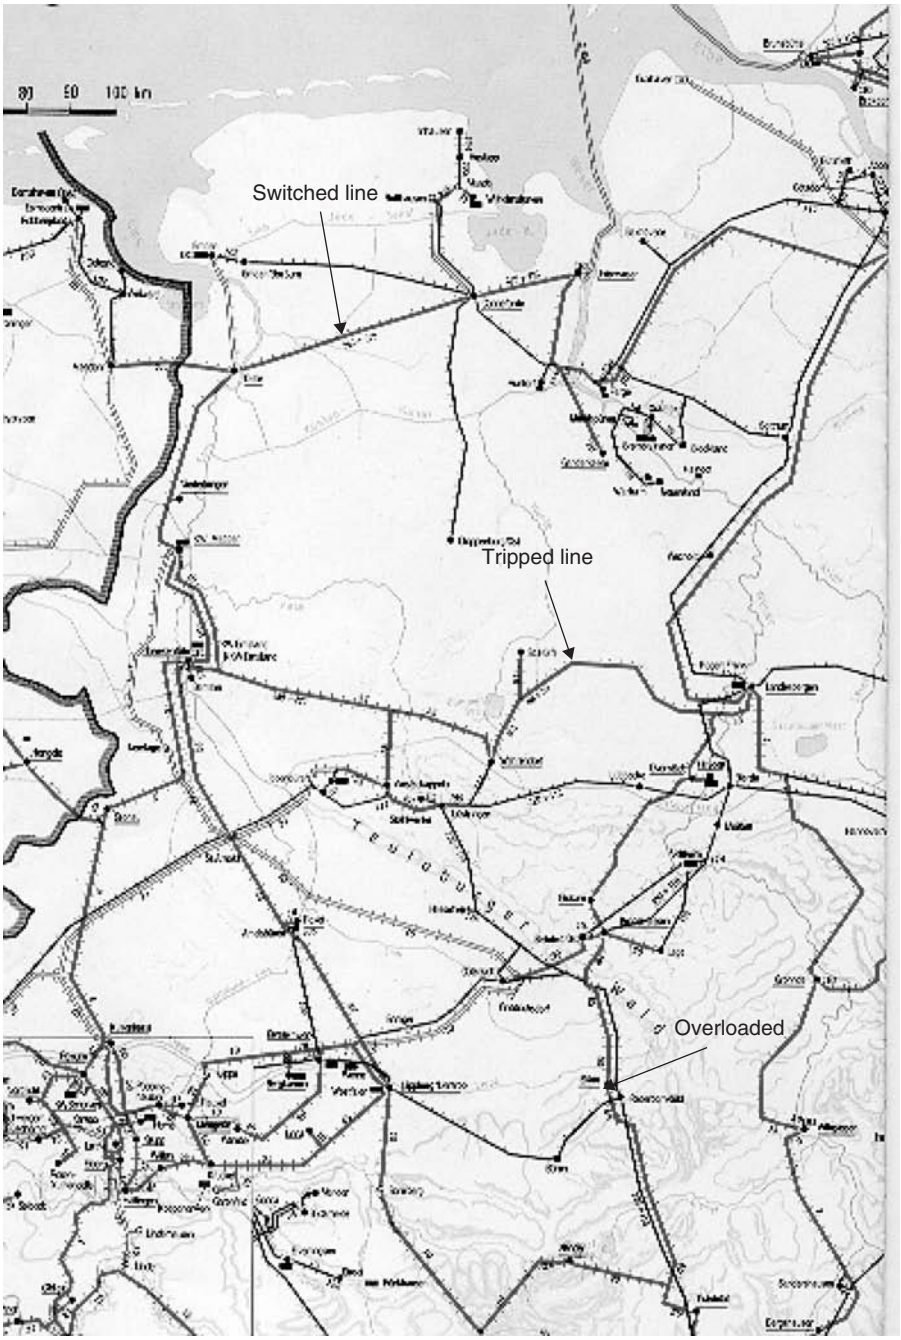

**FIGURE 5** Line diagram, section of northern Germany.

on a line south of the area shown in Figure 5 and at 9:41 p.m. RWE TSO informed E.ON Netz about the safety limit of 1795 A on the line Landesbergen–Wehrendorf, an interconnection between the E.ON network and the RWE network. This line is shown in Figure 5. However, at this point in time the critical current on this line has not been reached. The report [9] documents that the protection settings on either sides of this line were different and the TSO of E.ON was not aware of this fact, that is tripping current 3000 A on the E.ON side and 2100 A on the RWE side. In phone calls between the TSOs of E.ON, RWE, and Vattenfall, up to 10.00 p.m. the situation was considered to be critical and apparently RWE TSO informed E.ON Netz about the settings.

Between 10.05 p.m. and 10.07 p.m., the load on the 380 kV line Landesbergen–Wehrendorf increased and exceeded the warning value of 1795 A, which caused the RWE TSO to request from E.ON Netz an urgent intervention to restore the security of the system. E.ON Netz made an empirical assessment of corrective switching measures in terms of coupling of the busbars in Landesbergen expecting a reduction of the line current by about 80 A. The operation was done at 10:10 p.m., but resulted in the opposite effect. The line current increased and caused the tripping of the Landesbergen–Wehrendorf line, leading to a subsequent cascading opening of circuits along the vertical line shown in Figure 4 and separation of the southeastern network.

### 7.3 Consequences of the Opening

The European network was separated into three parts, as shown in Figure 6, whereby different frequency patterns developed. Since a substantial flow between the East and West part was interrupted, the area 1 experienced a drop and the area 2 a rise in frequency. In area 3, there was a frequency drop but it was only 200 mHz. The low frequency in areas 1 and 3 caused a series of load sheddings spread over the areas and the loss of loads was substantial, that is between 3% and 19% of the load. In some areas, pumps were disconnected between 240 and 450 MW. In all areas, generation was tripped, namely, 10,909 MW in total. The switching operations caused heavy intersystem

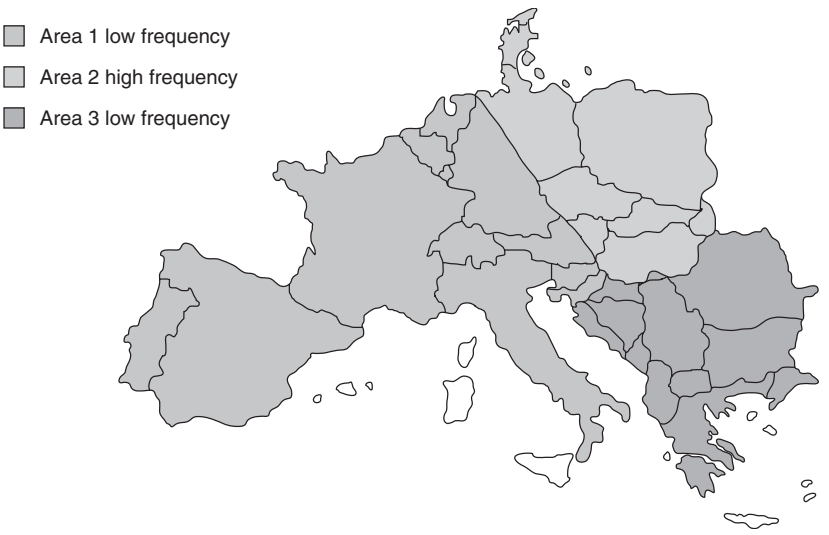

**FIGURE 6** Separation of the UCTE network into three parts.

flows after 10:10 p.m. A complete blackout did not result in neither of the areas. This allowed the restoration and the resynchronization of the areas fairly soon after the initial disturbance.

The actions of the resynchronization process showed three different phases, namely:

- resynchronization trials that did not result in real interconnection;
- resynchronization attempts that resulted in real interconnection, but failed after a few seconds;
- successful resynchronization steps.

The milestones of resynchronization were first successful reconnection of tie-lines between areas 1 and 2 at 10:47 p.m. when areas 1 and 2 were connected, and area 3 was connected at 10:49 p.m.

The problems in the resynchronization process were the missing information on the state of generating units and of the network, as well as noncoordinated trials of operators to synchronize generators. In particular, actions in the distribution network were completely non-coordinated.

### 7.4 Failures and Mistakes that Led to this Disturbance

On the basis of report [9], several items that caused the disturbance can be identified. The main cause is the omission of contingency analyses at various stages of the preparation of the switching operation, both by E.ON Netz and RWE TSO. This applies to the points in time before the opening of the line, right after the opening of the line, and before the coupling of the busbars in Landesbergen. It is not just an analysis of the respective own area, which should have been performed, but a comprehensive analysis of the own area including the surrounding network, that is E.ON network plus RWE network plus Tenne T network as it is possible today and described in [8]. Another item is the missing information of RWE TSO and Tenne T by E.ON Netz about the advance of the switching of the line. This did not allow the TSOs to check the consequences of the switching early enough.

A crucial item was the different protection settings on the Landesbergen–Wehrendorf line about which E.ON Netz was not aware. It was not only this line which was heavily loaded, but also several lines in the E.ON and RWE network, which when tripped, could have caused the disturbance. The load increase between 10:00 and 10:10 p.m., which led to the tripping, was also affected by the change in exchange programs that usually takes place around this time, for example, 340 MW from Germany to the Netherlands.

Generally, there was insufficient coordination between the TSOs. According to [9], this was considered the second main cause of the disturbance.

## 8 UNBUNDLING AND DECENTRALIZATION—FEATURES IN CONTRADICTION TO SECURITY

Further to the detailed discussions and conclusions from the reports on disturbances, there are general features of the liberalized system in Europe, which are detrimental for the security of the network. One of the features is the requirement of the Directive of the European Community to unbundle generation, transmission, and distribution.

Unbundling is justified in the normal state of the system. However, in a critical situation, the cooperation of generation and transmission is absolutely necessary and therefore unbundling has to be suspended. A TSO must have direct access to generation for the correction of a flow. Above all, the European system is decentralized. According to [9], there are 29 TSOs in 24 countries which manage an area or subsystem. But for the purpose of security, a comprehensive control over a wide region, that is overlapping the own, would be necessary. Each TSO is obliged to carry out such an analysis and TSOs have to cooperate and communicate in critical situations.

Thus, decentralization, congestion management, and security control in the European system are unresolved items.

## 9 CONCLUSIONS

The large-scale electricity transmission grid with a decentralized control structure, that is independent transmission operators as in the UCTE system, and under the concept of unbundling is only partly suited to manage disturbances and to avoid blackouts, at least with the presently implemented tools. Unbundling and decentralization are detrimental for security as the electricity grid acts as a whole, in terms of frequency, voltage, and flows, from one end to the other. Contracts over long distances and the ensuing flows are difficult to control by TSOs. Hence, cooperation and closer communication is needed.

# INTERDEPENDENT ENERGY INFRASTRUCTURE SIMULATION SYSTEM

G. Loren Toole and Andrew W. McCown

*Los Alamos National Laboratory, Threat Reduction Directorate/Decision Applications, Los Alamos, New Mexico*

## 1 INTRODUCTION

IEISS was derived from the energy interdependence simulation (EISim) and simulation object framework for infrastructure analysis (SOFIA) software architectures that have been applied routinely at Los Alamos since the mid-1990s. The National Infrastructure Simulation and Analysis Center (NISAC), supported by the Department of Homeland Security, Office of Infrastructure Protection, funds for the use of this software. The NISAC program was established to meet the need for a comprehensive capability to assess the national system of interdependent infrastructures. In the USA PATRIOT Act of October 2001, NISAC was chartered to "serve as a source of national competence to address critical infrastructure protection and continuity through support for activities related to counter terrorism, threat assessment, and risk mitigation".

This article discusses the underlying simulation concepts, application of interdependent energy infrastructure simulation system (IEISS) to an interdependency case study of urban infrastructure, and IEISS applications to other problems of national interest.

Interconnected and interdependent energy infrastructures are extremely complex systems, consisting of physical facilities (such as power plants and refineries), transmission lines, phone lines, roads, railways, waterways, and so on, as well as human decision makers (e.g. consumers, legislators, investors, and chief executive officers). Examples of critical infrastructures that are interconnected and interdependent are shown in Figure 1.

A comprehensive simulation tool is needed to model the nation's key infrastructures (e.g. energy, communication, and transportation) and their intra/interdependencies.

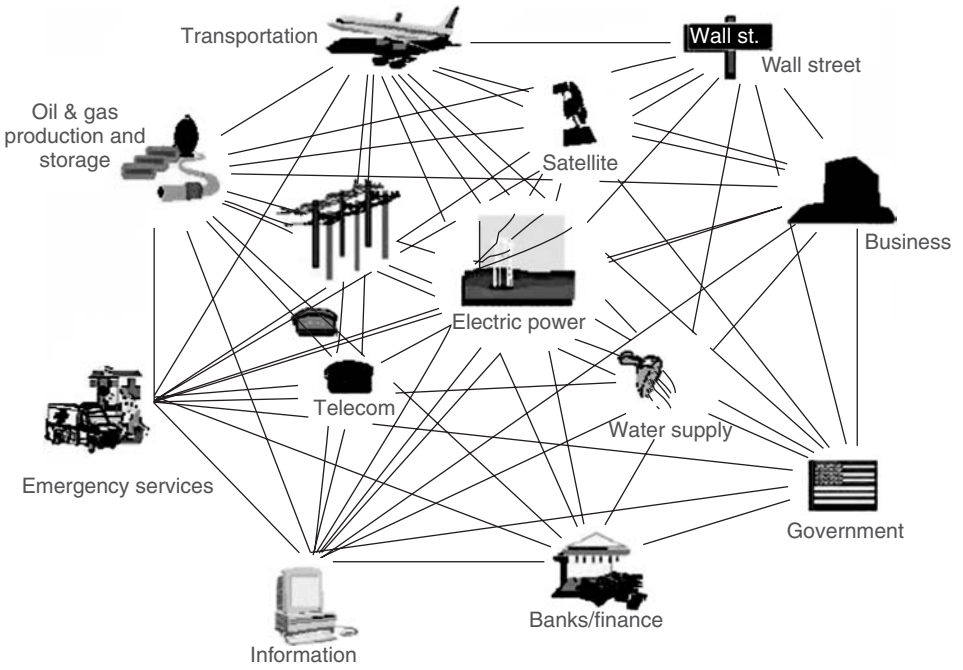

**FIGURE 1** National interconnected and interdependent infrastructures.

However, these dependencies must be identified and understood before infrastructure protection, mitigation, response, and recovery options can be provided. Although existing technology well analyzes single-domain infrastructures, severe limitations arise when this technology is applied to interdependent infrastructures. For these cases in which multiple infrastructures are considered, analysts typically treat these interdependencies in an *ad hoc* manner. To represent the complex, nonlinear, and interdependent nature of these infrastructures, advanced computer simulations are needed. Without these simulations, it is simply too expensive, too risky, and too time consuming to determine the impact of policy and security decisions.

## 2 IEISS SIMULATION CONCEPTS

An infrastructure interdependency is defined as a physical, logical, or functional connection from one infrastructure to another, where the loss or severing would affect the operation of the dependent infrastructure. Although short-term service interruptions of energy infrastructures routinely occur, catastrophic system failures, or large-scale blackouts, are rare events. As infrastructures become more complex and interdependent, the probability of having large-scale outages increases. Because a component failure in one infrastructure does not necessarily result in a propagating failure in another interdependent infrastructure (or for that matter, within the same infrastructure), this cascading phenomenon is difficult to analyze. An example of interdependencies among network-like infrastructures is given in Figure 2. "Network-like" refers to an inherent topological feature of the infrastructure itself, namely, a connected structure of linked nodes.

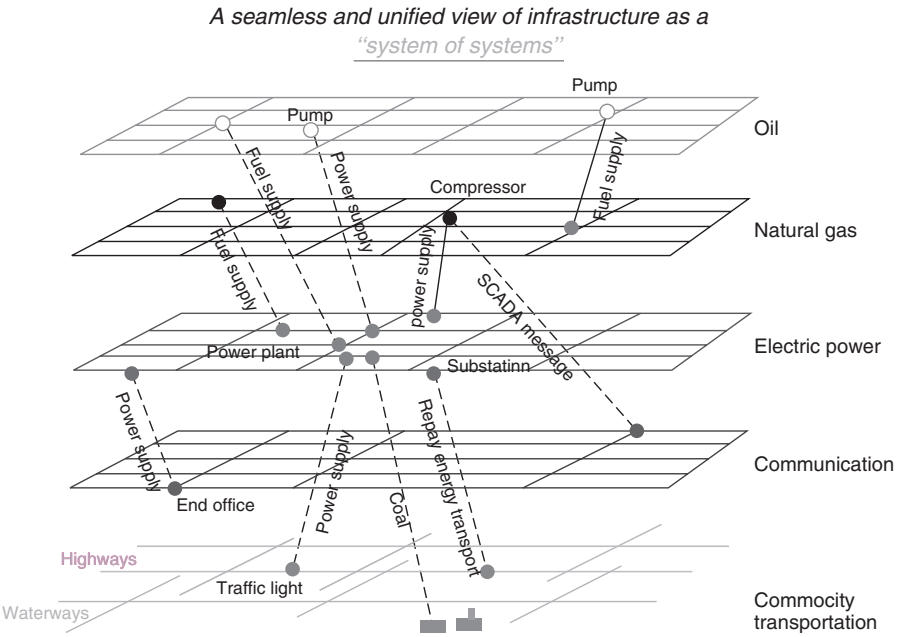

**FIGURE 2** Illustration of interdependencies among network-like infrastructures.

The horizontal layers in the figure represent dependencies within an infrastructure, and the vertical lines indicate interdependencies between infrastructures. Although Figure 2 shows only physical infrastructures, future capability will include nonphysical infrastructures as well, such as financial and/or other economic networks. IEISS does not replace single-infrastructure tools since existing technology analyzes these domains in sufficient detail. However, when this technology is applied to interdependent infrastructures, severe limitations usually exist.

IEISS relies on an actor-based (or object-oriented) modeling approach of infrastructures [1]. Each physical, logical, or functional entity in an infrastructure corresponds to a software a*ctor* (sometimes called a *software agent*) that has a variety of attributes and behaviors that mimic its real-world counterpart. The connections within or between infrastructures are represented by connections between the relevant actors, and the actors interact in the software through a message-passing protocol. Mathematically, infrastructures can be represented by graphs. Thus, any infrastructure(s) that can be represented in terms of a dependency graph can be modeled using this actor-based, message-passing representation. This approach is suitable for a wide variety of network-like infrastructures.

## 3 THE COMPLEXITY OF MULTIPLE INFRASTRUCTURES

A simulation of coupled infrastructures necessarily requires the use of multiple, heterogeneous algorithms [2]. Each infrastructure under consideration has its own dynamic laws and, thus, its own types of algorithms. It may be useful to mix different solution methods in the same simulation because of their varying accuracy and speed or to compare the

results of simulations using different algorithms. Ideally, "pluggable" algorithms could be attached individually to each actor in the system or to groups of actors. Mixtures of algorithms may be required by geography, infrastructure, or time.

Because of the potential complexity of coupled infrastructures, it is important that the solution algorithms be able to handle problems involving the "forward" simulation of systems and the "inverse" search problems. That is, given an initial state of the system, its evolution could be followed forward in time or, given the final state (typically involving loss of service), initial states could be determined that might evolve to this final state if a given number of contingencies were to occur.

When one or more interconnected components are forced out of service because of an operational or intentional failure, affected dependent or secondary components are also treated by IEISS as interdependency. This approach is based on the service area/outage area concept [3, 4]. For example, if an electric power substation is forced out of service, a polygonal representation of the service area normally served by the component is calculated. If components from other infrastructures lie within the calculated service area boundary and these components are dependent on the services of the failed substation, a propagation of the failure to dependent infrastructures is assumed. If the service areas of any affected infrastructures cannot be mitigated or reduced in extent through recovery measures, they are assumed to represent the outage area. This concept is further discussed in the next section.

Finally, if a service area can be estimated for all affected infrastructures, the simulation approach for interdependent cascading failures can be illustrated by the logic flow diagram shown in Figure 3. The simulation is initiated by creating a "contingency" event that

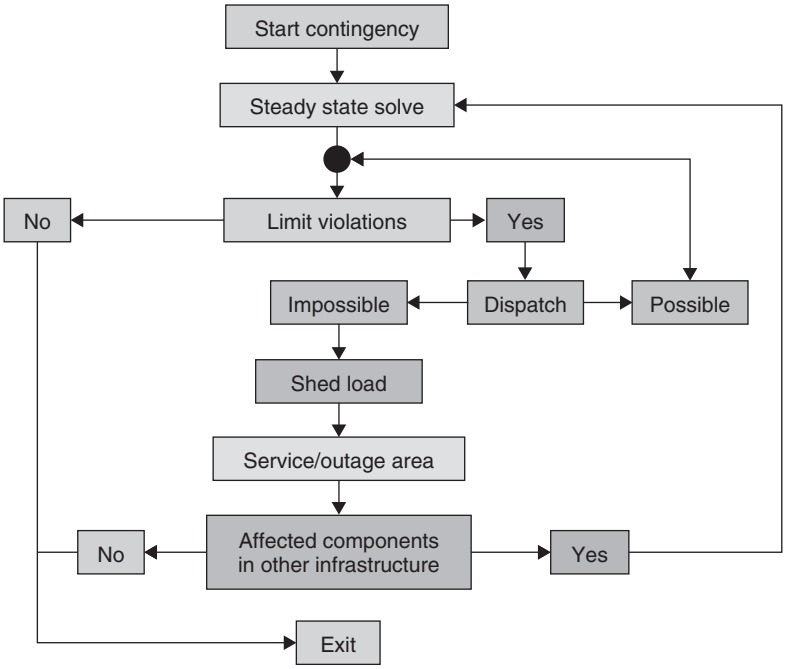

**FIGURE 3** IEISS logic diagram describing network limit violations.

involves single (or multiple) outages in one or more infrastructures. Steady-state solutions are then obtained for all infrastructures with key attributes reported (e.g. pressure or flow). If an attribute is not within its normal operating range, for example, a pipeline is operating above its maximum allowable operating pressure, the associated components are subject to limit violations [5]. Limit violations must be mitigated or else severe consequences can result. Mitigation can be accomplished by a variety of measures such as dispatching or reducing demand. Dispatching requires adjustments to operating parameters of variable equipment such as generators or compressors. The dispatch box shown in Figure 3 contains algorithms to eliminate limit violations.

If the contingency can be mitigated by dispatching, limit violations are rechecked and the simulation is ended ("possible"). However, if further violations exist ("impossible"), IEISS sheds customer load near the contingency and then calculates outage areas. Affected components in other infrastructures are also identified. Another simulation will be required to determine if loss of the affected components cause violations within their respective infrastructure(s) or propagation of effects is stopped. The IEISS simulation process ends when all limit violations have been eliminated. The final result is a list of outage areas, failed components, history of cascading events, and so on.

## 4 IEISS CASE STUDY: URBAN INTERDEPENDENCIES

A key element in modeling interdependent infrastructures is the ability to predict the propagation of a perturbation. This condition results from a component failure created within an infrastructure, which cascades to other interdependent infrastructures. This cascading effect is a key issue, but usually the least understood phenomenon. Although short-term service interruptions of energy infrastructures are routine in many areas, catastrophic system failures, or large-scale blackouts, are rare events. As urban infrastructures become more complex and interdependent, the probability of having large-scale outages increases.

The underlying concepts of interdependency and application of IEISS are illustrated by a fictitious example. Interconnected electric power and natural gas component attributes were input into the IEISS model, which are notionally representative of urban networks in most US cities. The model incorporated multiple layers of components operating at different voltages and pressures. Because of the network-like features, disruptions to key components in one layer can affect the operation of colocated components in other layers, creating an interdependency event. During the analysis, IEISS reported greater effects than would have resulted if single components were individually outaged.

The first phase of this event requires simultaneous loss of two components: an electric substation and a natural gas pipeline junction. An outage of the natural gas pipeline junction disrupts natural gas delivery to gas-fired power plants located approximately 10 miles to the south. The simultaneous outage of a 230-kV electric substation completes the initiating event. Components "A" and "B" are located approximately 30 miles apart as shown in Figure 4.

Following the initial loss of components, high-voltage electric transmission lines will be overloaded. This condition forces the utility to shed customer load to avoid equipment

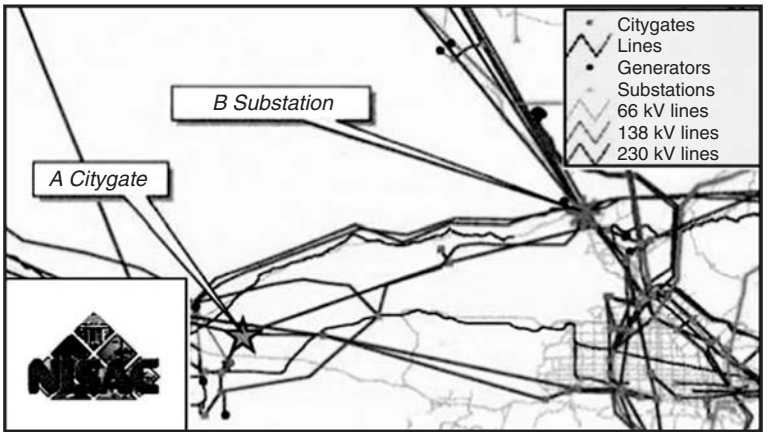

**FIGURE 4** Natural gas (NG) and electric power (EP) components in the IEISS model, highlighting locations of outaged nodes.

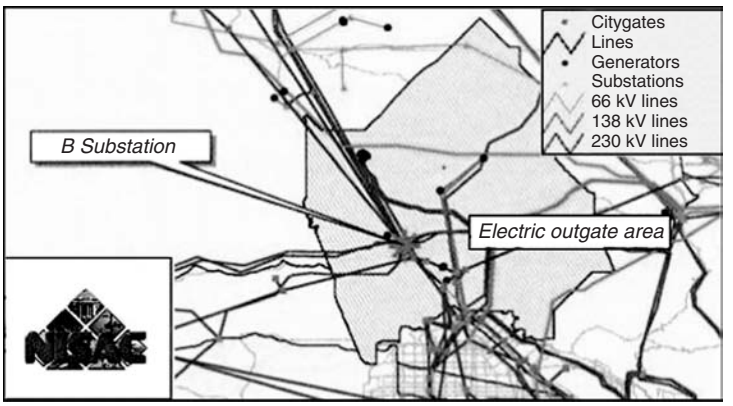

**FIGURE 5** Outage area (gray shade) resulting from the loss of substation "B".

damage and to stabilize the local network. In turn, this action will create an outage area, as shown in Figure 5.

The outaged electric substation provides connections to areas west of this location. Under normal operating conditions, electric generators are capable of providing more power than needed locally, so excess is exported to the east. Following a loss of electric generation due to pipeline junction "A" outage, customer demand must be met by supplying from the east. Three 230-kV transmission lines normally support this power flow. However, two of three lines originate at the outaged electric substation "B". Since this component is outaged, power can only be supplied by a single 230-kV line, which is severely overloaded. The result is an additional area of customer load shed, as shown in Figure 6.

Because large area is affected by this event, many businesses and facilities critical to continued operation of urban infrastructure would lose electricity and natural gas

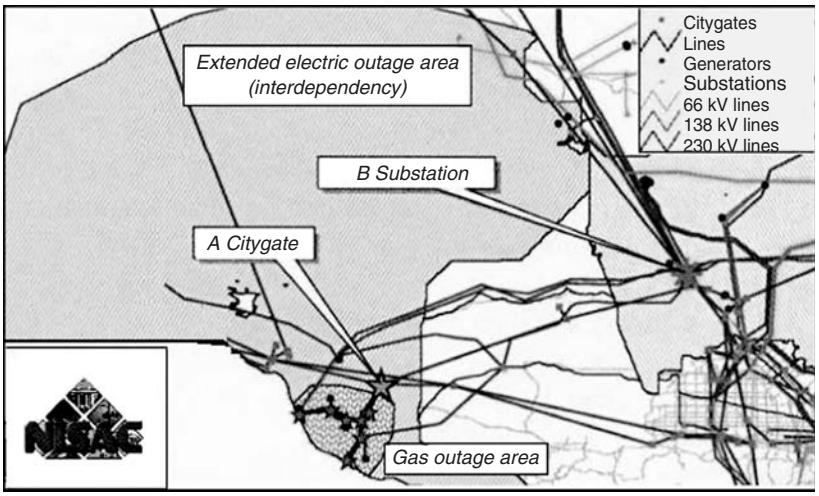

**FIGURE 6** Additional load shed due to transmission line overload from electric substation "B" results in the final interdependency event.

service. The total outage area encloses nearly 2700 sq. miles. On the basis of average business sales density, the direct cost of a 3-day interdependency outage would total approximately $150 million. Indirect costs due to supply chain disruptions, noninsured loss of perishable goods, and related items may also be significant. In addition, key emergency facilities such as hospitals, telecommunication end offices, police, and fire stations would be outaged forcing extended reliance on emergency backup power.

# SELF-HEALING AND RESILIENT ENERGY SYSTEMS

S. MASSOUD AMIN
*University of Minnesota, Minneapolis, Minnesota*

## 1 INTRODUCTION

The rise of our nation into a global economic power, which began with the opening of a vast continent in the mid-1800s by the railroads, was followed in the nineteenth century by expansion of the networks of commerce, navigable waterways, transportation, water supply and wastewater, dams, electric power networks, and rural electrification (in the early to mid-twentieth century), aviation, transit, and highways. This has dramatically transformed our nation and the resultant economic output has been unprecedented in history.

The tremendous value of infrastructure systems such as roads and bridges and the nation that help make possible indispensable activities of our modern societies cannot be overstated. I would submit that along with our bricks and mortar infrastructure—railroads, highways, bridges, seaports, and airports—another important part is the "hidden infrastructure" that supports the workings of all aspects of our $14 trillion economy.[2]

## 2 THE BIGGER PICTURE

Energy, telecommunications, transportation, and financial infrastructures are becoming increasingly interconnected, thus posing new challenges for their secure, reliable, and efficient operation. All of these infrastructures are themselves complex networks, geographically dispersed, nonlinear, and interacting both among themselves and with their

[2]A 24-page special feature in *The Wilson Quarterly* for Spring 2008 (Vol. 32, No. 2) includes three articles under the heading, "BACKBONE: Infrastructure for America's Future." The three are "The Secret Is the System," "Get Smart," and "Built to Last." An introduction notes that "building tomorrow's infrastructure will pose larger political and technological challenges than ever before-with potential payoffs to match." Examples cited are the huge new water tunnel being dug beneath New York City, started in 1970 and to be completed by 2020; the collapse of the I-35W bridge in Minneapolis, the 2003 blackout affecting 50 million people, and the proposed North American Super Corridor, from Mexico to Canada that would create a road, rail, and shipping system around the existing I-35. Some excerpts: Shopping for Infrastructure The American Society of Civil Engineers *Report Card for America's Infrastructure* (2005) offers a daunting menu of future needs and calls for more than $300 billion in additional annual spending (for more information please see http://www.wilsoncenter.org/index.cfm).

human owners, operators, and users. No single entity has complete control of these multiscale distributed, highly interactive networks, nor does any such entity have the ability to evaluate, monitor, and manage them in real time. In fact, the conventional mathematical methodologies that underpin today's modeling, simulation, and control paradigms are unable to handle the complexity and interconnectedness of these critical infrastructures.

Power, telecommunications, banking and finance, transportation and distribution, and other infrastructures are becoming more and more congested partially due to dramatic population growth, particularly in urban centers. These infrastructures are increasingly vulnerable to failures cascading through and between them. A key concern is the avoidance of widespread network failure due to cascading and interactive effects. Moreover, interdependence is only one of several characteristics that challenge the control and reliable operation of these networks. Other factors that place increased stress on the power grid include dependencies on adjacent power grids (increasing because of deregulation), telecommunications, markets, and computer networks. Furthermore, reliable electric service is critically dependent on the whole grid's ability to respond to changed conditions instantaneously.

Secure and reliable operation of complex networks poses significant theoretical and practical challenges in analysis, modeling, simulation, prediction, control, and optimization. The pioneering initiative in the area of complex interactive networks and infrastructure interdependency modeling, simulation, control, and management was launched and successfully carried out during 1998–2002, through the Complex Interactive Networks/Systems Initiative (CIN/SI). It studied closely the challenges to the interdependent electric power grid, energy, sensing and controls, communications, transportation, and financial infrastructures.

It comprised six university research groups consisting of 108 university faculty members and over 220 researchers who were involved in the joint Electric Power Research Institute (EPRI) and US Department of Defense program. During 1998–2002, CIN/SI developed modeling, simulation, analysis, and synthesis tools for damage-resilient control of the electric power grid and interdependent infrastructures connected to it. This work showed that the grid can be operated close to the limit of stability given adequate situational awareness combined with better security of communications and controls. A grid operator is similar to a pilot flying an aircraft as in monitoring how the system is being affected, how the "environment" is affecting it, and having a solid sense of how to steer it in a stable fashion.

In recent decades, in light of increased demand, we have reduced the generation and transmission capacity margins of the electric power grid, and we are indeed flying closer to the edge of the stability envelope. Ongoing programs at EPRI, Department of Energy (DOE) are continuing pursuit of these objectives.

Earlier work by the author during the 1990s on damaged F-15 aircraft in part, provided background for the creation, successful launch, and management of research programs for the electric power industry, including the EPRI/DOD CIN/SI mentioned above, which involved six university research consortia along with two energy companies, to address challenges posed by our critical infrastructures. This work was done during the period from 1998 to early 2002. CIN/SI laid the foundation for several ongoing initiatives on the self-healing infrastructure and subsets focusing on smart reconfigurable electrical networks. These have now been under development for some time at several organizations, including programs sponsored by the National Science Foundation (NSF), DOD,

DOE, and EPRI (including the "Intelligrid" program), and the US DOE's "Gridwise" and "Modern Grid" initiative.

To provide a context for this, the EPRI/DOD CIN/SI aimed to develop modeling, simulation, analysis, and synthesis tools for robust, adaptive, and reconfigurable control of the electric power grid and infrastructures connected to it. In part, this work showed that the grid can be operated close to the limit of stability given adequate situational awareness combined with better sensing of system conditions and communication controls. A grid operator steers it in a stable fashion by keeping the lines within their operating limits while helping a instantaneous balance between loads (demand) and available generation. Grid operators often make these quick decisions under considerable stress. Given that in recent decades we have reduced the generation and transmission capacity, we are indeed flying closer to the edge of the stability envelope.

As an example, one aspect of the Intelligrid program is aimed at enabling grid operators have greater look-ahead capability and foresight, overcoming limitations of the current schemes which at best have over a 30-seconds' delay in assessing system behavior. This is analogous to driving to the car by looking into the rear-view mirror instead of the road ahead. This tool using advanced sensing, communication, and software module was proposed during 2000 to 2001 and the program was initiated in 2002 by the author while at EPRI, under the Fast Simulation and Modeling (FSM) program. This advanced simulation and modeling program promotes greater grid self-awareness and resilience in times of crisis, in three ways: by providing faster-than-real-time, look-ahead simulations (analogous to master chess players rapidly expanding and evaluating their various options under time constraints) and thus avoiding previously unforeseen disturbances; by performing what-if analysis for large-region power systems from both operations and planning points of view; and by integrating market, policy, and risk analysis into system models, and quantifying their integrated effects on system security and reliability.

## 3 INFRASTRUCTURES UNDER THREAT

The terrorist attacks of September 11th exposed critical vulnerabilities in America's essential infrastructures: never again can the security of these fundamental systems be taken for granted. Electric power systems constitute *the* fundamental infrastructure of modern society. A successful terrorist attempt to disrupt electricity supplies could have devastating effects on national security, the economy, and the life of every citizen. Yet, power systems have widely dispersed assets that can never be absolutely defended against a determined attack.

The growing potential for infrastructural problems stems from multiple sources, including system complexity, deregulation, economic effects, power market impacts, and human error. The existing power system is also vulnerable to natural disasters and intentional attacks (terrorism). Regarding the latter, a November 2001 EPRI assessment developed in response to the September 11th attacks highlights three kinds of potential threats to the US electricity infrastructure.

We discuss them briefly and in very broad terms, without providing a "blue book" for potential attackers: The first is attacks *upon* the power system. In this case, electricity infrastructure is the primary target—with ripple effects, in terms of outages extending into the customer base. The point of attack could be a single component, such as a critical

substation or a transmission tower. There could also be a simultaneous, multipronged attack intended to bring down the entire grid in a specific region of the United States An attack could also target electricity markets which are highly vulnerable because of their transitional status.

The second type of attack is *by* the power system. In this case the ultimate target is the population, using parts of the electricity infrastructure as a weapon—similar to the way our transportation and mail delivery systems were used against our nation. Power plant cooling towers, for example, could be used to disperse chemical or biological agents.

The third means is attack *through* the power system. In this case, the target is the civil infrastructure. Utility networks include multiple conduits for attack, such as lines, pipes, underground cables, tunnels, and sewers. An electromagnetic pulse, for example, could be coupled through the grid with the intention of damaging computer and/or telecommunications infrastructure.

As seen from these scenarios, the specter of terrorism raises a profound dilemma for the electric power industry: How to make the electricity infrastructure more secure without compromising productivity in today's complex, highly interconnected electric networks? Resolving this dilemma requires short-term and long-term technology development and deployment, affecting fundamental characteristics of today's power systems.

The North American electric power system needs a comprehensive strategy to prepare for the diverse threats posed by terrorism. Such a strategy should both increase protection of vital industry assets and assure the public that they are well protected. A number of actions will need to be considered in formulating an overall security strategy:

- The grid must be made secure from cascading damage.
- Pathways for environmental attack must be sealed off.
- Conduits for attack must be monitored, sealed off, and "sectionalized" under attack conditions.
- Critical controls and communications must be made secure from penetration by hackers and terrorists.
- Greater intelligence must be built into the grid to provide flexibility and adaptability under attack conditions, including automatic reconfiguration.
- Ongoing security assessments, including use of game theory to develop potential attack scenarios, will be needed to ensure that the power industry can stay ahead of changing vulnerabilities.

A survey of electric utilities revealed real concerns about grid and communications security on the perceived threats to utility control centers. The most likely threats were bypassing controls, integrity violations, and authorization violations, with four-in-ten rating each as either a 5 or 4, out of 5. Concern about potential threats generally increased as the size of the utility (peak load) increased.

The system's equipment and facilities are dispersed throughout the North American continent, which complicates absolute protection of the system from a determined terrorist attack. In addition, another complexity needs to be considered—the power delivery systems' physical vulnerabilities, and susceptibility to disruptions in computer networks and communication systems. For example, terrorists might exploit the increasingly centralized

control of the power delivery system to magnify effects of a localized attack. Because many consumers have become more dependent on electronic systems that are sensitive to power disturbances, an attack that leads to even a momentary interruption of power can be costly. A 20-min outage at an integrated circuit fabrication plant, for example, could cost US$30 million.

**The Grid Then and Now**

*The first grids*. The worldwide electrical grid deployment, now costing trillions of dollars and reaching billions of people, began very humbly. The first grids came into being in the 1880s, for bringing electrical energy to a variety of customers for a variety of uses; at first mostly for illumination but later for turning power machines and moving trolley cars. The most important of these early grids, the first established big city grid in North America, was the network built by Thomas Edison in lower Manhattan. From its power station on Pearl Street, practically in the shadow of the Brooklyn Bridge, Edison's company supplied hundreds and then thousands of customers. Shortly thereafter, Edison's patented devices, and those of his competitors—devices such as bulbs, switching devices, generators, and motors—were in use, in new grids in towns all over the industrialized world.

**Grid Overview**

- Power, communications, and computing are all converging, making entire systems as sensitive as the most sensitive component.
- Secure and reliable combined electric power, communications, fuel supply, and financial networks are essential to today's microprocessor-based economy, public health and safety, and overall quality of life.
- The demands of our secure digital economy are outpacing the electricity and communication infrastructures that support it.
- It costs the United States $75–180 billion in annual losses from power outages and disturbances. On any day, typically half a million people are without power for 2 or more hours.
- The US power grid operates under ever more stress from increasing electrical traffic and from a changing economic climate. Here are four notable grid issues: (i) the regulatory problem: federal and state grid guidelines often conflict; (ii) the investment problem: demand for power is increasing faster than new grid construction; (iii) the reliability problem: operating rules should keep the grid up and running more of the time; (iv) the marketplace problem: in many instances, the production, transmission, and distribution of power is subject to unfair competition.
- Operating the grid will increasingly come to resemble the flight of combat aircraft, including the use of complex adaptive software.

**Smart Self-Healing Grid**

- What is "self-healing?"
  - A system that uses information, sensing, control and communication technologies to allow it to deal with unforeseen events and minimize their adverse impact.
- Why is self-healing concept important to the energy infrastructure?
  - It is a secure "architected" sensing, communications, automation (control), and energy-overlaid infrastructure as an integrated, reconfigurable, and electronically controlled system that will offer unprecedented flexibility and functionality. It will also improve system availability, security, quality, resilience and robustness.

## 4 A STRESSED INFRASTRUCTURE

The major outage on 14 August 2003, in the eastern United States and the earlier California power crisis in 2000–2001 are only the most visible parts of a larger and growing US energy crisis from inadequate investments in the infrastructure, leading to a fundamental imbalance between growing demand and an almost stagnant supply. The imbalance had been brewing for many years and is prevalent throughout the nation.

From a broader view, the North American electricity infrastructure is vulnerable to increasing stresses from several sources. One stress is caused by an imbalance between growth in demand for power and enhancement of the power delivery system to support this growth. From 1988 to 1998, the United States' electricity demand rose by nearly 30%, but the capacity of its transmission network grew by only 15%. This disparity is likely to increase from 1999 to 2009: analysts expect demand to grow by 20%, while planned transmission systems grow by only 3.5%. Along with that imbalance, today's power system has several sources of stress:

- *Demand is Outpacing Infrastructure Expansion and Maintenance Investments.* Generation and transmission capacity margins are shrinking and unable to meet peak conditions particularly when multiple failures occur, while electricity demand continues to grow.
- *The Transition to Deregulation is Creating New Demands That Are Not Being Met.* The electricity infrastructure is not being expanded or enhanced to meet the demands of wholesale competition in the industry; so connectivity between consumers and markets is at a gridlock.
- *The Present Power Delivery Infrastructure Cannot Adequately Handle Those New Demands of High End Digital Customers and Twenty-First-Century Economy.* It cannot support the levels of security, quality, reliability, and availability needed for economic prosperity.
- *The Infrastructure Has Not Kept Up with New Technology.* Many distribution systems have not been updated with current technology including IT.

- *Proliferation of Distributed Energy Resources (DERs).* DER includes a variety of energy sources—microturbines, fuel cells, photovoltaics, and energy storage devices—with capacities from approximately 1 kW to 10 MW. DER can play an important role in strengthening energy infrastructure. Currently, DER accounts for about 7% of total capacity in the United States, mostly in the form of backup generation, yet very little is connected to the power delivery system. By 2020, DER could account for as much as 25% of total US capacity, with most DER devices connected to the power delivery system.
- *Return on Investment(ROI) Uncertainties Are Discouraging Investments in the Infrastructure Upgrades.* Investing new technology in the infrastructure can meet these aforementioned demands. More specifically, according to a June 2003 report by the NSF, R&D spending in the United States as a percent of net sales was about 10% in the computer and electronic products industry and 12% for the communication equipment industry in 1999. Conversely, R&D investment by electric utilities was less than 0.5% during the same period. R&D investment in most other industries is also significantly greater than that in the electric power industry.
- *Concern about the National Infrastructure's Security (1).* A successful terrorist attempt to disrupt electricity supplies could have devastating effects on national security, the economy, and human life. Yet power systems have widely dispersed assets that can never be absolutely defended against a determined attack.

Competition and deregulation have created multiple energy producers that share the same energy distribution network, one that now lacks the carrying capacity or safety margin to support anticipated demand. Investments in maintenance, and research and development continue to decline in the North American electrical grid. Yet, investment in core systems and related IT components are required to ensure the level of reliability and security that users of the system have come to expect.

From a national security viewpoint, in the aftermath of the tragic events of September 11th and recent natural disasters and major power outages, there are increased national and international concerns about the security, resilience and robustness of critical infrastructures in response to evolving spectra of threats. Secure and reliable operation of these networks is fundamental to national and international economy, security and quality of life[3].

[3]Executive Order 13010, signed by President Clinton in 1996, defined critical infrastructures as "so vital that their incapacity or destruction would have debilitating impact on the defense or economic security of the United Stares" and included "telecommunications, electrical power systems, gas and oil storage and transportation, banking and finance, transportation, water-supply systems, emergency services and continuity of government." The US Department of Homeland Security (DHS) in the National Infrastructure Protection Plan has expanded the concept to include "key resources" and added food and agriculture, health and health care, defense industrial base, information technology, chemical manufacturing, postal and shipping, dams (including locks and levees), government facilities, commercial facilities, and national monuments and icons. The National Infrastructure Improvement Act (S. 1926) defines "infrastructure" as any of a number of components of the transportation system, water supply and control facilities, resource recovery facilities, and solid waste disposal facilities." While in our research we focus on a subset of (i) energy and power, (ii) cyber and telecommunications, (iii) transportation, (iv) banking and finance, and their couplings and interdependencies; elsewhere in our nation, all the 17 sectors identified by DHS are under study by the ASME, DHS, National Labs, and other organizations.

## 5 WHERE ARE WE AND HOW DID WE GET HERE?

The existing electricity infrastructure evolved to its technology composition today from the convolution of several major forces, only one of which is technologically based. Today opportunities and challenges persist in worldwide electric power networks, these include: reducing transmission congestion, increasing system/cyber security, increasing overall system and end-use efficiency while maintaining reliability, and so on. Many other challenges engage those who plan for the future of the power grid: producing power in a sustainable manner (embracing renewable fuels while accounting for their scalability limitations, for example, increased use of land and natural resources to produce more renewable electricity will not be sustainable, thus not being able to lower emissions from existing generators), delivering electricity to those who do not have it (not just on the basis of fairness but also because electricity is the most efficient form of energy, especially for things like lighting), and using electricity more wisely as a tool of economic development, and pondering the possible revival of advanced nuclear reactor construction. To prepare for a more efficient, resilient, secure and sustainable electrical system it is helpful to remember the historical context, associated bottlenecks and forcing functions:

As the readers of this article know, the trends of worldwide electrical grid deployment, costing trillions of dollars and reaching billions of people, began very humbly. Some obvious electrical and magnetic properties were known in antiquity. In the seventeenth and eighteenth centuries, partially through scientific experiments and partially through parlor games, more was learned about how electric charge is conducted and stored. But only in the nineteenth century, with the creation of powerful batteries, and through insights about the relations between electric and magnetic force could electricity in wires service large-scale industries—first the telegraph and then telephones.

And only in the 1880s did the first grids come into being for bringing electrical energy to a variety of customers for a variety of uses, at first mostly for illumination but later for turning power machines and moving trolley cars. The most important of these early grids, the first established big city grid in North America, was the network built by Thomas Edison in lower Manhattan. From its power station on Pearl Street, practically in the shadow of the Brooklyn Bridge, Edison's company supplied hundreds and then thousands of customers. Shortly thereafter, Edison's patented devices, and those of his competitors—devices such as bulbs, generators, switching devices, generators, and motors—were in use in new grids in towns all over the industrialized world.

From a historical perspective the electric power system in the United States evolved in the first half of the twentieth century without a clear awareness and analysis of the system-wide implications of its evolution. In 1940, 10% of the energy consumption in America was used to produce electricity. By 1970, this had risen to 25%, and by 2002 it had risen to 40%. (Worldwide, current electricity production is near 15,000 billion kWh/year, with the United States, Canada, and Mexico responsible for about 30% of this consumption.) This grid now underlies every aspect of our economy and society, and it has been hailed by the National Academy of Engineering as the twentieth century's engineering innovation that has been most beneficial to our civilization. The role of electric power has grown steadily in both scope and importance during this time and electricity is increasingly recognized as a key to societal progress throughout the world, driving economic prosperity, security and improving the quality of life. Still it is noteworthy that at the time of this writing, there are about 1.4 billion people in the world

with no access to electricity, and another 1.2 billion people have inadequate access to electricity (meaning that they experience outages of 4 h or longer per day).

Once "loosely" interconnected networks of largely local systems, electric power grids increasingly host large-scale, long-distance wheeling (movement of wholesale power) from one region or company to another. Likewise, the connection of distributed resources, primarily small generators at the moment, is growing rapidly. The extent of interconnectedness, like the number of sources, controls, and loads, has grown with time. In terms of the sheer number of nodes, as well as the variety of sources, controls, and loads, electric power grids are among the most complex networks made.

In the coming decades, electricity's share of total energy is expected to continue to grow, as more efficient and intelligent processes are introduced into this network. Electric power is expected to be the fastest-growing source of end-use energy supply throughout the world. To meet global power projections, it is estimated by the US DOE/EIA that over $1 trillion will have to be spent during the next 10 years. The electric power industry has undergone a substantial degree of privatization in a number of countries over the past few years. Growth in power generation capacity is expected to be particularly strong in the rapidly growing economies of Asia, with China leading the way.

The electric power grid's emerging issues include: creating distributed management through using distributed intelligence and sensing; integration of renewable resources; use of active-control high voltage devices; developing new business strategies for a deregulated energy market; and ensuring system stability, reliability, robustness, and efficiency in a competitive marketplace and carbon-constrained world.

In addition, the electricity grid faces (at least) three looming challenges: its organization, its technical ability to meet 25-year and 50-year electricity needs, and its ability to increase its efficiency without diminishing its reliability and security.

As an example of historical bifurcation points, the 1965 Northeast blackout not only brought the lights down, it also marked a turn in grid history. The previous economy of scale, according to which larger generators were always more efficient than small machines, no longer seemed to be the only risk-managed option. In addition, in the 1970s two political crises—the Middle East war of 1973 and the Iranian Revolution in 1979—led to a crisis in fuel prices and a related jump in electric rates. For the first time in decades, demand for electricity stopped growing. Moreover, the prospects of power from nuclear reactors, once so promising, now faced public resistance and the resultant policy threats. Accidents at Brown's Ferry, Alabama in 1974 and Three Mile Island, Pennsylvania in 1979, and rapidly escalating construction costs caused a drastic turnaround in orders for new facilities. Some nuclear plants already under construction were abandoned.

In the search for a new course of action, conservation (using less energy) and efficiency measures (to use available energy more wisely) were put into place. Electrical appliances were reengineered to use less power. For example, while on the average today's refrigerators are about 20% larger than those made 30 years ago, they use less than half the electricity of older models. Furthermore, the Public Utility Regulatory Policy Act (PURPA) of 1978 stipulated that the main utilities were required to buy the power produced by certain independent companies which cogenerated electricity and heat with great efficiency, providing the cost of the electricity was less than the cost it would take the utilities to make it for their own use.

What had been intended as an effort to promote energy efficiency, turned out, in the course of the 1980s and 1990s, to be a major instigator of change in the power industry

as a whole. First, the independent power producers increased in size and in number. Then they won the right to sell power not only to the neighboring utility but also to other utilities further away, often over transmission lines owned by other companies. With the encouragement of the Federal Energy Regulatory Commission (FERC), utilities began to sell off their own generators. Gradually the grid business, which for so long had operated under considerable government guidelines since so many utilities were effective monopolies, became a confusing mixture of regulated and unregulated companies.

Opening up the power industry to independent operators, a business reformation underway for some years in places like Chile, Australia, and Britain (where the power denationalization process was referred to as "liberalization"), proved to be a bumpy road in the United States. For example, in 2001 in the state of California, the effort to remove government regulations from the sale of electricity, even at the retail level, had to be rescinded in the face of huge fluctuations in electric rates, rolling blackouts, and amid allegations of price-fixing among power suppliers. Later that year, Enron, a company that had grown immense through its pioneering ventures in energy trading and providing energy services in the new freed-up wholesale power market, declared bankruptcy.

Restructuring of the US power grid continues. Several states have put deregulation into effect in a variety of ways. New technology has helped to bring down costs and to address the need for reducing emission of greenhouse gases during the process of generating electricity. Examples include high efficiency gas turbines, integrated "microgrids" of small generators (sometimes in the form of solar cells or fuel cells), and a greater use of wind turbines.

Much of the interest in restructuring has centered around the generation part of the power business and less on expanding the transmission grid itself. About 25 years ago, the generation capacity margin, the ability to meet peak demand, was between 25 and 30%. It has now reduced to less than half and is currently at about 10–15%. These "shock absorbers" have been shrinking; for example, during the 1990s actual demand in the United States increased by some 35%, while transmission capacity has increased by only 18%. In the current decade, the demand is expected to grow by about 20%, with new transmission capacity lagging behind at under 4% growth.

In the past, extra generation capacity served to reduce the risk of generation shortages in case equipment failed and had to be taken out of production, or in case there was an unusually high demand for power, such as on very hot or cold days. As a result capacity margins, both for generation and transmission, are shrinking. Other changes add to the pressure on the national power infrastructure as well. Increasing interregional bulk power transactions strain grid capacity. New environmental considerations, energy conservation efforts, and cost competition require greater efficiency throughout the grid.

As a result of these "diminished shock absorbers," the network is becoming increasingly stressed, and whether the carrying capacity or safety margin will remain to support anticipated demand is in question. The most visible parts of a larger and growing US energy crisis is the result of years of inadequate investments in the infrastructure. The reason for this neglect is caused partly by uncertainties over what government regulators will do next and what investors will do next.

Growth, environmental issues, and other factors contribute to the difficult challenge of ensuring infrastructure adequacy and security. Not only are infrastructures becoming more complexly interwoven and more difficult to comprehend and control, there is less investment available to support their development. Investment is down in many industries. For the power industry, direct infrastructure investment has declined in an

environment of regulatory uncertainty due to deregulation, and infrastructure R&D funding has declined in an environment of increased competition because of restructuring. Electricity investment was not large to begin with. Presently the power industry spends a smaller proportion of annual sales on R&D than do the dog foods, leather, insurance, or many other industries—less than 0.3% or about $600 million per year.

Most industry observers recognize this shortage of transmission capability, and indeed many of the large blackouts in recent years can be traced to transmission problems, either because of faults in the lines themselves or in the coordination of power flow over increasingly congested lines. However, in the need to stay "competitive," many energy companies, and the regional grid operators that work with them, are "flying" the grid with less and less margin for error. This means keeping costs down, not investing sufficiently in new equipment, and not building new transmission highways to free up bottlenecks.

## 6 CHIEF GRID PROBLEMS

Several cascading failures during the past 40 years have spotlighted our need to understand the complex phenomena associated with power network systems and the development of emergency controls and restoration. In addition to the mechanical failures, overloading a line can create power-supply instabilities such as phase or voltage fluctuations. For an AC power grid to remain stable, the frequency and phase of all power generation units must remain synchronous within narrow limits. A generator that drops 2 Hz below 60 Hz will rapidly build up enough heat in its bearings to destroy itself. So circuit breakers trip a generator out of the system when the frequency varies too much. But much smaller frequency changes can indicate instability in the grid: in the Eastern Interconnect, a 30 MHz drop in frequency reduces power delivered by 1 GW.

According to data from the North American Electric Reliability Corporation (NERC) and analyses from the EPRI, average outages from 1984 to the present have affected nearly 700,000 customers per event annually. Smaller outages occur much more frequently and affect tens to hundreds of thousands of customers every few weeks or months, while larger outages occur every two to nine years and affect millions. Much larger outages affect seven million or more customers per event each decade. These analyses are based on data collected for the US DOE, which requires electric utilities to report system emergencies that include electric service interruptions, voltage reductions, acts of sabotage, unusual occurrences that can affect the reliability of bulk power delivery systems, and fuel problems.

Coupling these analyses with diminished infrastructure investments, and noting that the cross-over point for the utility construction investment versus depreciation occurred in 1995, we analyzed the number and frequency of major outages along with the number of customers affected during 1991–2005. These data from the NERC's Disturbance Analysis Working Group (DAWG) are a subset of the total outages that are required to be reported to DOE's EIA. Going through the more comprehensive data sets from DOE's EIA, during 2001–2005 there were 162 outages of 100 MW or more, and 150 outages affecting >50,000 consumers.

In addition, analyzing outages in 2006 (NERC's data), in 1 year we had: 24 occurrences over 100 MW and 34 occurrences over 50,000 or more consumers.

At the core of the power infrastructure investment problem lie two paradoxes of restructuring, one technical and one economic. Technically, the fact that electricity supply

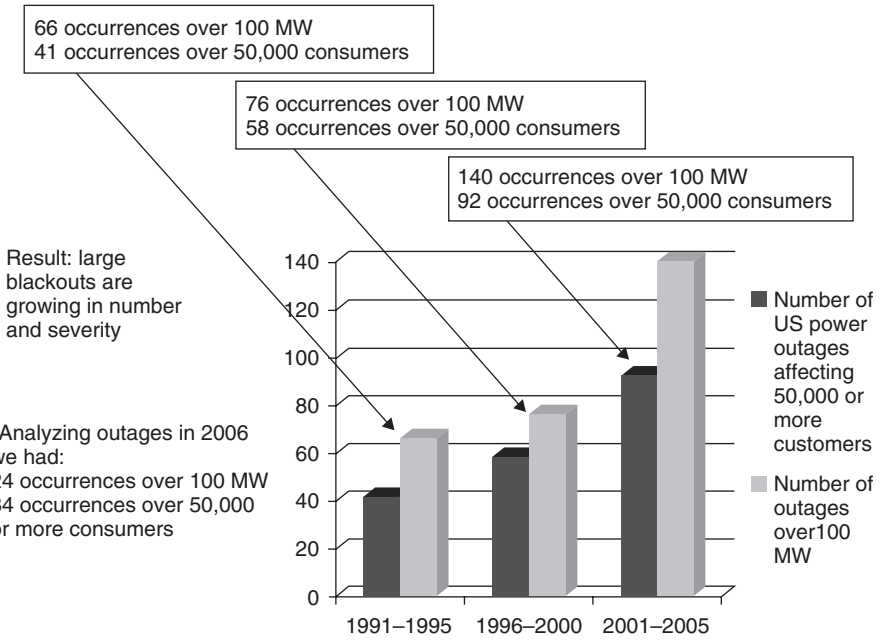

**FIGURE 1** Historical analysis of outages 1991–2005 (please also note that annual increases in load, about 2% per year, and corresponding increase in consumers should also be taken into account). [Data courtesy of NERC's Disturbance Analysis Working Group database.]

and demand must be in instantaneous balance at all times must be resolved with the fact that new power infrastructure is extraordinarily complex, time-consuming, and expensive to construct. Economically, the theory of deregulation aims to achieve the lowest price through increased competition. However, the market reality of electricity deregulation has often resulted in a business-focused drive for maximum efficiency to achieve the highest profit from existing assets, and not resulted in lower prices or improved reliability. Both the technical and economic paradoxes could be resolved by knowledge and technology.

Whether or not the power industry renews its traditional levels of investment in research and in new transmission lines, or the government clarifies its regulatory role in the making and dispatching of electricity, the grid will have to go on functioning. Fortunately, several recent innovations promise to make better use of the existing electrical network.

### Grid Challenges

Power produced in one place and used hundreds of miles away creates new opportunities, especially in terms of encouraging the construction of new power generation, possibly transmission, and in making full use of the power produced, rights of way and assets; but it also creates challenges:

1. *Regulatory Challenges.* More than ever power transmission is an interstate transaction. This has led to numerous conflicts between federal statutes applying

to energy and rules set up by public utility commissions in the various states. Generally the federal goal is to maximize competition, even if this means that traditional utility companies should divest themselves of their own generators. Since the 1990s, the process of unbundling utility services has brought about a major change in the way that energy companies operate. On the other hand, the goal of state regulators has generally been to provide reliable service and the lowest possible prices for customers in state.

2. *Investment Challenge.* Long-distance interstate routing, or "wheeling," of power, much encouraged by the federal government, has put the existing transmission network, largely built in the 1970s and 1980s in a time of sovereign utilities, under great stress. Money spent by power companies on research is much lower than in past decades. Reserve power capacity, the amount of power-making to be used in emergencies, which was 25–30% 25 years ago is now at 10–15%.
3. *Security, Reliability, and Innovation Challenges.* The August 2003 Northeast blackout, when operators did not know of the perilous state of their grid and how a local power shutdown could propagate for hundreds of miles, leaving tens of millions in the dark, demonstrated the need for mandatory reliability rules governing the daily operation of the grid. Such rules are now coming into place.
4. *Marketplace Challenges.* Some parts of the power business operate now without regulations. Other parts, such as the distribution of power to customers might still be regulated in many states, but the current trend is toward removing rules. The hope here is that rival energy companies, competing for customers, will offer more services and keep their prices as low as possible. Unfortunately, in some markets, this has the risk of manipulating the market to create energy shortages, even to the extent of requiring rolling blackouts in an effort to push prices higher.

These are recognized by the power companies and stakeholders in a rapidly changing marketplace. The public, usually at times of dramatic blackouts, and the business community, which suffers losses of over $80 billion per year, have taken notice. Even the Congress, which must negotiate the political fallout of power problems and establish laws governing the industry, takes up the problems of power transmission and distribution on a recurring basis, although usually in the context of the larger debate over energy policy. In the meantime, the US power grid has to be administered and electricity has to be delivered to millions of customers. Fortunately, many new remedies, software and hardware, are at hand.

## 7 OPTIONS AND POSSIBLE FUTURES—WHAT WILL IT TAKE TO SUCCEED?

Revolutionary developments in both information technology and material science and engineering promise significant improvement in the security, reliability, efficiency, and cost-effectiveness of all critical infrastructures. Steps taken now can ensure that critical

infrastructures continue to support population growth and economic growth without environmental harm.

As a result of increased demand, regulatory uncertainty, and the increasing connectedness of critical infrastructures, it is quite possible that in the near future the ability, for example, of the electricity grid to deliver the power that customers require in real time, on demand, within acceptable voltage and frequency limits, and in a reliable and economic manner may become severely tried. Other infrastructures may be similarly tested.

At the same time, deregulation and restructuring have added to the concern about the future of the electric power infrastructure (and other industries as well). This shift marked a fundamental change from an industry that was historically operated in a very conservative and largely centralized way as a regulated monopoly, to an industry operating in a decentralized way by economic incentives and market forces. The shift impacts every aspect of electrical power including its price, availability, and quality. For example, as a result of deregulation, the number of interacting entities on the electric grid (and hence its complexity) has been dramatically increasing while, at the same time, a trend toward reduced capacity margins has appeared. Yet when deregulation was initiated, little was known about its large-scale, long-term impacts on the electricity infrastructure, and no mathematical tools were available to explore possible changes and their ramifications.

It was in this environment of concern that the smart self-healing grid was conceived. One event in particular precipitated the creation of its foundations: a power outage that cascaded across the western United States and Canada on 10 August 10 1996. This outage began with two relatively minor transmission-line faults in Oregon. But ripple effects from these faults tripped generators at McNary dam, producing a 500 MW-wave of oscillations on the transmission grid that caused separation of the primary West Coast transmission circuit, the Pacific Intertie, at the California–Oregon border. The result: blackouts in 13 states and provinces costing some $1.5 billion in damages and lost productivity. Subsequent analysis suggests that shedding (dropping) some 0.4% of the total load on the grid for just 30 min would have prevented the cascading effects and prevented large-scale regional outages (note that load-shedding is not typically a first option for power grid operators faced with problems).

From a broader perspective, any critical national infrastructure typically has many layers and decision-making units and is vulnerable to various types of disturbances. Effective, intelligent, distributed control is required that would enable parts of the constituent networks to remain operational and even automatically reconfigure in the event of local failures or threats of failure. In any situation subject to rapid changes, completely centralized control requires multiple, high data rate, two-way communication links, a powerful central computing facility, and an elaborate operations control center. But all of these are liable to disruption at the very time when they are most needed (i.e. when the system is stressed by natural disasters, purposeful attack, or unusually high demand).

Had the results of the CIN/SI been in place at the time of the August 2003 blackout, the events might have unfolded very differently. For example, fault anticipators located at one end of the high voltage transmission lines would have detected abnormal signals, and made adaptive reconfigurations of the system to sectionalize the disturbance and minimize impact component failures several hours before the line failed. The look-ahead simulations would have identified the line as having a higher than normal probability of failure. Quickly, cognitive agents (implemented as distributed software and hardware in the infrastructure components and in control centers) would have run failure scenarios on their virtual system models to determine the ideal corrective response. When the

high voltage line actually failed, the sensor network would have detected the voltage fluctuation and communicated the information to reactive agents located at substations. The reactive agents would have executed the predetermined corrective actions, isolating the high voltage line and rerouting power to other parts of the grid. No customer in the wider area would even be aware that a catastrophic event had been impending, or have noticed the lights flickering.

Such an approach provides an expanded stability region with larger operational range. As the operating point nears the limit to how much the grid could have adapted (e.g. by automatically rerouting power and/or balancing by dropping a small amount of load or generation), rather than cascading failures and large-scale regional system blackouts, the system would be reconfigured to minimize severity or size of outages to shorten duration of brownouts or blackouts, and to enable rapid and efficient restoration.

This kind of distributed grid control has many advantages if coordination, communication, bandwidth, and security can be assured. This is especially true when the major components are geographically dispersed, as in a large telecommunications, transportation, or computer networks. It is almost always preferable to delegate as much of the control as is practical, to the local level.

The simplest kind of distributed control would combine remote sensors and actuators to form regulators (e.g. intelligent electronically controlled secure devices), and adjust their set points or biases with signals from a central location. Such an approach requires a different way of modeling—of thinking about, organizing and designing—the control of a complex, distributed system. Recent research results from a variety of fields, including nonlinear dynamical systems, artificial intelligence, game theory, and software engineering have led to a general theory of complex adaptive systems (CAS). Mathematical and computational techniques originally developed and enhanced for the scientific study of CAS provide new tools for the engineering design of distributed control so that both, centralized decision-making and the communication burden it creates, can be minimized. The basic approach to analyzing a CAS is to model its components as independent adaptive software and hardware "agents"—partly cooperating and partly competing with each other in their local operations while pursuing global goals set by a minimal supervisory function.

If organized in coordination with the internal structure existing in a complex infrastructure and with the physics specific to the components they control, these agents promise to provide effective local oversight and control without need of excessive communications, supervision, or initial programming. Indeed, they can be used even if human understanding of the complex system in question is incomplete. These agents exist in every local subsystem—from "horseshoe nail" up to "kingdom"—and perform preprogrammed self-healing actions that require an immediate response. Such simple agents are already embedded in many systems today, such as circuit breakers and fuses as well as diagnostic routines. The observation is that we can definitely account for loose nails and save the kingdom.

Another key insight came out of analysis of forest fires, by researchers at CalTech and UC-Santa Barbara, in the one of the six funded consortia, which I led during 1998–2002. They found forest fires to have "failure-cascade" behavior, similar to electric power grids. In a forest fire the spread of a spark into a conflagration depends on how close together the trees are. If there is just one tree in a barren field and it is hit by lightning, it burns but no big blaze results. But if there are many trees and they are close enough together—which is the usual case with trees because Nature is prolific and efficient in using resources—the single lightning strike can result in a forest fire that burns until it

reaches a natural barrier such as a rocky ridge, river, or road. If the barrier is narrow enough for a burning tree to fall across it, or it includes an inflammable flaw such as a wooden bridge, the fire jumps the barrier and burns on. It is the role of first-response wild-land fire fighters such as smoke jumpers, to contain a small fire before it spreads by reinforcing an existing barrier or scraping out a defensible fire line barrier around the original blaze.

Similar results hold for failures in electric power grids. For power grids, the "one-tree" situation is a case in which every single electric socket had a dedicated wire connecting it to a dedicated generator. A lightning strike on any wire would take out that one circuit and no more. But like trees in Nature, electrical systems are designed for efficient use of resources, which means numerous sockets served by a single circuit and multiple circuits for each generator. A failure anywhere on the system causes additional failures until a barrier—such as a surge protector or circuit breaker—is reached. If the barrier does not function properly or is insufficiently large, the failure bypasses it and continues cascading across the system.

These preliminary findings suggest approaches by which the natural barriers in power grids may be made more robust by simple design changes in the configuration of the system, and eventually show how small failures might be contained by active smoke-jumper-like controllers before they grow into large problems. Other research into fundamental theory of complex interactive systems explored means of quickly identifying weak links and failures within a system.

CIN/SI developed, among other things, a new vision for the integrated sensing, communications, and control of the power grid. Some of the pertinent issues are why or how to develop controllers for centralized versus decentralized control and issues involving adaptive operation and robustness to disturbances that include various types of failures.

Modern computer and communications technologies now allow us to think beyond the protection systems and the central control systems to a fully distributed system that places intelligent devices at each component, substation and power plant. This distributed system will enable us to build a truly smart grid.

One of the problems common to the management of central control facilities is the fact that any equipment changes to a substation or power plant must be described and entered manually into the central computer system's database and electrical one-line diagrams. Often this work is done some time after the equipment is installed and there is thus a permanent set of incorrect data and diagrams in use by the operators. What is needed is the ability to have this information entered automatically when the component is connected to the substation—much as a computer operating system automatically updates itself when a new disk drive or other device is connected.

## 8 THE ROAD AHEAD

A new mega-infrastructure is emerging from the convergence of energy (including the electric grid, water, oil and gas pipelines), telecommunications, transportation, Internet and electronic commerce. Furthermore, in the electric power industry and other critical infrastructures, new ways are being sought to improve network efficiency and eliminate congestion problems without seriously diminishing reliability and security.

Electric power systems constitute the fundamental infrastructure of modern society. Often continental in scale, electric power grids and distribution networks reach virtually every home, office, factory, and institution in developed countries and have made

remarkable, if remarkably insufficient, penetration in developing countries such as China and India.

The electric power grid can be defined as the entire apparatus of wires and machines that connects the sources of electricity and the power plants, with customers and their myriad needs. Once "loosely" interconnected networks of largely local systems, electric power grids now increasingly host large-scale, long-distance wheeling of power from one region to another. Likewise, the connection of distributed resources—at the moment, primarily small generators—are growing rapidly. The extent of interconnectedness, like the number of sources, controls, and loads, has grown with time. In terms of the sheer number of nodes, as well as the variety of sources, controls, and loads, electric power grids are among the most complex networks made.

Global trends toward interconnectedness, privatization, deregulation, economic development, accessibility of information, and the continued technical trend of rapidly advancing information and telecommunication technologies all suggest that the complexity, interactivity, and interdependence of infrastructure networks will continue to grow.

The existing electricity infrastructure evolved to its technology composition today from the convolution of several major forces, only one of which was technologically based. During the past 10 years, we have systematically scanned science and technology, investment, and policy dimensions to gain clearer insight on current science and technology assets when looked at from a consumer-centered future perspective, rather than just incremental contributions to today's electric energy system and services.

The goal of transforming the current infrastructures to self-healing energy-delivery, and computer and communications networks with the unprecedented robustness, reliability, efficiency and quality for customers and our society is ambitious. This will require addressing challenges and developing tools, techniques, and integrated probabilistic risk assessment/impact analysis for wide-area sensing and control for digital-quality infrastructure such as sensors, communication and data management, as well as improved state estimation, monitoring and simulation linked to intelligent and robust controllers leading to improved protection and discrete-event control. These follow-on activities will build on the foundations of CIN/SI and current programs that include self-healing systems and real-time dynamic information and emergency management and control.

More specifically, the operation of a modern power system depends on a complex system of sensors and automated and manual controls, all of which are tied together through communication systems. While the direct physical destruction of generators, substations, or power lines, may be the most obvious strategy for causing blackouts, activities that compromise the operation of sensors, communication and control systems by spoofing, jamming, or sending improper commands could also disrupt the system, cause blackouts, and in some cases result in physical damage to key system components. Hacking and cyber attacks are becoming increasingly common.

Most early communication and control systems used in the operation of the power system were carefully isolated from the outside world, and were separate from other systems such as corporate enterprise computing. However, economic pressures created incentives for utilities to make greater use of commercially available communications and other equipment that was not originally designed with security in mind. Unfortunately from a security perspective, such interconnections with office and electronic business systems through other layers of communications created vulnerabilities. While this problem is now well understood in the industry and corrective action is being taken, we are still in a transition period during which some control systems have been inadvertently exposed

to access from the Internet, intranets, and remote dial-up capabilities that are vulnerable to cyber intrusions.

Many elements of the distributed control systems now in use in power systems are also used in a variety of applications in process control, manufacturing, chemical process controls and refineries, transportation, and other critical infrastructure sectors and hence are vulnerable to similar modes of attack. Dozens of communication and cyber security intrusions, and penetration red-team "attacks" have been conducted by DOE, EPRI, electric utilities, commercial security consultants, KEMA, and others. These "attacks" have uncovered a variety of cyber vulnerabilities including unauthorized access, penetration and hijacking of control.

While some of the operations of the system are automatic, ultimately human operators in the system control center make decisions and take actions to control the operation of the system. In addition, to the physical threats to such centers and the communication links that flow in and out of them, one must also be concerned about two other factors: the reliability of the operators within the center, and the possibility that insecure code has been added to one of the programs in a central computer. The threats posed by "insider" threats, as well as the risk of a "Trojan horse" embedded in the software of one or more of the control centers is real, and can only be addressed by careful security measures both, within the commercial firms that develop and supply this software, and careful security screening of the utility and outside service personnel who perform software maintenance within the center. Today security patches are often not always supplied to end users, or users are not applying the patches for fear of impacting system performance. Current practice is to apply the upgrades or patches after SCADA vendors thoroughly test and validate patches, sometimes incurring a delay of several months in patch deployment.

As an example related to numerous major outages, narrowly programmed protection devices have contributed to worsening the severity and impact of the outage—typically performing a simple on/off logic which locally acts as preprogramme while destabilizing a larger regional interconnection. With its millions of relays, controls and other components, the parameter settings and structures of the protection devices and controllers in the electricity infrastructure can be a crucial issue. It is analogous to the poem "For want of a horseshoe nail . . . the kingdom was lost" that is, relying on an "inexpensive 25 cent chip" and narrow control logic to operate and protect a multibillion dollar machine.

As a part of enabling a smart self-healing grid, we have developed fast look-ahead modeling and simulation, precursor detection, adaptive protection, and coordination methods that minimize impact on the whole system performance (load dropped as well as robust rapid restoration). There is a need to coordinate the protection actions of such relays and controllers with each other to achieve overall stability. A single controller or relay cannot do all, and they are often tuned for worst cases, therefore control action may become excessive from a system-wide perspective. On the other hand, they may be tuned for the best case, and then the control action may not be adequate. This calls for coordinating protection and control—neither agent, using its local signal, can by itself stabilize a system; but with coordination, multiple agents, each using its local signal, the overall system can be stabilized.

It is important to note that the key elements and principles of operation for interconnected power systems were established in the 1960s prior to the emergence of extensive computer and communication networks. Computation is now heavily used in all levels of the power network for planning and optimization, fast local control of equipment, and processing of field data. But coordination across the network happens on a slower

time-scale. Some coordination occurs under computer control, but much of it is still based on telephone calls between system operators at the utility control centers, even (or especially!) during emergencies.

Systems should be motivated by living beings' resilience and robustness to operate to some degree after injury, by developing compensatory behaviors and to autonomously recover from unexpected damage through continuous self-modeling, thus providing increased "situational awareness," and ability to be "damage adaptive," to withstand and possibly recover from "injury," attacks, or unexpected damage.

Grid "self-modeling" could survive emergencies and adapt to new conditions quicker than grids that are not "self-conscious." Enabled by distributed sensing and measurement and combined with Fast Modeling and Simulation we have developed and pilot tested data-driven control and operation of regional power grids, analogous to the continuous self-modeling and compensation of damaged fighter planes and intelligent robots in the face of unexpected damage.

From a broader perspective, any critical national infrastructure typically has many layers and decision-making units and is vulnerable to various types of disturbances. Effective, intelligent, distributed control is required that would enable parts of the constituent networks to remain operational and even automatically reconfigure in the event of local failures or threats of failure. In any situation subject to rapid changes, completely centralized control requires multiple, high data rate, two-way communication links, a powerful central computing facility, and an elaborate operations control center. But all of these are liable to disruption at the very time when they are most needed (i.e. when the system is stressed by natural disasters, purposeful attack, or unusually high demand).

When failures occur at various locations in such a network, the whole system breaks into isolated "islands," each of which must then fend for itself. With the intelligence distributed, and the components acting as independent agents, those in each island have the ability to reorganize themselves and make efficient use of whatever local resources remain to them, in ways consonant with the established global goals to minimize adverse impact on the overall network. Local controllers will guide the isolated areas to operate independently while preparing them to rejoin the network, without creating unacceptable local conditions either during or after the transition. A network of local controllers can act as a parallel, distributed computer, communicating via microwaves, optical cables, or the power lines themselves, and intelligently limiting their messages to only that information necessary to achieve global optimization and facilitate recovery after failure.

Over the last 12 years, our efforts in this area have developed, among other things, a new vision for the integrated sensing, communications, protection and control of the power grid. Some of the pertinent issues are why or how to develop protection and control devices for centralized versus decentralized control, and issues involving adaptive operation and robustness to various destabilizers. However, instead of performing *in vivo* societal tests which can be disruptive, we have performed extensive "wind-tunnel" simulation testing (in Silico) of devices and policies in the context of the whole system along with prediction of unintended consequences of designs and policies to provide a greater understanding of how policies, economic designs and technology might fit into the continental grid, as well as guide in their effective deployment and operation.

Advanced technology now under development or under consideration, holds the promise of meeting the electricity needs of a robust digital economy. The architecture for this new technology framework is evolving through early research on concepts and the necessary enabling platforms. This architectural framework envisions an integrated,

self-healing, electronically controlled electricity supply system of extreme resiliency and responsiveness—one that is fully capable of responding in real time to the billions of decisions made by consumers and their increasingly sophisticated agents. The potential exists to create an electricity system that provides the same efficiency, precision, and interconnectivity as the billions of microprocessors that it will power.

## 9 COST AND BENEFIT

Electricity shall prevail at the quality, efficiency and reliability that customers demand and are willing to pay for. On the one hand the question is who provides it; on the other hand it is important to note that achieving the grid performance, security and reliability are a national profitable investment, not a cost burden on the taxpayer. The economic payback is three to seven times and in some cases an order of magnitude greater than the money invested. Further, the payback starts with the completion of each sequence of grid improvement. The issue is not merely who invests money because that is ultimately the public, whether through taxes or kilowatt hour rates. Considering the impact of regulatory agencies, they should be able to induce the electricity producers to plan and fund the process. That may be the most efficient way to get it in operation. The current absence of a coordinated national decision-making is a major obstacle. State's rights and State PUC regulations have removed the individual State's utility motivation for a national plan. Investor utilities face either collaboration on a national level, or a forced nationalization of the industry.

Simply replicating the existing system through expansion or replacement will not only be technically inadequate to meet the changing demands for power, but will produce a significantly higher price tag. Through the transformative technologies outlined here, the nation can put in place a twenty-first century power system capable of eliminating critical vulnerabilities while meeting intensified consumer demands, and in the process, save society considerable expense.

What is at stake is whether our national critical infrastructures and the underpinning interconnected networks will continue to function reliably and securely or not. This program will produce significant advances in the security, robustness, efficiency, and performance of the power grid and its interdependent infrastructures. The tools indicated will provide unprecedented stability, reliability, efficiency, and service quality. A major outage (affecting 7 million or more customers) occurs about once every decade costing over $2 billion—smaller disturbances are commonplace with very high cost to the customers and our society. On a given day, there are 500,000 customers without power for 2 h or more in the United States. The above programs cost about $170–200 million per year for R&D, and up to about $400 million per year over a decade for fielding, testing and integration into the system. Therefore we can save about five to sevenfold in prevention and mitigation of disturbances. Other benefits include the following:

- builds a smart generation and delivery infrastructure, an "electrinet," with in-built security;
- creates opportunities for a risk-managed integration of diverse risk-managed balanced portfolios of generation sources;
- improves security and observability of system operation and control;
- refines definition of system operating limits'

- serves transmission system market demands;
- minimizes transmission costs;
- reduces utage cost;
- improves system simulation models;
- improves management of system reliability and asset integration (from distributed generators and renewables, to central power plants).

As expressed in the July 2001 issue of *Wired* magazine: "The best minds in electricity R&D have a plan: Every node in the power network of the future will be awake, responsive, adaptive, price-smart, eco-sensitive, real-time, flexible, humming—and interconnected with everything else." The technologies included, for example the concept of self-healing electricity infrastructure, methodologies for fast look-ahead simulation and modeling, adaptive intelligent islanding and strategic power infrastructure protection systems, are of special interest for improving grid security from terrorist attack.

## 10 NEXT STEPS

How to control a heterogeneous, widely dispersed, yet globally interconnected system is a serious technological problem in any case. It is even more complex and difficult to control it for optimal efficiency and maximum benefit to the ultimate consumers while still allowing all its business components to compete fairly and freely. A similar need exists for other infrastructures, where future advanced systems are predicated on the near-perfect functioning of today's electricity, communications, transportation, and financial services.

From a national perspective, a key grand challenge before us is how do we redesign, retrofit, and upgrade the nearly 220,000 miles of electromechanically controlled system into a smart self-healing grid that is driven by a well-designed market approach.

Creating a smart grid with self-healing capabilities is no longer a distant dream; we have made considerable progress. But considerable technical challenges as well as several economic and policy issues remain to be addressed.

Funding and sustaining innovations, such as the self-healing grid, remain a challenge as utilities must meet many competing demands on precious resources while trying to be responsive to their stakeholders, who tend to limit R&D investments to immediate applications and short-term ROI. In addition, utilities have little incentive to invest in the longer term. For regulated investor–owned utilities there is added pressure caused by Wall Street to increase dividends.

Several reports and studies have estimated that for existing technologies to evolve and for the innovative technologies to be realized, a sustained annual research and development investment of $10 billion is required. However, the current level of R&D funding in the electric industry is at an all-time low. The investment rates for the electricity sector are the lowest rates of any major industrial sector with the exception of the pulp and paper industry. The electricity sector invests at most, only a few tenths of a percent of sales in research. This is in contrast to fields such as electronics and pharmaceuticals in which R&D investment rates have been running between 8 and 12% of net sales; all of these industry sectors fundamentally depend on reliable electricity.

A balanced, cost-effective approach to investments and use of technology can make a sizable difference in mitigating the risk. Electricity shall prevail at the quality, efficiency,

and reliability that customers demand and are willing to pay for. On the one hand, the question is, "Who provides it?" on the other hand, it is important to note that achieving the grid performance, security, and reliability are a profitable national investment, not a cost burden on the taxpayer. The economic payback is three to seven times greater than the money invested. Further, the payback starts with the completion of each sequence of grid improvement. The issue is not merely who invests money, because that is ultimately the public, but whether it is invested through taxes or kWh rates. Considering the impact of regulatory agencies, they should be capable of inducing the electricity producers to plan and fund the process; this may be the most efficient way to get it in operation. The current absence of a coordinated national decision-making body is a major obstacle. State's rights and State PUC regulators have removed the individual State's utility motivation for a national plan. Investor utilities face either collaboration on a national level or a forced nationalization of the industry.

## ACKNOWLEDGMENTS

I developed most of the context and many of findings presented here while I was at the EPRI in Palo Alto (during 1998–2003), and for the Galvin Electricity Initiative (during 2005–2006). I gratefully acknowledge the feedback from Mr John Voeller (the editor of this series) and Dr James Peerenboom. The support and feedback from numerous colleagues at EPRI, universities, industry, national laboratories, and government agencies with funding from EPRI, NSF, and the ORNL is gratefully acknowledged.

## 1 SCIENTIFIC OVERVIEW

As with portable consumer electronics, there is an insatiable demand for more power in most military applications. The exponential growth in integrated circuit performance over the past 30 years, as predicted by the Moore's law, accelerated the demand for power in many consumer electronics and military devices. Unfortunately, the pace of development of electrochemical cells or other power sources cannot keep up with the exponential growth of the integrated circuit and has become a limiting technology for electronic microdevices such as miniaturized communication devices (Fig. 1). Although the number

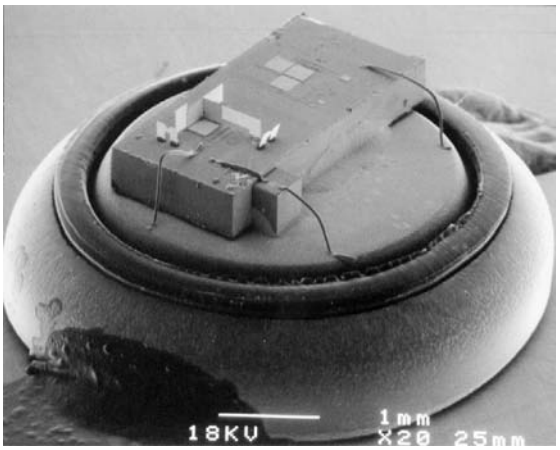

**FIGURE 1** Photograph of a sensor "mote" (only 2 mm × 4 mm) containing a sensor, microprocessor, and communications electronics mounted on top of a much larger coin cell (from www-bsac.eecs.berkeley.edu). The operation of this device is limited by the lifetime of the battery.

of transistors per integrated circuit has been doubled every couple of years since 1970, the performance gain per year for commercial cells is usually a small percentage, depending on the cell chemistry. Battery technology performance has increased about 2% per year. The newer lithium-ion (Li-ion) rechargeable chemistry performance gain in terms of capacity has been about 12% per year since the introduction in 1991, but still has not kept pace with demand. Thus, the accelerating growth in the digital devices has often been limited by the incremental improvement in battery performance.

Nanotechnology offers an opportunity for improvement in power and energy density of power sources [1]. Generally speaking, nanotechnology can be classified either as nanoscale fabrication technology of devices or the revolutionary enhancement of performance by using nanoscale materials. Nanomaterials are usually defined dimensionally, with features such as particle dimension or porosity in the range of 1–100 nm. Fabrication technology for nanodevices is based on the so-called "bottom-up" approach whereby complex structures are self-assembled from the atomic or molecular level, as is found in all biological systems. Progress in this area has been slow due to inadequate control at the atomic level with currently available equipment. On the other hand, much progress has been made in developing nanomaterials as evidenced by commercially available carbon nanotubes from many sources (recent search found >25 websites that claim to be "dedicated to nanotubes"). Nanomaterials hold the potential to be an enabling technology for energy storage and conversion devices by increasing energy storage capacity, discharge rate capability, or stability over the lifetime of the device. Thus, the focus of this article is to review nano-enabled power sources based on judicious implementation of nanostructured materials.

### 1.1 High Power Cells

Increasing power and rate capability of batteries are the important applications of nanoscale materials. By reducing the particle size of the active materials from submicron to nanoscale, one should be able to increase diffusion rates in these solids by two orders of magnitude and improve the power capability. Typical battery active materials

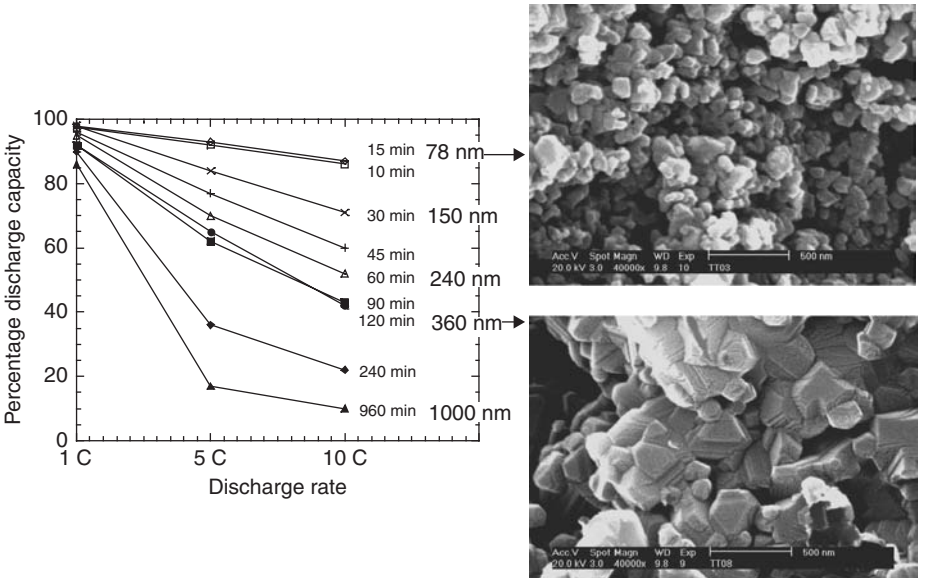

**FIGURE 2** Nano- versus macro-$Li_4Ti_5O_{12}$ capacity utilization under high discharge rates [2].

are on the order of 10 $\mu$m (10,000 nm). Because of the diffusion distance required, full charge and discharge usually require a period of 30 min to 1 h to diffuse through 10,000 nm. According to the diffusion equation, the diffusion time, $t$, is proportional to $r^2/D$, where $r$ is the diffusion length and $D$ is the diffusion coefficient. It is difficult to decrease drastically the intrinsic diffusion coefficient, but one can shorten the diffusion length by 2–3 orders of magnitude through the use of nanomaterials, and achieve minutes or subminutes charge or discharge rates. One such example is the nano-lithium titanate (nano-$Li_4Ti_5O_{12}$) of approximately 30 nm. Nano-$Li_4Ti_5O_{12}$ was demonstrated to have greater than 80% utilization at 10 C (6 min) continuous discharge rate while 1 $\mu$m macro-$Li_4Ti_5O_{12}$ had only about 10% utilization at the same discharge rate [2] (Fig. 2). As anode, nano-$Li_4Ti_5O_{12}$ enabled fast charge Li-ion cells was demonstrated in Toshiba's 1-min charge Li-ion cells [3].

Another example of a nano-enabling material is the olivine lithium iron phosphate, $LiFePO_4$. The low electronic conductivity of $LiFePO_4$ results in very poor rate performance. However, when $LiFePO_4$ is reduced to the nanodomain and coated with nanocarbon particles, the conductivity and power density were improved up to seven and one orders of magnitude, respectively [4]. High power Li-ion cells based on modified nano-$LiFePO_4$ are being commercialized by A123Systems. These cells were claimed to be capable of delivering about one order of magnitude more power (>3000 W/kg) than conventional Li-ion cells [5], similar to that of a supercapacitor but with the energy density of that of a rechargeable battery, albeit lower energy density than conventional Li-ion cells.

Similarly, by reducing the particle size to nanoscale, one can also enhance the high power performance of electrochemical capacitors. In an electrochemical capacitor, charge is stored on the surface of a porous, high-surface-area electrode, and not in the bulk of the material. Very high surface area leads to high power delivery, and capacitances of

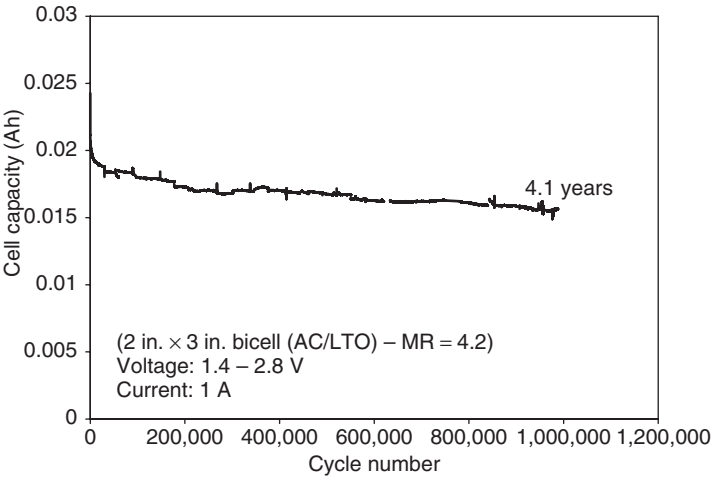

**FIGURE 3** Cycle life of nano-$Li_4Ti_5O_{12}$ versus carbon asymmetric electrochemical capacitor [courtesy of Prof. Amatucci of Rutgers University].

~100 F/g have been measured with carbon foams. Because there is no movement of mass within the electrode material and therefore no change in volume in the anode or cathode during charge and discharge, the cycle life of these systems is essentially infinite with a very poor specific energy, typically less than 1 Wh/kg. However, using asymmetric hybrid configuration, containing one battery electrode and one electrochemical double-layer capacitor electrode, Amatucci et al. have demonstrated energy density greater than 20 Wh/kg at a power density of 3000 W/kg [6]. The asymmetric capacitor was enabled by the nano-$Li_4Ti_5O_{12}$, which not only enabled high power but also high cycle life. Cycle life greater than 1 million cycle was demonstrated using the nano-$Li_4Ti_5O_{12}$ (Fig. 3), which has unique zero volume change during cycling. Thus, the asymmetric capacitors serve to bridge the performance gap between batteries (high energy but low power) and capacitor (high power but low energy).

Nanotech-enabled optimization should also lead to new high power-density electrochemical capacitors as a consequence of the recent determination of the true nature of pseudocapacitance in hydrous ruthenium oxide (designated as $RuO_2 \cdot xH_2O$). For $x=0.5$, 720 F/g can be stored in hydrous ruthenium oxide [7], 5-10 times greater than that stored at high-surface-area carbon supercapacitors. This form of the material appears amorphous to X rays, but upon medium-range structural analysis was shown to form a nanocomposite of metallic, anhydrous rutile-like $RuO_2$ nanocrystallites whose surfaces contain of proton-conductive structural water associated with Ru–O [8]. The competing percolation networks of electronic and protonic conduction pathways provide the optimized multifunctionality of hydrous ruthenium oxide for energy storage. This new structural understanding on the nanoscale can also serve as a new archetype for the design of charge-storage materials.

## 1.2 High Capacity Cells

Nanomaterials open new options in preparing high capacity electrode materials. Today's high energy batteries rely almost exclusively on lithium or lithiated compounds since

lithium is the lightest metal in the periodic table, has a high oxidation potential, large electrochemical equivalence, and good conductance. The energy density of lithium cells, and especially the state of the art (SOA) of Li-ion cells is limited by the energy density of the positive materials. The current SOA positive materials utilized intercalation reactions, which are limited to the amount of lithium transferred, thereby limiting electron transfer to typically less than 1e− per compound such as $LiMeO_2$, where Me is a transition metal.

$$1e^- + 1Li^+ + Me^{4+}O_2 \leftrightarrow LiMe^{3+}O_2$$

An alternative to the intercalation mechanism is to utilize the concept of reversible conversion compounds where multiple electrons can be transferred to the active electrode material to reduce it fully to the metal state and later reoxidize it back to the original compound.

$$3e^- + 3Li^+ + Me^{3+}X_3 \leftrightarrow 3LiF + Me^o$$

In theory, these reactions can lead to a specific energy greater than 1500 Wh/kg, or in a practical cell about 3*x* that of the SOA Li-ion cells based on $LiCoO_2$ positive electrode. Such reactions have been shown to exist for dichalcogenides and nitrides in the reaction range of 0.5–1.5 V [9]. To increase the potential of such reactions by at least 1 V, highly ionic halides are preferred over oxides, which are used in almost all lithium cells. Of the halides, the metal fluorides are most attractive due to their light weight and low solubility in nonaqueous electrolyte solvents relative to the heavier halides such as Cl and Br.

The theoretical attractiveness of metal fluorides as electrodes for primary cells has been known for over four decades. However, metal fluoride electrodes have not often been realized in part due to the fact that metal fluorides are very high bandgap materials resulting in electronic insulator characteristics. Amatucci et al. at Rutgers ESRG have demonstrated the enablement of a variety of high bandgap, insulating metal fluorides as reversible conversion electrodes through the use of nanocomposite technology [10]. By fabricating the desired metal fluoride materials as 20 nm crystallites in a small amount of conducting matrix, the electrochemical activity of these materials has been enabled. The reduction to nanocrystallite size (reducing electron path length by three orders of magnitude) has a threefold effect: developing a large volume of interface that is defect rich, creating surface states that assist both electron and ion diffusion, and enabling a larger portion of the material to be activated via electron tunneling reactions. A number of systems have been enabled, exhibiting near theoretical conversion voltages (2–3.2 V) and specific capacities from 400 to 700 mAh/g. Systems including fluorides and in some cases oxyfluorides of Fe, Ni, Co, Cr, Bi, and Cu have been enabled. Of these, $CuF_2$ has been identified as promising electrode material for primary cells, and $FeF_3$ and $BiF_3$ as promising electrode materials for rechargeable cells (Fig. 4) [11].

Nanotechnology also plays a key role in improving the effectiveness of the negative materials used in lithium cells. Firstly, in addition to aforementioned enhanced power performance, smaller particle sizes mean less internal stress on the electrodes during intercalation/deintercalation (the binder is more compressible and can more effectively tolerate the volume change), which could lead to increased cycle life. Secondly, smoother electrodes may also allow one to use thinner separators and/or electrolyte—again improving battery performance. Finally, one can replace carbon with a material that reversibly binds more than a single lithium atom per six host atoms (for example, Sn or Si). Nanosize composite anodes (e.g. carbon/silicon) offer the potential to take advantage of much

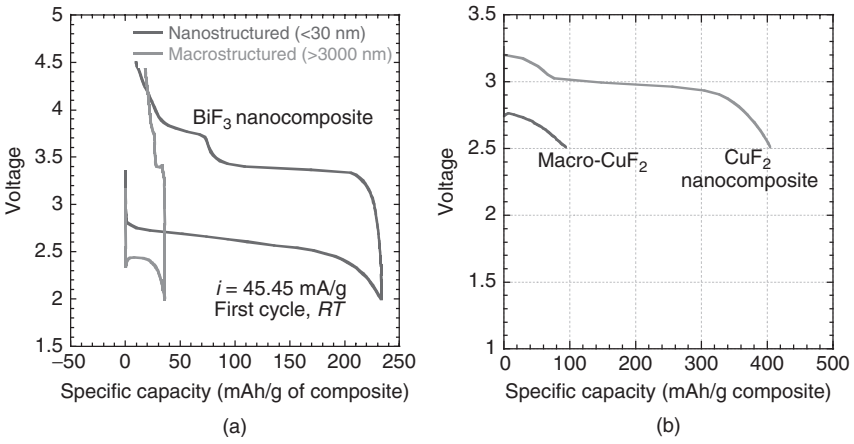

**FIGURE 4** Theoretical capacity utilization enabled in (a) nano-$BiF_3$ and (b) nano-$CuF_2$.

higher capacity anode materials (e.g. $Li_4.Si$ has 10 times the capacity of $LiC_6$) and the smaller particle size can accommodate stresses that would fracture larger particles. This gives both higher capacity and reasonable stability on cycling [12]. The 40 wt% Si composite, which was the most silicon-rich composite that was tested, had a maximum reversible capacity of 1345 mAh/g and it still delivered 745 mAh/g, more than twice the capacity of $LiC_6$ in the 20th cycle.

SONY announced "Nexelion" cell in 2005 with carbon/Sn alloy anode [13], which increased the capacity per volume by 30%. In February 2007, Panasonic announced a further 40% increase in capacity by using alloy anode [14] and, although we do not know the composition, nanomaterials are suspected because they can accommodate the strain produced by the >300% volumetric expansion that accompanies conversion to Li alloy (e.g. conversion of Si to the lithiated compounds $Li_{22}Si_5$ has a 325% expansion). These advances in materials enable the production of high energy cells and batteries—Panasonic claims to have reached 740 Wh/l at the cell level.

## 2 GLOBAL EFFORT ON NANO-ENABLED POWER SOURCE TECHNOLOGIES

Ongoing research programs in the government (e.g. National Nanotechnology Initiative) and commercial sector are likely to benefit energy conversion technology. Fuel cells are of worldwide commercial interest, and DARPA has existing programs in thermoelectric materials development. The Department of Homeland Security should analyze and exploit these developments if nanotech-related breakthroughs appear that are relevant to their special needs.

Outside the United States, the most publicized R&D effort on nanotechnologies for power sources is the European consortium, Alistore [15]. Launched in 2004, the main objective of Alistore is to develop high power and high energy lithium cells based on nanomaterials. The consortium consisted of 16 European university research groups and University of Picardie at Amiens, France, was the program administrator. Other European companies are also very active in developing nanomaterials for fuel cells

and energy harvesting technologies such as photovoltaic cells and thermoelectric energy harvester.

Government-sponsored nanotechnology efforts for power sources are not as well publicized among the Asian countries. However, there is already a strong effort by Japanese companies to commercialize nanomaterials such as carbon nanotubes for energy-related applications [16]. On the basis of the open literatures, we anticipated that other Asian countries such as Japan, China, and South Korea will become major players in nano-enabling materials for power sources within the next few years. NEDO in Japan has committed 2B ¥ for developing carbon nanotubes for high performance capacitors.

## 3 CRITICAL NEEDS ANALYSIS

Improved energy storage technology will benefit homeland security by providing increased performance across a wide range of portable electronic, including sensors, transmitters, and communication devices. Nanotechnology has strong potential to enable the development of batteries, capacitors, and hybrid systems with enhanced power and/or energy performance, which will enable the fabrication of micropower sources. In addition to the high power and high energy cells that were discussed above, technical areas that could be impacted by improvements in nanomaterials are other types of battery materials (e.g. electrolytes and separators) and fuel cells. The advent of micromachining and now nanomachining technology, combined with new and improved materials, provides opportunities for improving the performance of energy harvesting schemes.

### 3.1 3D Battery Architecture and Novel Fabrication Methods

Micropower sources capable of providing reliable rechargeable power under extreme conditions are critical to the development of security applications such as small autonomous distributed sensors. However, as Figure 5 illustrates, the energy density of the batteries decreases almost linearly as the size of the batteries decreases due to decreasing packaging efficiency. In addition, as batteries are reduced to the microscale,

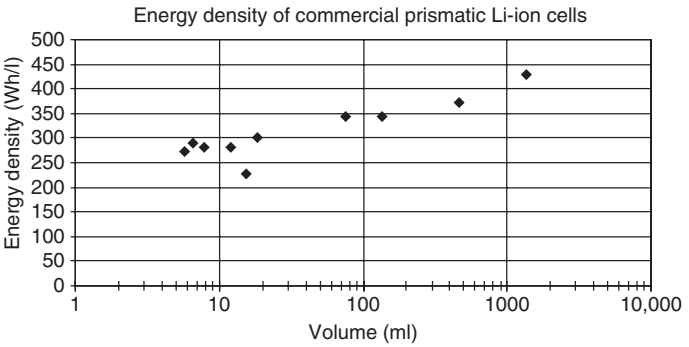

**FIGURE 5** Energy density decreases with cell size in commercial prismatic Li-ion cells. ((Table 35.13) D. Linden, and T. B. Reddy, Eds. *Energy Density Calculated Based on Data in Handbook of Batteries*, 3rd ed., McGraw Hill, New York, p. 35.36.)

it becomes impractical (and almost impossible) to assemble cell stacks via the conventional layer-by-layer stacking approach. Extreme alignment precision is required in order to avoid any shorting between the microelectrodes. This necessitates the use of microelectronic fabrication techniques such as vacuum deposition. To date, the most mature microbattery is based on the all solid-state thin-film technology, first developed by Bates et al. [17]. The active components are typically less than 20 $\mu$m thin and the solid-state lithium phosphorus oxynitride (LiPON) separator is only a few micrometers thick in order to compensate for the low conductivity of the LiPON electrolyte. However, because of poor packaging, most of the cells exhibit poor energy density (Wh/l). The core concept behind the 3D battery is to develop novel nanoarchitecture by more efficient use of available space in the $z$ direction, resulting in interpenetrating electrodes. The concepts, shown schematically in Figure 6, are the topics of current research. Scaling of these architectures to realistic battery sizes is not yet proven. 3D architectures are clearly optimal when one is constrained in volume (e.g. for thin-film cells or smart motes). Fabrication strategies play a key role here; novel techniques such as the use of Langmuir–Blodgett thin films, layer-by-layer self-assembly, template synthesis, and semiconductor processing (e.g. lithography and etching to define microstructures followed by and deposition to add materials) are not yet available or are prohibitively expensive. It is important to note that the periodic arrangements of 3D configured anodes and cathodes lead to nonuniform current distributions [18], while interpenetrating, conformal, aperiodic arrangements do not.

Finally, Belcher et al. in MIT [20] reported virus assembled electrochemically active cobalt oxide for use in lithium batteries. However, the complex command and control needed for viruses to self-assemble themselves to form the positive and negative electrodes remain to be demonstrated, in order to achieve the ultimate goal of virus self-assembled microbattery.

### 3.2 Membranes, Separators, and Electrolytes

Self-assembly of nanostructures may produce advanced functional materials for this application as well. Shape control can allow synthesis of tubular structures with enhanced ionic conductivity. Surfactant templating methods [21] have produced interesting materials for battery electrolytes and the same technology could be used for fuel cell electrolytes. This approach could also be applied to membranes in metal/air batteries (sometimes termed *semi-fuel cells*) to allow selective transport of oxygen while rejecting carbon dioxide and water. Additionally, commercialization of high energy rechargeable systems (e.g. Li/sulfur and Li/air) would be enabled by stabilizing the lithium interface, which results in cycle life and safety improvements.

Although nanotechnology may not play a role in the chemistry of liquid electrolytes, it can be potentially exploited to improve separator performance. For example, new separator materials designed with large numbers of nanoscale pores may allow for thinner materials with enhanced ionic conductivity. Opportunities also include tailoring the separator nanostructure using organic/inorganic composite electrolytes to improve both physical stability (i.e. prevent physical contact of the electrodes) and conductivity [22]. Self-assembly processes may also be effective in depositing extremely thin separator layers on anode and cathode surfaces. If both the pore size/shape and the pore chemistry could be controlled effectively, one can envision ions rapidly moving through empty channels, thereby forming a “liquid-like” separator without any liquid.

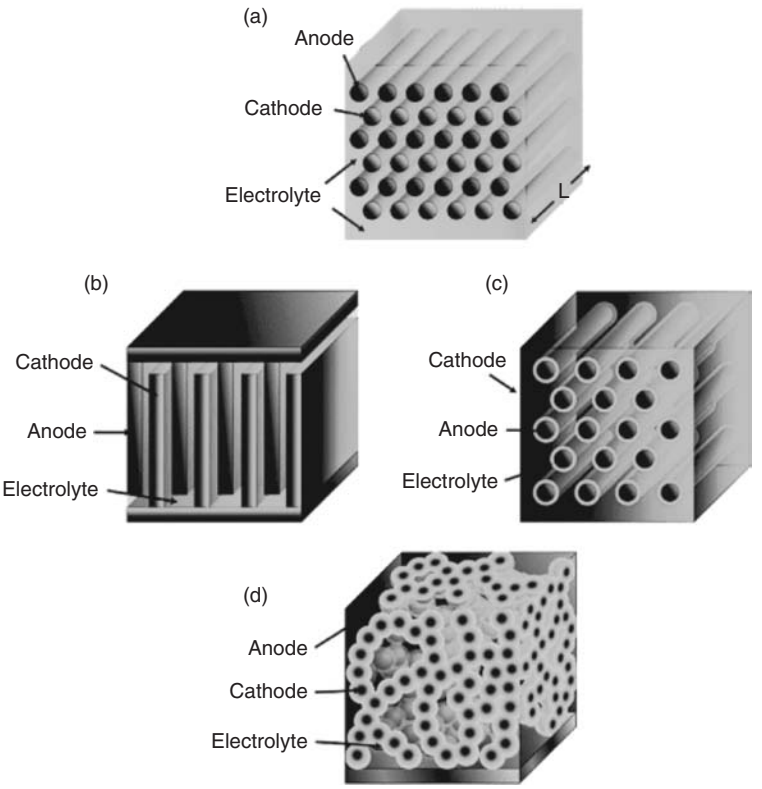

**FIGURE 6** Schematic representation of 3D architectures including (a) an array of interdigitated cylindrical cathodes and anodes; (b) an interdigitated plate array of cathodes and anodes; (c) a rod array of cylindrical anodes (cathodes) with a thin layer of ion conducting electrolyte with the remaining free volume filled with cathode (anode) material; (d) a sponge architecture in which the solid network of the "sponge" serves as both the cathode and the current collector, it is coated with a thin electrolyte and the remaining free volume is filled with an interpenetrating, continuous anode. [See Figure 2 in Reference 19, page 4466].

The ionic conductivity of solid-state electrolytes is generally far less than that of liquid electrolytes due to limited ion mobility and the hopping of charge from one unit cell to the next. However, by making the electrolyte layers extremely thin and stable, effective (albeit low power density) batteries can be made; for example, LiPON functions as a micrometer-scale electrolyte in rechargeable thin-film lithium batteries [23]. Optimization of the nanostructure of these materials may lead to increased conductivity (grain boundary/defect diffusion) and thinner layers without shorting (again leading to enhanced conductivity), and thus to improved power capability.

### 3.3 Electrodes and Electrocatalysts for Fuel Cells

These components are critical to the function of a fuel cell since they catalyze the electrochemical reduction of oxygen at the cathode and the oxidation of fuel at the anode. Breakthroughs in electrocatalysts might revolutionize fuel cells by giving them fuel flexibility and increasing power output, as well as by increasing their tolerance to

chemical species that tend to poison them (e.g. carbon monoxide or sulfur-containing moieties).

New synthetic methodologies might allow for the control of fuel cell electrode microstructures. Nanostructured catalysts may enhance reaction kinetics by dramatically increasing electrode surface area and restricting reactions to confined regions of the active surface. In one study, high catalytic activity resulted from high active surface area of the catalysts supported within an ultraporous electrode nanoarchitecture [24]. High-surface-area materials are extremely reactive, which often causes problems during synthesis (e.g. nanophase metals are often capped with organic ligands after synthesis to prevent sintering reactions). The goal is to maintain the high surface area of nanostructured catalysts, while avoiding agglomeration, sintering, or restructuring during use. Self-assembly on the nanoscale using shape control of catalytic materials (e.g. bimetallic catalysts) might also be important [25].

### 3.4 Thermoelectric Devices

Temperature differences can be used to generate power. The power density scales with temperature difference. A 5 $^{\circ}$C temperature difference can generate 40-80 $\mu$W/cm$^2$ with existing thermoelectric technology. This temperature difference can be generated from man-made sources (parasitic devices placed on warm surfaces such as automobile engines, pipelines, and heaters), environmental gradients (in the soil, water, or at their interface), and within animals (one company has announced one such device for human implantation) [26].

While static conversion of heat into electricity has been an area of research for many decades, the promise of producing tailored nanostructures has prompted renewed interest in several energy conversion schemes. Nanotechnology offers the potential for improved efficiencies, since shrinking the characteristic dimensions of a device to nanometer length scales influences electron and phonon behavior. The efficiency of thermoelectric devices can also be characterized by the figure of merit, $ZT$, where $Z$ is the power factor and $T$ is the absolute temperature. A limitation of thermoelectrics designed around standard bulk materials is that most metallic conductors (high $\sigma$ materials) have low Seebeck coefficients (a few microvolt per kelvin, whereas $\geq$100 $\mu$V/K would be more desirable), while the electron and phonon contributions to thermal conductivity make it difficult to achieve both high $\sigma$ and low $\kappa$ in the same material. As a result, the $ZT$ remained at 1 or less for the last 40 years. Recently, researchers from Research Triangle Institute were able to increase the $ZT$ to about 2.4 in p-type thin-film superlattices of $Bi_2Te_3/Sb_2Te_3$ [27]. The nanostructured superlattice layers vary from 1 to 5 nm. The thermal conductivity and the electrical resistivity are reduced due to blocked phonon transmission and enhanced carrier mobility, respectively, in the nanothick superlattice layer.

Quantum confinement of electronic charge carriers within regions of reduced dimensionality has the potential to increase the power factor [28]. Increased phonon scattering that occurs when interfaces are separated by distances compared to phonon wavelengths can reduce the lattice thermal conductivity [27]. These approaches require tailored nanometer-scale materials synthesis techniques, as the critical dimension for confinement is $\sim$10 nm. One can reduce dimensionality in one dimension (confinement in a plane) to three dimensions (confinement in a "quantum dot"). Improved materials synthesis and characterization techniques on the nanoscale, as well as advances in the theory and characterization of nanodimensional solids, are required.

### 3.5 Photovoltaics

The energy conversion efficiency of photovoltaics (including thermophotovoltaic or TPV devices) may also be increased by effects associated with reduced dimensionalities on the nanometer scale. Photonic lattices have sharp absorption and emission peaks at their photonic band edges. By tuning the emission peak of a photonic crystal (emitter) to the bandgap energy of a photodiode (energy conversion device), one could increase the overall conversion efficiency of TPVs [29]. The conversion efficiency might also be increased by evanescent coupling of an infrared emitter to a photodiode in very close (subwavelength) proximity [30]. Another approach to improve the photovoltaic (PV) efficiency is by increasing the intrinsic quantum efficiency of the PV material via the use of quantum dots. The exact mechanism for the quantum dot enhancement is still not well understood, though it is speculated to be related to enhanced electron–hole interaction due to quantum confinement. In conventional PV material such as Si, one electron–hole pair (or exciton) is generated per photon. The feasibility of generating multiple excitons per photon was demonstrated in various quantum dots materials such as PbSe quantum dots, leading to multiple increase in quantum efficiency [31]. However, it remains a challenge to design high efficiency PV devices based on the quantum dots, and PV device efficiency enhancement over 100% has yet to be demonstrated. Nanoscale optimization of the interfaces between disparate materials in organic light-emitting diodes (OLEDs), organic solar cells, and thin-film solar cells represents another opportunity. Nanosize oxide particles (e.g. $TiO_2$ or ZnO) with organic sensitizers bound to the surface are proposed as a new class of solar cells, and controlled interfaces are the key to improving the efficiency of these devices [32]. Modeling advancements are required to direct the materials synthesis and processing efforts.

## 4 RESEARCH DIRECTIONS

Nanotechnology enables the rational design of power source devices and structures with optimized storage, conductivity, density, and optical and electronic properties. The potential for tailoring of chemical composition and morphology at the nanometer scale will provide the opportunity for unprecedented control of materials properties. The following are specific areas that need to be investigated:

1. Nanomaterial synthesis and characterization.
   - Performance optimization is a balancing act between electron/ion/mass transport and electrode kinetics, but independent control of transport multifunction is difficult to do with bulk materials. In batteries, disorder improves mass transport of insertion ions, but sufficient order (even on the nanoscale) must be retained to move electrons. As the particle size is reduced, the relative fraction of atoms at the surface significantly increases, to the point that three-dimensional particles begin to exhibit the characteristics of two-dimensional objects.
   - By creating 2D structures with specific surface chemistry and morphology, one can control the interface between materials or phases, so as to elicit the desired behavior. Nanomaterials plus interface chemical approach have enabled the rapid implementation of the insulating $LiFePO_4$ phase in practical Li-ion cells and allowed us to foresee the use of Si as an alternative to the nanostructured

Sn-graphite-based negative electrode. There exists also the possibility to tailor the optical and electronic characteristics of a material, which strongly influence energy conversion processes, allowing us to envision the production of improved catalysts and electrolytes for fuel cells, as well as improved thermoelectrics and photovoltaics.

2. Nanoarchitectures to develop novel energy conversion and storage devices.
   - Nanotechnology will enable realization of devices with increased energy or power. For example, by maximizing the interfacial area between the anode and cathode while minimizing their separation, one can increase the power density of a cell dramatically. Improvements in energy density are attained by processing very thin electrolytes and better packing of materials. Such multifunctional concepts have the potential to further decrease the size and weight of a system for a given mission.
   - Nanomachining technology, combined with new and improved materials, opens up opportunities both for improving the performance of energy harvesting schemes and for realizing highly miniaturized versions of systems that are familiar at a larger scale.

Creation of exciting new materials and architectures for batteries, electrochemical capacitors, fuel cells as well as other energy conversion devices holds the potential to meet the intense need for increased energy and power for electronic devices of interest to homeland security community.

# PUBLIC HEALTH

# THREAT FROM EMERGING INFECTIOUS DISEASES

ROGER W. PARKER
*DoD Veterinary Food Analysis and Diagnostic Laboratory, Fort Sam Houston, Texas*

## 1 AGROTERRORISM POTENTIAL OF EMERGING INFECTIOUS DISEASES

The US National Strategy for Homeland Security identifies agriculture, food, and water among the critical infrastructure sectors that must be protected. Agroterrorism is an intentional criminal act perpetrated on some segment of the agriculture or food industry intended to inflict harm (e.g. public health crisis or economic disruption). Although the use of biological weapons against targets by state-sponsored terrorists, rouge terrorist groups, and even isolated individuals is highly unpredictable, there have been attempts to assess risks [1]. In June 1999, the US Centers for Disease Control and Prevention (CDC) convened a meeting of national experts to review potential general criteria for selecting the bioagents that pose the greatest threats to civilians, concluding in a list divided into three categories (A, B, and C) based on such criteria as threat to national security, public health impact (disease and death), production and delivery potential, public perception as related to public fear and potential civil disruption, and special public health preparedness needs [2]. Many of the agents are associated with emerging infectious diseases [3], an important subset because of potential limited experience in management of cases or outbreaks and lack of appropriate resources [4]. Emerging infectious diseases are those in which incidences have recently increased as a result of the introduction of a new agent, recognition of an existing disease that has previously gone undetected, a reappearance (reemergence) of a known disease after a decline in incidences, or an extension of the geographic range of a known disease [4].

## 2 THREAT DEVELOPMENT

This article offers description of risk factors involved in threats on agriculture and food systems critical for a nation's revenue or defense. It is important to predict plausible

targets and credible events to avoid being surprised by and be unprepared for terrorist attacks [1, 5]. Although examples used are kept to a minimum, considering the abundant possibilities as can be found in public literature, the threat risks from glanders and melioidosis are presented in more detail.

## 2.1 Availability and Cost

For many decades, widely published sources have identified the bioagents suitable for nefarious applications and have provided the technical information on how to produce them in bulk [6]. Despite efforts to restrict the acquisition of dangerous bioagents, it is likely that terrorists and criminals, with some microbiological expertise, will be able to obtain an agent that they want when they want it [7]. Agents have been rated as most available if readily obtainable from soil, animal, insect, or plant sources; somewhat available if mainly available only from clinical specimens, clinical laboratories, or regulated commercial culture suppliers; and, least available if only from nonenvironmental, noncommercial, or nonclinical sources such as high-level security research laboratories [2, 6].

Some examples of soil-borne pathogens include *Bacillus anthracis*, *Clostridium botulinum*, *Clostridium perfringens*, *Burkholderia mallei*, and *Burkholderia pseudomallei*. The ease with which such naturally occurring agents can be acquired varies among geographic regions, according to specific prevalence [1]. The anthrax agent, *B. anthracis*, can be found worldwide in areas of predominately alkaline soils. Endemic anthrax in nature characteristically occurs in herbivores grazing contaminated land or eating contaminated feed [8, 9]. Also, there can be contamination of naturally occurring *B. anthracis* in the wool, hair, or hides of these herbivores. Other environmental sources for pathogens include surface and coastal waters, the ecology of which can serve as reservoirs for *Giardia*, *Cryptosporidium*, *Naegleria fowleri*, *Vibrio cholerae*, and *Vibrio vulnificus*.

Zoonotic bioagents (transmissible from animal hosts or reservoirs to humans) naturally available in animals include *Yersinia pestis* (rodents), *Brucella melitensis* (small ruminants), *Francisella tularensis* (rodents, rabbits, and hares), *B. mallei* (equine), and Nipah virus (porcine). Naturally sourced foreign animal disease threats to US agriculture include foot-and-mouth disease (FMD) virus (in ungulates), hog cholera (porcine), rinderpest virus (bovine), African swine fever virus (porcine), African horse sickness virus (equine), and velogenic Newcastle disease virus (avian).

Among the plant pathogens available in nature, which could threaten agriculture production are *Candidatus Liberibacter americanus* (citrus greening disease), *Peronosclerospora philippinensis* (Philippine downy mildew of maize), *Phakopsora pachyrhizi* (Asian soybean rust), *Ralstonia solanacearum* (southern bacterial wilt in many plants), *Xanthomonas oryzae* (bacterial leaf blight in rice), *Xylella fastidiosa* (citrus variegated chlorosis strain), *Tilletia indica* (karnal bunt of wheat), and *Puccinia* fungi (stem rust for cereals and wheat).

It is not uncommon for biological weapons to be referred to as the "poor man's weapon of mass destruction." Bacterial pathogen and toxin production can use basic and easily available equipment (e.g. culture media, flasks, vials, incubators or fermenters, and microscopes) in facilities ranging from crude makeshift labs to advanced, state-run facilities [10]. Viral production using egg or cell cultures requires more advanced technology. It has been estimated that less than a few hundred thousand dollars would be needed for bioagent research, testing, production, and weaponization. However, Kathleen Bailey, a national security analyst and a former assistant director of the US Arms Control and Disarmament Agency, has speculated that it may only require tens of thousands of dollars,

using a modestly equipped 15 × 15 ft room [6]. Among the cost for terrorists to consider would be risk of self-inoculation of virulent organisms like *F. tularensis* and *B. anthracis*.

### 2.2 Ease and Route of Dissemination

The bioagent must be collected in sufficient quantities or cultured to reach the dose required to cause harm, and additional procedures may be necessary in the preparation of the final product in a gaseous, liquid, or solid form [1]. Because a bioagent may be inconspicuous during delivery, the first evidence of a biological attack may be the onset of disease, days or even weeks later, making it difficult or impossible to determine that an outbreak resulted from an intentional act [7]. Other dissemination factors to consider are the stability of the agent and potential for host-to-host transmission of the agent [2]. A contagious microorganism may be disseminated at lower doses because it could spread in secondary waves of infection following its multiplication in the infected hosts [1].

Of potentially greater impact but smaller probability (because of very complex technology) is terrorist dissemination of a bioagent in an aerosol cloud [7, 11]. During biological warfare defense programs, it was calculated that an ideal aerosol cloud should consist of particles of 1–5 μm in size, as particles much larger than 5 μm do not penetrate into the lungs (they tend to settle out of the air relatively quickly and are filtered out by the upper respiratory tract) and smaller particles do not remain in the lungs (they are likely to be breathed out) [12]. Intentional aerosol contamination of production crops would be less complicated in that plant pathogens could be disseminated by a crop duster or even hand spray pumps [13].

Terrorists can also spread bioagents by contaminating food anywhere in the food system's continuity. Tommy Thompson, former Secretary of the US Department of Health and Human Services, stated in 2004, "For the life of me, I cannot understand why the terrorists have not attacked our food supply, because it is so easy to do [14]." Contamination at a centralized facility may affect large numbers of people down the distribution chain. Contamination at the retail outlet may have more limited direct population reach but still escalate because of the terror aspect. Contamination of food that will not be subject to further cooking is the most vulnerable, unless a heat-resistant bioagent or toxin is used. The most successful recent foodborne attack was perpetrated by a religious cult, known as the Rajneeshees, employing *Salmonella typhimurium* in restaurant salad bars against the people of The Dalles, a small town in Oregon, in August and September 1984 [7]. Deliberate contamination of municipal water systems is also a target of concern but fortunately direct harmful effects would be limited by dilution, disinfection, filtration, and nonspecific inactivation [15]. Smaller water sources are more vulnerable as evidenced in 1990 when nine people in Edinburgh, United Kingdom, were infected with *Giardia lamblia* when the water-supply tank of their apartment building was deliberately contaminated with fecal material [16].

A reliable mode for small-scale dissemination of bioagents would be direct application or injection of victims with a pathogen or toxin [7]. On a larger scale, infected food handlers could maliciously serve as modern-day "Typhoid Mary(s)", purposely harboring and transmitting *Shigella*, *Salmonella*, *Campylobacter*, *V. cholerae*, *Giardia*, *Cryptosporidium parvum*, *Cyclospora cayetanensis*, *Balantidium coli*, *Entamoeba histolytica*, *Ascaris lumbricoides*, hepatis A virus, norovirus, and rotavirus. It would seem that nature does not need assistance from terrorists as one highly cited source estimates that foodborne diseases cause approximately 76 million illnesses, 325,000 hospitalizations, and 5000 deaths in the United States each year [17].

Intentional transmission of diseases through insect vectors is also a potential risk. Some examples include plague (transmitted by certain flea species), yellow fever (carried by a specific mosquito species, *Aedes aegypti*), and typhus (spread by the body louse, *Pediculus humanus corporis*) [7]. During World War II, Japanese planes were suspected of dropping plague-infected fleas in advance of plague epidemics affecting China and Manchuria [18]. Among the challenges to overcome is establishing a program to breed and infect the necessary vectors and controlling them following release [7].

An example of an agent that is potentially harmful regardless of its route of dissemination is *B. anthracis*. Anthrax in humans is frequently classified as per the route by which the disease is acquired: cutaneous anthrax acquired through a skin lesion, gastrointestinal tract anthrax contracted from ingestion of contaminated food (primarily meat from an animal that died of the disease), and pulmonary (inhalation) anthrax from breathing in airborne anthrax spores [9, 19].

It is commonly considered that FMD virus can be introduced into a free area by various means: direct or indirect contact with infected animals through aerosols, feeding contaminated garbage, and contact with contaminated objects. After a susceptible animal becomes infected, rapid and exponential spread via respiratory aerosols can occur.

### 2.3 Virulence and Susceptible Host Range

Biological agents can be used to attack a wide variety of targets including humans, animal herds, and food at any point during the farm-to-food continuum (including stored or processed food) [20]. The pathogens considered and attempted over history have involved a wide spectrum of virulence, from those with little ability to cause disease or disability to some of the agents deemed most deadly [7, 11]. The CDC Category A agents generally have the potential to cause high morbidity and mortality with Category B agents threatening moderate morbidity and mortality [2].

Many of the diseases in the CDC bioterrorism categories are of zoonotic nature. For example, apparently all warm-blooded species can be infected by *B. anthracis* [9]. While it appears that humans are moderately resistant to anthrax [9], such innate resistance can be overcome by sufficient exposure level, poor prior health or immune status of the exposed individual, or by the use of a strain of *B. anthracis* possessing critical virulence factors [7, 19].

Concerning susceptible animal populations, it has been recommended that farm operators and veterinarians maintain expertise in recognizing and reporting suspected foreign animal diseases [21]. Among the educational resources is the list published by the Office International des Epizooties (OIE) (available at http://www.oie.int/eng/maladies/en_classification.htm) concerning animal diseases that are highly infectious, capable of rapidly spreading across international borders, and having the potential to inflict catastrophic economic losses and social disruption. As an example, there are many subtypes of FMD virus of varying virulences, which can sicken cloven-hoofed domestic and wild animals. An FMD outbreak can widely spread through an area using sheep as maintenance hosts, pigs as amplifiers, and cattle as indicators.

### 2.4 Impact and Public Perception

Depending upon the efficiency of an aerosol dissemination system and the population density of targets, a biological weapon could produce up to hundreds of thousands of casualties [6]. Even without inflicting an actual illness or physical injury, a terrorist can achieve objectives of fear, societal disruption, and/or economic damage (considering the

usage of hoaxes) [1]. Notoriety of a bioagent can influence the public perception from its use or threatened use. The fearsome anthrax agent is the most frequent pathogen of recent historical use or threat. Dr W. Seth Carus has researched nearly 270 alleged bioterrorism or biocrime cases involving biological agents used in crimes and found *B. anthracis* associated with at least 113 cases, largely due to the growing popularity of anthrax threats [7]. Confirmation of an anthrax attack would result in expensive and time-, labor-, and resource-consuming control and decontamination measures to include treatment of human cases, isolation of animal cases, quarantine of exposed animals, animal carcass disposal, and environmental decontamination [9]. One published estimate of economic impact of an aerosolized anthrax attack scenario against humans reached $26.2 billion per 100,000 persons exposed [22]. Because of the uncertainty and fear surrounding anthrax attacks, it has been estimated that for every exposed person, an additional 15 may request medical intervention because of exposure concerns [22]. To a lesser extent but of still significant burden, will be the resulting control and recovery measures for confirmed agroterrorism events with any other agents.

Because agriculture disease outbreaks have the potential to cause economic chaos, plants and livestock are an attractive target to potential terrorists [13, 23]. In 2001, the US Food and Fiber system (FFS) provided employment for 23.7 million Americans (e.g. farmers, processors, manufacturers, wholesalers, retailers, restaurateurs, and transporters) and was a supplier of products worldwide [24]. The total FFS economy added $1.24 trillion to the nation's gross domestic product (GDP); 12.3% of the nation's total GDP [24]. Briefly, concerning economic downstream instability, every bushel of wheat, corn, or soybeans in addition to beef carcasses and pork bellies, has a futures contract written in United States and foreign exchanges, meaning multidimensional financial losses on unfulfilled contracts, including damage on handling and transportation commerce [13]. The scale of nationwide FMD outbreaks is mind-boggling (e.g. in 1997, Taiwan slaughtering over 8 million pigs, over $20 billion estimated total cost; in 2001, the United Kingdom destroying 4.2 million animals, approximately $9.6 billion in direct compensation payments) [13]. Similarly, introduction of foreign animal diseases in the United States would require drastic rapid measures, usually disease eradication, to reopen agriculture exports. Eradication efforts are costly. For example, in 1983–1984 the control and eradication of a highly pathogenic avian influenza outbreak cost the US Department of Agriculture $60 million and the average cost of one dozen eggs increased by 5% [25]. To complete hog cholera eradication during the 1971–1977 outbreak, the US government spent $79 million [26]. Because animals have special places in families and society, any animal disease tragedy reflects on and in people. For example, the 2001 FMD outbreak in England was accompanied and followed by human distress, feelings of bereavement, fear of a new disaster, and loss of trust in authority and control systems [27].

## 3 GLANDERS AND MELIODOSIS

The agents causing glanders (*B. mallei*) *and* melioidosis (*B. pseudomallei*) are closely related mesophilic (optimal temperature for growth is 37°C), gram-negative rods. Glanders is primarily a disease affecting equines, involving the upper respiratory tract (purulent nasal discharge) and the lungs (pneumonia). Farcy is the cutaneous form (nodules, pustules, and ulcers) of the equine disease. Melioidosis is primarily a human disease ranging from asymptomatic pulmonary consolidation to localized cutaneous or visceral abscesses, necrotizing pneumonia, or rapidly fatal septicemia [28].

### 3.1 Availability and Cost

The glanders agent has either disappeared or been eradicated from most areas of the world. Of particular concern is that recent reports of glanders are mostly from Middle Eastern and Asian countries such as Turkey, United Arabic Emirates, Iraq, Iran, India, Pakistan, Mongolia, and China [29]. Rogue or state-sponsored terrorists could acquire this agent via natural sources. The melioidosis organism can likewise be acquired by terrorists as it is free-living on dead organic material in certain soils, mud, and waters in many tropical and subtropical areas of Africa, America, Asia, Australia, Pacific Islands, India, and the Middle East [28, 30]. In Thailand it is considered to be a disease of rice farmers [28]. Both of the *Burkholderia* organisms can be cultured on simple media, including nutrient, blood, and MacConkey agar [31]. Bulk culture of the agents would expose laboratory workers to significant occupational disease risk [32]. Because both are Category B select agents, acquisition from laboratory sources would require theft or other illegal activities.

### 3.2 Ease and Route of Dissemination

Historically, *Burkholderia* agents were viewed as suitable bioweapons because of their ability to initiate infection in normal individuals via aerosol [31]. Inhalation delivery would require complex technical work by terrorists with uncertain success. Because wound infections are common in nature, a terrorist may be able to induce disease by contaminated wound-inducing debris or shrapnel. Oral exposure may be a concern because it is thought that ingestion could cause clinical disease especially in immunocompromised or overwhelmed hosts. Despite the apparent ease with which melioidosis may be acquired from the environment, there is little evidence of the secondary spread from cases of the disease [31].

### 3.3 Virulence and Susceptible Host Range

Glanders primarily affects horses, donkeys, and mules, but can be naturally contracted by goats, dogs, and cats [33]. Various animals, including sheep, goats, horses, swine, monkeys, and rodents can become infected with melioidosis [28]. Human clinical melioidosis is uncommon, generally occurring in individuals with impaired immunocompetence whose nonintact skin had intimate contact with contaminated soil or surface water [28]. Approximately two-thirds of melioidosis cases have a predisposing medical condition such as diabetes, cirrhosis, alcoholism, or renal failure [28]. Four clinical forms of glanders and melioidosis are generally described: localized infection (skin, brain, or visceral abscesses, lymphadenitis, osteomyelitis, septic arthritis), pulmonary infection, septicemia, and chronic suppurative infections of the skin, soft tissues, or viscera [33]. Of these two diseases, glanders is ranked as a higher threat than melioidosis because of a greater likelihood of death if not treated [2].

### 3.4 Impact and Public Perception

Although terrorism from the *Burkholderia* agents may not cause widespread direct clinical illnesses, there would still be significant psychological impact because of the infamous history of these biothreats. It is known that during World War I, Germany distributed cultures of *B. mallei* to undercover agents who attempted to infect livestock that were

to be shipped to Allied countries [34]. Glanders was among the agents used to infect human victims by Japan's notorious Unit 731 in Manchuria under the direction of Ishii Shiro [35]. Purported victims may worry for a long time because although the incubation period for melioidosis can be as short as 2 days, there are cases where years have elapsed between presumed exposure and appearance of clinical disease [28].

As an intentionally introduced foreign animal disease, the US agricultural system and horse-owning population would be significantly disaffected with required quarantine, test, and eradication programs for glanders. It may take time before it is recognized in a previously uninfected region. Initial cases may be misdiagnosed and animal carriers would spread the disease in the regular course of commerce and movement. It is a notifiable disease to the OIE and export restrictions would be placed on US origin equines. Environmental contamination or threatened contamination by *Burkholderia* agents may involve troublesome detection procedures to separate these agents from other ubiquitous microbiological relatives, including other *Burkholderia* spp. and the *Pseudomonas* spp.

# FOREIGN DENGUE VIRUS PRESENTS A LOW RISK TO U.S. HOMELAND

TERRY CARPENTER, KATHRYN L. CLARK, R. KEVIN HANSON, AND MICHAEL SARDELIS
*National Center for Medical Intelligence, Frederick, Maryland*

## 1 INTRODUCTION

Widespread dengue virus transmission in the continental United States is very unlikely. Media reporting in early 2008 [1, 2] speculating that the dengue virus may soon be

introduced and spread nationwide, as West Nile virus (WNV) did previously, have grossly overstated the threat. Once WNV was imported into the United States, many factors facilitated its spread and long-term establishment, which do not apply to dengue virus [3]. While sustained dengue virus transmission is unlikely, isolated cases or small case clusters of local transmission resulting from sporadic introduction by infected travelers will continue to occur in limited areas of the country where competent mosquito vectors are present. Such cases will likely be identified and contained by effective US public health responses.

## 2 BACKGROUND OF DENGUE AND WEST NILE VIRUSES

### 2.1 Worldwide Dengue Distribution

Dengue fever is transmitted at high levels year round throughout most tropical areas worldwide, including Central and South America, the Caribbean, southern and southeast Asia, the south Pacific, and parts of Africa. An estimated 50–100 million cases occur each year and the geographic distribution of dengue fever continues to expand (Fig. 1) [4].

### 2.2 History of Dengue Virus in the United States

Dengue fever, which was once endemic in the United States, was eliminated around 1950. No known outbreaks occurred between 1950 and 1980. However, small outbreaks of locally acquired dengue fever have been reported recently in southern Texas, usually in association with epidemic dengue spillover from adjacent Mexican states [5].

### 2.3 History of West Nile Virus in the United States

WNV has reemerged in the United States every year since 1999 and has expanded its range to include all states in the continental United States (Fig. 2). [6]. The spread of WNV has been aided by its ability to "overwinter" in birds and mosquitoes [7].

WNV has become widespread because it is maintained in nature principally in a mosquito-bird cycle [3]. Historically, migrating birds have spread WNV over a large are of the world, most recently in North America [6]. The spread and establishment of WNV has been assisted by the ability of the virus to infect many different bird and mosquito species [6].

**(U) Clinical dengue fever and WNV**

(U) Dengue virus causes dengue fever, dengue hemorrhagic fever, and dengue shock syndrome in humans.

(U) West Nile virus causes West Nile fever and neuroinvasive disease labeled as West Nile encephalitis, West Nile meningitis, or West Nile poliomyelitis.

(U) No vaccine is currently available to prevent any of these diseases.

**FIGURE 1** Clinical dengue fever and West Nile Virus.

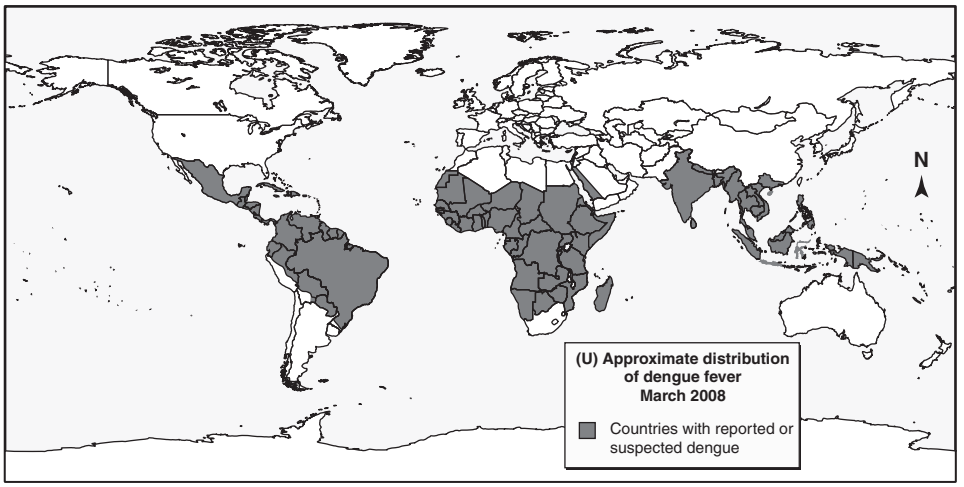

**FIGURE 2** Approximate worldwide distribution of dengue virus.

## 3 SEVERAL FACTORS REDUCE THE LIKELIHOOD OF SUSTAINED DENGUE VIRUS TRANSMISSION IN THE UNITED STATES AS COMPARED TO WNV

### 3.1 Disease Promulgation Multifactorial

For dengue virus to be transmitted in the United States, an infected traveler must arrive in the United States within the incubation period, typically 4–7 d (range 3–14 d) [4]. Persons already experiencing symptoms are unlikely to be well enough to travel. This relatively narrow time window reduces the odds that a traveler will arrive while incubating infection. Once in the United States, infected individuals must be bitten by a competent mosquito vector during the 3–5 d of viremia. Bites before or after this period, will not infect the mosquito. During viremia, the great majority of dengue fever patients will be severely debilitated or bedridden and unable to sustain normal activities, further limiting outdoor contact with mosquitoes. In order to transmit infection, the infected mosquito vector must bite another person 8–12 d after taking the blood meal from the original infected patient. The predominant competent mosquito vector in the United States is relatively inefficient at passing the infection to other humans, because it tends to feed only once, and also tends to bite other animals instead of humans [4].

### 3.2 Dengue Virus Mosquito Vectors Differ from those of WNV

Dengue virus mosquito vectors are not as numerous or as widely distributed in the United States as are WNV mosquito vectors (Fig. 3) [8]. WNV is transmitted by more than 60 species of mosquitoes, including the *Culex* species, which are distributed throughout the continental United States. Dengue virus is transmitted by *Aedes aegypti* and *Aedes albopictus*, which leave much of the United States uncovered. The overwhelming majority of dengue-infected people who travel to the United States do not encounter the mosquito vector to begin the transmission cycle.

**FIGURE 3** Approximate distribution of vectors of dengue virus and West Nile virus in the United States.

### 3.3 The Natural Ecology of Dengue Virus Differs from that of WNV in Ways that do not *Favor* Spread and Long-Term Establishment

Dengue viruses use humans as reservoir hosts. Neither migratory birds, nor any other bird species, have a role in the natural cycle and spread of dengue [9]. WNV has become widespread because it is principally maintained in a mosquito-bird cycle. Migrating birds act as vehicles to spread WNV over a large area [6]. The long-term establishment of WNV has been aided by its ability to "overwinter" in birds and mosquitoes, which allows WNV outbreaks to occur year after year in an area without reintroduction of the virus [7]. Dengue virus is transmitted in a mosquito-human cycle; birds have no role in the natural cycle and spread Table 1 [3].

In addition to dengue virus, other pathogens maintained exclusively in mosquito-man cycles (yellow fever virus and malaria) have been eliminated from the United States [10–12]. Socioeconomic development (improved housing, piped water systems, and air conditioning), sociobiological changes (people are indoors during early daylight hours, and late afternoon until dusk, the peak biting times), and vector control efforts have helped interrupt transmission of these pathogens despite the continued presence of the mosquito vectors, highlighting the requirement for a high level of mosquito-human contact to maintain dengue virus transmission.

## 4 OBSERVED DENGUE VIRUS IN THE UNITED STATES

### 4.1 Historical Importation

Despite frequent importation of dengue virus into the United States over the past 60 years by travelers to dengue virus endemic areas, no reports have surfaced of substantial outbreaks initiated by these travelers [13, 14]. An estimated 14 million travelers come to the

**TABLE 1 Comparison of Selected Aspects of West Nile and Dengue Viruses**

| Characteristics | West Nile Virus | Dengue Virus |
|---|---|---|
| Natural cycle | Mosquito-bird | Mosquito-human |
| Means of importation | Infected mosquitoes or migratory birds | Infected humans |
| Reservoir | Birds; nearly 300 native species found infected in the United States | Humans |
| Vector | Over 60 species of mosquito, principally *Culex* species | *Aedes aegypti* and *Aedes albopictus* |
| Natural evidence of ability to "overwinter" (e.g. survive during the winter in temperate regions, persist in nature during interepidemic periods) | Yes, using mechanisms involving birds and mosquitoes | None |
| Efficacy of mosquito control programs | Moderate; can be difficult because of the number of mosquito species that serve as vectors and their varied (and some times large) breeding habitats | Good; only two species of mosquitoes serve as vectors, and their breeding habitats (small containers) are readily accessible |

United States from dengue virus endemic areas each year, in addition to tens of millions of migrants who cross into the United States through Mexico. During 1980–2007, five small outbreaks (less than 40 confirmed cases each) occurred in Texas near the border with Mexico [15]. The origins of these outbreaks were associated with spillover from adjacent Mexican states. In addition, Florida has not reported an incident of local dengue virus transmission since 1934 [10]. Indigenous transmission is very rare.

### 4.2 Importation through Military Redeployment

The likelihood of military personnel redeploying from dengue-endemic areas and initiating local transmission of dengue virus in the United States is very low. Military personnel do deploy and travel to highly endemic areas, and in rare instances a limited number have contracted dengue fever while deployed (e.g. Haiti, Somalia) [16, 17]. Dengue fever outbreaks have not been observed in the United States upon redeployment because the deployed population is thoroughly screened for illness, consistent with established requirements for the military health system to conduct deployment health assessments.

## 5 UNITED STATES COUNTERMEASURES MITIGATE RISK

Public health readiness and public awareness of the threat of vector-borne viruses have been heightened, largely as a result of the introduction of WNV. Dengue fever outbreaks that do occur in the United States are relatively small and are quickly identified and contained by effective public health practices. Areas with increased risk for dengue introduction, such as Florida and Texas, have very well-developed and proven surveillance systems that remain alert for dengue cases [18]. Public health countermeasures

will prohibit transmission from progressing far enough to reach a sufficiently large enough reservoir of infected humans necessary to sustain a large outbreak.

## 6 SUMMARY AND CONCLUSIONS

Myriad infectious diseases exist throughout the world and conceivably could enter the United States. Careful identification and prioritization of significant foreign infectious disease threats which could be imported into the United States and develop into considerable public health challenges are critical to developing and maintaining appropriate Homeland Security countermeasures. A methodological scientific approach involving the cooperation of the intelligence community (with their assessments of diseases in foreign countries) and domestic agencies (with their knowledge of existing mitigating factors such as airport screening, vaccination, and vector control) would provide defensible rationale for allocation of countermeasure resources and establishment of homeland security procedures.

## 1 INTRODUCTION

As recognized recently in the 2005 revision of the International Health Regulations, early detection of disease is vital in responding to dangerous situations in a timely manner [1]. Researchers have explored the potential for identifying distinctive environmental [2–4],

climatic [5–7], and human behavior [8–10] signatures for rapid identification of outbreaks and epidemics [11]. Biosurveillance is the discipline in which diverse data streams such as these are characterized in real or near–real-time to provide early warning and situational awareness of events affecting human, plant, and animal health. Biosurveillance is distinct from the traditional public health surveillance; in that biosurveillance does not rely on classical epidemiologic studies or clinical data, the availability of which can be limited and nearly always lag the events they describe by days or months.

Many biosurveillance systems provide graded alerting of potential infectious disease outbreaks and refine the degree of confidence in these alerts as additional data becomes available. In this way, systems support graded response by public health, agriculture, and other decision makers [12]. Within such a process, evidence suggesting that an infectious disease outbreak is nascent in a particular region or locale cues a biosurveillance system (or perhaps a collection of systems) to search for additional information clarifying disease status. As more data are collected, surveillance becomes more directed and more actionable, ultimately leading to an evidence-based awareness of the situation. In such a way, public health and related organizations are postured to react in proportion to the degree of confidence inferred from biosurveillance and other surveillance activities as time evolves. Such a picture highlights the connectedness of biosurveillance and situational awareness.

## 2 SURVEY OF EXTANT BIOSURVEILLANCE SYSTEMS

This section provides brief descriptions of a sampling of current biosurveillance and situational awareness systems. Some are dedicated solely to global biosurveillance while others have biosurveillance as a component of their primarily domestic missions. Some are available and open to the general public while others limit user access. There is variability among capabilities for archiving and free-text searching, and these systems vary according to the languages included in sources. Each system was designed for a specific purpose, and each uses a customized approach to capture information useful to end users. In as much as this publication is dedicated to providing a resource for addressing homeland security issues, the compilation below should not be considered an exhaustive listing as similar, although largely domestic programs sponsored by many of the nearly 200 nations in the world are not included. There are systems (e.g. the US government BioWatch network of environmental sensors [13]) that are not included in this study because of a paucity of available information describing them. The systems are listed alphabetically; no ranking should be inferred from the order of presentation. This paper deals with systems that employ event-based unstructured data as opposed to structured data similar to that usually associated with syndromic surveillance.

### 2.1 Animal and Plant Health Inspection Service

Animal and Plant Health Inspection Service (APHIS) is a US Department of Agriculture organization, and its mission is to protect the health and value of American agriculture and natural resources.

- For animal health (http://www.aphis.usda.gov/animal_health/index.shtml), APHIS provides laboratory information services. It also has monitoring and surveillance components that include the National Animal Health Surveillance Systems

(NAHSS), the National Animal Health Reporting Systems (NAHRS), the National Animal Health Laboratory Network (NAHLN), the National Aquaculture Program (NAP), Emerging Animal Disease Notices, and the National Surveillance Unit.

- For plant health (http://www.aphis.usda.gov/plant_health/index.shtml), APHIS includes prevention (plant import regulations and permits, international safeguarding activities, and pest protection) and preparedness (Pest Identification & Diagnostics National Identification Service and National Plant Diagnostic Network) as well as response and recovery activities.

### 2.2 Argus

This project is a prototype biosurveillance system designed to detect and track biological events that may threaten global human, plant, and animal health. It is a cueing and alerting capability complementing both traditional and experimental biosurveillance activities. Argus examines real-time, local native-language media reports posted on the Internet to detect abnormal functioning of social systems; it is a taxonomy-based approach on the basis of direct, indirect, and enviroclimatic indication and warnings [3]. (An ontology is a set of concepts and keywords that are relevant to infectious disease surveillance. A taxonomy is a hierarchical organization of such concepts.) Analysts fluent in approximately 40 languages monitor the output of a large number of media sources and prepare approximately 40,000 reports per year. Argus scans about 1,000,000 articles per day of which 25% are archived. Argus reports can be accessed via http://www.opensource.gov.

### 2.3 BioCaster

BioCaster [14] is an experimental system for global health surveillance under development at the National Institute of Informatics in Japan and is a collaborative research project among five institutes in three countries (http://www.biocaster.org). The system is fully automated using Really Simple Syndication (RSS) feeds from over 1700 sources with no human analysts. Human analysis is assumed to take place downstream by the recipients of its output. BioCaster focuses on the Asia-Pacific region posting approximately 90 articles per day in three languages (English, Japanese, and Vietnamese) with plans for expansion to Thai, Chinese, and other regional languages. Article capture and dissemination is done every hour. Until recently the primary sources were Google News, Yahoo! News, and European Media Monitor, but the system is now expanding to include sources from a commercial news aggregation company which greatly increases its coverage. BioCaster produces an ontology [15] in eight languages (Chinese, English, French, Japanese, Korean, Spanish, Thai, and Vietnamese) that is openly available and is the basis for the Global Health Monitor [16], an open access Web portal for displaying maps and graphs of health events to users (http://www.aclweb.org/anthology-new/I/I08/I08-2140.pdf). The ontology covers approximately 117 infectious diseases of humans and animals as well as six syndromes. Future objectives include extending language and health threat coverage.

### 2.4 Centers for Disease Control and Prevention

The US Centers for Disease Control and Prevention (CDC) supports many resources dedicated to domestic and global public health issues, a number of which are described below (http://cdc.gov).

- Global Disease Detection Centers (http://www.cdc.gov/cogh/gdd/gddCenters.htm). This network of centers is being developed around the world in partnership with Ministries of Health. Six centers, many with regional collaborations, are currently in place (China, Egypt, Guatemala, Kenya, Thailand, and Kazakhstan). These centers will assist CDC in coordinating its resources and expertise more effectively including CDC intramural programs such as the Field Epidemiology Training Program (FETP) (http://www.cdc.gov/cogh/dgphcd/), the International Emerging Infections Program (IEIP) (http://www.cdc.gov/ieip/), and influenza activities (http://www.cdc.gov/flu). They also support implementation of the International Health Regulations (2005) by assisting countries with developing the required core capacities for surveillance and response.
- Global Disease Detection Operations Center (GDDOC). This center serves as the clearing house and coordination point for international outbreak information acquisition and response. It collects information from the GDDOC, other CDC programs, and a wide range of public and private sources. The GDDOC consolidates and interprets information from all its sources to assess severity of outbreaks and to determine and facilitate the appropriate CDC response.
- Early Aberration Reporting System (EARS) (http://emergency.cdc.gov/surveillance/ears/). This domestic capability was established as a method for monitoring bioterrorism and was put into operation in New York City and the national capital region after the terrorist attacks of September 11, 2001. It is used to acquire information about syndromic data, 911 calls, physician data, school and business absenteeism, and over-the-counter drug sales.
- Early Warning Infectious Disease Surveillance (EWIDS) (http://emergency.cdc.gov/surveillance/ewids/) EWIDS is an early warning infectious disease biosurveillance program for the states bordering Canada and Mexico. It is a collaboration of state, federal, and international partners to provide rapid and effective laboratory confirmation of urgent infectious disease case reports in the border regions. Regional collaborations include the Eastern Border Health Initiative, the Great Lakes Border Health Initiative, the Pacific Northwest Alliance, and the US-Mexico Border Region Group.
- Epi-X (http://www.cdc.gov/epix/) initiated in December 2000, is the CDC's secure web-based communications application for public health professionals. The network's primary goal is to provide timely information to health officials about important public health events, to help them respond to public health emergencies, and to encourage professional growth and exchange of information. The main features of Epi-X include scientific and editorial support by CDC personnel, controlled user access, digital credentials and authentication, rapid outbreak reporting, and peer-to-peer consultation. Epi-X access is limited to public health professionals designated by each health agency. Health officials have posted about 6700 reports to date and approximately 4200 users are notified routinely of these postings by e-mail or additionally by pager and telephone depending on the acuteness of the event. Event postings and support are provided 24 h per day, 7 days per week. Epi-X also provides communications to the public through the Morbidity and Mortality Weekly Report (MMWR) and other sources.
- National Electronic Disease Surveillance System (NEDSS) (http://www.cdc.gov/nedss/). NEDSS was developed to rapidly detect outbreaks, monitor the nation's

health and facilitate the electronic transfer of information from clinical information systems to public health departments. It promotes the use of data and information system standards for development of integrated and interoperable surveillance systems at the federal, state, and local levels. It is a major component of the Public Health Information Network (PHIN) (http://www.cdc.gov/phin/).

- BioSense (http://www.cdc.gov/Biosense/) is a national human health surveillance capability developed and hosted by the CDC. It is system of systems that links data from a variety of largely domestic sources to provide a unified national view. It is designed to assist in validating the existence of an outbreak, monitor its status and provide local, state, and national situational awareness.

### 2.5 Emergency Prevention Program for Transboundry Animal Diseases

This global animal health information system compiles, stores, and verifies animal disease outbreak information from many sources (http://empres-i.fao.org/empres-i/). For verification, Emergency Prevention Program for Transboundry Animal Diseases (EMPRES-i) uses both official and nonofficial sources and generates and disseminates early warning messages.

### 2.6 European Center for Disease Control and Prevention

The European Center for Disease Control and Prevention (ECDC), a European Union (EU) agency, was established in 2005 and is based in Stockholm, Sweden (http://ecdc.europa.eu/en/). Its mission (http://ecdc.europa.eu/en/Activities/Epidemic_Intelligence/) is to identify, assess, and communicate current and emerging threats to human health from infectious diseases. A number of information services/systems are operating or being developed at the ECDC that includes the following:

- the ECDC web site (http://ecdc.europa.eu);
- the Eurosurveillance journal (http://www.eurosurveillance.org);
- TESSy—the integrated European communicable disease surveillance system;
- EPIS—the epidemic intelligence portal developed to support outbreak detection, risk assessment, outbreak investigation, and control measures at EU level;
- Knowledge and Information service (KISatECDC)—the content management system for scientific documents produced at the ECDC;
- Preparedness and Response Unit (PRU)—working in partnership with member states across Europe to develop surveillance and early warning systems, the ECDC maintains a staff with 24/7 duty officers and has an emergency operations center. It develops threat tracking tools and issues daily reports collated from a variety of sources numbering among which is the Unit that monitors emerging threats. http://ecdpc.europa.eu/About_us/Preparedness&Response.html

### 2.7 European Influenza Surveillance Scheme

European Influenza Surveillance Scheme (EISS) collects data on influenza in Europe and shares the information with 30 member countries via weekly surveillance reports (http://www.eiss.org/. The reports are derived from information reported by 25,750 sentinel

physicians. EISS objectives are described in more detail at http://www.eiss.org/html/lb_objectives.html, and its methods are summarized at http://www.eiss.org/html/introduction.php.

### 2.8 Global Emerging Infections System

Global Emerging Infections System (GEIS) was established in 1996 within the Department of Defense (DoD) for prevention, surveillance, and response to infectious diseases that could threaten military personnel or their dependents, reduce medical readiness or affect national security (http://www.geis.fhp.osd.mil/). It has a global reach, a number of partners within the DoD, and working relationships with other US and international health agencies. Electronic Surveillance for the Early Notification of Community-based Epidemics (ESSENCE), first developed within GEIS, is a web-based system in support of the DoD health mission (http://www.ehcca.com/presentations/hithipaa414/4_06_1.ppt). It tracks ambulatory and pharmacy data from the US military treatment facilities and alerts users to possible outbreaks of infectious disease and biological incidents.

### 2.9 Global Public Health Intelligence Network

Global Public Health Intelligence Network (GPHIN) was established in 1997 and is managed by the Public Health Agency of Canada's Center for Emergency Preparedness and Response (http://www.phac-aspc.gc.ca/gphin/index-eng.php). It uses the Internet to gather information on eight topics of public health interest. It has global reach and acquires articles from newsfeeds Al Bawaba and Factiva using keywords and terms within a specific taxonomy. Articles about events that may have serious public health consequences are sent to users as e-mail alerts. Machine translation is provided for nine languages (Spanish, French, Russian, Arabic, Farsi, Chinese Simplified and Traditional, Portuguese, and English). GPHIN functions on a near–real-time basis with 24/7 coverage and is staffed with analysts who provide linguistic and interpretive expertise. Customers include the World Health Organization (WHO) and other public and private sector organizations [17].

### 2.10 Health Emergency Disease Information System

Based in Italy, Health Emergency Disease Information System (HEDIS) was developed by the European Commission (EC) to support Directorate General for Health and Consumer Protection (DG SANCO) and public health authorities in Member States (http://hedis.jrc.it/). Its emphasis is crisis management rather than biosurveillance. It provides situational awareness and as such is a central jumping off point for crisis communication. It has approximately 300 users (users are Member States responsible for communicable diseases, CBRN [chemical, biological radiological, nuclear], and communicators) and provides capabilities and tools to assist its customers in dealing with an identified health threat. Included among the rapid alert mechanisms linking Member States with the EU are the following:

- Early Warning and Response System (EWRS) is a web-based system linking the EC with public health authorities in Member States responsible for communicable disease control measures. (http://ec.europa.eu/health/ph_threats/com/early_warning_en.htm)

- Rapid Alert System for Biological and Chemical Agent Attacks (RAS BICHAT) is a system for information exchange on health threats from deliberate release of CBRN agents. (http://ec.europa.eu/health/ph_threats/com/preparedness/rapid_alert_en.htm)
- Rapid Alert System for Food and Feed (RASFF) facilitates information exchange on measures taken to ensure food safety. (http://ec.europa.eu/food/food/rapidalert/index_en.htm)
- Animal Disease Notification System (ADNS) provides detailed information on infectious disease outbreaks in animals in Member States. (http://ec.europa.eu/food/animal/diseases/adns/index_en.htm)
- European Food Safety Authority (EFSA) provides risk assessment advice on existing and emerging risks in food and feed safety. (http://www.efsa.europa.eu/EFSA/efsa_locale-1178620753812_home.htm).

### 2.11 HealthMap

HealthMap is a fully automated resource that collects information from 14 sources (representing about 20,000 web sites) including Google News, ProMED, WHO, and others (http://www.healthmap.org/about.php). It was created as a unified and comprehensive resource for information on infectious disease and public health events in humans, animals, and plants and is freely available with sources and user interface in English, Chinese, Spanish, Russian, and French. Data are aggregated by disease and displayed by location with a link to the original text. HealthMap processes approximately 300 alerts per day and has documented 141 unique infectious disease categories from 174 countries. The HealthMap web site has approximately 1000–10,000 visitors per day with about 200,000 visitors since its launch [18].

### 2.12 *Institute de Veille Sanitaire*

Among a number of other responsibilities, the French Institute for Public Health Surveillance, *Institute de Veille Sanitaire* (INVS) provides surveillance and alerts of infectious diseases (http://www.invs.sante.fr/presentations/presentation_anglais.htm). The INVS collaborates with other national networks and international organizations. It is part of the EWRS that links health ministries and surveillance organizations in EU Member States. Sources include WHO, ProMED, GPHIN, and OIE. Posting only verified news events, it has approximately 1400 subscribers.

### 2.13 Medical Information System

The EC's Medical Information System (MedISys) (http://medusa.jrc.it/medisys/aboutMediSys.html) is a fully automated 24/7 public health surveillance system run and maintained by the Joint Research Center (JRC) at the Institute for the Protection and Security of the Citizen (IPSC), in Ispra, Italy [19]. The developer team collaborates with the Health Threats Unit at the Directorate General for Health and Consumer Protection (DG SANCO) and University of Helsinki (PULS system).

MedISys covers infectious human and animal diseases, bioterrorism, chemical, biological, and CBRN threats reported in open source news media. Approximately 80,000 to 90,000 articles from 5000 news sites in 45 languages are screened. Currently, 26 languages are available via the Web portal, but news in 45 languages is processed in

predefined categories. MedISys started operating in August 2004 and is one of the several JRC-developed media monitoring applications that process news gathered by the Europe Media Monitor (EMM, on-line since 2002). MedISys provides daily automated e-mail alerts to subscribers and offers users a tool called *Rapid News Service* (RNS) to manage newsletters, e-mail distribution lists, and alerts via e-mail and/or mobile phone messages.

### 2.14 World Organization for Animal Health

Created in 1924, the Organization for Animal Health (OIE) is an intergovernmental organization with 172 member countries and territories and charged with improving animal health worldwide (http://www.oie.int/eng/en_index.htm). It maintains permanent relationships with other international and regional organizations. The World Animal Health Information Database (http://www.oie.int/wahis/public.php?page=home) provides access to OIE's World Animal Health Information System (WAHIS) data. The reports include immediate notifications and follow-up reports from Member States, country biannual reports on OIE-listed diseases, and annual reports on animal health, laboratory, and vaccine production. The OIE is a participating partner in WHO's Global Warning system for Major Animal Diseases, including Zoonoses (GLEWS) for early warning and responses to animal diseases.

### 2.15 Pattern-based Understanding and Learning System

Pattern-based Understanding and Learning System (PULS) is an information system at the University of Helsinki (http://puls.cs.helsinki.fi/medical/) that in partnership with the EC's JRC extracts metadata from MedISys articles [19, 20]. It is a fully automated global biosurveillance system designed to provide early warning of infectious and noninfectious disease outbreaks and its coverage will soon be extended to CBRN. Its focus is information retrieval, extraction, aggregation, and visualization, and it uses text mining and natural language processing to analyze incoming documents. Key attributes determined from text include disease/condition (if known), location, date, number of victims, whether human or animal, and victim survival.

### 2.16 Program for Monitoring Emerging Diseases

Program for Monitoring Emerging Diseases (ProMED)-mail (http://www.promedmail.org) was established in 1994 and currently operates as a program of the International Society for Infectious Diseases with contributing corporate, foundation, and individual donor support [21, 22]. With the goal of promoting rapid communication within the international infectious disease community, it is an Internet-based reporting system for disease outbreaks and toxin exposures affecting humans, animals, and plants. Sources include local observers, media and official reports, and others. In a nonautomated process, reporting is screened and comments provided by subject-matter experts prior to posting to subscribers of which there are over 50,000 in 188 countries. ProMED-mail sends an average of 7–10 reports per day and is available in English, Spanish, Portuguese, French, and Russian languages. ProMED-mail has five regional programs with a staff in 15 countries.

### 2.17 Real-time Outbreak and Disease Surveillance

As its name implies, Real-time Outbreak and Disease Surveillance (RODS) was created to investigate methods to detect disease outbreaks in real-time (https://www.rods.pitt.edu/site/index.php?option=com_content&task=view&id=14&Itemid=77). With support from US federal agencies and the State of Pennsylvania, its public health bioinformatics research includes outbreak detection algorithms, free-text classification, systems design, system evaluation, policy analysis, and outbreak simulation. RODS software has been made available to academia and health departments, and RODS operates the National Retail Data Monitor for information on sale of over-the-counter healthcare products [23]. RODS is currently in use in many cities, states, and countries and has served as a partner in the Department of Homeland Security's BioWatch program.

### 2.18 National Association of Radio-Distress Signaling and Infocommunications Emergency and Disaster Information Service (RSOE-EDIS)

Based in Hungary, the Havaria Information Service (http://www.oasis-open.org/events/ITU-T-OASISWorkshop2006/slides/rafael.pdf) was established to monitor catastrophic events in Hungary, Europe, and the world and to forward information to stakeholders via e-mail alerts and RSS feeds (http://visz.rsoe.hu/alertmap/index.php?lang=). The service collects information from approximately 600 Internet portals among which are numbered inputs from EISS for European influenza status, WHO, and the US CDC for global epidemic events.

### 2.19 World Health Organization

WHO has put into place or provides administrative assistance to a number of resources which contribute to the detection of disease outbreaks and the response thereto (http://www.who.int/en/).

- Epidemic and Pandemic Alert and Response (EPR, http://www.who.int/csr/en/). In addition to other services and capabilities, EPR provides Member States epidemic intelligence in the form of event verification, alerting, and coordinated outbreak responses within the framework of the International Health Regulations (2005). EPR seeks to ensure appropriate communications among stakeholders.
- Global Outbreak Alert and Response Network (GOARN) (http://www.who.int/csr/outbreaknetwork/en/). WHO provides administrative assistance and an organizational umbrella for GOARN although GOARN is not a formal component of WHO. GOARN is an association whose members and networks are brought together to assist in and enable early detection, identification, confirmation, and response to disease events with international implications.

## 3 ANALYSIS OF SYSTEMS

Public health markers providing indications and warning (I&W) of new and emerging infectious disease events can be conveniently segregated into direct and indirect components [24]. The I&W paradigm provides a useful framework for interpreting the landscape of international biosurveillance defined by the systems described above. For the purpose of this article, the following classifications of I&W types are used as follows:

- *Direct indicators* are those commonly used in traditional disease reporting and include data derived from public health, clinical, and laboratory sources. Examples of direct indicators are reports of unknown human disease (i.e. syndromes and diseases of unknown etiology), geographical features (i.e. extent of affected area such as city, region, nation, etc.), noncontiguous geographic involvement, unique or unexpected clinical presentation, high morbidity/mortality, unexpected appearance of disease in relation to season, discrete population(s) involved (e.g. specific ethnic group, nosocomial [hospital] setting, healthcare workers, patients contracting unusual disease while in a medical facility, specific age groups, and specific occupations). While some specific features of direct indicators of animal disease may be different, their pattern is similar to those of human disease [24].
- *Indirect indicators* include human responses to infectious disease outbreaks that are expressed as social behavior. Other indirect indicators include environmental and climate/meteorological trends such as temperature and precipitation variations. Social behavior deviating from the norm in a particular group or society [24] include such items as (i) public health response including preparedness, implementation of countermeasures, activation of biosurveillance or screening, and demand for medical services; (ii) other government reaction such as official acknowledgment or denial of the bioevent, official action, information suppression, or criminal prosecution; (iii) business/organizational changes including business practice changes and integrity of infrastructure; and (iv) other social behavior such as local perception of threat.

While extensive details regarding specific ontologies and taxonomies are not publically available for all the systems described above, it is possible to think of them within an I&W paradigm. When that is done for examples of direct and indirect indicators described in the preceding paragraph, some interesting features emerge that are illustrated in Figures 1–3.

As shown in Figure 1, all systems monitor and report on direct I&W of disease. Fewer systems utilize indirect I&W markers, and those include Argus, GPHIN, HealthMap, ProMED, RODS, and RSOE.

Figure 2 illustrates the results when direct I&W elements are broken down into specific categories. Not surprisingly, all the systems utilize public health information and 11 of the 19 systems collect clinical and laboratory information as well. While the direct I&W categories in Figure 2 are not inclusive of all that might be considered, they serve to both: (i) illustrate the diversity of the systems and (ii) suggest areas for capitalizing on system complementarities.

Figure 3 suggests that coverage of indirect indicators is much less complete than coverage of direct indicators. As might be expected, "Public Health Response" is the most frequently used indirect I&W followed by "Meteorological Data." Although the potential value of enviroclimatic indicators is yet to be demonstrated for a large class of diseases, compelling evidence for the role climate issues play for particular diseases can be found in the literature [25–27].

The lack of coverage of any particular direct or indirect I&W marker in any given system should not be considered a criticism or fatal system flaw, but rather as an opportunity to exploit complementarities between systems. It can also be argued that, since no system is perfect, some redundancy can be a positive attribute. The systems described above were designed to serve varying missions and stakeholder populations, and therefore, no one

**FIGURE 3** System usage of indirect I&W subdivided by category. "Public Health Response" is action by health officials to contain a disease event (e.g. health alerts and quarantine), "Other Government Reaction" denotes an official action in response to a disease event (e.g. implementation of countermeasures and official investigations), "Business/Organization Changes" refers to changes in normal business or organization practices (e.g. profiteering, business closure and black market formation), "Other Social Behavior" denotes societal anxiety or panic (e.g. fleeing and stockpiling of commodities), "Meteorological Data" refers to enviroclimatic, satellite and vegetation, and other data that could be used to identify favorable conditions for a biological event (e.g. flooding, abnormal temperature, and water contamination).

system can or should be expected to deliver insight into all possible variables associated with effective biosurveillance, especially, on a global scale where the need is greatest.

## 4 RESEARCH AND DEVELOPMENT NEEDS

A dynamic approach to risk assessment and public health reaction remains difficult given current limitations in both early warning and real-time situational awareness of emerging biological events. If the paradigm of graded public health response is to be viable, a capability must exist to detect evidence of outbreak activity at the earliest stages and monitor them accurately and precisely as they progress. Such a capability would likely be a "systems of systems," composed of discrete and complementary components acting in concert. Included in any such system would be a component that provides I&W of potential events. This I&W component would provide the first cueing and alerting of a potential disease event (or, potentially, risk of a future event). It is expected that with time after the event, additional information provided by other components in the graded alerting and response chain will refine and better characterize the event. The systems listed in this study (and potentially others not included here) likely provide the basic ingredients for such a system of systems.

Important technological and methodological challenges remain in constructing a system providing comprehensive, dynamic situational awareness [28]. For both individual systems as well as systems of systems, some of the more prominent challenges facing surveillance systems include interoperability, interface customizability, scalability, and event traceability. Integration of geospatial visualization, event mapping, modeling, and

trending tools are important for establishing metrics and baselines necessary for data interpretation and analysis. Additionally, expansion of the current biosurveillance capabilities via incorporation of emerging media such as video, digital audio, images, blogs, Short Message Service (SMS), and others is critical.

### 4.1 Source Assessment

The value of various data sources must be defined. There are a massive number of sources on the Web (e.g. news media text, images, audio, and video; blogs; social networking sites; traditional public health; syndromic [29, 30], and laboratory surveillance [31]). Each source type will likely have associated with it varying degrees of confidence and geographic coverage, and at some point the value of each component in biosurveillance systems must be assessed. Quantifying variation in source reporting standards as well as catchment (i.e. the regions from which a source collects) and target population will be a critical first step toward understanding how these issues affect the validity of biosurveillance system output. Metrics must be defined, and these metrics need to be generalized to individual systems that may use different data and take a variety of analytical approaches.

### 4.2 Standards Development

Approaches to integrating complementary systems must be investigated. Since the biosurveillance systems described in this study were created to address specific issues and utilize different methods and standards, integration of these systems will be challenging. No standards for collecting, processing, and exploiting biosurveillance products exist that can be applied across the spectrum of systems described here. Such standards, once agreed upon and implemented, would facilitate communication between international and domestic systems alike.

### 4.3 System Metrics

Techniques for evaluating system performance must be developed. It is unclear how to evaluate the impact of biosurveillance on spatiotemporal detection and monitoring (i.e. situational awareness) of infectious disease outbreaks. In addition, standardized metrics quantifying the performance of different biosurveillance systems are needed to understand how different systems complement and add value to one another. Such metrics are also needed if end users are able to understand the performance of a given system, let alone any aggregation of systems.

### 4.4 System Communication

Efficient and meaningful ways of communicating system outputs and findings must be identified. Current systems display and present the results of biosurveillance differently. How to present best results to the broader user community, which includes researchers as well as public health workers and decision makers, is an issue that will have to be addressed. Many unknowns remain including identifying the most appropriate interactive visual interfaces; best practices regarding techniques for visually synthesizing biosurveillance data; and how to present dynamic, ambiguous, and potentially conflicting information to consumers of biosurveillance. Can a biologically common operating system be developed that effectively addresses the needs of different users?

There are nearly 200 countries in the world. Although much effort has been devoted to the automated acquisition of massive amounts of relevant information (e.g. from the Internet), global biosurveillance must sooner or later have the ability to capture and analyze information in many languages. In the future, the most informative and useful systems will likely have access to an analyst cadre collectively fluent in many languages and cultures.

## 5 ASSESSMENT OF THE CURRENT GLOBAL BIOSURVEILLANCE LANDSCAPE

That rapid reporting of disease outbreaks is vital for both the public health and national security communities is not disputed. It is also clear that this can only be accomplished with an effective, integrated global biosurveillance capability with a near–realtime reporting component. While such a capability does not yet exist, similarities and differences among systems such as those described in this work suggest that exploiting system complementarities could provide a very powerful global biosurveillance resource.

In 2003, Woodall and Aldis reported "enormous gaps in terms of geographical and disease coverage and timeliness of reporting" and concluded that open source on-line reporting with an emphasis on speed would likely heavily use the Internet [32]. More recently, Morse [33] reviewed the gaps that hindered progress to global biosurveillance, and those gaps included among others, political will, resources for reporting, and improved coordination and sharing information; he also noted that increased availability of communications and information technologies offered new opportunities for reporting. These observations are certainly consistent with the analysis of the biosurveillance systems presented in Section 2 above and with the recent results of studies using Internet search engines to track influenza [34–36].

With the appropriate communication and data sharing regimes, there do not appear to be technical barriers to integrating existing global and regional biosurveillance systems, biosurveillance systems dedicated to single diseases, and open source reporting into an effective global biosurveillance capability. Even a cursory examination of the systems presented here shows a tremendous reservoir of creative thought and achievement that, if policy and political barriers were to be eliminated, could be the foundation of global biosurveillance in the not too distant future. Although, each of the individual systems examined here have different missions and approaches, most complement the others. There is no obvious reason why a hierarchal system of systems could not be assembled with currently existing biosurveillance systems. This would require enlightened leadership and the will to cooperate, not new technology. Although much remains to be done that will require dedication of the appropriate financial and intellectual resources, there is a solid foundation upon which to build.

## ACKNOWLEDGMENTS

The authors thank system owners Drs John Brownstein (HealthMap), Nigel Collier (Biocaster), Jens Linge (MedISys), Larry Madoff (ProMed-mail), Abla Mawudeku (GPHIN), Germain Thinus (HEDIS), and Roman Yangarber (PULS) for their gracious review and helpful comments during preparation of this manuscript. CDC's Dr Ray Arthur provided valuable insights and comments on this manuscript.

## 1 INTRODUCTION

The term "biosurveillance" is not currently associated with a universally accepted definition [1]. For the purposes of this article, we consider the definition of biosurveillance to be the detection and tracking of biological events that represent a deviation of what is considered normal endemic baseline. A "biological event" refers to disease events affecting humans, animals, and/or plants; here we focus primarily on biological events

affecting humans or animals. The prospect of rapid detection of socially disruptive biological events that are triggered through natural, accidental, or intentional mechanisms is of interest not only to the public health community but to the agricultural, law enforcement, intelligence, and homeland security communities as well.

From a public health perspective, biosurveillance must embrace grounded public health surveillance methodology as well as near-real-time situational awareness (i.e. event detection). The public health community has traditionally focused on health-related information such as patient care, disease reporting, and diagnostic information. This represents but a small portion of the necessary data potentially useful to detect and track an evolving biological event [1].

## 2 EMERGENCE OF THE BIOSURVEILLANCE TRADECRAFT

At the time of writing this manuscript, there did not exist a formalized professional discipline in operational biosurveillance with rigorous research, education, and training support. Biosurveillance requires a synthesis of analytic approaches derived from the natural disaster, intelligence, public health, epidemiological, medical, veterinary, agricultural, meteorological, anthropological, and sociological communities, among others. Functional modes of biosurveillance analysis span the tactical, strategic, and forensic domains.

The tradecraft of biosurveillance follows similar tenets of the intelligence cycle, which is a useful construct to codify operations. Figure 1 displays an overview of the biosurveillance cycle.

Data collection is driven by a comprehensive targeting analysis, which stems from a mission analysis (see below). Targeting enables identification of the key required information elements and what sources can provide such information in a timely and credible manner. Analysis of the information is driven by mission objectives (see below).

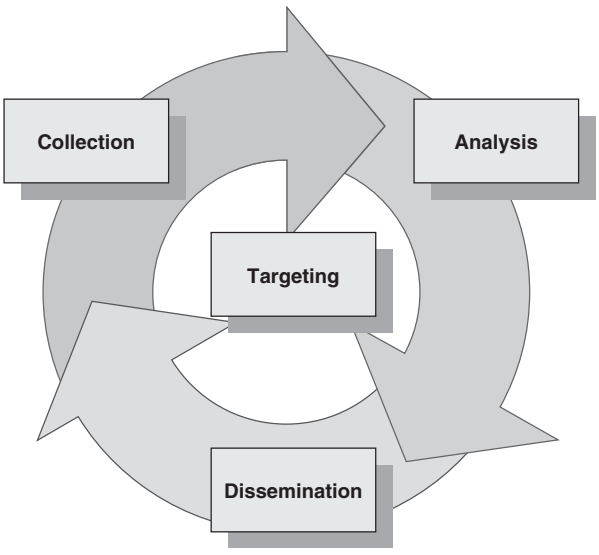

**FIGURE 1** The biosurveillance cycle.

Dissemination is an important step; control of information flow can be as much an asset to an operations team performing biosurveillance as well as a detriment if information is not controlled appropriately. Feedback provided from customers of the information enables refinement of the overall process through never-ending targeting analysis. Targeting is a perpetual component of operational biosurveillance that ensures improvement.

## 3 MISSION ANALYSIS

An operational biosurveillance organization, especially if it is to function in the tactical environment, must exist as a highly disciplined entity. The creation of such an organization begins with a mission analysis, which comprises a mission statement, critical information requirements (CIRs), targeting analysis, and operations plan that eventually evolves into standard operating procedures (SOPs). It is the operations plan that codifies the process of data collection, analysis, and information dissemination.

The mission statement is an important first step. It defines the customer(s), the product outputs and operational objective, and implies the eventual CIRs and primary operational tempo (tactical, strategic, and forensic). An example of a mission statement might be the following:

> The ACME Biosurveillance Organization provides decision makers early recognition of biological events of potential local and regional significance, to include natural disease outbreaks, accidental, or intentional use of biological agents, and emergent biohazards through the acquisition, integration, analysis, and dissemination of information from existing human disease, food, water, meteorological, and environmental surveillance systems and relevant threat information.

The CIRs are typically a list of 5–10 (preferably five) statements that define the key items the customer is primarily concerned about. An example of a CIR is *any credible evidence of an act of intentional biological agent release*.

Targeting analysis refers to defining the data collection requirements and implied social networks and information providers needed to obtain the data. For national, state, and local considerations, reporting requirements are legally mandated for specific diseases such as plague. These requirements have not traditionally included indication and warning (I&W) reporting, which are additional important considerations. I&Ws fall into two categories: direct and indirect. Direct indications refer to explicit local reporting of disease in humans, animals, or plants that may describe epidemiological features of the event [2]. Here, it is important to monitor with a species-agnostic approach. Species tropism exhibited by diseases may give important initial clues as to the diagnosis. For example, prairie dog illness in Colorado is an important indicator of the possible presence (and imminent threat to human health) of plague. Indirect indicators are further subdivided into additional categories such as official acknowledgement, official action, local perception of threat, business practice changes, and integrity of infrastructure. The indicators within these categories are numerous and beyond the scope of this article, however, they enable approximation, over time, of social functioning in the context of a biological event. The key objective in the use of indirect indicators is to provide an assessment of containment status and concurrent level of social disruption [2]. When considered as a whole, these reporting requirements enable operational monitoring of an entire society as though it were a patient in a hospital bed.

Once a combined disease-specific and I&W reporting requirement table has been established, the next step involves prioritization. For example, a report of diarrhea in a day care center may take lower precedence than reports of the primary trauma care hospital for the city reporting a sudden inundation of its infrastructure with an unidentified influenza-like illness. Such prioritization will naturally lead to categorization of reporting requirements into classes that are easily understood by the user community, such as "warning", "watch", and "advisory". Note, this prioritization is dependent upon, and partly defined by the user community, whether for internal monitoring purposes or to provide reporting to the health care community or the general public. Examples of this process are highlighted in Table 1.

Once prioritized reporting requirements have been established, an examination of social networking is required that attempts to cross-match the requirements to data and information sources; the product of this analysis is referred to as a *targeting matrix*. For example, if a key direct indicator is *reports of disease in rodents*, then one may need to consider building a network of reporting that includes the local sanitation authority. If a key indirect indicator is *local depletion of ventilator supplies*, then one may need to build a relationship with the local distributor of ventilators as well as medical facilities that use ventilators.

Prioritized reporting requirements drive the operations tempo, where "warning" implies a tactical, near-real-time reaction by the analyst versus an "advisory" that may be monitored over the course of a week. In other words, this categorization is an easy way to impart the severity and importance of the report to the user community.

The operations plan draws together all of these components into a document that precisely defines how the mission will be executed, from mission statement to CIRs, prioritized reporting requirements, operation tempo modes, communication channels that

**TABLE 1 Example of Prioritized Reporting Requirements**

| Events | Warning | Watch | Advisory |
|---|---|---|---|
| Any indication of intentional use of any biological agent or a biowarfare attack | X | | |
| Any indication of public health system failure or social collapse associated with a biological event involving humans or animals | X | | |
| A biological event associated with illness of health care, veterinary, or laboratory workers | X | | |
| Public panic documented by local media in context with an active biological event (includes mass evacuations and conflict with officials) | X | | |
| Any incident of unexplained illness requiring additional response or assistance, especially of health care, veterinary, or laboratory workers | | X | |
| Any acute cluster (>3) of unexplained illness in humans | | X | |
| Any acute cluster (>10) of unexplained illness in animals | | X | |
| Vaccine accident triggering a biological event | | | X |
| Any increased demand for ventilator or intensive care unit support | | | X |
| Vaccine or therapeutic failure or compromise | | | X |

include the social network of reporting, and so on. While the document itself eventually becomes a desk reference for the biosurveillance analyst, it is a living document that is modified to reflect changes in operational requirements and refinements in the analytic process.

## 4 BIOLOGICAL EVENT EVOLUTION

Investigators have attempted to define event evolution as a function of media reporting. Cieri and colleagues [3] proposed that an event be defined as "a specific thing that happens at a specific time and place along with all necessary preconditions and unavoidable consequences" [3]. Makkonen [4] observed that a seminal event can lead to various related events and outcomes, and the initial cause of these events may become less obvious over time [4]. Chen and colleagues proposed that a media-reported event can be considered "a life form with stages of birth, growth, decay, and death"; maintenance of the reported event is dependent on sensationalism [5]. We propose that biological events are reported through various data inputs as increasingly complex phenomena over time, whose "nourishment" is dependent on whether the biological agent in question continues to transmit above what is locally considered baseline disease [2].

For example, in 2002, the emergence of severe acute respiratory syndrome (SARS) in the People's Republic of China (PRC) appeared to be largely unnoticed by the international community. I&Ws of "unseasonal bad flu" appeared in September in local Chinese vernacular media. Diagnosis of the pathogen in question would not have been apparent beyond "bad flu"; however, "unseasonal" indicated a local awareness of a potential departure from local baseline disease. In October, social anxiety was reported. By November, official concern was expressed regarding potential public panic. In December, an abrupt decrease in reporting, indicating possible information suppression, was a key indicator of a change in local awareness of this novel threat. In January, reports of supply depletions and mobilization of resources appeared, indicating severe shifts in supply and demand. By April, reports documented martial law and rioting due to SARS-related social disruption. This event likely was a complex event involving a variety of respiratory pathogens; to date, there remains uncertainty as to precisely when SARS emerged within this context. In any case, reports of "unseasonal bad flu" in September and, more important, of social anxiety in October would have been key to the analyst's assessment of whether unusual disease was present. The overall pattern was one of recurrence, elevation, and diversification of the I&Ws of a biological event declared unusual followed by reports of containment loss [6].

As recent history has shown, SARS was not recognized to be a transnational threat until it had translocated through the air traffic grid to eight countries including the United States. The challenge revolved around near-real-time access to transparent disease reporting, understanding of what were indications of social disruption due to containment loss, and effective analysis to determine the nature of what ultimately constituted a true transnational issue [6].

The 1995 epidemic of Venezuelan equine encephalitis (VEE) in Venezuela and Colombia presented a complex picture of flood-induced infrastructure collapse; the presence of a disease affecting horses and humans (i.e. VEE), and possibly the presence of other diseases as well, such as dengue fever. In March and April 1995, flooding was reported in local vernacular Venezuelan media. In April, equine health evaluations were reported,

but there was no explicit declaration of an outbreak of disease. By June, enough information was available to note the presence of a multifocal biological event in equines, co-occurring with at least a unifocal event in humans. In July, infrastructure strain was reportedly related to equine disease (e.g. depletion of local vaccine supplies), along with indications of a multifocal human disease also present. In August, strain on the medical infrastructure was reported (e.g. hospitals overrun with infected individuals), followed by signs of social collapse in September. Flooding was a key factor promoting the vigorous progression of this epidemic because of not only its effects on expansion of the vector population, but also its direct effect of disrupting multiple sectors of Venezuela's local infrastructure, such as power lines, roadways, and communication. In this example, although documentation of infrastructure collapse due to flooding appeared as early as June, local reporting of social collapse specifically due to disease did not appear until September. It could easily be argued that the effects of flooding on local infrastructure greatly increased the probability of rapid loss of containment. It was later hypothesized that this epidemic was due to a possible laboratory accident, highlighting the time-delays inherent in determination of attribution [7].

The VEE epidemic represented a possible translocation issue for the United States given air traffic from Maracaibo, Venezuela, connected directly to Miami (with unknown connector flights to other destinations within the United States) that seasonally peaked during the month of containment loss. To date, it is unknown whether it would have been possible that VEE could translocate to Miami, trigger an outbreak that progressed to an epidemic, ecological establishment, and repeated seasonal transmission thereafter for years to come. A comprehensive assessment of the transmission competency of endemic mosquito species in Miami would be necessary to determine if this was a valid hazard concern [7].

In 1979, a laboratory accident involving aerosolized anthrax occurred in Sverdlovsk, Russia. From April 14 to May 18, 1979, local media in Sverdlovsk explicitly reported the occurrence of a series of human cases of inhalation anthrax along with draconian countermeasures as officials sought to rapidly contain and conceal the true etiology of the event. In 1992 and 1993, a team of American and Russian researchers led by Meselson and colleagues traveled to Sverdlovsk to investigate evidence for two hypotheses of anthrax epidemic of 1979, the official USSR version that infected meat caused the outbreak and the US intelligence claims that the true etiology of the epidemic was an accidental release of aerosolized anthrax spores from the Compound 19 within the Voyenny Gorodok 47 biological weapons laboratory located in the city. The Meselson team concluded that an accidental aerosol release had indeed occurred on April 2, 1979, resulting in what is thought to be the largest documented outbreak of human inhalation anthrax in history. Declassified US intelligence archives suggest that the intelligence community was unaware of this event until months after the fact [8].

This example highlights the requirement for a tactical approach to detect biological events and baseline not only the epidemiological data for the disease itself, but social responses as well. Identifying "unusual" biological events that are evolving rapidly, with an attendant recurrence, elevation, and diversification of the I&Ws, may assist in a time-sensitive evaluation of whether there may be questions of attribution [8].

In each of these case scenarios, the biological event in question produced a "ripple effect" whereby I&Ws appeared in media. However, to fully capture the range of indications that appear over time, other sources of data produced through a wide variety of scientific disciplines and mechanisms are needed.

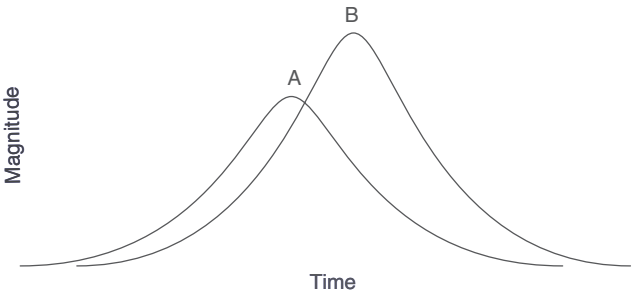

**FIGURE 2** Naturally occurring epidemic with attendant social disruption [A = epidemic and B = social disruption]. The *y* axis represents time and the *x* axis represents magnitude (case count for curve A and number of reports of social disruption for curve B).

**TABLE 2 Surveillance Modes and Example Data Sources Required to Detect and Track the Hypothetical Biological Event Shown in Figure 2**

| | Surveillance Mode | Example Data Source |
|---|---|---|
| Human epidemic (curve A) | Syndromic, voluntary reporting | Clinical encounter data and public health hotlines |
| Social disruption (curve B) | Tactical open source monitoring, infrastructure status monitoring | Pharmaceutical purchase information, real-time hospital census data, real-time ambulance diversion data, and media |

## 5 TARGETING THE ANATOMY OF A BIOLOGICAL EVENT

Figure 2 shows a hypothetical naturally occurring biological event. Table 2 shows example data necessary to detect and track the event. Syndromic surveillance is considered an important asset. Originally funded in the early 1990s as a means to rapidly detect acts of biological terrorism, syndromic surveillance utilizes hospital data thought to contain early disease information such as patient chief complaints and emergency department-generated diagnostic codes for disease. To date, however, no public health organization in the United States has demonstrated consistent operational validation of the use of syndromic surveillance as a means to rapidly detect first appearance of a biological event. The astute clinician is still considered the primary source of this information [9–12]. Our team's observations, however, indicate perhaps a different reality, where public health organizations utilize a wide variety of sources that "tip" the analyst; provide context and relevancy; enable decisions to increase sensitivity of their network of sources (e.g. health care provider advisories); or enable a decision to engage in a full epidemiological investigation or response campaign.

In Figure 3, a naturally occurring zoonotic epidemic for pathogens such as VEE (i.e. an epidemic affecting both animals and humans) may produce essentially two time-lagged periods of disease with attendant social disruption. Experientially, our team has noted that social disruption for animal disease tends not to be of the same magnitude as social disruption caused by human disease. Table 3 outlines example modes of surveillance and data sources. Note that some zoonotic diseases such as the example of VEE above, require monitoring of meteorological, environmental, and vector insect species.

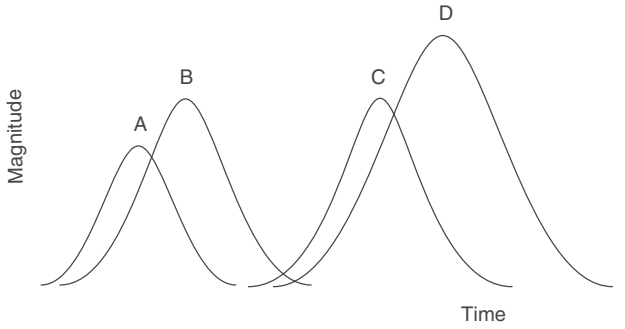

**FIGURE 3** Naturally occurring zoonotic epidemic with attendant social disruption (A = animal epidemic, B = social disruption due to animal epidemic, C = human epidemic, and D = social disruption due to human epidemic).

**TABLE 3 Surveillance Modes and Example Data Sources Required to Detect and Track the Hypothetical Biological Event Shown in Figure 3**

| | Surveillance Mode | Example Data Source |
|---|---|---|
| Animal epidemic (curve A) | Syndromic, voluntary reporting | Veterinary encounter data, agricultural and public health hotlines, and media |
| Human epidemic (curve B) | Syndromic, voluntary reporting | Clinical encounter data, public health hotlines, and media |
| Social disruption (curves B and D) | Tactical open source monitoring, infrastructure status monitoring | Agricultural commodity monitoring, pharmaceutical purchase information, real-time hospital census data, real-time ambulance diversion data, and media |
| Other Parameters | Meteorological, vector, environmental | Meteorological data, satellite imagery, mosquito surveillance data |

"Other parameters" would become important if the pathogen in question is a mosquito-transmitted virus such as VEE.

These modes of surveillance provide such information, for example, as identification of conditions favorable for mosquito emergence and whether the mosquito pools are increasingly positive over time for the pathogen in question. It is known that for some mosquito-transmitted viruses, ambient environmental temperature is an important driver of transmission. Obviously, it is important to determine up front whether local endemic mosquitoes are transmission competent for the pathogen in question.

What is poignant to note in this example is the anticipatory information potentially available when tracking animal illness. Die-offs or illness in different species of animals may portend eventual presence of disease in humans. Understanding the signs of disease and apparent tropism expressed through the involvement of different animal species can provide valuable clues to the possible diagnosis. In the case of mosquito-vectored viral disease such as VEE, an awareness of when ambient temperature optimization will occur provides anticipatory information regarding when the height of human cases may be observed.

Figure 4 and Table 4 shows a hypothetical biological event that followed a natural disaster such as flooding. This is often the case in equatorial regions of the world involving

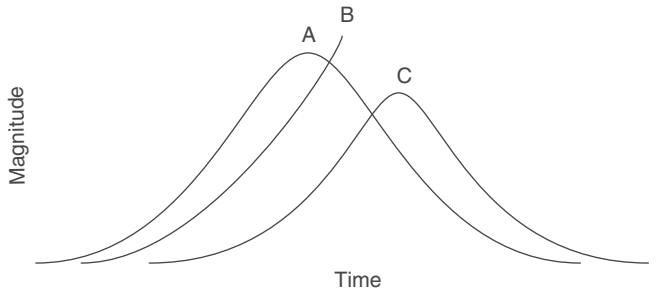

**FIGURE 4** Natural disaster-induced social disruption preceding biological event (A = flooding, B = epidemic, and C = social disruption).

**TABLE 4 Surveillance Modes and Example Data Sources Required to Detect and Track the Hypothetical Biological Event Shown in Figure 4**

| | Surveillance Mode | Example Data Sources |
|---|---|---|
| Natural disaster (curve A) | Tactical open source monitoring, meteorological, disaster reporting services, environmental sensors | Disaster response community listservs, satellite imagery, disaster and humanitarian emergency reporting, seismic sensors, and media |
| Social disruption (curve B) | Tactical open source monitoring, infrastructure status monitoring | Agricultural commodity monitoring, pharmaceutical purchase information, real-time hospital census data, real-time ambulance diversion data, and media |
| Human epidemic (curve C) | Syndromic, voluntary reporting | Clinical encounter data and public health hotlines |

countries with poor access to safe drinking water. For example, in many parts of India, seasonal monsoon rains result in reports of heavy rainfall, followed by flooding, civil infrastructure and crop damage, and attendant social disruption. This information can be captured in local media sources, nongovernmental organization reporting, meteorological data, and satellite imagery. In time, public anxiety about possible increase in waterborne illness such as cholera beings to appear, followed by scattered reports of cholera that may or may not represent true excession of baseline disease. If an outbreak is triggered by compromised sanitation, then reports of high cholera case counts with attendant social disruption are observed. In this case, we see natural disasters potentially accelerating the time to local loss of containment of a biological event that may have international public health implications. As with the example in Figure 3, anticipatory information is present should the operator be sensitive to which areas of the world report this kind of phenomenon. Each piece of anticipatory information is a driver for increased analytic sensitivity to the evolving event.

In Figure 5 and Table 5, a hypothetical foreign biological event, with its attendant social disruption, is translocating to the United States to generate a domestic biological event. In this case, tactical detection and tracking of the foreign biological event can provide anticipatory information regarding a potential transnational issue. The challenge

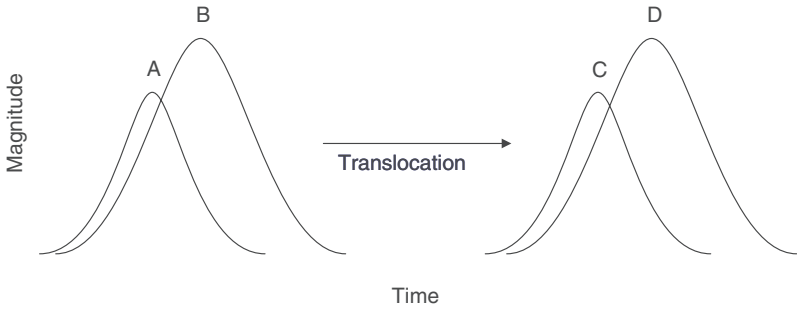

**FIGURE 5** Naturally occurring epidemic translocating from one site to another with attendant social disruption (A = epidemic at the donor site, B = social disruption at the donor site, C = epidemic at the recipient environment, and D = social disruption at the recipient community).

**TABLE 5 Surveillance Modes and Example Data Sources Required to Detect And Track The Hypothetical Biological Event Shown in Figure 5**

| | Surveillance Mode | Example Data Sources |
|---|---|---|
| Foreign epidemic (curve A) | Tactical open source monitoring, voluntary reporting, international public health surveillance | CDC advisories, WHO Global Outbreak Alert and Response Network, and media |
| Social disruption (curve B) | Tactical open source monitoring | Media |
| Translocated domestic epidemic (curve C) | Syndromic, voluntary reporting | Clinical encounter data and public health hotlines |
| Social disruption (curve D) | Tactical open source monitoring, infrastructure status monitoring | Agricultural commodity monitoring, pharmaceutical purchase information, real-time hospital census data, and real-time ambulance diversion data |
| Other parameters | Transportation and commerce monitoring | Commodities trade and transportation data |

CDC, United States Centers for Disease Control and Prevention; WHO, World Health Orginization.

is determination of the criteria for declaring a true translocation advisory, whom to advise (i.e. which local departments of health or agriculture), and advise regarding how they should respond. Nevertheless, anticipatory information resides in detection of the foreign biological event for which containment has been lost; in other words, indicators of this event are essentially pre-event indicators from the perspective of the United States given the event is not directly affecting the domestic infrastructure yet. On the other hand, US assets deployed in the same countries may become directly or indirectly affected by this event, whether or not translocation takes place.

Figure 6 and Table 6 displays a hypothetical intentional release of a biological agent (curve A), followed by an epidemic (curve B) with attendant social disruption (curve C). In this particular example, biosensors become an important asset to rapidly detect a possible release and cue local public health response before human cases actually present

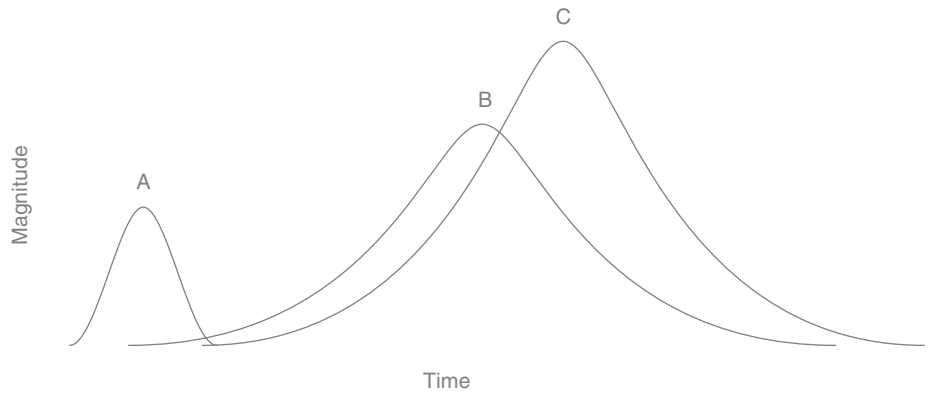

**FIGURE 6** Intentional release of biological event, followed by epidemic and social disruption (A = biological agent released, B = epidemic, and C = social disruption).

**TABLE 6 Surveillance Modes and Example Data Sources Required to Detect and Track the Hypothetical Biological Event Shown in Figure 6**

| | Surveillance Mode | Example Data Sources |
|---|---|---|
| Release of biological agent (curve A) | Biosensor | BioWatch |
| Human epidemic (curve B) | Syndromic, voluntary reporting | Clinical encounter data and public health hotlines |
| Social disruption (curve C) | Tactical open source monitoring, infrastructure status monitoring | Pharmaceutical purchase information, real-time hospital census data, real-time ambulance diversion data, and media |
| Other parameters | Meteorological | Meteorological data |

to health care providers. Thus, detection of a biological agent by a biosensor can prompt sensitization of the entire surveillance network and possibly cue response planning ahead of reports of actual human casualties.

In summary, a wide variety of data sources are required for biosurveillance, which have varying usefulness in biological event detection, providing context and relevance of the information, enabling outbreak alert and verification, and determination of attribution. Table 7 displays a summary table of example data sources required for biosurveillance.

Discussion of data requirements for biosurveillance would be incomplete without consideration of how the data would be used and whether data or information derived from data is more operationally relevant. Process and operational requirement definition is a critical consideration. This includes consideration of whether the organization in question is functioning at the national, state, or local level and whether the operations tempo is tactical, strategic, or forensic. How the information is to be used, by whom, and under what distribution control are additional considerations. Although biological events themselves cause social disruption, improperly managed risk communication stemming

**TABLE 7 Summary of Example Data Sources and Functional Modes of Biosurveillance**

| Surveillance Mode | Primary Function | Example Data Sources |
|---|---|---|
| Disaster reporting services | Anticipatory information regarding conditions favorable for rapid containment loss should a biological event appear; anticipatory information regarding environmental conditions favorable for disease emergence | International: disaster response listservs; domestic: National Geological Survey reporting and seismic sensors |
| Environmental sensors | Anticipatory information regarding environmental conditions favorable for disease emergence | International and domestic: satellite imagery |
| Biosensor | Anticipatory information regarding possible act of biological terrorism | Domestic: BioWatch |
| Threat reporting | Anticipatory information regarding potential for act of biological terrorism | International and domestic: intelligence |
| Meteorological | Anticipatory information regarding transmission rate influencing by meteorological conditions | National Weather Service meteorological data |
| Infrastructure status monitoring | Biological event detection and tracking | Domestic: pharmaceutical purchase information, real-time hospital census data, and real-time ambulance diversion data |
| International public health surveillance | Biological event detection and tracking | International: CDC advisories, WHO Global Outbreak Alert and Response Network, FAO and OIE reporting, and nongovernmental organization reporting |
| Tactical open source monitoring | Biological event detection and tracking | International: media; domestic: media |
| Voluntary reporting | Biological event detection and tracking | Domestic: public health and agricultural community hotlines |
| Syndromic surveillance (animal) | Context | Domestic: veterinary encounter data and laboratory data |
| Syndromic surveillance | Context | Domestic: clinical encounter data and laboratory data |
| Vector surveillance | Context | Domestic: local department of health mosquito surveillance reporting |
| Transportation and commerce monitoring | Determination of hazard relevance | International and domestic: commodities trade and transportation data |

This is not an all-inclusive list but meant to provide an illustrative example. FAO, Food and Agriculture Organization; QIE, World Animal Health Organization.

from biosurveillance information can generate social disruption as well to the detriment of the organization seeking to maintain resources for their activities.

## 6 SOCIAL NETWORKING FOR SOURCE MANAGEMENT

The "astute clinician", be they a human or animal health care provider, is generally thought to be the primary source of valuable biosurveillance data. It is through the astute clinician that the first case of what may eventually be a health catastrophe is most likely reported. As mentioned above, there are other indicators that may precede human cases such as animal die-offs or runs of over-the-counter drug purchases. This requires engineering a complex social network of reporting that is heavily based on human–human interactions, regardless of whatever information technology may or may not be supporting the particular data source. Several important considerations should be kept in mind when utilizing social networks.

It is important to understand the incentive, or abject lack thereof, to report. Physicians, while socially conscientious, may not have the time in a resource-constrained clinical environment to report on a list of over a hundred reporting requirements. However, a health care data management system that can be configured to automatically report certain infrastructure indicators such as ventilator census would be nonintrusive to the busy clinician. Pet store owners, fearing regulatory intervention, may not be inclined to report rodent illness in their stock. However, if they could be educated about the potential risks of importing exotic rodents, it may result in protection of their business' assets.

Social networks can function both passively and actively against reporting requirements. Detection of a key indicator such as avian die-offs in the city park may prompt a health care advisory to "be on the lookout" for human encephalitis, other animal species illness, and refer to mosquito surveillance data due to a concern for the potential presence of actively transmitting West Nile virus in the local environment. Thus, indications of a potential problem may prompt a verification cycle. A social network of partners who can reliably and credibly report is essential to the biosurveillance analyst.

Reporter fatigue is a major consideration that is mitigated through a careful management of the social network that includes judicious use of network sensitization. A health care provider network that has received frequent advisories of what are deemed inconsequential reports may be less likely to pay attention to the organization in times of a serious need to report. Further, social network development that leads to timely reporting may, in some cases, require a monitoring group to assure a reporting source of a certain level of anonymity depending upon that source's personal considerations, much like a media reporter protects his/her sources.

Finally, components of a social network report in different ways that can be considered from the standpoint of specificity, credibility, reliability, and timeliness. For example, a report from a sanitation worker suggesting that the sewer is full of dead rats is associated with a different specificity than a laboratory reporting a plague-positive rat. One may receive the information earlier from the laboratory; however, this depends on sampling location and frequency versus reliable reporting from a sanitation worker who monitors the sewers on a daily basis. These considerations will influence the circumstances and degree to which the network will need to be "pinged" to obtain more specific information. Table 8 provides an example of an indicator cross-matched to sources associated with information type, credibility scores, and estimated reliability of reporting.

**TABLE 8 Example Indicator Cross-Matched to Sources and Source Characteristics**

| Indications and Warnings | Potential Source? | Information Type (Event Tipping, Clinical/Syndromic, Diagnostics or ALL OF THE ABOVE) | Credibility (1 is LOW, 5 is HIGH) | % Probability of Receiving Daily Report IF There is a Perceived Issue |
|---|---|---|---|---|
| Reports of disease or death in: | | | | |
| Birds (including poultry) | General public | Event tipping | 4 | 100 |
| Birds (including poultry) | Fish and Wildlife Service | All of the above | 5 | 100 |
| Birds (including poultry) | Animal hospital | All of the above | 5 | 100 |
| Birds (including poultry) | Poultry farmers | Event tipping and clinical | 5 | 50 |
| Birds (including poultry) | Local zoo | All of the above | 5 | 50 |
| Birds (including poultry) | Birdwatchers/ naturalists | Event tipping | 5 | 100 |
| Birds (including poultry) | Veterinarians | All of the above | 5 | 100 |

## 7 CONCEPTUALIZING OPERATIONS: THE PERSPECTIVE OF LOCAL PUBLIC HEALTH

Until the anthrax attack of 2001, the US public health and agriculture communities had not conceived of a concept of biosurveillance operations that functioned in a near-real-time environment. Their operations were, up to that point, focused on preventive strategies coupled loosely to response and recovery operations within a highly reactive, versus proactive, organizational posture. The idea of coupling graded biosurveillance I&Ws to graded response remained highly experimental.

Figure 7 displays an actual decision-making framework for the District of Columbia Department of Health (DC DOH). Of interest is the number of sources of information and how the information is actually used. Each source either tends to function as an event detection (or "tipping") source or as a source that provides context after a tip is received. As event information from sources such as laboratory notification of a select agent is discovered, DC DOH analysts engage in discussion as to the relevance of the information, whether a shift from a passive to active surveillance posture is warranted, and whether health care providers should be sensitized.

Decisions made at one point in the process may be reassessed as new information becomes available. Gradual shifts in local network sensitivity in reaction to biosurveillance information may be considered a form of response in effect, acting as a feedback loop to further refine reporting and response. It is within this framework that biosurveillance influences tactical situational awareness within local public health.

The investigative process is typically one of increasing specificity of information over time. Thus, depending on the timeliness, validity, and access to information, the process

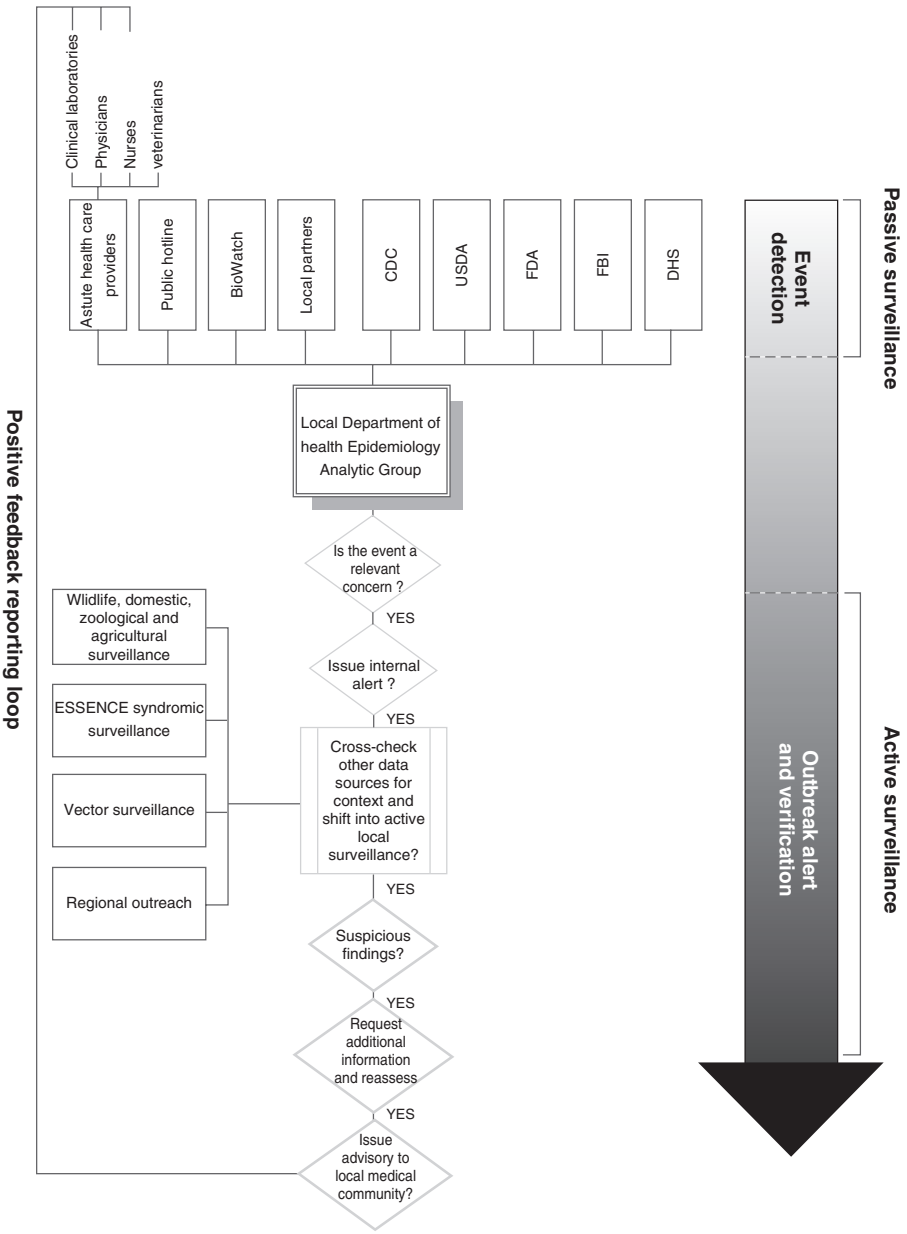

**FIGURE 7** Biosurveillance information processing within the DC DOH.

involves a certain length of time until informed decisions are able to be executed at each step.

Table 9 shows estimates provided by the DC DOH in regards to local sources of information and how relative percentages of information may change with community sensitization. A decision made to sensitize the health care community is used judiciously due to the high risk of desensitization and reporter fatigue. The DC DOH understands

**TABLE 9 Relative Percentages of Source Reporting Within the Category of "Astute Clinician" and Comparison Between Nonsensitized and Sensitized Situations**

| | Not Sensitized—Passive Surveillance (%) | Sensitized—Active Surveillance (%) |
|---|---|---|
| Laboratory worker | 80 | 45 |
| Nurse | 15 | 25 |
| Physician | 4 | 25 |
| Veterinarian | 1 | 5 |

fully that physicians in particular have little time in their daily routines to report issues not perceived to be of immediate importance.

Local public health organizations are typically resource constrained, and therefore have a low tolerance for high daily volumes of nonrelevant biosurveillance information. The challenge of determining information relevance is a critical one to the local public health professional.

## 8 BRIDGING RAW DATA TO ACTIONABLE INFORMATION

There is an important difference between raw data and actionable information. Releasing raw data to a user community is fraught with risk such as inappropriate interpretation and user desensitization. Translating raw data into preliminary information typically requires subject-matter expert input. Without context, it is difficult for end users to interpret the data. Another step is processing the preliminary information by comparing it with other data or information sources for additional context. This may then be followed by first-, second-, or third-order analytics. The final piece of information, or finished information product, may require additional analysis to determine relevance for the individual user. The typical public health analyst, in a resource-constrained environment, will not be as willing to engage in examination of noncontextualized raw data versus a finished assessment. Finished assessments resulting from the abovementioned process take a significant amount of time to produce. Further, the typical public health analyst is generally focused on his/her immediate local health concerns and not necessarily aware, in a timely fashion, of developing regional and international situations that have potential to translocate to his/her area of responsibility. When considering the need for near-real-time detection and tracking of biological events, a balance must be struck whereby a form of preliminary information is passed to the user community *in lieu* of a finished assessment that follows later.

## 9 AN ADVISORY SYSTEM FOR BIOSURVEILLANCE

For several decades, the National Weather Service and the natural disaster community have made effective use of an advisory system to alert users and the general public of impending issues. The advisory system for storms not only informs and cues the meteorological community to closely follow the event in question but also has a translated response implication for the lay public. For example, the average citizen has an inherent

**TABLE 10 The Wilson–Collmann Scale for Biological Event-Related Social Disruption**

| Stage | Condition |
|---|---|
| 0 | Conditions favorable to support the appearance of a biological event |
| 1 | Unifocal biological event |
| 2 | Multifocal biological event |
| 3 | Severe infrastructure strain and depletion of local response capacity |
| 4 | Social collapse |

understanding that a category 1 hurricane is associated with a lower implied need to evacuate the area than a category 5 hurricane [13, 14].

The Wilson—Collmann Scale, a prototype staging system for social disruption due to biological events, has been established and in use by Project Argus since 2004, as summarized in Table 10. This heuristic model enables an analyst to rapidly assess the severity of a biological event based on the level of social disruption generated using a standardized terminology. This information, when placed in context with the suspected pathogen, can assist the analyst in making a decision to issue an advisory to the user community [2].

However, this staging system has not been tested domestically in the United States. Standards for a biosurveillance-informed advisory system have not been developed at the national, state, or local levels for biological events that affect humans, animals, or plants. Reporting requirements beyond legally mandated disease-specific reporting for the biosurveillance environment have not been integrated and standardized across different communities of interest. This then presents a key challenge: how does one define data requirements when no operational requirements have been generated? What should national, state, and local level watchboards post as advisories? What would a warning, watch, and advisory look like from each of these perspectives? How would a warning posted on a national level watchboard be translated in a local watchboard? And of key importance, precisely who at the national, state, and local levels should receive these advisories? This becomes a particularly difficult question when considering the community health care provider is likely to be the first line of response. A nonsensitized health care provider is not as likely to consider exotic diagnoses versus one who has been sensitized to look for a particular disease.

Relevance of the information to the user is difficult to predict. Some users are interested in select agents such as anthrax, others are primarily interested in international public health issues such as polio, and other users are concerned about any disease that may affect a ground deployment. This translates to a high degree of complexity when attempting to design an advisory system. Defining relevance is partly a user-defined process; however, the use of disease risk and transmission models may enable refinement of what advisories are relevant to which US local communities and which biological event may truly present a critical national or homeland security issue.

Advisory systems have value in controlling distribution, in a net-centric manner, to the biosurveillance community. Further, they enable control of network sensitization, where various components of the community can be cued to look for certain indicators of an event of interest. Advisory systems enable operational translation of biosurveillance data into actionable information, which is the key objective.

## 10 DISCUSSION

Biosurveillance as a professional discipline is nascent but rapidly emerging. While the process is largely art versus science, the discipline is certainly approaching a point where robust modeling and statistical rigor may be applied. Similar to medicine, this is a discipline of processing uncertainty, intuition, and hunches. Computer algorithms and sophisticated IT platforms cannot replace such experience gained by trial and error over time by an operational biosurveillance group; however, facilitation of effort is a key objective when dealing with global biosurveillance information. We often liken the emergence of the biosurveillance tradecraft to the history of tornado forecasting, where in the 1950s humans learned how to collect and process information related to an event associated with morbidity and mortality (i.e. tornadoes). Over the decades, enough information was gathered to enable mathematical modeling and eventual expansion of a multidiscipline community of professionals that span the private, academic, and public sectors. We see biosurveillance following this same exciting evolutionary path.

## 1 INTRODUCTION

On October 17, 2007, President George W. Bush issued the Homeland Security Presidential Directive 21 (HSPD 21) [1]. HSPD 21 outlines immediate steps for improving the nation's preparedness for natural and intentional disasters, and includes specific criteria

for effective biosurveillance systems. Biosurveillance systems must be able to "identify specific disease incidence and prevalence in heterogeneous populations and environments and must possess sufficient flexibility to tailor analyses to new syndromes and emerging diseases". In addition, all stakeholders, from public health officials at all levels to data providers and clinicians, must be involved in system design. The North Carolina Disease Event Tracking and Epidemiologic Collection Tool (NC DETECT), is North Carolina's statewide biosurveillance system. Although its roots date back to an electronic emergency department (ED) data collection initiative launched in 1999, NC DETECT embodies those characteristics outlined in HSPD 21.

## 2 BACKGROUND

NC DETECT is an advanced, statewide public health surveillance system made possible through a unique combination of leaders in North Carolina from public health, business, and research working together toward a common goal: to enhance the protection of the NC population. NC DETECT is managed through a collaboration between the North Carolina Division of Public Health (NC DPH) and the University of North Carolina at Chapel Hill Department of Emergency Medicine (UNC DEM).

### 2.1 Data Sources Timeline

The North Carolina Emergency Department Database (NCEDD) project, spearheaded by UNC DEM in 1999, laid the groundwork for electronic ED data collection in North Carolina by developing best practices for collecting and standardizing quality ED data. NC DPH and UNC DEM jointly started developing the hospital arm of the NC DETECT syndromic surveillance system in 2002. In 2004, a partnership between the North Carolina Hospital Association (NCHA) and NC DPH was instrumental in establishing ED data transmissions from the hospitals not yet participating in NC DETECT, including support for a new law making this reporting mandatory as of January 1, 2005 [2]. As of January 7, 2008, there are 109/111 (98%) hospital-based, acute care, 24/7 EDs submitting over 10 000 new visits on a daily basis to NC DETECT, as shown in Figure 1. These data are also transmitted twice daily to the Centers for Disease Control and Prevention's (CDC's) BioSense program.

In addition to ED data, NC DETECT initiated the collection of additional data sources in 2004. Data collection from multiple data sources provides a more comprehensive view of population health and offers redundancy on the occasion one data source has lapses in data transmission. Currently, NC DETECT loads data from roughly 1800 new records for ambulance runs and 285 statewide poison center calls a day. Animal health data from a regional wildlife center and veterinary medicine laboratories are in pilot testing. Future goals include the incorporation of additional animal health data, as well as data from ambulatory and urgent care centers and Veterans Administration (VA) hospitals.

## 3 TECHNOLOGICAL OVERVIEW

NC DETECT is an electronic biosurveillance system that does not require any manual data entry [3]. All data are secondary or dual use; in other words, data are generated as part of the registration, treatment, and/or billing of human and animal patients. Data

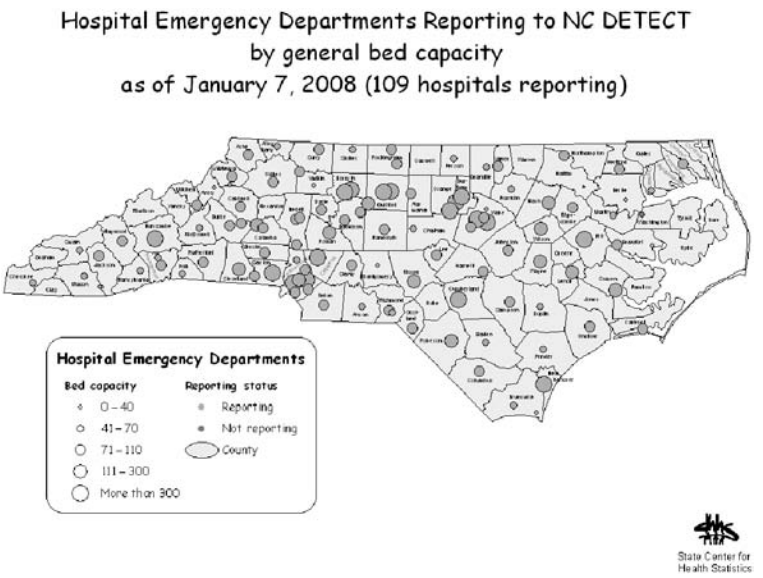

**FIGURE 1** Hospitals reporting ED data to NC DETECT.

are transmitted securely to a centralized server. Before loading into NC DETECT, all data are automatically checked to ensure that all values match established business rules for acceptable quality. Outliers are logged for future follow up and data providers with missing data are notified. As part of the data processing, all data sources are "binned" into one or more syndromes. Public health epidemiologists (PHEs) monitor these syndromes daily, by facility and/or patient's county of residence, to detect unusual events of potential public health significance.

### 3.1 Syndrome Development and Classification

NC DETECT classifies ED visits into zero, one or more "syndromes" based on the presence of certain keyword terms in either the chief complaint or triage note, as well as the documented temperature (if available). Syndrome definitions are designed to capture both potential bioterrorist threats and common community-acquired disease outbreaks.

The keyword terms searched for include both syndrome-specific (e.g. dyspnea, cough, or tachypnea for respiratory syndrome) and constitutional (e.g. fever, malaise, or myalgias) signs and symptoms. Each syndrome definition also searches for common misspellings, abbreviations, truncations, and acronyms for these terms. In order for a record to match a syndrome, it must contain either a single term, which, by itself, is highly suggestive of the syndrome in question (e.g. "flu" for influenza-like illness (ILI)) or the mention of a bioterrorism (BT) related agent. A record will also match a syndrome if it contains the combination of both a syndrome-specific and a constitutional term.

Text-based syndrome case definitions published by the CDC [4] form the basis for the syndrome definitions. The syndromes have been developed and refined through an iterative process by the NC DETECT Syndrome Definition Workgroup and are based on the experience and judgment of the workgroup members with feedback from NC DETECT end users. The workgroup comprises state and local public health officials,

epidemiologists, physicians, and public health informatics researchers. A collaborative research project between the UNC DEM and RTI International is ongoing and has the overarching goal of optimizing the sensitivity and specificity of syndrome definitions for the purposes of early event detection and situational awareness [5]. This work is funded by the CDC's BioSense program.

While the ED data can provide a wealth of information for effective syndrome binning, the chief complaint and triage notes most often contain free form text. The textual data are unstructured and include abbreviations, misspellings, and negation, which require specialized processing. Tools available in the public domain to assist with this processing include the Emergency Medical Text Processor (EMT-P) for chief complaint standardization [6] and NegEx [7] for negation processing, both of which are in use in NC DETECT. While NC DETECT does capture ICD-9-CM final diagnosis codes from all EDs, the codes are most often sent from hospital billing systems that are updated days to weeks after the initial visit [8]. This latency severely limits the utility of this data element for early event detection.

In contrast to the ED data, poison control center data are entered into a nationally standardized electronic system, the National Poison Data System (NDPS), by trained nurses and, therefore, are relatively easily binned into syndromes based on documented clinical effects. EMS data are grouped into seven syndromes based on the standardized pick lists for dispatch complaint and primary symptom. Table 1 lists the syndromes monitored for these three data sources and the bioterrorism agents the syndromes are designed to detect.

### 3.2 Web-Based Application

The NC DETECT Web application provides authorized users with secure, Java-based reports with various customization options. It provides syndrome-based monitoring by patient's county of residence and, for ED data, by hospital. Users can review signals or aberrations using the CDC's EARS CUSUM algorithms [9] for the entire population, as well as stratified by nine age groups. In addition to aggregate views, the application provides users with access to patient-specific line listing reports for the ED, poison center, and EMS data. Authorized users are able to drill down further to retrieve identifiable data as needed for further public health investigation. All NC DETECT Web functionality is developed in a user-centered, iterative process, with user feedback from all stakeholder groups guiding enhancements and new development. This feedback, along with the need for improved situational awareness and the desire to improve communication among users, drove the development of the Annotation Reports and the Custom Event Report.

As explained in HSPD-21, effective disease surveillance alone does not constitute a comprehensive surveillance system. The system must be flexible enough to respond to emerging infections and other public health events not previously anticipated [1]. The NC DETECT Custom Event Report is a separate module that allows for the rapid implementation of new reports designed to monitor known or suspected events that might not be captured by existing syndromes. New custom reports can be added to the system as soon as the search criteria have been finalized and tested, usually 1–2 h. These reports search for suspected cases in the chief complaint and triage notes, as well as ICD-9-CM final diagnosis codes (keeping the latency effect in mind). The queries account for misspellings and abbreviations, and exclude terms that would create false positives; for example, search for *fire* but not *fire ant*. Again, authorized users can retrieve

the hospital's original medical record number from the Web-based report for follow up directly with the hospital.

While early event detection systems aim to detect disease outbreaks before traditional means, following up on the many alerts generated by these systems can be time-consuming and a drain on limited resources [10]. NC DETECT offers Annotation Reports to allow users to view the EARS signals for each syndrome, drill down to the patient-specific information, add comments to signals, and view the comments of other users who have access to the same signals. Users also assign an investigation status to the signal: *active investigation, monitoring, no action needed, or investigation complete*. If NC DETECT does not generate a signal for a known or suspected public health situation, users have the option of adding an event with their own parameters to the Annotation Reports for comments and monitoring, as shown in Figure 2. The NC DETECT Annotation Reports have improved communication and information exchange among active NC DETECT users. However, these tools need to be more widely adopted by less active local health departments, regional surveillance teams, and infection control practitioners before statewide situational awareness can reach its potential [11].

### 3.3 Users Roles and Users

As a statewide system, NC DETECT serves users in multiple jurisdictions with varying responsibilities. As a result, the Web-based application provides access to the data based on state mandates governing public health investigation [2]. Users whose job responsibilities include outbreak investigation and response have more data access privileges than users at similar levels in more administrative and/or managerial roles. The NC DETECT role-based security model is based on geography, data source, the right to access aggregate data, line listing data, protected health information (PHI), and annotations. While most of the user roles can be predefined, the system is flexible enough to allow for

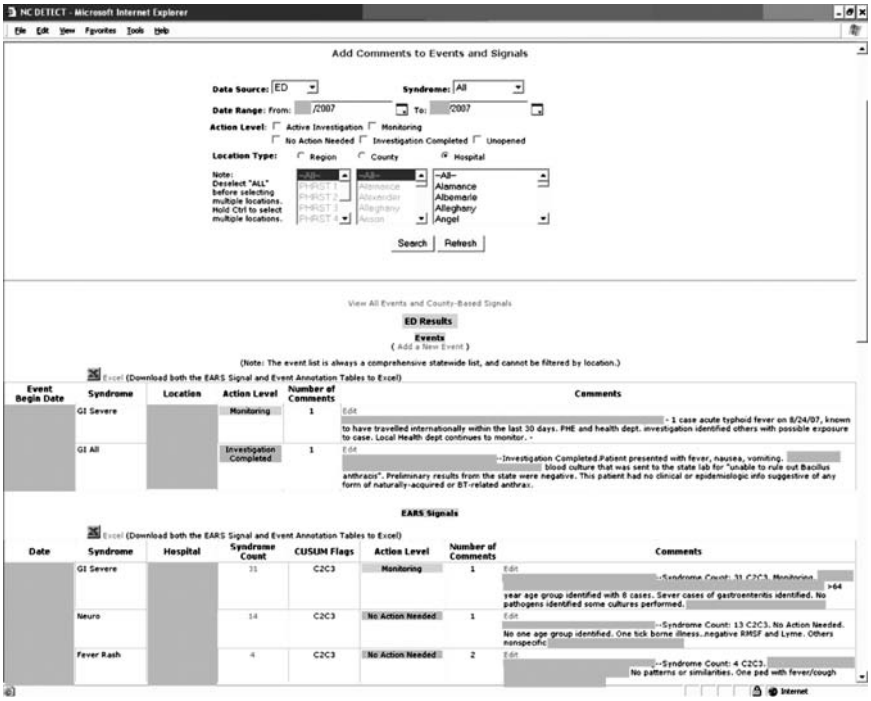

**FIGURE 2** NC DETECT screenshot of Annotation Report.

customized data access; thus, it is possible to meet the needs of all potential NC DETECT users. Access to PHI is strictly controlled. PHI is encrypted in the database and only authorized users have access to it through the SSL-enabled Web portal. The window that displays the PHI closes automatically after 1 min and all access to PHI is logged in detail.

In addition to state level epidemiologists who monitor NC DETECT on a daily basis, the most active user group is the hospital-based PHEs. The PHEs have been funded by NC DPH for over four years as part of state efforts to strengthen public health preparedness and disease surveillance in North Carolina, while fostering communication and relationships between local hospitals and public health departments. Currently staffed in North Carolina's 11 largest hospitals, PHEs serve as in-hospital liaison to local health departments, perform active in-hospital surveillance for community-acquired infections, and conduct biosurveillance using NC DETECT [12].

## 4 NC DETECT OUTCOMES 2005–2008

NC DETECT allows PHEs and infection control specialists to significantly increase the speed of detecting, monitoring, and investigating public health events statewide. The system has proven useful for a variety of public health surveillance needs, including, but not limited to, early event detection, public health situational awareness, case finding, contact tracing, injury surveillance, and environmental exposures.

### 4.1 Early Event Detection

The early event detection capabilities of NC DETECT have contributed to more timely and effective public health intervention in North Carolina, as illustrated in the following examples.

- A Norovirus outbreak was detected in a sorority at UNC Chapel Hill, in 2006. The spread of the disease was prevented by rapid case finding and implementation of control measures.
- Investigation of a possible familial cluster of meningitis in Pitt County, in 2006. The NC DETECT signal helped public health officials to trace the meningitis case, and to provide follow up for the family of five children and one adult through the local health department.
- In early 2007, a public health epidemiologist's investigation of a NC DETECT fever/rash signal in Rowan County revealed a positive diagnosis of meningococcemia (a severe bacterial infection in the blood stream) in a child, prior to reporting by the laboratory or the attending physician. Meningitis prophylaxis was provided to 30 of the patient's close contacts through the Rowan County Health Department.
- The most recent event was a Salmonella London outbreak in a Catawba County Mexican restaurant. From October 29 through November 5, 2007, NC DPH documented 173 cases. NC DETECT was used to monitor this outbreak. The application of age stratification in NC DETECT helped to define the affected population, the majority of which were young adult employees of a nearby plant, as shown in Figure 3.

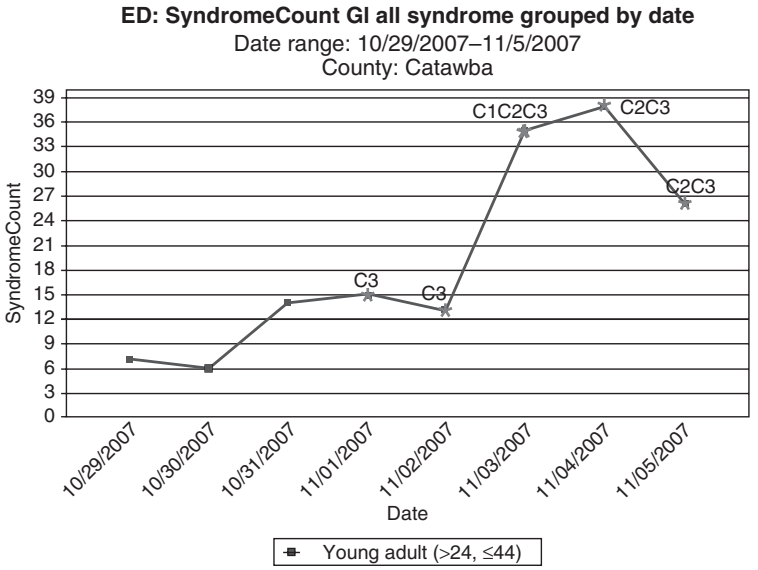

**FIGURE 3** Salmonella outbreak, Catawba County, NC, October–November 2007 evident in NC DETECT GI-All syndrome.

### 4.2 Public Health Situational Awareness

With the NC DETECT system in place, surveillance for new conditions can be established easily and rapidly, as demonstrated with injury and illness surveillance after hurricane Ophelia in NC in 2005. Setting up the specific criteria for surveillance took 2 h, in contrast with similar surveillance after hurricane Isabel in 2003, which required months of labor-intensive data collection, entry, and analysis [13, pp. 26–27]. Querying programs maximize accuracy in analyzing the free text ED data to the greatest extent possible. Detecting unexpected cases and outbreaks earlier in their course than traditional disease-based surveillance has allowed prompt implementation of public health control measures when needed.

***4.2.1 Hurricane Katrina Evacuees.*** At the time of hurricane Katrina, 51 of 111 NC EDs were transmitting data daily to NC DETECT. A new filter was rapidly applied to capture hurricane-associated events. This filter was applied to data transmitted from August 28, 2005, the date of issue of the voluntary evacuation order in the city of New Orleans. Terms used in this filter included: "hurri, storm, flood, Katrina, evacua, New Orleans, refuge, Louisiana, Texas, Alabama, Mississippi, Florida, and fema and not (female)", including variations of misspellings and abbreviations. Surveillance of these data rapidly provided information on the medical needs of hurricane Katrina evacuees in North Carolina. The information from these sources was available to public health officials at the state level on a daily basis, within 24–48 h of the visits. Reasons for evacuee's visits to EDs in North Carolina included medications and prescription refills (15%), specific illnesses and injuries (62%), and mental health issues (7%) [14].

***4.2.2 Apex Chemical Explosion.*** In October 2006, a chemical plant fire forced thousands of people to evacuate from areas of Apex, North Carolina. NC DPH monitored ED data (updated daily) and poison control center data (updated hourly) in NC DETECT to monitor potential human health impact. Near real-time investigation of patients associated with this event was essential, as the list of chemicals stored at the explosion site went unknown for several days. NC DETECT users documented 83 ED visits related to the explosion, including 14 evacuees from an area nursing home and 13 emergency responders. Nearly all patients reported only minor complaints, including gastrointestinal, upper respiratory, and eye and skin irritation, and were discharged home following treatment.

***4.2.3 Peanut Butter Contamination.*** On February 14, 2007, the FDA warned consumers not to eat certain jars of Peter Pan or Great Value peanut butter due to risk of contamination with *Salmonella tennessee* [15]. Surveillance for peanut butter–related ED visits and poison center calls was established within an hour. During the week of February 14, statewide hospital data included 135 ED admissions with peanut butter related gastrointestinal complaints from 39 counties. The poison control center received 370 peanut butter related symptomatic food poisoning calls from 30 counties and adopted a public health message in line with guidance from the NC DPH. In this particular example, the use of the poison center data provided a population-based measure of the reaction to the recall in the general public from persons affected to a degree that did not warrant a visit to a hospital ED.

NC DPH staff documented 16 confirmed cases associated with the *S. tennessee* outbreak in February 2007 in 12 different counties, 7 of which were under 18 years old. Two closely related DNA fingerprint patterns of *S. tennessee* isolates were associated with this outbreak.

***4.2.4 Canned Food Botulism Recall.*** Following reports of four botulism cases in Texas and Indiana associated with commercially canned chili products, the CDC issued a recall in July 2007 [16]. NC DPH increased surveillance for botulism by sharing available information with public and private health care providers through regular communication and also by issuing an alert with the NC Health Alert Network. The NC Department of Agriculture led the product recall activities. Using NC DETECT helped the epidemiologists reviewing North Carolina data by: (i) having immediate access to ED data from 104 hospitals throughout the state, where botulism patients would likely be seen due to the severity of the disease; (ii) having immediate access to all ED patient records matching botulism-like illness, a syndrome continuously monitored with NC DETECT, regardless of this recall; and (iii) focusing on ED visits with records that included words that could associate them with the recall. As an indicator of the "zooming" power of NC DETECT, while 233 patients were picked up by the system between July 16 and July 25 due to the presence of one or more signs or symptoms compatible with the "botulism-like" case definition, only 9 cases during all of July matched a more narrow case definition, restricted to those with records including key words used in this recall. The situation specific "filter" was designed and installed in less than 2 h using the Custom Event Report.

***4.2.5 Heat-Related Illness.*** A report to monitor effects of record heat was added to NC DETECT in early August 2007. Results not only showed an increase of heat-related ED visits as expected but also found that 15–19 year olds and 25–44 year olds had the highest rates of ED visits. As a result, warnings during future heat waves will target these age groups as well as prior target populations, the elderly and those who care for young children [17].

### 4.3 Case Finding and Contact Tracing

With NC DETECT, users with investigative access rights are able to view patient-specific line listing information and to retrieve the hospital's original medical record number. With this information, users are able to conduct follow-ups with much greater ease and reduce the burden on hospital staff.

- In January 2007, users in Guilford County were able to use the arrival date and time information in NC DETECT to locate potential contacts of an ED patient diagnosed with measles more easily and efficiently.
- During a Hepatitis A outbreak investigation in 2006 in Buncombe County, additional Hepatitis A cases were identified and followed up using NC DETECT.
- NC DETECT and another North Carolina-based system called the *investigative monitoring capability* (IMC) were used in a salmonellosis outbreak investigation in New Hanover County (May 2007). Five additional cases were identified using these systems.

**TABLE 2 Carolinas Poison Center Chemical Exposure Signals**

| Exposure | Date | Number of Cases | Site | Co | Syndrome |
|---|---|---|---|---|---|
| Mercury | 10/20/05 | 10 | Residence | Orange | Gastrointestinal |
| Prime 2B | 11/06/05 | 3 | Hospital | Alleghany | Respiratory, dermal |
| Tetrachloroethylene | 04/26/06 | 8 | School | Granville | Respiratory, neuro |
| Apex hazardous exposure | 10/06/06 | 83 | Residence | | Gastrointestinal, respiratory, neuro |
| Pepper spray | 10/10/06 | 11 | School | Wake | Respiratory, dermal |
| Hydrochloric acid | 06/07/07 | 12 | Hotel | Mecklenburg | Respiratory |
| Lead exposure | 06/12/07 | 5 | Residence | Davidson | Gastrointestinal |

### 4.4 Environmental Exposures

Data from poison center calls (Carolinas Poison Center, CPC) allow public health officials to detect and monitor environmental exposures that may otherwise go unreported. For example, a signal investigation during the summer of 2007 revealed a pesticide exposure in Davidson County. The landlord treated the house with an unknown pesticide. The family of 9 (6 adults, 1 of them pregnant, and 3 children) developed gastrointestinal (nausea) and neurological (headache) symptoms, and called CPC for advice. Additional public health investigation revealed that the family lives in a house with bats. The family was provided rabies vaccination and immune globulin prophylaxis through the state program.

Numerous clusters of exposure to chemicals have been identified analyzing signals in the NC DETECT CPC data stream. Some examples are shown in Table 2.

While some of the CPC signal investigations listed in Table 2 did not pose a widespread public health threat, they demonstrate the ability of NC DETECT to identify both environmental and infectious disease clusters and potential bioterrorism events.

***4.4.1 Influenza.*** The NC DETECT ILI definition is used to monitor the influenza season in NC each year, providing data up to two weeks earlier than the traditional, manually tabulated sentinel provider network. The difference in proportion of ILI seen in Figure 4 reflects differences in the case definitions and patient populations rather than a difference in the sensitivity of these surveillance systems.

NC DETECT continues to evolve in response to changing user needs and the increased adoption of timely public health surveillance. While NC DETECT was designed and continues to be used primarily for early event detection and situational awareness, the utility for broader public health surveillance continues to be explored. NC DETECT data have been used to monitor varicella *in lieu* of mandated reporting and have also been used for a variety of injury-related analyses, from the use of all-terrain vehicles to injuries from specific toys to heat-related injuries. Use of the NC DETECT data for chronic diseases continues to expand. Throughout the development of NC DETECT,

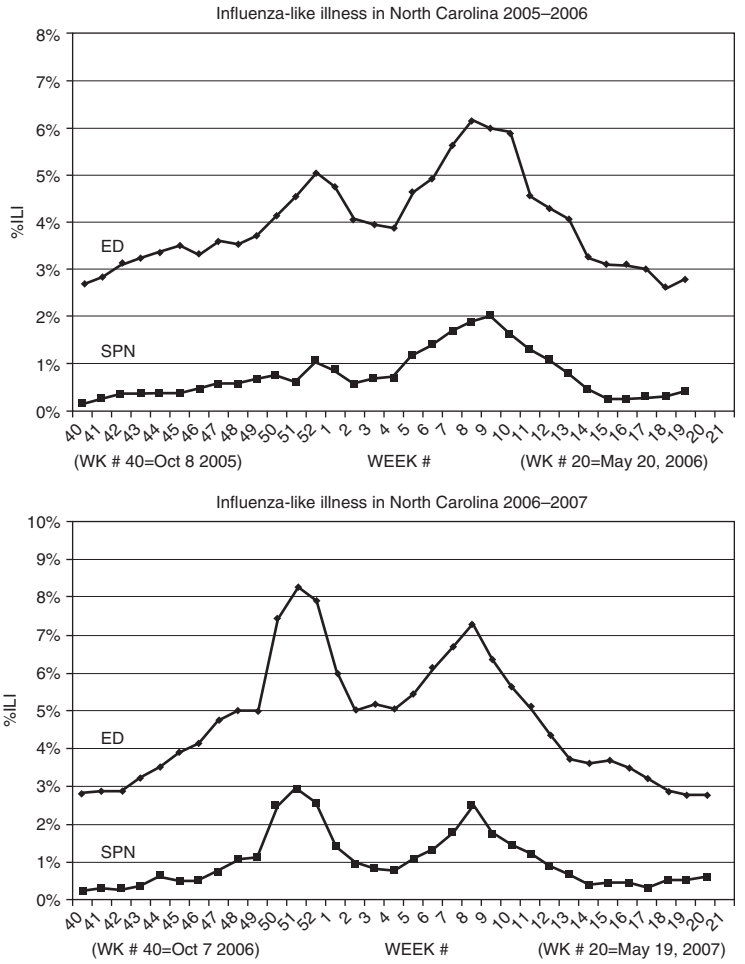

**FIGURE 4** Influenza-like illness in North Carolina, 2005–2007. SPN: 74 volunteer practitioners report weekly their patient workload; using ILI case definition: "fever and cough or sore throat". ED: as of 5/19/2007, 103 hospitals report daily ED visits electronically through the NC DETECT System, using ILI case definition: "ILI cases must include any case with the term "flu" or "influenza" or have at least one fever term and one influenza-related symptom".

leaders from UNC DEM and NC DPH have adhered to the goals of comprehensive, timely, and quality data; strong partnerships; flexibility; and user-centered design.

## 5 LESSONS LEARNED AND CONCLUSIONS

Biosurveillance systems that aim to provide comprehensive population health views need to extend beyond ED chief complaints. The additional ED data elements in NC DETECT, including triage notes, dispositions, and final diagnosis codes, provide opportunities for more efficient case finding, investigation, and follow up. The American Health Information Community (AHIC) Biosurveillance minimum data set aims to establish the ideal

set of data elements for detailed but de-identified surveillance using hospital data, including ED, inpatient, and laboratory data [18]. Leaders involved in the implementation and testing of the AHIC Biosuveillance MDS must be well prepared for the increased data quality vigilance necessary to ensure that this larger data set—that goes far beyond basic demographics and chief complaint—is as accurate and timely as possible for the public health decision-makers relying on it.

### 5.1 Emergency Department Data Collection

Collecting timely, electronic ED data that include clinical data elements, rather than just billing data, is a complicated process. Typically, previous efforts to work with the ED data from a hospital have been limited; therefore, no one really knows what is and is not available or how complete and accurate the data actually are. Bringing a hospital into production with NC DETECT often requires several iterations of test data feeds and programming modifications, primarily because the data must frequently be extracted from multiple hospital information systems. In addition, electronic health records (EHRs) may not store clinical data elements useful for biosurveillance in an easily extractable format, as these data are not normally exchanged between health information systems. EHR vendors must develop systems that store clinical information in discrete data elements so that these data can be used by multiple entities for public health surveillance and research.

Because NC DETECT was designed from the beginning to meet public health data needs beyond bioterrorism surveillance, both administrative and clinical data elements were included from the outset. Although leaders from UNC DEM and NC DPH took an opportunistic approach, accepting the data readily available electronically, the data elements and data sources collected have proven useful beyond original expectations. Within the ED data, triage note is a very valuable data element for a variety of public health surveillance purposes. However, it is not available electronically from all EDs. The data from the poison center calls have provided insight into environmental exposures and community concerns that would not be possible with the ED data alone.

### 5.2 Other Data Sources

The data sources other than ED data in NC DETECT present different challenges. As other organizations collect and store these data and provide only a subset of their information to NC DETECT for biosurveillance, troubleshooting data quality and completeness issues in a timely manner is more difficult. The desire to add novel data sources for biosurveillance continues to grow in North Carolina as it does nationally. Ideally, this process should include an assessment of the data needs of NC DETECT end users and a thorough feasibility assessment. Adding data from less familiar data sources presents challenges of accurate data interpretation. For example, interpreting veterinary laboratory results, including tests for a variety of species, is very different than interpreting human patient lab results, particularly without veterinary medicine expertise on staff.

### 5.3 Data Quality

ED data are notoriously dirty, even by health care data standards. NC DETECT policies require that specific business rules be met before data are available in the production

system. Metadata collected about each data source are extremely helpful in making sense of the data collected in NC DETECT. The metadata allow data quality checks to go beyond the file level (such as, file format, file receipt, and presence of mandatory data elements); each data element is checked for accuracy, timeliness, and appropriate distributions. Examples of typical metadata questions include the following:

- What is the expected percentage of admitted and discharged patients on a given day?
- What is the average daily visit count?

Data checks must be performed using metadata as well as trends. If the data are inaccurate or incomplete from the start, then trends analysis will never be accurate. The metadata also act as the Gold Standard for data quality for several indicators *in lieu* of performing labor-intensive periodic data audits for each data provider. A small data validity audit is in progress for just a few hospitals, which will be comparing the data available in the hospital's electronic ED record for each visit to what is stored in NC DETECT. The goal of this audit is to understand and document the potential data quality issues that arise as dual use data are transmitted and used by disparate systems.

Addressing data quality is an ongoing and never ending effort for NC DETECT. Daily communications occur among UNC DEM, NC DPH, and data providers about data quality issues and effecting improvements to data quality. This issue is complicated by the myriad of stakeholders in the system and the fact that the burden of remedying identified problems often falls back on the data providers. The impact of biosurveillance systems on data providers, both to provide and maintain their data feeds, cannot be underestimated.

### 5.4 Engage Users

The developers of NC DETECT at UNC DEM and NC DPH have been committed to a user-centered, iterative design process that informs how our data are collected, analyzed, and reported. NC DETECT is a biosurveillance system that *requires* a human element. PHEs at the state, regional, and local levels actively use the system everyday for public health surveillance. Because they are familiar and comfortable with the system, they are ready to use it in an emergency situation. Another benefit of involving end users in the design and development of NC DETECT is that they trust the system to provide the information they need. When it does not, they know how and to whom to communicate what changes and improvements are needed.

### 5.5 Security

While North Carolina has mandates for the collection of ED and EMS data for public health use [2], role-based access ensures that users see only the data they need and are authorized to see. The data in NC DETECT belong to NC DPH; all access to the data is through a standardized authorization process and must be approved at the state level. Data use agreements and business associate agreements are used as appropriate and for most access. Aggregate data are more readily shared than visit level data. Balancing privacy/security concerns with the need for public health information is an ongoing challenge.

### 5.6 Conclusions

Timely, flexible public health surveillance tools are crucial for effective preparedness and response. North Carolina has demonstrated that such a system can be built, and used daily, for statewide public health surveillance including biosurveillance. Continuous evaluation of NC DETECT is required to insure a quality, evidence-based system. We continue to strive to meet our goal of a well used and useful system for biosurveillance in North Carolina.

## 1 BACKGROUND

In 1999, the Department of Defense Global Emerging Infections Surveillance and Response System (DoD-GEIS) piloted a disease surveillance system using data collected

at outpatient visits in the national capital area. This system, the electronic surveillance system for the early notification of community-based epidemics (ESSENCE), collected diagnostic information from International Classification of Diseases, 9th Revision (ICD-9) codes entered after outpatient and emergency room visits at all military treatment facilities (MTFs) in order to detect and track potential infectious disease outbreaks. With advances in knowledge of the utility of newly available data sources, statistical programs for aberration detection, and visualization techniques, the ESSENCE program has expanded to incorporate medical information from all MTFs worldwide and has developed partnerships with universities and government agencies to coordinate population health information for military and civilian public health agencies across the United States.

Publications before the US anthrax mail attacks in 2001 discussed how public health infrastructure had declined over time and decried our nation's lack of readiness for an emergency relating to a lethal disease outbreak [1–3]. Besides the intentional release of anthrax spores in the US mail, natural disease outbreaks, such as hantavirus pulmonary syndrome [4], West Nile virus [5], monkeypox [6], SARS [7], and avian influenza [8], have caused considerable concern for US security. With new ideas proliferating for ways to more rapidly detect and monitor the spread of disease outbreaks, the DoD-GEIS held a symposium in May 2000 to share experiences and foster efficient progress in creating innovative, responsive surveillance systems [9]. Partnerships formed consequent to this meeting have resulted in enhanced methods for disease monitoring that continue to be used and improved in both the military and civilian sectors.

### 1.1 Traditional Surveillance Practices

Traditionally, most infectious disease surveillance systems have relied on laboratory reporting for a list of diseases of public health importance. As in the civilian community, military health providers are required to report any cases of these diseases, whether hospitalized or not, to the public health officials on the military installation as well as the local public health department. Unfortunately, many health care providers are unaware of the notifiable disease list, or whom to contact, or cannot find the time to report; therefore, most reporting is done by laboratory staff after confirmation of a positive test result. However, many diseases are not diagnosed in the laboratory, either because there is no test available or because a specimen is not taken. Reports on completeness and timeliness of active reporting of *hospitalized* notifiable conditions in the military to the respective service's reporting system show rates of 57% in the Army, 30% in the Navy, and 31% in the Air Force for 2003 based on the ICD-9 codes recorded as diagnoses upon discharge of the patient from the hospital [10–12]. In addition, the cases were not reported in a timely fashion, with 15% of Navy, 69% of Army, and 80% of Air Force cases reported within one month.

### 1.2 Other DoD Surveillance Systems

To supplement reportable disease surveillance, the DoD initiated special surveillance programs for high-risk populations or diseases. The Air Force Institute of Operational Health (now known as the US Air Force School of Aerospace Medicine (USAFSAM))

has been operating a military global influenza surveillance program since 1976 [13, 14]. This system now covers all three services as well as local residents in areas where DoD overseas research activities occur and collects respiratory specimens for viral isolation and typing. The Naval Health Research Center operates a febrile respiratory illness surveillance program at all basic training sites [15]. This system collects symptom data on trainees and calculates when rates of respiratory illness exceed the expected rate in order to initiate preventive measures. The Army performs acute respiratory disease (ARD) surveillance at all basic combat training sites [16]. This program monitors the incidence of positive streptococcal cultures in the trainee population and allows the local preventive medicine staff to decide whether to initiate or expand penicillin prophylaxis.

The DoD maintains the Defense Medical Surveillance System (DMSS) [17], which integrates a wide range of health event-related data on all military beneficiaries. The DMSS includes individual demographic information, outpatient/inpatient events, immunization status, and other data for care provided within all permanent MTFs worldwide as well as from the TRICARE purchased care network. As most of these data are received monthly, DMSS has not been useful for near-real-time surveillance purposes, but plays a critical role in retrospective analyses.

The DoD also monitors deployed troops who are routinely in areas with high rates of endemic diseases and at risk for deliberate attacks involving biological agents. Most deployed medical units capture health event data using electronic patient encounter modules. These data, which include ICD-9 codes as assigned by the attending health care provider, and other related information in both structured-note and free-text formats are forwarded at least daily to the Joint Medical Workstation (JMeWS). Analysts monitor trends in various groupings of diseases and nonbattle injuries (DNBI) on at least a weekly basis. During periods of high threat, the frequency of reporting and analysis is on a daily basis, and more focused category definitions related to biological attacks are activated. Additional deployed health event data are available from newer systems including the joint patient tracking application (JPTA) and the US TRANSCOM Regulating and Command and Control Evacuation System ($TRAC^2ES$). Both of these systems support direct clinical care of casualties as they move between different medical treatment facilities, both inside and outside of the military theater of operations.

The Armed Forces Institute of Pathology (AFIP) includes a full medical examiners office, which maintains a DoD mortality registry. AFIP performs full autopsies and extensive investigations on all service members who die while on active duty with special emphasis on identifying sentinel infectious deaths.

The DoD established the Department of Defence serum repository (DoDSR) in 1989 for the purpose of storing serum specimens that remained following mandatory HIV testing within the active and reserve components of the Army and Navy [18–20]. Later, the mission expanded to include the collection and storage of specimens collected before and after operational deployments, for example, Operation IRAQI FREEDOM, and to include Air Force, US Coast Guard, and Federal civilian employee specimens. The DoDSR currently houses more than 40 million specimens and continues to grow by approximately 2.3 million specimens per year. The availability of serial serologic specimens throughout an individual's career, as well as relevant demographic, occupational, and medical information, within the DMSS enables the DoDSR to make significant contributions to clinical and seroepidemiologic investigations.

### 1.3 Need for Improved Surveillance

Despite the previously mentioned surveillance programs for specific illnesses and populations, a real-time, comprehensive system to determine disease status for all military beneficiaries was still needed. With increasing amounts of electronic health data available, to include early diagnostic information, it became feasible to develop ways to visualize and analyze multiple health data streams in novel and potentially useful ways. New surveillance systems such as ESSENCE, initially envisioned for early outbreak detection and later adapted for outbreak investigation aids, situational awareness, temporal and geographic disease tracking, and other augmentations, started to provide the immediate knowledge that public health officials, decision makers, and military leaders required.

## 2 ESSENCE RESEARCH AND DEVELOPMENT

Many academic, public health, commercial, and government institutions have designed what is termed *syndromic surveillance systems* to have more timely knowledge of disease impact in communities. "Syndromic surveillance" typically refers to the use of routinely collected early or prediagnostic health information for timely disease surveillance. It is defined by secondary use of early or prediagnostic data and a focus on prospective disease surveillance and timely outbreak detection. Syndromic systems typically use electronically collected and disseminated data, but can include paper-based, manual methods such as daily reviews of chief complaint logs.

On the basis of the work done by the New York City Department of Health and Mental Hygiene using prescriptions of antidiarrheal medications and number of stool samples submitted for testing to detect gastrointestinal outbreaks [21] and on the basis of the use of coded 911 calls to track influenza outbreaks [22], the DoD-GEIS investigated the use of ICD-9 codes to detect potential infectious disease and bioterrorism outbreaks in the greater Washington, DC area [23]. This project resulted in the creation of the ESSENCE surveillance system.

### 2.1 History of ESSENCE Development

ESSENCE initially relied on the use of ICD-9 codes, grouped into syndromes such as respiratory, gastrointestinal, febrile, and neurological illnesses, to detect abnormal changes in disease incidence rates. At every MTF, the health care provider codes each outpatient and emergency room visit with up to four ICD-9 codes that are recorded electronically. These codes are entered at or near the time of patient visit, but transfer to a central facility could be delayed by 2–3 days or longer. (This situation is changing with the implementation of the Armed Forces Health Longitudinal Technology Application (AHLTA) as the new enterprise health information system. With AHLTA, the data are transmitted in real time, as soon as the provider closes out the record, to a central data repository. The analyzed data are available to military public health officials on a password protected website.) Since its inception in 1999, ESSENCE has expanded from the DC region to all MTFs worldwide and has undergone numerous revisions to improve usefulness, data quality, and algorithm sensitivity and specificity.

Early in the development of the ESSENCE project, DoD-GEIS and the Johns Hopkins University Applied Physics Laboratory (JHU/APL) developed a collaboration to work jointly on a syndromic surveillance system for the Washington, DC region. JHU/APL

had already developed a system in Maryland using nursing home illness cases, medicare billing information, and civilian hospital emergency room chief complaints. With the combination of the two systems, the new ESSENCE II provided a more representative view of the region. Together, the DoD-GEIS and JHU/APL team received a grant from the Defense Advanced Research Projects Agency (DARPA) to further develop a prototype disease surveillance test bed and to evaluate new data sources [24].

Under the DARPA program, ESSENCE II expanded to include over-the-counter (OTC) pharmacy sales, school absenteeism, medication prescriptions, laboratory test orders, and veterinary clinic data in the Washington, DC region. The system also included improved statistical methods to detect both temporal and spatial anomalies and advanced web-based interfaces for the user. ESSENCE II integrated military and civilian data and became the first system to make both available for daily disease surveillance [24].

Development and testing of ESSENCE continued with the ESSENCE III project, funded by the Defense Threat Reduction Agency (DTRA), to evaluate different syndromic surveillance systems in the Albuquerque, NM region. BioNet, a cooperative program between DTRA and the Department of Homeland Security, then selected San Diego as a pilot city to test how to improve detection and event characterization of a biological attack. At the same time, the Joint Services Installation Pilot Project (JSIPP) expanded chemical, biological, and radiological detection and response capabilities at nine military installations and the surrounding communities. As part of JSIPP and BioNet, ESSENCE IV was created to use summary data from military emergency room and outpatient visits, pharmacy prescriptions, procedure codes, and civilian hospital emergency room chief complaints together in an integrated system with advanced on-line analysis capabilities. In addition, depending on the data sources available at each location, sets of daily records of school absenteeism, school nurse visits, ambulance runs, nurse advice calls, and OTC pharmacy sales were also integrated, and their surveillance utility was evaluated. The time series plot in Figure 1 includes a sharp early January increase in case counts representing an outbreak detected by ESSENCE IV.

### 2.2 Lessons Learned

During the initial expansion of ESSENCE, extensive evaluations were conducted through research of data sources and statistical techniques and surveys of users. The results of the evaluations were disseminated to all stakeholders. The major conclusions included the need for validation of data sources for both accuracy and usefulness, utility for public health use beyond bioterrorism detection, simplicity of web-based interaction, portability between different information technology systems, and designated funding for continuation of programs. Table 1 summarizes these findings. Data sources need to be validated before inclusion into any syndromic surveillance system. The validation does not need to be extensive, but should include, at a minimum, comparison between an existing, evaluated surveillance system and other data sources being included in the syndromic surveillance system.

### 2.3 Strengths and Limitations

There are limitations to any surveillance system, and syndromic surveillance systems are no different. It is important to clearly state the goals of a system being developed to decrease false expectations. Syndromic systems like ESSENCE should augment existing

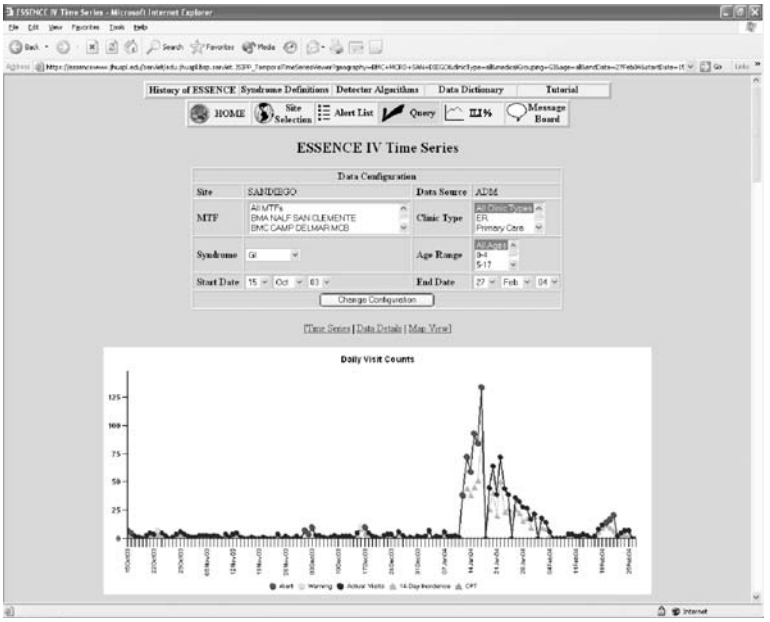

**FIGURE 1** Gastrointestinal outbreak in military personnel depicted in the ESSENCE IV system.

systems by extending the ability to detect and track disease outbreaks in a community. Some of the strengths and limitations found in ESSENCE development and piloting are listed in Table 2.

## 3 IMPLEMENTATION

A surveillance system has value only if people use it. ESSENCE has clearly demonstrated its value as a key tool in the practice of military public health. Still, it is important to establish policy explaining this value and identifying performance expectations.

### 3.1 Recent ESSENCE Enhancements

One of the best ways to gain user acceptance and loyalty is to provide a product that meets the user's needs and minimizes additional work. DoD has redesigned ESSENCE based on user feedback. The most common criticism of earlier versions of ESSENCE was the inability of the local user to access the personal identifying information of individuals contributing to an alert or alarm. This made investigation difficult and time consuming. Consequently, the new ESSENCE allows role-based access at the local level to protected health information [supervisor approved, following Health Insurance Portability and Accountability Act (HIPAA) guidelines]. Since this change, the local military public health practitioner is instantly able to access the name and other personal identifying information. The system will also map outpatient diagnoses against the current tri-service reportable medical events list, allowing local staff to promptly investigate these events. Additionally, automated e-mail and mobile phone alerts of possible disease outbreaks

**TABLE 1 Recommendations for Evaluation of New Disease Surveillance Systems**

Validate data sources
- Ensure that any "gold standard" comparison sources are truly gold standard. It is possible that the standard could be less accurate than the new data source being tested
- The data source should be evaluated across different types of outbreaks. For example, a more severe disease indicator such as ambulance dispatches might be an indicator during influenza season, but may not show any abnormality during a gastrointestinal outbreak
- Before eliminating or including a data source, the elements that make up the syndrome groups should be manipulated to determine the best groupings possible for the population and the database
- Many disease outbreaks are small and of low impact. Data sources that detect these outbreaks are not necessarily unreliable as an indicator of disease rates

Use reliable and user-preferred data sources—most often from interactions with medical care providers
- Emergency room chief complaints and diagnostic information from outpatient visits are the most useful. Ambulance runs provide information slightly earlier, but may miss less severe outbreaks that do not require ambulance transport
- Earlier alerting data such as OTC sales and school absenteeism are good collaborating sources, but cannot be relied upon for confirmation of an outbreak

Evaluate data sources from specific populations for their contribution to the overall surveillance
- Representative populations are best for determining disease rates in large geographic areas, but special subsets of the population can provide critical information if properly utilized

Evaluate timeliness and representativeness
- A new data source should provide population information previously unavailable at low cost and should be timely enough to improve the current surveillance system
- Even if the initial purpose of the system is for bioterrorism detection, ensure the surveillance system can recognize and assist with response to other public health infectious disease outbreaks
- Data sources should also be evaluated for *any* potential public health use, including noninfectious disease related ones. This will make the overall system more cost effective and sustainable

Allow link to identifiers within public health and privacy laws
- Rapid access to identifying information can assist with a public health emergency and in finding and tracking reportable disease events

User interfaces should emphasize simplicity while still allowing advanced users access to manipulate variables
- For example, provide the ability to manipulate ICD-9 codes or text words in syndrome groups and to select algorithms and change their sensitivity

Ensure portability of systems to new locations for ease of expansion
- Information technology support should be obtained in the beginning to ensure ease of transitions later on

Out-year funding or designation of the organization that will provide financial and personnel support after the initial program ends needs to be determined early and continually updated throughout the life of the program
- Without dedicated support, no one will invest the time and commitment a successful system needs

**TABLE 2 Strengths and Limitations of ESSENCE**

| | |
|---|---|
| Strengths | Tracking of community-wide disease outbreaks, both locally and across geographic regions |
| | Quick method to find most up-to-date information on general disease status of a community (situational awareness during threat of outbreak) |
| | Ability to link identifiers if needed for outbreak investigation |
| | Increased ability to find and investigate notifiable diseases |
| | Sharing information with local public health officials |
| Limitations | Inability to detect small outbreaks for some disease syndromes |
| | Lag-time for some data acquisition can result in outbreak detection occurring after optimal time for intervention |
| | False alarms occur and detract from user confidence |
| | Lack of trust that data reflects true health status since acquired early in course of illness |
| | Complex detection algorithms can be difficult to interpret |

are now available. This new version of ESSENCE was fielded on September 28, 2006, by the TRICARE Management Activity Executive Information and Decision Support (EIDS) (now known as the TMA Defense Health Services Systems (DHSS)) office.

### 3.2 Monitoring Requirements

A Health Affairs policy memo published January 17, 2007 identifies ESSENCE as an essential component of military installation protection and a key part of the US national public health surveillance system [25]. The Services must have appropriately trained public health or preventive medicine professionals monitoring ESSENCE at each military installation. These individuals will routinely monitor ESSENCE alerts and associated graphs and data tables for any MTF within their direct jurisdiction as well as other nearby military installations.

The monitoring frequency will be at least once each routine work day, but will increase to include weekends and holidays during periods of increased threat, for example, specific local terrorist threat, World Health Organization/national pandemic influenza alert phase 5 or 6, and so on. There must be active communication between the ESSENCE monitors and the local public health emergency officer [26]. The installation medical professionals responsible for public health must maintain a strong relationship with the local civilian public health office, advising them of potential outbreaks and forwarding reportable medical events information as required by local, county, or state law.

### 3.3 Future ESSENCE Enhancements

In keeping with the lessons learned by DoD and other syndromic surveillance experts across the country, a number of enhancements are planned for the near future. For instance, potential complementary data streams are undergoing evaluation for possible inclusion. These include laboratory orders and results, radiology orders and results, and chief complaints from primary and emergency care settings. The DoD continues to collaborate closely with JHU/APL, the Centers for Disease Control and Prevention's BioSense program, and other national research and development centers in order to identify the best data sources and statistical analytical procedures.

## 4 CONCLUSIONS

In development and use of a surveillance program such as ESSENCE, it is most important to first determine the overriding purpose of such a system. The purpose of a surveillance system determines which attributes are most important. To monitor long-term trends in disease rates or to evaluate the effectiveness of a public health prevention program, accuracy is more important than timeliness. However, to decrease the time needed to detect an outbreak or to monitor its spread, the rapid acquisition and analysis of surveillance data become a priority, as long as it can be done with enough correct information to be useful.

Rapid access to disease surveillance data can provide more than an early indication. Information in this system, such as geographic location of the patients, can assist in a more in-depth outbreak investigation. Once detected, it can be used to monitor the rate and spread of the outbreak, and the effectiveness of control measures. It can also provide situational awareness, letting health officials know the general status of acute disease in a population. And finally, surveillance information can be used by decision makers to determine at-risk populations, decide how to best allocate resources, and provide the public information on how to decrease their risk.

## 1 BACKGROUND

The attacks of September and October of 2001 have resulted in heightened awareness of the vulnerability of the United States civilian population to terrorist groups or individuals armed with unconventional weapons. While most of the attention has been given to biological agents, the civilian threat spectrum encompasses radioactive, explosive, and

chemical weapons as well. Chemicals are particularly attractive to terrorists because they are relatively inexpensive and easy to obtain, and have the potential to cause mass casualties when used in a variety of scenarios. Unlike biological and radiological threats, there have actually been several recent chemical attacks that have resulted in mass casualties. For example, sulfur mustard and nerve agents were used against Iraqi Kurdish villages in the late 1980s, and more recently, nerve agents were used by the Japanese cult organization Aum Shinrikyo in two separate attacks against civilians in Japan [1, 2]. Not only does this stress the importance of increasing efforts to prepare for future chemical attacks in the United States, but it also provides the opportunity to analyze these events to learn about potential gaps in our response capabilities.

Chemical threat agents can be categorized on the basis of the target tissues and types of primary acute effects they produce (Table 1) [3]. The traditional chemical warfare agents (CWAs) developed during the first and second World Wars include the organophosphorus

**TABLE 1 Examples of Chemical Warfare Agents and Toxic Industrial Chemicals**

| Type | Common Name (Symbol) | Time to Onset of Initial Symptoms | Acute Effects |
|---|---|---|---|
| Nerve agents | Tabun (GA) | Seconds to minutes | Miosis, anxiety, confusions, excess secretions, muscle fasciculations, bronchoconstriction, paralysis, cardiorespiratory depression, convulsions and seizures, coma, and death |
| | Sarin (GB) | Seconds to minutes | |
| | Soman (GD) | Seconds to minutes | |
| | Cyclosarin (GF) | Seconds to minutes | |
| | VX | Minutes | |
| Vesicants or blister agents | Sulfur mustard (H and HD) | 4–6 h | Tearing, burning eyes, rhinorrhea, sneezing, cough, erythema, corneal damage, dyspnea, pulmonary edema, and vesication |
| | Sulfur mustard-T mixture (HT) | 4–6 h | |
| | Nitrogen mustard (HN-1, 2 or 3) | 4–6 h | |
| | Lewisite and other arsenicals (L) | Immediate | |
| Pulmonary (choking agents) | Phosgene (CG) | Immediate irritant effects; pulmonary edema 4–48 h postexposure | Cough, dyspnea, pulmonary edema, and respiratory failure |
| | Chlorine (Cl) | Immediate irritant effects; pulmonary edema in 2–4 h | |
| | Diphosgene (DP) | Similar to CG | |
| Blood agents (cellular poisons) | Hydrogen cyanide (AC) (vapor and liquid) | <1 min (persistence <1 h) | Convulsions, hemolysis, coma, respiratory and renal failure, bradycardia, and cardiac arrest |
| | Cyanogen chloride (CK) (vapor) | <1 min (nonpersistent) | |

(OP) nerve agents such as sarin and VX, and the mustard vesicating agents. As a consequence of previous state-sponsored CWA programs, several stockpiles remain around the world. A terrorist group could illegally obtain or manufacture traditional CWAs and use them as weapons of terror. The United States also produces and uses over 80,000 chemicals, many of which are highly toxic and lethal at relatively low doses. Chemical agents in this broad category include the toxic industrial chemicals (TICs) manufactured and stored in large volume at industrial facilities, and transported across the nation for various uses. The threat from CWAs is mitigated by restricted access, difficulty in synthesis of purified agent, and international treaties against their use. But the TICs are not regulated as strictly, and many chemicals are readily available or stored in large enough amounts to pose a serious threat to human health if released by accident, natural disaster, or by a deliberate act of sabotage to manufacturing plants, storage sites, or transport vehicles. According to a 2003 report published by the General Accounting Office [4], the US Environmental Protection Agency (EPA) has identified 123 chemical plants in the United States where a terrorist attack or accident could potentially expose more than 1 million people to a cloud of toxic gas. Unfortunately, there are also examples of industrial accidents with chemicals, such as the deadly incident in Bhopal, India, where methyl isocyanate was released from an industrial storage tank in 1984 killing 5,000 people and injuring thousands more, some with long-term health effects [5], and the more recent fatal accidents involving chlorine gas releases during transportation in the United States [6]. Chemical plants are also vulnerable to natural disasters such as the recent hurricanes Katrina and Rita [7]. Many are not built to withstand high wind and water, which may be significant because of recent trends in extreme weather.

The US military has developed countermeasures to protect the war fighter from a chemical attack on the battlefield, but many of these are not well suited for civilian chemical terrorism scenarios. Protective clothing, gas masks, and prophylactic drugs used by the military can be effective with advanced preparation, but a chemical attack against civilians or accident is likely to come without warning. Requirements for an effective response to a civilian chemical attack or large-scale accident or natural disaster include (i) postexposure treatments that are effective within an often short therapeutic time window, (ii) drugs and devices that can be used by medical personnel at the scene of the event or in a prehospital setting to treat many victims, (iii) drugs and devices that are appropriate for a diverse population including pediatric and elderly victims, and individuals with preexisting medical conditions, and (iv) rapid and effective diagnostic technologies to determine the chemical agent and pathophysiology. Some available treatments for chemicals that affect cellular respiration (e.g. cyanide) or the nervous system (e.g. nerve agents) have dangerous side effects and a short therapeutic window. Postexposure treatments for chemicals that affect the respiratory system, skin, and eyes are largely limited to supportive therapy and alleviation of symptoms. To address potential gaps in our medical emergency preparedness, and at the request of the US Department of Health and Human Services (DHHS), the National Institutes of Health (NIH) developed the "NIH Strategic Plan and Research Agenda for Medical Countermeasures Against Chemical Threats" for the development of improved medical countermeasures that could be used in the case of chemical terrorist attack or accident [3]. The plan focuses on therapeutics and diagnostics for chemicals that affect the nervous system; respiratory tract; skin, eyes, and mucous membranes; and cellular respiration. Much of the information

in this article has been obtained and paraphrased in some cases from the NIH Strategic Plan, which was authored in part by the authors of this article.

The implementation of the NIH Strategic Plan was established through the Countermeasures Against Chemical Threats (CounterACT) Research Program in fiscal year 2006 to develop new and improved diagnostic technologies and therapies for conditions caused by chemicals that could be used in a terrorist attack or released by accident http://www.ninds.nih.gov/funding/research/counterterrorism/index.htm. The program includes a network of academic, private, and federal laboratories funded through large research centers of excellence, individual research projects, small business grants, and targeted contracts. The network conducts basic, translational, and clinical research aimed at the discovery and/or identification of better therapeutic and diagnostic medical countermeasures against chemical threat agents, and the movement of promising products through the regulatory process. Research areas supported within this program include the development and validation of *in vitro* and animal models for efficacy screening of compounds, efficacy screening of compounds using these models, advanced efficacy and preclinical studies with appropriate animal models including nonhuman primates using current Good Laboratory Practices (cGLPs), and clinical studies, including clinical trials with new drugs.

## 2 OVERVIEW OF THREATS AND SOLUTIONS

### 2.1 Chemicals Affecting the Nervous System

Several chemical agents of highest priority target the nervous system, including some highly toxic insecticides and rodenticides, and the OP nerve agents that have been used as chemical weapons. The OP nerve agents belong to a chemically diverse group of organic compounds, which have in common at least one carbon atom bound to a phosphorous atom. They are sometimes referred to as *nerve gases* because of the high volatility of some of the specific agents, but in fact they are clear colorless liquids at room temperature. The OP nerve agents were synthesized during World War II by the Nazis to be used as CWAs against the allied forces. They are closely related to the OP pesticides that were also being developed during that time. Traditional OP nerve agents fall into two groups, the G-series and the V-series, based on their chemical and physical properties. The G-series nerve agents include GA (tabun), GB (sarin), GD (soman), and others. These are volatile liquids at room temperature that can be deadly when inhaled as a vapor or from percutaneous exposure to the vapor. V-series agents (VX and others) have a consistency similar to oil and have low volatility. V-series agents can remain on clothing and other surfaces for a long time and pose more of a risk from dermal exposure or by ingestion. Agents in the V-series are approximately 10- to 100-fold more toxic than those in the G-series.

OP nerve agents inhibit the catalytic function of acetylcholinesterase (AChE) (EC 3.1.1.7; AChE) by phosphorylating the esteratic site of the enzyme [8]. This removes the capacity of the enzyme to catalyze its endogenous substrate acetylcholine (ACh). As a consequence, the hydrolysis of ACh is prevented, leading to accumulation of ACh in the synaptic cleft, and overstimulation and subsequent desensitization of ACh receptors in brain, glands, and skeletal and smooth muscles. These effects cause disruption of nerve function that leads rapidly to a progression from miosis, excessive secretions, and muscle fasciculation to epileptic seizures, muscle paralysis, cardiorespiratory depression, and death due to respiratory failure. The OP nerve agents are more toxic than the related

OP pesticides still in use today. They are lethal at minute doses. For example, the median lethal dose (LD50) of VX for a 70 kg person is only 10 mg.

Acute poisonings with OP nerve agents and pesticides are treated with atropine sulfate to inhibit central muscarinic effects, and pralidoxime (2-PAM) chloride to reactivate the inhibited AChE. Atropine blocks muscarinic cholinergic receptors in the parasympathetic nervous system to reduce excessive secretions and smooth muscle contraction. It does not have a significant therapeutic effect for central nervous system (CNS) toxicity or does not appear to work well at cholinergic synapses on skeletal muscle. Atropine works well as an antidote to OPs, but it can have significant side effects if dosing is not carefully monitored. Other cholinergic drugs and drugs that interact with other neurotransmitter systems are under development, which may be more selective and have fewer side effects.

The oxime 2-PAM chloride appears to be most effective at nicotinic cholinergic synapses on skeletal muscle [8]. It removes OP nerve agents and pesticides from the OP-AChE complex by virtue of its highly nucleophilic oxime moiety. Both OP pesticides and nerve agents undergo a deacylation process called *aging* during which the bond strength between the OP and AChE significantly increases, and after which oximes are ineffective. Once aging has occurred, the AChE is irreversibly inactivated and enzyme activity can only be restored by *de novo* resynthesis. Aging times vary according to the nerve agent, and ranges from very fast with soman (2 min) to much slower with sarin (3–4 h) and longer for others. Research on improved AChE reactivators is focused on increasing activity within the CNS, and increasing the therapeutic window, especially for fast-aging nerve agents. This includes developing novel compounds as well as investigating alternative oximes used in other countries such as trimedoxime and HI-6. Atropine and 2-PAM chloride are packaged together for civilian use in the Strategic National Stockpile's CHEMPACK program, and in spring-powered auto-injectors used by the US military. Other treatment strategies for OP nerve agents include sequestration or inactivation of the agent using endogenous or modified proteins to bind free nerve agent stoichiometrically or the introduction of enzymes with high catalytic activity to remove the nerve agent from circulation before it reaches the target site. An enzyme similar to AChE, butyrylcholinesterase (BChE), is under development by the military as a prophylactic agent. It remains uncertain if this could be given safely and effectively in humans, and if it could be used to treat civilians after exposure to nerve agents has already occurred.

Exposure to sufficient doses of OP nerve agents cause epileptic seizures. Prolonged seizure activity after nerve agent exposure has been shown in animals to cause neuropathologic lesions in the CNS that are associated with long-term impairment of cognitive function and other behaviors [9–12]. It is believed that the long-term effects of nerve agent-induced seizures involve stimulation of the glutamatergic system causing eventual excitotoxicity, calcium accumulation, increased catabolic activity, and cell death [13]. Research in the area of antiglutamatergic drugs and prevention of excitotoxcity is being pursued since in many cases first responders may not be able to administer any treatment until this latter excitotoxic phase. Alone, the atropine and 2-PAM treatment regimen is not effective against OP-induced seizures once they are established, but these antidotes are crucial to the effectiveness of anticonvulsants, and the dose of atropine influences the effectiveness of anticonvulsants [14]. The benzodiazepine diazepam is an anticonvulsant used for treatment of exposure to OP nerve agents, and is included in 10 mg doses in the antidote treatment regimen used by the US military convulsant antidote, nerve agent (CANA). It is also included in the civilian CHEMPACK stockpile. Administering

diazepam is an effective treatment for the seizures associated with nerve agent exposure, but it has limited bioavailability when administered intramuscularly, and there is a loss in efficacy after prolonged seizure activity. As with most drugs that suppress CNS activity, the potential for over-sedation and respiratory depression exists with diazepam, especially in cases where patients may already be suffering from paralysis or hypoxia from the nerve agent. This last point regarding OP-induced paralysis is also important when considering the diagnosis of seizure activity and appropriate treatments. The muscular effects of OP nerve agents may mask or mimic signs of seizure activity. A field deployable electroencephalograph (EEG) suitable for use by first responder medical personnel could be used to detect potential nonconvulsive seizures during a chemical event.

## 2.2 Chemical Affecting the Pulmonary Tract

Many TICs produced and transported in high volume in the United States can severely disrupt normal pulmonary function and lead to respiratory failure if individuals are exposed to high enough levels. The volatility of many TICs and CWAs is of particular concern because of the ease at which many people can be exposed by inhalation. Of the several hundred chemicals identified by the US EPA as TICs, sulfuric acid, ammonia, chlorine, nitric acid, and ammonium nitrate are among the most abundant. Ammonia and alkali agents like sodium hydroxide, as well as acids used in industries such as hydrochloric and sulfuric acid, are highly corrosive to the upper airways. Sulfur mustard, a highly corrosive CWA, targets the upper airways and can cause acute inflammation, painful ulcerations, increased secretions, and difficulties in breathing and swallowing. Secondary bacterial infections may result from and further exacerbate the initial injury. Damage to the upper airways can lead to respiratory failure and death. Exposure can also lead to long-term health problems. For example, chronic respiratory problems such as scarring and narrowing of the trachea have been observed in Iranians exposed to sulfur mustard during the Iran–Iraq War of the 1980s [15].

Other toxic chemicals used in industry may reach the lower respiratory tract and cause life-threatening injuries such as pulmonary edema. These include ammonia, chlorine, phosgene, and perfluoroisobutylene. Pulmonary edema is the leakage of fluid into the lungs, which prevents oxygen delivery to the blood, ultimately preventing oxygen from reaching the brain, kidneys, and other organs. Symptoms may be immediate or delayed, for example, chlorine causes immediate airway irritation and pain, whereas phosgene exposure may not be evident for 24–48 h (Table 1) [3]. People who survive a single, acute exposure to respiratory airway toxins generally show little or no long-term health problems, although some may eventually develop asthma or chronic bronchitis. Individuals at greatest risk are those with preexisting cardiopulmonary disease. Chlorine is a greenish-yellow volatile gas with pungent order and is 2.5 times heavier than air as a gas. It produces severe pain and irritation almost immediately within the conjunctiva and mucous membranes in the nasal passages and upper airway. Coughing and choking is very common early after exposure. Chlorine was first used during World War I by the Germans in Ypres, Belgium, and caused more than 15,000 British and French casualties with 5,000 deaths. Phosgene is a colorless gas that has an odor described as in new-mown hay. It is 3.5 times heavier than air as a vapor and more stable than chlorine when used with explosives. It is also 10 times more toxic than chlorine and far less irritating than chlorine when initially inhaled, which results in an insidious delayed action promoting continued inhalation and more prolonged exposure. Other agents used in warfare such as

sulfur mustard and nerve agents also have severe deleterious effects on the pulmonary tract, and these are discussed in detail in other sections of this article.

Specific drugs to prevent chemically induced damage to the respiratory airways are not available. Analgesic medications, oxygen, humidification, and ventilator support currently constitute the current standard of care for most chemical exposures affecting the pulmonary tract. Hemorrhaging, signifying substantial damage to the lining of the airways and lungs, can occur with exposure to highly corrosive chemicals and may require additional medical interventions. Treatment of injuries to the lower respiratory tract is also supportive and usually includes administration of oxygen, the use of mechanical ventilation to include positive airway pressure, and bronchodilators to treat bronchospasms. Drugs that reduce the inflammatory response, promote healing of tissues, and prevent the onset of pulmonary edema or secondary inflammation may be used following severe injury to prevent chronic scarring and airway narrowing. Current diagnostic capabilities are limited. Exposure to chlorine, phosgene, or any of the major alkali agents is determined based on clinical signs and symptoms. If newer, more specific therapies are to be developed for chemical agents, then diagnosis of exposure to specific agents may be important, as will screening tests to identify individuals exposed to low levels of chemicals.

The need for prehospital treatments for exposure to pulmonary agents is evident because most of the current treatments can only be administered in a controlled hospital setting, and many hospitals are ill suited for a situation involving mass casualties among civilians. Inexpensive positive-pressure devices that can be used easily in a mass casualty situation and drugs to prevent inflammation and pulmonary edema are needed. Several drugs that have been approved by the US Food and Drug Administration (FDA) for other indications hold promise for treating chemically-induced pulmonary edema. These include $\beta$ 2-agonists, dopamine, insulin, allopurinol, and nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen. Ibuprofen is particularly appealing because it has an established safety record and can be easily administered as an initial intervention. Studies have shown that ibuprofen improves survival and reduces lung fluid levels in mice exposed to phosgene [16]. Inhaled and systemic forms of $\beta$ 2-agonists used in the treatment of asthma, and other commonly used medications may also be fruitful avenues of future research on new treatments for chlorine and phosgene exposure. Some of these potential drugs target the inflammatory response or the specific site(s) of injury. Others modulate the activity of ion channels that control fluid transport across lung membranes or target surfactant, a substance that lines the air sacs in the lungs and prevents them from collapsing.

It is clear for chemical agents that affect the pulmonary tract that basic mechanistic research is needed to discover new targets for therapeutic development; however, research is also needed to test the effectiveness of the many drugs already approved by the FDA for other diseases and disorders with similar pathologies. The anti-inflammatory drugs probably hold the greatest potential at present as a first step for treating mass chemical exposures. Research will require the identification and validation of appropriate *in vitro* systems and animal models for preclinical testing of drugs to treat chemically induced injury to the upper and lower respiratory tract. Since it is clear that some of the chemicals may cause long-term chronic health effects, studies are needed to fully characterize these effects for the purpose of developing effective medical interventions. Finally, some chemicals generate metabolic byproducts that could be used for diagnosis, but detection of these byproducts may not be possible until many hours after initial exposure. Diagnostic

tools and biological markers associated with acute lung injury are needed to help guide medical interventions in both the pre- and in-hospital settings.

### 2.3 Metabolic and Cellular Poisons

Metabolic poisons can be inhaled or ingested. Many of the TICs of concern affect cellular respiration. These include chemicals such as phosphine, arsine, and the infamous and highly toxic cyanide compounds. Exposure to high concentrations of hydrogen cyanide (HCN) gas can cause death within minutes. This narrow therapeutic window presents a formidable challenge for treatment, but emphasizes the need for immediate medical intervention. Inhalation of lower concentrations of cyanide vapor or cyanide salt ingestion may result in a slower development of symptoms. Metabolic poisons, such as hydrogen cyanide and cyanogen chloride, inhibit cellular respiration, whereby oxygen is extracted from the blood at the cellular level and sugar molecules are transformed into energy. All systems of the body are ultimately affected but the cardiovascular system and the CNS are most strongly affected due to their high demands for oxygen and energy and limited ability to use alternative pathways for energy production. Exposure to metabolic poisons can quickly cause seizures, respiratory failure, cardiac arrest, and death (Table 1). Long-term effects are poorly understood and may include gradual neurodegeneration [17].

No pretreatment for cyanide poisoning is available and it may not be practical. Since 1933, a cyanide antidote kit has been marketed for use in the United States, but as a kit, it has never received formal regulatory approval by the FDA. The cyanide antidote kit includes crushable ampoules of amyl nitrite for inhalation, and sodium nitrite and sodium thiosulfate, which are administered intravenously. The nitrites bind with hemoglobin in the blood to produce methemoglobin molecules. The methemoglobin then binds with cyanide to produce a much less toxic cyanomethemoglobin, which is eventually eliminated from the body. Sodium thiosulfate, often referred to as a *sulfur donor drug*, converts cyanide into nontoxic thiocyanate, which is then excreted by the kidneys. The cyanide antidote kit can be very effective, but it carries the risk of toxic side effects. High levels of methemoglobin can be lethal. Dosing is especially challenging for pediatric casualties because of this toxicity [18]. Individuals with preexisting glucose 6-phosphate deficiency have a risk of red cell hemolysis if given sodium thiosulfate [19]. Individuals with renal deficiency, or anemia, could also suffer toxicity from the treatment. The ability to predictably quantify the amount of amyl nitrite that would be absorbed through inhalation may also be difficult.

In 2007, the FDA approved Cyanokit (hydroxocobalamin for injection) for treatment of cyanide poisoning. It has not yet been determined how effective this new countermeasure would be in a mass casualty situation since it needs to be administered intravenously. Administration of 10% hyperbaric oxygen is a major component in the treatment of cyanide poisoning, typically used even before the administration of any cyanide antidotes. However, the value of hyperbaric oxygen has not been determined, especially with products that form methemoglobin.

Government and private sector organizations have developed research agendas on next generation cyanide antidotes and new approaches. For example, cobinamide, one of the precursor compounds in the biosynthesis pathway of hydroxocobalamin, is a promising drug that warrants further investigation [20]. Cyanohydrin-forming compounds (e.g. $\alpha$-ketoglutarate and pyruvate) and vasodilatory drugs that act similar to nitrite compounds are potential new cyanide antidotes, as are drugs that act at the cellular level,

such as synthetic S crystallized rhodanese (an enzyme that promotes the conversion of cyanide to nontoxic thiocyanate). Sulfur-containing medications may also have potential benefits in the treatment of cyanide poisoning, especially those that remain in circulation for longer periods of time than sodium thiosulfate. The identification of FDA-approved drugs containing sulfur may have a therapeutic value in the treatment of cyanide poisoning. Drugs that form methemoglobin may have an advantage, but there are significant health risks associated with high levels of methemoglobin.

Within the NIH Strategic Plan, both short- and long-term strategies are being pursued in order to develop countermeasures against metabolic poisons [3]. Short-term goals include the improved understanding of the mechanisms of injury from cyanide-containing compounds, and identification of potential targets for medical intervention. The determination of optimal and novel routes of drug administration of promising compounds, to include administration through inhalation is a goal being pursued. The identification of screening tests and biological markers consistent with the identification of hydrogen cyanide and/or cyanide metabolite(s) and the level of exposure to such agents are under investigation. Also of concern is the identification and validation of appropriate *in vitro* systems and animal models for preclinical testing of drugs that could be useful in cyanide poisoning. The validation for the use of oxygen therapy in the initial treatment of cyanide poisoning, alone or in combination with other medical countermeasures along with the understanding of the differences in cyanide intoxication between different age ranges, and establishment of a treatment plan for susceptible populations are also short-term goals being pursued.

Long-term goals include the conduct of safety and efficacy studies with promising drugs, and the identification of effective routes of administration that would lead to timely intervention. The identification of major mechanisms and pathways by which sulfur donors, methemoglobin formers, and cobalt compounds counter cyanide toxicity in different systems of the body is an area of ongoing research. The expansion of the current NIH research infrastructure to enable preclinical and clinical studies on compounds with promising anticyanide activity is also a goal. NIH research is pursuing the development of rapid diagnostic tests and assays to identify specific biological markers consistent with cyanide exposure. The identification of any long-term or chronic health effects resulting from exposure to hydrogen cyanide, the cyanide-containing salts, and/or cyanogen chloride is an important long-range goal. Also, NIH is establishing databases of clinical, epidemiological, and laboratory information that will contribute to the understanding of the acute and chronic health effects of high- and low-level exposures to cyanide-containing compounds. Lastly, the review of current therapeutic interventions with oxygen and the assessment of the value of other proposed alternatives, such as the use of hyperbaric oxygen in treatment are being pursued.

### 2.4 Chemicals Affecting the Skin, Eyes, and Mucous Membranes

Vesicating (blister) agents, such as sulfur mustard, nitrogen mustard, lewisite, and caustic industrial chemicals, can cause severe blistering and burns to the eyes, mucous membranes, skin, and upper airways, as well as chronic eye inflammation and blindness. The eyes are the organs most sensitive to these chemicals. Vesicants may also affect other parts of the body, including the respiratory tract, immune system, and bone marrow. Sulfur mustard can cause tissue damage within minutes of exposure. Physical injury from other vesicants agents may not be evident for several hours and may result in delayed

recognition of exposure (Table 1). Many vesicating agents including sulfur mustard are oily liquids and considered "persistent" chemicals, that is, they do not evaporate quickly and remain active for an extended time. Clothing, skin, and hair may remain contaminated with sulfur mustard for hours, presenting a challenge to health care providers. The military and first responders rely heavily on individual physical protection (e.g. protective masks and suits) to prevent exposure to vesicants. No medical pretreatment drugs are yet available.

Although mustard agents were used in World War I, there is still no antidote for this vesicant. This is of great concern in view of the history of use and present day arsenals. Additionally, despite over 80 years of research, there is still no clear understanding of the biochemical mechanism of action. Despite the fact that the chemistry of mustard interaction with cellular components is well defined in the literature [21], the correlation with actual injury has not been made and is still under investigation. Current treatment of vesicant injuries is largely symptomatic and supportive. Eye injuries require the use of special eye drops, antibiotics, and other drugs to prevent secondary infection and steroids to limit the inflammatory response and speed the healing process. Skin wounds, especially when severe with blister formation, require specific medical attention to reduce pain, prevent infection, and reduce inflammation. Debridement (removal) of a layer of the injured skin may be necessary to speed the secondary healing process. British-Anti-Lewisite (BAL, dimercaprol) is a specific antidote for the chemical agent Lewisite and is also used for the treatment of heavy metal poisoning. BAL skin and eye ointments were developed for the military and these may decrease the severity of skin and eye lesions when quickly applied. BAL may be useful in the topical treatment of other injuries from vesicants besides Lewisite. However, because of reported toxicities associated with BAL, this compound has not been considered to be a useful prophylactic drug. Other therapeutic compounds are needed that can prevent/reduce the redness and deep tissue damage (blisters) in a short period. Also needed are improved skin protectants, reactive skin protectants that can neutralize the agent, new skin and eye therapies, and improved healing techniques.

Diagnosis of vesicant injury is based on clinical signs and symptoms and the detection of specific agents in the environment. There are no FDA-approved clinical laboratory tests for sulfur mustard in blood or tissue. However, compounds such as thiodiglycol (TDG) are produced in the body after exposure to sulfur mustard and can be detected in blood, urine, and tissue. These compounds can be analyzed in a research setting and require the use of complex laboratory equipment such as gas chromatographic mass spectrophotometers.

Short-term goals being pursued by the NIH include the comparison of medical countermeasures used by the Department of Defense (DoD) for the treatment of vesicating injuries for their use in civilian populations during mass casualty situations. Also, the evaluation and monitoring of promising ophthalmic drugs developed in the DoD program is being assessed for applicability for civilian populations and first responders. Further investigation with FDA-approved skin protectants against chemical agents for potential use in civilian populations is underway. The identification and validation of appropriate *in vitro* systems and animal models for preclinical drug testing is being pursued. This is to address both caustic agents and vesicants.

Long-term goals include the development of novel therapeutic strategies, including reactive therapeutic compounds, to prevent blister formation and inflammatory effects in skin and eyes. The goals also include the evaluation of the effectiveness of new

immunotherapeutic compounds and their applicability in the treatment of acid/alkali and mustard injuries. The identification of the specific mechanisms of action of specific chemical agents and their sites of injury to the skin, eyes, and mucous membranes, down to the molecular level is being pursued, as well as the investigation of the healing mechanisms following chemical injury. Part of this research is to identify novel ways of accelerating the recovery process following injury. Long-range strategic goals also will consider the mechanisms of action of vesicants on tissues, organs, and the hematopoetic system for the development of therapeutic interventions. This will be critical for the evaluation of novel therapeutic strategies for acid and alkali injuries. Additionally, the identification of biological markers consistent with types of chemical agents and the level of exposure to such agents are being investigated. The evaluation of "reactive" or "catalytic" skin protectants for use in civilian populations, such as first responders who must operate in a contaminated environment, is a long-range strategy. The evaluation of decontamination approaches for patients with open wound injuries and the identification of novel opportunities for medical intervention is a planned research effort. These efforts will potentially assist in the development of practical therapies that can be easily and safely administered to decontaminate the skin during mass causality situations.

## 3 SUMMARY AND CONCLUSIONS

It is impossible to predict when or where the next deliberate or accidental release of chemical weapons or TICs will occur. Unpredictable circumstances require a two-pronged approach. Firstly, a solution that reduces the threat or the unpredictability of the threat, which is beyond the scope of this article. Secondly, a solution that prepares one to mitigate the deleterious effects of the event once it has occurred. Part of the overall strategy employed by the US government to enhance emergency preparedness involves improving our medical response capabilities in order to reduce casualties and the strain on the health care system after an emergency event. Chemical agents that can be regarded as posing a threat to civilians at the mass casualty level include traditional CWAs such as nerve agents and sulfur mustard, and TICs such as chlorine and cyanide. These could be either used in attacks against civilians or released in large quantity after an industrial accident or natural disaster. These toxic chemicals cause a wide variety of health effects, both acute injuries and lethality at relatively low doses, and long-term, sometimes, delayed chronic illnesses.

Currently, many medical interventions that reduce mortality and morbidity after exposure to chemical threat agents are available. Antidotes, diagnostic tools, and drugs to treat symptoms are available for all of the highest priority chemical threats to civilians. However, research has identified several new opportunities to develop even better medical intervention strategies that will enhance medical response capabilities. These include better therapies that treat the most severe symptoms such as safer, faster-acting anticonvulsants to treat exposure to nerve agents, antidotes based on basic knowledge of the specific agents such as those that target the metabolic pathway of cyanide, and broad spectrum drugs that target common physiological mechanisms of injury such as anti-inflammatory drugs that could be used to treat victims exposed to many different kinds of chemicals.

The NIH in collaboration with the DoD has developed a research and development program to enhance the Strategic National Stockpile and better prepare health care professionals for an emergency event involving the release of toxic chemicals. The goal

of this program is to identify existing FDA-approved drugs, new drugs, and better diagnostic tools that could be rapidly deployed and used during a mass casualty event. The CounterACT and other programs at DHHS charged with this important goal are essential to national security and will require strong support to meet the challenges ahead. It will require a commitment that is consistent with the cost and time required for drug discovery and development, and should support research at the basic, translational and clinical levels.

# DEVELOPMENT OF RADIATION COUNTERMEASURES

TERRY C. PELLMAR

*Armed Forces Radiobiology Research Institute, Uniformed Services University of the Health Sciences, Bethesda, Maryland*

## 1 INTRODUCTION

With the increasing concerns about the possibilities of misuse of nuclear or radiological materials comes the requirement for appropriate medical treatment of the biological consequences of exposure to ionizing radiation. Radiation injury results from exposure to sources both external and internal to the body. Penetrating radiation, such as high-energy $\gamma$ rays or neutrons, presents the greatest hazard of external radiation injury. Internal exposures result from the internalization of radionuclides through inhalation, ingestion, or absorption through the skin or wounds. After detonation of a nuclear device, internal exposure is a relatively minor component of the injury. For this reason, efforts to develop countermeasures have focused on the acute radiation syndrome (ARS) resulting from penetrating radiation. With radiological acts of terrorism, scenarios do exist where internal contamination is the primary threat. This article will review the injury that results from radiation exposure and explore some of the efforts in the development of radiation countermeasures. With a long history of research and the recently renewed energy in this area, many agents have already been evaluated and new options continually arise. This review cannot be comprehensive; instead, it presents examples of countermeasures under investigation to convey the past and future status of the field.

## 2 RADIATION INJURY

### 2.1 Acute Radiation Syndrome

ARS is the spectrum of syndromes named for the organ system that is most likely to cause lethality after whole-body exposure to radiation [1, 2]. Doses of radiation less than 1 Gy elicit few acute symptoms. Within the first day, some people might experience mild prodromal symptoms such as nausea and a slight decrease in circulating lymphocytes, but long-term survival is probable [1, 3]. As the radiation dose increases over 2 Gy, prodromal symptoms become more severe with an earlier onset. After a transient recovery (or latent phase), the hematopoietic syndrome becomes evident as neutrophil and platelet counts drop after a few weeks. Neutropenia increases susceptibility to infection, and loss of platelets leads to bleeding, which can lead to death. With increasing radiation doses, the integrity of the gut wall is also impaired, allowing the translocation of gut bacteria, which can lead to sepsis. Both hematopoietic and gastrointestinal (GI) consequences are more severe with increasing doses. With exposures between 8 and 12 Gy, the GI syndrome predominates with severe loss of intestinal crypts and extensive breakdown of the mucosal barrier. Death results from the GI effects, usually within a couple of weeks. At doses greater than 12 Gy, death can result relatively quickly from cardiovascular and nervous system effects. Without treatment, the LD50 for ARS is about 3.5 Gy [4]. Several factors can modify this LD50 value. The effects of radiation are mitigated by poorly penetrating radiation, partial-body exposures, low dose rates, and good supportive care; they are exacerbated by extremes of age, coexisting trauma or infection, poor nutritional status, and neutron radiation. A concurrent traumatic injury also significantly increases the likelihood of lethality from radiation exposure.

### 2.2 Internal Contamination

The biological consequences of internalized radionuclides depend on their absorption, distribution, metabolism, and excretion pathways [5, 6]. Particular organs may be targeted by the agent, but if the distribution is broad and the radioactivity is high, ARS can also result. Radioactive materials can be internalized through inhalation, ingestion, or transdermal absorption. Inhalation is the most likely route of exposure. Larger particles, deposited in the upper bronchi, can be cleared relatively quickly. However, smaller particles (5–10 μm) can penetrate deeply into the lungs, reaching the alveoli. Soluble forms of the radionuclides are absorbed into the blood stream or the lymphatic system. Insoluble forms may stay in the lung causing radiation and chemical damage to the surrounding tissue. Contaminated food and water, as well as aerosolized particles that enter the nasal and oral cavities, provide routes for ingestion of radioactive materials. As with inhalation, the absorption from the GI tract depends on the solubility. Soluble particles are distributed through the circulation but nonsoluble particles remain in the gut. Although these particles will eventually be excreted, the transit time provides opportunities for radiation exposure of GI tissue. Intact skin presents a physical barrier through which few radionuclides can penetrate. (Tritiated water, which can permeate skin, is the primary exception to this.) Wounds and burns, however, provide more direct access to the circulation. Again, solubility as well as other factors (e.g. tissue reactivity and particle size) affects the absorption from a wound. Once internalized, radionuclides distribute in the same way as their nonradioactive counterparts. Depending on the element, it may be evenly distributed through the body (e.g. tritium or cesium) or concentrated

in particular organs (e.g. iodine to thyroid, uranium to bone and kidney). Elimination of absorbed radionuclides occurs primarily through the urine or secretion via the bile into the intestine.

### 2.3 Current Status of Medical Countermeasures

Although no drugs have yet been specifically approved for treatment of ARS, the medical approach to radiological accidents and our knowledge of the response to clinically used whole-body radiation have provided insights into regimens that are likely to be effective. For internal contamination, three countermeasures have been approved: potassium iodide (KI) to block the uptake of I131, Prussian blue to enhance the excretion of cesium, and Ca- and Zn-DTPA (diethylenetriaminepentaacetic acid) to chelate the transuranic elements. A number of reviews and manuals provide guidance for medical management of radiation injury [3–5, 7–9]. In contrast to accidents, where the few victims receive intensive clinical care from a medical staff knowledgeable about radiation injury [3], mass casualties pose serious logistical challenges. Breakdowns in transportation, communication, and access to medical care [10–12] are possible. Thousands of patients with poorly defined radiation exposures will converge on the hospitals. Extensive medical support (e.g. antibiotics and platelet transfusions) may not be available. A licensed drug for ARS that is safe and efficacious even in the absence of ancillary care is essential. Nonmedical personnel should be able to administer the agent on a schedule that is logistically achievable. An ideal drug will be inexpensive and stable without any special storage requirements to allow long-term storage even if refrigeration is unavailable. These ideals are yet to be attained.

The cytokine granulocyte colony-stimulating factor (G-CSF) (Neupogen) is currently the pharmaceutical most likely to be recommended for hematopoietic reconstitution following radiation injury [3, 7, 13–15]. Neupogen and the pegylated form of G-CSF (Neulasta) are Food and Drug Administration (FDA) approved for treatment of severe neutropenia that occurs with chemotherapy for cancer. Neupogen received investigational new drug (IND) status for treatment of radiation injury and can now be used if an emergency waiver is authorized [16]. Neupogen must be stored under refrigeration and must be injected subcutaneously for several days (up to 2 weeks) starting as soon as possible after radiation exposure. The recommended dosage of Neulasta is a single subcutaneous injection [3]. Both Neupogen and Neulasta can cause moderate bone pain. Symptomatic treatment with antibiotics, antifungals, blood transfusions, intravenous fluids and electrolytes [3, 4, 7], and platelet transfusions [17] are generally necessary, as well.

Accidents have taught us that, in addition to hematopoietic effects, GI damage is usually present after radiation injury as well. With partial-body exposures, GI effects may actually be the more critical component of ARS because shielding of marrow-producing bones spares critical stem cells and promotes recovery of neutrophils and other cells. Kepivance (palifermin), a modified keratinocyte growth factor (KGF), recently has been approved by FDA to reduce the incidence of mucositis after radiation therapy followed by stem cell rescue. For this indication, palifermin is administered as a daily injection for several days. As with Neupogen, the route of administration poses logistical issues for mass casualties.

In the event of a radiological/nuclear terrorist attack, first responders, remediation workers, and given advanced warning, the resident population, would benefit from a radioprotectant to prevent the effects of ionizing radiation. A radioprotectant given to

healthy individuals needs to be long-lasting, easily self-administered, and with very low toxicity. Currently, nothing of the kind is available. Amifostine has been shown to be an effective radioprotectant in animals, and it is approved as a preventive measure for xerostomia with clinical radiation, but its side effects of hypotension and nausea limit its usefulness [18].

Current treatment of internal contamination aims to dilute, block, or remove the radionuclides [5]. Nonpharmaceutical approaches can be used to minimize absorption. This includes pulmonary or gastric lavage, emetics, or enemas. Excretion of tritium can be enhanced by increasing oral fluids. In the event of release of radioactive material from a nuclear reactor, KI will be used to prevent radioiodine from accumulating in the thyroid [19]. To be effective, KI must be administered within a few hours of exposure. Radioactive iodine has the most serious effects on the thyroid of children and young adults. Adults above 40 years show little benefit from treatment [20, 21]. Prussian blue, ferric hexacyanoferrate, when administered orally, enhances fecal excretion of cesium and thallium by means of ion exchange. It was used effectively in the accidental dispersal of cesium-137 in Goiania, Brazil [22–24].

Clearly, there is a need for development of new pharmaceuticals for treatment of radiation injury. As our understanding of the mechanisms of radiation injury increases, new drugs can be targeted toward specific mechanisms.

## 3 APPROACHES TO INTERNAL CONTAMINATION

The effects of internalized radionuclides depend on the amount absorbed and the distribution in the body. As a result, the effects are agent specific. Countermeasures for internal contamination focus on expediting the removal from the body (decorporation) or protecting their primary site of activity. Decorporation is generally less effective if the radionuclide has already distributed to target tissues. Because of this, early treatment is usually more efficacious. Although there are FDA-approved treatments (Prussian blue, DTPA, and KI) and therapeutic approaches (e.g. lavage, emetics), gaps exist regarding treatment for internalized nuclides. Yet, research into the development of new decorporation and blocking agents has been very limited over the past couple of decades.

### 3.1 Blocking Agents

KI is the prototype for a countermeasure that blocks the site of activity. The primary site of toxicity of iodine-131 is the thyroid gland, increasing the risk of thyroid cancer [19, 21]. Nonradioactive KI displaces the radioactive element, thereby protecting the thyroid gland. Similarly, calcium gluconate can be used to prevent strontium binding at the bone surface by competing with calcium ions at binding sites [25, 26]. Through this mechanism it has some efficacy as a treatment for internal contamination from inhalation of radioactive strontium.

### 3.2 Decorporation Agents

DTPA chelates many heavy metals to form a water soluble compound that is excreted through the kidneys. The disadvantages of this approved therapeutic approach is the requirement for intravenous injection and the toxicity associated with prolonged

exposure to the chelator, which can cause trace metal deficiencies. Aerosol formulation of Ca-DTPA for use in a nebulizer is also available. This approach may be effective when used soon after inhalation exposure if lung function is normal. Oral delivery DTPA would be logistically easier to use in a mass casualty setting [27].

Prussian blue given orally enhances the elimination of cesium that is ingested or released through the bile into the GI tract. Through this mechanism, it reduces the biological half life of the element. In patients treated in Goiania, the half life was reduced from 80 days in untreated adults to 26 days with Prussian blue treatment [28].

Blocking absorption through the GI track is an effective strategy for Sr ingestion. Alginates have traditionally been used to treat internal contamination with radioactive strontium [29, 30]. Alginates are substances obtained from brown sea algae and sodium alginate binds tightly with strontium, significantly reducing absorption in the GI tract. The high viscosity of the alginates makes them difficult to ingest and limits their usefulness. Attempts to incorporate alginates into bread has had limited success [30]. Ingested strontium absorption can also be significantly reduced by aluminum phosphate gel and by barium sulfate, when used soon after exposure [5]. Sodium bicarbonate ($NaHCO_3$) can increase the excretion of uranium by alkylating the urine, creating a nontoxic uranium complex, which is promptly excreted.

More recent efforts are exploring new chelating agents such as catecholicpolyaminopolycarboxylate ligands 9501 and 7601 for thorium [31] and hydroxypyridinonate (HOPO) ligands such as 3,4,3-LIHOPO for plutonium and other actinides [32–34] and the biphosphonate, ethane-1-hydroxy-1,1-biphosphonate (EHBP) for uranium [35]. The HOPO ligands have the advantage of having oral efficacy [32, 35].

## 4 ARS CASCADE: TARGETS FOR COUNTERMEASURES

Ionizing radiation deposits much of its energy in biological tissue through the generation of free radicals in the aqueous environment. These very reactive free radicals damage the lipids, proteins, and DNA, which are integral to the function of cells. As a consequence of this damage, intra- and intercellular signaling can be impaired. An inflammatory cascade of events is initiated (Table 1). The cell cycle signals, as well as other cellular activities, are disrupted. Death of mitotic cells causes the loss of progenitor cells in bone marrow and in the crypts of the GI tract, resulting in neutropenia, thrombocytopenia, anemia, and loss of gut integrity. With increased susceptibility to infection, bleeding, and loss of fluid and electrolytes, death occurs. Countermeasures are being developed to address each step of this cascade (see Table 2).

### 4.1 Free Radical Damage

Through deposition of its energy in the aqueous environment of biological tissue, $\gamma$ radiation generates free radicals that mediate the injurious effects. Higher LET (linear energy transfer) radiation such as $\alpha$ radiation is more likely to cause direct damage to the biological tissues rather than the free radicals that cause indirect damage. Free radicals are damaging to the macromolecules of biological tissues. Free radicals produce DNA strand breaks and altered bases, which if not repaired impact cell activity. Lipid peroxidation of polyunsaturated fatty acids disrupts the lipid bilayers that comprise the

**TABLE 1 The Cascade of Radiation Injury and Targets for Countermeasures**

| | | | | |
|---|---|---|---|---|
| **Radiation Exposure** | | | | |
| Damage: | Free radical generation | Damaged macromolecules affect signaling pathways | Cell death, failure to proliferate, progenitor cell depletion | Organ failure, bacterial translocation, sepsis, and death |
| Goal: | Prevent lipid peroxidation, DNA damage, protein oxidation | Prevent apoptosis, restore proper cell signaling | Stimulate proliferation of surviving progenitor cells | Prevent infection and lethality |

cell membranes. Protein thiols are particularly sensitive to free radicals; their oxidation can affect many cell functions.

Because free radicals are a normal part of oxidative metabolism, the body has evolved antioxidant mechanisms to mitigate the damaging aspects of free radical generation. Superoxide dismutase (SOD) modifies superoxide ($O_2^-$) to produce hydrogen peroxide and water. Removal of the peroxide is also important since it can interact with metals to create the extremely reactive hydroxyl radicals ($OH^\bullet$). Catalase converts hydrogen peroxide into water and oxygen. Glutathione (GSH) peroxidase expends peroxide in the oxidation of a GSH to glutathione disulfide (GSSG).

Interventions at this level of the cascade of injury are usually either free radical scavengers or enzymatic mimics.

***4.1.1 Free Radical Scavengers.*** The earliest radiation countermeasures focused on the free radical scavenging ability of aminothiols [18, 36–38]. Unfortunately, although cysteine, the first aminothiol radioprotectant, was efficacious, it caused nausea and vomiting that precluded its use [39]. In the 1960s, Walter Reed Army Institute of Research conducted an intense search for an effective radioprotectant. Among the most promising compounds produced was WR2721, also known as *amifostine*. Amifostine has been approved as a preventive measure for xerostomia with clinical radiation. As with cysteine, however, the associated hypotension and nausea have limited its usefulness in healthy individuals at risk of radiation injury [18]. In addition, amifostine has a short duration of effectiveness, requiring injection within 30 min of exposure. More recent studies have explored different formulations and dosing of amifostine that might improve its usefulness. Reducing the administered concentration reduced the toxicity while sustaining some efficacy but still only within a very short time window [40]. Use of a slow release formulation (implanted pellets) broadened the time window, up to a couple of hours in the mouse, but toxicity was still a problem [40]. Reformulation of amifostine with nanoparticles that allowed oral administration showed some measure of success [41]. Although

**TABLE 2 Selected Drugs in Development for Acute Radiation Syndrome**

| Drug | Endpoint(s) | Comments |
|---|---|---|
| | **Antioxidants** | |
| Amifostine | FDA approved for mucositis | Significant toxicity |
| Alpha tocopherol | Survival in mice | |
| Tempol | Survival in mice | IND for radiation-induced alopecia; systemic toxicity |

| OK-432 | Survival in mice | |

not quite as effective as the injected amifostine, treatment with the oral nanoparticles 1 h prior to lethal radiation exposure conferred significant improvement in the 30-day survival of mice [41]. Additional assessment and optimization is necessary before this approach can be implemented.

Naturally occurring antioxidants have attracted attention because of the expectation of low toxicity [see 37, 42 for reviews]. Among the most promising agents to date are the vitamin E analogs. $\alpha$-Tocopherol, for example, reduces lethality in rodents when administered prophylactically or therapeutically [43–45]. A single subcutaneous injection of 400 IU given 24 h prior to lethal irradiation shifted the 50% lethal dose from 8.96 to 11.14 Gy (a dose reduction factor, [DRF] of 1.23) [46]. The radioprotective action of $\alpha$-tocopherol has long been attributed to its antioxidant activity [47], protecting membranes from radiation damage [48] by inhibiting lipid peroxidation [49]. In addition, $\alpha$-tocopherol and its analogs decrease free radical- and radiation-induced DNA damage [37, 50, 51]. Non-antioxidant mechanisms [52, 53] such as inhibition of protein kinase C [54] also have been proposed for the efficacy of $\alpha$-tocopherol as a radioprotectant.

***4.1.2 Antioxidant Enzymes.*** SOD, catalase, and GSH peroxidase are effective natural defense mechanisms for free radical injury following radiation exposure. As proteins, however, they are not readily administered as drugs. Several laboratories have been exploring approaches to use these enzymes through novel delivery systems [55–58]. For example, proof of principle for gene therapy was generated in an *in vitro* study where retroviral SOD gene transfer decreased DNA fragmentation and increased clonogenic survival [58] in irradiated murine hematopoietic progenitor cells. In a mouse model, liposomes were used to deliver the SOD gene to the esophagus or to the lungs. This treatment increased survival after thoracic irradiation [55, 56].

Another alternative is the development of small compounds that mimic the antioxidant enzyme activity [59–63]. One example of this approach is the development of nitroxides such as Tempol. These nitroxides are small molecules that act as an SOD [64]. When mice were injected intraperitoneally, 5–10 min prior to irradiation, the LD50/30 shifted from 7.84 to 9.97 Gy, corresponding to a DRF of 1.27 [65]. However, hypotension and epileptic activity were associated with the administration of Tempol [66, 67]. Several other nitroxides have been tested and Tempol-H (the reduced, hydroxylamine form of Tempol) was found to provide similar radioprotection with fewer hemodynamic side effects [61]. Recently a new SOD-catalase mimetic Eukarion-189 (EUK-189) was tested for its effects against radiation damage in the rat. Intraperitoneal injection of EUK-189, 1–2 h after lung irradiation reduced the formation of micronuclei in lung fibroblasts, reflecting reduced DNA damage [63]. Additional studies will be necessary to assess its potential as a countermeasure for ARS.

Selenium, a nutritional requirement in trace amounts, is present at each of four active sites of GSH peroxidase [68] and is necessary for the enzyme's activity. Selenomethionine injected intraperitoneally, any time between 24 h and 15 min prior to a lethal radiation exposure improved the 30-day survival [69]. Selenium appears to synergize with vitamin E. Together they are more effective than either alone in promoting survival from lethal radiation exposure [37]. The combination of injected sodium selenite and vitamin E for 10 days prior to radiation normalized the levels of blood GSH, GSH peroxidase, SOD, and plasma lipid peroxides after exposure [70]. The actual mechanism by which selenium might confer a radioprotective effect is not yet known; possibilities under consideration are direct induction of GSH and a mimetic effect of the enzyme [37].

## 4.2 Altered Cell Signaling

As a consequence of radiation exposure and the resulting damage, a variety of intracellular and extracellular signaling pathways [71–74] are activated. Signals that trigger apoptosis, cell cycle arrest, and cell repair provide opportunities for the cell to either recover from the damage or die. Therapeutics are being developed to prevent apoptosis and thereby, promote survival of progenitor cells. Targets for this strategy can be the upregulation of nuclear factor kappa-B (NF$\kappa$B), which usually acts to enhance cell survival. Alternatively, drugs may be designed to block the proapoptotic pathways, such as those involving p53 or p73. Another approach for countermeasure development is to trigger cell cycle arrest to allow time for cell repair and to promote survival of progenitor and stem cells. In addition, radiation causes functional changes in growth factor receptors, such as members of the ErbB family and tumor necrosis factor $\alpha$ (TNF$\alpha$) and transforming growth factor $\beta$ (TGF$\beta$) receptors, which affect proliferation, growth, and apoptosis [71]. These receptors can serve as targets for new drugs.

Radiation also initiates an inflammatory response with the release of proinflammatory cytokines (induced, in part, by NF$\kappa$B) and other messengers. Countermeasures can intervene in the stimulated inflammatory responses. Included in this approach are modulators of heat shock protein, iNOS (inducible nitric oxide synthase), prostaglandins, and thrombin [72, 74, 75].

***4.2.1 Stimulation of Antiapoptotic Pathways.*** Several drugs are currently in development that are designed to block apoptosis. These include agents with direct activity on the apoptotic signaling pathways and drugs that activate the pathways through receptor mechanism (e.g. toll-like receptors, TLRs).

ON01210 is a dual kinase inhibitor of Chk2 and c-Abl that reduces radiation-induced p73 expression and apoptosis *in vitro* [76]. When injected prior to irradiation, it has been shown to enhance the survival of mice [77]. Activation of toll-like receptor 5 (TLR5) releases NF$\kappa$B and stimulates the innate immune system [78–80]. Acting through TRL5, CBLB502, a derivative of the flagellin secreted by *Salmonella typhimurium*, can promote survival from a lethal radiation dose in nonhuman primates when injected prior to exposure [81, 82]. Through interaction with TLR9, CpG-ODN (cytosine-phosphate-guanosine oligodeoxynuclides) mimics bacterial DNA to stimulate the innate immune system and activate NF$\kappa$B [83, 84]. Preradiation treatment of mice with CpG-ODN improved 30-day survival [85].

***4.2.2 Other Pathways.*** Genistein is a soy-derived isoflavone that inhibits protein tyrosine kinase acting through the ErbB-2 pathway [86]. Genistein, injected subcutaneously 24 h prior to radiation, enhanced the 30-day survival of mice with a DRF of 1.16 [87]. No toxicity was observed, even with doses more than 10 times the radioprotective dose. Studies in mice demonstrate that oral administration is also effective in promoting survival when given for 4–7 consecutive days prior to radiation exposure [88, 89]. The survival benefit conferred by Genistein was related to the protection of the hematopoietic progenitor cells in the bone marrow and accelerated recovery of circulating neutrophils and platelets [90].

Endothelial thrombomodulin (TM) plays an important modulatory role in endothelial microvasculature. Through interaction with Protein C, it has anti-inflammatory properties; by binding thrombin, it suppresses coagulation [72, 91]. Clinical and animal studies show that ionizing radiation reduces intestinal endothelial TM down to 10–15% of unirradiated tissue levels [92, 93]. The decrease correlates with the severity of structural and functional tissue injury [93, 94]. Statins, used clinically to lower cholesterol, appear to have some promise in modulating this pathway and mitigating the effects of radiation. In endothelial cells *in vitro*, statins upregulate TM [91, 95], protect against radiation-induced cell death [96], and reduce levels of proinflammatory cytokines induced by radiation [97]. *In vivo*, they protect the intestines [98] and lungs [99] from the effects of radiation after localized exposure. The TM-Protein C pathway and the possible role of statins as radiation countermeasures require additional attention.

The prostaglandin, 16,16-dimethyl prostaglandin E2 (dmPGE2), has shown significant survival benefit in the mouse. DRFs between 1.25 and 1.72 have been reported [100–103] after preradiation administration in various strains of mice. The effects were even more dramatic when dmPGE2 was used in combination with other agents such as WR2721 [101]. Although effective, the toxicity of the drug may preclude its use. Toxic side effects include diarrhea, reduced locomotor activity, and sedation [100, 102, 104].

### 4.3 Progenitor Cell Depletion

Disruption of cell signaling pathways leads to organ failure from cell death, failure of cells to proliferate, and progenitor cell depletion. In the bone marrow, the hematopoietic progenitor cells are very vulnerable to damage from ionizing radiation and the mature cells are much less so. As a result, the cells are maintained in the circulation until the mature cells complete their normal life span (8–10 days). As these cells die, fewer cells are available to replace them and the overall population drops. It can be several weeks before the cells reach their minimum level. The rate and severity of the cell loss is radiation dose dependent. The loss of neutrophils increases susceptibility to infection. Platelet loss results in deficits in coagulation and concomitant hemorrhage.

In the gut, the progenitor cells of the intestinal villi, crypt cells, also are sensitive to radiation. As the crypt cells die, mature cells are not available to repopulate the villi. In addition, there is injury to the microvasculature of the mucosa and submucosa. These events occur within 5–10 days of irradiation, depending on the radiation dose. At the lower ranges of GI syndrome, damage to the functional properties of the epithelial cells can occur, which can lead to a loss of fluids and electrolytes.

Countermeasures at this level of the cascade of radiation injury are usually designed to stimulate the proliferation and differentiation of surviving progenitor cells.

#### *4.3.1 Cytokines: G-CSF and GM-CSF.*

A number of studies have demonstrated the efficacy of G-CSF and granulocyte-macrophage colony-stimulating factor (GM-CSF) in animal models. They are approved for use for neutropenia associated with cancer chemotherapy and have been used off-label for several radiation accident victims [14]. In rodents, [105–107] the cytokines have been shown to increase survival after an otherwise lethal radiation exposure and to speed the recovery from myelosuppression.

These observations have been extended to radiation injury in nonhuman primates and canines. In lethally irradiated dogs [108–110] recombinant G-CSF, started within a few hours of radiation exposure and injected daily for about 3 weeks, reduced the duration of neutropenia and had a significant survival benefit compared to supportive care alone, with a DRF of approximately 1.5 [7]. The efficacy of G-CSF was lost if initial administration was delayed by a week [109]. Nash [111] found that, in the dog, GM-CSF was much less effective than G-CSF both in preventing lethality and promoting hematopoietic recovery.

As in the canine model, recombinant human granulocyte colony-stimulating factor (rhG-CSF) was found to significantly reduce the duration of neutropenia [112] in another model. Nonhuman primates (NHPs) were exposed to 7-Gy $\gamma$ radiation, and received rhG-CSF subcutaneously daily, beginning 1 day after radiation for 23 days. All irradiated animals received clinical support (including antibiotics, blood transfusions, and fluids). Although the cytokines (GM-CSF and G-CSF) significantly shortened the period of neutropenia, whole blood or platelet transfusions were required to prevent lethality. Addition of thrombopoietin (TPO) to the treatment protocol eliminated this requirement [113, 114]. In contrast to prior studies in the dog, a study in the NHP demonstrated efficacy of GM-CSF that was not lost if treatment was delayed for 7 days [115].

Although G-CSF and GM-CSF are tolerated fairly well by patients, they do have occasional severe side effects that mandate supervision by a physician [116]. The requirement for multiple injections has been addressed by a reformulation into a pegylated form that can be injected on a weekly basis instead of daily [3].

As noted above, the combined use of G-CSF and TPO has been proposed to enhance platelet recovery [117]. Current investigations are exploring additional combinations of cytokines designed to stimulate recovery of multiple hematopoietic lineages (granulocyte-macrophage, erythrocytic, thrombocytic, etc. ) [117].

***4.3.2 Other Cytokines.*** Interleukin 1 (IL-1) is a stimulator of normal hematopoiesis, acting both directly on the primitive stem cells and indirectly through release of other factors. IL-1 has been shown to be effective against radiation injury in the mouse primarily when administered before radiation exposure [118–127] and to some extent when administered early after exposure as well [122]. Because of its pyrogenic and inflammatory properties [118], clinical applications for radioprotection are limited. In an effort to produce a molecule that maintains the functional domains but lacks the toxicity of IL-1, a synthetic nonapeptide was developed that mimics immunostimulation in vivo without the inflammatory effects [128]. Preliminary studies in a mouse demonstrate potential efficacy as a radioprotectant in mice exposed to 8.5 Gy irradiation [129].

KGF has recently been approved for treatment of mucositis after radiation therapy. Since it promotes the regeneration of crypt cells in GI mucosa, it has been proposed as a possible therapy for the GI syndrome after whole-body irradiation. Preliminary assessments on the survival of the irradiated mouse show promise [130–132].

***4.3.3 Other Immunomodulators.*** 5-Androstenediol (5-AED) is a naturally occurring, nonandrogenic adrenocortical steroid. It has been shown to promote survival in both mice and nonhuman primates [133–137]. In mice, the 50% lethal dose of $\gamma$-radiation was shifted from approximately 9.5 to 12 Gy, corresponding to a DRF of 1.26 [133]. In nonirradiated mice, 5-AED increased the numbers of circulating neutrophils and platelets; histologically, bone marrow showed marked myelopoiesis [133, 138]. Administration of 5-AED resulted in increased numbers of NK (natural killer) cells and their activation [133]. In addition, the steroid promoted resistance to infection when radiation was combined with a bacterial [133] or viral [136] challenge. With administration 24 h prior to sublethal irradiation of mice, 5-AED mitigated the expected neutropenia and thrombocytopenia; the AED-induced changes in blood elements in irradiated animals persist for at least several weeks [138]. In an *in vitro* model, 5-AED enhances clonogenic survival of irradiated human hematopoietic progenitor cells through NF$\kappa$B-dependent pathways [139]. The efficacy of 5-AED on radiation injury has been confirmed in nonhuman primates. 5-AED reduced the magnitude and duration of neutropenia, thrombocytopenia, and anemia when given once a day for 5 days starting within several hours of radiation exposure [137]. In addition, preliminary data demonstrate that 5-AED provides survival benefit in nonhuman primate. Since 5-AED is a small, stable molecule that, to date, has no demonstrated toxicity, it may provide a viable alternative to G-CSF as a treatment for the hematopoietic syndrome.

Beta glucans are polysaccharides that act as nonspecific immune system stimulants. Particulate glucan-P and soluble glucan-F have shown significant capabilities of survival enhancement after lethal radiation in the mouse [140–142]. The most pronounced effects were observed when glucan was administered 1 day before irradiation. The enhanced survival in glucan-treated mice in part appeared to be mediated by an enhanced resistance to the enteric pathogens that cause infection following radiation-induced hematopoietic and immune depression. Both glucan-P and glucan-F appear to function specifically by enhancing hemopoietic recovery, enhancing the recovery of peripheral blood white

cell and platelet numbers and increasing endogenous pluripotent hemopoietic stem cell numbers in sublethally irradiated mice. Glucan-P consistently offered slightly better protection than glucan-F at all radiation doses. More recently, Betafectin PGG-glucan (poly-[1-6]–D-glucopyranosyl-[1-3]–D-glucopyranose glucan), a beta-(1,3)glucan with broad-spectrum anti-infective activities, was tested on hematopoietic recovery in the irradiated mouse and cyclophosphamide-treated cynomolgus monkeys. PGG-glucan accelerated hematopoietic recovery and reduced the duration of the neutropenia in both models [143]. PGG-glucan was also found to mobilize peripheral blood progenitor cells (PBPC) that would promote reseeding of ablated bone marrow [144].

OK-432 is an immunomodulator derived from a killed streptoccocus preparation. It has been tested in clinical trials as an anticancer agent [e.g. 145]. Data from animal models suggest that it may provide survival benefits when used either alone or in combination with other agents after radiation exposure. Several studies demonstrated an increase in the number of animals surviving a lethal radiation dose [146–151]. With a single treatment given to a mouse immediately after radiation, the 50% lethal dose shifted from 7.55 Gy to 8.45 Gy. The efficacy was significantly improved when multiple injections of OK-423 were given, every other day through day 11. Under these conditions, the LD50 was 9.56, a DRF of 1.26. A delay in the onset of treatment course for 72 h was less effective but still significantly increased survival [150]. OK-432 in combination with other agents such as G-CSF [149] and antibiotics [151] improved the efficacy.

### 4.4 Organ Failure and Infection

Even with the use of efficacious radiation countermeasures that intervene at various steps in the cascade of injury, additional interventions are likely to be necessary. G-CSF for example does not reverse the thrombocytopenia, necessitating platelet transfusions. Because of the neutropenia and reduced integrity of the gut, sepsis is likely and antimicrobials are inevitably needed. These treatment regimens are briefly addressed here.

***4.4.1 Supportive Care.*** The availability of supportive care, even without any other countermeasures, can provide significant therapeutic efficacy. MacVittie [152] assessed the value of supportive care in irradiated dogs over a wide dose range. Antibiotics with fluids, nutrition, and platelet transfusions provide a DRF of 1.3 in irradiated canines [152]. The radiation dose that caused 50% lethality increased from 2.59 Gy to 3.37 Gy with supportive care alone. Studies demonstrate a similar shift in the LD50 in nonhuman primates with supportive care [113, 115, 153, 154] compared to historical controls [155, 156].

Antibiotics by themselves can provide significant improvements in outcome following radiation exposure, since control of infection during the severe postradiation neutropenia is a limiting factor for survival [157]. The most effective antimicrobial therapy is directed toward both gram-negative and gram-positive bacteria, sparing indigenous intestinal anaerobic bacteria. In irradiated mice, the radiation exposure significantly reduces both aerobic and anaerobic bacteria in the gut within the first few days of exposure; but the aerobic bacteria rebound in about a week while the anaerobes stay depressed [158]. Translocation of these pathogenic organisms through the gut poses the risk of fatal bacteremia. An antibiotic strongly effective on both anaerobes and aerobes (e.g. metronidazole) increased mortality in irradiated mice [159] while quinolones promoted survival after lethal radiation, in part due to their ability to preserve the anaerobic gut flora [158, 160].

***4.4.2 Cellular Therapies.*** Bone marrow transplants and stem cell transplants can save lives in patients with malignant hematological conditions. Allogenic transplants have been performed in the treatment of a number of radiation accident victims [3, 161–165]. Despite transient engraftment with the transplanted cells, almost all patients showed autologous hematopoietic reconstitution. The benefits of cellular therapies have been difficult to validate; most do not survive. It is uncertain whether the transplants have had any impact on survival. The accident victims who showed hematopoietic recovery, died from failure of other organs [14, 166, 167]. In the 1999 accident in Tokaimura, Japan [14], two of the three victims received allogenic stem cell transplants. Although both began to show proliferation of the donor cells, this was only transient; their own cells eventually took hold. The impact on survival time is hard to assess. Advances in the technology may eventually allow production of adequate supplies of hematopoietic progenitor cells that can be easily administered without immunological complications. These approaches will need to be administered in combination with therapeutic approaches to enhance recovery of other organs.

## 5 ADDITIONAL TREATMENT CONSIDERATIONS

### 5.1 Radiation Quality and Dose Rate

Many disaster scenarios could involve high levels of neutrons mixed with $\gamma$ radiation. Unfortunately, far less is known about the effects of neutrons on hematopoiesis and immune function than about the effects of $\gamma$ radiation. Moreover, there are very few studies of pharmacological countermeasure efficacy in the context of neutron irradiation. Comparable clinical support (fluids, antibiotics, and platelets or whole blood) is more effective with gamma exposure (DRF = 1.3) compared to a mixed neutron/gamma field (DRF = 1.21) in dogs [152]. The radioprotectant effects of aminothiols [168–170], synthetic trehalose dicorynomycolate [171–174], and prostaglandins [175] have been examined in mice exposed to neutrons. A small number of studies have examined the effects of cytokines on animals recovering from acute whole-body neutron irradiation [115, 176, 177].

The dose rate of radiation exposure also can have a significant effect on the biomedical consequences, which would impact medical treatment. For the same total radiation dose, exposure at a lower dose rate has a sparing effect. Prolonging the dose rate significantly increases the LD50. At an exposure of 7 Gy/min the LD50 in mice was 7.88 Gy. At about 0.7 Gy/min, this increased to 8.5 Gy. With further reduction of the dose rate to 0.025 Gy/min, the LD50 increased to almost 11 Gy [see 178]. Although the effects of very low dose rates have been assessed particularly on the hematological response to radiation [e.g. 179], the biomedical consequences associated with dose rates that might be expected in a heavy fallout field (1–6 Gy/day) have not been well characterized.

### 5.2 Partial-Body Exposures

An exposure in an uncontrolled environment is likely to be nonhomogeneous because of the physical environment and partial-body shielding that would occur. Any shielding of bone marrow increases the probability of sparing progenitor and stem cells that can

repopulate the hematopoietic system and improve survival and recovery. The nadir of neutropenia correlated with the volume of irradiated bone marrow [180]. Recovery depends on the reseeding of the damaged bone marrow with cells from the protected marrow [181–184]. A myeloablative dose of 11.7 Gy to the upper body of the dog, which damages about 70% of the bone marrow, causes an increase in proliferation and differentiation of granulocyte/macrophage colony forming cells (GM-CFC) in the protected marrow. The reseeding becomes evident by day 7 with the appearance of progenitor cells in the ablated bone marrow [180, 183, 184]. The hematopoietic recovery continues for about 3 weeks but then levels off until a secondary increase begins about 4 months after the radiation exposure. It takes about a year for the marrow to fully repopulate in this dog model [180, 183, 184]. When only the lower body is exposed, ablating 30% of the bone marrow, the time course is the same [180]. Currently, research is exploring approaches to enhance the repopulation of the bone marrow by mobilizing cells from the spared marrow [13, 182, 185].

Because of the repopulation of progenitor cells from spared marrow, radiation doses that would be lethal if given as a total body exposure can be survived, even without treatment, with partial-body exposures. Hematopoietic reconstitution has been observed in accident victims with partial-body radiation exposure of up to 10–12 Gy [14]. Ultimate survival, however, may depend on the extent of damage to other organs.

### 5.3 Combined Injury

In the event of a nuclear or radiological incident, concurrent exposures of radiation with traumatic injuries, infectious disease, or toxins are likely. These combined injuries can dramatically exacerbate the lethality of radiation.

Traumatic injuries increase the mortality associated with the ARS [186–188]. In a mouse model, for example, a wound that by itself caused minimal lethality shifted the 50% lethal radiation dose from 9.60 Gy to 7.6 Gy, and had a dose modification factor (DMF) of 1.26. Similarly a minimally lethal burn had a DMF of 1.17 [188]. Radiation doses that by themselves were fully survivable become fatal when combined with a traumatic injury. The mechanism of synergism is not known but an increase in the susceptibility to infection and enhanced translocation of gut bacteria are thought to contribute to lethality [189, 190]. Radiation delays recovery from wounds [191]. Although closing a wound may reduce some of the synergistic effects [192], treatment (excision and closure) of a thermal burn may not provide the same benefit [193]. Because of these interactions, current recommendations are to perform any surgical procedures as soon as possible after radiation exposure; waiting can increase lethality [194–196].

Similarly, combined exposures to radiation and an infectious agent can be lethal even if neither insult by itself causes significant lethality. Since radiation impairs the immune system, susceptibility to infection increases. Animal studies demonstrate that after radiation exposure, fewer microbes are required to establish an infection and the clinical manifestations are more severe [133, 197–200]. For example, exposing sublethally irradiated mice to *Klebsiella pneumoniae* that caused 5% mortality without radiation elicited 100% mortality [133, 199]. The higher the radiation dose, the fewer microbes that were needed to induce lethality. Susceptibility to infection and mortality from *K. pneumoniae* increased within 1 day of exposure to $\gamma$ radiation and remains high for at least 2 weeks.

## 6 FUTURE RESEARCH DIRECTIONS

With the increasing concerns about radiological and nuclear terrorism, the requirement for adequate medical countermeasures has become a national research priority. Although few drugs are currently approved for treatment of radiation injury, many are in the pipeline. New efforts are beginning to focus on drugs directed at particular pathways in the cascade of radiation injury. As more is discovered about the apoptotic pathways and cell cycle checkpoints, new agents will be defined that can modulate these processes. With countermeasures directed toward specific targets, it may be possible to limit the toxicological side effects of more broadly effective agents. New delivery systems, such as slow release capsules or transdermal patches, may simplify the logistics of administration.

Current efforts are generally focused on single compounds. Using drug combinations may be an effective approach to limiting toxicity by reducing the dosage of each component of a cocktail. Because ARS is a spectrum of syndromes afflicting multiple organ systems, it is likely that multiple drugs will be needed to allow survival at the higher radiation doses. For example, combinations for both the hematopoietic syndrome and the GI syndrome are likely to be required. As prospects of survival at increasingly high radiation doses improve, the late effects of radiation such as fibrosis of the lung and kidney will need to be addressed. While some efforts in this area are ongoing, they have not been emphasized.

The current focus for radiation countermeasures has been on treating radiation injury alone. In future efforts, it will be important to consider many other factors that can modulate the radiation response and possibly affect the efficacy of the treatments. For most of the countermeasures under development, it is unknown if their efficacy will be affected by combined injury, neutron exposures, dose rates associated with heavy fallout fields, or partial-body exposures.

While much work remains to be done, the recent advances in the field demonstrate great promise for development of effective countermeasures for radiation injury.

# CHALLENGES TO MEDICAL COUNTERMEASURES AGAINST CHEMICAL, BIOLOGICAL, RADIOLOGICAL, AND NUCLEAR (CBRN) AGENTS

ANDREA MEYERHOFF

*GexGroup Inc, Washington, D.C., and Division of Clinical Pharmacology, Johns Hopkins University School of Medicine, Baltimore, Maryland*

## 1 BACKGROUND

The public health threat of biological and chemical agents has persisted for centuries; that of radiation-emitting and nuclear agents for more than a half-century. But it is only in the past decade that the pace of efforts to address these threats has accelerated to the point where we might now take a step back and evaluate what has been accomplished and, based on what we have learned, how we might proceed. This article first recognizes the unique challenges presented by the need for medical countermeasures against chemical,

biological, radiological, and nuclear (CBRN) agents and then examines early twenty-first century efforts to develop them. Because of both the 2001 occurrence of an anthrax release in the United States and the subsequent robust investment in medical countermeasures for this and other biothreat agents, a focus on biodefense will provide useful examples. Nonetheless the issues raised, with necessary modifications, pertain equally to other threat agents as well. The subsequent discussion of future directions for CBRN drugs and vaccine research is based on unanswered questions regarding countermeasure safety and efficacy.

## 2 THREATS, CHALLENGES, SOLUTIONS

In 1998, the US Centers for Disease Control (CDC), an agency of the Department of Health and Human Services (HHS) was charged by Congress to build the National Pharmaceutical Stockpile (NPS). Its purpose was to provide emergency medical supplies in the event of a terrorist attack or naturally-occurring epidemic. A wide range of medical material made up the NPS, including antibiotics, antitoxins, and chemical antidotes to be shipped to state and local authorities within 12 hours of the declaration of an emergency. Subsequently the name NPS was changed to the Strategic National Stockpile (SNS) [1, 2].

In 1999, the CDC, in concert with the intelligence community, identified the biological agents considered to be of greatest potential concern [3]. The resultant list was divided into three categories. The pathogens in Category A were thought to represent the highest risk, warranting surveillance and the availability of therapy or prophylaxis for diseases caused by them. The threats represented by Category A pathogens guided early efforts to build the NPS and later the SNS. They are presented in Table 1.

The evaluation of medical countermeasures against Category A pathogens presents unique challenges. The diseases they cause are rare or are known to contemporary physicians and public health officials only by historical reputation. Other diseases, while continued public health problems, occur in remote areas of the world where the collection of data and conduct of clinical trials are difficult. Further, it is unethical to introduce any of the agents into a human population for any purpose, including the evaluation of drugs or vaccines.

Until 2001, there had been 18 cases of naturally occurring inhalational anthrax reported in the United States. The events of 2001 resulted in an additional 11 cases [4]. Inhalational anthrax differs from many other diseases that result from exposure to Category A biothreat agents in that there was a large outbreak of human disease in 1979 in Sverdlovsk in the

**TABLE 1 Category A Biological Agents (US CDC, June 1999)**

| Organism | Disease |
|---|---|
| *Variola major* | Smallpox |
| *Bacillus anthracis* | Anthrax |
| *Yersinia pestis* | Plague |
| *Clostridium botulinum toxin* | Botulism |
| *Francisella tularensis* | Tularemia |
| Filoviruses/Arenaviruses | Hemorrhagic fever |

former Soviet Union. This is thought to have resulted from a leak at a military research facility and resulted in at least 66 deaths. After several years an international team of pathologists published their postmortem findings on these patients, thus expanding the knowledge on the course of the infection in humans [5]. A paucity of available information on treatments used meant that systematic study of any drugs given to these anthrax patients was not possible.

This rather sparse database on inhalational anthrax is one of the more robust ones for diseases caused by Category A pathogens. Naturally occurring smallpox was declared eradicated from the world in 1980 and last seen in the United States in 1947 [6]. Few physicians practicing today have seen a case. Pneumonic plague occurs naturally, but small foci of disease have been found in remote locations that make systematic study difficult.

Intentionally caused disease by a state actor or terrorist that deploys a biological weapon may differ from what occurs naturally by a number of variables including inoculum size, route of exposure, number of individuals exposed, and rate at which an infection progresses through a population.

Thus there is little precedent of the study of such rare diseases, and little regulatory precedent that sets safety and efficacy standards for the drugs and vaccines needed to treat or protect against these diseases. Even for inhalational anthrax, noted above to be the subject of some body of data on human disease, the size of the database is scant when compared with the thousands of patients usually enrolled in Phase III clinical trials to study drugs and vaccines for more common indications.

In 2000, the Food and Drug Administration (FDA), another HHS agency, approved the first antibiotic for use in an intentional biological release when it determined that ciprofloxacin (Cipro®) was safe and effective for the postexposure prophylaxis of inhalational anthrax. The approval was based on a surrogate human marker of efficacy (Accelerated Approval Regulations) and made extensive use of data from an animal model of disease [7]. At the time, also approved for anthrax were antibiotics in both the penicillin and tetracycline classes. The data for these two classes of drugs were developed in patients with naturally-occurring disease. The stockpiling of any drugs by the US government with the plan to deploy them in the event of an emergency necessitates regulatory oversight by the FDA. Thus any drug or vaccine deployed from the SNS must meet FDA standards of safety, efficacy, and manufacturing.

The 2001 terrorist attacks of September 11, and the release of anthrax through the US Postal Service soon afterward, resulted in a concerted effort to speed the development of the required CBRN countermeasures by the US Government. The Bioterrorism Act of 2002 created a new office within HHS, the Assistant Secretary of Public Health Emergency Preparedness (ASPHEP) which was charged with overseeing this effort. Post 9/11, the National Institutes of Health (NIH) budget for basic research for drugs and vaccines for bioterrorism and other CBRN threats experience rose five-fold to $1–2 billion per year [8]. In 2004, the passage of the Project BioShield Act gave to HHS new authorities and a special reserve fund of an additional $5.6 billion for advanced product development and procurement [9].

Among the new authorities accorded to HHS by the 2004 BioShield Act was the mechanism of Emergency Use Authorization (EUA) by the FDA. With the goal of streamlining the availability of needed medical countermeasures in an emergency, the EUA permitted for the first time, the use of a drug or vaccine prior to FDA approval, that is, the use of

an investigational agent outside of the Investigational New Drug (IND) regulations and without the requirement of obtaining prior, written, informed consent [10].

Another new regulatory mechanism introduced during this period was the 2002 finalization of the Animal Efficacy Rule by the FDA, which recognized the use of animal models to demonstrate efficacy of drugs and vaccines used for CBRN countermeasures [11]. While the animal model must be found by the FDA to meet certain scientific requirements of predictability in humans, by definition each model presents gaps in disease pathology and host response between animals and humans. Any use of such countermeasures in an attack on a human population must recognize these attendant gaps and the risk they present. The use of animal models to establish efficacy and support regulatory approval creates a need, arguably an imperative, to add to such knowledge with the study of the efficacy of any such medical countermeasure if it is used in a human population.

An older regulatory mechanism that became pertinent to CBRN countermeasures was the 1997 Accelerated Approval Regulations (also known as Subpart H) that permitted the use of surrogate endpoints, and therefore smaller studies, for the evaluation of needed drugs and vaccines. As noted above, it was this mechanism that was invoked in the 2000 approval of Cipro® for post-exposure inhalational anthrax.

All three of the regulatory mechanisms described above—EUA, Animal Efficacy Rule, and Accelerated Approval Regulations—require the collection of safety data -adverse events following the emergency use of the medical countermeasure [11].

Thus by 2004, with the passage of BioShield legislation, a unique development model had evolved for medical countermeasures for CBRN defense. Rather than the traditional market forces that drive most drug and vaccine development, federal policy and funding became the driver of CBRN medical countermeasure development. The federal government had become the developer, the procurer, and the regulator of these products.

In December 2006, the Pandemic and All-Hazard Preparedness Act was passed. This bill created the Biomedical Advanced Research and Development Authority (BARDA, also known as BioShield II). It also resulted in an additional $1.07 billion for medical countermeasure development for CBRN threats and influenza for fiscal years 2006–08. The legislation established HHS ASPHEP, renamed the HHS Assistant Secretary of Preparedness and Response (ASPR), as the lead authority for policy setting and procurement for CBRN medical countermeasures and made possible "milestone payments" to companies before actual delivery of the countermeasure to the stockpile [12]. While this provision was included as a means to encourage what was only modest industry participation in medical countermeasure development under Project BioShield, it has resulted in a highly unusual situation in drug development. A company may receive federal funds before it delivers the product, indeed before it receives regulatory approval for a product intended for the SNS.

While at the time of writing this HHS/ASPR efforts are understandably focused on what is now pandemic H1N1 influenza, a review of HHS BioShield/BARDA programs since their inception provides summary information on CBRN medical countermeasures funded and stockpiled to date. These are presented in Table 2.

Most recently the Obama administration has proposed a budget to combat pandemic influenza, which uses the remaining $3 billion of the original $5.6 billion of the BioShield special reserve fund [14]. If this plan comes to pass, it is unclear how much more funding HHS will provide to CBRN medical countermeasure advanced development and procurement.

[a]BARDA website describes these countermeasures as purchased by HHS for CBRN defense, however, they were not funded by BioShield/BARDA funds.

[b]Funded by CDC-Strategic National Stockpile.

[c]Funded by HHS 2001,$428 million for 155 million doses, non-BioShield/BARDA funds.

Newer regulatory pathways such as the Animal Efficacy Rule and EUA, may result in the use of these countermeasures without the development of data and the use of informed consent that the medical community and the general public have come to expect. Thus with the passage of the 2006 BARDA legislation it is possible for the federal government to purchase and deploy medical countermeasures at a stage far earlier in product development than has been traditionally the case. A new pathway for medical countermeasure development and use is the result and new challenges arise. The following discussion

proposes research questions to meet these challenges in medical countermeasure safety and efficacy.

## 3 FUTURE RESEARCH DIRECTIONS

Growing threat awareness in the late 1990s coupled with the terrorist attacks of 2001—9/11 and the anthrax mailings—drove the development of new funding mechanisms and new regulatory pathways to speed medical countermeasure development. Subsequent efforts recognized the similarities between public health needs for disease caused by the intentional release of a CBRN agent and epidemics of naturally occurring disease such as Severe Adult Respiratory Distress Syndrome (SARS) and influenza. The use of these new funding streams and alternate regulatory pathways raise new questions about how best to evaluate countermeasure safety and efficacy.

### 3.1 Medical Countermeasure Safety

The need for accelerated development of medical countermeasures has made use of the existing Accelerated Approval Regulations and driven the finalization of the Animal Efficacy Rule as well as the legislation of the EUA. All three of these mechanisms may permit the development of efficacy data and therefore countermeasure availability with the study of smaller numbers of patients than would otherwise be the case. Accelerated Approval Regulations, developed originally to address the critical need for drugs to treat HIV, permit the use of a validated surrogate marker of efficacy, for example, diminution of HIV viral load rather than survival rate. This results in statistically sound data with a far smaller sample size than would be necessary to recruit for a study of survival benefit [15]. The Animal Efficacy Rule permits the development of efficacy data in animal models, though it does require safety study in humans [16], and EUA is determined on a case-by-case basis depending on the safety and efficacy data available at the time of the emergency requiring the countermeasure [10]. In all three cases, there is a requirement for human safety data, but there are no thresholds that specify how much is "enough". How do we determine the necessary size of a safety database for medical countermeasures for use in a public health emergency?

A look at the anthrax attacks of 2001 provides some context in which to consider this issue. During a period of several weeks in the fall of 2001, somewhere between 10,000 and 33,000 individuals received the antibiotic ciprofloxacin. The total number of individuals to receive any antibiotic during this period was larger. The drugs that were used in this public health emergency—ciprofloxacin and members of the penicillin and doxycycline classes—were well-studied and had all been in use for decades. Ciprofloxacin, the newest of these three, had been on the market since 1987 and at the time of the anthrax mailings given to approximately 300 million ($3 \times 10^8$) individuals worldwide. An expansion by the largest estimate of individuals exposed to this drug (33,000 or $3 \times 10^4$) is a relatively small one and would not be expected to greatly increase the chance of uncovering new or unanticipated safety problems. However it should be noted that even in the case of a well-studied and well-characterized drug like ciprofloxacin, the prolonged regimen of 60 days required for postexposure prophylaxis of inhalational anthrax was found to be associated with more frequent side effects [17].

Indeed even when rigorous premarketing trials have enrolled the traditional cohort of thousands of patients, there are instances when widespread market distribution and the subsequent expansion of the safety population has revealed rare, adverse events. There are two such instances in which vaccines were subsequently removed from the market. The rotavirus vaccine, RotaShield, was tested in premarketing clinical trials that enrolled 11,000 ($\sim 10^4$) patients and in 1998 was licensed by FDA to prevent diarrhea. Nine months and about 1 million ($10^6$) doses after licensure, RotaShield was associated with an unexpectedly high rate of intestinal intussusception in pediatric patients and shortly thereafter withdrawn from the US market [18]. Also, in 1998, the recombinant Lyme disease vaccine, LYMErix, was licensed by FDA. Premarketing trials enrolled about 10,000 patients ($10^4$). Nineteen months after licensing and the distribution of 1.4 million ($10^6$) doses, questions arose about the possibility that the vaccine caused or exacerbated arthritis. Though a cause-and-effect relationship could not be established, persistent concerns about this safety issue coupled with poor sales resulted in a withdrawal from the market in 2002 [19]. These cases are presented to demonstrate that even with premarket safety evaluation in a traditional cohort of $10^3$ or $10^4$, the expansion of the size of the population exposed to a drug or vaccine that results when the product is marketed, or deployed in a public health emergency, carries with it an inherent risk of uncovering new adverse events simply by enlarging the number of individuals who receive the product.

When we consider the possibility of a highly accelerated expansion of the size of a population likely to be exposed to a new countermeasure in the event of a public health emergency, we may anticipate an even greater likelihood of uncovering a previously unseen adverse event. The rate at which patient-exposures accrue may also affect the likelihood of uncovering a new adverse event not seen in premarket study. To take a simple example, a drug that is used in 10 patients per month will require 100 months of use to expand the safety database by 1000 patients. In a public health emergency, one might imagine the same drug may be used in 10 new patients per day, thus accruing an additional 1000 patients in 100 days or 3 months. If adverse events are reported, a clustering over 3 months is far more likely to be attributable to the new drug than a more attenuated series of reports over 100 months that may never pass the threshold of "background rate."

So how do we strike a balance between availability of needed countermeasures and adequate safety study such that the risk of unforeseen serious adverse events is minimized? What is also unique about CBRN medical countermeasures stockpiled by HHS compared with drugs developed for the commercial market is that with CBRN countermeasures, the denominator is known from the beginning. As shown in Table 2, BioShield/BARDA contracts specify a certain number of doses. Risk-benefit balances differ for every countermeasure. Pharmaco-epidemiologic tools may be invoked to assist in answering such questions as: "What is the number of patients in a safety database required to give adequate support to the number of doses of a countermeasure that the government seeks to purchase? Can we assess the risk of uncovering unforeseen serious adverse events for an investigational medical countermeasure, studied in perhaps 500 ($10^2$) or 1000 ($10^3$) patients, and intended to be given in an emergency to a population of 10,000 ($10^4$), 100,000 ($10^5$), or even millions ($10^6$ or more) of individuals? How do we factor in the rate of deployment when we assess such risk? Should available safety data guide the number of doses of a countermeasure that the government intends to purchase?

Should safety database requirements be linked to the number of doses the government seeks to purchase?"

These questions are made even more acute by the prospect of the use of the EUA, in which the federal government may decide to administer a drug or vaccine that is still in its investigational stages without informed consent. Generally the design of Phase III trials, including the size of the premarket safety database, is the subject of discussion between the manufacturer and FDA. However, when the federal government is the procurer of the product, in effect an investor in the manufacturer, public health policy makers become a third party to such discussions, which may then be an issue beyond the regulatory mandate of FDA. Recourse to established pharmaco-epidemiologic tools will greatly aid such decision-making and enhance preparedness.

### 3.2 Medical Countermeasure Efficacy

Because the diseases caused by CBRN threat agents are rare and ethical considerations preclude the intentional introduction of these agents into a human population for the purposes of scientific investigation, the use of animal models under the Animal Efficacy Rule has been and is expected to be a commonly used regulatory pathway for approval of such medical countermeasures. While animal models provide insight into human disease, the accuracy of such models depends on the similarity of the disease and the immune response in animals compared to humans. The only opportunity to evaluate efficacy in the human population of a medical countermeasure approved under the Animal Efficacy Rule may be the real test of a CBRN release.

Countermeasure development invariably opens new avenues of inquiry about a drug or vaccine, and no amount of planning, no matter how meticulous, can anticipate the specific public health needs of an ongoing attack or outbreak. Every effort should be made to learn more about such medical countermeasures when used in humans, and preparedness for a CBRN release, influenza, or any other public health emergency should include prospectively designed clinical trials to evaluate the performance of these countermeasures in the human population for whom they were intended. Even when an emergency calls for the use of countermeasures that have been studied previously in humans, the deployment of such a countermeasure represents a unique real-time opportunity, perhaps an imperative, to add to our knowledge base [20].

One of the stated goals of BioShield was to bring the benefits of advances in biotechnology to counterterrorism [10]. Indeed, since the program was launched, there have been government purchases of a next-generation smallpox vaccine specifically developed for those whose immunosuppression or other underlying health problems made them unable to take the traditional live vaccinia vaccine. While its first attempt was ultimately unsuccessful, HHS has sought to fund a next-generation anthrax vaccine that was based on recombinant technology. HHS has also purchased anthrax antitoxins intended for use in the treatment of patients with inhalational anthrax. These last two examples raise new questions that warrant investigation. How do we determine to replace an existing product in the stockpile with a "next-generation" drug or vaccine? Current FDA regulations do not require a head-to-head comparison for approval or licensure. But for a product for which the federal government both purchases and sets policy, this question falls outside the mandate of FDA. Should a head-to-head comparison be required as part of the efficacy evaluation of a next-generation product? What would such trials look like? Should different criteria apply when considering a countermeasure for civilians as compared to

the US military, the latter being a relatively young and healthy population for whom countermeasure administration can be mandatory?

The development of antitoxins or anticytokine drugs envisioned as treatment modalities to be used in concert with traditional antibiotic therapy raises additional research questions. How are such products used with antibiotics? What is the appropriate timing—both relative to disease progression and relative to the administration of antibiotics—for the most effective use of such countermeasures?

Developments in existing treatment modalities may also give rise to new questions. Prior to the anthrax attacks of 2001, standard of care for the treatment of inhalational anthrax was penicillin or some other single agent active against *B. anthracis* [21]. During the attacks of 2001, 5 of 11 patients (45%) who developed inhalational anthrax died. This mortality rate was far less than the traditionally reported 80–100% mortality for this disease. Empirical data showed that most of these patients received multiple antibiotics; this was often motivated by a common practice in toxin-mediated illness in which it is believed that a second drug that inhibits protein synthesis may be of added benefit to the patient. As a result of the association of this unproven practice with an empirically improved mortality rate, there has been a change in formal CDC recommendations for the treatment of inhalational anthrax. Now the standard of care is to start with two antibiotics [22]. To date there has been no prospective, randomized, controlled trial to evaluate the efficacy or safety of single versus double drug treatment. In addition to its implications for patient care, this recommendation can have a significant effect on the cost of drugs stockpiled by the federal government to treat inhalational anthrax.

Any study of efficacy of countermeasures against CBRN agents raises the issue of the use of animal models. In a few diseases, a preferred model, such as the rhesus monkey or green monkey has been established [23]. The supply of such experimental primates is finite, in some instances extremely limited. The prospect of more efficacy studies raises the issue of how to prioritize such efforts in a public health program that is federally funded. What alternative animal models provide comparable efficacy data? Or more important, what pharmacokinetic or pharmacodynamic models that do not use animals, provide efficacy data of comparable quality?

In addition to the issues described, a number of special categories of research in countermeasure development deserve mention here. As demonstrated by the anthrax attacks of 2001, a biological release may result in the sharp acceleration of the number of individuals who receive a given countermeasure over a short period of time. Swab and culture of the nares and also of environmental surfaces produced results that were used to make treatment decisions about the need for postexposure prophylaxis. In an unprecedented effort at countermeasure standard-setting, in 2002 the White House released a statement attesting to the unreliability of several of these environmental test kits [24], thus highlighting the need for accurate and reliable diagnostics for Category A pathogens. It should be noted that FDA regards any test used to make patient care decisions as subject to the regulations—and therefore the standards—for medical diagnostic devices. While BARDA influenza efforts include funding for diagnostics, till date there is little activity in this area for CBRN threats. A review of BARDA/BioShield contracts to assess funding of diagnostics shows that over the duration of the programs, only a single 2008 “Request for Information” on dosimetry techniques useful in triage after a nuclear or radiological release has been issued [25]. When we consider the number of regulatory mechanisms

now in place to make investigational countermeasures available in the event of an emergency, including without informed consent, the need for accurate diagnostic assays is particularly acute. Risk is best mitigated when certainty regarding exposure is optimized.

The unpredictability of what the human imagination might devise for release, for example, resistant or otherwise genetically modified pathogens, coupled with the lengthy process of countermeasure research and development raises the issue of multipotential vaccines based on a warm-base manufacturing process which is modified to accommodate a specific antigen based on a specific need. Investigators at the University of Oregon funded by the Department of Defense have reported on the development of a novel vaccine vector for multiple Category A pathogens with plans to test for immunogenicity in rhesus monkeys [26]. While present BioShield/BARDA efforts remain focused on countermeasure development for individual pathogens, further study and subsequent development of such a large capacity vaccine vector would elevate preparedness to a new level.

A similarly useful effort would be to evaluate drugs that target the cytokine cascade of sepsis that results from infection with any number of pathogens, including several biothreat agents. The survival advantage conferred by Protein C for patients with severe sepsis has been followed by identification of several potential targets in the sepsis cascade, many of which have reached a stage of development that warrants clinical investigation [27]. An added advantage to such a research effort is the utility of such drugs in patients with sepsis due to naturally acquired infections, another important public health challenge.

## 4 CONCLUSIONS

The past decade has seen an acceleration of research and development in medical countermeasures for CBRN threats. Beginning with the Bioterrorism Act of 2002, and subsequent legislation creating BioShield in 2004 followed by BARDA in 2006, the federal government has invested billions of dollars in the development and procurement of drugs and vaccines to meet these threats. Unique issues raised by efforts to accelerate development and make countermeasures available in an emergency warrant scientific investigation that will best protect the public and spend taxpayer funds in this important area of need.

# MEDICAL COUNTERMEASURES AGAINST EMERGING THREAT AGENTS

GIGI KWIK GRONVALL

*Center for Biosecurity of the University of Pittsburgh Medical Center, Baltimore, Maryland*

## 1 INTRODUCTION

The outcome of an infectious disease outbreak may depend on the resources to manage it. If medical countermeasures are available, and can be delivered in time, they could potentially save lives and save medical resources. Drugs could be used to treat the ill. Vaccines could be used to protect health care workers providing care to the sick. If the disease is contagious, vaccination may limit the spread of the disease, and some vaccines may be used even after exposure to prevent symptoms. Diagnostic tests can be used to rapidly distinguish people who need treatment, saving valuable medical resources for those who need them.

Although medical countermeasures could limit the numbers of deaths in a public health emergency, they may not be available. Vaccines, drugs, and diagnostic tests take years to develop, they are expensive, and technical hurdles add more money and time to their development. If a countermeasure is not available prior to a public health emergency, it may not be available for years afterwards. For example, in 2003, the severe acute respiratory syndrome (SARS) epidemic was managed without a vaccine or drug specific to the disease. Years later, a vaccine or drug is still not available. For other diseases, the technical challenges may seem insurmountable: for example, decades of research have not yet produced an HIV/AIDS vaccine, and much more research is needed [1].

In spite of the hurdles, making medical countermeasures available for use in an emergency is a major part of the US strategy to prepare for and respond to attacks involving biological weapons [2–5], as well as infectious disease threats such as pandemic influenza [6]. As there are many disease agents for which countermeasures are needed, it is also part of the US strategy to research new ways to shorten the time it takes to make medical countermeasures, as well to procure countermeasures that could be applied more than one threat [2, 4].

## 2 MANY BIOLOGICAL THREATS NEEDING COUNTERMEASURES

Medical countermeasures are needed for an array of biological threats. There are biological agents that are thought to be particular risks for bioterrorism, such as *Bacillus anthracis*, which causes anthrax disease, and *Variola* virus, which causes smallpox.[1]

[1]This article will use “anthrax”, “smallpox”, and so on, to describe both the causative agent of disease as well as the disease itself.

There are also emerging health threats such as multidrug resistant (MDR) tuberculosis, West Nile viral encephalitis, and the ongoing possibility that H5N1 avian influenza will become transmissible from person to person. In addition, diseases such as HIV/AIDS and malaria have some treatment options, but no effective vaccine countermeasures are yet available.

The Homeland Security Presidential Directive 18 (HSPD-18), also called *Medical Countermeasures against Weapons of Mass Destruction*, describes four broad categories of biological threats for which countermeasures are needed [4]:

- *Traditional agents.* These are biological agents or toxins that are naturally occurring, and have the potential to cause mass casualties if used as a weapon. Anthrax is an example of a traditional agent. It is a naturally occurring disease, and the bacteria can be isolated from infected animals, culture collections, or laboratories. In 2008, there have been reports of natural anthrax disease in livestock in India, South Africa, and Argentina [7].
- *Enhanced agents.* These are biological agents or toxins that have been "modified or selected to enhance their ability to harm human populations or circumvent current countermeasures". An example in this category could be antibiotic resistant anthrax. The former Soviet bioweapons program developed antibiotic resistant forms of anthrax [8], and methods to create resistance in the laboratory are readily available in the open scientific literature [9–11].
- *Emerging agents.* These are naturally occurring diseases, but could cause a serious risk to human populations. SARS would be an example of an emerging agent. There are many surveillance networks in place to detect new outbreaks of naturally emerging threats, including ProMed-Mail, Global Public Health Intelligence Network, and the Global Influenza Surveillance Network. For an overview see http://www.upmc-biosecurity.org/website/special_topics/global_disease_surveillance/.
- *Advanced agents.* These agents are more engineered than "enhanced" agents, and are not naturally occurring. They are "novel pathogens or other materials of biological nature that have been artificially engineered in the laboratory to bypass traditional countermeasures or produce a more severe or otherwise enhanced spectrum of disease".

In addition to these categories, there are other lists of pathogens for which countermeasures are needed, from the Department of Health and Human Services (HHS) and the Department of Homeland Security (DHS).

### 2.1 CDC and APHIS Select Agent Lists

The possession, use, and transfer of select agents from one facility to another are regulated by the Centers for Disease Control and Prevention (CDC) within HHS, and the Animal and Plant Health Inspection Service (APHIS) within the US Department of Agriculture (USDA). The CDC and APHIS have separate lists of biological agents, but there are some that overlap both agencies, including *B. anthracis*, the causative agent of anthrax disease.

The select agent list contains biological organisms and toxins that "have the potential to pose a severe threat to public health and safety" [12]. There are 81 select agents and toxins, 13 of which are found naturally in the United States. With the exception of the

1918 influenza virus, which includes any portion of the coding region of all eight gene segments, all of the select agents are "traditional" biological threats.

To be listed as a select agent, these biological agents were evaluated for their anticipated potential health impact, their dissemination potential, the public perception of them, and the degree of preparation required for public health officials to manage an outbreak caused by the agent. The biological agents were binned into three categories: A, B, and C, with category A having the highest priority, and being the most dangerous. Category A diseases, which include anthrax, botulism, plague, smallpox, tularemia, and viral hemorrhagic fevers, were judged to be the worst: they are highly lethal, cause serious public health threats, cause social disruption, and are either easily disseminated or they spread from person to person. Category B agents, which include glanders and Q fever, are in general less lethal than A agents. Category C agents are not necessarily less lethal than the other categories, but include emerging disease threats like Nipah virus and hantavirus, which are thought to be a bioterrorism threat in the future.

### 2.2 DHS Threat Agents

The 2006 Bioterrorism Risk Assessment, carried out by the DHS, included 28 biological agents that could lead to deliberate exposure of civilian populations [13]. Genetically engineered threats, to be considered in future DHS risk assessments, will further expand the number of agents. The specific disease agents on the list have not been publicly released.

DHS also issues material threat determinations (MTDs) for those chemical, biological, radiological, and nuclear (CBRN) agents thought to pose a threat sufficient to affect US national security, and population threat assessments (PTAs) to estimate the number of people who would be exposed to these threats in "high-consequence" scenarios. The agents that have MTDs are the top priorities for countermeasure development and acquisition into the strategic national stockpile (SNS).

To date, 12 MTDs have been issued for biological agents. These include *B. anthracis*, the causative agent of anthrax disease, as well as an MDR form of the bacteria; Marburg, Ebola, and Junin viruses, which cause hemorrhagic fever; botulinum toxins, which cause botulism; *Burkholderia pseudomallei*, which causes meliodosis; *Burkholderia mallei*, which causes glanders; *Rickettsia prowazekii*, which causes typhus; variola virus, which causes smallpox; *Franciscella tularensis*, which causes tularemia; and *Yersinia pestis*, which causes plague.

## 3 DEVELOPING COUNTERMEASURES TAKES A LONG TIME AND IS TECHNICALLY AND FINANCIALLY RISKY

Ideally, medical countermeasures would be available to counter all of these disease threats, whether they are the result of natural outbreaks or bioterrorism. Medical countermeasures would also be made quickly in response to new disease threats as they arise. However, the costs and logistical and technical challenges of developing and stockpiling medical countermeasures against each threat are considerable and possibly prohibitive. In addition to the costs of developing the countermeasures, acquiring sufficient quantities for the SNS and maintaining these supplies adds further expense and time.

The costs of developing and licensing a single drug or vaccine have been estimated at $880 million to $1 billion, and it typically takes 8–10 years to reach licensure by the Food and Drug Administration (FDA) [14, 15]. Investing this time, effort, and money does not guarantee success; most drugs fail. The technical difficulties of producing an effective drug may result in a lack of therapies or vaccines for many illnesses, even though much effort and money have gone into the attempt. The FDA approves between one in five [14] or nine [16] drug candidates that enter clinical trials.

The process of developing a countermeasure either for biodefense or for an emerging pathogen that does not have frequent outbreaks may be even more difficult than the usual path to FDA licensure, because efficacy tests may not be performed in humans. Usually, a countermeasure is challenged with the disease, either in a field trial or in a controlled clinical trial setting. This is not possible to do with many diseases on the select agent list or DHS MTD list: people rarely come down with these diseases naturally, and it is not ethical to expose healthy human volunteers. For some emerging health threats, such as West Nile virus, outbreaks are sporadic and thus not suited for a traditional clinical trial.

To address the problem of countermeasure efficacy testing in humans, the FDA created the Animal Efficacy Rule in 2002 [17]. The rule states that for FDA licensure, a countermeasure must protect animals from deliberate infection, and it must be safe in humans. The Rule does not eliminate testing in humans; clinical trials are still required to evaluate safety of the medical countermeasure and to help determine the appropriate dose. Although the Rule provides a path to licensure for biodefense and emerging threat countermeasures, for many of these diseases, however, there are no well-characterized animal models available [18]. Therefore, as an additional step, scientists need to develop, test, and validate animal models, as well as determine the efficacy and optimal dose of their countermeasures [19].

The novel challenges of the Rule requirements, compared with the traditional licensure pathway, may be one reason it has rarely been used to approve new drugs. The first countermeasure approved was pyridostigmine bromide in 2003, indicated for use after exposure to Soman, a nerve agent [20]. As a different dose of the drug had previously received FDA approval for treating myasthenia gravis, the Rule was not used for a novel compound, but to extend the indicated use of an already existent countermeasure. The second, recent approval was for hydroxocobalamin, indicated for victims of cyanide terrorism as well as smoke inhalation. [21]. This drug had been approved in France in 1996 and was available in the United States at a much lower dose [22]. To date, a totally novel countermeasure has not yet been approved using the Animal Efficacy Rule, 6 years after the rule was created.

## 4 GOVERNMENT IS THE SOLE DRIVER OF BIODEFENSE MEDICAL COUNTERMEASURES

A commercial market does not exist for vaccines, drugs, and other needed countermeasures for emerging threats or biodefense. HHS acknowledges that pharmaceutical and biotechnology companies are “reluctant to develop medical countermeasures for which there is no clearly defined, robust, sustainable, commercial market. In many cases, the anticipated rate of return on development of a new medical countermeasure for a specific threat may not justify the required resource allocations” [2].

The US government has thus had to create a market, and encourage drug and vaccine developers to participate. Largely, it has done this through Project BioShield [23] and also through the Biomedical Advanced Research and Development Authority (BARDA), created through the Pandemic and All-Hazards Preparedness Act [24].

President Bush announced the creation of Project BioShield in his State of the Union address on January 28, 2003 [25], and the Project BioShield Act was signed into law on July 21, 2004 [23]. The Act created a Special Reserve Fund for use in procuring CBRN countermeasures for the stockpile. Congress advance appropriated $5.6 billion to the fund for use over 10 years (Fiscal Year 2004–2013)[26]. In addition to the fund, BioShield increased the authority and flexibility of the National Institutes of Health (NIH) to develop the so-called "qualified countermeasures" (a drug, biological product, or device that the HHS Secretary determines is a priority) for CBRN threats and it permitted the use of medical treatments not approved by the US FDA in an emergency [27].

Project BioShield was intended to encourage industry to develop medical countermeasures for CBRN threats, primarily by creating a market for such products. Having a 10-year fund specifically for procurement of countermeasures was thought to be an incentive for industry, as it reduces the usual year by year change in governmental appropriations and political priorities [28]. However, even with this security, it was generally felt that Project BioShield did not go far enough to encourage industry participation in medical countermeasure development [29].

Project BioShield had a number of limitations, including that could not be used for the advanced development of medical countermeasures, and could only be used for late-stage procurement. This created a "Valley of Death" funding gap between early stages of product development and the acquisition of medical countermeasures for the SNS [30]. In addition, 5.6 billion over 10 years was not seen as sufficient to entice involvement of larger pharmaceutical companies. Thus, the experience of those companies in bringing products to market was not available to the government. Finally, BioShield contracts put developers at risk, as the government was the sole purchaser and could cancel contracts. The largest BioShield contract awarded, $877 million contract to VaxGen for the delivery of 75 million doses of rPA (recombinant protective antigen), was canceled on December 17, 2006, for failure to meet a contract milestone [31].

Title IV within the Pandemic and All-Hazards Preparedness Act legislation [24], signed on December 19, 2006, was intended to correct some of the shortcomings in BioShield. The Act created the BARDA to support advanced-stage research and development (R&D) funding for medical countermeasures against CBRN threats to bridge the Valley of Death for countermeasure developers. It gave HHS authority to make milestone payments, among other contracting authorities, to facilitate medical countermeasure development by sharing the financial burden of development with the manufacturers.

These authorities are managed by the new BARDA office within HHS, "the focal point within HHS to accelerate, facilitate, and support the development of medical countermeasures for the public against the highest priority man-made and natural public health threats facing the Nation" [2]. Since the creation of BARDA, there has been reason for optimism: there have been several contracts awarded, and a director for the office has been announced [32].

It is too early to tell whether BARDA will be successful in its aims. Its success will depend on a great deal whether its authority is funded commensurate with its purpose, and in line with the commercial market [33]. Unfortunately, one analysis of the cost estimates for medical countermeasures against biological threats found that the current level of funding for BARDA, $102 million, would only be sufficient to support only two

medical countermeasure developments in advanced development, with only a 30% chance of either candidate being successful [34]. Considering the long list of emerging threat and biodefense agents for which countermeasures are needed, this is not encouraging.

Regardless of funds, these efforts will take a long time, and so countermeasures will not be available for many disease threats for years. Even for a known threat, it can take years to build up the capacity needed to respond: one of the goals of the National Strategy for Pandemic Influenza is to have the capacity to "vaccinate the entire US population within 6 months of the emergence of a virus with pandemic potential". This capacity will be available in 2011, but an outbreak of pandemic influenza could occur at any time [35].

## 5 A FLEXIBLE STRATEGY TO GET NEEDED MEDICAL COUNTERMEASURES

The difficulty and costs of developing and procuring medicines and vaccines for each biological threat have spurred interest in alternatives to a "one bug, one drug" strategy. These alternatives have been referred to as *flexible defense* [36], though that remains a term of art [37].

The HSPD-18, issued January 31, 2007 [4], expresses the impracticality of developing and stockpiling medical countermeasures against every possible threat. It states that the US government should pursue novel medical countermeasures that could be used against multiple threats, "a rapidly deployable and flexible capability to address both existing and evolving [CBRN] threats". HSPD-18 also requires that HHS "target some investments to support the development of broad-spectrum approaches to surveillance, diagnostics, prophylactics, and therapeutics that utilize platform technologies ... [and that flexible defense] goals could include identification and use of early markers for exposure, greater understanding of host responses to target therapeutics, and development of integrated technologies of host responses for rapid production of new countermeasures" [4].

HHS intends to develop or acquire "broad-spectrum solutions using technologies that enable more flexible next-generation interventional concepts and to consider approaches and technologies derived from the commercial drug development sector to support the biodefense mission" [5]. HHS will "work with industry, academia, public health organizations, other government agencies, and stakeholders to foster innovation and promote strategic initiatives, such as the development of rapid diagnostics, broad-spectrum antimicrobials, and next-generation vaccine manufacturing technologies" [2].

A flexible defense may technologically be a ways off, and HHS has stated that a fixed defense approach is "effective and viable for some of the highest priority threats such as smallpox and anthrax". As the list of material threats increases, and technology advances, HHS will be focusing its medical countermeasures research, development, and acquisition efforts on broad-spectrum and platform approaches [5].

HHS classifies innovative or flexible approaches into three categories: broad-spectrum medical countermeasures, broad-spectrum technologies, and broad-spectrum platforms [2].

### 5.1 Broad-Spectrum Countermeasures that could be Used Against a Wide Range of Threats

Broad-spectrum medical countermeasures could include new antibiotics, antivirals, or drugs that target the clinical consequences of an infection, such as inflammation or

sepsis (infection in the blood). Another broad-spectrum approach is to minimize the transmission of a contagious disease by reducing the bioaerosols that a patient exhales [38]. Broad-spectrum products might also include point-of-care diagnostics capable of diagnosing a variety of biological infections.

Broad-spectrum products have several theoretical advantages over other biodefense-specific countermeasures: they could be developed and stockpiled prior to an emergency, reducing the need for rapid development and manufacturing during an infectious disease crisis; development would also benefit the treatment of illnesses that are not the result of an attack or a sporadic outbreak; also, if the drugs would be effective against other bacterial or viral diseases, they could be tested for effectiveness in humans. Companies would not need to solely rely on the FDA Animal Efficacy Rule for approval of the countermeasures.

### 5.2 Broad-Spectrum Technologies that Improve Product Performance

If the process of drug and vaccine development could be made much faster and cheaper, it could be possible to produce medical countermeasures against new, unanticipated threats in time to save lives. New methods to shorten and improve the development process are needed for *all* countermeasures, not just emerging threats. FDA developed the Critical Path Initiative in 2004 [39] to "stimulate and facilitate a national effort to modernize the sciences through which FDA-regulated products are developed, evaluated, and manufactured" [40]. As part of the Initiative, there are a "list-specific opportunities that, if implemented, can help speed the development and approval of medical products" [18]. Many opportunities are targeted to other countermeasure needs, including cancer and autoimmune diseases, but some would benefit the development and manufacture of medical countermeasures against infectious disease threats, such as being able to extrapolate from animal data to human experience, improving the measurement of vaccine potency and streamlining clinical trials.

HHS cites the need for new technologies that are "broadly available to improved product performance" [2]. These technologies could make countermeasures more affordable, if they include adjuvants (which boost the effectiveness of smaller amounts of a medical countermeasure), temperature stabilization processes (to ease the distribution and storage of medical countermeasures), and innovative delivery mechanisms (such as oral doses or patches, for ease of use). Other possible technologies cited by HHS include improvements in the formulation of drugs so that they are more bioavailable and immunomodulators.

## 6 PLATFORM TECHNOLOGIES TO ENABLE RAPID, COST-EFFECTIVE DEVELOPMENT OF DRUGS AND VACCINES AGAINST A WIDE RANGE OF THREATS

One example of a platform technology is the annual influenza vaccine. Every year, the influenza strains from which the vaccine is derived may differ, but the process of selecting the strains and producing the vaccine is the same. FDA approval, once received, is not necessary for year-to-year variations of the seasonal flu vaccine. Similarly, one can envision medical countermeasures platforms for other infectious diseases. A successful platform would be useful to respond to attacks employing unanticipated threat agents or attacks requiring quantities of countermeasures that would exhaust stockpile supplies.

The capacity to very quickly produce large quantities of countermeasures might also diminish the need to maintain large and expensive national stockpiles. There are some technology platforms in development, which may eventually prove useful for emerging disease threats: RNAi, a potential platform technology that could be used in therapies against a variety of biological agents such as ebola, SARS, or influenza; prophylactic and therapeutic antibodies; DNA vaccines; and virus-like particles (VLPs).

Flexible defense technologies are being worked on in multiple areas in government. NIH has funded the bulk of countermeasure research, including alternative delivery technologies, and has pursued research on adjuvants for influenza vaccines. Within the Department of Defense (DoD), the Defense Advanced Research Projects Agency (DARPA) has pursued the Accelerated Manufacture of Pharmaceuticals program, which is intended to create a rapid, cost-effective manufacturing system capable of producing 3 million doses of good manufacturing practice (GMP)-quality vaccines or monoclonal antibodies within 12 weeks. The Defense Threat Reduction Agency (DTRA) has initiated the Transformational Medical Technologies Initiative (TMTI) program, which focuses on developing broad-spectrum defenses against intracellular bacterial pathogens and hemorrhagic fevers.

## 7 CONCLUSIONS

The availability of medical countermeasures could change the outcome of a public health emergency, whether it is caused by bioterrorism or is the result of a natural outbreak. However, countermeasures are not yet available for most potential bioterrorist threats and emerging pathogens. For unanticipated threats, countermeasures could not be developed in time to be of assistance in the public health response. In the future, a twofold approach is needed: "fixed" countermeasures for specific threats and research into a more broad-spectrum, flexible defense, approach. For both approaches, however, the funding needs to be commensurate with the task.

# BIODEFENSE WORKFORCE

KAVITA M. BERGER

*American Association for the Advancement of Science, Washington, D.C.*

## 1 INTRODUCTION

Biodefense is defined as defensive measures against a biological weapons attack, while biosecurity has been more broadly defined as measures to protect against harm from a biological agent and includes traditional biodefense and public health activities. Since 2001, activities associated with biodefense and biosecurity seemed to have conflated so that both terms describe the full range of activities to prevent and mitigate an attack using biological weapons.

Prior to 2001, US biodefense activities were mainly restricted to the Department of Defense (DoD). These included policy discussions, threat characterization, countermeasure development, and scientist redirection (termed *cooperative threat reduction*) activities. Toward the end of the 1990s, the Department of State (DoS) started their own scientist and facility redirection activities. A few select biosecurity programs, like the select agent program and export control program, were overseen by other US agencies. Much of the biodefense workforce came from a military, public policy, or nuclear arms control background. Civilian life scientists in the United States either were generally not aware of these activities nor were they formally trained in biological arms control and nonproliferation. Although a few scientists were working with select biological agents, their goal was not biodefense but rather to understand pathogenesis and host immune response for improved public health. Even following the public admission of the Soviet Union's large-scale offensive biological weapons program [1, 2], few practicing scientists were educated on or engaged in traditional biodefense activities. Similarly, much of the public policy or government biodefense workforce did not have formal training in biodefense policy or the biological sciences; they learned from their past nuclear arms control experiences.

Today, the situation is very different. Following 9/11 and the anthrax letters in 2001, biodefense has significantly expanded to incorporate global health, public health preparedness and response, government service, and active participation by the nongovernment research community in biodefense activities. The Department of Health and Human Services (HHS), Department of Homeland Security (DHS), United States Department of Agriculture (USDA), DoS, Department of Energy (DoE), DoD, Environmental Protection Agency (EPA), and the Intelligence Communities (IC) have responsibilities in biodefense. HHS and DHS support biodefense research, including select agents (http://www.cdc.gov/od/sap/docs/salist.pdf), at centers of research excellence in academia. HHS, DoD, and the Office of the Director of National Intelligence have advisory or expert groups involving academic scientists. Civilian scientists working on select agents have been contacted by the Federal Bureau of Investigation (FBI) during investigations for their subject-matter expertise [3, 4]. In addition, HHS contracts with private biotechnology companies to develop medical countermeasures (vaccines, drugs, delivery devices, and other medical devices) against chemical, radiological, nuclear, and biological threats that are considered of highest priority to the United States. Total funding of civilian biodefense activities rose from $576 million in 2001 to over $5 billion in 2008 [5]. Thus, the academic and private biological sciences community became immersed in the post-2001 biodefense infrastructure.

Much of the biodefense workforce is being trained on-the-job. More academic and industrial biodefense researchers are being trained in laboratories on how to work with select agents, develop diagnostic tests and medical countermeasures against priority threats, and evaluate their research for dual use potential. Public health officials and health care providers are being trained in hospitals and public health departments to properly recognize and diagnose unusual disease outbreaks and respond appropriately. Younger biosecurity experts are being trained mainly through apprenticeships in government agencies or nongovernmental organizations. This unstructured training of today's biodefense workforce fosters an environment where different biodefense communities function independent of one another and lack a clear and comprehensive understanding of the other communities.

### 1.1 Biodefense Education Programs

Education programs, though not many, have recently emerged at a few universities to address the lack of education of biological scientists and public policy or government personnel in biodefense. Three types of programs currently being developed are (i) public policy courses in biosecurity, biological weapons, and public health preparedness; (ii) courses educating practicing life scientists about biosecurity for scientific responsibility and biosafety; and (iii) bioterrorism preparedness and response courses for educating public health and health care workers in responding to a chemical, biological, radiological, or nuclear (CBRN) attack. A few examples of existing programs are described below.

Georgetown University has two programs, one for biological scientists in Biohazardous Threat Agents and Emerging Infectious Diseases (http://grad.georgetown.edu/pages/certif_biohazard.cfm), and the other for nonscientists in Biodefense and Public Policy (http://grad.georgetown.edu/pages/certif_biodefense_ppol.cfm). The first program is designed to educate scientists in the characterization of biological and chemical agents, disease surveillance, medical countermeasures, biological and radiological safety, and the history of infectious diseases. The second program is designed to educate students on the technical facets of emergency and incident response. The George Mason University offers a masters and doctoral program in biodefense (http://bioterrorism.slu.edu/DegreeProg07/IBS07index2.html), which professes to train the next generation of biodefense professionals and bridge the gap between scientists and public policy. The University of California (UC), San Diego's Institute for Global Conflict and Cooperation (http://igcc.ucsd.edu/PPBT.php), provides a 3-week short course on biodefense policy for doctoral students and postdoctoral fellows in the UC system. The University of Virginia offers a biodefense track for doctoral students in Microbiology, Immunology, and Infectious Diseases (http://www.healthsystem.virginia.edu/internet/bims/advancedresearch/biodefense_res.cfm). This program offers students the opportunity to combine their scientific courses with biodefense-related courses. Texas Tech University offers a concentration in biodefense law for law students (http://www.ttu.edu/biodefense/) and the St. Louis University School of Public Health offers a program in Biosecurity and Disaster Preparedness for health care workers and public health officials (http://www.bioterrorism.slu.edu/DegreeProg07/IBS07index2.html).

A few universities, nongovernmental organizations, and university consortiums have incorporated biosecurity into their ethics programs for scientists. These courses are focused mainly on educating life scientists about biosecurity and scientific responsibility. These courses, however, do not educate scientists from the computer, engineering, physical, and chemical sciences who work in the biological sciences (e.g. biophysics and systems biology) in biosecurity. Much of the discussion of biosecurity in these courses is related to dual use research (legitimate research that could be misused for malicious purposes) and the select agent regulations. The National Science Advisory Board for Biosecurity, an advisory committee to the US federal government on education and oversight of dual use research, has currently recommended that laboratory Principal Investigators perform initial review of their research for dual use potential, which would then be followed up with subsequent review by the Institutional Biosafety Committees (IBCs) at universities if necessary. This two-tiered review strategy requires that both individual scientists and the IBCs are capable of identifying research with dual use potential and that they consider ways to minimize potential national security risks. The Southeastern Regional Center of Excellence for Emerging Infections and Biodefense (SERCEB), an HHS center of excellence, developed an on-line education module for their

researchers regarding dual use research (http://www.serceb.org/modules/serceb_cores/index.php?id=3). Similarly, the Federation of American Scientists has developed an on-line portal (http://www.fas.org/biosecurity/education/dualuse/index.html) using case studies to educate scientists and others about potential dual use experiments and concerns. A few Americans and British have also engaged scientists abroad to evaluate the potential risks of their research and determine how to minimize those risks while still conducting their research [6–11].

As a result of the rapid growth of civilian biodefense funds and establishment of academic centers of excellence, more scientists have started working with select agents and more high-containment laboratories are being built to accommodate the increased select agent research. While all research institutions working with select agents are required to follow the biosafety guidelines listed in the Center for Disease Control and Prevention (CDC)'s Biosafety for Microbiological and Biomedical Laboratories, training biosafety officers and laboratory scientists varies among institutions. These are examples and not the only programs in existence. The National Institutes of Health administers a 2-year fellowship program, the National Biosafety and Biocontainment Training Program (http://www.nbbtp.org/), to train biosafety and biocontainment professionals. These individuals then go and train biosafety officers at institutions, who in turn train their laboratory personnel. The program's goal is to establish uniform standards by which biosafety officers can train laboratory personnel in laboratory biosafety. Emory University has a more extensive biosafety training program that incorporates training in mock biosafety level 3 and 4 laboratories (http://www.sph.emory.edu/CPHPR/biosafetytraining/index.html). In addition, the US DoS's Biosecurity Engagement Program (http://www.bepstate.net/) aims to upgrade public health and research laboratories to prevent theft of harmful agents by non-state terrorist organizations and educate the laboratory personnel on effective biosafety techniques to prevent accidental infection of laboratory workers in Asia.

### 1.2 Challenges

Several key challenges emerge from discussions surrounding the biodefense workforce. The main challenge is making the training program sustainable. Regardless of the audience, the programs must be self-sufficient and sustainable to withstand political will and funding fluctuations. The DoS's efforts for enhancing pathogen security and biosafety training in Asia is intended to be sustainable; their program is designed to train local laboratory personnel in biosafety and these individuals then go and train other local biosafety personnel and/or laboratory workers. Any education programs developed to build and maintain a knowledgeable biodefense workforce in the US would also have to sustain fluctuations in funding and political will.

Although most existing university-based biodefense programs are important for educating the future workforce in the basics of biosecurity, specialized skill sets are required for different biodefense activities. To best tailor training programs for different biodefense programs, one must assess the needs of these programs. In support of this, a published study of HHS's biodefense agencies suggests that a needs assessment, federal hiring strategies, and funding for training and salaries are all critical to improving the government biodefense workforce [12]. Another published study assessed the needs of public health officials required to prepare for and respond to a bioterrorism incident [13]. This study identified cross-disciplinary training, funding for training and salaries, and

integrated, large-scale exercises where lessons are easily learned as major components to establishing a public health workforce knowledgeable in responding to biological attacks. On the basis of a needs assessment, program specific training courses can be designed to help develop the workforce for each biodefense activity.

The skills needed for specific biodefense activities must be by definition cross-disciplinary to best address the needs of the programs (e.g. DoS's Asia pathogen security program requires an understanding in the life sciences, public health, and cultures of the countries engaged). Cross-disciplinary education is extremely important to establish and maintain a complementary, coordinated, well-integrated, and cooperative biodefense workforce, which allows people of differing expertise (i.e. scientists, health care practitioners, and the security community) to accept each other's perspectives and work together. In addition, this cross-disciplinary education extends to international relations and political science. As the US moves to engage scientists and public health workers in friendly nations or nations outside the Former Soviet Union (FSU), biodefense personnel must adapt and understand the new economic and political climates, cultures, and languages of the non-FSU nations they work with. This type of cross-disciplinary training will be essential for effective scientific and security engagement with nations. The cross-disciplinary biodefense workforce working in concert with a number of subject-matter experts will ultimately be the key to success for biodefense activities.

### 1.3 Case Study

This article focuses on the workforce and skill set needed to initially review the potential threat of an emerging biotechnology. Using the rapidly advancing technology of synthetic biology, the case study presented below highlights the skills necessary for the threat characterization workforce to address key policy questions related to advancing biotechnologies. This initial evaluation is essential for determining whether an emerging biotechnology is a potential national or international security threat or whether it is completely benign. Further policy discussions would require advice from subject-matter experts and the intelligence community. This tiered approach with a knowledgeable workforce to initially triage which technologies could pose reasonable threats to national security allows for in-depth discussion of the more serious threats while minimizing the impact on the scientific community. Since threat characterization is just one of many biodefense activities, this article ends with a short description of workforce needs in other areas of biosecurity.

## 2 CASE STUDY: SYNTHETIC BIOLOGY: NATIONAL SECURITY THREAT OR BENEFICIAL SCIENCE

Although many case studies, real or fictional, have been described to understand capabilities or concepts, few, if any, have been described to address workforce issues. The case study presented here addresses the question, "What workforce training is needed to assess the potential threat of an emerging biotechnology?" Although subsequent analyses may require subject-matter experts and intelligence information, initial evaluation of whether an advancing technology poses a potential national security threat requires knowledgeable staff to address key scientific and social questions. These questions include, but are not limited to, the following:

1. What is the current state of the science and how rapidly is it advancing?
2. Can the technology be used to generate harmful pathogens or toxins (novel or known) for nefarious purposes?
3. How effective are (synthetic) pathogens at surviving outside the laboratory and causing harm to the target population?
4. Does the technology reduce the utility of our current defenses?
5. Does the technology pose a greater threat than more traditional techniques, like isolating pathogens from the environment or sick individuals? Is this true for all pathogens or some?
6. What are the risks and benefits of the science? What are the burdens placed on science by potential risk management strategies?
7. Who has the capability to replicate the science?
8. Are there opportunities for maximizing transparency of researchers using the technology and minimizing misuse of the technology?

This case study starts by describing the technology of synthetic biology, followed by a discussion about the expertise needed to evaluate whether synthetic biology poses a threat to national security in a globalized world.

### 2.1 Background in Synthetic Biology

Narrowly defined, synthetic biology (commonly grouped with synthetic genomics) is the creation of biological organisms (or whole genomes) from scratch—i.e. an intact biological organism is generated from a complete genome made from chemically synthesized genes or small DNA fragments. It is a rapidly advancing biotechnology with many beneficial applications to medicine and public health as well as development of alternative energy sources. The biosecurity community, however, views synthetic biology as a real threat to national and international security. The speed at which the DNA synthesis technology is advancing suggests to the security community that the technology will be affordable and easily attainable within the next 5–10 years.

In 2002, the Wimmer laboratory at the State University of New York at Stony Brook published an article in *Science* on chemical synthesis of poliovirus [14]. In the publication, Wimmer and colleagues discussed how they created the poliovirus genome by joining together short fragments of DNA, which they ordered from a DNA synthesis company. To distinguish their synthetic genome from one simply isolated from a laboratory strain of poliovirus, they incorporated a very short piece of DNA into the synthetic genome sequence in a manner that would not affect the protein sequence. They used a cell-free system to grow the virus from the synthetic genome. The authors created a live poliovirus, but its ability to infect mice was greatly reduced compared to the wild-type laboratory strain. This experiment raised alarms within the scientific community as a potential security concern since it was the first time a live pathogen could be generated without an existing template. The National Research Council used this and other examples in their report, *Biotechnology Research in an Age of Terrorism*, to highlight the potential security problems associated with some biological research [15].

Shortly after Dr Wimmer's paper was published, researchers at the J. Craig Venter Institute published a paper claiming the complete chemical synthesis of a bacterial virus, bacteriophage PhiX174, in just 2 weeks [16]. The paper described in detail how the

bacteriophage was synthesized and tested. This paper alarmed the White House resulting in greater concern about synthetic biology as a potential security concern. The National Science Advisory Board for Biosecurity, created in 2004 under the auspices of the National Institutes of Health, was tasked to review synthetic biology and provide recommendations for how the federal government could oversee such research.

The American scientific community working in synthetic biology came together in 2004 to discuss the science. Since then, they held annual meetings on synthetic biology expanding their audience to include domestic and international scientists and government and nongovernmental organizations, and broadening the scope of the discussion to include social and security implications of the technology. At the second annual meeting, Synthetic Bio 2.0, in 2006, participants recognized that synthetic biology could pose some threat to national security and responded by drafting recommendations for self-governance by the scientific community. As the scientific and policy communities began considering the potential threat of synthetic biology, they responded by recommending actions that the scientific community could adopt to prevent misuse of the technology, such as monitoring synthesis requests, educating life scientists about the safety and security risks, and overseeing academic research for their dual use potential [17]. Several DNA synthesis corporations have also considered the potential threat of synthetic genomics, and developed and implemented measures to screen orders for their similarity or identity to select agents (http://polysynth.info/). [18] One company, Blue Heron, stated that they rejected at least one order for international security reasons. Despite the concerns that synthetic biology can be misused to generate harmful pathogens, researchers at the J. Craig Venter Institute continue to streamline and advance protocols for the chemical synthesis of pathogens [19].

The perception of the threat of synthetic biology has extended beyond the United States to European nations. Actions taken by Western nations and companies do not necessarily translate well to other parts of the world where the advancing biotechnology industry is expected to provide great benefit to public health and economic growth. For example, nations with economies in transition, such as India and China, have thriving biotechnology industries. Given this globalization of biotechnology and the value of advancing biotechnology to health and economies, having cross-disciplinary training in science, public health, and the cultural and political climate will allow those assessing threats, like synthetic biology, to integrate information gathered from intelligence and subject-matter experts to make informed reasonable evaluations about the risk of the emerging biotechnology.

The following sections break down the expertise needed to address key questions in assessing risk using synthetic biology as an example of an advancing biotechnology. This article will not address intelligence gathering or communication and collaboration with subject-matter experts *per se* but does recognize that these expertise are essential to fully address whether a given technology poses a threat. Existing educational programs will be referenced where appropriate.

## 2.2 Scientific Expertise Needed

Creating a dangerous pathogen or toxin from a published sequence requires obtaining the sequence, the DNA fragments or DNA synthesizer and reagents, laboratory materials, cells, and expertise needed to create the pathogen from a chemically synthesized genome as well as testing the infectivity and virulence of the pathogen in cells and/or animals,

weaponization, production, and dissemination. Although some of the steps in this process are available, inexpensive, and relatively easy to perform, others are not. Also, the fact that many large DNA synthesis companies, for example Blue Heron, are screening their orders for suspicious sequences adds a layer of complexity to the entire threat characterization process. Alternatively, isolating many harmful pathogens from nature is relatively easy and low cost. A strong science background is necessary to place the emerging technology on a spectrum of risk, which would not only include all other available techniques for creating or isolating harmful pathogens and toxins but also the risk of theft, accidental exposure, and natural infection. Placing the technology on such a risk spectrum would contribute to determining credibility of the threat, its priority compared to other threats, and potentially available options for action.

Life scientists, engineers, physicists, and computer scientists all play a role in advancing biotechnologies. The rapidly growing field of systems biology and computational biology is possible only because of the expertise of bio-savvy computer scientists. Development of medical devices, advanced technology for vaccine or drug delivery, and gene and protein arrays require knowledge in biophysics and bioengineering. Characterizing the current and future state of the technology and downstream applications requires a broad interdisciplinary training in the physical, chemical, and computer sciences as well as life sciences. Over the last 15 years, a few academic institutions have started interdisciplinary programs incorporating bioengineering, biophysics, and the life sciences. Two notable examples of this are Georgia Institute of Technology's Institute for Bioengineering and Biosciences (http://www.biology.gatech.edu/facilities/) and the Georgia Institute of Technology and Emory University Biomedical Engineering Program (http://www.bme.gatech.edu/).

Although synthetic biology requires knowledge of basic molecular biology techniques, advances in synthetic biology are dependent on DNA synthesizer technology, which is designed and built by engineers, physicists, and chemists. Four major features of DNA synthesizers contribute to the pace of its technological advancement—accuracy of the synthesized DNA, speed of generating DNA molecules, ability to multiplex, and ability to be fully automated. As these features improve, chemical synthesis of DNA is likely to become cheaper and easier to do. This not only benefits individuals who are interested in acquiring the end product, DNA fragments or genes, but also those who want to purchase older models of DNA synthesizers. Training in engineering and chemistry can greatly enhance one's ability to predict future technological advancements and how fast these advancements can occur.

Life scientists are best qualified to address the emerging capability of synthetic biology technology. The J. Craig Venter Institute reported that they synthesized the entire genome of bacteriophage PhiX174 in just 2 weeks [16]. They did not publish that they spent more than 2 years troubleshooting the system to streamline the chemical synthesis process [20]. This delay demonstrates two problems with the security community's assessment of the current capabilities of the science: (i) although a PhD in the life sciences is not a necessity, tacit knowledge of the procedure for generating the genomes and subsequent pathogens is required to troubleshoot any problems during the experiments [20] and (ii) the technological requirements needed to synthesize large pathogens and priority threat agents are orders of magnitude more complex than synthesizing a bacteriophage and small viruses and may require new scientific discoveries to achieve. Training in the life sciences would provide the necessary expertise to take into account these problems when assessing the ability of the technology to create a functional and dangerous

pathogen. Furthermore, experience in microbiology, virology, and ecology, specifically, could be very useful in determining whether a synthetic pathogen could survive outside the laboratory setting, thereby increasing the possibility it could be used to cause significant harm to human, animal, or plant populations and the surrounding environment.

This assessment may differ for chemical synthesis of toxins. Synthetic genes could serve as templates for chemical synthesis of proteins, like toxins, immunoregulators, neuroregulators. Training in the life sciences, including biochemistry and toxicology, and chemistry is necessary for assessing the impact of the chemically synthesized protein on life functions. These expertise can help when assessing the stability of the synthesized protein, determining whether it requires further chemical or structural modification to function properly and the ease of adding these modifications accurately, and predicting the body's reactions to the synthesized protein. With their advanced knowledge of the science, life scientists and chemists are well suited to determine the minimum requirements for creating harmful and functional toxins from scratch.

Assessing whether technology, such as synthetic biology, can produce biological agents that subvert or reduce the effectiveness of current defenses (vaccines, drugs, medical devices, and nonmedical interventions such as isolation) requires knowledge of epidemiology and outbreak response as well as the life sciences. Relatively few public health students get trained in infectious disease epidemiology, but being well educated in conducting epidemiologic analyses of infectious diseases and outbreak response are critical when assessing whether an emerging technology can evade current defenses. This training helps to determine whether synthetic biology can create functionally dangerous pathogens or toxins that reduce the impact of current public health interventions. Although the life sciences allow one to determine the ease of creating vaccine and drug resistant dangerous pathogens, the public health training allows one to determine possible outbreak scenarios for the synthetic pathogen or toxin. This added knowledge can help to inform whether a chemically synthesized biological agent truly has the ability to reduce the effectiveness of public health interventions.

Knowledge of the physical, chemical, and life sciences as well as public health, medicine, and veterinary medicine is important for comprehensively assessing the risks and benefits of the emerging technology as well as placing the technology on a risk spectrum with other currently available technologies. Although synthetic biology can pose national and international security risks, many legitimate laboratories are using the technology for beneficial purposes (http://sb4.biobricks.org/). The potential risk of misuse of the technology by a nefarious group and the risks associated with policies and regulations to prevent the misuse of the technology should be weighed against the potential benefits of the technology to health and agriculture. Moreover, any risk management strategy should also be weighed against the potential burdens to industry and science. Those who have knowledge of the science and consequences of regulations and policies on current research may be in the best position to consider the spectrum of risks and compare them with the benefits and burdens. Finally, interpreting scientific publications and engaging in international scientific collaborations, though currently complicated by visa issues and export control and select agent regulations, offer a sense of transparency in the international scientific community by leaving lines of scientific communication and cooperation on research activities open.

### 2.3 Cultural and Political Expertise Needed

Beyond scientific characterization of the threat, vulnerability, and consequences, determining the immediacy of the threat requires yet another set of skills. Those skills include cultural anthropology and political science as well as intelligence gathering. To understand whether a subnational group or a nation could be misusing beneficial technology or developing technologies for nefarious purposes, one has to have a good understanding of the political and economic climate, history, and cultures and religions of various nations throughout the world. Nations that do not have a history of biological weapons development or harboring terrorists may have a lower likelihood of using biotechnology for malicious purposes. However, nations that are known to have terrorist organizations living within their borders or interacting with their population may provoke a higher level of suspicion. This is also true for nations or groups that support martyrdom and have a history of violence toward other cultures, religious groups, and nations to achieve their political objectives. Thus, training in world cultures, history, and political and economic climates is essential for contextually assessing the risk of a technology. Also critical to these questions is the ability to gather human intelligence, a function which scientific collaboration and communication facilitate.

### 2.4 Suggested Training Program

Any training program developed to evaluate the risk of an advancing biotechnology to national or international security must include the relevant scientific and sociological expertise described above. This program would include courses in the life, physical, chemical, and engineering sciences, outbreak response and epidemiology as well as courses in biological weapons and biosecurity, cultural and political anthropology, and current events. One option for developing a curriculum could be to have bright scientists from interdisciplinary science programs, like those offered at Georgia Tech, and students from schools of public health, medicine, or the veterinary sciences take courses in the relevant social and political sciences. To enhance the students' experiences, they could be required to do several internships to better understand the needs of the threat characterization and other biodefense communities. Such a program would provide the broad background needed to ask key questions to triage emerging biotechnologies as potential threats or not. As previously stated, further policy discussions and threat determination would require subject-matter experts and intelligence information.

### 2.5 Conclusion

Does the current biodefense workforce have the necessary expertise to address the following question: "Is there enough evidence that unfriendly nations have the knowledge and tools to create, from published sequence, a functional dangerous pathogen or toxin that could evade existing defenses and be devastating to human, animal, or plant health or the environment?" The workforce does not currently have the specialized expertise to appropriately address this question. To assess the potential threat of synthetic biology, or any emerging biotechnology, the workforce needs to be trained in the hard sciences, epidemiology, and social sciences. With this broad, cross-disciplinary training, the workforce can ask and initially address key questions to determine whether a biotechnology poses a threat or not. Subsequent consultation with subject-matter experts and the intelligence community can enhance or diffuse that threat determination.

## 3 ADDITIONAL BIODEFENSE WORKFORCE NEEDS: GLOBAL HEALTH SECURITY AND AGRICULTURE SECURITY

### 3.1 Global Health

Prior to the anthrax mailings in 2001, the public health community was largely removed from national security activities. Since 2001, however, the public health sector has been tasked with the responsibility of preparing for and responding to CBRN attacks. The health care and public health communities are now considered vital to national security interests because they help mitigate the consequences of a CBRN attack and help recovery efforts following an incident. To fulfill this task, public health officials and health care professionals now require training in biodefense preparedness and response. This added requirement is complicated by the fact that the current public health workforce will be retiring within the next 5 years and very few public health officials are being trained to replace them. In individual hospitals and doctors' offices, few physicians and nurses are being trained in biodefense and few, if any, have experience detecting diseases caused by many of the US priority threat agents. Many developing nations do not have sufficient health care and public health capabilities to effectively identify and respond to an outbreak of potential international concern. The recently revised International Health Regulations (IHR2005), although mostly relevant to unusual CBRN disease outbreaks, were designed to push nations to upgrade their national health care systems to a minimum standard. Many nurses and physicians from developing nations leave their home country to work in developed countries, where they are able to earn more money and therefore could contribute more effectively to their family's well-being. Thus, there is a real need to train health care professionals in bioterrorism and public health response throughout the world.

### 3.2 Agriculture Security and Food Defense

The increased interdependence of nations in trade of agricultural and food products presents a very important biosecurity concern. Protecting their products from natural, accidental, or intentional contamination is in the industry's best interests and required to protect market value and consumer confidence. The DoS is working with the Asia Pacific Economic Cooperation (APEC) countries on food defense out of recognition that the food industry is critical to global economic prosperity and the availability of food (http://www.state.gov/r/pa/prs/ps/2006/75537.htm). Educating individuals on biosecurity measures to prevent contamination, identify contaminated products, and disinfect and dispose of contaminated food products is critical to international agricultural security and food defense.

## 4 CONCLUSION

Building a sustainable workforce for all biodefense activities requires training programs to meet the needs of those activities and to be cross-disciplinary and broad, sustainable, and standardized. The case study presented in this article uses synthetic biology to address the question of what expertise and training is needed for threat characterization of emerging biotechnologies. Cross-disciplinary training in the hard sciences, epidemiology, and social sciences allows the threat characterization workforce to ask and address

several key policy questions to effectively assess whether a given technology is a potential threat or not. Following this first tier of review, subject-matter experts and the intelligence community can be engaged to provide additional understanding and contextual information regarding the threat. More education programs in biodefense for scientists, the public policy workforce, public health professionals, and agricultural and food scientists are needed to build and maintain a knowledgeable and comprehensive workforce for all biosecurity programs.

# HEALTH RISK ASSESSMENT FOR RADIOLOGICAL, CHEMICAL, AND BIOLOGICAL ATTACKS*

ELLEN RABER AND ROBERT D. KIRVEL
*Lawrence Livermore National Laboratory, Livermore, California*

## 1 INTRODUCTION

A working definition of "risk" in the context of human health and intentional contamination events is the probability of adverse effects resulting from exposure to an environmental agent or a mixture of agents [1]. An "agent" has been defined [2] as a chemical, physical, mineralogical, or biological entity that may cause deleterious effects in an organism after exposure to it. Risk assessment can be generally regarded as either a scientific discipline or a professional process that involves the quantitative or qualitative estimation of potentially adverse health effects arising from exposure to hazards, such

as the agents identified above. This principle and its importance regarding human health exposure are supported by guidance recently issued by the Office of Management and Budget (OMB) and the Executive Office of the President [3].

Rather than being a stand-alone process, risk assessment is usually viewed as one component of a broader process known as "risk analysis", which includes risk assessment, risk management, and risk communication [4]. Risk management is a decision-making process that accounts for political, social, economic, and engineering implications together with risk-related information to develop, analyze, and compare management options and select the appropriate managerial response to a potential chronic health hazard. Risk communication is a field in the area of environmental health through which a communicator hopes to provide the receiver with information about the expected type and magnitude of an outcome. Risk communication is typically a discussion about an adverse outcome and the probability of that outcome occurring [5]. Various aspects of risk management are discussed in more detail in other articles of this *Handbook*.

Risk assessment has a long history—often linked to Federal governmental policies—that has sometimes been characterized as "controversial" [4, p. 86; 6, p. 17]. Many different definitions of risk assessment and its current limitations can be found in the recent literature (see [6], pp. 16–17 for several examples). In a human health context, risk assessment is the evaluation of scientific information on (i) the hazardous properties of environmental agents (hazard identification or hazard characterization), (ii) the extent of human exposure to these agents (exposure assessment), and (iii) the dose–response relation (dose–response assessment). The product of a risk assessment is risk characterization, a statement integrating information from items (i) through (iii) above, to estimate the probability and degree to which exposed populations of individuals will be harmed [1].

For drinking water, the history of risk assessment got its start within the regulatory community in the 1970s with the *Safe Drinking Water Act* (reauthorized in 1996; National Primary Drinking Water Regulations, 40 CFR Part 141); for air, with the *Clean Air Act* (42 USC 7401 et seq.). To better estimate the potential hazards involved, the National Research Council (NRC) initiated studies that culminated in what is commonly known as the Red Book [7] wherein risk assessment was officially recognized as a field. Although one of the recommendations in the Red Book was that risk assessments for cancer and noncancer effects follow uniform guidelines, such assessments have generally followed different approaches [4, p. 87].

## 2 RISK-INFORMED DECISION MAKING APPLIED TO REMEDIATION AND RESTORATION

To evaluate potential residual health effects for a particular radiological, chemical, or biological agent following intentional contamination—whether to water, air, or environmental surfaces—some type of health risk assessment as previously described would be necessary. A risk-based approach means that cleanup guidelines should be based on a defined, "acceptable" or "tolerable" level of risk to health. Many factors would have to be considered in developing standards and realistic cleanup goals to protect health, property, and resources. The following considerations are among the most important.

First, it is necessary to determine whether a risk actually exists or is perceived to exist. An actual risk depends on the presence of at least three elements: a hazard as previously

discussed, a receptor (human or ecological), and a pathway (physical or environmental migration route) that connects the two. If any one of the three elements is absent, then by definition, no actual risk exists. If a risk does exist, then determining the timing and potential severity of an incident must be made. Interrelated considerations are the type of release scenario and site descriptions; contaminant migration and longevity; projected water, land, resource, or property use; and any use restrictions.

Cleanup and decontamination decisions must then be made with input from stakeholders representing both public and regulatory concerns. Relevant risk-informed decision-making considerations include the following:

- Potential acute and long-term chronic health impacts, including health effects on key populations such as pregnant women or immunocompromised individuals.
- Damage to water, land, property, and equipment as a function of cost.
- Detectability of the agent(s) in the contaminated medium and the long-term fate of contaminant(s) or degradation product(s).
- Cost of decontamination or other remediation options.
- Time constraints associated with decontamination or other remediation options.
- Availability of decontamination methods and methods for the associated sampling, analysis, and verification of decontamination.
- Aesthetic considerations.
- Other site-specific factors that might be relevant.
- Potential overreaction that may cause more panic or chaos than warranted.

An important factor underlying each risk-based decision is the uncertainty and reliability of available data. Uncertainties in the magnitude and location of residual agents, site-specific features, and prediction of natural attenuation or potential dilution effects, all contribute to decisions about whether appropriate decontamination levels have been reached. In most cases, some type of statistically valid sampling could be used to reduce uncertainty both during site characterization and regarding the likelihood that an appropriate decision has been made. The sampling strategy would take into account the way any decontaminant reagents or treatments, if used, are applied, as well as spatial or volumetric considerations regarding the contaminated site.

A recommended, limited health risk assessment approach begins with a multimedia, multipathway dose assessment. For example, the possible resuspension or transport and fate of a substance or microorganism must be determined. This means that the ability of a contaminant to move into, off of, or through contaminated materials must be determined or assumed. Consideration must be given to the mobility of a contaminant under both unusual conditions, such as fires or floods, and mundane ones, such as repainting a building. The toxicology of the agent must be evaluated; and the human morbidity, mortality, and latency of effects must be determined, if known. Integrating multimedia transport and fate with multipathway exposure (e.g. inhalation, ingestion, or dermal absorption) and physiologically based pharmacokinetics (if available) for modeling toxicity should yield an estimate of noncarcinogenic hazard and carcinogenic risk, especially from short-term exposures. If possible, an empirical biomarker or biodosimetric procedure should be identified so that those given permission to reoccupy a building or structure, or allowed to resume using a drinking-water source, can be monitored.

An alternative and commonly accepted approach is to study contaminated versus uncontaminated environments. Elevated concentrations of an agent can then be used as an index for evaluating relative contamination levels and to determine whether decontamination treatment should be repeated. For example, to evaluate coliform or *Cryptosporidium* contamination in a drinking-water source, where such microbes are indigenous at very low levels, one could measure the relative concentration in intentionally contaminated water sources versus adjacent sources not deliberately contaminated to ascertain whether decontamination should be implemented or repeated. Acceptable levels should be somewhere between background and the lowest dose for infection.

Researchers at Lawrence Livermore National Laboratory have developed a conceptual decision process for chemical and biological decontamination following a terrorist attack [8, 9]. The details of this preliminary decision framework are beyond the scope of this article. However, an important point is that the eight major decision areas defined in the framework are derived from risk-based decision making. The steps that should be followed include evaluation of the timing and severity of impact of an incident; whether specific site conditions pose unacceptable risk to health, ecosystems, or property and thereby warrant decontamination; and a definition of decontamination goals, including cleanup concentration and target time frame to achieve the goals. The framework includes key decision points for regulatory and stakeholder review. Stakeholder involvement is critical whether the risk is actual or perceived. Any perceived risk, and potential community outrage associated with the perceived risk related to an intentional contamination incident, would need to be addressed carefully. Such a risk-informed decision framework needs to be considered when applying the information provided in this article to an actual, intentional contamination event.

## 3 HAZARDS AND EXPOSURES FOR RADIOLOGICAL, CHEMICAL, AND BIOLOGICAL AGENTS

Early during any response and recovery effort following intentional contamination, it is essential to identify the agent(s) used in the attack; specific characteristics of the prepared agent and its ability to cause harm; to the extent possible, the amount of contaminant initially present (source term); mechanism of release; and the extent of spread at a contaminated site. The site-specific nature of the area and its initial or planned usage are also key to understanding the actual potential hazard(s). Such information, which pertains to the hazard posed by the agent(s), is key in defining the level of remediation and restoration that may be required. If an identified contaminant in water or air were known to dissipate quickly through degradation or natural attenuation, then simply waiting might be all that is required to reduce the health hazard. If an agent were persistent however, knowing the amount present and other details on its specific properties—such as its ability to aerosolize or reaerosolize, stay in solution, or quickly degrade to nontoxic by-products—along with environmental parameters and conditions, would help to define the type and level of remediation actually necessary.

When evaluating the potential hazards associated with water resources, one must consider the potential for contamination of both surface water and groundwater from soil contamination. The potential for contaminant transport in soils has been extensively studied, and key geochemical and hydrogeological characteristics have the ability to influence the spread of source contamination from any event [10]. The same characteristics in both

soil and water have the potential to provide conditions favorable for natural attenuation for some of the agents of concern [11]. It is important to consider such characteristics during an overall risk assessment because they may play an important role in risk-informed decision making and in determining whether actual remediation is needed.

Hazard identification involves specifying not only the agent involved but also the range of clinical outcomes in humans, which can vary from asymptomatic conditions to death. Hospitalization studies, case studies, epidemiological data, and the clinical literature are all important sources of information. The World Health Organization has outlined the format and types of information that should be included in a hazard characterization of pathogens and how the identified factors affect the likelihood of disease [12, Appendix A, p. 51]. Although the outline was developed for a food matrix, it can with slight modification be applied to water as well. Table 1 captures the principal WHO recommendations pertinent to characterizing the hazard. The words highlighted in italics modify the WHO outline and apply it more broadly to the topic being discussed in this article.

With respect to the hazards posed by biological agents, current scientific data suggest that a single microorganism (such as a single spore of *Bacillus anthracis*) could cause harm in a particular subgroup of the human population [13, 14]. Such a position, which is by no means new, is known as the single-organism hypothesis [15] or the independent-action theory [16, p. 96]. In their assessment of risks arising from exposure to microorganisms, the NRC [6] stated, " ... it has frequently been asserted that there exists a threshold (minimum infectious dose) below which there is no risk to a population. Such a concept in not consistent with the current understanding of microbial risk assessment .... [p 110]" The NRC concluded that " ... it is not possible to calculate a threshold for environmental contamination with *B. anthracis* spores (or other pathogens or toxins) below which there would be zero risk of disease." [p 112] This conclusion has important implications for dose–response assessment.

Added to the hazard issue of virulence of agents such as *B. anthracis* is the fact that spores of the genus *Bacillus* can survive in a dormant state for decades and probably much longer [17, 18]. With regard to water contamination, ingestion and cutaneous exposure pathways would represent the key exposure pathway(s) of concern. Microorganisms can potentially multiply; conversely, they might be killed by acidity in the gastrointestinal tract or through action of the immune system, and the susceptibility varies greatly in humans. Another hazard-related consideration for certain microbes is their transmissibility and the potential secondary spread of disease from one person to another, which is of enormous concern for *variola major* virus, the causative agent of the disease smallpox. This article does not specifically address the potential threat from genetically modified or engineered organisms.

In contrast to the key biological agents of concern, chemical or radiological exposures are concentration-dependent and require a certain level of exposure for illness to occur. Person-to-person transmissibility is of minimal or no concern for chemicals or radioisotopes. Unlike radiation exposures that occur daily from natural sources (e.g. cosmic radiation), humans are not normally exposed to the chemical and biological agents that have been identified by the Centers for Disease Control and Prevention (CDC) as most likely to be used in an intentional contamination event. Many of the chemical warfare agents (CWAs) are man made and do not occur naturally in the environment. Although many of the biological warfare agents actually do occur in the environment, exposure to them is much more infrequent than that to radiation. The likelihood of exposure to

biological and chemical agents as a result of an intentional contamination event would be a function of the proximity to the source location and the exposure pathways.

Exposure to a contaminant involves contact at a boundary between a human and the environment with a contaminant of a specific concentration for a specified time [19, p. 90]. Thus, exposures in the risk assessment process have been defined (specifically for chemical risk assessment) as an average lifetime daily dose (concentration × contact rate × duration/body weight × lifetime [4, p. 88]. In the case of *Superfund*, 30 years of exposure was used as the reasonable maximum exposure; the *Clean Air Act* uses

70 years for a maximally exposed individual. But regardless of how the "average" is defined by any particular legislative statute, exposure assessments estimate the dose encountered, and dose is the amount deposited or absorbed in the body over time. However, even with good concentration data, variability in actual exposures, sensitivity, and susceptibility in a heterogeneous population make estimates of risk associated with certain agents, especially biological ones, inherently uncertain [6, p. 90]. The US Environmental Protection Agency (EPA)'s *Exposure Factors Handbook* [20, see http://www.epa.gov/ncea/pdfs/efh] is a valuable resource for information on the broad range of exposure-related factors that must be considered in quantitative risk assessment. The steps described in the EPA *Handbook* for performing an exposure assessment are as follows:

1. Determine the pathways of exposure.
2. Identify the environmental media that transport the contaminant.
3. Determine contaminant concentration.
4. Determine exposure time, frequency, and duration.
5. Identify the exposed population.

By their nature, the hazards posed by radiological agents are different from those posed by biological or chemical agents. Although some radiological agents can also be chemically toxic to humans, it is the actual radiation damage that must be evaluated for its longer-term impacts to human health. Radionuclide sources emit three principal types of potentially harmful ionizing radiation: $\alpha$ and $\beta$ particles with low and medium penetration, respectively, and $\gamma$ rays with high penetration ability [21, 22]. To give some general sense of what "penetration" means in the context of ionizing radiation, $\alpha$ particles are shielded by paper or skin, $\beta$ particles by aluminum or wood, and $\gamma$ rays by concrete. Exposure from ingestion would be the most likely mode of transport from a contaminated water supply. Regulations and guidelines for radiological, chemical, and biological agents are discussed below in that order.

## 4 REGULATIONS AND GUIDELINES FOR RADIOLOGICAL AGENTS

For weapons of mass destruction, regulations and guidelines for what constitutes a "safe" or "acceptable" human dose are clearest for radiological agents, somewhat less clear for chemical agents, and least codified by far for biological agents. For that reason, radioisotopes are discussed first.

### 4.1 Radioisotopes of Concern

The International Atomic Energy Agency (IAEA) has identified $^{192}$iridium, $^{60}$cobalt, $^{137}$cesium, $^{90}$strontium, and $^{241}$americium as the top radioactive isotopes that are involved in illicit trafficking and pose a potential security threat [23]. Several of these radionuclides are generated by, or used in, research facilities; some are used in the medical, food processing, and well logging industries; and others result from nuclear power generation. Table 2 lists the five radioisotopes of concern to the IAEA along with other relevant information. In this table, the radioactivity level associated with each radioisotope, expressed in curies (a common quantity measurement term), is also shown. A curie is the quantity of a radionuclide that has $3.7 \times 10^{10}$ disintegrations per second.

**TABLE 2 Radioisotopes of Concern, Example Applications, and Typical Curie Content [23]**

| Radioisotope | Example Applications and Sources | Typical Radioactivity Level (Curies) |
|---|---|---|
| $^{241}$Americium | Well logging, smoke detectors, medicine, industrial gauging | 0.027–22 |
| $^{137}$Cesium | Teletherapy | 13,500 |
| $^{90}$Strontium | Radioisotope thermoelectric generators | 30,000–300,000 |
| $^{60}$Cobalt | Food irradiation | 2700–11,000,000 |
| $^{192}$Iridium | Industrial radiography | 3–250 |

In addition to those radioisotopes identified by the IAEA, other radioisotopes have also been identified as environmental health threats to the public from industrial processes. Although they are not discussed here in detail, some exposure guidelines specific to water are included. These other radioisotopes may well be used or considered for some terrorist scenarios.

Health risks associated with radioisotopes are relatively well understood. In general terms, health risk depends on the dose received, type of ionizing radiation involved, and the genetic makeup of an individual, among other factors. Higher doses have serious, acute health effects; lower accumulated doses have chronic health effects often expressed as one or another type of cancer; and very low doses have no observed health effects.

Two dose-measurement terms are common (see, e.g. http://www.osha.gov, accessed Sept. 6, 2007), where "dose" means the quantity of ionizing radiation absorbed, per unit of mass, by the body or by any portion of the body. The radiation absorbed dose (rad) is a measure of dose of any ionizing radiation to body tissues in terms of the amount of energy absorbed per unit of mass of the tissue. One rad is the dose corresponding to 100 ergs of energy per gram of tissue. As a rule of thumb, a dose of 1000 rad is fatal 100% of the time; a dose of 500 rad is fatal 50% of the time; and dose of 100 rad typically results in radiation sickness. Another dose-measurement term, the roentgen equivalent man (rem), is the amount of energy absorbed into a material multiplied by the quality factor. Applying the quality factor to absorbed dose provides a dose equivalent that reflects the biological risk associated with the radiation quality. To lend some perspective on what this measure means, the total annual dose equivalent that an individual typically receives from all natural sources (such as cosmic and terrestrial radiation, food, and consumer products) is estimated to be in the range of 360 mrem/year (1 mrem = 1/1000 rem). An accumulated dose of 25 rem results, on average, in 1% risk of developing cancer. The occupational exposure limit (whole body) is 5 rem/year [29 CFR Standard 1910.1096 (b)(1)—Ionizing Radiation]. In Order 5400.5, the Department of Energy (DOE) sets the primary dose limit at 100 mrem/year for a member of the general public (see [24]). The same dose limit is used in 10 CFR 835 for members of the general public entering a controlled area, the dose limit for minors, and the threshold requiring appropriate personnel dosimetry for general workers.

### 4.2 Exposure Guidelines for Radiological Agents

A regulatory structure separate from that for chemical (and more recently, biological) agents has evolved for response guidelines associated with radiological agents, primarily driven by the Nuclear Regulatory Commission (NRC), the EPA, and the DOE. The

cleanup and final release of an area or resource that is contaminated with a radiological agent is carried out under the guiding principle of limiting the dose to the general public. The NRC, EPA, and DOE have historically approached the criteria differently: the NRC and DOE use a dose-based approach, whereas the EPA uses a risk-based approach. As a result, the EPA and NRC have different cleanup standards.

The EPA has developed updated Protective Action Guides (PAGs) intended to help state and local authorities make radiation-protection decisions during the various phases of an emergency [25]. During the early phases of response (first hours to days, corresponding to the notification and first-response phases of an incident), the PAG is to consider evacuation if the projected dose exceeds 1 rem in 4 days. During the intermediate phase (days to months after an attack, corresponding to the remediation or cleanup phase of an incident), the PAG is to relocate a population if the projected dose during the first year exceeds 2 rem and to use dose-reduction techniques if the dose is less than 2 rem. During the recovery phase (months to years after an attack), the PAG involves no set dose limits; rather, the Department of Homeland Security (DHS) along with other Federal agencies and state and local governments set the final release criteria.

Meeting a specific clearance goal can have a large impact on the total cost of remediation or cleanup following a contamination event. The EPA considers radionuclides to be carcinogens and, from a risk-based approach, requires that cleanup or clearance levels achieve a standard that places the risk of developing cancer between 1 in 1000 and 1 in 1,000,000. The result is usually a more conservative cleanup level than that mandated by the NRC.

No uniform set of cleanup standards for radionuclides exists at present. However, the DHS is in the process of issuing PAGs specifically designed to address response operations [26]. The proposed PAGs outline the projected dose of radiation to an individual, from an accidental or deliberate release of radioactive material, at which a specific protective action to reduce or avoid such a dose of radiation is recommended. The PAGs are based on four criteria: (i) to prevent acute health effects, (ii) to reduce the risk of chronic effects; (iii) to balance protection with other important factors that affect the public welfare; and (iv) to ensure that the actions taken result in more benefit than harm. Representatives from eight Federal agencies developed and approved the proposed guidance. The DHS posted its proposed guidelines in the *Federal Register*, and the public and interested stakeholders were invited to submit comments.

In the absence of uniform Federal guidelines to protect the public, emergency responders, and the surrounding environment from the effects of radiation, acceptable exposure and associated cleanup levels for water as well as other media would likely be derived from existing laws and regulations. The DHS is expected to play a key role in determining acceptable levels for final clearance of items. As per the American National Standards Institute [27], the consensus for item clearance criteria (a voluntary standard) is currently 1 mrem/year (or 10 $\mu$Sv/year) total effective dose equivalent (TEDE) above background. The stated purpose of the standard is "to provide guidance for protecting the public and the environment from radiation exposure by specifying a primary radiation dose criterion and derived screening levels for the clearance of items (which may include water-contaminated areas) that could contain radioactive material". Because Federal agencies are to use voluntary industry standards developed by the private sector when possible, this ANSI standard should play a large role in the regulatory process [28].

The guidance for concentrations of various radioactive isotopes in groundwater and drinking water is specified under several different regulations [29]. Because of the importance of groundwater as a source of drinking water for so many communities and individuals, the EPA has been designated as the responsible entity for Federal activities relating to the quality of drinking water to include groundwater and other surface water-supply resources [30]. Some of the Federal laws enacted to protect groundwater include the *Safe Drinking Water Act*, the *Resource Conservation and Recovery Act*, the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA, also known as the *Superfund* law), the *Federal Insecticide, Fungicide, and Rodenticide Act*, the *Toxic Substance Control Act*, and the *Clean Water Act*. The EPA standards for groundwater and drinking water are shown in the upper tier of rows of Table 3. Because it is possible that radioactive isotopes other than the five specified by the IAEA [23] could be involved in an attack involving the intentional contamination of water, other radiological contaminants are identified in Table 3 when water guidelines for them are available. The Agency for Toxic Substances and Disease Registry (ATSDR) was established by Congress in 1980 under CERCLA to conduct public health assessments at each site on the EPA National Priorities List. For some radiological contaminants, the ATSDR specifies a "comparison value", which is a concentration or amount of substance in air, water, food, or soil that is, upon exposure, unlikely to cause adverse health effects. The values identified in Table 3 as "ATSDR estimates" [31] are such values for the maximum concentration of radionuclides in water based on the consumption of 2 liters per day for 1 year, a limit of 4 mrem/year, and Federal cancer risk coefficients for environmental exposure to radionuclides.

The *Safe Drinking Water Act* (1974, amended 1986, reauthorized in 1996) specifications provided in the middle rows of Table 3 represent national primary drinking-water standards. Maximum contaminant levels (MCLs) are the highest level of a contaminant or a naturally occurring mineral that is allowed in US domestic drinking water from distributed systems. The MCLs are enforceable EPA standards for water-treatment utilities [32]. The MCL values shown in this middle part of Table 3 reflect updates per the Radionuclides Rule (final rule for radionuclides in drinking water), published in the *Federal Register* on December 7, 2000 (65 FR 76708) [33, p. I-4]. The EPA guidance from the Office of Solid Waste and Emergency Response (OSWER) under Directive 9283.1-4 is shown in the bottom rows of Table 3.

## 5 REGULATIONS AND PROPOSED GUIDELINES FOR CHEMICAL AGENTS

### 5.1 Chemical Agents of Concern

Hazardous chemicals are classified by the CDC [34] into 13 categories, which include biotoxins, blister agents and vesicants, blood agents, caustics, choking agents, nerve agents, and others. Among the blister agents, sulfur mustard (NATO code H, or distilled mustard, NATO code HD; chemical formula $C_4H_8Cl_2S$) is widely recognized as a chemical warfare agent of concern in an intentional contamination event. Among the nerve agents, the G agents sarin (NATO code GB; chemical formula $C_4H_{10}FO_2P$), cyclosarin (NATO code GF; $C_7H_{14}FO_2P$), soman (NATO code GD; $C_7H_{16}FO_2P$), tabun (NATO code GA; $C_5H_{11}N_2O_2P$), and the V agent VX ($C_{11}H_{26}NO_2PS$) are Chemical Warfare

**TABLE 3 Guidance for Radionuclides in Groundwater and Drinking Water**

| Regulation or Standard | Regulated Radionuclide |
|---|---|
| USEPA standard for groundwater [31] | 15 pCi/L gross $\alpha$ (MCL) |
| | 50 pCi/L gross $\beta$ (MCL) |
| Or | 6 pCi/L plutonium 238 (ATSDR estimate) |
| ATSDR estimate for groundwater, where a "comparison value" is specified [31] | 6 pCi/L plutonium 239/240 (ATSDR estimate) |
| | 5 pCi/L radium 226 + radium 228 (MCL) |
| | 300 pCi/L radon 222 (proposed MCL) |
| | 21 pCi/L thorium 228 (no existing MCL; ATSDR estimate) |
| | 7 pCi/L thorium 222 (no existing MCL; ATSDR estimate) |
| | 20,000 pCi/L tritium (H-3) (MCL) |
| | 30 pCi/L uranium 233/234 (no existing MCL; ATSDR estimate) |
| | 32 pCi/L uranium 235/236 (no existing MCL; ATSDR estimate) |
| | 15 pCi/L uranium 238 (as an $\alpha$ emitter; see gross $\alpha$, above) |
| MCLs specified in the Safe Drinking Water Act (40 CFR Part 141) and modified per the Radionuclides Rule, published in the *Federal Register* on December 7, 2000 (65 FR 76708) | 4 mrem/year $\beta$ + photon emitters (MCL) |
| | 15 pCi/L gross $\alpha$ particle (MCL) |
| | 5 pCi/L combined radium 226 + radium 228 (MCL) |
| | 30 $\mu$g/l uranium (MCL) |
| | For other radionuclides, no MCL in drinking water is specified |
| Office of Solid Waste and Emergency Response (OSWER) Directive 9283.1-4 | Total concentration corresponding to a 4 mrem/year limit, i.e. |
| | 200 pCi/L $^{137}$Cs |
| | 100 pCi/L $^{60}$Co |
| | 8 Ci/L $^{90}$Sr |

Agents (CWAs) of concern. In addition, three toxic industrial chemicals are often identified as being of importance: two are the blood agents cyanogen chloride (CK; chemical formula CNCl) and hydrogen cyanide (AC; chemical formula HCN); and one is the choking agent, phosgene (CG; chemical formula $COCl_2$). Of these nine chemicals, the first six listed above are referred to collectively in the following discussion as CWAs, and the last three are referred to collectively as toxic industrial chemicals (TICs). The term "chemical agents" refers to all nine collectively.

## 5.2 Exposure Guidelines for Chemical Agents of Concern

For chemical agents, data from animal models are often relied on as the basis for dose–response or potency information. Unlike biological warfare agents, chemical agents have various quantified health-based guidelines that can be used as clearance goals.

Among the authorities and agencies that have published guidelines for chemical agents are the following:

- CDC of the US Department of Health and Human Services [35, 36].
- Committee on Toxicology of the National Research Council [37–39].
- American Conference of Governmental Industrial Hygienists [40].
- USEPA's Integrated Risk Information System [1, 41].
- American Industrial Hygiene Association [42].
- USEPA, Regions 9 and 3 [43–46].
- CDC National Institute for Occupational Safety and Health (NIOSH) and Occupational Safety and Health Administration (OSHA) [47].

Whereas site-, situation-, and population-specific factors must all be considered when selecting "acceptably safe" levels for chemical agents, various scientifically defensible levels have been applied as appropriate for some CWAs and TICs. Another important definition is the acute exposure guideline levels (AEGLs). AEGLs represent federally endorsed guidance criteria for the assessment and management of single-exposure emergency events, such as accidents or intentional terrorist attacks. AEGLs, published by the National Research Council Committee on Toxicology and developed in collaboration with the USEPA National Advisory Committee for AEGLs for Hazardous Substances [37–39], are threshold airborne concentrations of a chemical above which different health effects could begin to occur among members of the general public. Three levels, called AEGL-1, AEGL-2, and AEGL-3, for each of five exposure periods (10, 30 min; 1, 4, and 8 h) are distinguished by varying degrees of severity of toxic effects.

Table 4 shows an example of how certain airborne exposure guidelines might be applied following an intentional contamination scenario. If the maximum airborne concentration resulting from an event was lower than the general population limit (GPL), it is unlikely that drinking-water resources would be affected. The GPL is an atmospheric concentration level (milligram per cubic meter) below which no adverse effects would occur in the general population, including sensitive subpopulations, assuming a continuous, daily (24/7), chronic (lifetime) exposure [48–50].

The second column of Table 4 lists the NRC-endorsed AEGL-1 concentrations—the mildest-effect tier of AEGL values—for an 8-h exposure to the six CWAs. An AEGL-1 value is defined as the airborne concentration (in milligram per cubic meter) of a substance at or above which it is predicted that the general population, including "susceptible" but excluding "hypersusceptible" individuals, could experience notable discomfort after the specified time (8 h in this example). Airborne concentrations less than AEGL-1 represent exposure levels that could produce mild odor, taste, or other sensory irritations, but nothing more serious.

Depending on the specific type of contamination event that might occur involving chemical agents, soil or other types of sediment could be susceptible to contamination. Health-based environmental screening levels (HBESLs), which are calculated using EPA chronic risk assessment methods, represent the current guidelines for soil contamination. The levels shown in the two columns on the right side of Table 4 are low-level concentrations of individual CWAs in residential and industrial soil, which, if not exceeded, are unlikely to present a human health hazard for specific exposure scenarios [52]. The values are derived from the USEPA Region 3 Risk-Based Concentration (RBC) model [44] and are appropriate for use where cumulative effects are not anticipated. Several

**TABLE 4 General Population Limits, Airborne (Inhalation, Ocular) Exposure Guidelines (AEGL-1 Values), and Health-Based Environmental Screening Levels (HBESLs) for Selected CWAs in Residential and Industrial Soil**

| CWA | GPL (mg/m3) for Chronic (Lifetime) Exposure | AEGL-1[a] Protective Estimate ($mg/m^3$) 8-h Exposure | HBESL for Residential Soil (mg/kg) | HBESL for Industrial Soil (mg/kg) |
|---|---|---|---|---|
| Tabun (GA) | $1 \times 10^{-6}$[b] | 0.0010[c] | 3.1 | 82 |
| Sarin (GB) | $1 \times 10^{-6}$[b] | 0.0010[c] | 1.6 | 41 |
| Soman (GD) and Cyclosarin (GF) | $1 \times 10^{-6}$[d] | 0.00050[c] | 0.31 | 8.2 |
| VX | $6 \times 10^{-7}$[b] | 0.000071[c] | 0.047 | 1.2 |
| Sulfur mustard (H/HD) | $2 \times 10^{-5}$[e] | 0.008[c] | 0.55 | 14 |

[a]NRC/COT [38].
[b]DHHS [35].
[c]NRC/COT [39].
[d]Department of the Army [51].
[e]DHHS [36].

assumptions underlie these values. One is that the exposure pathway is ingestion but not inhalation or dermal contact with contaminated soil. In addition, the values do not account for potential runoff or groundwater contamination, and that risk to ecological receptors is not evaluated. If groundwater were a concern, then cleanup levels would need to be re-evaluated on the basis of depth to groundwater and other parameters [53]. Hydrogeological conditions and potential contaminant transport through soils are clearly important parameters in understanding potential risk and for optimizing remediation actions.

In terms of the topic of central concern in this article, both the EPA and the military use the MCL as enforceable guidelines for CWAs in drinking water. MCLs are the highest level of a contaminant or naturally occurring mineral that is allowed in US domestic drinking water from distributed systems. MCLs are enforceable EPA standards for water-treatment utilities [32]. Table 5 lists suggested groundwater and surface water guidelines, to the extent they are specified, for the six CWAs and three TICs identified earlier as being of concern in an intentional contamination event. Furthermore, it is possible that certain chemical agents could absorb on or into certain porous media, such as concrete or porous plastics, and potentially present a continued source of exposure particularly in scenarios where liquid aerosol droplets are released. Thus Table 5 also identifies chronic reference doses (previously published RfDs or estimated $RfD_{est}$) that could be applied to meet waste-disposal requirements and landfill agreements with state and Federal agencies and help them determine that an agent is not present at levels of concern.

## 6 REGULATIONS AND GUIDELINES FOR BIOLOGICAL AGENTS

### 6.1 Biological Agents of Concern

The CDC has prioritized biological agents that pose the greatest threats to civilians for the purpose of public health preparedness activities [60]. In June 1999, a meeting of national

**TABLE 5 Drinking Water and Ingestion Guidelines for Chemical Agents**

| Agent Type and Name | Published Water Guideline | Reference Dose (RfD or $RfD_{est}$) (mg/kg/day)Ingestion: Estimate of Daily Exposure Level for General Population; Chronic Exposure Duration (7 years to Lifetime) |
|---|---|---|
| **Nerve Agents** | | |
| Tabun (GA) | Field drinking-water standard MCL[a] = 12 $\mu$g/l | $4 \times 10^{-5}$[b] |

[g]Opresko et al. [59]. The value of 0.03 mg/kg-day for cyanogen chloride is an estimate ($RfD_{est}$) and has not been reviewed by IRIS. USEPA Region 9 (2004), Region 9 Preliminary Remediation Goals 2004 Table. The RfD of 0.05 mg/kg/day for cyanogen chloride is from http://www.epa.gov/region09/waste/sfund/prg/index.html, accessed March 2, 2006.

experts was convened to review selection criteria. Criteria included public health impacts, delivery potential, public perception related to civil disruption, and special public health preparedness needs. Final assignments of agents into three categories (A, B, or C) were based on overall ratings in those four areas. The results are as follows:

- *Category A biological agents* are those that pose the greatest potential for adverse impact and have the highest priority for preparedness. They are *Variola major, B. anthracis*, *Yersinia pestis*, *Clostridium botulinum*, *Francisella tularensis*, Filoviruses, and Arenaviruses.
- *Category B biological agents* have a high threat potential, but less impact than that of Category A agents. They are *Coxiella burnetii, Brucell* spp., *Burkholderia pseudomallei*, Alphaviruses (VEE, EEE WEE), *Rickettsia prowazekii*, certain toxins (including ricin and *Staphylococcal enterotoxin B*), *Chlamydia psittaci*, certain food-safety threats (such as *Salmonella* spp. and *Escherichia coli* O157:H7, and certain water-safety threats (such as *Vibrio cholerae* and *Cryptosporidium parvum*).
- *Category C biological agents* are emerging threats. Examples include Nipah virus and Hantavirus.

### 6.2 Exposure Guidelines for Biological Agents of Concern

The dose–response concept has been used since at least the 1950s, and it is widely applied in industrial hygiene applications [6, p. 107]. A dose–response curve is a graph showing the quantitative relation between administered, applied, or internal exposure (dose) of an agent and specific, biologically significant changes in incidence, or degree of change, to that agent (i.e. response, such as infection, illness, or death) [modified after [1]]. Dose–response assessments differ considerably for microorganisms and chemicals agents.

Dose–response modeling has been used extensively to posit the risk associated with ingestion of organisms [61–65]. Although dose–response models have not been published for Category A biological agents in humans (ethics prohibit their use in human studies), other data are available from which to infer doses and responses for those agents (see Table 6). Mathematical models have been advocated to assist in dose–response modeling, especially for extrapolation to low doses, and such models have been used for decades in toxicology [12]. The use of animal models for extrapolating health effects to humans, and the type of mathematical model used to extrapolate from high doses to low are two of the methods in risk assessment that have been associated with controversy [4]. The two most successful of the family of mechanistic models are the exponential model and the beta-Poisson model, which vary principally in the way they treat survival probabilities. Both models assume that a single organism is sufficient to initiate infectious disease in some individuals, and that the probability of any ingested organism will survive to colonize is independent among all organisms inhaled or ingested. This modeling approach and conclusion was also reaffirmed by the 2005 National Academy of Sciences Study, which reviewed cleanup levels for biological agents following a potential indoor airport attack [6].

Whereas nearly all biological warfare agents are intended for aerosol application, many “have strong potential as waterborne threats” and could inflict heavy casualties when ingested [66, p. 975]. Perhaps most pertinent to the focus of this article is that scientific investigations have led to recommended guidelines in drinking water (Table 6)

**TABLE 6 Dose–Response Information (Published Data or Inferred) and NPDWR Drinking-Water Guidelines for Microbes Identified as Category A or B Agents by the CDC [60] and of Medical Importance in Water Per Haas et al. [4] or a "Water Threat" According to Burrows and Renner [66] or the USEPA [32]**

| Biological Agent | Dose–Response Available?[1] | Dose–Response Source[1] | Water Guideline Available?[2] |
|---|---|---|---|
| **Bacteria** | | | |
| *Bacillus anthracis*[2] | Yes | [67] | None identified |
| *Salmonella*[1] | Yes | [68–70] | No MCL identified. *Salmonella* is on the list of agents for which the EPA is developing the Groundwater Disinfection (GWD) Rule[3] |
| *Shigella*[1] | Yes | [62] | No MCL identified. *Shigella* is on the list of agents for which the EPA is developing the Groundwater Disinfection (GWD) Rule[3] |
| Enteropathic *E coli*[1] | Yes | [4] | Yes (for total coliform). MCL |
| *E. coli* O157:H7[1] | Yes in animals | [71] | violation if more than 5% of samples are total coliform positive in 1 month. Heterotrophic plate count $\leq$500 CFU/ml[3] |
| *Vibrio cholerae*[1] | Yes | [4] | No MCL identified |
| *Campylobacter*[1] | Yes | [65] | No MCL identified. *Campylobacter* is on the list of agents for which the EPA is developing the Groundwater Disinfection (GWD) Rule[3] |
| *Francisella tularensis*[1] | Yes in animals | [72] | No MCL identified |
| **Viruses** | | | |
| Adenovirus[1] | Yes | [4] | MCLs have only been specified for |
| Coxsackievirus[1] | Yes | [4] | viruses considered to be "enteric." |
| Echoviruses[3] | Yes | [4] | Recommendation is for 99.99% removal or inactivation of enteric viruses |
| | | | Adenovirus, Coxsackievirus, and Echoviruses are on the Contaminant Candidate List, but MCLs are not yet established by the EPA[2] |
| Ebola | Yes, in animals | [73] | No MCL. Ebola transmission in water is "not known" [66] |
| *Variola major*[2] | Yes | [74] | No MCL. Smallpox (from *Variola major*) is identified as a "possible" water threat [66] |
| **Protozoans** | | | |
| *Giardia lamblia* (cysts)[1] | Yes | [75] | Yes. 99.9% removal or inactivation. (Not identified by CDC as Category A, B, or C.) |
| *Cryptosporidium* (oocysts)[1] | Yes | [64]; [76]; [77] | Yes. 99% removal as of 1/1/2002 for systems serving >10,000; 99% removal as of 1/14/2005 for systems serving <10,000 |

for only some of the biological warfare agents that have been identified by the CDC [60] as priority microbes and by Haas et al. [4] or others [66] as microbes of medical importance in water. For many other biological agents, no water guidelines have been established.

Even though the US National Primary Drinking Water Regulations (NPDWRs) are enforceable and must be health protective [78], some have argued that in light of new epidemiological evidence, water-quality guidelines for pathogenic microorganisms have not kept pace with microbiological risk assessments, and that a new framework linking assessment of risks with health targets and outcomes should be used to converge on what constitutes a "tolerable risk" of infection from water [13]. However, the issue of exactly what constitutes an acceptable risk is a complex matter. The importance of education should not be underestimated when considering what risk the public is willing to accept. For example, the public accepts hospital disinfectant methods even though such methods do not guarantee zero risk. Similarly, public swimming pools are required to meet defined treatment standards that are also accepted by the public, yet there have been instances in which children have died from exposure to and ingestion of *E. coli* from public swimming pools. Examples of public health standards for swimming pools are as follows:

- Combined available chlorine $<0.2$ mg/l, and pH from 7.2 to 8.0 [79].
- 1.5 ppm free chlorine and pH from 7.2 to 8.0 (22 CCR §65529).
- Total coliform bacteria of less than 2.2 MPN (most probably number or median) per 100 ml (22 CCR §65531).
- Total coliform level using the membrane filter (MF) procedure not to exceed 2 colony forming units (CFU) per 100 ml of sample tested [79].
- Heterotrophic plate count not to exceed 200 CFU per 100 ml in 85% of samples tested [80].

Individual states have their own regulations regarding drinking water based on their stakeholders and this must be taken into account when trying to determine and/or develop guidelines related to an unnatural event. As an example, the California Code of Regulations (22 CCR, Division 4, Article 20, Article 3) specifies that a public water system is in violation of the total coliform MCL when any of the following occurs:

- For a system collecting more than 40 samples/month, more than 5% of the samples collected during any month are total coliform positive; or
- For a public water system that collects fewer than 40 samples/month, more than one sample collected during any month is total coliform positive; or
- Any repeat sample is fecal coliform positive or *E. coli* positive; or
- Any repeat sample, following a fecal coliform positive or *E. coli*-positive routine sample, is total coliform positive.

A summary of the various health factors involved in assessing microbial risks associated with drinking water can be found in Haas et al. [4], Tables 3–5 [p 101]; a summary of exposure factors in such an assessment can be found in Haas et al. [4], Tables 3–6 [p 102]. Exposure factors include transmission routes, environmental sources of microbes, their survival potential, their regrowth potential, their occurrence in raw water supplies, resistance to treatment, environmental transport, and the availability of methods for assessing

source water and treated water, among others. A variety of methods are used to isolate and identify microbes from environmental samples [81], such as those identified in *Standard Methods for the Examination of Water and Wastewater* [82]. The problem is that quantitative and statistically evaluated databases and improved models, rather than nonquantitative presence versus absence reports, are needed to assess the reduction of microbial populations through treatment and process controls. This major gap in risk assessment associated with drinking water-treatment efficacy in the United States has been clearly recognized by several experts publishing on the topic [e.g. [16]].

The challenges associated with setting an "acceptable cleanup level" leading to clearance following a biological attack are discussed in many reports [see e.g. [53, 83, 84]]. Almost all researchers writing on the topic agree that there is currently insufficient information to develop an "infectious dose" and to quantify a "safe" amount of residual biological agent in a decontaminated facility or outdoor environment [4, 6, 14, 15, 85, 86]. There exists even less information regarding safe levels for water-related resources. Currently, there are no risk-based developed guidelines for biological warfare agents that are equivalent to the AEGLs endorsed for chemical agents or the PAGs that have been developed for radiological agents.

However, after the anthrax letter attacks in the United States in 2001 and the unprecedented remediations that followed these attacks, many experts concurred that the clearance goal (acceptable level of residual contamination), at least for a *B. anthracis*-contaminated facility (indoors), should be no growth of spores on all postremediation environmental samples [see e.g. [6, 87]]. Therefore, it is anticipated that in the event of an actual biological attack on water supplies or resources, a similar type of conservative clearance goal may need to be implemented.

An issue closely associated with decontamination and clearance following any biological attack—and one that illustrates the complex nature of potential problems that can arise from remediation efforts—is the possibility that certain decontamination reagents used to address biological contamination might themselves become problematic during a cleanup operation. Some investigators have suggested that decontamination with powerful chemicals to decrease the exposure to a given microbial pathogen could result in increased exposure to those chemical contaminants used, particularly in drinking water [78]. The concern thus is health risk arising from the treatment (decontamination) process rather than the microbes per se, especially if high levels of treatment were applied over a wide area, and if the by-products of treatment were disposed as untreated wastewater and found their way into drinking-water supplies. The balancing of chemical risks associated with disinfection, potential cancer risks arising from disinfection by-products that might be formed, and the risks from biological agents themselves in water that the management option of treatment is invoked to address is "a worldwide issue in drinking water and cannot be solved without appropriate risk assessment" [16, p. 100.]. Clearly, risk trade-offs must be considered as part of the decision-making process whereby decontaminant chemicals and treatment methods are selected and applied to minimize microbial risks, but approaches to strictly limit or prevent secondary contamination of water systems should be incorporated into remediation planning. Account must be taken during remediation planning of all regulations applicable to potential waste streams that could be generated. Depending on their destination, wastewater from decontamination technologies is regulated by *Clean Water Act* pretreatment requirements specified in 33 USCA 1317, 40 CFR 403, state regulations regarding pretreatment, and any local publicly owned treatment works (POTW) pretreatment requirements.

## 7 CRITICAL NEEDS AND FUTURE DIRECTIONS

As is apparent from the literature surveyed in this article, meeting the critical needs of homeland security and counterterrorism in the area of risk assessment will be challenging. The complexities associated with evaluating human health hazards, exposures, responses, and risks, although well documented, are numerous. However, several key areas continue to represent technical gaps in addressing the issue of risk for radiological, chemical, and biological contaminants. Additional study and research in the following areas are needed to better minimize the potential human health consequences associated with radiological, chemical, and biological contamination resulting from terrorist attacks.

1. A risk assessment approach should be incorporated as a required component of decision making for ascertaining the adequacy of decontamination processes or treatments, if used, following the release of a contaminant. This need—largely in the context of indoor, surface decontamination—was acknowledged by the NRC [6, pp. 5–6]. In particular, microbial risk assessment models and tools are lacking. More generally, a scenario-specific risk assessment approach is needed to understand appropriate cleanup levels and potential residual health effects regardless of the media that are contaminated (water, air, or environmental surfaces). Key site-specific parameters and the relations among them in a given scenario must be carefully defined. They include the sources and extent of contamination, applicable receptors, and potential environmental and physical pathways between them [8].
2. Essential experimental data needed to support quantitative risk assessment are lacking for biological warfare agents in the area of dose–response relations. This need was acknowledged by the NRC [6, p. 4]. In addition, chronic low-dose exposure data needed for better risk assessments are lacking for CWAs. To develop dose–response information and better assess the human risk of exposure to biological agents, targeted research should be directed toward ways to extrapolate dose–response data between species. Use of animal and human tissues, and of *in vitro* techniques, may become increasingly important [6, p. 118]. Available dose–response data for pathogens of concern should be analyzed by nonthreshold dose–response models [6, p. 117].
3. Consensus with regard to protective estimates that can serve as clearance goals (standards) for the general public are especially needed for both water resources and soil (in terms of the potential to impact groundwater and other water resources from surface runoff) that have been contaminated with radiological, chemical, or biological agents. Such standards will require a consensus among subject-matter experts, regulatory authorities, and local, state, and Federal health agencies. With respect to drinking-water contamination and cleanup in particular, clearly defined, health-based clearance goals or national standards are lacking for some radiological isotopes of concern, certain chemical agents, and nearly all biological warfare agents that are viewed as potential threats to water.

   A national committee of experts including representatives from regulatory agencies—the EPA and CDC in particular—should be appointed to work on developing consensus-based clearance goals (standards) for the radiological, chemical, and biological agents ascertained to be of concern in the event of a terrorist attack and for which such standards are currently lacking. Review of, and comment on, proposed standards should be solicited in the *Federal Register*.

For example, no official primary drinking-water standard exists for at least one chemical agent of concern, and MCLs are generally lacking for biological warfare agents. Efforts should be made to fill these and other gaps. The experts who develop the standards must consider not only scientifically based information but also public perceptions about what is safe. Appropriate risk communication techniques, including explanations of scientific terminology and methods, should be used when making recommendations based on scientific criteria. The risk communication techniques that have been recently used in association with the demilitarization of the US chemical weapons stockpiles may provide a useful framework on which to build.

4. Additional risk-based evaluations should be performed, and explicit guidelines developed, to avoid the secondary contamination of water and wastewater systems by the application of potentially hazardous decontamination reagents, their by-products, or the degradation products of CWAs or hazardous TICs.
5. Since reauthorization of the *Safe Drinking Water Act* in 1996, there has been renewed interest in emerging microorganisms that pose increased risk to the safety of drinking-water supplies [88]. However, current methods used to monitor environmental samples, particularly biological agents in water, do not always provide the necessary levels of sensitivity that are required to ascertain the efficacy of treatment processes [16].

   To address the problem of inadequate sensitivity of some methods used to monitor environmental samples, particularly biological agents in water [16], researchers need to assemble a larger database on the inactivation or removal of microorganisms via various treatment processes, such as disinfection and filtration. Improved quantitative, statistically evaluated databases for adequate risk assessments will be useful in estimating concentrations of microbes in treated water.
6. A better understanding of natural decontamination or natural attenuation with regard to biological and chemical agents of interest is needed. Few studies have assessed the survivability of biological agents in water under various environmental conditions. Little information exists on the degradation kinetics for CWAs as a function of time under different geochemical conditions. Such factors have a major impact on risk assessment and long-term public health risks.

## ACKNOWLEDGMENT

This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

# TRANSPORTATION SECURITY

# ROLES AND IMPLICATIONS OF TRANSPORTATION SYSTEMS IN HOMELAND SECURITY

David Ekern
*Virginia Department of Transportation, Richmond, Virginia*
Joe Crossett
*High Street Consulting Group, Pittsburgh, Pennsylvania*

## 1 INTRODUCTION

In the United States, state Departments of Transportation (DOTs), working with agencies at the local and federal governmental levels, have responsibility for planning, delivering, operating, and maintaining a vast surface transportation network that includes not only four million miles of roads serving local, regional, and national travel needs [1], but also many rail lines, bus and rail transit systems, ferries, ports, and waterways. The emergency preparedness capabilities that public-sector transportation agencies are acquiring are critical to safe and efficient operation of the nation's transportation network in the twenty-first century.

Surface transportation is uniquely positioned among critical infrastructures and key resources in terms of its management by agencies with broad policy responsibility, public accountability, large and distributed workforces, heavy equipment, communications infrastructure, and ability to directly and swiftly take action (akin to the private sector). This institutional heft and continuous programmatic investment provide a stable base for a campaign to systematically reduce risk exposure over time through hazards capital budgeting.

Whether moving by car, truck, bus, train, ferry, bicycle, or on foot, Americans depend on surface transportation for safe and predictable mobility. On trips through town or across the country, vehicles drive an estimated eight billion miles on roads in the United States every day [1] and a considerable share of daily travel is associated with moving the estimated 89% of all freight by value that is shipped on highways [2].

The apparent scale and redundancy of the nation's transportation network gives a false sense of security, but in many parts of the country that network is straining to keep

up with the transportation demands of society and the economy. A single unexpected interruption in one location may have a dramatic ripple effect on travel across a wide region.

In August 2007, for example, the collapse of Minnesota's busiest bridge (I-35W) that carried 140,000 vehicles a day over the Mississippi River between downtown Minneapolis and its northern suburbs, not only caused tragic loss of life, but is also expected to have an economic impact of about $60 million in road user detour costs incurred before it is fully replaced [3] at an expected cost of at least $393 million. The US Department of Transportation estimates that there are at least 1000 bridges across the country where substantial casualties and economic disruption would result from isolated terrorist attacks [4].

Homeland security is one among many threats to safe and efficient operation of the nation's transportation network. An act of terrorism at a busy bottleneck or malevolent destruction of a major bridge would almost certainly cause unacceptable loss of life and temporary disruption of economic stability and necessitates costly infrastructure repairs. Historically, a range of threats, such as floods, earthquakes, extreme weather, wildfires, or major traffic incidents, have all proven capable of generating similarly adverse outcomes.

As travel grows with economic prosperity, lower density land use, and more mobile populations, incidents of any kind pose greater potential to disrupt the transportation network. Transportation agencies have no choice but to enhance their emergency preparedness capabilities to ensure that they can meet five fundamental responsibilities [5]:

1. prevent incidents within their control and responsibility;
2. protect transportation users, agency personnel, and critical infrastructure;
3. support regional, state, and local emergency responders with resources, including facilities, equipment, and personnel;
4. recover swiftly from incidents; and
5. evaluate response(s) and continually improve plans, training, skills, and protocols.

Meeting these responsibilities requires the engagement of skilled employees in a transportation agency, leadership by senior executives, and critical targeted investment in technology, people, and infrastructure.

Fortunately, transportation agencies can build from a strong foundation as they enhance their emergency preparedness capabilities. This is because, successful prevention, protection, response, and recovery from terrorist attacks depend on many of the same technologies, staff skills, and organizational structures needed to handle other hazards. As a consequence, many transportation agencies, including over 90% of state DOTs, have in place all-hazards emergency preparedness plans that enable them to respond to serious incidents regardless of their cause [6].

No two transportation agencies share exactly the same characteristics and one-size-fits-all fixes are not the solution for stronger homeland security, but some common themes are emerging that merit further scrutiny. These include organizational elements and planning approaches that are critical to developing effective all-hazards emergency preparedness capabilities and building the roles that transportation agencies are expected to perform in preventing, preparing for, responding to, and recovering from serious incidents.

## 2 ORGANIZATIONAL ELEMENTS OF PREPAREDNESS

A transportation agency's organizational structure is the framework that allows it to establish successful all-hazards emergency preparedness capabilities. The agency must be willing to blend new all-hazards functions with traditional organizational elements. Transportation agencies with strong all-hazards emergency management programs exhibit the following organizational elements [7].

### 2.1 A High Level All-Hazards Manager

State DOTs are recognizing that all-hazards preparedness cannot be achieved without a full-time, senior-level manager who is the agency's focal point for building and maintaining its all-hazards management capabilities. Many all-hazards preparedness activities involve sharing ideas among traditional transportation disciplines, such as traffic operations, maintenance, engineering, and construction, so the all-hazards manager in a transportation agency must have a broad understanding of many disciplines, from traffic operations and highway maintenance to information technology or bridge and tunnel design. The all-hazards emergency manager must be in close communication with executive staff so that critical issues before, during, and after incidents can be quickly raised to the highest levels, as needed. Many state DOTs have learned that colocation of all-hazards emergency management with their maintenance and operations functions makes sense because this is where the greatest overlap occurs among field staff awareness, emergency traffic operations, and other direct service activities. This becomes an even stronger function when colocation can be integrated with public safety agencies.

### 2.2 All-Hazards Leadership Team

The all-hazards manager should form and lead an interdisciplinary team that brings together key agency personnel from disciplines, such as maintenance, traffic operations, planning, design, and construction on a regular schedule. The functions of the team should include regular review of emergency incident reports, trends, program audit findings, and preparation of recommendations to senior management on changes in emergency preparedness plans and processes.

### 2.3 All-Hazards Technical Specialist Staff

Depending on factors, such as the size of the agency, existing staff capabilities, and criticality of risks, one or more additional staff are needed to support the all-hazards manager. Core focus areas of experienced specialist(s) include responsibility for training, exercises, evacuations, technology, and intelligence. In large state DOTs, the headquarters all-hazards and security team must have close links to districts that act for the DOT on the frontline during incidents. Each DOT district must have an experienced professional whose responsibilities include all-hazards emergency preparedness.

### 2.4 External Partnerships

Organizational exchange must be strengthened between transportation agencies and partners, such as emergency management agencies, the first responder community, law

enforcement, public health, and intelligence. An effective all-hazards manager must be active in a wide variety of state and federal networks for addressing emergency management issues. These connections promote sharing of ideas and information among disciplines and agencies, which can greatly enhance a DOT's all-hazards preparedness program.

## 3 ALL-HAZARDS EMERGENCY PREPAREDNESS PLANS

Transportation agencies' all-hazards emergency preparedness plans are vital to prevention, protection, response, and recovery from emergencies of all kinds. They enable every employee to understand their responsibilities; they help leadership hold staff accountable; and they allow the agency to work effectively with other organizations. Exemplary transportation agencies stand out because they have concentrated on integrating their plans into a single plan document. Their plans feature the following elements [7].

### 3.1 Consistency with National Emergency Planning Principles

The National Incident Management System (NIMS), Incident Command System (ICS), and National Response Framework (NRF) are initiatives headed up by the US Department of Homeland Security and they are the standard for emergency management planning. Many transportation agencies have built their emergency preparedness plans around NIMS, ICS, and the NRF.

### 3.2 A Single Emergency Preparedness Plan

A transportation agency's emergency preparedness plan must be an overarching document that is adopted by senior leadership and is the day-to-day resource within the agency for describing all general incident management planning, emergency operations center activation, and command and control and communications architecture that are applicable to incidents.

### 3.3 Hazard Type Annexes

Hazard annexes can be attached to the primary emergency preparedness plan, which provide details about threat-specific roles and responsibilities for addressing specific hazards, such as terrorism, biochemical, nuclear, fire, tornado, earthquake, snowstorm, or flood emergencies. Likewise, an annex can be included for continuity of operations planning, which describes how the agency will continue to operate if a disaster impacts key infrastructure or critical assets.

### 3.4 Distribution and Regular Updating

Appropriate staff must have ready access to the latest version of the emergency preparedness plan. Furthermore, the plan and its annexes must be treated as a living document that is adapted as changes in the local operating environment and global situation dictate.

The cycle for conducting a comprehensive update of the plan could be as frequent as once a year, but should certainly occur at least once every two years.

## 4 INCIDENT PREVENTION CAPABILITIES

Terrorist attacks differ from natural and accidental disasters because they are intentionally perpetrated acts that could possibly be prevented or deterred. The heightened threat of terrorism has led transportation agencies to pay much closer attention to countermeasures for preventing malevolent attacks against assets.

State and federal transportation agencies are working together with researchers to use seismically safe technologies and knowledge to enhance the blast resilience of their transportation structures. Blasts, such as those caused by a truck bomb parked near a bridge for example, have very similar structural effects to those that take place in an earthquake. Some of the tools and techniques developed over the past 25 years to make structures seismically safe may be used to make structures more resistant to terrorist attacks. These include use of redundant structural systems that are designed to reduce the risk of catastrophic collapse by transferring loads supported by lost or damaged columns to columns still intact, and structural dampers that are designed to absorb and reduce damaging vibrations.

The cost of installing countermeasures for even a handful of transportation infrastructure assets is high. Much of the transportation system is characterized by features, such as physical robustness, system redundancy, and limited potential for mass casualties that make it a relatively unappealing terrorist target. By contrast, specific transportation facilities, such as those that span large natural barriers, such as rivers, bays, or mountains, and serve unique regional or national transportation and economic roles, may be attractive targets. Key transportation agency prevention capabilities should include the following elements.

### 4.1 Risk Management

Risk assessment or vulnerability assessment involves considering the probability of an event and its likely consequences on people and assets. Transportation agencies are constantly refining risk management techniques to identify and protect high risk assets, such as multitier bridges, overpasses that traverse navigable waters, flammable pipeline crossings, tunnels, heavily congested truck routes, and roadways adjacent to other targets. Armed with accurate information about risks, transportation agencies can identify and implement cost-effective countermeasures to reduce risks to transportation assets, including risks from natural disasters and from sources of intentional harm such as terrorism.

### 4.2 Deterrence and Detection Improvements

Transportation agencies are putting in place a variety of deterrent and detection measures for better protecting critical facilities and assets. These measures work by creating a greater likelihood that potential aggressors will be caught and may even be deterred from

attacking an asset. The effectiveness of deterrence varies with the aggressor's sophistication, the asset's attractiveness, and the aggressor's objective.

Measures undertaken by transportation agencies include installation of fences to increase standoff distances from vulnerable structural components such as bridge piers or tunnel ventilation systems; secure access to structures; better lighting; electronic detection systems; elimination of parking areas beneath structures; security patrols and cameras; use of identification badges for employees and visitors; and background investigations on employees and contractors with access to critical information and facilities.

### 4.3 Infrastructure Hardening

As facilities are added or renovated on the transportation network and old structures are replaced or rehabilitated, transportation agencies must take advantage of opportunities to incorporate more advanced design features for critical infrastructure assets, which make them more resilient to attacks, such as location and design considerations, pier placement, and blast survivability.

### 4.4 Public Awareness Building

Transportation agencies are using communication tools, such as rest stop information centers, highway variable message signs, and congestion reporting websites to implement high visibility emergency awareness programs for the public, which emphasize the importance of vigilance and provide clear direction on reporting of suspicious activities.

### 4.5 Information Sharing

Transportation agencies must regularly participate in a variety of forums for sharing threat and intelligence information, including networks or arrangements with state and local emergency management, law enforcement, and homeland security officials. For example, transportation's large workforce of broadly distributed field staff can be trained and encouraged to report anomalies as part of their day-to-day responsibilities and to provide local intelligence input to fusion centers, which, in turn, may use the supplied intelligence to detect preoperational surveillance activities. To date, across the country tens of thousands of frontline transportation workers in all modes have been trained; this active network makes it harder for would-be attackers to conduct their preoperational surveillance.

### 4.6 Control of Sensitive Information

Transportation agencies must take steps to control access to documents that contain sensitive information about security critical systems and facilities. Steps include creation of an oversight committee for setting sensitive information policies; development of protocols to cover handling of access to documents, marking documents, storing documents, and requests for documents; establishment of a single point of contact for managing sensitive information; identification and protection of documents, such as vulnerability or risk assessments, emergency response plans, and other documents on security critical systems; and education of staff about sensitive information handling protocols.

## 5 INCIDENT PREPAREDNESS CAPABILITIES

Transportation agencies do not lead emergency preparedness, response, and recovery efforts, but they can and do play a vital support role to first responder, public safety, and law enforcement partners.

Since they do not have high visibility roles, transportation agencies are perceived by others as public works agencies with limited support capabilities. Public safety and emergency management agencies, meanwhile, may not understand how to assess an emergency situation in terms of its likely impacts on the transportation system. Technical resources—such as advanced surveillance systems possessed by state DOTs—are not well known to the public safety community, and are underutilized.

All-hazards preparedness means that transportation agencies are ready to work with emergency responders whenever an incident occurs. When incidents directly affect the transportation network, DOT field personnel must become first responder so preparedness is critical. Preparatory actions enable a transportation agency to anticipate and minimize the impacts of incidents via advance planning. Many preparatory actions are relevant regardless of threat or hazard type. Key preparatory capabilities often include the following elements.

### 5.1 Employee Training

Training ensures that transportation agency employees are educated about their emergency management roles, responsibilities, and duties, and ensures proficiency in their performance. Establishing all-hazards training programs that are consistent with Department of Homeland Security, Federal Emergency Management Agency, and Transportation Security Administration curriculums to provide training to all employees in security awareness, emergency response, and critical infrastructure protection. Advanced training programs must be provided for managers, including CEOs, senior staff, maintenance operations managers, and all-hazards managers. All-hazards training programs are in development, which are consistent with Department of Homeland Security, Federal Emergency Management Agency, and Transportation Security Administration curricula to provide training to all employees in security awareness, emergency response, and critical infrastructure protection.

### 5.2 Drills and Exercises

Transportation agencies should conduct their own tabletop and functional drills at least every 3–6 months to exercise emergency management plans and participate as active players in full-scale exercises held at least annually. They must use drills and exercises to develop follow-up actions, including debriefings and updates to plans, protocols, and processes to incorporate after-action findings.

### 5.3 Enhanced Traffic Management Centers

Many DOTs are developing and expanding sophisticated “intelligent transportation systems” that use electronic technology, such as traffic cameras, ramp monitoring, roadway sensors, and message signs to monitor and manage traffic in urban areas. Transportation agencies are upgrading their transportation management center (TMC) capabilities

from passive information collection to fusing multiple sources of data that are capable of supporting on-scene responders and the general public during incidents. These changes involve "24-7" operational requirements, access to special agency information systems, and should require the TMC to evolve into an auxiliary emergency operations center, closely networked with other emergency responding agencies and centers. As we move deeper into the twenty-first century, colocation of TMCs, emergency operations centers, and public safety answering points will become a critical security and economic necessity.

### 5.4 Emergency Traffic Operations

Transportation agencies must establish procedures for working with state and local emergency responders to provide emergency traffic operations during an incident. This should include determining how to assign equipment, such as mobile signs, trailblazer detour signs, and barriers as well as development of procedures for use of DOT maintenance and safety patrol personnel in assisting police in road closures and traffic management in major emergencies when police resources are stretched thin.

### 5.5 Evacuation Planning

Transportation agencies must work with personnel from city and county transportation, police, fire, and emergency management agencies; metropolitan planning organizations; and major hospitals to develop plans for primary and alternative evacuation routes for major population centers. This work usually includes identification of preplanned detour routes for the Interstate highway system and major thoroughfares, maps of each major highway access point showing where emergency vehicles should be parked to block traffic, permanent ramp gates at critical interstate entrances, and assistance in preparation of major metropolitan areas and downtown evacuation plans.

### 5.6 Communications Interoperability

Transportation agencies must participate in communications interoperability initiatives with first responders who have security responsibilities. This includes multiple means for disseminating emergency notifications, including web distribution, blast fax systems, radio codes, paging, and telephone calling lists, as well as development of an integrated communications system and establishment of mobile emergency response command centers to support various radio frequencies, including those for state DOT, state patrol, and local police and fire departments.

### 5.7 Equipment, Facility and Personnel Inventory Management

Transportation agencies are developing geographic information system-based databases for tracking their emergency response resources, including specific equipment and its location, and personnel and their home addresses. This enables managers to quickly pinpoint the closest available resources to emergency or incident sites. The systems are often accessible via laptop computer to supervisors in the field. Critical vehicles are equipped with automatic vehicle location transponders to enable rapid location of vehicles

during emergencies and appropriate personnel, such as motorist assistance patrols and state patrol officers should be equipped with respirator masks or place gas masks.

## 6 INCIDENT RESPONSE AND RECOVERY CAPABILITIES

Transportation agencies have maintenance forces and equipment active across the transportation network. As a result, they can play key response and recovery roles during and after an incident. For example, on a weekday in July, 2001, just before rush hour in Baltimore, a CSX freight train derailed and caught fire in a rail tunnel directly beneath the downtown's central business district. By 4:30 p.m., the City Fire Department had ordered all major roads into the city to close including several interstate routes. Maryland DOT's modal agencies played vital roles throughout the tunnel fire in maintaining traffic flow. The coordinated highways action response team (CHART) posted notices on variable message signs notifying motorists on closure of major routes into the city. State toll authority personnel coordinated temporary closure of I-395 into Baltimore. The state's transit operators coordinated light rail, bus, and commuter rail operations.

As the story of a major incident begins to leave the headlines, recovery efforts are just starting, particularly when infrastructure damage is severe. If transportation facilities are targeted or they experience ancillary damage, a stiff economic toll may be exerted if they are closed to traffic, particularly when alternate routes are not readily available. In such instances, pressure to rebuild quickly is often intense. Transportation agencies are equipped to oversee hundreds of infrastructure construction projects every year. Their access to heavy equipment and contracting capabilities make them uniquely qualified to lead reconstruction efforts.

The Los Angeles earthquake generated a year's worth of reconstruction work in a single event. The dramatic roadway damage caused by the earthquake placed a significant strain on auto-dependent southern California. Bridges and roads were completely knocked out at four locations on several interstate and state highways. CALTRANS, the state's DOT, however, had its first emergency debris and demolition contracts in place by 7:00 a.m. that day. CALTRANS maintenance crews implemented initial detours, while commuter rail and bus service was expanded to provide transportation alternatives. CALTRANS highway advisory radio, variable message signs, closed circuit television camera (CCTV), speed monitoring loop detectors, and traffic signal timing capabilities helped keep traffic moving in the days and weeks after the earthquake. Subsequent recovery efforts involved round-the-clock operations to accelerate reconstruction of earthquake resistant structures. CALTRANS' Traffic Management Center served as the center for mobility decision-making throughout the recovery.

Capabilities developed by transportation agencies to support responders during an incident and return to normal include the following.

### 6.1 Mobilization of Equipment, People, and Private Sector Resources

Mobilization of emergency transportation operations by transportation agencies and their partners involves assembling and organizing resources, including people, equipment, communications systems, expert technical support, and public information systems and

protocols. It is a capability that requires that the right people will deploy appropriate resources at the correct time.

Effective mobilization requires a partnership of local, regional, state, and federal agencies. Joint preparedness training is important, while response and recovery voice and data communications must be interoperable, and information must be shared. Key roles for transportation agencies include the following.

- Dispatch of personnel to incident scenes, including specialized service patrols and incident response teams to help secure the incident scene; provide emergency medical aid; support fire, rescue, and emergency medical services in their operations; relocate or remove vehicles and debris from the roadway; assist stranded motorists and others on the roadway; provide for emergency traffic control; and initiate longer-term traffic control for approaching traffic and affected areas.
- Arranging emergency contracts to engage specialty towing and recovery services or special clearance equipment in a timely manner and to minimize responder risk and traffic disruption.
- Assessment of transportation infrastructure condition and closure of unsafe components.
- Transportation of equipment, personnel, and supplies for supporting emergency activities, and provision of any highway clearances and waivers needed to speed up such movements.
- Provision of transportation-related resources, such as vehicle repair facilities, fleet parking, and storage areas to be used for servicing, refueling, parking, and storage of emergency vehicles.
- Provision of general traffic management assistance, including posting of temporary signing, portable variable message signs, temporary traffic controls, one-way systems, barricades, detour routings, lowering of freeway speed limits through use of dynamic message signs or variable speed limit signs, modification of ramp metering rates or signal timing to slow the flow of traffic, use of flashing beacons and Highway Advisory Radio to issue public warnings and advisories, and provision of vehicular traffic flow data and information from permanent and temporary monitoring sites.
- Use of traffic management centers operated by DOTs in many larger cities that offer electronic technology, such as traffic cameras, ramp monitoring, and roadway sensors, to monitor and manage traffic.
- Design and implementation of alternate transportation services to temporarily replace capacity lost to disaster damage.
- Provision of information for the public about issues, such as road closures, infrastructure damage, debris removal, and restoration activities via contacts with radio, television, and other commercial media and use of technologies, such as highway advisory radio, 511 travel information, variable message signs, and Internet web pages.

## 6.2 Recovery of Transportation Infrastructure

As emergency management activities switch from response to recovery, transportation agencies play either a key supporting role or a leading role if transportation facilities

have been damaged. Recovery of transportation infrastructure helps communities reestablish economic and social vitality. Key roles for transportation agencies include the following.

- Deployment of trained and skilled teams for rapid clean up, repair, and inspection of incident areas.
- Restoration of critical transportation routes and facilities, *via* deployment of emergency contracting procedures for restoration of transportation assets, services, and systems.
- Issuance or waiver of permits and other assistance required to restore utility lines or pipes that are immediately adjacent to, or run over or under transportation infrastructure.
- Continuing to keep travelers informed about important information on road closures, detours, and evacuation routes to travelers.
- Assistance with site investigation procedures, including crime scene preservation and documentation, use of data collection technology, and team procedures to minimize disruptions to traffic and responder exposure on roadways.
- Documentation of expenses used in cleanup or incident management for possible reimbursement by FEMA or other entity.
- Establishment of an employee assistance program and mental health services for responders, which includes professional counseling and peer discussion groups.
- Audits of entire incident response after each event and revisions to plans and procedures as necessary to improve the key activities of prevention, mitigation, preparation, response, and recovery in the future.

## 7 CONCLUSIONS

The costs of failure to prepare for a terrorist attack that affects the nation's transportation infrastructure, in terms of loss of life and economic disruption, could be catastrophic. Transportation agencies were able to act swiftly on September 11, 2001, and in other major incidents because they were already equipped to meet the challenges of responding to and recovering from the devastation caused by natural and man-made disasters. When incidents, such as hurricanes, wildfires, earthquakes, snowstorms, or major traffic crashes threaten safety and mobility, transportation agency personnel and equipment are part of response and recovery activities. Their sophisticated traffic management systems helps keep traffic moving, their information systems help keep communications flowing, and their construction expertise helps speed recovery.

The threat of terrorism, however, poses new challenges for transportation agencies. Because 80% of state DOTs report they have incurred additional costs to improve transportation security, continual investment in training, equipment, infrastructure hardening, and research for transportation agencies is vital.

# TRANSPORTATION SYSTEM AS A SECURITY CHALLENGE

MICHAEL D. MEYER
*Georgia Transportation Institute, Georgia Institute of Technology, Atlanta, Georgia*

## 1 INTRODUCTION

Over the past 30 years, more terrorist attacks have occurred against transportation facilities and services in the world than any other target [1, 2]. The main reason for this is that the extent and use of transportation systems make them highly valued targets, not only for the relative ease by which they can be attacked but also because of the highly visible and lasting psychological effect the attacks will have on the day-to-day lives of those who need transportation for their livelihood. For example, given the highly publicized attacks against the public transportation systems in London and Madrid, it is not hard to imagine that commuters in these cities will continue to wonder for some time if another attack is imminent. The important role that the transportation system plays in the nation's economy makes it a strategic economic target as well. Given the vulnerability of transportation networks to attack, providing security for the nation's transportation system is one of the most difficult challenges facing transportation and security organizations in today's world—and will likely to remain so in the foreseeable future (see, for example, [3–7]).

The purpose of this article is to define the context of the transportation security challenge as it relates to the characteristics of transportation systems. What are the characteristics of transportation systems that make the provision of security so challenging? How do these characteristics relate to the types of strategies that should be considered as part of a comprehensive program?

## 2 SECURITY-RELATED CHARACTERISTICS OF TRANSPORTATION SYSTEMS

It is difficult to describe the transportation system in general terms, especially when interested in potential attacks against the facilities and services that comprise it. These facilities and services, and their respective vulnerabilities, are very different. For example, public transportation systems by their very nature tend to concentrate riders on a limited number of transit routes and at an even smaller number of terminals and transfer points. Attacks against such a system could be concentrated on a few strategic components of the system, resulting in likely harm to large numbers of people. The highway system, on the other hand, is extensive and offers many redundant paths through the road network,

although in some cases such as bridges, there are strategic links that, if severed, would cause great disruption. Even with such differences, the transportation system does exhibit some generic characteristics that are important points of departure for any discussion of the challenge of providing security on this system.

## 2.1 Extent of the Transportation System

The United States has the most extensive and advanced transportation system in the world. Although some components of this system, such as urban transit and intercity passenger systems, are not as prominent as those in other countries, overall there is no other country that exhibits a greater level of mobility and accessibility provided by its transportation system. However, the consequence of having such an extensive and accessible system is that there are many opportunities to disrupt system operations—in other words, there are many potential strategic targets.

Table 1 provides an estimate of the extent of the different components of the US transportation system [8]. Not all of these components offer appealing targets to attacks. For example, the vast majority of the approximately 4 million miles of roads in the United States carry limited traffic volumes and do not serve any strategic economic purpose. A subset of this larger road network, the 162,373 miles of roads designated as part of the National Highway System, consists of the more important roads from the perspective of national connectivity, but even here, disruption to many of these roads would not have significant impact on economic activity. Similarly for bridges and tunnels, of the hundreds of thousands of such facilities in the US transportation system, 450 bridges and 50 tunnels are considered to be of strategic value in that their destruction would have significant economic consequences as determined from the criteria in Table 2 [9]. Similar observations can be made of the other components of the nation's transportation system. However, if the objective of an attack is to expose the vulnerability of the transportation system and not necessarily to cause the maximum amount of harm, then the sheer extent of the nation's transportation system makes it almost impossible to deter such an attack.

Table 3 shows another characteristic of the extent of the transportation system, this being the numerous components that make up the system [10]. The transportation system described in this table is for a road network, but similar types of components comprise almost any transportation system. Disrupting any of these components will disrupt a significant portion of the system; the large extent of the transportation system makes it very vulnerable to attack.

## 2.2 Network Characteristics

Every transportation system can be described in terms of networks, an interconnected set of links and nodes that provide for the movement of people and goods from an origin to a destination. Several characteristics of networks can be detrimental to providing effective transportation security throughout the system.

Transportation flows moving through a network most often traverse some critical link or node that can serve as a congestion bottleneck if disrupted. Thus, for example, freight containers arrive in the United States at ports are transshipped to either a truck or train, moved to an inland location, transferred to a truck, and delivered to the final destination. This movement includes at least two critical nodes—the port and the inland intermodal yard—the productivity of which significantly affects the overall efficiency of the trip.

**TABLE 1 Extent of the US Transportation System (2005)**

*Highway*
Public roads
- 46,873 miles of interstate highway
- 115,500 miles of other National Highway System roads
- 3,849,259 miles of other roads
- 580,000 bridges

*Air*
Public-use airports
- 5,270 airports

Airports serving large certificated carriers
- 26 large hub areas (69 airports), 484 million enplaned passengers
- 37 medium hub areas (60 airports), 141 million enplaned passengers
- 66 small hub areas (82 airports), 53 million enplaned passengers
- 930 nonhub areas (968 airports), 23 million enplaned passengers

*Rail*
Miles of railroad operated
- 95,664 miles by Class I freight railroads
- 15,388 miles by regional freight railroads
- 29,197 miles by local freight railroads
- 23,000 miles by Amtrak (passenger) (2004)

*Urban Transit (2004)*
Directional route miles
- Bus: 165,854
- Trolley bus: 425
- Commuter rail: 4,407
- Heavy rail: 1,596
- Light rail: 1,097

Stations
- Commuter rail: 1,153
- Heavy rail: 1,023
- Light rail: 723

*Water*
Navigable channels
- 26,000 miles (2003)

Ferry routes
- 623 directional route miles (2004)

Commercial waterway facilities (2004)
- Great Lakes: 600 deep-draft
- Great Lakes: 154 shallow-draft
- Inland: 2,320 shallow-draft
- Ocean: 4,298 deep-draft
- Ocean: 1,761 shallow-draft
- Locks: 257

*Pipeline*
Oil
- Crude lines: 60,043 miles of pipe
- Product lines: 71,310 miles of pipe

(*continued overleaf*)

**TABLE 1 (*Continued*)**

| |
|---|
| Gas (2004) |
| Transmission: 298,900 miles of pipe |
| Distribution: 1,139,800 miles of pipe |

**TABLE 2 Determination of "Critical" Bridges**

| Criticality Factor | Function of: | Proxy | Source |
|---|---|---|---|
| | | Main span >165 ft | |
| Casualty risk | Users exposed | Average daily traffic (ADT) >40,000 | National Bridge Inventory (NBI) |
| Economic disruption | Role in national economy | ADT >40,000 | NBI |
| | | Functional system: interstate plus STRAHNET[a] | |
| | | Navigation preservation | |
| | Replacement/ down time | Main span length >165 ft and structure types | NBI |
| | Replacement cost | Main span length | NBI |
| | Redundancy | Detour distance >3 miles for ADT >60,000 | NBI |
| Military function | Support power projection platform | ON STRAHNET and/or on MTMC[b], power projection routes serving forts <400 miles from ports with main span >165 ft; no ADT limits | MTMC |
| | | Metro size (top 78) | |
| Emergency relief function | Major evacuation routes | Functional system: freeways, expressways, and principal arterials | Federal Highway Administration (FHWA) |
| National recognition | Symbolic importance | 5% of critical bridges | NA |
| Other | Collateral exposure | Roads on dams, pipelines, utilities, and so on. | NA |

[a]STRAHNET is the strategic defense highway network.
[b]MTMC is the military traffic management command.

*Source:* [9].

In passenger transportation, the critical nodes would include airports, train stations, bus terminals, and so on. The net effect of this network characteristic is to concentrate flows at well defined locations, resulting in potential targets that not only provide the maximum harmful physical and psychological effect at that location (for example, harming large numbers of people at a rail terminal), but which could also produce economic effects beyond that location (for example, the domino effect in the logistics supply chain of not being able to transship goods at a port).

**TABLE 3 Critical Highway System Assets**

| Infrastructure | Facilities | Equipment | Personnel |
|---|---|---|---|
| Arterial roads | Chemical storage areas | Hazardous materials | Contractors |
| Interstate roads | Fueling stations | Roadway monitoring | Employees |
| Bridges | Headquarters | Signal and control systems | Vendors |
| Overpasses | Maintenance yards | Variable messaging systems | Visitors |
| Barriers | Materials testing labs | Communications systems | |
| Roads on dams | Ports of entry | Vehicles | |
| Tunnels | District/regional complexes | | |
| | Rest areas | | |
| | Storm water pump stations | | |
| | Toll booths | | |
| | Traffic operations centers | | |
| | Vehicle inspection stations | | |
| | Weigh stations | | |

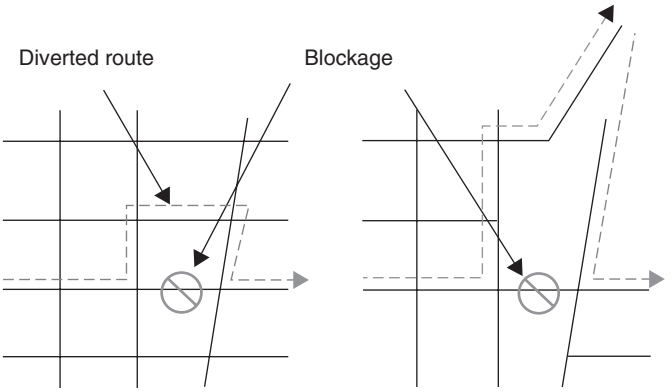

**FIGURE 1** Effect of network design on disruption: (a) network redundancy and (b) critical link disruption.

The above discussion focused on critical network nodes, but a similar phenomenon occurs in networks when, for efficiency or cost reasons, movements are "funneled" into critical links. Figure 1 illustrates this phenomenon. As shown in the figure, a disruption to the network in Figure 1a would cause much less disruption to network flows than severing a network critical link as shown in Figure 1b. The network redundancy shown in Figure 1a allows a network to recover more quickly by moving flows through different parts of the network, whereas the lack of such redundancy in the second network has more serious economic consequences and, depending on the circumstances, potentially catastrophic impacts.

The level of redundancy in the US transportation system varies by mode and by geographic area, depending largely on how a network has been designed. The national railroad network, for example, has a high level of redundancy built into it. A disrupted link at

one location could be handled by rerouting cargo along other network paths or, for certain types of cargo, even by transferring the goods to trucks, both options most likely increasing the costs of transport. At national flow levels similar network redundancy exists for the air, road, and port networks. The most disruptive aspects associated with deficient network redundancy occur at smaller geographic scales. Thus, for example, severing a critical bridge over a river in a major metropolitan area could be very disruptive for local travelers and to the local economy, even though flows going through the metropolitan area would most likely find alternative bypass routes. Given the transportation network design in most metropolitan areas, which often does not provide much network redundancy, there are numerous opportunities to create significant disruption in the nation's metropolitan areas.

Another characteristic of a network, especially one that is connected to a much larger transportation system, is the spatial nature of movement along the network links. In other words, a person or commodity located at one location at time $t$ will most likely be located somewhere else on the network at time $t + 1$. Thus, for attacks whose intent is to spread fear and disruption as wide spread as possible, such as the release of a biological agent in an airport whose effects might not be felt hours or days after the release, the structure of the transportation network permits the potential spread of harmful pathogens worldwide. Given the size and extent of a typical transportation network, tracking those entities that have been exposed or infected by some form of contagion would be challenging.

### 2.3 Transportation Nodes as Gateways

Transportation systems provide the major points of access into the United States, both for international freight and passengers. Thus, they can be viewed as one of the most vulnerable points of access for someone entering the United States with the intention to cause harm. For freight movements, they represent gateways to the US economy for much of the international trade entering the country. For example, it is estimated that over 26 million containers enter US ports each year, originating from all directions. Table 4 shows container flow through the top 30 container ports in the United States. With the flow of containers, which occurs at ports throughout the country, security monitoring of container movement becomes an important, albeit challenging, task.

The international nature of freight movement introduces additional complexity into transportation security. For example, a recent report from the Department of Homeland Security identified the following principles in enhancing the security of the international supply chain [11].

1. Accurate data in the form of advance electronic information is necessary to support the risk assessment of the cargo. This information is needed early in the process to identify high-risk cargo before it approaches the United States. In the case of containers, the information is needed before vessel loading in a foreign port.
2. Information must be appropriately shared among US government agencies and US trading partners, while simultaneously being safeguarded from improper disclosure.
3. Secure cargo requires a procedure to ensure that the cargo conforms to the cargo information electronically transmitted to the authorities. This process connects first-hand knowledge of the cargo with the validation of the cargo information. This process also ensures that safeguards are in place to prevent unlawful materials (or

**TABLE 4 Top US Container Ports, Twenty-Foot Equivalent Units (TEUs), 2005**

| Port | Rank | Import | Export | Net |

| United States, total | | 25,868 | 8578 | 17,290 |

*Source:* [8].

persons) from being combined with the legitimate cargo. This part also includes a risk management process that includes the scanning and/or inspection of cargo identified as high risk before loading at foreign ports and, in some cases, after arrival at the US port.

4. Secure transit is a procedure designed to ensure that cargo remains secure as it enters and moves through the supply chain. Successful implementation requires a method of detecting if security has been compromised during transit and a response protocol to be enacted in the event of such a compromise. Securing the conveyances and transportation facilities used in the movement of commerce is critical to maintaining the security of the cargo while it is in transit.

5. Improvements to security—must be addressed in a way that will ensure consistency and substantive improvements across the supply chain. This can only be achieved via engagement with the appropriate international organizations, for example, the World Customs Organization (WCO) and the International Maritime Organization (IMO), and international trade partners in the development of standards. Standards are the only meaningful way that the government will be able to ensure that a high level of security across the supply chain.

As indicated, the extent of the security needs for international freight movement extends far beyond the borders of the United States.

The security challenge at international gateways will become even more significant in the future given expected trade flows into the United States. Figure 2, for example, shows the value of international trade crossing US borders and how it has changed dramatically since 1980 [12]. Almost every economic forecast of future trade shows continued growth in the amounts of international freight entering the United States.

## 2.4 Transportation as a Means

Transportation systems, by their very nature, exist to allow people and goods to accomplish some other objective. Thus, for example, we make trips not because of the pleasure of traveling in a vehicle or of moving along a road, but rather to arrive at work, deliver goods, go to school, take the kids to soccer practice, and so on. In technical terms, this is referred to as *derived demand*. It is assumed that the major purpose of a transportation service or facility is to allow a trip to be made as quickly as possible in order to accomplish some end goal.

The importance of this transportation system characteristic to security is that when the transportation system is disrupted, there are potentially significant consequences

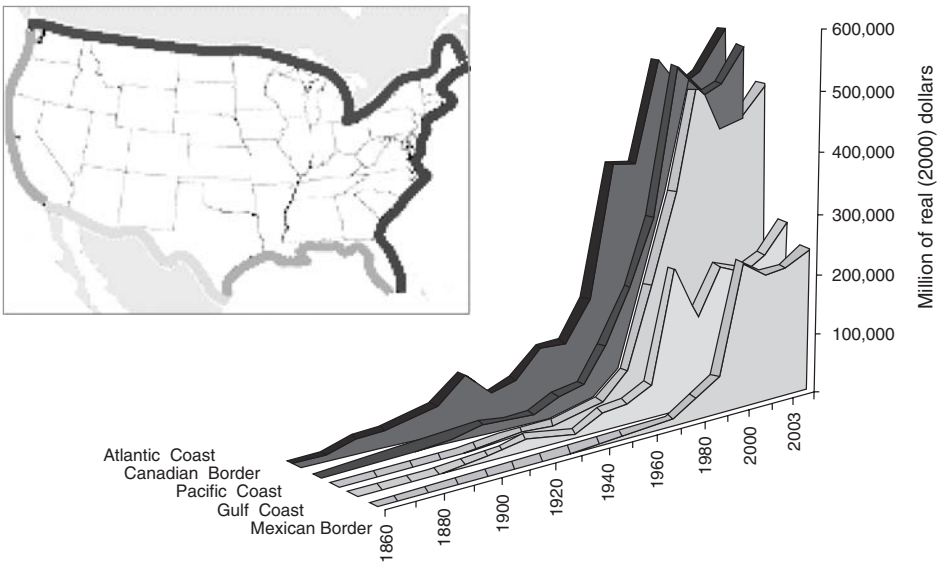

**FIGURE 2** Growth in US trade by border crossing ($2000). (Source: [12]).

to other societal functions. The impact of severing a highway or rail link at a major US port could have significant impact on the nation's economy. Or as was seen after the 9/11 terrorist attacks, the economic consequences to the US airline industry of a loss in customer confidence in air travel caused significant economic losses to US airlines.

The transportation of hazardous materials represents a particularly dangerous use of the transportation system, but one that is necessary in today's economy [13]. The delivery and disposal of hazardous materials reflect the types of economic activities that characterize today's manufacturing, service, medical, and research/development industries. Approximately 800,000 shipments of hazardous materials are transported on the US road and inland water networks each day, with over 4 billion tons being transported each year [13]. Roads and waterways account for 95% of these shipments. Not only severing a link in these networks would cause disruption to these movements, but also if hazardous materials were involved in the aftermath, the consequences to the local population could be much more severe.

### 2.5 Time Lag to Recover

Transportation networks are infrastructure intensive. Because of the time it takes to design and build any major infrastructure facility, physically destroying or making a structure or facility incapable of serving its function will most often require an in-kind replacement. In many locations in the United States, this infrastructure is nearing the end of its useful life, thus potentially making it easier to destroy. Although physical structures take little time to destroy, they do take time to replace. Thus, destroying a critical piece of infrastructure could have long-lasting effects given the time it takes for reconstruction. Many of the major interstate highway bridges destroyed by Hurricane Katrina, for example, have taken anywhere from 9 to 18 months to put back into service—and this was an expedited recovery program.

### 2.6 System Command, Control, and Communications

Transportation networks are often managed by command and control systems. Passenger and freight rail flows, for example, are directed by signaling and scheduling systems that provide safe movement often over tracks that serve both flows. Air traffic control systems provide similar functions for aviation. Increasingly, most metropolitan areas have traffic management systems that monitor road network operations and provide information to travelers. Although most of these command, control, and communications systems have redundancy and backups built into their structure, some level of disruption would result by removing these systems from direct contact over the networks they control, by either physical or cyber attacks.

Another important aspect of the system control nature of traffic flows is that system efficiency and reliability objectives often result in scheduled operations, thus providing commonly available knowledge on when trains, buses, and planes will be arriving at a given point.

### 2.7 Institutional Structure

Given the importance of transportation to the nation, states, metropolitan areas, and local governments, there are many organizations that have responsibility for some element of

this system. This is also true for private companies that provide transport services (such as carriers) and those who need such services (such as shippers). In the United States, the federal government has numerous agencies that have some say in transportation policy and finance; there are 50 state departments of transportation (53 if you consider the transportation agencies for the District of Columbia, Puerto Rico, and Guam); 376 metropolitan planning organizations (MPOs) having responsibility for coordinating metropolitan-level transportation planning activities; 6429 transit agencies; 6000 city, county or township transportation departments; 85 major port authorities; and an estimated 200 special purpose transportation authorities such as toll agencies or park districts that control key roads. With respect to security, there are thousands of police and security organizations that will likely interact with transportation agencies in response to a particular incident.

The benefit of having so many organizations is that they can specialize in providing the most cost-effective service for the markets they serve. However, the problem becomes one of coordinating all of the different participants that might be relevant to a specific issue [14]. Figure 3 illustrates this concept as it relates to security planning for urban transit systems. As noted, the larger the metropolitan area, the larger the number of likely transit providers and the greater the need for planning security in a coordinated manner [15].

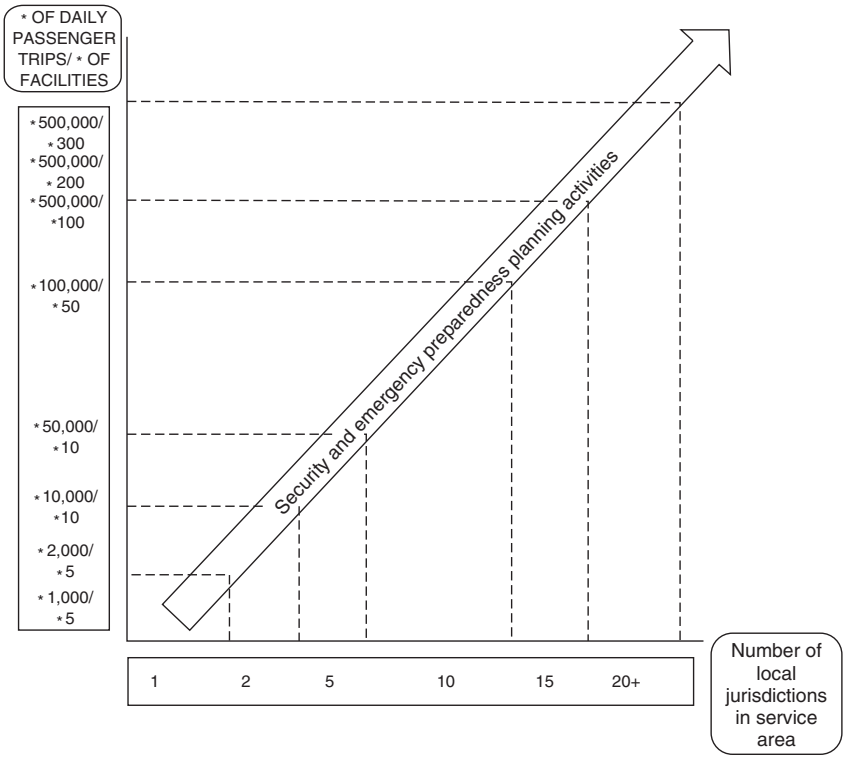

**FIGURE 3** Requirements for security and emergency preparedness. (Source: [15]).

Federal law requires that every urbanized area over 50,000 population must have an organization called the *metropolitan planning organization* (MPO) that is responsible for coordinating the transportation planning process for that urbanized area. In most cases, the MPO acts as a forum for collective transportation decision making as it relates to regional transportation investments, as well as addressing other issues of regional concern. In all but a rare number of circumstances, the MPO is primarily a planning agency; it is not an operating or implementing agency, and thus it depends on the willingness of transportation agencies and service providers to implement adopted regional strategies. This role is one that presents significant challenges for issues such as security that cross jurisdictional boundaries, especially given the fact that police and security agencies have seldom participated in the regional transportation planning process. As noted by Meyer [16] in a meeting focusing on the potential role of MPOs in security planning, possible MPO-led actions might include the following:

Given the MPO's strengths in *technical analysis and transportation planning*,

- conduct vulnerability analyses on regional transportation facilities and services;
- analyze transportation network for redundancies in moving large numbers of people (e.g. modeling person and vehicle flows with major links removed or reversed, accommodating street closures, adaptive signal control strategies, and impact of traveler information systems), and strategies for dealing with "choke" points such as tollbooths;
- analyze transportation network for emergency route planning/strategic gaps in the network.

Given the MPO's responsibilities for *funding strategies and projects*,

- fund new strategies/technologies/projects that can help prevent events;
- fund and perhaps coordinate regional transportation surveillance system that can identify potential danger before its occurring;
- fund communications systems and other technology to speed response to incident;
- fund programs and projects to recover from an attack.

Given the MPO's role as a *forum for cooperative decision making*, the following are the actions that seem most appropriate for the MPO in the context of security/disaster planning:

- providing a forum for security/safety agencies to coordinate surveillance and prevention strategies;
- coordinating drills and exercises among transportation providers to practice emergency plans;
- coordinating with security officials in the development of prevention strategies;
- providing forum for discussions on coordinating emergency response;
- coordinating public information dissemination strategies;
- acting as a forum for developing appropriate recovery strategies;
- coordinate the stockpiling of strategic road/bridge components for rapid reconstruction;
- coordinate changes to multiagency actions that will improve future responses.

The institutional coordination challenge becomes even more complex when the multitude of private transport carriers (such as trucking firms, railroads, and barge companies) and shippers become part of the larger security discussion.

## 3 ATLANTA AS AN EXAMPLE

The Atlanta metropolitan area is used as an example of the transportation security challenge facing a typical metropolitan area. Since 2000, the Atlanta area has been the fastest growing metropolitan area in the United States, with an estimated population of approximately 4.2 million in 2007. There are 16,000 miles of road in this region (excluding relatively minor streets and alleyways), including 987 freeway miles and 200 bridges. On a daily basis, over 154 million vehicle miles (number of vehicles times average miles traveled) occur on the road network. The world's busiest airport is located just south of the downtown, and the metropolitan area serves as an intermodal hub for two of the nation's major railroads. Much of the freight entering the United States through the port of Savannah (one of the largest container ports in the United States) passes through Atlanta on either truck or rail. There are six transit agencies in the region. The Metropolitan Atlanta Rapid Transit Authority (MARTA), the largest, carries 450,000 passengers on an average day on both 451 buses and in 184 subway cars that are used on a 38-station rapid rail system. The subway network is designed in a north/south and east/west line configuration, with both lines meeting in a major downtown rail station. Disrupting this downtown station would, in essence, disable the entire rail network. Several military bases and airfields are located in the region, each requiring convenient and reliable access to the nation's transportation system.

With respect to other strategic assets, Atlanta region is the fourth largest logistics center in the United States, is considered one the nation's largest telecommunications centers, and is home of the Centers for Disease Control, itself considered a vulnerable target due to activities relating to disease and pathogen research. The international headquarters of CNN in Atlanta guarantees that any major incident in the transportation system will be broadcast to the world very shortly after it occurs.

The freeway system is one of the most heavily congested in the United States, in some locations carrying over 300,000 vehicles per day. The design of the freeway system is such that there is very little redundancy in paths through the network. Indeed, vehicle crashes on the freeway link through the center of the downtown regularly bring much of the freeway system to a standstill. The freeway system is thus very vulnerable to disruption.

Institutionally, the region reflects the complexity of other major metropolitan areas. Being the state capital, Atlanta has numerous state agencies responsible for transportation and enforcement. It houses the state's emergency response center for disaster response. Atlanta is also a major federal center and is thus home to numerous federal transportation, security, and enforcement agencies. There are 10 core counties in the Atlanta region (28 in the expanded study area), 65 cities and towns, and an estimated 25 agencies that focus primarily on transportation issues. The Board of Directors of the Atlanta Regional Commission, the region's MPO, includes 39 members, of which 23 are elected

officials, 15 are citizen appointees, and 1 represents the state's department of community affairs.

The state department of transportation operates a regional traffic management center that includes video surveillance on most of the region's interstate highway system, as well as real time information dissemination via variable message signs and digital messaging. MARTA has real time surveillance of subway operations, including a system to identify the location of buses and rail cars on the network.

Enforcement on the region's highway network is primarily the responsibility of local police, although the state police do have a limited presence on the interstate highway network. MARTA has its own police department, as do major institutions such as the numerous universities in the region. The airport, which is part of the Atlanta city government, is policed by the Atlanta police department. Memoranda of agreement for mutual aid have been established among the region's police, fire, and emergency response units.

Atlanta's transportation system is a microcosm of the transportation system characteristics described earlier. It is heavily used, and serves critical economic purposes. It is very vulnerable having several choke points that could bring much of the region's transportation system to a standstill if disrupted. The airport and freight rail lines serve major international gateways, thus creating even more of a challenge in monitoring and policing the movement of people and goods. Institutionally, the region has many agencies and organizations with some interest and responsibility in transportation, and although transportation officials often claim that transportation decision making is efficient and effective, there is a long history in the region of a fragmented institutional structure for operating the transportation system. And finally, the visibility of Atlanta's transportation system in this case to the world (because of CNN) makes it a tempting target for those wishing to "make a statement" about how vulnerable the transportation system really is.

Although every metropolitan area is unique in its institutional structure and transportation system characteristics, it is not a stretch to suggest that the Atlanta is a good example to varying degrees of the other 375 metropolitan areas in the United States. Some are more complex; some are less so. However, the level of vulnerability to disruption and the often complex institutional structure for decision making are characteristics that will be found in all parts of the country.

## 4 SUMMARY

The primary intent of this article has been to describe the characteristics of the transportation system, which make it so vulnerable to disruption. Other articles in this book focus on the specific types of strategies that can be used to avoid or at least minimize the damage caused by attacks against this system. It seems clear from the historical record, and from a description of the extent of the transportation system, that it will be very difficult, if not impossible, to protect every component of the nation's transportation system. As has been seen in other countries, there are many ways of disrupting transportation services and of spreading fear among the population.

Transportation and the mobility it provides is too fundamental to today's society for it not to be a logical target for terrorist attack. Through rigorous vulnerability and risk

assessment efforts, however, the most important parts of this system can be protected. The challenge to transportation and security officials is to develop a collaborative process for developing and using a security-conscious approach toward transportation planning and decision making.

## 1 INTRODUCTION

For any emergency, originated from either a natural disaster (hurricanes, floods, forest fires, etc.) or a man-made event (a release of a toxic gas to the atmosphere, a radiological accident at a nuclear plant, etc.), there are six basic aspects that need to be considered: prevention, preparedness, detection, protection, response, and recovery. Different emergency management activities are associated with each one of these six aspects and many agencies at local, state, and federal levels cutting across several jurisdictions are generally involved.

Specifically related to the preparedness, response, and recovery tasks, emergency evacuation is, perhaps, the most viable alternative that can be undertaken in response to natural and man-made disasters involving large geographic areas. Other significant protective actions include sheltering in place and sheltering at public (government designated) facilities. Depending on the type of event, these two protective actions (evacuation and sheltering) can be combined and integrated to achieve the maximum risk reduction of the threatened population. In any case, sheltering always requires the mobilization of the population either at the beginning (sheltering at a public facility) or at the end (evacuation of the area in which shelter-in-place has been implemented after the threat has passed) and therefore, in what follows, it will be included in the broader category of emergency evacuation.

Emergency evacuation can be divided into two main phases: the planning phase and the implementation phase. The former is associated with the preparedness and the recovery tasks and, in general, focuses on the creation of evacuation plans for the area potentially at risk. These planning activities involve the development and evaluation of various alternatives (all of them with strong traffic management components), and the identification of the best course of action to be implemented in case a regional evacuation is required. The latter, which is the implementation phase, in which the selected alternative is deployed in the field, is associated with the response and recovery tasks.

The type of event (threat) plays a very significant role in the planning and implementation of emergency evacuations, since it dictates what type of protective actions (e.g. vehicular evacuation only, sheltering of some areas, and evacuation of others) are potentially feasible. As important as the type of threat in the evaluation and implementation of an emergency evacuation are the characteristics of the transportation network of the area at risk (and beyond), as well as the distribution and reaction times of the population to be evacuated. All this information is discussed in the next section. Following that, the different models that are used in planning and evaluation of emergency

evacuations are presented. Those include not only traffic simulation models, but also pedestrian simulation and threat evolution models. A discussion focusing on the integration of these models is also included in that section. The requirements for implementation of the selected plan of action are presented in the following section, which is followed by a discussion on "no-advance notice" evacuations. The final section presents future research needs in this area.

## 2 OVERVIEW OF RELEVANT INFORMATION FOR EMERGENCY EVACUATION MODELING

For the planning phase, the estimate of the time required for evacuation (i.e. the time associated with clearing the population in an area at risk to areas considered safe) as well as the spatial and temporal determination of traffic congested areas—which, in turn, affects the percentage of the population at risk during the evacuation; i.e. population clearance—is a key variable in evaluating the effectiveness of evacuation as a protective action option. The quantification of these decision variables requires the integration of traffic simulation models and demographic information models and the location and availability of shelters, among others. Traffic simulation models—that are traditionally used in developing and assessing emergency evacuations—permit to combine the demand that the transportation network of the area at risk will be experiencing during the evacuation and recovery stages, with the capacity of that transportation network to determine how congestions patterns will evolve during both stages.

Traditionally, when considering the type of problem described here, two geographic boundaries are customarily defined around the location of the event: (i) the immediate response zone (IRZ) and (ii) the protective action zone (PAZ). The IRZ is defined as an area where an effective and prompt response is critical in order to avoid the loss of human lives while the PAZ is an area slightly farther and removed from immediate danger but one that can be potentially threatened depending upon the type of disaster and weather conditions. Beyond the PAZ, there is an area known as the *precautionary zone* or *PZ*, where no adverse effects may be expected for the population [1, 2]. The boundaries of the IRZ and PAZ are delineated by models that predict how the threat would evolve spatially, and these boundaries may be static or dynamic depending on the type of threat. For all practical purposes, it is assumed that when reaching the PZ the evacuating population is no longer at risk; therefore, the boundary of the PAZ delimits the transportation network that needs to be considered when assessing evacuation as a protective action alternative.

When dealing with evacuation only, the intersection of the evacuation routes with the boundary of the PAZ defines the exit points of the network, which from the modeling standpoint determines when a vehicle has been evacuated. If sheltering is also considered, then there will be destination points (i.e. shelters) within the PAZ at which vehicles/passengers may be considered to have been evacuated. If due to the type of event there is a need to evacuate these shelters after the threat has passed, then a delayed evacuation for these places has to be considered and modeled. Similarly, when considering sheltering in place as a protective action to be deployed in some areas within IRZ/PAZ, the effect would be a reduction in the demand of vehicles accessing the network at the beginning of the evacuation and depending on the threat, an increase in that demand at a later time.

### 2.1 Demographic Model

The determination of traffic demand estimates (i.e. the number of evacuees and evacuating vehicles by location) is a critical piece of information needed in assessing the feasibility of emergency evacuation and other protective action alternatives. This traffic demand that is a necessary input to determine evacuation times, is obtained from demographic data models. To construct these models, it is possible to assume that during the interval of time between late-evening and early morning hours the vast majority of an area's population is at its place of residence. Therefore, the primary source of data on the study area's nighttime population is, in general, census information. The spatial location of the daytime population is a far more difficult problem to solve, with no standardized procedures for generating estimates of at-work daytime populations. The level of confidence in determining the location and number of the daytime population is, therefore, much lower than that of the nighttime population. These uncertainties could have a great impact in the evacuation evaluation and analysis tasks since evacuation time estimates, and the strategies to minimize those times, are very sensitive to the spatial distribution of the population at risk.

Research is being conducted to minimize these demographic uncertainties. One such effort is the LandScan USA effort that is part of the LandScan global population project sponsored by the Department of Defense [3–5]. The LandScan USA project focuses on the development of very high resolution population distributions (i.e. 3 s $\times$ 3 s, or 90 m $\times$ 90 m, cells) data set for the entire United States. This population distribution grid is more spatially refined than the census block-level resolution, and includes spatial distributions for "residential nighttime population" as well as for "daytime population", for every hour of the day.

Besides the distribution of the population within the area potentially at risk, the reaction of the population to the order to evacuate also plays a very significant role in the viability of an emergency evacuation. The emerging traffic congestion patterns that would be observed during the evacuation of the affected area (and in consequence the evacuation time of the population at risk) greatly depend on the dynamic characteristics of the demographic model. Relatively, small variations in departing times, intermediate stops, and final destinations can produce significant changes in congestion patterns and, hence, evacuation times. Therefore, it is necessary to determine as accurately as possible these demographic dynamic characteristics.

Some research has been conducted in this area to determine what is known as *population mobilization curves* or *departing times*, although much works needs to be addressed on this critical topic. The work of Sorensen et al. [6, 7] has concentrated on the reaction times for release of toxic gases to the atmosphere, while others [8] have focused on hurricanes. The mobilization curves greatly depend on the type of event. Therefore, each particular threat and even geographic area (due to, e.g., population age distributions) has an associated mobilization curve that needs to be known with a sufficient degree of certainty in order to be able to predict evacuation times.

Also related to the traffic demand generated in an emergency evacuation is the vehicle occupancy information. This parameter depends on many factors, including the type of disaster, the location of the evacuating population (i.e. urban vs. rural areas), and the time of the day [9].

Other relevant issues regarding the behavior of populations during emergency evacuations are related to the determination (and modeling) of intermediate stops before leaving the area at risk, the selection of the final destinations, and the relocation of the displaced

population. Intermediate stops, such as parents stopping at their children's schools to gather them before leaving the area, can create unanticipated traffic flows that could greatly affect the evacuation times of the area at risk. Moreover, and depending on the geographic area under consideration, this may be an inward traffic flow (i.e. going toward the source of the threat), and can potentially impede or delay the movement of emergency vehicles. The selection of the final destinations is also a critical piece of information that can greatly impact the modeling and results of emergency evacuation simulations. Very little research exists on these topics.

## 2.2 Network Topology, Capacity, and Geometry

The characteristics defining the transportation network of the area at risk obviously play a critical role in the determination of the feasibility of an emergency evacuation. While the demographic model provides the demand-side of this problem, the capacity (in a broad sense) of the transportation network dictates whether or not there will be a reasonable interval of time available for the evacuation given that expected dynamic demand. This "network capacity" relates mostly to the physical characteristics of the network (number of lanes, lane widths, type of traffic controller, ramp metering, slopes, etc.), but also to the performance of the vehicles (e.g. a truck cannot climb a very steep slope at the same speed of a car, thus reducing capacity of that particular roadways segment).

As discussed previously, once the boundaries of the emergency planning zones (EPZs) have been delineated and include the area potentially at risk, it is necessary to have an accurate and reasonably detailed representation of the highway network within these zones to estimate evacuation times and to develop evacuation plans. The network data describes the topology of the roadway system and its characteristics, including geometry and channelization of traffic, traffic control devices, and other traffic parameters. Some of this information (e.g. network topology and geometry) can be obtained reasonably easily from maps or GIS (geographic information systems) databases. The remaining information; that is, traffic control settings, speed limits, and other traffic parameters, has to be gathered from other sources and, in general, is not as readily available, at least not in the format that is required by the traffic simulation models used to develop and evaluate the evacuation plans. In particular, the traffic control settings of actuated and semiactuated controllers (the most commonly used traffic signal equipment in major arterials in the United States) can be very demanding in terms of the parameters that define the operations of such devices. This information is necessary, at least to evaluate the "do-nothing" alternative (i.e. evacuation under regular network conditions and without any traffic management strategy deployed), which in some cases may become the *de-facto* deployed alternative. Most of the delay in a network occurs at the intersections, and therefore those should be modeled as accurately as possible. The problem of gathering all this information becomes more acute when one moves from a planning environment to assessments of emergency evacuations with no-advance notice (see discussion below).

There is also the issue of a constantly changing environment. That is, it is safe to say that while these traffic parameters hardly vary over time (unless, for example, new land-use developments bring larger traffic demands), changes in the capacity of the roadway system are very likely. Road or lane closures due to construction and road maintenance are a common sight in urban and rural areas alike. While this information has a relative low value during normal conditions (except, of course, for travelers), in case of an emergency evacuation it becomes crucial. Traffic management strategies may

depend heavily on the topology of the network; knowing which streets are unavailable or have a significant capacity reduction may be the difference between a successful strategy implementation and an aggravation of the problem. Some research has been conducted in this area to try to take advantage of remote sensing technology to automatically detect changes in roadway capacities (e.g. lane closures) and to incorporate that information directly into traffic simulations models in an attempt to determine the currency and validity of evacuation plans [10, 11].

### 2.3 Threat Evolution

Each type of threat, being either a consequence of a natural or a man-made disaster, has a particular temporal and spatial evolution. These predictions are extremely important since they not only delineate the areas that would be most affected by the threat but also provide information regarding when that peak is likely to occur. There are many models currently available, which can provide information in this regard.

Models such as ADMS 3 (atmospheric dispersion modeling system) [12], American Meterological Society/Environmental Protection Agency Regulatory Model (AERMOD) [13], PUFF-PLUME [14], and HPAC (hazard prediction and assessment capability) [15], among others permit to assess the atmospheric dispersion of vapors, particles, or liquid droplets from multiple sources and calculate concentrations of these gases spatially and temporally. Many of these plume dispersion models accept arbitrary meteorological inputs going from simple surface wind speed and direction up to multidimensional grids containing wind and temperature information to account for dense gas effects and dynamic plume rise as well as time- and space-dependent boundary layers, and flow over complex terrain.

For storm surges predictions for hurricane flooding there are many models available, including SLOSH (sea, lake, and overland surges for hurricanes) [16], ADCIRC (advanced circulation model) [17], CEST (coastal and estuarine storm tide model), and FVCOM (finite-volume coastal ocean model) [18] among many others. These models, together with existing hydrologic flood prediction models, fire propagation models, and tsunami propagation models provide analytical capabilities to assess and evaluate the potential consequences of these threats.

Although at the present time there are no integrated models that combine threat evolution with traffic simulation, this is a necessary step in the evaluation of emergency evacuations and sheltering as protective action alternatives. An integration of these threat evolution models and traffic simulation models is discussed below.

### 2.4 Real-Time Information

If vehicular evacuation (i.e. either the “do-nothing” alternative or an option that calls for the deployment of a traffic management strategy) is determined to be the optimal protective action for the conditions analyzed, a plan that implements the selected alternative must be deployed. In that case, it is paramount to collect real-time traffic and road conditions, as well as weather information, to support the emergency evacuation operations decision-making process and to keep informed the evacuating population.

The need for real-time information adds another (perhaps the biggest) layer of complexity to the problem at hand. Intelligent transportation systems (ITS) are capable of

delivering real-time information about traffic, and in some cases weather, but up to now the deployment of these systems has been sparse, at best, and concentrated only on major urban areas. Emergency evacuation of areas outside these instrumented regions (i.e. most of the country) will have to proceed without real-time traffic information or using field staff reports produced by handheld traffic counters, which, in general, cannot provide complete and/or accurate coverage of the entire system.

There is undergoing research [19] that is evaluating new technology, capable of generating travel times and other traffic information through fast-deployable sensors that can be set up in any area that requires evacuation and can provide real-time traffic information on selected segments of roadways.

## 3 MODELING EVACUATIONS

The first step in modeling an emergency evacuation consists in gathering the basic information described previously. This includes the delineation of the IRZ and PAZ areas (usually done with the assistance of a threat evolution model); the creation of a demographic model detailing the spatial distribution of the population that can potentially be affected; and the gathering of information describing the geometric/operational characteristics and topology of the transportation network. Combining these three data sources, a traffic simulation model of the area to be evacuated is usually developed and run, producing output that basically defines the location of each evacuating vehicle at given intervals of time.

This modeling task takes place during the planning phase and a traffic simulation model is used to analyze different scenarios and courses of action. Generally, a "do-nothing" alternative—i.e. evacuation without any traffic management strategy deployed—is compared against alternatives that basically increase the capacity of the evacuation routes—for example, reverse-lane strategies, traffic signal strategies—and/or try to "smooth out" demand peaks—for example, holding traffic at certain intersections while allowing traffic on the main evacuation route to go through. If the event could be predicted beforehand, other countermeasures, such as building new or upgrading existing evacuation routes and other long-term strategies, can be modeled to assess their impact in reducing the expected time to evacuate (ETTE) the area at risk.

The traffic simulation model used has to be not only reasonably accurate, but also be able to simulate with high level of fidelity the different components of a transportation network (including traffic controllers, driver behavioral characteristics, vehicle performances, and many other aspects and elements). Very few of these traffic simulation models are specifically tailored to evaluate emergency evacuations providing specific outputs such as ETTE, clearance time (i.e. the percentage of the population that is still within the area at risk during the evacuation, and other measure of effectiveness that are specific of this type of problems). Nevertheless, general purpose traffic simulation models (e.g. CORSIM [20] and VISSIM [21]) can also be adapted, although with some constraints, to model an emergency evacuation. In general, these traffic simulation models deal with just a single mode of transportation (i.e. passenger cars) and in some cases are able to simulate public transit as well. However, no multimodal models exist that can combine pedestrian and vehicular interactions.

### 3.1 Traffic Simulation Models

There are basically three types of traffic simulation models: (i) macroscopic, (ii) mesoscopic, and (iii) microscopic models. If the model traces the vehicles' movements implicitly and link performances (i.e. modeled segments of roadways) are expressed in an aggregated way, the simulation is defined as macroscopic. If the model follows the vehicles' movements explicitly, two cases are possible, depending on whether link performances are expressed in an aggregate or disaggregate way. In the first case, the simulation is mesoscopic, otherwise it is microscopic.

Due to the way in which vehicles are modeled and result statistics kept, the macroscopic models are the fastest (in terms of CPU time), followed by mesoscopic and microscopic models, in that order, for the same network and inputs. The speed of execution is one of the main characteristics of a traffic simulation model. In an ideal environment, the traffic simulation model should be run many times (i.e. many replications) to obtain probability distributions of the measures of effectiveness (MOEs) on which the decisions (whether to evacuate or shelter the population, which areas to evacuate or shelter, when to evacuate, etc.) will be made. The modeling process is an iterative one, especially when the "best alternative" is sought, so it should be possible to run the necessary replications fast and then run the model again after adjustments are made based on the results of previous runs.

Depending on the type of disaster being evaluated, emergency evacuations may involve the analysis of very large geographic areas, in many cases in the order of several thousands of square miles. The modeling of different traffic management strategies under these conditions can be very taxing in terms of computer run time, even with today's fast computers. Particularly, when using microscopic simulation models for the evaluation of these alternatives with the additional requirement of running many replications (to obtain statistically significant comparisons of alternatives), the speed of computation problem is aggravated. In fact, the fine granularity that microscopic traffic simulation models provide is not necessary, at least during the planning phase, except to simulate some detailed and localized traffic management strategies such as, for example, the optimization of traffic controllers along an arterial within the area at risk. Depending on the type of event being analyzed, macrosimulation models that can run very fast permitting the rapid modeling and evaluation of different strategies are more appropriate.

One such macrosimulation model is the Oak Ridge Evacuation Modeling System (OREMS), which is based on the Federal Highway Administration—Traffic Simulation Family of Models (FHWA-TRAF) family simulation models and was developed for the Federal Emergency Management Agency (FEMA) and the US Army under the Chemical Stockpile Emergency Preparedness Program (CSEPP). This traffic simulation model was specifically developed to analyze large-scale emergency evacuations, permitting to experiment with alternate routes, destinations, traffic control and management strategies, and evacuee response rates. For any scenario, it is possible to identify evacuation or clearance times, traffic operational characteristics, such as average evacuation speed, bottlenecks, and other information necessary to develop effective evacuation plans, at any spatial level of aggregation from a single segment of freeway to the entire evacuating area [22].

Whether a microscopic or a macroscopic simulation model is used, validation of that model is extremely important but difficult, particularly for emergency evacuations since these are very rare events. Nevertheless, the models should be calibrated and validated,

at least using normal traffic conditions to roughly determine the level of accuracy that can be expected in modeling an emergency evacuation of the area potentially at risk.

### 3.2 Trip Distribution and Traffic Assignment Model

In general, before running the traffic simulation model, it is necessary to know where the demand will be generated during an evacuation, and equally or even more importantly, where these travelers will go. In many cases when modeling an emergency evacuation, the former (i.e., the population distribution) can be determined with an accuracy that is proportional to the effort invested in creating the demographic models described previously. The latter (i.e., the identification of destination points), however, is more difficult to obtain, but can be derived by using so called trip distribution models. Those, in general, are simplistic models and may not address the issue of intermediate destinations (and dwelling times at these locations) discussed before.

The other set of models that are used in conjunction with traffic simulation models are traffic assignment models. These models basically "map" on the transportation network, the paths that will be followed by vehicles that want to reach a given destination when departing from a given origin at a given time. There are many traffic assignment models, but the most common are static traffic assignments (STAs) and dynamic traffic assignments (DTAs). In the planning mode, as well as in the operation model, DTA should be used only if it is possible to assume that (i) there will be a way of determining traffic conditions on the transportation network in real-time, and (ii) it is possible to convey information to the traveling population. If any one of these assumptions does not hold, then using a DTA model will produce more optimistic results (i.e. less congested network and therefore smaller ETTE) that it would be expected in a real evacuation of the same area that is being modeled (assuming that the demographic and transportation network models are reasonably correct). This is because, DTA models will find "excess" capacity in the network (i.e. less congested paths between an origin and destination) and reroute some of the demand through these paths. This will only be reproduced in an actual evacuation if there is a way to obtain real-time traffic information (to know the status of the network and to be able to predict how the congestion patterns would evolve) and if it is also possible to inform the driving population of the availability of these less congested paths.

There is, however, a case where even without real-time traffic information and/or a way of conveying information to travelers it would be reasonable (an in fact desirable) to use DTA. A DTA model can be assumed to hold in a localized area such as, for example, the trip from home or work to the nearest freeway on-ramp. This is because, in this case, due to his/her familiarity with the network, it is possible to assume that the traveler can react to congested roads by selecting other paths that will take that traveler from the origin (home or office) to the destination (nearest freeway on-ramp) of this leg of the trip. Beyond that, some other traffic assignment model should be used, where the main assumption is that the driver only has a limited number of routes (i.e. a limited knowledge and familiarity with the transportation network) from which he/she can choose.

### 3.3 Multimodal Evacuations

The models described previously assume, in general, that in an emergency evacuation the population would evacuate the area traveling on a vehicle from origin to destination. This

is clearly not the case in many instances, particularly those cases that involve events in downtown areas of large cities. New trends in the revitalization of downtown areas across the nation have produced development configurations, which purposely induce pedestrian movements. Shopping and other service areas, and more importantly, large sport venues have been built in these downtown districts without their own parking facilities to compel visitors to walk around the area. Instead, distributed parking facilities, which during the working hours service offices, are used during the evenings by downtown visitors and also during sport events. The distributed parking facilities across downtown for patrons of these venues could generate significant levels of traffic congestion due to heavy pedestrian volumes in the area if evacuation is required.

This presents a difficult modeling problem that the traffic simulation models described before cannot solve because they are designed to handle just vehicular movements. There are many pedestrian simulation models available that have been developed over many years with empirical studies going back almost five decades. Those early studies resulted in guidelines to design facilities that are efficient, safe, and aesthetically pleasant to be used by pedestrian [23, 24]. Models that simulate the behavior of large crowds are regularly used to study and evaluate practical solutions in terms of both crowd safety and emergency evacuation when designing large buildings and other structures. Pedestrian movement models exist to simulate the flow of large crowds, and are used to assess evacuation strategies for sites with multiple buildings and to study large-scale evacuations from buildings, offices, and sports venues.

Those sophisticated models can be used for the planning of evacuation in areas with very high pedestrian densities likely to be created, for example, by spectators evacuating large sport venues in these newly redesigned downtown areas. However, they cannot model the pedestrian–vehicle conflicts that would naturally arise, when evacuating pedestrians try to reach the scattered parking lots to access their vehicles and leave the area. These pedestrian models can also be used for the analysis of particular threats such as tsunamis where the more efficient course of action is a vertical evacuation; that is, the access to shelters that are high above ground level such that at risk population can quickly reach a safe area and be out of harm from the threat.

In many cases, it is necessary to use public transportation to move people out of the area[1], especially those parked in the vicinity of the venue with a sport event in progress. The use of public transportation and its interaction with pedestrian flows are also important for the evacuation of special populations such as the elderly and the poor who may not have accessibility to any other means of transportation to evacuate the area at risk.

All these cases require multimodal simulation models to study the different protective action alternatives. There are very few studies dealing with multimodal issues in emergency evacuations, and even fewer studying the complex interrelationships between vehicles and pedestrians. In one such study, these interactions as well as behavior that is unique to parking lots are implemented in a model that can simulate the evacuation of large parking lots [25].

[1]Under certain weapons of mass destruction scenarios producing an intense electromagnetic pulse, the sophisticated computerized components of today's vehicles may be damaged rendering those vehicles undrivable. As a consequence, streets may be blocked by many stopped vehicles; in that case it would be more efficient to clear few roads and use buses from outside the area to evacuate the affected population.

### 3.4 Integration of Threat and Evacuation Models

When modeling and evaluating vehicular evacuations as a protective action alternative, the ETTE (in conjunction with clearance information) is the decision variable that is used to determine the merits of a proposed evacuation plan and any traffic management strategy. The ETTE is the predominant decision variable when studying evacuations due to natural disasters, such as hurricanes and forest fires, since in these cases there is enough advance notice such that it is feasible for the evacuating population to clear the area at risk before the threat arrives. That is, in these cases the ETTE provides an estimation of when the mobilization should start given the predicted time of arrival of the threat.

In other cases, particularly for man-made disasters such as the release of a toxic gas to the atmosphere, ETTE may not be the correct decision variable. The reason for this is that in these instances, because of the short reaction time available to clear the area at risk, it is likely that the threat could be in contact with the evacuating population. Therefore, a more appropriated decision variable to assess protective action alternatives for these cases is the number of affected people that will suffer consequences—i.e. expected fatalities (EF) and expected number of people with permanent disabilities (ED)—if that particular alternative is deployed (note: in both cases, other decision variables such as deployment costs are also considered, but in general those variables play a secondary role).

At the present time there are no models that integrate both traffic simulation and plume dispersion models to evaluate evacuation plans for this type of scenarios, which after 9/11 have become more likely to occur. Analyzing those scenarios using the traditional ETTE computation approach could result in a decision process that may select the wrong protective action strategies, which, if implemented, could result in the loss of many lives. However, an integration of these two types of models (plume dispersion and traffic simulation) is a reasonably simple task, which could significantly improve the current decision-making process for these type of problems. A brief description of how this task could be accomplished is given below.

***3.4.1 Traffic Simulation and Threat Evolution Model Integration.*** From the previous discussions about traffic simulation models, it is obvious that those models do not provide a direct way of quantifying the outcomes of different alternatives in terms of EF and ED. However, they supply important and intermediate information, such as temporal and spatial distribution of the evacuating population, which can be used to estimate these variables. That is, the traffic information can be combined with threat evolution models (i.e. plume dispersion models in this scenario) to obtain probability distributions of EF and ED for each alternative analyzed, thus allowing the evaluation of the different strategies and ultimately, with the intervention of a relevant decision maker, the selection of the "best one". Notice that, unless an alternative stochastically dominate all the others, there is no quantitative methodology (other than naïve approaches such as using the averages of the distributions) to select the "best" strategy without the intervention of some relevant decision maker who could evaluate, explicitly or implicitly, trade-offs among the distribution of the different outcomes of the alternatives being analyzed.

The plume dispersion models produce temporal and spatial distributions of the concentrations of the released agent, based on topography and predicted weather conditions. Due to the fact that weather conditions are not known with certainty (e.g. at any given time there is a certain probability $p_1$ that the wind will blow from sector—i.e. direction—$s_1$, a probability $p_2$ that it will blow from sector $s_2$, ..., a probability $p_n$ that it will blow

from sector $s_n$, with $\sum_{i=1}^{n} p_i = 1$), the concentration distributions of the released agent are stochastic. That is, each concentration distribution (in time and space) will have a certain probability of occurrence attached to it. These concentration distributions can be overlaid, both spatially and temporally, on a map of the area affected, which translates into information about the dynamics of the concentration of the agent on each link or roadway segment of the transportation network and on each point where there is population.

With information about the network topology and attributes, as well as the demographic model completed, a traffic simulation model can be created and run, first for a "do-nothing alternative" (i.e. the network as it is, without any traffic management alternative deployed) and then with different strategies deployed. The output of any of these alternatives consists basically a list of travel times on each of the network links and the number of vehicles that enter, are on, and exit the link at fixed intervals of time (as low as 1 s-interval for some traffic simulation models). Moreover, since at the start of the evacuation the total number of vehicles at each network entry point within the affected area is known (from the demographic model), the outputs also provide information about the spatial distribution of the "not-yet" departed population by time. By merging this information with the distribution of the concentration of the agent it is possible to compute the dosage that the passengers of each vehicle are likely to accumulate from the moment the evacuation starts until that vehicle crosses the PAZ. The accumulated dosages then translate into number of EF and ED, with a certain probability of occurrence. This probability is the results from combining (through the simulation and integration of the results from both models) the probability of observing the particular concentration that gave rise to the observed dosages and probability distributions of the outputs of the traffic simulation model if many replications are considered. Repeating this computational process for all the possible concentration distributions (i.e. $n$ distributions and each replication $r$), it is possible to construct probability distributions of EF and ED for the particular alternative being analyzed.

Figures 1–4 illustrate this process. The first figure presents a map of an affected area, where the location of the event is shown as a circle located on the north-central part of that map. Given a scenario $i$ (let us say, certain weather conditions that can occur with probability $p_i$), the evolution of the plume is represented spatially and temporally in Figure 1 by superimposing on the map snapshots of the plume at constant intervals of time, with different levels of concentration represented by areas of different colors within the profile of the plume. The white circle southwest of the event shows an urban area that could be affected and where some protective action (e.g. evacuation) may need to be taken. To analyze the evacuation of that urban area, it is necessary to generate a demographic model and a transportation network model, which are inputs to the traffic simulation model. In turn, the outputs of the latter are combined with the plume dispersion model information to obtain a dosage distribution similar to the one shown in Figure 2, which would produce estimates of $EF_i$ and $ED_j$ based on the type of agent, and would be assigned a probability $p_i$ of being observed, for replication $r_m$ (for simplicity reasons in presenting these graphs, these computations are based on just one replication of the traffic simulation model).

The particular scenario shown in Figure 1 is not a deterministic one,—i.e. $p_i$ is greater than 0 but less than 1—and therefore there are other scenarios, such as scenario $j$, for example, that are also likely to be observed (see Fig.3). The dosage distribution for scenario $j$ is represented in Figure 4; with the characteristics of the agent, estimates

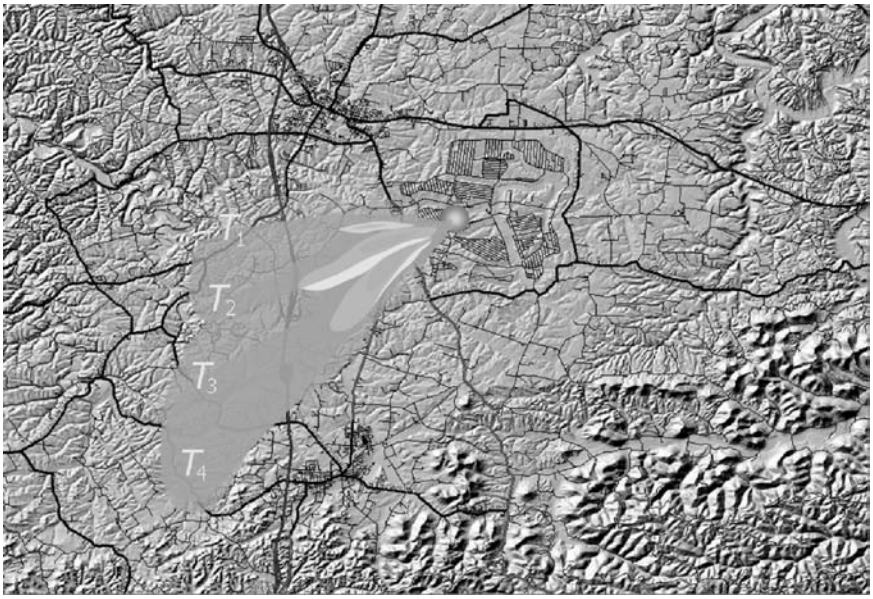

**FIGURE 1** Area at risk and plume dispersion evolution for scenario $i$.

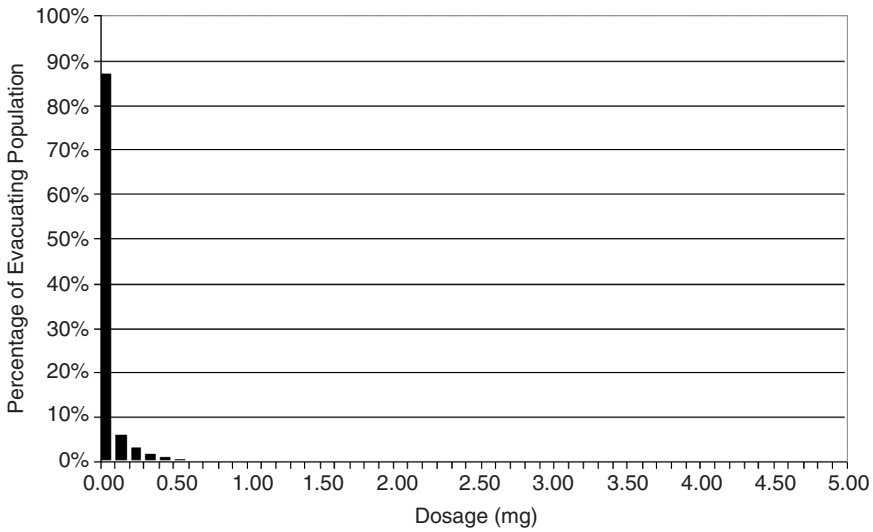

**FIGURE 2** Population dosage distribution for scenario $i$.

$EF_j$ and $ED_j$ can be determined from that dosage profile, and these estimates would be observed with probability $p_j$ (i.e. the probability of occurrence of scenario $j$). Repeating this procedure for all possible scenarios, a probability distribution of EF and ED can be constructed, which would represent the outcomes of the alternative under consideration (in this case, the "do-nothing alternative"; or in other words, evacuate under day-to-day network operation conditions).

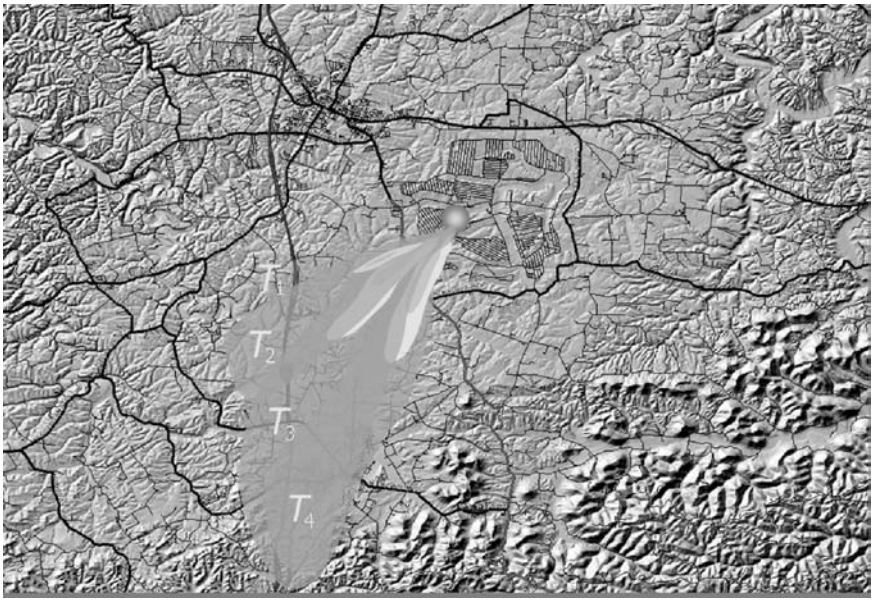

**FIGURE 3** Plume dispersion evolution for scenario $j$.

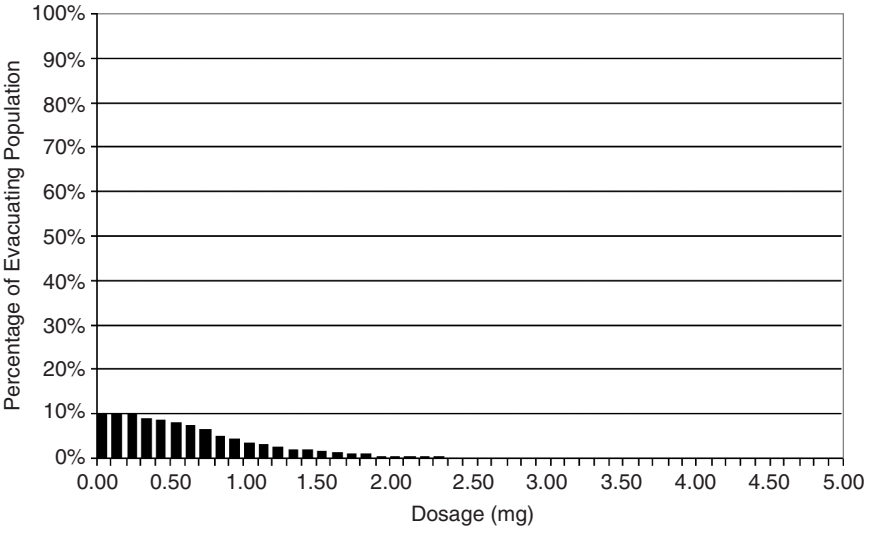

**FIGURE 4** Population dosage distribution for scenario $j$.

Figure 4 also shows that the exposure of the population to the agent under scenario $j$ is larger than that of scenario $i$. Of course, this dosage profile also depends on the type traffic management strategy deployed. So, if Figure 4 represents the dosage profile for scenario $j$ under a "do-nothing" evacuation strategy, a "reverse-lane" strategy may change that profile to one that could be closer to that of Figure 2, if, for example, the

evacuation time under this new strategy is reduced enough so that the population is outside the dangerous area before the plume reaches it.

## 4 EVACUATION OPERATIONS

Independently of the methodology used to determine the feasibility of an emergency evacuation as a protective action alternative, if the threat under analysis materializes then the planned strategies (the arterials/freeway segments that would operate in a reverse-lane fashion, the intersections that would be controlled by security personnel, etc.) have to be implemented. Even with the best tool to evaluate every possible traffic strategy and to create an efficient evacuation plan, it is not possible to anticipate what will actually happen during the evacuation. Because of this, it is necessary to collect, in real-time, traffic and road condition information to support the emergency evacuation operations' decision-making process and to keep informed the evacuating population.

During an emergency evacuation, continuous information on traffic conditions must be collected in order to assess the progress of the evacuation and to optimize evacuation operations to ensure the safety of the population. Where deployed, ITS can provide real-time traffic information. However, the coverage of this type of infrastructure is mostly restricted to large metropolitan areas, and in the majority of these cases only on freeways, with just a few urban areas having also arterial coverage. As mentioned previously, research is being conducted to provide real-time traffic information where there is no infrastructure deployed.

In order to evaluate how the evacuation plan is performing, the traffic simulation models used to develop the deployed traffic management strategies must be able to accept real-time information from the field. Where the traffic is flowing normally, this real-time information is compared to the traffic conditions obtained from the traffic simulation to determine if the evacuation plan is proceeding according to predictions. If the evacuation is not proceeding as planned,—for example, the evacuation time under current conditions will be longer than predicted—and there is a risk that bad weather, or any other conditions related to the disaster that triggered the evacuation may endanger the life of travelers or state officials in the field (highway patrolmen, Department of Transportation (DOT) personnel, etc.), then the traffic simulation model can be used to analyze and evaluate new traffic strategies. An example of such strategy is traffic rerouting in an attempt to expedite the evacuation. The same approach is used when an incident is detected. If the evolution of the threat has to be taken into consideration, then the complexity of the operations increases significantly.

Obviously, to implement these new strategies it is necessary to provide information to the public in the areas affected. This is a difficult task since at the present time it is almost impossible to communicate detailed routing instructions to a large pool of drivers as it would be required to adapt new traffic management strategies in real-time. New technologies such as those proposed under the US DOT VII (Vehicle-Infrastructure Integration) initiative [28] will one day make possible not only to get field information in real-time, but also to communicate instructions to drivers in a hazardous area. In the meantime, one of the few options to deploy on-the-fly rerouting strategies on the field is to manually control the traffic at key intersections.

## 5 NO-ADVANCE NOTICE EVACUATIONS

There are many situations in which it is possible to plan in advance for an emergency evacuation. Those scenarios include, for example, an explosion at a chemical processing facility or a radiological accident at a nuclear plant. In these cases, if an accident or a terrorist attack were to happen, then the best evacuation plan for the prevailing network and weather conditions would be deployed. As discussed previously, during the deployment or implementation phase, traffic conditions, collected in real time, would provide feedback information to some command and control center to permit assessing whether operations are proceeding as planned or if changes are needed to assure the safety of the evacuating public. Ideally, these evacuation plans, as well as other protective action measures, are developed ahead of time in preparation for such an event. As a result of these plans, long-term improvements to the transportation network may be undertaken to maximize the safety of the population. These types of situations are mainly characterized by the static nature of the potential source of the disaster (i.e. the facilities where an accident or an attack could happen are at fixed locations), or by the predictability of the threat (e.g. coast areas subject to hurricanes).

In other instances,—for example, the derailment of a train transporting hazardous materials—there may not be any previously developed plan to be implemented and decisions must be made *ad hoc* on if and how to identify and proceed with the best course of action to minimize losses. Those scenarios have two characteristics that make the analysis particularly difficult. The first one is related to the location of the event, which, by its very nature, does not have a particular location and it can happen anywhere in the nation. The second characteristic is that the type of event requires any mitigating strategy to be deployed within a very short window of time after the event has been identified. These two characteristics impose a heavy tax on any analytical tool used to support the decision-making process, since the tool has to be able to generate outcomes of all the possible strategies within a very short notice and with no advance groundwork.

Research has been conducted in this area [26, 27] to develop a prototype decision tool that can provide within a very short notice the inputs—both the demographic and the transportation network models—for the traffic simulation model. After the IRZ and PAZ have been identified either by the user of the tool or by a threat evolution model, a network creation module generates, in real-time and almost without human intervention[2], the topology and attributes of the transportation network for those cases in which this information cannot be extracted from existing databases. The network capacity attributes, particularly the traffic control settings, are generated using stochastic models that are based on information collected by the US DOT Federal Highway Administration. At the same time that the transportation network is being generated, a demographic model of the population within the at-risk area is built using information derived from LandScan USA for the region surrounding the event. This information consists not only of the spatial distribution and size of the population to be evacuated, but also of what is known as *mobilization curves*.

[2]Some human intervention is always required to resolve some inconsistencies and connectivity issues in the transportation network.

## 6 CONCLUSIONS AND RESEARCH NEEDS

The evacuation of large populations due to either natural or man-made disasters is a very complex problem involving many different issues, both technical and institutional/jurisdictional. This paper concentrated on the former and discussed the critical components that are necessary to plan for and implement a large-scale vehicular evacuation.

Two basic models are required to determine the feasibility of evacuation as a protective action alternative: a demographic and a transportation network models. The demographic model covers many aspects of the population within the potential area at risk, including its spatial distribution, reaction times (or mobilization times), selection of intermediate and destination points, and other information. All this provides the demand-side of this problem; the capacity side involves the information about the transportation network, including geometry, topology, traffic signal settings, and other traffic parameters. As discussed here, at the present time only a subset of scenarios can be modeled with reasonable accuracy, and although this field of research has received considerable attention after 9/11, much remains to be done.

The spatial distribution of the population during the daytime is still an issue that needs to be resolved, although substantial research is being conducted in this area. Mobilization times (or reaction time) of the affected population strongly depend on the type of disaster being analyzed and are only known, with certain accuracy, for very few of them. Little is known about the selection of destinations and intermediate stops during an evacuation and the relationship, from a behavioral point of view, of these choices to the type of event. The congestion patterns that would develop during an evacuation are tightly related to this demographic information making it crucial for the analysis of these problems.

Work is also required in relationship to the capacity side of the problem; that is, the definition of the characteristics of the transportation network. The determination of these characteristics is a lengthy process and one that does not end once the evacuation plans have been developed. Those plans are intimately related to the topology (i.e. connectivity) and capacity (number of lanes on each roadway segment, traffic control settings, etc.) of the transportation network and require constant update if they are going to be useful when needed. Some research is being conducted in this area to simplify both the creation and update process of the transportation network information, but there are areas that need further research, especially those related to the gathering of relevant traffic parameter information that cannot be found on GIS databases or determined through remote sensing technology (e.g. information about traffic control settings).

Once all the relevant information has been gathered, the evaluation of the proposed alternatives and traffic management strategies to be deployed during an evacuation requires the usage of a simulation model. Traffic simulation software has been available for many decades now to analyze general (i.e. day-to-day) traffic operation problems. Even before 9/11, some of these models (e.g. OREMS) have been specifically adapted to study and evaluate vehicular evacuations, and after 2001 other general purpose traffic simulation models have been used for the analysis of these types of problems.

Many issues still remain to be addressed in this area. One of the most important ones is related to the modeling of multimodal evacuations, including not only transit but also

pedestrian flow modeling and the interactions between pedestrians and vehicles that can arise under certain scenarios (e.g. evacuation sport venues located in downtown areas). The validation of these new models, and even the existing ones, for their use in assessing emergency evacuations is also a task that remains mostly unfinished.

Although, threat evolution models are somehow used in the modeling process (at least to determine the EPZs), the integration of these models and traffic simulation models is necessary to correctly evaluate alternatives under some scenarios. The typical decision variable to assess emergency evacuation plans (i.e. ETTE) may not be the correct measure to analyze certain problems, since there may be certain cases in which alternatives with shorter ETTE may have larger expected casualties than other ones with higher ETTE.

All these issues are related to the planning phase of emergency evacuations. If the evacuation plans need to be deployed, then real-time traffic information needs to be collected to determine whether the evacuation is proceeding according to plan or any changes are required. If changes are needed (almost a certainty), then availability of real-time information distribution is also required. Some efforts are underway to provide this type of capabilities until systems such as the ones proposed under the VII initiative are fully deployed.

# EMERGENCY TRANSPORTATION OPERATIONS AND CONTROL

VINCENT PEARCE
*U.S. Department of Transportation, Washington, D.C.*

## 1 OBJECTIVES

Here we address three of the important objectives to consider when carrying out emergency transportation operations. The first is to obtain the necessary situational awareness. Situational awareness is the phrase used to describe having sufficient information and understanding in order to make and carry out decisions. Typically situational awareness requires information with three characteristics: timeliness, accuracy, and completeness.

Planning and decision making occur based upon the information obtained through situational awareness. Often the necessary decisions are multifaceted and may require the support of tools, models, simulations, or other products that analyze the data and provide feedback in a manner or form that makes it usable to decision makers and to those who will then implement the decisions.

Carrying out the decisions should result in influencing the behavior of the population and the responders. This means that decisions must include not only the desired outcome, but also the manner in which it will be communicated to achieve the desired outcome. In some cases, the action desired is communicated directly, such as by changing the timing of traffic signals. In many other cases, the action desired is also communicated indirectly. This is being achieved through sharing information in a manner that persuades the population to take the desired actions, such as traveling at specific times and along specific routes.

A possible additional objective, typically not separated from the others, is the ability to modify the chosen strategy after it is implemented on the basis of the results and changing conditions. This capture and consideration of feedback from the actions occurs at many levels, from the most strategic consideration to the finest tactical action.

## 2 REQUIREMENT

The requirements of an emergency transportation operations program begin with monitoring the transportation conditions. This includes both the status of the infrastructure/systems and the operational conditions. The information needs to arrive in real time and needs to be capable of being converted to usable form. Raw output from many of the sensor systems available is not usable. Further, the information needs to be filtered, as there is potentially far too much information to absorb and to choose from for the operators. The varying types of information may need to be integrated or "fused" in order for

the decision makers to comprehend what is often referred to as the *common operational picture*. The preexisting information, such as the characterization of the roadway itself, also needs to be in a usable form, so that operational conditions can be overlaid upon it, impacts understood and predicted, and alternatives identified and analyzed.

Tools to support the decision-making process need to be capable of working in the kind of environment that will exist in emergency operations. Typically, one of the most critical features is the ability to process quickly. Models that take hours to run are of little use. Once processed, the output needs to be expressed in manners that are easily understood by an audience with a widely varying level of technical expertise. Often, critical decisions such as when to initiate an evacuation order are passed on to elected or senior appointed officials who may have no grasp of the technical fundamentals at all. Making the output usable may also require the ability to integrate the output with other data, either output from other processes or actual real-time data, a further form of "fusion."

Influencing the behavior of the responders is relatively easy in a classic command and control environment; they are given direction and they proceed using the training, information, and tools that they have received. Influencing the behavior of the general public is considerably more challenging. Much of this is achieved by informing the public of the situation, the decisions, and the likely conditions, and providing such recommendations as may make sense. Classic examples include sharing information on shelter and hotel availability and on road conditions to potential evacuees. The end objective is to get the evacuees from a specific area to take specific routes to specific shelters, thus making effective use of the transport and shelter capacity that is available, while perhaps also sustaining some transport capacity for responders as well. Under normal emergency operations conditions, it is essentially impossible (and may thus be unrealistic) to force evacuees onto specific routes. Particularly in situations where the population would be evacuating from their work locations due to an unexpected incident, planning assumptions such as "everyone in the southern half of the city will evacuate south" may be totally unrealistic, due often to family commitments, that may cause evacuees to actually move closer to the hazard they flee away from it.

The requirements necessary in order to control and direct the population's actions, to the degree possible, are often technology driven. The tools used to control traffic, whether on roads or on other modes of transport, are typically composed of electronic and electromechanical devices. In situations where such devices do not exist, or where actions are needed that are outside the available working parameters of the existing equipment (such as a signal timing plan that has not been loaded into the necessary signal controllers), it may be necessary to place temporary devices such as signs, or even humans, into the operating environment to carry out the direction and control. The effectiveness of the technology depends, as it does every day, upon the technology's flexibility, speed, accessibility, and other design and operational factors.

## 3 MODES OF TRANSPORTATION

Technically, all modes of transport can be and periodically are applied to emergency transportation operations. For example, while planning evacuation for the 12 most impacted parishes in southern Louisiana, the heaviest transportation components are road, rail, transit, and aviation. Maritime has also figured in the evacuation, not only in New Orleans

but also in moving people out of New York City following the 9/11 attacks, and later when the blackout of 2003 struck.

Obviously, each mode has its unique characteristics. Some modes are owned and operated by government agencies, some by pseudogovernment entities, and others by the private sector either for their own profit or under contract to government. Each mode is regulated differently and each has its own command, control, and communications structure. Capabilities may also vary considerably from one jurisdiction to another.

It is particularly important to remember that all modes may be at play, or may have something to offer in planning for and carrying out emergency transportation operations, and that allowances must be made for the uniqueness of each. Integration between modes, or at least reasonable synchronization and coordination of actions by different modes, is vital. For example, instituting contraflow travel, in a manner that stops evacuation buses from returning to pick up additional evacuees, or slows down the progress of busloads of evacuees being taken to train stations or airports is a dangerous outcome of poor coordination. Post-Katrina evacuation planning in Louisiana has highlighted the importance of intermodal connections, as well as intramodal connections such as when school buses bring evacuees to a pickup point, where motor coaches then board and take them to further destinations.

## 4 EMERGENCY TRANSPORTATION OPERATIONS ON HIGHWAYS

When it comes to determining how to carry out emergency operations, roadways are often classified into two fundamental categories: controlled access and uncontrolled access. Which of these two categories describes a given roadway has a significant influence on the emergency transportation operations strategies that can be carried out on that facility.

Controlled access facilities, such as interstates, ordinarily allow the free flow of traffic with few controlling devices. Ramp meters can control access to the facility, but other than high occupancy vehicle lanes with either indicators or possibly gates, most controlled access facilities allow a free flow of the traffic. Thus, if emergency operations dictate that changes in traffic flow on the controlled access facility are needed, manual intervention combining information and signs/barrels/cones/personnel will be required. An excellent example is contraflow, where vehicles are allowed to travel "the wrong way" on highways that have been closed to and cleared of traffic desiring to travel in the "normal" direction. Strict measures are necessary to control the ability of motorists to get on to and off of the contraflow lanes, as well as considerable information to allow the motorists to operate safely and efficiently in an operating environment that is totally unfamiliar (it has been remarked that driving in a contraflow situation is somewhat disorienting).

Uncontrolled access facilities such as typical city streets allow many more tools, particularly traffic signals, which help to carry out emergency transportation operations. Within limits, traffic signal timings facilitate control of flow speed and volume in each direction, including even potential ingress to and egress from the facility. Signals may have limited impact; however, as congestion builds up, travel conditions exert a greater influence on speed and throughput than the signal timing itself does during free flow conditions. In the extreme, conditions may develop where ordinary signal timing, operating under far-beyond-saturation conditions of an evacuation, may stimulate unpredictable motorist behavior, such as violating red lights deliberately after excessive wait periods.

## 5 TECHNOLOGIES

There are many forms of technology that can support emergency transportation operations. Sensors are available using many different technologies to feed into situational awareness. Each sensor technology has its own unique characteristics, influencing how the technology is deployed and operated and the data it produces. Consideration of temporary, portable sensors that can be quickly put into place and then removed before an incident with advance notice, such as a hurricane, may also be worthwhile. There have also been demonstrations of the use of vehicles themselves, or items that they contain such as cellular telephones, which allow the vehicles to serve as probes in the traffic stream, thus relaying similarly useful information on travel speed and incident locations.

Video surveillance is an increasingly important tool in emergency transportation operations. Again, many different forms of video devices are available, not all compatible with one another, and each with possible limitations on how it can be applied to gathering the necessary understanding. Video should be viewed as a system; cameras without controllers, communications, and displays are useless. The way in which a video system is installed, for example, may limit its utility. If a camera has been installed for use in documenting red light violations, its positioning may not support the longer and broader view of traffic that is desired in assessing localized traffic flow conditions. Again, temporary, portable options may be available for uninstrumented areas.

Decision-making support systems and tools are essential to making quality decisions in a timely manner. Unfortunately, many of the current models were developed for use under nonemergency conditions and for very different objectives. Loading the models can be time-intensive, particularly if the conditions have changed significantly from the baseline. Running "what-if" scenarios, to evaluate multiple alternatives is an important capability. Information on current traffic analysis tools work by the US Department of Transportation's Federal Highway Administration (FHWA) can be found at http://www.ops.fhwa.dot.gov/trafficanalysistools/index.htm.

There is a good variety of traveler information tools. Some tools are focused on pretrip traveler information and others focus on en route information. Each type of system typically has limits, though, on the amount and type of information that it can deliver. Misusing a traveler information technology can by itself create hazardous conditions substantially. Imagine the disruption to traffic flow created by motorists traveling at 70 miles/hour trying to read four panels of text on a variable message sign. As with any tool, such systems can work well and be used effectively, or can fail to meet expectations. Early traveler information radio systems have been criticized as difficult to understand. Other challenges may exist, such as communicating effectively to drivers to whom English is not a primary language, or drivers who are unfamiliar with the area through which they are passing. Similarly, onboard navigation systems may find it difficult to develop and provide useful directions when typical routes have been limited or closed. Excellent resources from FHWA on traveler information systems and program are available at http://www.ops.fhwa.dot.gov/travelinfo/index.htm.

Traffic signals have evolved substantially since the days of Garrett Morgan and they continue to improve. Their flexibility and capacity to handle complex and numerous timing plans, and to make their own decisions based on developing flow conditions support their inclusion into emergency transportation operations plans. However, there are still many traffic signal systems in place with earlier and much more limited

technology, so the effectiveness of emergency transportation operations may be limited. More details about the work the FHWA has done on traffic signal systems are available at http://www.ops.fhwa.dot.gov/arterial_mgmt/traffic_sig.htm.

Reliable high-speed communication is fundamental to receiving the information and controlling the devices, as well as to coordinating across multiple systems, modes, and jurisdictions. Many options exist, but interoperability is key. Good design practices (such as building in redundancy and upgradeability) are essential to gain the most from a possibly significant investment. During disasters, communications systems may be overloaded or damaged, perhaps limiting the agency's ability to remotely modify the traffic control devices. The results of over a decade of work on telecommunications and transportation can be found at the website of the USDOT Intelligent Transportation Systems Joint Program Office, http://www.its.dot.gov/telecom/index.htm.

Traffic barriers, once limited to cones and barrels, now include automated gates, barriers that store below ground, and barrier systems that can be moved by specialized vehicles. These options may allow considerably a more rapid reconfiguration of traffic and roadways than would be possible manually and with greater safety as well. Even simple measures, such as having mapped out in advance where barriers will be implemented and pre-staged, the barrier materials can reduce considerably the time necessary to implement these measures, and to remove them before the arrival of tropical storm force winds.

## 6 CHALLENGES

Not surprisingly, those conducting emergency transportation operations face numerous challenges. For example, during and after the incident, transportation may need to be carried out on impact facilities; thus, they end up working under degraded conditions. Capacity may be reduced, additional hazards may exist, and devices may be impaired. Unfortunately, the transportation technology may be least functional when its assistance is most needed.

Decision quality is strongly influenced by the information that operators have, and frequently information is either imperfect or inadequate. Much of the information may be based upon models and observations, either of which may have limited fidelity. Risk is also a factor, so understanding how a risk changes with time is also important.

Coordination across jurisdictional boundaries is always challenging. For example, inland states may be hesitant to accept a free flow of evacuees who are receiving their guidance from coastal states anticipating tropical storm conditions. In other types of situations, the evacuees may, in fact, present a hazard, if for example, they have been contaminated or are contagious due to chemical/radiological and biological situations, respectively.

The political decision-making process/timeline may not work as rapidly as would be desired. There will be considerable hesitancy to make major decisions such as calling for an evacuation because of the economic impacts, and even possibly due to the impacts on resident health and safety. Evacuations are difficult particularly for persons who are hospitalized, so evacuation decisions are typicallymade very cautiously.

Resource shortages may impact the ability to conduct emergency transportation operations. If local law enforcement normally conducts traffic, but they are diverted to higher priority law enforcement missions, a major gap exists in the ability to dictate (and report) what traffic is doing.

Coordination within the overall response can be quite challenging. For example, assuring that victims picked up by search and rescue services are brought to locations from which they can be evacuated is critical. Similarly, transportation plans during an evacuation are strongly influenced by shelter availability and the knowledge of shelter availability. Poorly coordinated decisions can worsen, instead of improving, the situation.

Coordination between modes of transport is fundamental. If an evacuation by air is planned, adequacy of and coordination with transport to/from the airports are critical. Individual modes may be impacted by the disaster, not all at the same time. For example, it is important to know when airlines plan to stop flying into an airport that is in the path of a hurricane. On a smaller scale, movement of motor coaches and trucks across a bridge or a similarly exposed area may also be limited as wind speeds increase or as weather conditions worsen.

It is almost assured that, unfortunately, incidents will occur during the emergency transportation operations. Thus, incident clearance—rapid and efficient, is a vital component of emergency transportation operations. Clearance is only one component of overall incident management, which is itself an effort involving multiple agencies, each with its own priorities, objectives, technologies, and systems. Fortunately, the FHWA has been working diligently on improving traffic incident management in a comprehensive manner for a number of years. You can find more information on their work on-line at http://www.ops.fhwa.dot.gov/incidentmgmt/index.htm.

Fuel shortage, often caused by lack of electrical power, can strongly influence the process of evacuation. Impact comes not only from vehicles that run out of fuel, but from motorists who leave and reenter the traffic stream frequently attempting to obtain fuel at one station after another. Of course, fuel for the response vehicles is also a critical resource. The impact of fuel shortage may extend beyond the transportation, fire, and police department's vehicles. Fuel support to an evacuation fleet of hundreds of motor coaches and school buses is an even greater undertaking.

Unpredictability of transportation demand is a serious challenge. The first major hurricane to hit the United States after Hurricane Katrina was Hurricane Rita. With the memory of the devastation of Katrina fresh in their minds, thousands more Texans evacuated than any model predicted, resulting in impossible traffic volumes and all of the other problems that come with them.

## 7 IMPROVING THE WAY FORWARD

Clearly, technology is fundamental to successful emergency transportation operations. The technology can help resolve, but can also in some cases actually cause, some of the complex issues that transportation managers face. Several actions can help to bring progress in the area:

Continued improvement of models and simulations, particularly focusing on emergencies and disasters, will be highly beneficial.

Enhanced integration of data and of systems facilitates achieving the understanding necessary for decision making.

Lower cost systems support wider implementation.

Improved portability, through less weight and lower power consumption or alternate power sources (solar) will assist in temporary implementation for areas under construction and areas that do not have fixed systems for other reasons.

Improving the ability of the technology to withstand the rigors of disaster conditions improves the likelihood that the technology will be working when it is most needed.

Increased flexibility of technology to deal easily and rapidly with changing conditions makes it possible to "stay ahead of the curve" instead of constantly being caught behind the latest condition or forecast, or worse yet, having to supplement the technology with the very limited available manpower.

Improved representation of the data, in formats and forms focused on decision makers will help get the best decisions made as quickly as possible.

The ability of technology to support multiple modes of transport and across jurisdictional boundaries will facilitate coordination. Principles such as interoperability and the ability to share and integrate data can be major contributors to progress in this area.

# ULTRA-SCALE COMPUTING FOR EMERGENCY EVACUATION

BUDHENDRA BHADURI, JAMES NUTARO, CHENG LIU, AND THOMAS ZACHARIA
*Oak Ridge National Laboratory, Oak Ridge, Tennessee*

## 1 INTRODUCTION

Disasters impose a high level of risk on human lives within a physiographic space and evacuation is the physical movement of the population at risk to safer locations. In a broader sense of that definition which includes situations relevant to homeland and national security, emergency evacuations may occur in a variety of physiographic spaces such as passenger vessels in accidents (airplanes, trains, buses, and ships), buildings (and facilities) on fire, as well as large geographic areas (multiple counties) impacted by natural (hurricanes, floods, volcanic eruptions) or technological disasters (atmospheric dispersions of harmful gaseous agents). In all of those situations, modeling the evacuation process involves accounting for the number of people, the available evacuation routes and transportation modes (pedestrian, vehicular), and, most significantly, the behavioral characteristics of the evacuating population. High resolution databases are becoming available at an increasing rate which in turn facilitates development and incorporation of detailed behavioral processes in evacuation models. Computational complexity can originate from increasing resolutions in data (population and transportation), which increase the number of entities to be modeled, or from increasing complexity in the evacuation behavior represented in the models. Here, we focus the discussion on vehicular evacuation

of large geographic areas since this scenario potentially involves the initial complexity of large volumes of input data and consequent compounding of that complexity by the many individual and traffic behavioral processes that can be represented in the evacuation model.

The goal of this article is to provide a new perspective on the potential role of ultra-scale simulations, which require beyond single desktop processing of data, and execution of algorithms on hundreds or thousands of parallel processors in the context of existing approaches for evacuation modeling. In the subsequent sections, we propagate the use of ultra-scale computing as an enabler of new emergency evacuation models that incorporate high resolution geospatial databases and relevant human behaviors. These "use cases" are contrasted with the present state of transportation modeling to highlight the primary challenges posed by our vision.

## 2 MOTIVATION FOR ULTRA-SCALE SIMULATIONS

The use of transportation network simulation for evacuation modeling has been in practice since the mid-1980s [1]. A number of existing transportation simulation models characterize the interaction between human dynamics and transportation infrastructure and require the integration of three distinct components, namely data, models, and computation. These include detailed physical models of transportation engineering, such as is found in CORSIM [2], TRANSIMS [3–5], VISSIM [6], PARAMICS [7], and OREMS [8, 9]. Very recently, a few models have started to address the human dynamics of physical and social systems, such as Repast/Mason [10] and SEAS [11, 12].

However, none have been able to successfully integrate both the physical as well as behavioral aspects to characterize the interdependencies within the transportation systems. Progress has also been limited by data and computational challenges necessary for accommodating the required high resolution along spatial, temporal, and behavioral dimensions. With the exception of TRANSIMS [13, 14], no other model has demonstrated the aspect of ultra-scale simulations.

There are a few plausible reasons behind the apparent lack of motivation to develop beyond-desktop simulations for transportation or evacuation models. First, the lack of high resolution primary databases for transportation network and other infrastructure assets such as traffic lights and controllers; spatially explicit demographic attributes; and other critical infrastructural features such as schools, hospitals, banks, and so on, that would provide large volumes of data and therefore impose a high level of computational complexity, have only been available to the modeling community in the last decade. Moreover, evacuation modeling has traditionally been a component of emergency preparedness and planning rather than an operational tool. Estimation of evacuation time for an area given network availability, or determination of evacuation routes given available time for evacuation have been the primary applications of evacuation modeling and simulation. However, there are a couple of reasons for which evacuation modeling, even for planning purposes, can demand large-scale simulations.

First, let us consider the scenario of large-scale hurricane evacuation in the coastal states handled by divisions such as South Carolina Department of Transportation (SCDOT) [15], Louisiana Department of Transportation and Development (La DOTD) [16], and Florida Division of Emergency Management [17]. These states identify the state emergency evacuation routes that could be used for disaster situations. For the

reason of simplicity, their emergency evacuation plans only identify the state and federal highways as evacuation routes. Those plans are easy to understand and easy to follow. However, for realistic planning purposes, it would be more accurate if the street networks were also considered since the elimination of detailed street networks could lead to overestimation of the evacuation time.

For example, Figure 1 is a 3-mile distance circle around downtown Knoxville, Tennessee with only state and interstate highways. The yellow dots are the population distribution within this circle. If the evacuation plans consider only the highway networks, then there are just 36 exit points. Figure 2 is the same map with a higher resolution street network; it has 140 exit points. Therefore, many evacuees can escape from their locations within the evacuation area by utilizing local streets. However, since only the highways are designated as evacuation routes, both in models and in reality, the smaller streets remain underutilized hence adding to the total evacuation time. Another problem is that without the street network, it is difficult to estimate the local flow pattern and therefore, difficult to estimate the highway loading factor. The advantage of using only the highway network is that the data is small (it has 878 highway links in Fig. 1) and the model execution time is correspondingly diminished. On the other hand, a model using the street networks must deal with larger data (it has 7926 highway and local street links; Fig. 2); the local street network data is 10 times larger than highway data in the example above. Therefore an increased computational power is needed to solve this problem especially when the study area becomes large.

Second, the recent availability of very high resolution demographic and socioeconomic data has allowed development of detailed activity-based behavioral models that can be integrated with transportation simulations. For example, a plethora of household

**FIGURE 1** Intersection of the highway network and low resolution street data results in 36 exit points for a circular area with 3-mile radius around downtown Knoxville, Tennessee.

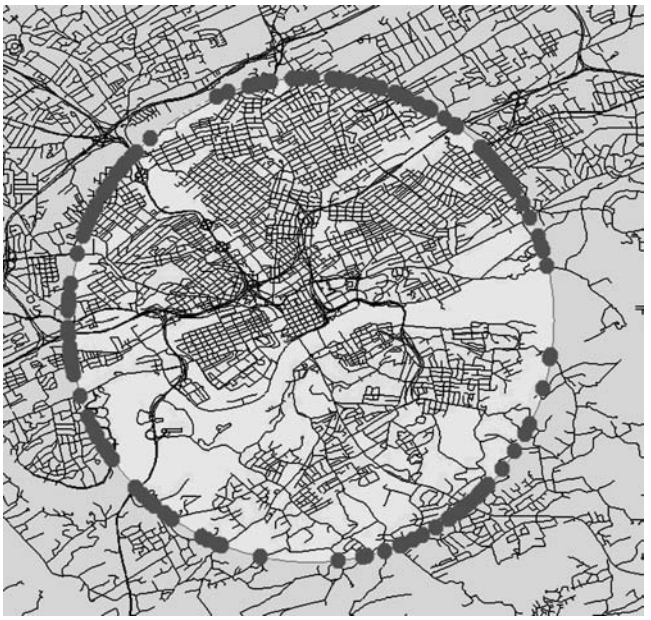

**FIGURE 2** Intersection of the highway network and a higher resolution street network data results in 140 exit points for a circular area with 3-mile radius around downtown Knoxville, Tennessee.

and microlevel data on socioeconomic and activity-based behavioral data have been collected and are disseminated primarily by the US Census Bureau and the Bureau of Transportation Statistics (www.bts.gov/data) of the US Department of Transportation. The American Community Survey (ACS) from the US Census is a new nationwide survey-based data on general demographic, social, economic, and housing characteristics. In addition, significant advancements have been made in developing very high resolution population distribution data through advanced spatial data integration and modeling through pycnophylactic [18], dasymetric [19] and smart interpolation [20] approaches. Among them, Oak Ridge National Laboratory (ORNL), as part of its LandScan Population Projects, has developed the finest resolution (1-km cell) population distribution model for the entire world [21], and an even higher resolution (90-m cell) for the United States, the latter including a time variant distribution of population [22, 23]. Such high resolution population distribution data, when combined with corresponding behavioral attributes, quickly provides a much-desired way to model individual (driver and other evacuee) behavior during evacuations and consequently adds computational complexity to large-scale simulations.

For example, explicit representation of various demographic groups in space and time provides a way to modify the simple Origin–Destination (OD) models in a transportation system. Figure 3 shows a daytime population distribution scenario of Washington, DC where some workers (parents) in downtown have their children attending schools across the river (southeast part of the figure). During an emergency, those parents are most likely to head toward their children before evacuating out in another direction. Such behavioral models become easy to formulate and integrate but add considerably to the computational complexity of evacuation scenarios. For successful emergency evacuation planning, assessing the effectiveness of possible planning strategies and discovering their

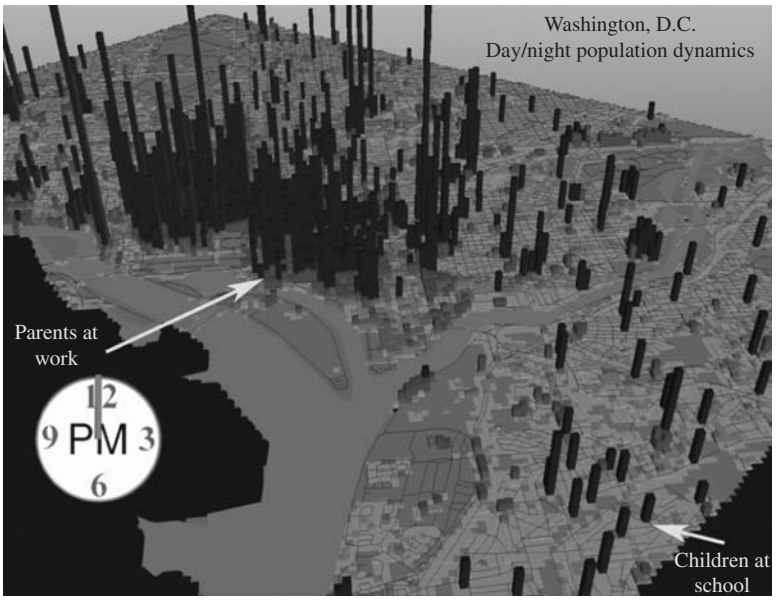

**FIGURE 3** Modeled daytime population distribution scenario for the Washington, DC area where some workers (parents) in the central business district are likely to move toward their children at school across the river (southeast part of the region) after a disaster.

unanticipated consequences can be achieved by data collection, modeling, and simulation at the finest data, process, and societal-response levels coupled with the system's behavior over large spatial and temporal scales. Modeling at this scale provides a strong impetus for ultra-scale simulations.

Finally, simulation execution time becomes a critical bottleneck when evacuation modeling needs to be implemented as an operational tool, either for short-term planning (i.e. days ahead) or to anticipate congestion quickly enough for simulation output to be used in real-time modifications of transportation network controls in order to optimize the flow of traffic. Such a modeling framework will require processing of dynamic data streams from a variety of sensor networks that can be used in description and updation of network status in real time as well as in calibration of the model outputs; in faster than real-time execution of the model to simulate emerging situations; and in evaluation of consequences of mitigation strategies to address the behavior of the system. No such modeling and simulation system exists today and it can only be developed by utilizing ultra-scale simulation frameworks.

## 3 MODELING APPROACHES FOR POPULATION MOBILITY

Evacuation models can be considered as a special situation where movement of people is expected to have certain directionality since the objective is to move the population residing inside a geographic area across and outside its boundary. This section describes and illustrates three approaches to building models of transportation systems that allow modeling of such population mobility. These approaches also represent the general methodological principles of moving vehicles along transportation networks. The

focus of this section is on microsimulations; the modeling techniques described here deal with individual vehicles. Although the approaches are presented separately, large microsimulations are unlikely to use a single approach and elements from each are frequently intermingled. For example, TRANSIMS uses both vehicle-oriented and cell-based modeling techniques in its microsimulation module [5]; MITSIM has elements of both link-based and vehicle-oriented models [24]. Nonetheless, the categories that are identified here represent three distinct elements of a transportation system: space, structure, and human behavior.

### 3.1 Spatially Oriented Models

Spatially oriented models of transportation systems focus on change as it is seen from a fixed vantage point. Cell-based models are one popular approach for constructing spatially oriented models. With this approach, the road network is divided into uniform squares called cells. Each cell has a set of attributes that describe the road type (e.g. a merging lane, freeway, surface street etc.), speed limit, direction of travel, the vehicle occupying the cell, and other items of interest. Every cell also has a set of rules that are used to change its state.

Simulation proceeds in one of two ways: time-driven or event-driven. In a time-driven simulation, the state of every cell is recomputed at regular intervals of time. This is done by sweeping through the cell space and applying each cell's transition rules. Conceptually, updates occur simultaneously at each cell; if a cell requires its neighbors' state to determine its own subsequent state then it uses the state of those neighbors at the previous instant of time.

In an event-driven simulation, the transition rules at a cell are applied only when specific event conditions are satisfied. For example, a cell that represents a freeway segment changes its state only when it, or its neighbor upstream, is occupied by a vehicle. Event-driven models have the potential for more accuracy than their time-driven counterparts; events can occur at any instant of time and are not restricted to the predetermined calculation points of a time-driven model. In principle, event-driven simulation can also reduce the amount of time that is needed to complete a simulation run by reducing the number of cells that must be updated. An event-driven simulation, however, requires considerably more supporting machinery (in the form of event-scheduling algorithms, activity scanning, event set management, etc.) than a similar time-driven simulation. Consequently, real gains in execution time or accuracy are contingent on the type of traffic problem that is being considered.

To illustrate this modeling approach, consider the single-lane road shown in Figure 4. The road is divided into uniform segments. Each segment is either occupied by a vehicle or it is not. A vehicle that occupies a cell has a speed $v$ and every cell has a maximum allowable speed $v_{\max}$. Every occupied cell also has a gap distance that is the number of cells separating the occupied cell from its next occupied neighbor, in the direction of travel. Each cell in this time-drive simulation has four rules for moving a vehicle [25]:

1. Accelerate. $v' \leftarrow \min(v + 1, v_{\max})$
2. Decelerate to avoid accidents. $v'' \leftarrow \min(v', gap)$
3. Randomize $v'' \leftarrow \max(v'' - r, 0)$ where $r$ is a random variable that yields 0 or 1 with a certain probability $p$.
4. Move. Advance the vehicle position by $v'''$ cells.

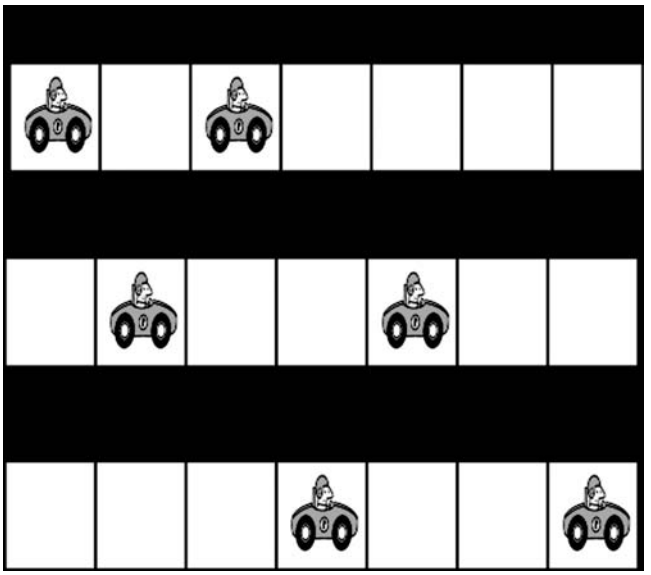

**FIGURE 4** Three time steps of a cell-based traffic model. The numbers above each vehicle indicate their individual speeds.

Figure 4 shows the motion of two vehicles over three time steps. The maximum speed in this example is two and neither vehicle undergoes random deceleration (i.e. $r$ is always zero).

### 3.2 Link-Based Models

Link-based models of transportation systems focus on the state of individual road segments within the road network. The major dynamic elements in a link-based model are road segments and intersections. Road segments are characterized by the road type, speed limit, number of lanes, occupancy limit, a speed-density function, and other attributes of interest. Interactions are characterized by control signals, permissible turning movements, and possibly other items. Vehicles move from link to link and some models also incorporate vehicle motion within a link (e.g. to permit midlink lane changes).

Links are commonly modeled as discrete event systems that act on at least two kinds of events: a vehicle arrives or a vehicle departs. Other events can be included to model congestion that crosses several links, traffic control signals, or special vehicle behaviors within a link. The queuing model developed by Gawron [26] is a good example of a link-based transportation model. Gawron's original model was designed for discrete-time simulation; a discrete event variation of it is presented here.

Every link in Gawron's model has four attributes: the free-flow speed $v_0$, the length $L$, the maximum number of vehicles per unit time $C$, the average vehicle length $l$, and the number of lanes $n_{\text{lanes}}$. When a vehicle enters a link that vehicle is assigned an earliest exit time $L/v_0$; this is the amount of time needed to cover the link distance at the best possible speed. Once the vehicle has traversed the link distance, it is placed into a queue. Vehicles in the queue are moved to the next link on their path at a maximum rate of $1/C$; the total time required for a vehicle to traverse the link is approximately $L/v_0 +$

*(Queue length)/C* where *Queue length* is the size of the queue when the vehicle enters it. A vehicle can advance to the next link when three conditions are satisfied:

1. the vehicle has advanced to the front of the queue;
2. the total number of vehicles in the next link is less than $L \cdot n_{\text{lanes}}/l$; and
3. conditions 1 and 2 have been satisfied for $1/C$ units of time while the vehicle is at the front of the queue.

Table 1 shows the first 10 iterations of a simulation of this model when applied to the traffic circle shown in Figure 5. A total of five vehicles enter the traffic circle: the first at time 2.5, the second at time 5, the third at time 7.5, the fourth at time 10, and the fifth at time 12.5. Each link has two lanes, a free-flow speed of 10 m/s, a length of 50 m, a maximum vehicle flow rate of 10 cars per second, and the average vehicle length is 7.5 m.

**TABLE 1 The First 10 Event Times in a Simulation of Five Vehicles in the Traffic Circle**

| Time | Link 1 | Link 2 | Link 3 | Link 4 | Link 5 | Link 6 |
|---|---|---|---|---|---|---|
| 2.5 | 1 | 0 | 0 | 0 | 0 | 0 |
| 5 | 2 | 0 | 0 | 0 | 0 | 0 |
| 7.5 | 3 | 0 | 0 | 0 | 0 | 0 |
| 7.6 | 2 | 1 | 0 | 0 | 0 | 0 |
| 10 | 3 | 1 | 0 | 0 | 0 | 0 |
| 10.1 | 2 | 2 | 0 | 0 | 0 | 0 |
| 12.5 | 3 | 2 | 0 | 0 | 0 | 0 |
| 12.6 | 2 | 3 | 0 | 0 | 0 | 0 |
| 12.7 | 2 | 2 | 1 | 0 | 0 | 0 |
| 15 | 2 | 2 | 1 | 0 | 0 | 0 |

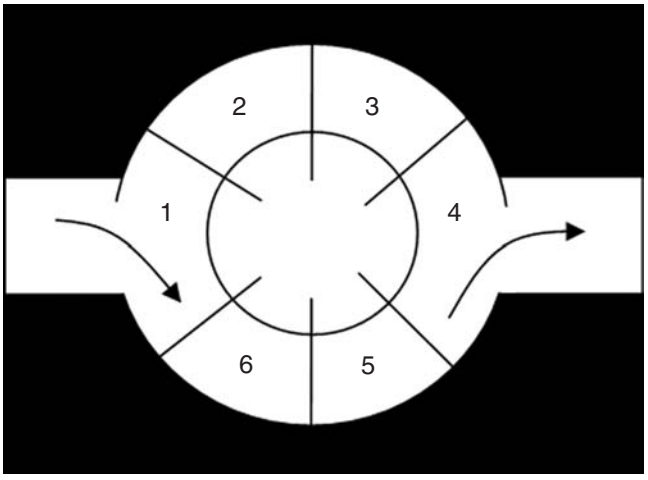

**FIGURE 5** A traffic circle that is modeled with six links.

### 3.3 Vehicle-Oriented Models

Vehicle-oriented models are constructed from the driver's point of view. The dynamic unit in a vehicle-oriented model is the vehicle itself; the driver of a simulated vehicle observes and reacts to his simulated surroundings. These types of models are attractive because they can easily incorporate models of the driver's decision-making processes and information technology that could influence driver behavior (e.g. digital maps, real-time traffic reports etc.).

The road network can be modeled just as in the link-based and spatially oriented modeling approaches. Elements of the road network, be they cells or links and intersections, have attributes that describe speed limits, road type, traffic signals, and other relevant items. It is frequently helpful to maintain a list of vehicles that occupy each part of the road network; this can simplify the calculations that are needed to model driver behavior by making nearby vehicles easy to find. The major difference between the vehicle-oriented approach and link-based or spatially oriented models is that the road network is acted on by the vehicles and not the other way round.

The car following algorithm that is used by MITSIM is a good example of a vehicle-oriented model [24]. In this model, the road network is represented as a graph with links and intersections. The simulation periodically (usually at 1-s intervals) updates the position, velocity, and acceleration of every vehicle. At each simulation update time, the driver of a vehicle observes his surroundings and changes his acceleration to either avoid a collision or reach a desired speed. In the car following regime, the acceleration is given by:

$$a = \alpha^{\pm} \frac{v_{lead}^{\beta^{\pm}}}{g^{\gamma^{\pm}}} (v_{lead} - v) \tag{1}$$

where $a$ is the acceleration, $v$ is the vehicle speed, $v_{\text{lead}}$ is the speed of the vehicle immediately ahead (i.e. leading), $g$ is the distance between this car and the leading vehicle, and the exponents $\alpha$, $\beta$, and $\gamma$ are parameters for calibrating the model ($a^+$ is an acceleration parameter and $a^-$ is used for deceleration). The vehicle speed and position at time $t + h$ is computed from its speed and position and the lead vehicle's at time $t$ by:

$$v_{t+h} = v_t + h\alpha^{\pm} \frac{v_{lead}^{\beta^{\pm}}}{g^{\gamma^{\pm}}} (v_{lead\ t} - v_t)$$

$$x_{t+1} = x_t + h v_t$$

where $x$ is the position of the vehicle relative to the start of its current link. Table 3 shows a simulation with this model of a car decelerating as it approaches the lead vehicle. The gradual approach of the following vehicle to a safe following distance is clearly apparent in the data.

The car following algorithm clearly differentiates this model from the previous cell-based and link-based models. The simulation is executed vehicle by vehicle, and individual vehicles may occupy any point on a link and perform arbitrarily complex maneuvers (e.g. MITSIM also includes lane changing, emergency breaking, and free-flow models that are influenced by the driver's perception of the current traffic conditions).

## 4 EXPERIMENTAL COMPARISON OF EXISTING MODELS

It is clear that the input data is easy to prepare and the model execution times are fast for macroscopic traffic simulations. Although the microscopic traffic simulation models take more time to prepare the data and need more simulation execution time, they generate more detailed information of the traffic flow conditions. However, microscopic models can vary, sometimes substantially, in their execution times and predictions of traffic flow even when given similar data. To illustrate this fact, we selected a macroscopic evacuation model, OREMS, and two open source microscopic traffic simulation models, MITSIM and TRANSIMS. Evacuation simulations with these models were run on a CPU (running Windows XP) with 3.79 GHz processor and 4 GB of RAM.

A set of artificial networks were generated to perform the comparison. The network was designed as a square matrix of cells. Each link was 1 mile long and the speed limit was 25 miles per hour. The horizontal nodes, the left-most and right-most were entry nodes and the vertical nodes, the top-most and bottom-most were exit nodes. The OD matrix was that each entry node had $n$ vehicles to every exit node. Figure 6 is a 10 $\times$ 10 matrix network with 100 vehicles from each entry node to every exit node. The total vehicles for each entry node is 800 vehicles because there are eight exit nodes. Figure 7 is a 16 $\times$ 16 matrix network with total 9600 vehicles for each entry node. Table 2 is the summary for all scenarios. For example, in the largest dataset scenario, 16 $\times$ 16 $\times$ 9600, there are 32 entry nodes and 14 exit nodes and the corresponding total number of vehicles that need to be evacuated is 297,200.

Though these models share several common data sets—the transportation network, an origin and destination matrix for travelers, and often a travel schedule—it is nonetheless difficult to evaluate them in a standard context. Each model incorporates particular effects

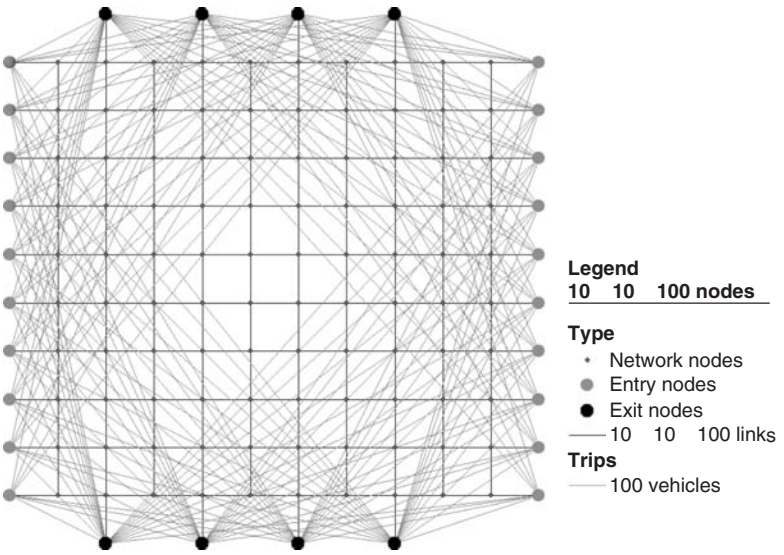

**FIGURE 6** A 10 $\times$ 10 network of nodes where the number 800 vehicles are entering each entry node.

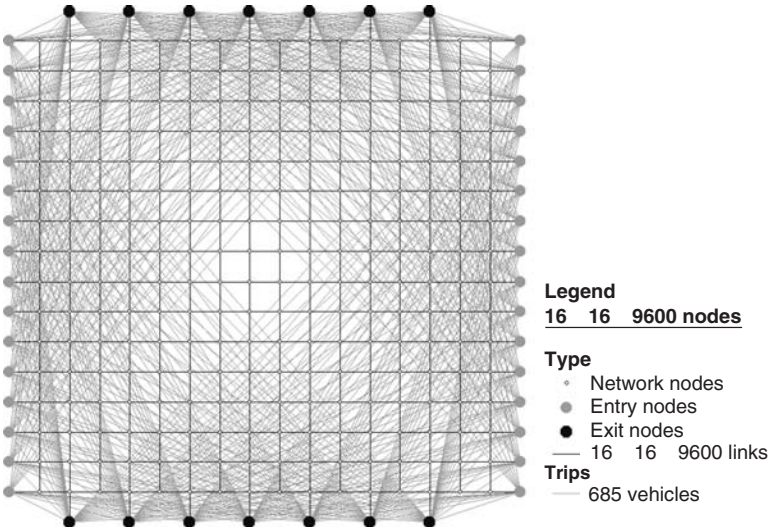

**FIGURE 7** A 16 × 16 network of nodes where the number 9600 vehicles are entering each entry node.

**TABLE 2 Characteristics of All Scenarios**

| Scenarios | No. of Entry Nodes | No. of Exit Nodes | Total Links | No. of Vehicles for Every Entry Nodes | Total No. of Vehicles |
|---|---|---|---|---|---|
| 10 × 10 × 800 | 20 | 8 | 208 | 800 | 16,000 |
| 10 × 10 × 4000 | 20 | 8 | 208 | 4000 | 80,000 |
| 10 × 10 × 8000 | 20 | 8 | 208 | 8000 | 160,000 |
| 10 × 10 × 9600 | 20 | 8 | 208 | 9600 | 192,000 |
| 12 × 12 × 800 | 24 | 10 | 298 | 800 | 19,200 |
| 12 × 12 × 4000 | 24 | 10 | 298 | 4000 | 96,000 |
| 12 × 12 × 8000 | 24 | 10 | 298 | 8000 | 192,000 |
| 12 × 12 × 9600 | 24 | 10 | 298 | 9600 | 230,400 |
| 14 × 14 × 800 | 28 | 12 | 404 | 800 | 22,400 |
| 14 × 14 × 4000 | 28 | 12 | 404 | 4000 | 56,000 |
| 14 × 14 × 8000 | 28 | 12 | 404 | 8000 | 112,000 |
| 14 × 14 × 9600 | 28 | 12 | 404 | 9600 | 268,800 |
| 16 × 16 × 800 | 32 | 14 | 526 | 800 | 25,600 |
| 16 × 16 × 4000 | 32 | 14 | 526 | 4000 | 128,000 |
| 16 × 16 × 8000 | 32 | 14 | 526 | 8000 | 256,000 |
| 16 × 16 × 9600 | 32 | 14 | 526 | 9600 | 297,200 |

and assumptions that are unique to it and, therefore, requires input data that is not common to the others. For example, TRANSIMS uses a pedestrian model to simulate the travel time from buildings (population centers) to parking lots while OREMS and MITSIM ignore the pedestrian mode. Models also vary in their representation of traffic controls

**TABLE 3 Data from a Car Following Experiment Using the MITSIM Car Following Model**

| Time | Lead Vehicle Position | Following Vehicle Position | Following Vehicle Speed |
|---|---|---|---|
| 0 | 70 | 0.0 | 30.0 |
| 1 | 90 | 30 | 26.0 |
| 2 | 110 | 56 | 23.8 |
| 3 | 130 | 80 | 22.5 |
| 4 | 150 | 102 | 21.7 |
| 5 | 170 | 124 | 21.2 |
| 6 | 190 | 145 | 20.8 |
| 7 | 210 | 166 | 20.6 |
| 8 | 230 | 187 | 20.4 |

(such as stop signs and traffic lights). Where possible, this particular study uses whatever default values are in the models to drive their unique behaviors.

Figure 8 is the egress time among the three models and Figure 9 is the execution time among the three models. For the network with fewer amounts of vehicles, all models generate almost the same egress time. When the network became congested the egress time is increased. It is predictable that OREMS and MITSIM generate the same

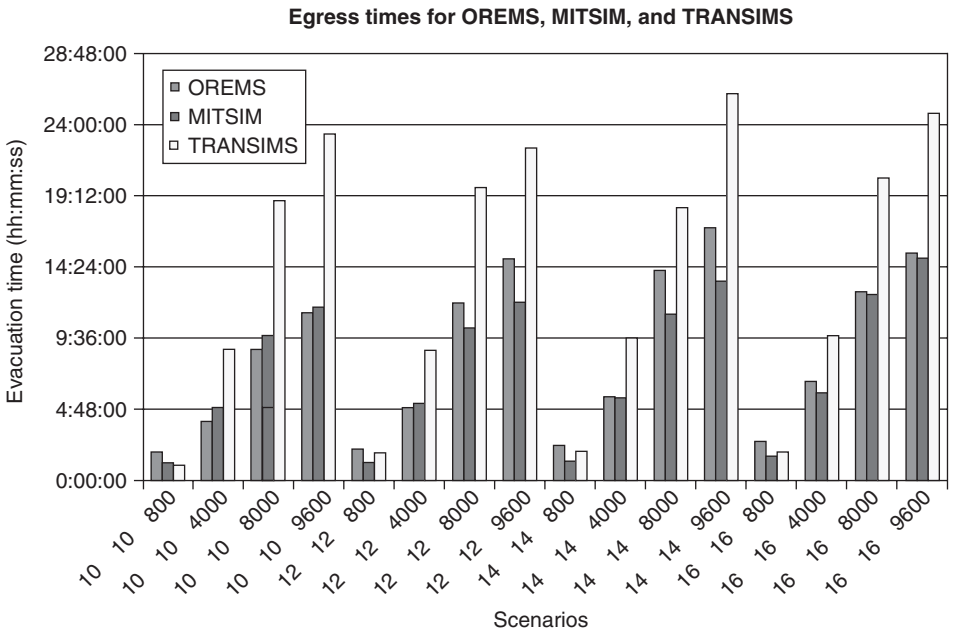

**FIGURE 8** Egress times for OREMS, MITSIM, and TRANSIMS.

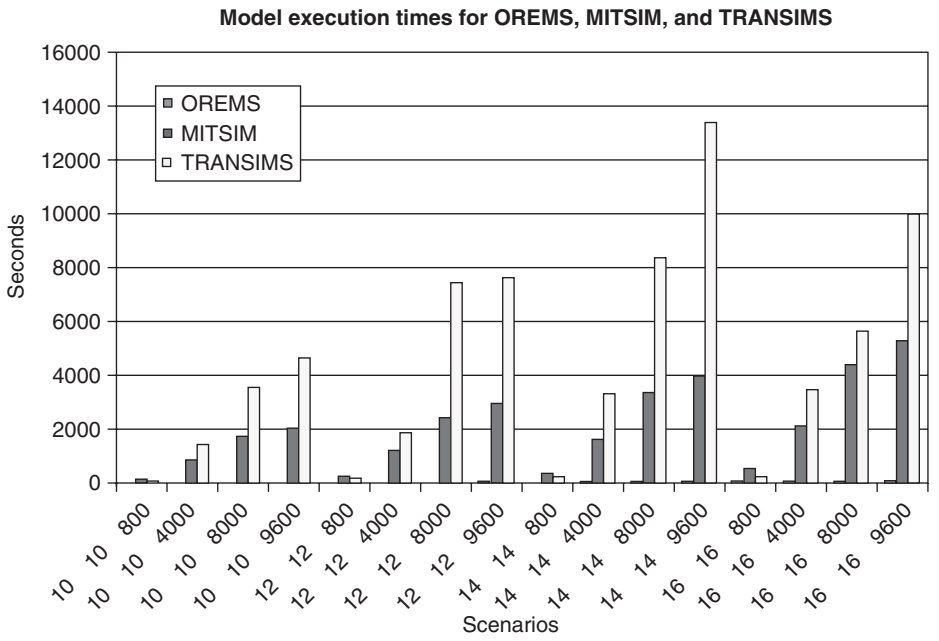

**FIGURE 9** Model execution times for OREMS, MITSIM ad TRANSIMS.

egress time because both models are based on car following, lane-switching, and human behavior models describing the between-vehicle (gap-acceptance) distance tolerance. It is worth noting that the egress time generated by TRANSIMS is different from the other two models because TRANSIMS is based on different assumptions. The reason that TRANSIMS generates longer egress time needs to be explored further. Figure 8 is the result for execution times. It is also predictable that the macroscopic model OREMS runs faster than the other two microscopic models (the range is 10–100 times faster). However in this experiment, MITSIM and TRANSIMS execution times are in the same order of magnitude, but MITSIM performs slightly better than TRANSIMS.

## 5 CHALLENGES FOR LARGE TRAFFIC SIMULATIONS

There are two major barriers to realizing our vision of high resolution multifaceted evacuation modeling. These are scalable simulations and model validation. The least onerous, but still challenging, of these are scalable simulations. The scope of the computational challenge can be estimated by extrapolating from existing simulators. For example, the Alexandria data set for TRANSIMS open source model [27] has about 240,000 vehicles that are simulated for 26 h using a time-step of 1 s. The running time of this simulation—which includes pre- and post- processing of the simulation data as well as the simulation execution itself—requires approximately 2 h. Assuming that the execution time is proportional to the number of vehicles, we can estimate that about 30 CPU hours

would be needed to simulate a Los Angeles sized area, and 140 CPU hours for an area the size of the state of Florida.

Even for a contingency plan that is constructed well in advance of the event, these execution times are too long. Modeling and simulation most effectively supports decision-making when it is used iteratively: a scenario is posed, a plan of action devised, that plan is assessed via simulation, the plan is revised in light of the assessment, and assessment and revision are done again. Assessment and revision will occur dozens of times in the course of making a decision, and sensitivity studies which are necessary to determine the robustness of a particular course of action in the face of reasonable variation, further exacerbate the computational requirement. It is not unreasonable, therefore, to expect thousands of CPU hours to be consumed by microsimulations that are used routinely and effectively for evacuation planning. To reduce thousands of CPU hours to the tens of hours that are needed to reasonably support public officials who make evacuation plans, a 100-fold speed up is needed. To support planning for near-term contingencies, such as day ahead or week ahead events, thousands of CPU hours must be reduced to single digits: a 1000-fold speed up is required.

Moreover, the decision-making process is iterative, using simulation results from earlier iterations to inform changes in a plan. The simulation tools, therefore, will be used iteratively as well with earlier simulations providing, albeit indirectly, input to later simulations. Speed up of the simulation tools themselves is therefore essential. Progress in this direction has been demonstrated with transportation models being scaled to very large parallel computers [28, 29]. But simulating the motion of vehicles is only a part of the computational problem, and the entire tool set—activity scheduling, route selection, and reporting and visualization—must be scalable to effectively support decision makers.

Model validation, however, is the most onerous, but also the most critical and least explored, aspect of transportation modeling. Lack of data about the progress of an evacuation at a suitable resolution in both time and space has been the single greatest barrier to validation, but recent advances in technology as poised to overcome this problem. Global positioning systems are becoming ubiquitous in mobile phones, personal digital assistants, and in vehicles themselves. This data, if it was available to the community of transportation modelers and could be used for validation in the context of typical, day-to-day traffic flow; fire, storm, and flood, will provide ample opportunity to acquire invaluable data on traffic flows during evacuation.

Over a period of several years, this validation activity and the consequent refinement of models will significantly reduce the discrepancies in the outcomes of different simulation tools. The relative value of microsimulations with respect to meso- and macromodels could likewise be determined; though it is widely thought that microsimulations are generally superior in their predictive power, this is still just a matter of speculation. Hard data is needed to achieve a meaningful consensus on the value of these models, and to direct the research community in the most useful directions.

## 6 FUTURE RESEARCH DIRECTIONS

High resolution, data driven simulation of urban evacuation models over large geographic areas is an emerging frontier for more efficient evacuation planning. Existing urban evacuation models are primarily at the mesoscopic scale, open source microsimulation

(traffic) models could be modified for evacuation modeling, and thus hold promise for developing large-scale simulation frameworks to support both near and long term evacuation planning. Moreover, ability to execute such simulations in real time or faster than real time opens up the new paradigm of traffic management during evacuation events. Integration of high resolution geospatial data, namely transportation network and population distribution, coupled with incorporation of finer behavioral assumptions for realistic depiction of population dynamics hold strong promise for achieving such capability [30].

Dynamic data collection and assimilation methodologies are essential to support validation efforts and for model initialization and dynamic calibration. A variety of sensor networks [31] are appearing that can actively or passively monitor traffic conditions, and this will enable accurate assessments of traffic conditions in real time. It is imperative that the exploitation of these data resources be given equal footing with the computational and visualization problems that have in the past have dominated transportation modeling and simulation.

# HARDEN SECURITY OF HIGH-RISK AND CRITICAL SUPPLY CHAINS

GLEN HARRISON

*Transportation Policy and Planning Group, Center for Transportation Analysis, Energy and Transportation Science Division, Oak Ridge National Laboratory, Knoxville, Tennessee*

## 1 INTRODUCTION

Container transportation forms the circulatory system of the world economy. Over 48 million cargo containers move between major seaports each year. More than 16 million containers arrive in the United States each year by ship, truck, and rail. Ninety percent of the world's nonbulk cargo moves through container supply chains. A supply chain is defined as a "linked set of resources and processesthat begins with the sourcing of raw materials and extends through the delivery of products or services to the end user across the modes of transport [1]". Supply chains include the infrastructure of raw materials and parts suppliers, manufacturers, containers, transport vehicles (sea vessels, rail cars, and motor carriers), intermodal facilities (ports, rail yards, and truck terminals), distribution centers, and retail centers. The financial and logistics support organizations facilitate the movement of containers through the supply chain. There is no single government regulatory system that governs the movement of container shipments through the international supply chain. In fact, there is a mosaic of international and national regulations that govern container shipments. The regulatory framework that is applicable to a specific container shipment is determined by its origin and destination, contents, and the mode of shipment [2].

In the post-September 11 era, there is a greater focus on ensuring the security of goods, people, information, and facilities involved in global supply chains. Container transport is vulnerable to terrorists through (i) interception of a legitimate shipment and tampering with the contents of the container by introducing a chemical, biological, radiological, or nuclear weapon or by contaminating the contents in some way or (ii) obtaining control of a legitimate shipping company, and placing a container with dangerous or illegitimate cargo into the supply chain. The major vulnerability points for the container are in its initial loading, rail yards, truck stops, and intermodal terminals. US Coast Guard officials estimate that the closure of a single major port for a month because of a terrorist attack could cost the US' economy $60 billion in losses [3]. The impact of such a port closing in the United States would also have a domino effect on the economy of many of its trading partners and on the flow of world trade.

Actions taken to reduce the threat of terrorism in the container supply chain include scanning, ensuring the integrity, controlling access, tracking, background checks on personnel, and risk assessment [2]. Rather than inspecting all containers and goods as they

enter a port, there is more reliance on security measures implemented throughout the product supply chain. Governments are investing in enhanced inspection technologies and staffing not only at their own borders and ports but also at overseas production, distribution, and port locations. Companies are reconfiguring their business processes, security systems, information systems, and staffing practices to increase security. Many companies also require their business and supply chain partners to implement compatible security measures. These changes result in increased costs of doing business, but at the same time can also enhance efficiencies in the supply chain and reduce losses due to theft and pilferage [4].

## 2 WORK TO IMPLEMENT A SECURE SUPPLY CHAIN

There is work at several different levels to increase security in the container supply chain, including introduction of processes and procedures, as well as technologies. The following section will discuss increased security measures that have been introduced for the containers, at port facilities, and in the container supply chain.

### 2.1 Containers

Smart containers incorporate electronic systems in the shipping container, which include an electronic seal requiring a code to open the container door, tracking to provide location information, and communications technology that transmits a signal to provide information on the location of the container and any breach of container integrity. After the container is loaded, an electronic data key is used to lock the door of the container at the point of origin. When the container is locked, the security tag sends a signal with status information to other supply chain partners and any authorized government agency requiring the information. The data transfer can occur by mobile telephone or satellite communications. The smart container can be tracked at points along the supply chain. Geo-fencing can be incorporated into the system so that if the container is moved outside of the normal supply chain flow, a signal is sent to the supply chain partners and governmental authorities. A signal is also sent if an unauthorized breach or opening of the container occurs along the supply chain. When the container arrives at the consignee's location, an electronic data key is used to open the container. This generates a signal that results in termination of the container tracking. Future smart containers will include sensors that can detect chemical, biological, radiological, or nuclear weapon devices. They will also include cameras to allow for remote viewing of the container interior [5].

The Container Security Initiative (CSI) places US Customs and Border Protection (CBP) inspectors at foreign ports of embarkation to target containers for inspection. Currently, CSI inspectors are assigned to 54 global ports. CSI requires that the manifest for a container be sent to CBP for review at least 24 h before the container is loaded on a vessel bound for the United States. The CBP's Automated Targeting System rule-based mathematical decision support tool assesses the information and assigns a risk value to each container. If the risk value is high, the container is selected for inspection. All questions must be resolved before the shipment is allowed to be loaded on a vessel bound for a US port [3].

The Secure Freight Initiative began in 2007 at six overseas ports (Port Qasim, Pakistan; Puerto Cortes, Honduras; Southampton, United Kingdom; Port Salalah, Oman; Singapore;

and Busan, South Korea). The program uses local port staff to inspect containers bound for the United States for nuclear and radiological materials. The scanned container images are sent to a CBP operations center for analysis. Containers judged suspect, require physical inspection before being allowed to be loaded on the vessel [6].

## 2.2 Port Security

Port security is an ongoing challenge. It involves ensuring that the cargo containers transiting the port are safe and secure, there is no tampering with the cargo containers while they are in the port, and that the personnel working at the port (dock workers, maritime workers, and transportation workers) are secure. A number of international and US initiatives address these security concerns.

***2.2.1 Scanning Equipment at Ports.*** Two types of scanning equipment are used at ports for container inspection. Radiation portal monitors are used to detect the presence of nuclear and radiological materials in the container. Each container is driven through the portal for a reading. Nonintrusive inspection imaging systems use x rays or y rays to penetrate containers and produce an image of the contents. The image is then reviewed to identify dense areas within the container that could be shielding radioactive material. If there is an alarm generated by either of these systems, then the container is subject to physical inspection [7]. These scanning systems will not detect chemical or biological agents.

***2.2.2 International Ship and Port Facility Security (ISPS) Code.*** The International Maritime Organization (IMO)'s International Ship and Port Facility Security (ISPS) Code provides a common international framework to assess security vulnerabilities and threats, implement security measures, respond to security incidents, and facilitate international cooperation. It was adopted in 2002 as a part of the International Convention for the Safety of Life at Sea (SOLAS). An assessment of the risks must be made to determine the security measures that are appropriate for each ship and port facility. The code provides a standard framework for evaluating risk, so that appropriate response actions can be taken to ensure that security measures correspond with the threat level for ships and port facilities [8].

The code requires that ports conduct a security assessment that includes three components. The first step is to identify and evaluate important assets and infrastructures that are critical to the port facility, as well as those areas or structures that, if damaged, could cause significant loss of life or damage to the port facility's economy or environment. Secondly, the actual threats to those critical assets and infrastructure must be identified in order to prioritize security measures. Finally, vulnerabilities of the port facility must be addressed by identifying its weaknesses in physical security, structural integrity, protection systems, procedural policies, communications systems, transportation infrastructure, utilities, and other areas that may be a likely target. Upon completion of this assessment, the risk level of the port can be determined. Security requirements for ports include the implementation of a port facility security plan based on the risk assessment, the designation of a port security officer, and the acquisition of certain security equipment. The port must change its level of security activities based on the level of risk at any time. Each ship entering the port is also required to have a security plan, designated security officer, and security equipment [9].

***2.2.3 United States Maritime Transportation Security Act of 2002.*** The Maritime Transportation Security Act of 2002 requires vessels and port facilities to conduct vulnerability assessments and develop security plans that may include passenger, vehicle, and baggage screening procedures; security patrols; establishing restricted areas; personnel identification procedures; access control measures; and/or installation of surveillance equipment. The Act also requires the establishment Area Maritime Security Committees at US ports. The purpose of the Committee is to coordinate plans and information exchange to ensure the security of the port. This includes determining the best use of resources that would be used to deter, prevent, respond to, and recover from terror threats or attacks.

***2.2.4 United States Transportation Worker Identification Credential (TWIC).*** The Transportation Worker Identification Credential (TWIC) is a tamper-resistant biometric credential for workers who require unescorted access to secure areas of ports, vessels, outer continental shelf facilities, and all credentialed merchant mariners. An estimated 750,000 workers including longshoremen, truckers, port employees, and mariners are required to obtain a TWIC. TWIC enrollment began in October 2007, and will be phased in through 2008 [10].

***2.2.5 Prenotification.*** Section 343 of the Trade Act of 2002 requires prenotification for cargo entering or leaving the United States by air, land, or sea. The prenotification includes detailed descriptions of the contents of containers. This allows CBP officers to analyze the content information of the container, and identify potential terrorist threats before the US-bound container arrives by highway or rail or is loaded onto a vessel at the foreign seaport. The specific prenotification times are shown in Table 1 [11].

"Do-Not-Load" messages, which forbid the loading, are issued to vessels that violate the 24-h rule. Vessels that disregard the "Do-Not-Load" messages (and load the cited container) are denied permission to unload the container at any US port [12].

All vessels over 300 gross tons must contact the US Coast Guard 96 h before scheduled arrival at a US port. The vessel must provide information on destination, scheduled arrival time, cargo, and crew roster to the Coast Guard. This information and associated information from intelligence agencies are reviewed to identify "high-interest" vessels and are used to determine if the vessel should be boarded, inspected, escorted, or denied entry [13].

**TABLE 1 Prenotification Times**

| Mode | Prenotification Time (h) Import | Export |
|---|---|---|
| Air | 4 h prior to arrival at the border | 2 h prior to departure |
| Rail | 2 h prior to arrival at the border | 2 h prior to arrival at the border |
| Truck | 1 h prior to arrival at the border | 1 h prior to arrival at the border |
| Vessel | 24 h prior to loading on the vessel in the foreign port | 24 h prior to departure from US port where cargo is loaded |

### 2.3 Supply Chain Security

Supply chain security programs apply to the movement of goods and information in commerce. Standards for supply chain security have been developed and implemented at the international, national, and commercial sector levels.

***2.3.1 International Standards Organization's Supply Chain Security Management Standards.*** The International Standards Organization (ISO) has developed security management standards for supply chains [1]. The ISO standards provide a means for organizations to review the security environment of their supply chain, and determine if it is adequate. If inadequacies are found, the standards recommend mechanisms and processes to enhance supply chain security. The finance, manufacturing, information management, and facilities for packing, storing, intermodal transfers, and transporting freight are considered in the security standards. The process for implementing the organization's security management system based on the Plan-Do-Check-Act methodology involves the following steps:

- The organization develops an overall security management policy based on its needs.
- A security risk assessment mechanism is implemented to determine security threats, and target security goals and implementation programs to achieve these security targets are established.
- The organization establishes the structure, provides the resources, and staffs the security management system operation. This includes awareness training, information security, physical security, emergency preparedness, and recovery planning.
- There is continuous monitoring of the security management system and the changing security threat environment. The supply chain changes as technology improves, threat conditions change, and lessons are learned. The security management system is adjusted to ensure that appropriate security measures are in place as changes occur.
- Management performs periodic reviews of the security management system to ensure that it continues to meet overall security objectives.

***2.3.2 Smart and Secure Trade (SST) Lanes Initiative.*** The smart and secure trade (SST) lanes initiative, initiated by the Strategic Council on Security Technology, is an industry-based initiative to improve supply chain security and efficiency. The initiative has four major objectives. Objective 1 is to rapidly deploy a baseline functional infrastructure to secure, track, and manage containers and leverage proven technology and the global networks of the major port operations companies, such as Hutchinson Port Holdings, PSA, P&O Ports, SSA Marine, and China Merchants Holdings Company Limited. Objective 2 is to collaborate with international shippers and their supply chain partners to implement end-to-end container security. Objective 3 is to synchronize and ensure compatibility with existing government freight security initiatives, such as the CSI, Customs Trade Partnership against Terrorism (C-TPAT), Operation Safe Commerce, and ISPS Code. Objective 4 is to demonstrate operational efficiencies through real-time in-transit visibility for supply chain partners [14].

The ports of Singapore, Hong Kong, Kaohsiung (Taiwan), Bangkok, Walvis Bay (Namibia), Cape Town, Tacoma, Seattle, Los Angles, Long Beach, New York/New Jersey, Rotterdam, Antwerp, and Felixstowe (United Kingdom) are currently integrated into the SST system. The Strategic Council on Security Technology's goal is to expand to additional ports, inland distribution centers, and intermodal terminals in the future.

***2.3.3 World Customs Organization (WCO) Framework of Standards to Secure and Facilitate Global Trade (SAFE Framework).*** The World Customs Organization's SAFE Framework of Standards to Secure and Facilitate Global Trade facilitates the implementation of standard and best practices between the customs services of different countries. The goal is to move toward one set of inspection standards that would not duplicate or overlap others [15].

***2.3.4 Secure Trade in the Asia-Pacific Economic Cooperation (APEC) Region (STAR).*** Asia-Pacific Economic Cooperation (APEC) is an organization of Pacific Rim nations working together to promote trade and investment liberalization, business facilitation, and economic and technical cooperation. In 2002, APEC formed the Secure Trade in the Asia-Pacific Economic Cooperation Region (STAR) initiative to accelerate action on screening people and cargo for security before transit; increasing security on ships and airplanes while en route; and enhancing security in airports and seaports. The STAR plan of action for cargo security included (i) identifying and examining high-risk containers, assuring in-transit integrity, and providing advance electronic information on containers to customs, port, and shipping officials as early as possible in the supply chain; (ii) implementing common standards for electronic customs reporting; and (iii) promoting private-sector adoption of high standards of supply chain security. The plan of action for vessel operations involved (i) promoting ship and port security plans and installation of automatic identification systems on certain ships and (ii) cooperating to fight piracy in the region [16]. APEC Private Sector Supply Chain Security Guidelines were also developed to recommend actions on physical security, access control, personnel security, education and training awareness, procedural security, documentation processing security, trading partner security, conveyance security, and crisis management and disaster recovery [17].

***2.3.5 United States Customs Trade Partnership against Terrorism (C-TPAT).*** The C-TPAT is a joint US CBP and business voluntary initiative to enhance security procedures along supply chains. The program provides a trade-off between enhanced security measures along the supply chain for expedited cargo processing at the US border. This program enables CBP to reduce screening efforts for C-TPAT partners who have adequate supply chain security procedures and controls in place for their imported cargo. This enables CBP to focus its screening efforts on unknown or high-risk import cargo transactions [18].

The initiative is based on five overall goals. Goal 1 is to ensure that C-TPAT partners improve the security of their supply chains on the basis of C-TPAT security criteria. When a company joins the C-TPAT partnership, it works with CBP to implement a review of its supply chain, identify security gaps, and implement security measures and best practices to enhance the security of the total supply chain. The areas covered in the review include personnel security; physical security; procedural security; access controls; education, training, and awareness; manifest procedures; conveyance security; threat awareness;

document processing; business partners and relationships; vendors; and suppliers. Upon certification of a company's supply chain, CBP and the company validate the supply chain processes to ensure that the implemented security procedures are effective, efficient, and accurate, which helps ensure that best security practices are in place. The security review and validation process are iterative, recurring on an ongoing basis.

Goal 2 is to provide incentives and benefits to include expedited processing of C-TPAT shipments to C-TPAT partners. This activity involves seminars for sharing information on best practices for securing supply chains. C-TPAT partners receive expedited border crossing procedures that reduce processing time for goods entering the United States. Corollary benefits from the C-TPAT program have been more efficient supply chain operations and reduced inventory loss due to theft and diversion of cargo.

Goal 3 is to internationalize the core principles of C-TPAT through cooperation and coordination with the international community. C-TPAT membership has a multiplier effect. C-TPAT companies require supply chain partners, including foreign manufacturers, shippers, and distribution operations to comply with C-TPAT security measures, which results in the impact of C-TPAT going far beyond the C-TPAT partners to other members of their supply chain operations.

Goal 4 is to support other CBP security and facilitation initiatives. These include the Free and Secure Trade (FAST) program between the United States, Mexico, and Canada, Operation Safe Commerce, the Advanced Container Security Device program, the CSI, and the Industry Partnership Program.

Goal 5 is to improve administration of the C-TPAT program. This involves increases in CBP Supply Chain Specialists, expanded training of staff, and enhanced data collection and information management capabilities.

***2.3.6 United States Operation Safe Commerce.*** Operation Safe Commerce is a federal grant program under the Department of Homeland Security (DHS) that established partnerships with the three largest US container ports (Seattle-Tacoma, Port Authority of New York and New Jersey, and the Ports of Los Angeles and Long Beach) to develop, test, and share best practices to improve the security of container supply chain movements. Specific objectives of the program are (i) validating security at the point of origin, (ii) securing the supply chain from the point of origin to final destination, (iii) enhancing accuracy and communication of cargo information used by Federal agencies, carriers, and shippers, and (iv) monitoring movement and integrity of cargo in transit. Eighteen separate supply chains moving containers through one or more of these ports were evaluated [19].

## 3 MAJOR CONCERNS

Cargo containers may be used to smuggle chemical, biological, radiological, or nuclear weapons into a country. Assuring container supply chain security is a major priority of governments and private sector trade partners around the world.

Efforts to strengthen supply chain security face a number of institutional challenges that include (i) developing a comprehensive risk management approach, (ii) ensuring that funding needs are identified and prioritized and that costs are controlled, (iii) establishing effective coordination among the many responsible public and private entities, (iv) ensuring adequate workforce competence and staffing levels, and (v) implementing security standards for transportation facilities, workers, and security equipment [13].

For the United States and internationally, funding is a major issue in implementing security measures. Individual ports in the United States require funding for security upgrades for basic security measures, as well as the implementation of changes required by legislation or technology enhancements. Funds are also required for ongoing security activities, exercises, and training of staff. Funding is required by the different government regulatory agencies that are involved with port and supply chain security. Funding for agencies in DHS includes the Coast Guard, which is responsible for port security, CBP, which is responsible for the inspection of cargo and passengers entering the United States, and the Transportation Security Agency, which is responsible for cargo and passenger security within the United States. As the security threat has increased, additional legislation has been passed that has expanded the responsibilities for each of these agencies. The Coast Guard and CBP have roles to play at ports in the United States, as well as overseas. Budget allocations for security upgrades in US ports and for the additional DHS staff to enforce these security requirements have not always kept up with the increased requirements mandated by legislation or the potential of increased threats from terrorists. The question that has also not been resolved is the funding of increased security requirements in overseas ports. If an overseas port does not have adequate security infrastructure and staff in place based on international standards, who pays for it?

There are a multitude of national government, international government, international business, and corporate initiatives to increase supply chain security. There is no one overall coordinating agency to eliminate the overlaps or conflicts between these different entities. Some of the programs initiated by the US government involve actions in foreign countries. This includes the installation of imaging systems and inspection of containers at foreign ports by Customs and Border Protection (CBP) staff, inspection of port security measures by the US Coast Guard, and the inspection of the security of international supply chains that can include the manufacturer, transportation, distribution, and ports in a foreign nation. All of these issues involve the negotiation of agreements with these nations to allow US government officials to be involved in these security activities in their country.

There is a major need for the ability of government security agencies to share proprietary business sensitive information on cargo container movements in a secure manner. This would include the manifest, shipping papers, detailed description of the cargo, seller and purchaser, origin and destination of the goods, origin of the container loading operation, transport companies, and freight forwarders [20]. Currently, there is no system to do this. A worst case scenario for international cargo inspections would be that a multitude of countries will want to station inspectors at foreign ports that ship goods to their country. In this case, each port would need to provide information on the shipments and meet the security requirements of these different national security interests. Currently, the United States shares the data on its foreign port security operations only with the host country. Yet, a container ship will make stops in a number of countries as it moves cargo around the world. A better way to share this data with other nations needs to be developed.

Container shipments that are bound for a specific port in the United States are thoroughly reviewed by CBP. But, in-bond container shipments transit an arrival US port to another domestic port location without officially entering US commerce. The purpose of in-bond cargo is to facilitate trade that moves between ports in the United States. For instance, an in-bond container shipment from Asia to Europe could be off-loaded from a ship on the west coast of the United States, be transferred to a railcar, and taken to

an east coast port for transfer to a ship bound for Europe. This in-bond cargo is not as thoroughly screened as normal containers shipments bound for a single port in the United States. Also, CBP does not track the arrival of the in-bond cargo at the second destination US port. Diversion of this cargo could lead to reduced duty collection on imports and increased security vulnerabilities. More attention needs to be given to inspection and tracking of in-bond cargo [21].

Legislation introduced in Congress in 2007 to require 100% screening for all containers entering the United States failed in the Senate [22]. The requirement for 100% screening of containers would change the current process that uses intelligence and information on the cargo shipment analyzed with the use of a rule-based algorithm to determine the need for inspection of individual containers. This process reduces the need for equipment and staffing for inspections of containers, and facilitates the flow of containers through ports. The requirement for 100% screening of containers would require a substantial increase in funding for equipment and staff, training of this staff in the operation of the equipment, and the agreement of overseas governments to allow for the installation of inspection equipment and expanded inspection activities at their port facilities. There is also the need to transmit the data on the screened cargo for review and analysis to an operations center that may be at a location thousands of miles from the actual port. This would result in greater delays in the movement of containers through port facilities [23].

Improved technologies are required to enhance the security of the container supply chain. The Directorate for Science and Technology (S&T Directorate) is the primary research and development arm of DHS. The Domestic Nuclear Detection Office is responsible for implementing research, development, testing, evaluation, and implementation of radiation detection equipment that can be used to monitor containers. Issues that require additional technology development include imaging systems with enhanced patter recognition capabilities; sensors that detect explosives and biological or chemical hazards in containers; and radiation detection systems with improved signature detection systems to identify specific hazards. The development of Advanced Spectroscopic Portals enables users to both detect and identify the type of radioactive material in a container. These portals are now being deployed at ports around the United States [23].

## 4 SUMMARY AND CONCLUSIONS

Significant improvements have been made in the security of containers, ports, and supply chains since the 11 September 2001 attack. Still, there is more to be done. The 2006 “Global Survey of Supply Chain Progress” performed by the Computer Sciences Corporation and Supply Chain Management Review surveyed 134 supply chain organizations. On the question of supply chain disruptions, only 40% of the respondents said they had contingency plans for significant disruptions [24].

There is also a need for greater coordination and consistency among the security programs initiated by the private sector, government, international governments and international organizations. Each of these sectors is initiating programs that improve security, but in many cases there is overlap and inconsistency. One of the greatest needs is the ability to share business sensitive information between international government security agencies. Security initiatives that are initiated need to be funded at an adequate level for the equipment, staffing, training, maintenance, and regulatory supervision. Funding is a crucial issue as technical advances result in better container tracking, container security

systems, screening equipment, communications systems, and risk assessment systems that will need to be deployed at ports around the world.

# TRANSPORTATION SECURITY PERFORMANCE MEASURES

RUSSELL LEE
*Oak Ridge National Laboratory, Oak Ridge, Tennessee*

## 1 INTRODUCTION

Transportation security organizations—both public and private—face difficult challenges in deciding which security systems to deploy. Advances in science and engineering continue to offer a wide range of new technologies and systems that might reduce the risks of natural and terrorist threats. Although it is impossible to precisely predict the effectiveness of these systems, it is important to assess how well they are likely to perform prior to commercializing or deploying them. In this regard, it is useful to define a concise set of measures that can be systematically and uniformly used to assess the value of alternative technologies and systems under different scenarios. This article defines a

framework for defining these performance measures, suggests specific metrics within this framework, and provides illustrations from previous studies. These metrics are primarily intended for use in science, technology, and R&D organizations in homeland security agencies and offices, such as the US Department of Homeland Security, to assess the value of candidate technologies and systems prior to their commercialization or deployment (i.e. the purchase, installation, and operation of a system).

## 2 PERFORMANCE MEASURE CONCEPTS

"Measures" in this article refer to ways of gauging how well a system will perform. A broadly defined measure could have one or more specific measures under that general category. For example, a general measure is the "benefits" of a system; and under benefits, a specific measure is "reduced harm to human health." *Metrics* refer to one or more quantitative indicators for a given measure. For example, the "estimated reduction in lives lost due to a terrorist attack" is a metric for "reduced harm to human health."

In this article, the term, *performance measures*, differs from another common application that defines criteria to *retrospectively* evaluate the *management* or *programs* of an organization [1, 2]. Whereas, this article uses performance measures to *prospectively* assess the *value* of transportation security *technologies and systems*.

Another important distinction is that these measures focus on the expected value of these systems *in practice*, rather than solely on their technical specifications or performance under controlled *laboratory* conditions, as commonly stipulated in American National Standards Institute and other similar standards (e.g. [3, 4]). The latter are an important consideration, but the performance of the systems and their benefits and impacts, in the *field* are ultimately more important in gauging their value.

## 3 FRAMEWORK TO DEFINE PERFORMANCE MEASURES FOR TRANSPORTATION SECURITY SYSTEMS

This section defines a framework for defining performance measures to assess the value of transportation security technologies, systems, and operations (other related work includes [5, 6]). The framework is applicable to assessments of systems that are to monitor for, prevent, respond to, mitigate, or recover from natural disasters, terrorist attacks, or other threats to transportation systems and to the activities and economies that depend on them.

### 3.1 Elements in a Risk-Based Approach

We use the following terms to describe the basic elements in a risk-based approach for considering transportation security:

1. *Threats.* The nature and quantity or magnitude of an event, material, or substance that does harm (e.g. explosives, biological, or chemical weapons of mass destruction, illicit radiological material).
2. *Transportation systems.* Transportation networks, nodes, corridors or other infrastructure; the flow of vehicles, trains, ships, ferries, containers, goods, or people who use that infrastructure. There are parts of a transportation system that can be used

to deliver a threatening agent (e.g. airplanes used as weapons), or they can be the target of a threat (e.g. a bridge with high traffic volume).

3. *Targets.* The infrastructure, population, or other entities that are at risk from a threat (e.g. a critical bridge, transit facility, or airport terminal).
4. *Vulnerability.* Aspects of targets that are at risk of damage from threats, the probabilities of damage, and factors affecting these probabilities.
5. *Damages.* The adverse effects of an attack on, or catastrophic disruption to, a target (e.g. physical damage, economic costs).
6. *Transportation security systems.* Technologies, operations, and systems whose function is to detect, identify, reduce, or respond to a threat (e.g. video surveillance systems, automated biological, and chemical threat detection systems).

These elements help frame the problem at hand, the associated risks and the transportation security systems that might be deployed to address these risks.

### 3.2 Performance Measures Framework

The performance measures framework provides a consistent and systematic means of assessing transportation security systems for different scenarios, threats, and targets. There are four major categories of performance measures: (i) system performance, (ii) benefits, (iii) resources, and (iv) impacts. Each is discussed in turn.

1. *System performance* refers to the technical and operational performance of the transportation security system under actual field conditions. It is worth emphasizing that the measures of system performance address both technical *and* operational considerations.
   - *Technical* performance measures gauge the technical capabilities of the system in terms of the number of vehicles, or items it can process, the system's effectiveness, and its reliability (e.g. throughput of baggage scanning systems).
   - *Operational* performance measures gauge whether the system, including the operational and response protocols, is easy to deploy and operate and provides information that helps personnel to perform their tasks (e.g. ease of operating a scanner).
2. *Benefits* refer to the ultimate reasons for deploying such systems—ensuring the safe movement of people and goods on our nation's transportation systems, and the safety of other affected parties, by efficiently detecting and responding to threats. Usually, the reasons for deploying a transportation security system are to reduce the risk of loss of life or injury, or the economic costs of damages, or disruptions to the operation of a transportation system. Thus, "benefits" are the *ultimate*, underlying reasons for deploying these systems. In many situations, however, it is difficult to estimate these outcomes. Thus, in practice, system performance metrics such as the percentage of false negatives, can be used as surrogates for some of the benefits of a system.
3. *Resources* are the technologies, supplies, equipment, space, personnel, and other resources needed to deploy, maintain, and operate these systems, including the cost of training personnel. Initial, capital costs of purchasing equipment, one-time

setup and training costs, and periodic maintenance and operating costs are resource requirements that should be taken into account as well.

4. *Impacts* are effects associated with the operation of the system, such as possible delays to freight and other traffic, safety or discomfort issues, and the economic cost of delays. Another impact could be interference with activities normally carried out at the site, for example, interfering with truck weigh-station staff and their routine responsibilities.

Collectively, these measures comprise a comprehensive set of considerations for assessing systems and ultimately for helping decide which to deploy.

## 4 DEFINITIONS AND ESTIMATION OF PERFORMANCE METRICS

This section suggests specific metrics for each of the measures and describes how to estimate the values of these metrics in practice.

### 4.1 Metrics for System Performance

The first set of performance measures summarizes key technical and operational aspects of the system. These measures are subdivided as follows:

Technical performance
- throughput
- effectiveness
- reliability

Operational performance
- ease of operations
- usefulness of the information from the transportation security system for operators

Other technical or operational performance measures could be used, but the ones listed above are a basic set to consider. We discuss each in turn.

***4.1.1 Throughput Metrics.*** *Throughput* refers to the number of items, such as vehicles, rail cars, or passengers who can be processed through the security system per unit time. For example, a metric for throughput would be the number of vehicles per minute that can be scanned for explosives before driving onto a ferry. Assessments of system throughput can be compared to throughput without any security system in place.

***4.1.2 Effectiveness Metrics.*** The effectiveness of a system is a key measure of its value. For systems that provide domain awareness and prevention, their effectiveness can be characterized by their ability to accurately predict the presence of threatening material or activity. For technologies that detect the presence of radiological, chemical, or biological threats, the standard metrics to use are the "false negative" and "false positive" rates. For medical diagnostic technologies, "sensitivity" and "specificity" are commonly used

**TABLE 1 Sensitivity, Specificity, False Positive Rate, False Negative Rate, Positive Predictive Value and Negative Predictive Value are Common Metrics for the Effectiveness of a Transportation Security System**

| | Predicted | |
|---|---|---|
| Actual | Positive | Negative |
| Positive | a = True Positive | d = False Negative |
| Negative | c = False Positive | b = True Negative |

[a]Definitions of metrics of system effectiveness:
[b]Sensitivity = a / (a + d)
[c]Specificity = b / (b + c)
[d]False Negative Rate = d / (d + b)
[e]False Positive Rate = c / (c + a)
[f]Positive Predictive Value = a / (a + c)
[g]Negative Predictive Value = b / (b + d)

metrics to gauge their ability to identify the presence of a threatening health condition. Table 1 and the notes accompanying the table define these terms. Illustration 1 is an example of the use of these metrics for a system that detects the transportation of illicit radiological material.

In other situations, the effectiveness of a system can be assessed by its ability to reduce a certain threat or damaging condition. Illustration 2 discusses this situation in the context of screening airline passengers for pandemic influenza. Other systems might be geared more toward protection (e.g. enhanced shielding), response or recovery. Similar principles for defining system performance measures apply to these types of systems as well.

In assessing the effectiveness of systems, it is also important to study the reasons for their technical and operational performance. For example, certain environmental conditions might affect the operation of an instrument or limit its ability to detect or identify certain types of material (e.g. specific radionuclides, or specific types of explosives). Such assessments help identify vulnerabilities and the need to develop ways of addressing them.

***4.1.3 Reliability.*** The concept of reliability refers to a system's long-term ability to perform with little variability in effectiveness, in the face of disturbances that could affect performance. Thus, a reliable system is one whose performance is predictable. Suitable metrics for reliability include:

- frequency or rate of system outages or malfunction, per day
- variability of technical performance, from day to day, or under different conditions.

***4.1.4 Ease of Operations.*** In practice, the ease of operating a system is important to its performance. A system could be technically superior but if it is difficult to operate then its overall performance in the field suffers. Metrics to gauge the ease of operations can be based on either the operators' direct assessments or on the frequency of operator errors observed in a field operational test.

***4.1.5 Usefulness to Operators.*** Some systems provide useful data, information, or other insight to help system operators to carry out their responsibilities better. A metric for this measure would likely depend on input from the operators in a field operational test.

**TABLE 2 Metrics to Gauge System Performance**

| Type of System Performance | Metrics | Estimation Methods |
|---|---|---|
| Throughput | Quantity or number of units processed per unit time (e.g. number of vehicles screened per minute) | Observations from a field operational test.<br>Simulation model of the process |
| Effectiveness | Sensitivity.<br>Specificity.<br>False negative rate.<br>False positive rate.<br>Positive predictive value.<br>Negative predictive value | Compilation of data from a field operational test.<br>Subject matter experts' estimates.<br>Vendors' specifications provide preliminary estimates, under laboratory conditions |
| Reliability | Rate of system malfunction per unit time (e.g. number per week) | Data from a field operational test.<br>Subject matter experts' estimates.<br>Vendors' specifications or estimates provide an initial estimate |
| Ease of operation | Assessment of ease of operation on, say, a five-point scale.<br>Operator error (e.g. number per week) | Survey of system operators in a field operational test.<br>Data from a field operational test |
| Usefulness to operators | Assessment of usefulness, to system personnel, of the information or other outputs from the system on, say, a five-point scale | Survey of operators who participate in a field operational test |

Table 2 summarizes different metrics for system performance and methods to estimate them.

### 4.2 Metrics for the *Benefits* of Transportation Security Systems

By the "benefit" of a transportation security system, we refer to desirable outcomes. The concept, "outcome," implies some ultimate, end result that relates to human health, economic or social well-being, or the state of the environment. It is important to distinguish between these *ultimate* outcomes and capabilities. Outcomes are the fundamental reason for having a system, for example, to save lives. Whereas, capabilities are an enabling attribute such as a system's ability to, for example, detect a threat.

The benefits of interest vary depending on the threats and the possible damages. In practice, it might not be possible to estimate the benefits, *per se*, and in these instances, we use metrics that are surrogates for more direct measures of benefits. For instance, in Illustration 1, it is difficult to estimate the human health repercussions if the transport of illicit radiological material is not interceded. In this example, the false negative rate, which is a metric of technical performance, is also used as one of the metrics for the benefits of the system. Table 3 lists important types of benefits, specific metrics for these benefits, and ways of estimating them.

**TABLE 3 Metrics for the Benefits of a System**

| Type of Benefits | Metrics | Estimation Methods |
|---|---|---|
| Health and safety | Expected reduction in loss of life and injury or illness | Field operational tests (e.g. "Red-Team" exercises with role playing to gauge operator performance and the likelihood of system failure).<br>Simulation modeling (e.g. using plume models and geographic information systems to simulate the spread of a chemical and exposure to population).<br>Subject matter experts' assessments of reduced vulnerability and effectiveness of a system |
| Economic | Expected reduction in direct financial loss.<br>Expected reduction in economic damage due to indirect impacts (e.g. industries that depend on businesses that are directly impacted by an attack) | Econometric model.<br>Financial analysis.<br>Subject matter experts' estimates based on estimates of technical performance (e.g. estimate of economic impact from a terrorist attack at a certain location) |
| Social | Expected reduction in damage to social well being in the region or country | Previous studies of similar situations.<br>Subject matter experts' assessments |
| Value to stakeholders | Assistance or support to stakeholders to help them carry out their responsibilities more efficiently or more effectively, as measured on a five-point scale, say | Survey of stakeholders involved in a field operational test of the system |

### 4.3 Metrics for the *Resources* Needed for a Deployment

Resources include technologies, supplies, equipment, space, personnel, and items needed to deploy, maintain, and operate a transportation security system. Table 4 lists key resources needed in most deployments, and ways of defining and estimating the amount of resources.

### 4.4 Metrics for the *Impacts* of Transportation Security Systems

Deployment of transportation security systems often result in impacts on the people or vehicles monitored, or on activities in the area. Such impacts are an indirect consequence of deploying a system. Table 5 lists potentially important impacts, specific metrics for these impacts and ways of estimating them.

## 5 ILLUSTRATIONS OF THE USE OF PERFORMANCE MEASURES

This section gives two illustrations of the application of the performance measures framework and the definition of specific metrics. Each illustration describes the threat,

**TABLE 4 Metrics for Resource Needs**

| Type of Resources | Metrics | Estimation Methods |
|---|---|---|
| Personnel: type, number and cost | Number of personnel, by type | Estimates from simulation model.<br>Subject matter experts to estimate number of personnel needed.<br>Labor cost estimates (including fringe benefits, overhead) |
| Supplies: type, amount and cost | Quantity of supplies, by type | Simulation model to estimate amount of activity and supplies.<br>Subject matter experts' estimates of amount of supplies needed per unit of deployment activity |
| Capital costs: type and amount of equipment; cost of equipment, installation and supplies | Quantity, size or amount.<br>Cost (dollars) | Calculations of quantities required.<br>Subject matter experts' and planners' estimates of types and amount of equipment and supplies.<br>Survey vendors' quotes, or literature or information on cost estimates |
| Annual operations and maintenance costs | Cost | Engineering cost estimates |

**TABLE 5 Metrics for the Impacts of a System**

| Type of Impacts | Metrics | Estimation Methods |
|---|---|---|
| Delays | Average delay time per unit, e.g. seconds of additional transit time per passenger | Estimate from a field operational test.<br>Estimate from a simulation model |
| Economic effects | Cost of delays to commerce, e.g. in dollars per week.<br>Value of time delays to individuals, e.g. in dollars per week | Calculated based on estimated time delay and on the dollar value of a unit of time delay.<br>Survey information from affected party |
| Safety | Assessment of risk to operators or those being monitored, assessed on a five-point scale, say.<br>Predicted accident rate | Survey of people impacted.<br>Subject matter experts' assessment |
| Social or psychological | Assessment of social or psychological impact on those monitored, on operators, or the public in general, assessed on a five-point scale, say | Survey of people impacted.<br>Estimate of some indicator based on the scientific literature |
| Changes in operations | Assessment of either adverse or desirable change in operations or other processes, assessed on a five-point scale, say | Survey of people in organizations impacted |

transportation system, targets, vulnerability, possible damages, and the transportation security system under consideration. Specific metrics are defined, based on the general framework. Since the illustrations are from studies whose results are For Official Use Only (FOUO), we do not list the actual values for the performance metrics. Any numbers presented in this article these illustrations are for illustrative purposes only.

### 5.1 Illustration 1: Assessing Performance of a Transportable Radiation Monitoring System

The first illustration of the use of the performance measures framework is an operational test of a transportable radiation monitoring system (TRMS) [7–9]. The technologies in this system detect and identify $\gamma$ and neutron radiation. They monitor the possible, illicit transport of radiological material in vehicles along highways, or in containers at rail and port facilities. The transportable system is similar to stationary portal monitors found at land border crossings, which detect radiological material in vehicles crossing the border into the country. A distinguishing feature of the transportable systems is that they can be deployed virtually anywhere along a transportation network or at special events that might be targets of terrorists, such as high-profile political, sports or entertainment events.

In this illustration, the risk-related aspects for considering the transportation security system are as follows:

*Threat.* Illicit transportation of radiological material.

*Transportation system.* Interstate or other major highways, or rail or port facilities.

*Target.* Any people exposed to the illicit radiological material.

*Vulnerability.* Radiological material sources are easily concealed; releases will affect population exposed; likelihood is low but general impact could be significant.

*Damages.* Human health effects of exposure to radiation and, more generally, the panic and fear inflicted on the country.

*Transportation security system being assessed.* Deployment of TRMS that detects and identifies materials emitting $\gamma$ or neutron radiation from packages in vehicles or containers.

Field operational tests on actual roads (not test facilities) were used to compile data to calculate the metrics. The first test monitored vehicles on roads entering and exiting a US Department of Energy facility [8]. The facility's security personnel controlled vehicle entry and exit from the facility; other conditions of the test replicated field conditions. The second test involved local and state responders, Red Teams, and reachback to the Joint Analysis Center in the Domestic Nuclear Detection Office of the US Department of Homeland Security. The system was deployed at a rest area on an interstate highway [9]. Key metrics were defined and estimated as follows. The first set was the system performance metrics.

#### *5.1.1 System Performance Metrics*

*5.1.1.1 Metric—Throughput.* The counts of the number of vehicles monitored each hour were recorded each day in the field operational tests. This estimate provides a lower-bound estimate of the throughput because field experience showed that the system

is capable of monitoring at least this number of vehicles. An upper-bound estimate was calculated based in the maximum speed that vehicles can drive past the monitoring system without affecting its operation.

*5.1.1.2 Metric—Effectiveness of Detection System.* The effectiveness of the system was gauged by its ability to correctly detect $\gamma$ and neutron radiation from packages in vehicles. In Table 6, the predicted attribute is whether "Radioactive Material (is) Detected" by the system. The actual attribute is whether the "Vehicle (is) Carrying Radioactive Material." The ability of the system to detect vehicles carrying radiological material was assessed using data from shipping manifests and other documentation, which were used to verify the contents of each vehicle. The top number in each cell in Table 6 is the number of vehicles in the category:

- carrying radioactive material that was detected (true positives—cell "a"),
- without radioactive material and which were appropriately released with minimal delay (true negatives—cell "b"),
- carrying radioactive material that the system did not detect (false negatives—cell "c"), and
- without radioactive material, but which were detained because the vehicle triggered an alarm in the system, indicating presence of radioactive emissions (false positives—cell "d").

These metrics were compared to percentages established in technical standards for accuracy under controlled laboratory conditions [3, 4]. Incidentally, these standards were used as a frame of reference, not as a formal basis for evaluating these systems because the test conditions differed from the controlled conditions used in setting the standards.

Several other metrics were used in the study, such as the number and types of radionuclides the system was able to correctly identify, and which radionuclides it was unable to identify [8, 9].

**TABLE 6 Data to Calculate the Effectiveness of a Detection System**

Number of Vehicles and *Percentage of Total Vehicles*
(Percentages in parentheses are the standard for accuracy under controlled laboratory conditions, per ANSI N42.43-2005 and ANSI N42.35-2004)

| | Vehicle Carrying Gamma or Neutron Emitting Radioactive Material? | |
|---|---|---|
| Radioactive Material Detected? | Yes | No |
| Yes | 381<br>*a*%<br>(98.3%) | x<br>*d*%<br>(0.1%) |
| No | y<br>*c*%<br>(1.67%) | 42,058<br>*b*%<br>(99.9%) |

*5.1.1.3 Metric—Reliability of Detection System.* The reliability of the system was assessed on the basis of the number of hours the system was not in operation due to equipment failure or other cause, during the field operational tests. Table 7 is taken from the study (the actual results of the study are not listed because they are FOUO).

*5.1.1.4 Metric—Ease of Operating the Detection System.* The operators who manned the system during field operational tests were asked about the ease of operating the system. Nine questions were asked, with the responses given on a five-point scale. An example of one of the questions is: "The inspection procedures were easy to carry out." Individual operators' responses were either strongly agree = 5, agree = 4, somewhat agree = 3, disagree = 2 or strongly disagree = 1. Responses were averaged to produce overall scores.

*5.1.1.5 Metric—Usefulness of Detection System to Operators.* In the field operational tests, operators were asked seven questions about the usefulness of the system; responses were on a five-point scale. An example of one of the questions is: "Information/data from the system at the primary inspection location helped me decide what action(s) to take with each vehicle at the secondary inspection location."

***5.1.2 Metrics for the Benefits of the Detection System.*** The performance measures for the benefits of the system were detector accuracy and the value of the system to stakeholders.

*5.1.2.1 Metric—Detector Accuracy.* It is extremely difficult to estimate the ultimate benefits of the system, in terms of its expected ability to reduce morbidity or mortality from exposure to radionuclides. Thus, the technical performance metrics used for "effectiveness" were used as surrogates for the benefits of the system. In this example,

**TABLE 7 Reliability of Transportable Radiation Monitoring System as Measured by Frequency and Duration of System Downtime**

| | Sites | | | |
|---|---|---|---|---|
| | In-bound East | In-bound West | Out- bound | All |
| Number of days system deployed | | | | |
| Number of times out of service | | | | |
| Total amount of time out of service (hours) | | | | |
| Total hours that system should have been in service during the deployment period | | | | |
| Average number of shutdowns/hour | | | | |
| Cumulative hours system shut down/total hours | | | | |
| Average time spent out of service (minutes) | | | | |

the purpose of the system is to detect vehicles carrying radiological material with an acceptable degree of accuracy, and without nuisance alarms. Among the metrics used, then, were the system's false negative and false positive rates. These rates depend on the operators' interpretations of the data, which the system provides, and the operators' responses to alarms.

*5.1.2.2 Metric—Value to Stakeholders.* The value to stakeholders is an "enabling" benefit. By assisting stakeholders, the system enables them to reduce risk or damage. This metric was gauged by asking stakeholders questions about the use and usefulness of information the system provides. For example, one of the questions is: "*Specific* information/data from the TRMS, or from a TRMS operator, would greatly aid my organization in our response to the incident." Respondents answered these questions on a five-point scale.

***5.1.3 Metrics for Resource Needs and Costs of the Detection System.*** The primary resources needed, in this example, are the system itself and trained personnel to operate it. The cost estimate for the system was based on the actual cost of purchasing it from the vendor, who assembled the system using commercial off-the-shelf components, based on a set of technical specifications [7]. The total number of personnel was estimated based on the number needed to operate the system at any one time, the number of shifts per day, and the number of backup personnel needed. The estimates were verified in the field operational tests.

***5.1.4 Metrics for Impacts of the Detection System.*** The impacts of the detection system were assessed on the basis of:

- the length of inspection delays (which were recorded, in minutes);
- observations of the operation in the field in terms of the extent to which normal traffic and activities were disrupted; the operators' impressions were supplemented by their evaluations on a five-point scale; and
- operators' responses to questions about whether operating the system led to safety concerns, either to operators or others in the area.

## 5.2 Illustration 2: Assessing Performance of Airport Entry Screening of Passengers during a Pandemic

The second illustration of the definition and use of performance measures is a study of the usefulness and impacts of airport passenger screening during a global influenza pandemic [10, 11]. Once the World Health Organization recognizes human-to-human transmission of a problematic subtype of influenza, the organization elevates the situation to a Phase 4 pandemic condition. At this point, many countries plan to screen passengers and crew on inbound international flights.

In this second illustration, the risk-related aspects of the transportation security system are as follows:

*Threat.* Human-to-human transmission of pandemic influenza virus.

*Transportation system.* International air travel.

*Target.* Any people potentially exposed to the virus.

*Vulnerability.* New strain of virus could cause high incidence of infection; daily human activities and contacts mean that spread is likely once the pandemic is "seeded."

*Damages.* Illnesses and deaths, and associated economic losses.

*Transportation security system being assessed.* Deployment of multilayered screening protocol to screen international passengers entering the country at airports to identify those infected with the pandemic influenza virus.

Performance metrics calculated in this study were based largely on results from simulation models of the passenger screening process and the spread of the epidemic in the country. The performance metrics were defined as follows.

### *5.2.1 System Performance of Screening System Metrics*

*5.2.1.1 Metric—Throughput of Passenger Screening System.* The throughput of the screening system was estimated by assessing the specific activities in different phases of the screening process. Subject-matter experts estimated the time needed by the screening station to complete each activity for a passenger, assuming that there is no one waiting in line.

*5.2.1.2 Metric—Effectiveness of Passenger Screening System.* The effectiveness of the system was assessed by considering the number and percentage of false negatives and false positives (false negatives are undetected infected passengers who enter the country; false positives are uninfected passengers who are significantly detained because they are thought to be infected). These estimates were tied to:

- the number and type of personnel needed to man the screening stations at the primary and secondary screening areas (the effectiveness of the system can be improved by devoting greater resources to it), and
- passenger waiting times (the effectiveness of the screening system is inherently tied to its impacts).

A passenger screening simulation model was used to calculate these metrics.

No metrics were calculated in the study for the reliability of the screening system, the ease of operating it or its usefulness to screeners.

***5.2.2 Metrics for the Benefits of Passenger Screening System.*** The overarching purpose of having airport entry screening of international passengers is to reduce the ultimate incidence and associated mortality of pandemic influenza in the country. Thus, the measures of benefits are the estimated reduction in cumulative incidence and associated number of deaths in the country, which are averted by having entry screening at the airport.

In the study cited, the incidence and number of deaths were estimated using simulation models. The major steps in that analysis are illustrated in Figure 1. The numbers in the figure are keyed to the steps in the simulation analysis:

1. Assumptions were made about the prevalence of the epidemic (i.e. the rate of illness in the population) in foreign regions from where passengers travel on international

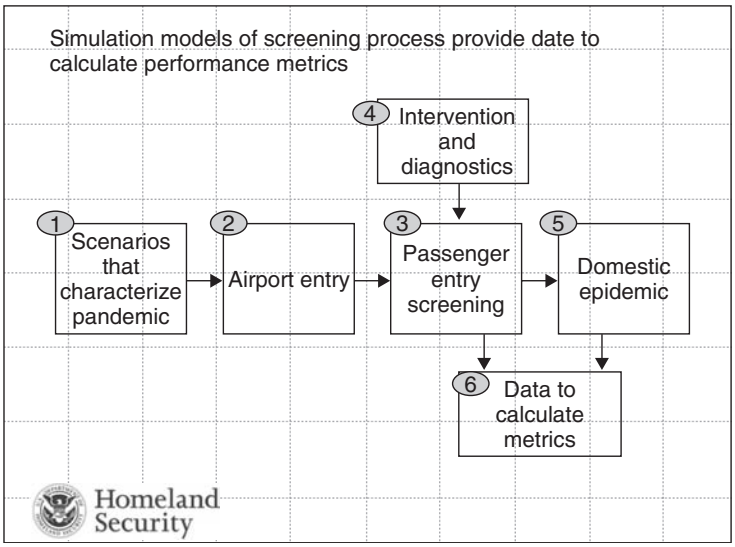

**FIGURE 1** Steps in simulation to develop data inputs to calculate performance metrics.

flights into the United States; these assumptions were made by subject-matter experts on the basis of past pandemics and their assessments of the severity of a future pandemic.

2. The volume of inbound international air traffic was estimated using data on individual flights, regions of origin, numbers of passengers on each flight and arrival times of flights, growth in future traffic, and the likely reduction in traffic volumes as a result of the pandemic.
3. A passenger screening simulation model was developed based on the passenger screening Concept of Operations (ConOps); it simulates the processing of each passenger at each stage of the screening process.
4. Estimates of the effectiveness of selected screening methods and screening processing times (if there is no waiting) were used in the passenger screening simulation model.
5. The key prediction of the passenger screening model is the number of false negatives, that is, the number of infected passengers who are not detected and who thus enter the country and soon infect others; the numbers of false negatives at each airport on each day were used as input data for a detailed agent-based epidemic simulation model that predicts the spread of the epidemic in the country.
6. The epidemic model computed the incidence each day, depending on the likelihood of an infected individual spreading the illness (based on evidence from other influenza epidemics) and mitigative measures implemented within communities such as vaccination, prophylaxis, and social distancing (e.g. closing schools and other activities); mortality was estimated using an assumed ratio of fatalities to cases.

***5.2.3 Metrics for Resource Needs and Costs of Passenger Screening System.*** Various resource needs were estimated using the passenger screening simulation model. For example, the ConOps calls for the possible use of antiviral prophylaxis at the airport, for passengers who might be exposed to the virus. Based on this protocol, the simulation model estimated the quantity of antiviral supplies needed. The quantity was based on the predicted number of suspected cases the screening system culls out.

***5.2.4 Metrics for Impacts of Screening System.*** One of the main impacts of passenger screening is that it causes delays. The passenger screening simulation model estimated the delay experienced by each passenger. The calculations were based on queuing principles that account for the number and timing of passenger arrivals at the airport, the prevalence of symptomatic passengers, the methods used in each screening layer to identify ill passengers, the effectiveness of these methods and the staff resources available for the screening activities.

The key metrics of the impacts were as follows:

- passengers' average delay time;
- passengers' maximum delay time.

The US government is using these metrics to help plan for the personnel needed for entry screening and to reduce these delays.

## 6 KEY CONCEPTS AND RECOMMENDATIONS ON FUTURE DIRECTIONS

Performance measures, and specific metrics for quantitatively evaluating these measures, are important means of gauging the value of alternative transportation security systems. Consistent definition and systematic use of performance measures are at a relatively early stage of development in terms of their application for *prospectively* assessing the *operational* performance of transportation security systems.

The focus of this article is on "prospectively" assessing their value, prior to making an investment and deploying a system. Testing under actual field conditions is the best means of developing the data needed to calculate performance metrics; computer models that simulate the system's operation in the field are an alternative means of compiling data, though not as good as actual field data. We emphasize that systems should be assessed by how they will perform *in practice*, after they are tested under controlled conditions.

# INTELLIGENCE SYSTEMS

# FILE FORENSICS AND CONVERSION

Brian D. Carrier
*Basis Technology, Cambridge, Massachusetts*

## 1 INTRODUCTION

File forensics is the analysis of digital files to answer some form of question. For example, the question could be "which files contain the keyword X." This type of question is frequently asked in law enforcement and intelligence gathering contexts and the answer can identify if someone is guilty or innocent or identify people or places that are a threat or that are threatened. Files contain user-created content and are therefore crucial to learning about the actions of the computer's user. This article focuses on the state of the art and the challenges associated with file forensics. The other areas of digital forensics are outlined in other articles of this book. The first section outlines the general process of file forensics and the second section outlines the technology areas used. The third section describes the unique need areas that exist and the fourth section provides requirements for future file forensics efforts.

## 2 PROCESS OVERVIEW

### 2.1 Digital Investigation Process

File forensics fits into the larger area of digital investigations, which is also called digital forensics or media exploitation [1]. Digital investigations analyze digital data to answer questions about the current or previous state of the data or about previous digital events. The full process is similar to a physical crime scene investigation [2]. At a physical crime scene, the state is preserved by limiting access and taking pictures. Next, the scene is searched for evidence and the evidence is analyzed. Lastly, events are reconstructed based on the evidence at the scene to determine who did what and when.

At a "digital crime scene," the state of the digital media is preserved by making a copy of the data. Next, tools are used to analyze the data and the investigator searches for files or fragments of deleted files that could be relevant. In the physical world, evidence can typically be seen by the naked eye, but specialized tools are needed in the digital world to process and display the digital evidence. These tools can process various types of file systems, file formats, and network protocols. After the evidence has been identified, the

investigator tries to put them into context. Which user and program created them, when were they created, or what do they mean?

Because of the design of storage media, there are several layers of data analysis that occur [3]. When analyzing a hard drive, first the volume system and partition tables must be analyzed to identify how a hard drive was partitioned. Next, the file systems in each volume are analyzed to identify the files and to recover deleted content [4]. The next step, which is file forensics, is to analyze the contents of each file. Similar layers exist for network and memory data.

### 2.2 File Forensics Process

The file forensics process starts with a file or some other discrete amount of data. The file could be from a hard drive, a network trace, or extracted from memory. Because files are used to store data ranging from text to video, there is no single analysis process. For the sake of this article, we will start with the high-level process, which has two steps: file type identification and analysis.

The first step in the high-level process is to identify the file type, such as JPEG or PDF. The most reliable method for doing this is to look for signatures in the file content. For example, Adobe PDF files start with the bytes 0x25, 0x50, 0x44, and 0x46, which represent the letters "%PDF" in ASCII. JPEG files start with the bytes 0xffd8 and end with the bytes 0xffd9.

Signatures are not guaranteed to be unique and because a file has a sequence of bytes that matches a signature does not mean that it is that file type. Therefore, it is important to validate other data in the file after a signature is found and to look for all known file type signatures instead of stopping after the first match.

Some programs, such as Microsoft Windows, use file name extensions to identify the file type, but this is not reliable because the user could have changed the extension to avoid detection. Also, some deleted files do not have names.

After the file type is identified, the second step in the high-level process is to analyze the data using knowledge about that file type. This step allows tools and analysts to access the user created content. Although there are many tools that can open files, it is often best to use specialized tools that can display deleted and hidden content and that do not modify the file.

## 3 RESEARCH AREAS USED

File forensics can encounter any type of file and therefore its needs are diverse. The process of identifying file types is well understood, but the analysis process has many challenges. Specifically, the challenges include having a single tool that supports all file formats and being able to process large amounts of data. Fortunately, these challenges are not unique to digital forensics and are shared by the information retrieval, natural language processing, and graphics communities. In this section, we will outline the research areas that are used in file forensics. Because of space limitations, the high-level concepts and areas will be identified, but detailed approaches are not given.

### 3.1 File Formats

One of the largest challenges with digital investigations is dealing with the vast number of different file formats. The breadth of file types that are relevant to investigations is increasing and no single analysis tool supports them all. A computer intrusion

investigation will need to analyze executable files to detect malware and rootkits [5] and will need to analyze log files to look for suspicious activity. An investigation about downloading contraband images (i.e. child pornography) from the Internet will need to analyze web history files and graphic file formats [6]. Terrorism cases may focus on web histories, e-mails, chat sessions, and videos.

The extraction of text or multimedia data from files is largely an engineering problem. Each file format is created using a specification and if the specification is known then a program is created to support it. If the format is not known, then reverse engineering techniques are typically used to identify the data structures and algorithms used.

The unique need for file forensics is that deleted content and change histories, if they exist, need to be recovered. For example, there are many tools that can extract messages from PST Outlook files, but they do not return the deleted messages that are still in the file.

### 3.2 Metadata Extraction

A general forensics concept that applies to all file formats is metadata extraction. In general, file formats are created to store a specific type of data, such as image data or text. Many formats also have metadata, which is data about the data.

Metadata typically contains information such as which application or user created the file content and the date the file content was created. The metadata may also contain information about the computer or digital device that was used to create the content. For example, JPEG files frequently contain metadata about the camera and settings used to take a picture.

The amount of metadata varies by file type and not all programs that create the files will fill in all metadata. For example, PDF and Microsoft Office files allow the user to save metadata about the author and title of the documents, but they are not required to be entered.

Metadata can be used by an investigator to determine who created the file and on what computer. It can also be used to correlate documents that may have been created by the same person.

### 3.3 Documents

Documents store text by mapping the characters in the text to numbers. Those numbers are saved in the file and are remapped to the characters when the file is read. Over the years, many character to number mappings have been defined and many are script-specific. The exception is the Unicode specification, which supports nearly all scripts [7].

Documents come in many forms, which can be organized into two basic categories. At the most basic, there are raw text files that contain only the encoded text with no markup for sections, fonts, or styles. These files have no file type signature. To process these types of files, a program must identify the text encoding, which can be done using statistical techniques.

The second category of documents has structure that describes the font and style of the text and may contain embedded data, such as images and tables. Common examples of this category include HTML, XML, Microsoft Office files, PDF, e-mails, and chat logs. Most documents fit into this category. To process these types of files, a program must know the internal structure of the file format and process it accordingly. In many cases, the file stores the text encoding that was used.

Once the files have been processed and the text has been decoded, there are many analysis techniques that are conducted. The most basic technique is that the text is

displayed to the investigator so he/she can read it. However, the text in each file could be long and the investigator may not have enough time to read all files. This problem has also been researched by the Information Retrieval community.

To reduce the number of files to look at, the documents are typically searched for keywords. While this is a technique that we all use to find documents on internal servers and websites, the requirements for doing a search during a digital investigation can be stricter. The document that contains incriminating or exculpatory evidence may have a typo or spelling variation of the keyword. To deal with this situation, searches can be conducted using "fuzzy" matching [8] or text normalization. With text normalization, words are reduced to a normal form using text analytics. For example, the British word "colour" could be normalized to "color".

There are several techniques that can be used to reduce the time required to analyze each document. If names are important, then information and named entity extraction techniques can be used to statistically analyze the text and highlight or extract the people and places that are mentioned [9]. Another approach is to use automated text summarization techniques to create a summary of the key ideas in the document [10].

Clustering and classification can be used to reduce the number of files that need to be looked at [11]. Clustering takes the search results and groups them together based on concepts. This allows the investigator to examine one of the files in the cluster and then move on to another cluster if its topic is not relevant. Classification will organize the search results based on specified categories, such as topics or file types.

When investigations deal with text in languages that the investigator does not speak, then machine translation becomes a needed technology. Machine translation automatically translates text from one language to another. Because machine translation is difficult and the result of the process can be difficult to read, name translation [12] is an alternative middle step. In this approach, names in the text are identified and transliterated from the native script to Latin script (i.e. A to Z) so that the phonetic sound of the names can be determined.

### 3.4 Multimedia Files

Multimedia files are also of interest during digital investigations. Picture and video files may contain images of relevant people or locations. Audio files may contain relevant messages or instructions.

Digital image processing techniques [13] can be used to identify similar images, to identify which images contain skin tones, and to perform object or face recognition. Images are also frequently analyzed to detect if messages are hidden in them using steganography [14].

Like documents, multimedia files also have challenges with search and summarization. Multimedia files cannot be easily searched to identify ones with content on a specific topic. Also, it is time consuming to review long movies and audio. Summarization techniques can help to show summaries of the data when major things change, such as when the scene in a video changes or when the audio profile changes. These summarization techniques could help to find data that is hidden among other data. For example, a movie could start off with scenes from a family vacation, but could then have a message from a terrorist leader a few minutes into the movie.

### 3.5 Executable Files

Some investigations require the analysis of executable files. This can occur when unknown programs are installed during a computer intrusion or found on a suspect's

computer. Analysis techniques for executables include static analysis where the executable file is analyzed and dynamic analysis where the file is run and monitored [15].

Static analysis can provide basic information by identifying what libraries and system functions the file uses. Text from the file can also be extracted to provide insight about what messages are displayed to the user.

Dynamic analysis is more dangerous, but can provide more insight because the file and network traffic can be observed. However, the program could damage the local computer, spread to other computers on the investigator's network, or send a message that would alert someone that the program was run from the investigator's network. Virtual machines are commonly used for dynamic analysis because they can be easily restored to a clean state. However, some malware can detect when it is being run in a virtual machine and will stop running to prevent dynamic analysis.

### 3.6 Correlation

The previous sections outlined high-level techniques for extracting information from different file types, but sometimes it is useful to correlate data among the different file types. From a time perspective, it could be useful to correlate log entries, web browser histories, e-mail messages, and file modification times so that a timeline of activity can be created. Similarly, it could be useful to correlate IP and e-mail addresses found in log messages, e-mails, and executables. Social networks can be created by the analysis of e-mail messages and chat logs. The ability to correlate results may identify new systems or people on which to focus.

## 4 CRITICAL NEEDS ANALYSIS

As described in the previous section, much of the nonengineering file forensics challenges are not unique to digital forensics. They are challenges common to information retrieval, text analytics, digital image processing, and software engineering.

Advances in machine translation, video and audio search, object recognition in images, and multimedia and text summarization will all have a positive impact on file forensics. These advances will help to sift through the growing amount of data that investigators encounter and their needs are outlined in other sections of this book. In this section, we will outline some of the unique needs of file forensics.

### 4.1 Plug-in Infrastructure

While many of the need areas are not unique to file forensics and research is underway, it is unique that file forensics needs to leverage all of these areas at the same time. Currently, no single tool supports all of the techniques needed for file forensics, including the ability to extract text from all document formats, process multimedia files, and reverse engineer executables. There is a need for an open plug-in infrastructure that allows multiple file forensics modules to be used in a single analysis tool. This infrastructure would allow an investigator to use a single interface to analyze all of the file types that they would encounter instead of needing to export and import files between multiple tools.

A plug-in infrastructure could also allow the investigator to use modules from competing vendors and have them vote on the result. It is best practice in digital forensics to verify the results of one tool with another tool. This process could be automated with a plug-in infrastructure.

### 4.2 File Carving

A unique requirement of file forensics is the need to extract files from a blob of data. This scenario can occur when you have a large amount of unallocated space in a hard drive. A file could be inside of this data, but the file system structures that identified the file layout have been overwritten.

The traditional method of recovering these files, [16], is to scan for file type signatures. When a byte sequence is found, which matches the header signature, it is assumed that the file starts at that location and the algorithm then searches for the end of the file. Some files have a footer signature, but others do not. If a footer signature exists, then the basic algorithm is to assume that everything in between the header and footer is part of the file. If the file type does not have a footer signature and there is no value for the size of the file in the header, then a default length is assumed and all data between the header and the default length is extracted.

The problem with this approach is that files are not always contiguous on the disk. Files are broken up into blocks, typically from 4 to 16 KB, which can be stored in any order in any part of the disk. Files that have noncontiguous blocks cannot be recovered by this simple carving method.

Initiated by the DFRWS 2006 and 2007 Forensics Challenges [17, 18], new carving algorithms have been developed that take more of the file structure into account so that fragments can be detected. See [19] and the challenge submissions for more details. Additional work into this area is needed to improve the algorithms and expand the file formats that are supported.

### 4.3 Non-English Text Extraction

During a digital investigation, an unknown file format may be encountered or a blob of data may exist that cannot be carved any further. In this situation, it is common to analyze the data to look for possible text.

For English text, this approach will search for four or more consecutive 1- or 2-byte values that could be printable ASCII or Unicode characters. This is the approach used by the Unix strings command. In general, this approach is successful at extracting text and it has a low false positive rate. With ASCII, 37% of the 1-byte values are printable characters and the probability of finding four consecutive printable values in random data would be 1.8%.

When non-English text is considered, the false positive count dramatically increases because the probability of finding four or more printable Unicode characters is much higher. With Unicode, 80% of the 2-byte values are printable characters and the probability of finding four or more consecutive printable values in random data would be 41%. New approaches that reduce the false positive rate are needed to extract non-English text.

## 5 RESEARCH DIRECTIONS

The requirements for the research areas previously mentioned are as follows:

- Accuracy
- Speed
- Scalability

- Modular with plug-in support
- Multilingual

Accuracy is needed to ensure that investigators can state that data does not exist when searches do not find it. Similarly, it is needed so that an investigator can state that something existed because it was observed.

Speed is a requirement because some incidents will require quick results. There could be a time limit on the duration that a suspect can be held and his computer needs to be analyzed in that time frame. In the battlefield, a soldier may want to quickly scan a computer to extract intelligence about where threats and targets are located.

As hard drives increase in size and more portable devices are used, scalability is a requirement so that systems can handle the data. Distributed systems, central databases, and analysis interfaces that encourage collaboration are needed to sort through the massive amounts of data.

Because the needs of file forensics are diverse, systems should be modular with plug-in support so that a single system can be used to handle the diverse set of scenarios that can be encountered. The need to export data from one tool to import it into another can introduce errors and prevents the systems from being more fully automated.

Lastly, digital forensics has historically focused on searching English text. As investigations involve computers in multiple languages and as the military and intelligence increasingly focus on non-English systems, the tools need to better handle searching non-English text. When analyzing systems that contain text in languages that the analyst does not understand, the tools need to help with translating keywords and text. The tools also need to help with identifying spelling variations of a word.

## 1 SCIENTIFIC OVERVIEW

Medical and forensic studies have been conducted for quite some time on various aspects of human aging and its relation to changes in the face [1–4], but few studies have

addressed the effects of aging on face biometric technologies. There have been a few studies conducted recently with regards to modeling the effects of growth and development (i.e. the stage from birth to maturation) for application to face recognition technologies [5–10]. Although similar approaches to studying growth and development and adult aging may yield improvements in biometric technologies, the two processes are distinct, and therefore, should be studied separately for more accurate modeling of the underlying processes [3, 4].

Some work has been conducted concerning simulation of aging in facial images or models, considering a few different approaches. One approach is biomechanical simulation, and work in this area has included a layered facial simulation model for skin aging with wrinkles [11], an analysis–synthesis approach to aging the orbicularis muscle in virtual faces [12], and a flaccidity-deformation approach [13]. Anthropometric deformation approaches have also been attempted for both adult aging [14] and growth and development [15]. In one of recent works [16], a twofold approach toward modeling facial aging in adults is proposed. In this work, a shape transformation model that is formulated as a physically based parametric muscle model that captures the subtle deformations facial features undergo with age is developed. Next, an image gradient–based texture transformation function that characterizes facial wrinkles and other skin artifacts often observed during different ages is developed. Other approaches have also simulated aging through direct image manipulation of shape and texture, mainly for testing human perception [17, 18]. A summary of existing research on craniofacial aging, age-progression, and face biometric techniques that address the effects of aging directly are presented in the following sections.

### 1.1 Craniofacial Aging: Findings in Anthropology and Forensics

The craniofacial region of a human is where, effects of aging that would significantly impact human or computer recognition of individuals occurs. These changes include both the bony portion of the head as well as the overlying soft tissues that produce the external appearance of one's face. There is a large body of literature concerning this facial morphology due to aging that may be referenced to learn aspects that should be considered for face recognition technologies [4, 19, 20].

Our modern approach to studying age-related changes to the craniofacial complex can be traced back to D'Arcy Thompson's now classic work, first published in 1917—*On Growth and Form*—in which he explained shapes in the biological world in part through mathematics [21]. Contemporary studies indeed suggest that cardioidal strain transformation, a nonlinear topographical transformation, may be a reasonable mathematical model through which to observe major changes in craniofacial shape affected by growth [22, 23]. However, cardioidal strain transformations cannot account for other aging features such as hair, skin elasticity and texture, adipose tissue, nose, ears, eyes, and lips [24]; therefore, its importance in recognizing faces as they age should not be overestimated [25]. While three-dimensional shape changes may affect perceptions of aging, there is also evidence to suggest that age perception is highly dependent on internal facial features as well—eyes, lips, nose, and ears [26]. Indeed, the distinction between feature-based and configurational information is one of the ultimate challenges in face recognition [26]. Key features changing with adult age are noted below.

Degenerative soft tissue changes and small shifts in skeletal form ultimately affect the appearance of the face during aging. The skeletal changes include cranial expansion,

anterior face-height increase, and jaw shrinkage [20]. Soft tissue appearance is affected by decreasing muscle tone or atrophy, diminishing collagen and elastin, and skin wrinkling and sagging. Along with these natural changes that occur with aging, there are other aspects that affect facial appearance over time. Of these, photoaging is one of the most significant—largely impacting fair-skinned individuals and those residing in sunny regions [4]. Other major factors include ancestry, gender, health and disease, tobacco and drug use, diet, stress-related sleep deprivation, biomechanical factors, gravity, and hyperdynamic facial expressions [4, 20]. In addition, there are factors that can exacerbate age-related changes such as weight loss due to illness, drug use, and/or some medications [4, 19].

These changes are not consistent but vary in rate over adulthood. As expected, fewer changes generally occur in the twenties, accelerating a little in the thirties, and increasing even more in the forties and fifties—typically the period of greatest change. This period of greater morphology is fairly consistent across race and gender. Past the fifties, the changes that have begun increase significantly and other associated degenerative affects may appear.

Figure 1 illustrates the changes in an aged female with annotated points. Changes to note beginning in the twenties and thirties include horizontal creases in the forehead (areas 1 and 2), slight drooping of the eyelids (area 6 and 9), nasolabial lines or "laugh lines" (areas 16 and 17), lateral orbital lines or "crow's feet" (area 7), circumoral striae (which are lines around the mouth) (areas 18 and 20), hollowing of the cheek (around area 15), decrease in upper lip size (area 21), and retrusion (which is a backward movement of the upper lip that is more apparent in females) [4, 19, 20].

Through the adult aging process these changes become more noticeable, and by or around the age of 50, there are other changes that have begun including the appearance of fine lines, and thinning and sagging of skin as shown in Figure 2. Skin also becomes rougher, drier, and shows loss of tone and elasticity. This combined with atrophy in corrugator and orbicularis muscles can affect facial appearance greatly. Wrinkles appear on the neck, and discolorations in skin may begin to appear. Loss of hair and depigmentation may occur. Hair may also grow in areas that previously had little or no growth [4, 20].

In general, trends occur that affect facial size as well. Small skeletal changes in height and width affect the outer appearance of the soft tissue. Nose height and length increases, and ear length increases. Mouth width also increases. In very aged people, faces may appear smaller due to overall degeneration of the boney substructure (craniofacial complex) and tissue degeneration.

Table 1 summarizes the soft tissue and hard tissue changes that occur at various age spans [3].

## 2 CRITICAL NEEDS ANALYSIS

Face recognition has been a key biometric research area for more than a decade. This technology has had mixed, almost disappointing, results when applied in commercial venues [27–29]. Nonetheless, robust face recognition systems are needed to meet the demands of intelligence agencies, military, and, more broadly, homeland security. Face recognition systems used for identification or watch lists require enrollment, which is the process of learning known faces. The performance of these systems deteriorates after a

**FIGURE 1** Annotated diagram of craniofacial morphology.

few years unless the system is updated with current faces of the known subjects. The degradation of performance of these systems has been demonstrated, but not studied in depth, as far back as the original Face Recognition Technology (FERET) evaluations [30]. They were also further highlighted in face recognition vendor test (FRVT) 2002 [31]. The paucity of research on this topic can be summarized as (i) the algorithm developers had little to no understanding of the complete biomechanical processes that affect facial aging and (ii) there are only a few publicly available longitudinal face databases. The following section details the known longitudinal databases and summarizes the results of recent work in quantifying the effects of age-progression and automatic synthesis of adult aging in facial images.

### 2.1 Longitudinal Face Databases

The FERET, FRVT, and face recognition grand challenge (FRGC) are programs sponsored by Defense Advanced Research Projects Agency (DARPA)/National Institute of Standards and Technology (NIST)/Central Intelligence Agency (CIA) to further biometrics research and each has created vast data corpora to facilitate the analysis and evaluation of various biometrics. Furthermore, each program contains face databases designed to meet the mandate of each challenge. The FERET face database (1994), which continues to be used by researchers worldwide, contains a set of longitudinal images in its Duplicate I and Duplicate II data sets. The Duplicate I probe set holds 722 images whose matches were taken between 0 and 2.8 years after the match. The median is 2 months

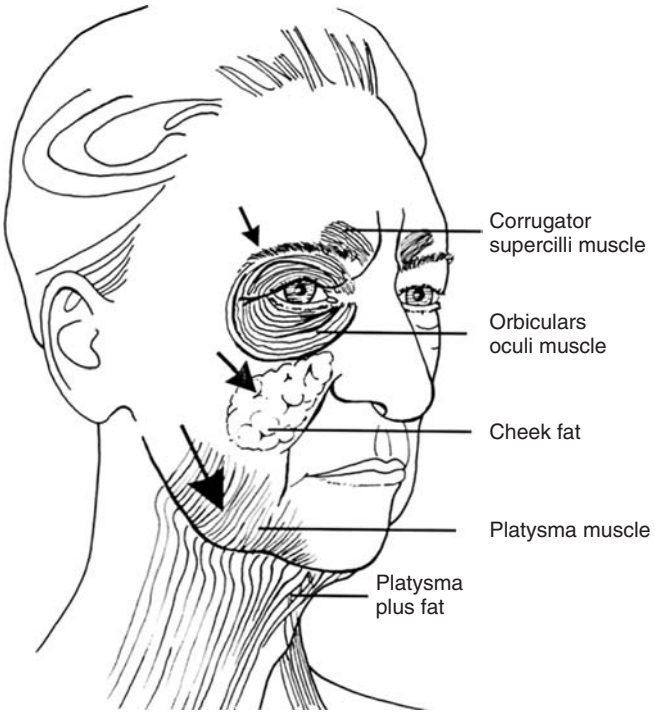

**FIGURE 2** Illustration of aging: impacts on soft tissue (musculature and skin) demonstrating wrinkling and muscle sagging.

and the mean is 8.25 months. The Duplicate II probe set contains 234 images from subjects whose match was taken between 540 and 1031 days beforehand. The median is 1.5 years and the mean is 1.7 years. The challenge of using FERET is sparseness of subjects, unknown ages, and diversity of gender and ethnicity. The FRVT 2002 database was comprised of longitudinal images of subjects with some ethnic diversity, but this was not released for general public research as was the FERET. Additional information can be obtained on this database from the website (www.frvt.org). The FRGC primary objectives did not include the problem of age-progression or gallery-probe acquisition differences.

The Face and Gesture Recognition Research Network (FG-NET) Aging Database [32] constructed by Andreas Lanitis at Cyprus College, is constructed from scanned photographs provided by volunteers. The photographs range from childhood to senescence of 82 subjects under various pose and facial expressions. The database does not provide researchers with important parameters like ethnicity, height, or weight.

The Craniofacial Morphological Face Database, MORPH, is a longitudinal face database developed for researchers investigating all facets of adult age-progression [33]. The MORPH database includes metadata on the face images within the database: subject's ethnicity, height, weight, gender, and age. Figure 4 is a sample of two subjects from the database highlighting appearance changes of adult faces. The database is partitioned into two albums, Album 1 and Album 2. Album 1 consists of 1690 images of 628 subjects that were scanned from photographs taken as far back as the 1960s. Album 2 has over 55,608 digital images of 13,673 subjects which consist of males

**TABLE 1 Adult Hard and Soft Tissue Age-related Changes**

| Approximate Age Range (years) | Likely Bony Change | Probable Soft Tissue or Facial Appearance Effect |
|---|---|---|
| 20–30 | Slight craniofacial skeletal growth | Upper eyelid drooping begins |
| | Slight anterior (mostly lower) face height *increase* | Eyes appear smaller |
| | | *Nasolabial* lines begin to form |
| | *Mandibular* length increase | Lateral orbital lines begin to form |
| | | Upper lip *retrusion* begins in females |
| 30–40 | *Dentoalveolar* regression suggesting eruptive movement of teeth | *Circumoral striae* begin to form |
| | | Lines begin to form from lateral edges of nose *to* lateral edges of mouth. |
| | Maxillary *retrusion* progressing, contributing to *nasolabial* folds | |
| | *Mandibular* length increase | Upper lip thickness decreasing |
| 40–50 | Craniofacial skeletal remodeling progresses | Facial lines and folds continue to increase in depth |
| | Dental alveolar regression and dental eruption progressing | Nose and chin positioning affected as dental arch lengths decrease |
| | Maxillary and *mandibular* dental arch lengths decreasing | Most profound morphological changes of the head, face, and neck are evident |
| 50–60 | Craniofacial remodeling continues | Facial lines and folds continue to increase in depth. |
| | Cranial thickness likely unchanging | |
| | Alveolar bone remodeling | Protuberance of nose and ears due to greater craniofacial convexity |
| | Possible dental attrition affecting vertical face height | |
| <60 | Decrease in craniofacial size | Protuberance of nose and ears continues |
| | Greater craniofacial convexity (excluding maxilla and mandible) | Concave appearance in cheek hollows due to alveolar bone remodeling |
| | Possible *temporomandibular* joint arthritis and joint flattening | |
| | Alveolar bone remodeling continues | Diminished jaws |

and females of the Caucasian, Asian, Hispanic, and African ethnic groups; however, there are very few Asian and Hispanic samples. Detailed statistics are shown in Tables 2 and 3. The MORPH database is an ongoing project in the Computer Science Department at the University of North Carolina Wilmington and can be requested from www.faceaginggroup.com.

### 2.2 Effect of Adult Aging on a Standard Face Recognition Technique

The work of Ricanek and Boone 2005 [34] was an early attempt to quantify the effects of normal adult aging, age-progression, on a face recognition technique. In this work, the

**TABLE 2 Statistics for Morph Album 1**

| General | | Age Statistics (yr) | | | | |
|---|---|---|---|---|---|---|
| Number of Subjects | Number of Images | Minimum | Maximum | Average | Median | SD |
| 515 | 1690 | 16 | 68 | 27.28 | 26 | 8.65 |

Morph Album 1: Number of Facial Images by Gender and Ancestry

| | Americans of African Descent | Americans of European Descent | Americans of "Other" Descent | Total |
|---|---|---|---|---|
| Male | 1037 | 365 | 3 | 1405 |
| Female | 216 | 69 | 0 | 285 |
| Total | 1253 | 434 | 3 | 1690 |

Morph Album 1: Number of Facial Images by Decade of Life Categories (yr)

| | <18 | 18–29 | 30–39 | 40–49 | 50+ | Total |
|---|---|---|---|---|---|---|
| Male | 142 | 803 | 345 | 93 | 22 | 1405 |
| Female | 15 | 182 | 70 | 18 | 0 | 285 |
| Total | 157 | 985 | 415 | 111 | 22 | 1690 |

authors sought to quantify the impacts of aging against the standard principal components analysis (PCA)-face recognizer as implemented in the Colorado State University's Face Identification and Evaluation System (FIES). The FERET and MORPH databases were used for the evaluation. MORPH album 1 was used which contained large longitudinal images of more than 500 subjects whose images were scanned from photographs. The largest span was 20.3 years and the average was 6.45 years.

The work concluded that there was a statistically significant degradation in rank-N performance as evaluated as a function of age difference between enrolled and probe. To this end, the researchers were able to generate a function of performance loss using logistic regression. Table 4 shows the results of the logistic regression on correct classification on the time-differenced images. The table illustrates that the time difference is an important factor in determining the recognition rate with a p value $<0.0001$. Table 4 also shows the odds ratio associated with a 1 year increase in time between the enrolled image and the test (probe) image such that a 1 year increase would result in a rank-N performance decay of 0.6707. Figure 3 shows a graph of this relationship across time for rank 1 and Figure 4 illustrates the relationship for rank 5.

### 2.3 Face Recognition Using Synthetic Facial Aging

One of the several reasons that make testing variation in human faces due to aging, a difficult task, is data collection. Current face databases suffer from small number of subjects, less than a few hundred, and/or small number of or inconsistent age spans for subjects. There has been indication, though, that face recognition technologies are not well suited to perform invariantly across images of the same individual at different ages [6, 8]. As discussed in the previous section, the MORPH database has been developed to

**TABLE 3 Statistics for Morph Album 2**

| General | | Age Statistics (yr) | | | | |
|---|---|---|---|---|---|---|
| Number of Subjects | Number of Images | Minimum | Maximum | Average | Median | SD |
| 13,673 | 55,608 | 18 | 77 | 32.69 | 33 | 10.9 |

Morph Album 2: Number of Facial Images by Gender and Ancestry

| | Americans of African Descent | Americans of European Descent | Americans of "Other" Descent | Total |
|---|---|---|---|---|
| Male | 37,093 | 8119 | 1845 | 47,057 |
| Female | 5803 | 2617 | 131 | 8551 |
| Total | 42,896 | 10,736 | 1976 | 55,608 |

Morph Album 2: Number of Facial Images by Decade of Life Categories (yr)

| | <18 | 18–29 | 30–39 | 40–49 | 50+ | Total |
|---|---|---|---|---|---|---|
| Male | 2964 | 17,728 | 12,587 | 10,248 | 3530 | 47,057 |
| Female | 373 | 2783 | 2924 | 2017 | 454 | 8551 |
| Total | 3337 | 20,511 | 15,511 | 12,265 | 3984 | 55,608 |

**TABLE 4 Logistic Regression Parameters: Longitudinal Difference MORPH Training and FERET Training**

| Rank | Training | Time Difference | Standard Error | $p$ value | Odds Ratio |
|---|---|---|---|---|---|
| 1 | MORPH | −0.39941 | 0.07429 | <0.0001 | 0.6707 |
| | FERET | −0.36261 | 0.06714 | <0.0001 | 0.6958 |
| 5 | MORPH | −0.35702 | 0.05291 | <0.0001 | 0.6997 |
| | FERET | −0.33250 | 0.04983 | <0.0001 | 0.7171 |

help research improvements for face technologies across a wide span of age with this in mind. It has been used to make some initial tests of face recognition performance across wide spans of age samples [8]. A few other studies have also begun to investigate the possible effects of age and aging-related variation in the human face-to-face recognition technologies [5–10]. All of these initial studies have concluded that there is the possibility of significant degradation on the methods tested. Further study will need to expand these tests to very recent developments in face recognition technology that have shown significant performance increases in areas other than aging. Although it is still not known completely to what extent aging affects face-based biometric technologies, it is certain that it does have a strong impact on the appearance of the face and likely on most face recognizers.

Although the overarching theme is to develop robust, and to this end insensitive, face-based biometrics to the problem of age-progression the practical approach appears to be the development of synthesized imagery for enhancement of current methods.

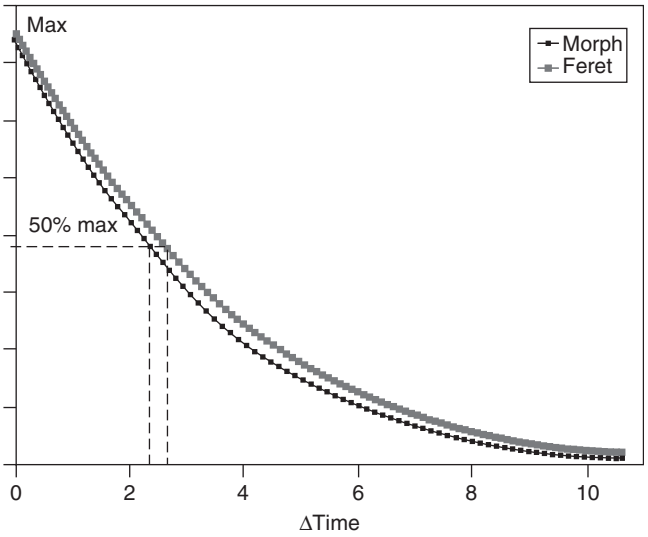

**FIGURE 3** Probability of rank 1 recognition performance against time span (years) between enrolled and probe image. Logistic regression was used to formulate the model and projected over a time span of 10 years (FERET projection used both Duplicate I and Duplicate II partitions).

Intelligently crafted synthetic images may be used to augment training galleries or be used to manipulate current test images to improve performance in a variety of areas. This approach is broadly known as *template aging* via generative synthetic templates.

Orlans et al. demonstrated augmenting FRVT 2000 findings for pose and temporal experiments by support with synthetic face image galleries using Singular Inversions' FaceGen software [35] and the Viisage [36] FaceTools commercial face recognition packages. They achieved a performance increase across pose variation tests by use of the synthetic images, and they demonstrated the individuality of the images in the synthetic gallery, but they also mentioned that it may be difficult to validate large galleries of synthetic faces. Also, 50 random faces were used and "aged" from 20 to 60 in 5-year increments with FaceGen [6]. FaceGen builds 3D faces synthetically using methods similar to those in [37] and allows for a gradient-based shifting of facial features, including age, but the statistical validity of these is not confirmed. With 128 principal components computed from 300 face scans, there may not be enough representation of aging among the population scanned, particularly across individuals to indicate idiosyncratic modes of aging [38]. Orlans et al. did mention that the statistical significance of this approach may be light but that recognition results degraded over "time" as represented by the synthesized test images.

Zhang et al. attempted to use a texture synthesis approach to correct for pose and illumination effects that degrade face recognition performance. Combined with a generic 3D face model and single frontal views, virtual views under different poses and illumination conditions were synthesized and used to augment the training gallery in a PCA-based recognizer and achieved a significant improvement in recognition accuracy across pose and illumination variations [39].

Lanitis and Taylor as well as Wang et al. have both conducted tests over the use of aging functions to improve recognition performance. Both of these cases, however,

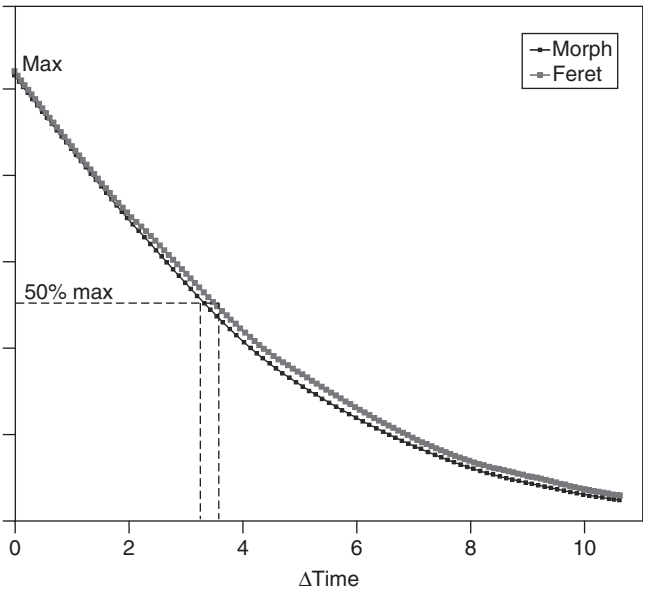

**FIGURE 4** Probability of rank 5 recognition performance against time span (years) between enrolled and probe image. Logistic regression was used to formulate the model and projected over a time span of 10 years (FERET projection used both Duplicate I and Duplicate II partitions).

considered images from human growth and development (birth to 18, 19–30 in the first case, and unknown in the second case), not specifically adult aging—a different period with different aspects and rates of change as represented in the anthropological literature. Growth and development has larger scale changes of structure as bones shift during growth. Adult aging in general has smaller structural shifts for a long period of time marked by larger changes of textural information in images. The system used by Lanitis and Taylor estimates the age of a test image and parametrically shifts it to the mean age of those represented in training [5]. Wang et al. appear to have used images from both growth and development and adult aging (a mean of 15-year age representation over 60 individuals, although the exact range of ages is not specified) and generate feature vectors of test faces at different ages [40]. Both cite improved performance in recognition, the first using an active-appearance-model (AAM)-based recognizer and the second a PCA-based recognizer. We have conducted brief initial tests indicating similar results. On a small subset of the MORPH database, with individual ages ranging from 18 to 40, PCA-based recognition was tested by augmenting the training gallery with "aged" images to match the current age of a test subject. Also, current test images were "de-aged" to match the range of ages of the individuals when gallery photos were taken. Although it was a very small test, the "de-aging" of the test images appeared to perform best for the given setup [9]. All of these initial studies have indicated a potential in some use of synthesized face information to improve biometric techniques.

We have recently conducted two initial studies using AAM-based approaches to synthetically age progressing and regressing images to represent adult aging effects to the face [41]. The first contained a small subset of the MORPH database [33]. Such is necessary to consider constructing individual or idiosyncratic models of face aging versus

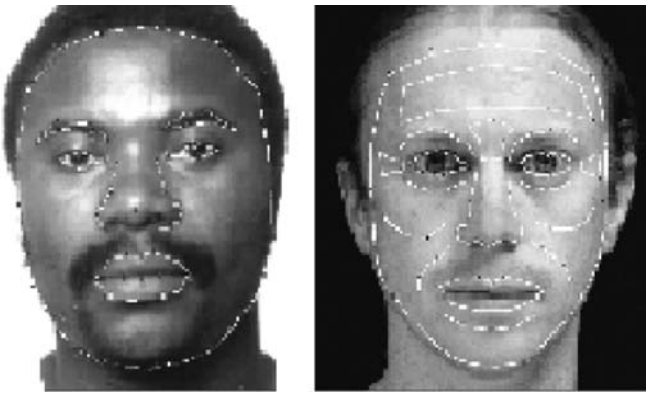

**FIGURE 5** Landmarks used in first and second setups.

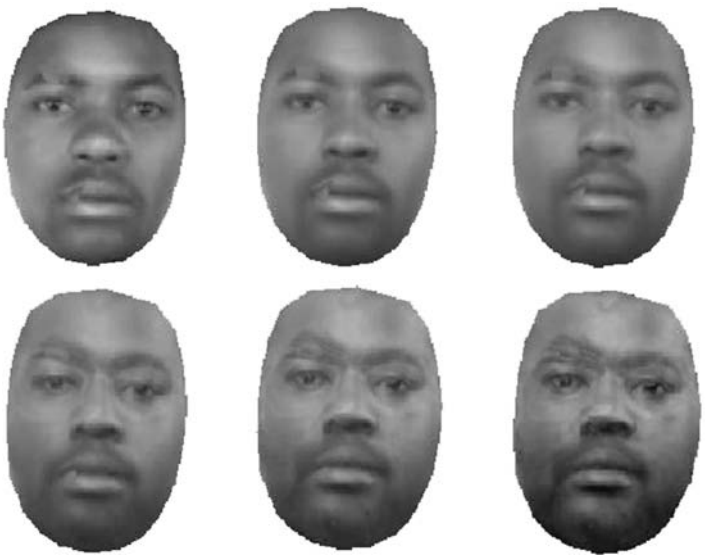

**FIGURE 6** Average faces over age-progression with first setup, from age 18 to 40.

generalized models which could be based on large databases of individuals of a variety of ages.

In the first setup, images from 9 individuals over a roughly 20-year period were used along with a set of 65 landmarks (which were mostly a superset of the anthropometric landmarks made popular by Farkas), shown in Figure 5, to construct an AAM with 30 parameters and representations of an aging estimation function and aging-lookup table similar to that presented in [42] but geared specifically toward adult aging. More details concerning the first tests are presented in [9]. A new image that will be progressed or regressed has its AAM parameters shifted by a difference of parameters taken from the difference of the average age parameters in the lookup table generated by Monte Carlo simulation [9, 42]. Examples of the average age-progression as represented by the lookup table are shown in Figure 6.

**FIGURE 7** Average faces over age-progression with second setup, from 20 to 70.

The second setup was designed to emulate a forensic sketch artist's approach to age-progression and was built with 99 images from a family, including young images of an individual along with images of parents and grandparents from the same family. One hundred and sixty one landmarks, also shown in Figure 5, were used to attempt to better track specific regions of aging in the face, and 55 AAM parameters were used, retaining 98% of the combined shape and texture variation. The desire was to present a better case study with improved image quality and texture resolution before continuing efforts on labeling and modeling the entire MORPH database.

A forensic sketch artist was employed to render sketches to be compared to the synthetic images. Examples of the average age-progression as represented in the second study are shown in Figure 7. Figure 8 demonstrates the loss of visual information and model construction as fewer parameters are chosen. The second setup uses 99 images but relatively few people, five individuals, to build a model, but it is in a sense a "family face space" that should and was proven to perform a reasonable representation of an individual and aging based on a wide representation of family images. It also represents one of the widest age ranges attempted so far, from approximately 20 to 70.

Age progressions generated with this setup and technique are shown in Figure 9. Similar experiments were likewise conducted in de-aging the family members, as shown in Figure 10. Also shown here is the difference image between the reconstructed AAM image of the individual at age 50 and the AAM image age regressed to 30. Although it may be difficult perceptually to notice changes depending upon presentation, and changes may be mild, the difference image demonstrates changes in both shape and texture and in probable regions as discussed henceforth. Parallels may be drawn about the regions in the face where rhytids, ptosis, loss of elasticity, and atrophy occur. Differences around

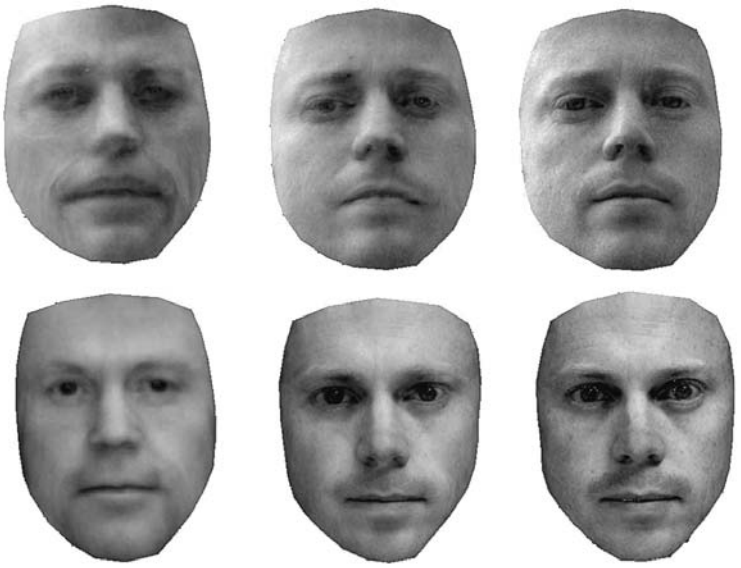

**FIGURE 8** Parameter variation with 10, 30, and 50 parameters.

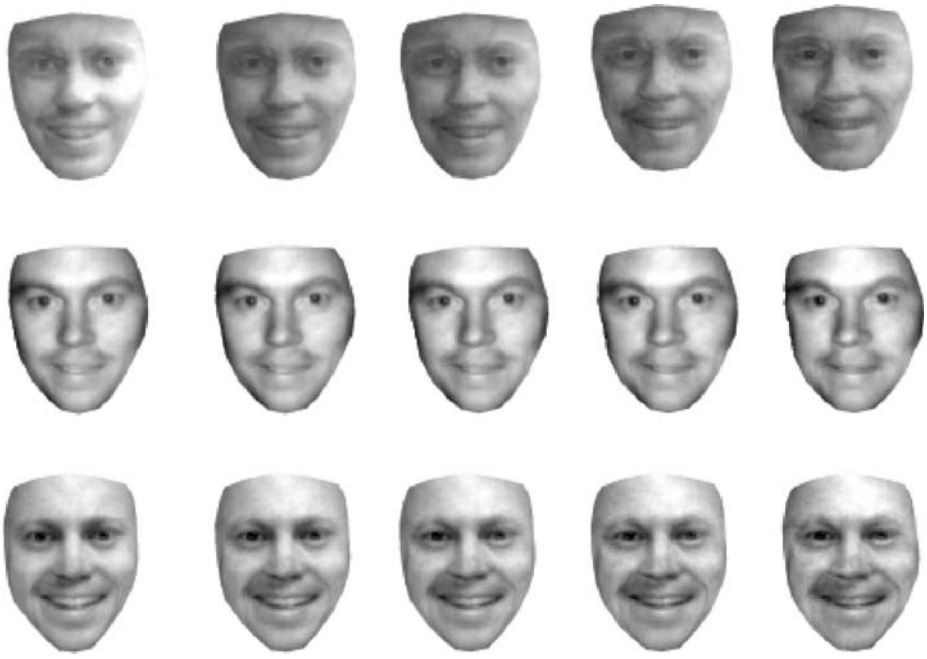

**FIGURE 9** Different images of an individual synthetically progressed from ages 23, 25, and 34 (top to bottom) to 40, 50, 60, and 70 (left to right).

**FIGURE 10** De-aging example from 50 to 30. Top images include original reconstruction, de-aged image, and difference image of reconstructed and de-aged. Bottom images are original and composite.

the outer edge of shape may correspond to suggested small changes in the face length and shape due to skeletal remodeling as well [3]. The difference image presented in Figure 11 demonstrates changes from 34 to 70 in an individual. Regions of change include the center forehead where documented rhytids and ptosis occur. Just inside of the orbital regions, changes are indicated, such as are present in the glabellar rhytidosis that occurs there. Regions above, below, and around the eyes also indicate change represented by the aging model that correspond to the areas where lid ptosis and rhytidosis and lateral

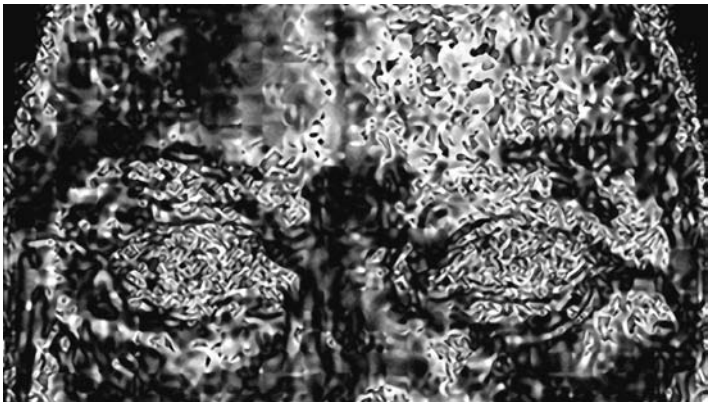

**FIGURE 11** Aging effects, upper facial region, as demonstrated by difference of progression.

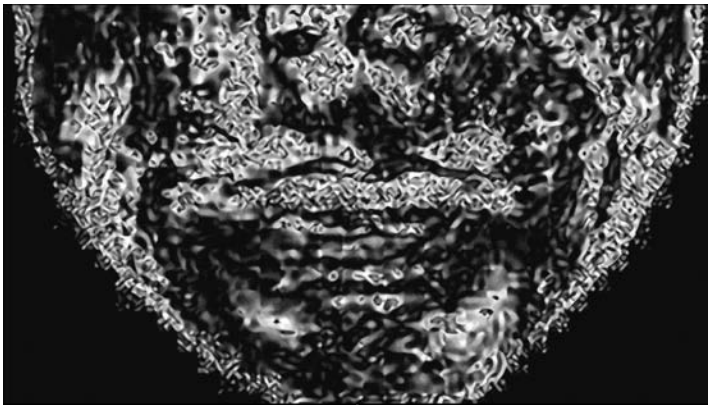

**FIGURE 12** Aging effects, lower region, as demonstrated by difference of progression.

canthal rhytidosis occur. In Figure 12, the lower region, similar comparisons may be made. Change is evident in the nasolabial regions that typically develop creases in older age; change is also apparent in the lip regions where thinning and atrophy often occurs; and some change is evident in the chin region where ptosis and retraction occurs [3, 4].

## 3 RESEARCH DIRECTIONS

The temporal results of FRVT 2000 show that recognizing faces from images taken more than a year apart remains an active area of research. Given the inadequacy of the existing databases, emphasis should be laid on significant data collection—both in breadth and depth of individuals which is the approach being sought by the developers of MORPH [33] and the collection work by Notre Dame's Kevin Bowyer and Patrick Flynn.

Some previous work in the area of growth and development centered on the deformations of bony changes as modeled with cardioidal strain maps, [43, 44] are arising for the study and modeling of adult age-progression. Cardioidal strain transformations can be described as geometric transformations of the face. Although this approach has been predominately used to model cranioskeletal changes of the face due to growth and development, researchers are applying this method to soft tissue (texture) deformation [7].

Fundamentally, the objective is to create face recognition (FR) systems that are resilient to adult age-progression by exploiting a feature space that is invariant over time; however, there has been a paucity of work in this area. Therefore, work in developing aggregate systems as in synthetic templates must continue. To this end, research should be directed toward quantifying the performance of FR systems on existing databases, generating metrics to judge synthesized age-progressed likeness, investigating and authenticating various aging techniques, and modeling age-progression with more input from metadata. From this work, a deeper understanding of aging will drive the development of age-robust FR systems.

To encourage more work in this critical area, more attention should be directed to this problem via workshops, symposia, and grand challenges. Finally, more funding should be made available in this active area of research (US and European Union funding of

this problem has dwindled whereas corporate research dollars are on the rise in many Asian countries).

## 1 INTRODUCTION

The key step in many current iris pattern recognition algorithms is to transform the iris pattern into a two-dimensional code [1–3]. To eliminate the effect of eye tilt, circular rotation or area-based image registration of the iris pattern is usually necessary in iris matching and identification algorithms [1–3]. Generally, iris recognition systems require

a cooperative subject [3] who willingly stares into a camera for a few seconds. The performance range (from subject to camera) of commercially available iris recognition systems is usually less than 2 ft [4]. Recently, Matey [5] from the Sarnoff Corporation has developed a remote iris recognition system, which can perform iris recognition up to 10 ft. As with other iris cameras, the user must look at the camera while moving toward it. The current functional speed is 1 m/s. Under these conditions, the iris image is obtained with the maximum amount of iris information. On the other hand, for a noncooperative subject, who may be facing away from the camera, only a portion of the iris information may be captured (a partial iris). Partial iris recognition algorithms would be very important in surveillance applications where capturing the entire iris may not be feasible. Little research has been performed in this area. The one-dimensional approach is different. The grayscale invariant local texture pattern (LTP) is developed to extract the local iris features. The one-dimensional (1D) signature is then generated for each iris image. The Du measure is used to evaluate the similarity between a test iris signature and those signatures in the database. The system will output the top $n$ closest matches. This method enables partial iris recognition and is more tolerant of the noise (such as eyelids, eye lashes, and glare), since the system only needs local information for processing instead of global information. In addition, no circular rotation is needed.

## 2 SCIENTIFIC OVERVIEW

Figure 1 shows a general iris recognition system, which is composed of four main modules:

1. Image acquisition. This module captures one or multiple iris image(s) from the subject using an iris camera [1–5]. Typically this is a near-infrared (NIR) camera.
2. Preprocessing. In this step, the image is first enhanced if needed, and then eyelashes, eyelids, pupil, and sclera are detected. With this information, the iris patterns are then extracted from the iris image. Usually, normalization is performed in this step to reduce the effect of pupil contraction or dilation [6–16].
3. Template generation. In this step, feature extraction of the iris is performed. A mathematical model is used to generate the template from the extracted iris patterns. In the literature, there are various approaches to generate the templates [1–16].
4. Pattern recognition. The newly generated iris template is compared with the iris templates in the database using some similarity measure. If a match is found, the iris will be identified.

In 1987, ophthalmologists Flom and Safir first patented an iris recognition system using a manual approach [17], in which the light intensity is manually adjusted to get

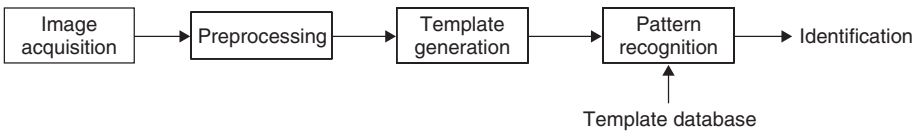

**FIGURE 1** Block diagram of typical iris recognition system.

the same pupil size iris images for iris pattern comparison. In 1994, Daugman invented the first automatic iris recognition system. Since then, various algorithms have been proposed for iris recognition using a waveform that is bounded in both frequency and duration to extract information. Daugman used the phase measure of 2D Gabor wavelets as the iris code. The phase is quantized to four values (2 bits) and the iris code is 256 bytes long. This method has been adopted by Iridian Technologies [1] and is currently used in commercial iris recognition systems. Masek and Kovesi used the Log-Gabor wavelet for iris recognition and made their MATLAB code available [6]. Boles and Boashash [7] used 1D zero-crossing wavelets for encoding iris patterns. Sanchez-Avila et al. [8] used a similar approach. Lim et al. [9] also used the wavelet transform to extract features from the iris region. Both the Gabor wavelet and the Haar wavelet are used as the mother wavelet. Muron et al. [10] have analyzed iris patterns in the frequency domain using the Fourier transform. Wildes et al. decomposed the iris region by constructing a Laplacian pyramid from an iris image [11]. Ma et al. [12] have designed a series of Gabor-wavelet-like spatial domain filters to analyze and extract iris pattern information. This was later followed by their iris recognition algorithms based on local intensity variation [13]. Recently, the authors designed a local texture analysis algorithm to calculate the LTP of iris images to generate a 1D iris template [14]. This approach relaxed the requirement of a significant portion of the iris for identification and recognition [15]. Some researchers have used independent component analysis (ICA) or principle component analysis (PCA) [16].

The methods used to perform template matching can be grouped into two categories: binary matching and nonbinary matching. Daugman [1] encodes the iris patterns into binary numbers. Then the Hamming distance [1] is calculated between the input iris template and iris templates in the database. Many other methods also encode the iris patterns into binary numbers. Hamming distance and Euclidean distance methods are the popularly used binary matching methods. Wildes et al. [11] used the Laplacian pyramids to represent the iris patterns, and the normalized correlation method is used for template matching [11]. In 1D method, Du measure is developed to calculate the similarities between two iris templates.

In terms of the number of dimensions of iris template, these algorithms can be grouped into multidimensional methods [11], two-dimensional (2D) methods [1, 12], and 1D methods [7, 14]. For the 1D cases, both methods [7, 14] transform the iris images to polar coordinates; however, their ways [7] of generating the 1D iris templates are very different. Ma et al. [12] generated the 1D iris signals from successive horizontal scan lines in the polar axis image and concatenated them to constitute an ordered 1D binary vector. The circular rotation would be needed at template matching stage. Du et al. [14] have a different approach. They used normalized image to compute the LTP values, which results in a 2D array of values with the same dimensions as the polar image. Each row of this LTP array becomes an element in the 1D template vector. In this way, the 1D template generated is rotation invariant [14].

## 3 ONE-DIMENSIONAL IRIS RECOGNITION SYSTEM ARCHITECTURE

The 1D system is composed of the following modules: iris acquisition, preprocessing, mask generation, LTP, iris signature generation, enrollment, iris identification, and iris signature database. The system architecture is depicted in Figure 2, and is described in the following sections.

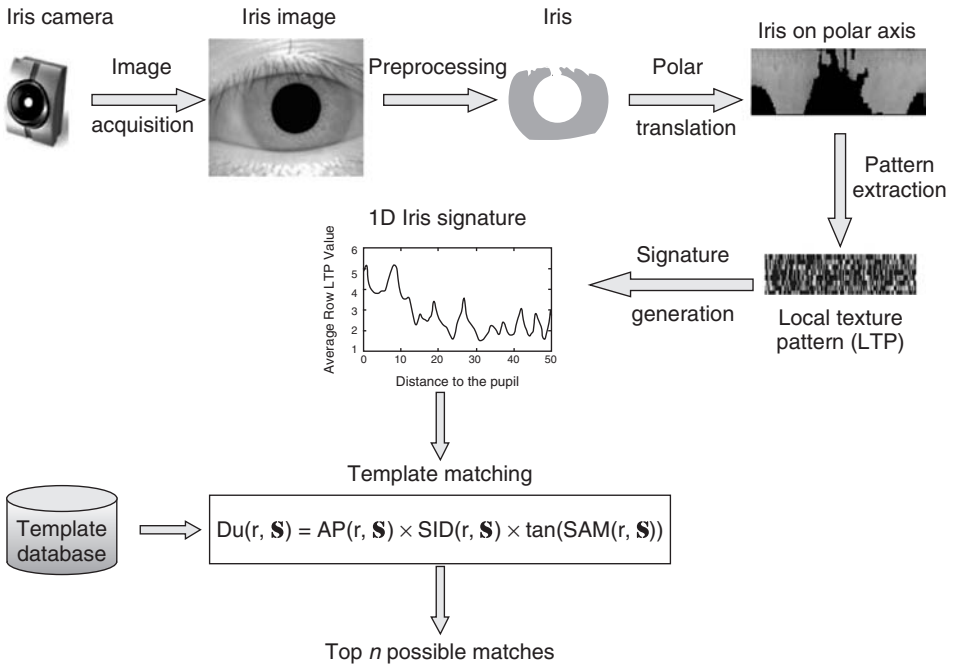

**FIGURE 2** The 1D iris identification system architecture.

### 3.1 Image Acquisition and Preprocessing

***3.1.1 Image Acquisition.*** The iris acquisition module uses an NIR camera to acquire an image of the eye. An NIR camera is used in most iris recognition systems to better capture the underlying features of the iris. The NIR range is especially useful for individuals with dark irises, or with contacts or glasses.

***3.1.2 Image Preprocessing.*** The preprocessing module locates the various components of the iris boundary. In particular, it is to find the inner and outer boundaries of the iris, the eyelids, and eyelashes.

Edge detection method is used to detect the rough inner and outer boundaries of the iris. Sometimes, the edges are not perfect, which may have broken points, spurious edges, and various thicknesses. The curve fitting or model based fitting is used to detect the fine boundaries. Usually, for cooperative users with frontal iris patterns, the pupillary and limbic boundaries are assumed to be circular. In such a case, circular Hough transform could be used. Some researchers have found that even for frontal irises, it could be noncircular. In such cases, ellipse fitting or general curve fitting method is used to solve the problem.

The edges above and below the circle are the edges of eyelids and eyelashes, which are usually identified after the detection of inner and outer boundaries of iris.

As a result of changes in the camera-to-face distance, the size of the same iris taken at different times may vary in the image [1, 14]. Because of stimulation by light or other reasons (such as hippus, the natural continuous movement of the pupil) the pupil may be constricted or dilated [14]. These factors will change the iris resolution, and the actual

distance between the pupillary and the limbic boundary. Normalization is necessary to reduce the effect of these problems. Usually, the distance between the pupillary and limbic boundary should be normalized in all iris images.

The iris area is then transformed using resolution invariant polar coordinates (which are different from the standard polar coordinates used below) to address the potential iris size difference [14]. For each pixel in the original iris image located at rectangular coordinates $(x_i, y_i)$, its polar coordinates $(r_i, \theta_i)$ are calculated as follows:

$$r_i = \frac{\tilde{L}}{L}\left(\sqrt{(x_i - x_0)^2 + (y_i - y_0)^2} - r_0\right) \tag{1}$$

$$\theta_i = \begin{cases} \arcsin\left(\dfrac{y_i - y_0}{x_i - x_0}\right), & y_i \geq y_0 \\ \pi + \arcsin\left(\dfrac{y_i - y_0}{x_i - x_0}\right), & y_i < y_0 \end{cases} \tag{2}$$

Here, $(x_0, y_0)$ is the center of the pupil, $r_0$ is the radius of the pupil, $L$ is the actual distance between the pupillary and limbic boundary in the original image, and $\tilde{L}$ is the normalized distance between the inner and outer boundaries of the iris. Here, it is assumed that the inner and outer boundaries are circular and they share same center. If they share a different center, the calculation principle will be similar to this approach, but it will be a little more complex. Usually, the center difference between the inner and outer boundaries for a frontal iris is very small. For a nonfrontal iris, it could be very different. In that case, their shape would not be circular and the transfer function could be much more complicated.

The location of the boundaries of eyelids and eyelashes is transformed to the respective polar coordinates. In this way, a mask for the iris in polar coordinates is generated.

### 3.2 Computation of Local Texture Patterns (LTP)

Analyzing iris patterns is a key step in iris pattern recognition and verification. A major problem in analyzing iris pattern (iris texture) images is that they are often not uniform due to variations in orientation, scale, contrast, and/or illumination. To solve the problem of illumination (grayscale) variations, the grayscale invariant LTP is developed.

The LTP computation begins with the definition of two windows. Let $T$ be a set of pixels inside a window and let $B$ be the center subset of pixels in window $T$. The grayscale value of the window $T$ is subtracted from the grayscale values of the pixels in the window $B$ to form the LTP for the pixels of set $B$.

Window $T$ is selected slightly larger than window $B$ so that the local mean be can be a better approximation to the true mean value and is less affected by noise. The $T$ windows overlap to reduce any edge effects of windowing. In addition, by computing LTPs using an overlapping $T$ window, the effects of noise on the LTP function is reduced.

After applying the mask to the iris pattern in the invariant resolution polar coordinates, the LTP module generates the local iris patterns. Note that the left-most column of the iris image in polar coordinates wraps around to the right-most column, so there are no actual left or right edges that would introduce artifacts.

### 3.3 1D Iris Signature Generation Module

After local iris patterns are calculated by the LTP module, the iris signature generation module will generate a 1D signature for each iris image by averaging the LTP values of each row. The generated 1D iris signatures are rotation invariant.

This is very different from any other iris templates or signatures, which are rotation dependent. Circular rotation or special registration is needed for traditional approaches in the pattern matching/identification step. Usually, this registration will pose a limitation for the angle of the eye tilt. For example, Daugman's method [1] requires an eye tilt less than $45^{\circ}$ in both directions.

For an iris pattern to be recognizable in the system, it should be enrolled in the database. Enrollment usually takes multiple iris images of the same iris to register and generate the enrollment iris patterns. It could be single or multiple iris images. In general, the iris signature generated from multiple iris images would be more robust than that generated from single iris image. But, it could take longer time to enroll if multiple iris images were used.

### 3.4 Template Matching

The spectral angle mapper (SAM) [17] has been widely used as a spectral similarity measure for multi/hyperspectral signals. The SAM measures the angle between the spectral vectors $\mathbf{r} = (r_1, r_2, \ldots, r_L)^{\mathrm{T}}$ and $\mathbf{s} = (\mathrm{s}_1, \mathrm{s}_2, \ldots, \mathrm{s}_{\mathrm{L}})^{\mathrm{T}}$ and is given as

$$\mathrm{SAM}(\mathbf{r}, \mathbf{s}) = \cos^{-1}\left(\frac{\langle \mathbf{r}, \mathbf{s} \rangle}{||\mathbf{r}||_2 \times ||\mathbf{s}||_2}\right) \tag{3}$$

Here, $\langle \mathbf{r}, \mathbf{s} \rangle$ is the inner product of vectors $\mathbf{r}$ and $\mathbf{s}$,

$$\langle \mathbf{r}, \mathbf{s} \rangle = \sum\nolimits_{i=1}^{L} r_i s_i \tag{4}$$

$||\mathbf{r}||_2$ and $||\mathbf{s}||_2$ are two norms of vectors $\mathbf{r}$ and $\mathbf{s}$. The two norm is defined as

$$||\mathbf{x}||_2 = \sqrt{\langle \mathbf{x}, \mathbf{x} \rangle} \tag{5}$$

Let $\mathbf{p} = (p_1, p_2, \ldots, p_L)^{\mathrm{T}}$ and $\mathbf{q} = (q_1, q_2, \ldots, q_L)^{\mathrm{T}}$ be the two probability mass functions generated by vectors $\mathbf{r}$ and $\mathbf{s}$. The spectral information divergence (SID) [14, 16] between vectors $\mathbf{r}$ and $\mathbf{s}$ is defined as

$$\mathrm{SID}(\mathbf{r}, \mathbf{s}) = D(\mathbf{p}||\mathbf{q}) + D(\mathbf{q}||\mathbf{p}) \tag{6}$$

Here, $D(\mathbf{p}||\mathbf{q})$ is the relative entropy (also known as *Kullback–Leibler information measure*) [14, 16] of $\mathbf{q}$ with respect to $\mathbf{p}$, where

$$D(\mathbf{p}||\mathbf{q}) = \sum\nolimits_{j=1}^{L} p_j \log(p_j/q_j) \tag{7}$$

Also, $D(\mathbf{q}||\mathbf{p})$ is the relative entropy of $\mathbf{p}$ with respect to $\mathbf{q}$, where

$$D(\mathbf{q}||\mathbf{p}) = \sum\nolimits_{j=1}^{L} q_j \log(q_j/p_j) \tag{8}$$

Note that $D(\mathbf{p}||\mathbf{q})$ is usually different from $D(\mathbf{q}||\mathbf{p})$. From information theory, we know that $D(\mathbf{q}||\mathbf{p})$ and $D(\mathbf{p}||\mathbf{q})$ are always nonnegative.

Recently, Du et al. [14] developed the (SID,SAM)-mixed measure. It is defined as

$$\text{mixed measure} = \left[D(\mathbf{q}||\mathbf{p}) + D(\mathbf{p}||\mathbf{q})\right] \times \tan\left[\cos^{-1}\left(\frac{\langle \mathbf{r}, \mathbf{s}\rangle}{||\mathbf{r}|| \times ||\mathbf{s}||}\right)\right] \tag{9}$$

The spectral discriminability of such a mixed measure is greatly enhanced by multiplexing the spectral abilities of the two measures [18]. However, it does not consider the energy difference. A better measure of similarity is given by the *Du* measure, which is defined as

$$\text{Du}(\mathbf{r},\mathbf{s}) = \text{APD}(\mathbf{r}, \mathbf{s}) \times \text{mixed measure} \tag{10}$$

where APD is the average power difference. Here instead of using the two norm, we use the single norm. In this way, the effect of the noise in some dimensions relative to the overall noise will be reduced. The APD is found as follows:

$$\text{APD}(\mathbf{r}, \mathbf{s}) = \frac{1}{N}||\mathbf{r} - \mathbf{s}||_1 \tag{11}$$

where $||\mathbf{x}||_1$ is the single norm defined by: $||\mathbf{x}||_1 = \sum_i |x_i|$. In this equation, $N$ is the total number of nonzero pairs of $r_i$ and $s_i$. In this way, the Du measure is defined as

$$\text{Du(r,s)} = \frac{1}{N} \times ||\mathbf{r} - \mathbf{s}||_1 \times \left[D(\mathbf{q}||\mathbf{p}) + D(\mathbf{p}||\mathbf{q})\right] \times \tan\left[\cos^{-1}\left(\frac{\langle \mathbf{r}, \mathbf{s}\rangle}{||\mathbf{r}|| \times ||\mathbf{s}||}\right)\right] \tag{12}$$

The Du measure is shown to be an effective measure of the similarity between two iris signatures because it takes three important perspectives of signature similarities into consideration: energy, angle, and information.

When an iris image is presented for identification, its iris signature is generated by the iris signature generation module, and it is compared with the enrolled iris signatures in the database using Du measurement. Each iris signature is a vector. Let us assume that two signatures to be compared are vectors $\mathbf{r}$ and $\mathbf{s}$ with same dimensions. Du measurement score is the result of product of three scores: *SAM*, *SID*, and *APD*.

The smaller the Du measurement score is, the closer the two signatures would be. In this way, this module outputs the $n$ closest matches from the database, where $n$ is selected by the user.

## 4 PARTIAL IRIS ANALYSIS USING 1D IRIS RECOGNITION METHOD

Generally, iris recognition systems require a cooperative subject [1–3] who willingly stares into a camera for a few seconds. Recently, Matey et al. from the Sarnoff Corporation developed a remote iris recognition system, which can perform iris recognition up to 10 ft. Different from conventional iris cameras, their iris camera is mounted with a telescope-like lens and stronger IR illuminator. As with other iris cameras, the user must look at the camera while moving toward it. The current functional speed is 1 m/s. Under these conditions, the iris image is obtained with the maximum amount of iris information. On the other hand, for a noncooperative subject who may be facing away

from the camera, only a portion of the iris information may be captured (a partial iris). Partial iris recognition algorithms would be very important in surveillance applications where capturing the entire iris may not be feasible.

In a partial iris image, depending on the percentage of the iris image available, it could be very difficult or even impossible to detect the pupil, the limbic boundary, the eyelids and eyelashes. The partial iris segmentation itself could be a challenging research topic. The purpose is to analyze the use of partial iris patterns. Therefore, a full iris image is used to generate the partial iris image as follows:

- Tear duct-to-outside: The "tear duct-to-outside" model gradually exposes the iris beginning at the near tear duct side and ending at the outside part of the eye. For the subject's left eye, this corresponds to the "left-to-right" model and for the subject's right eye, it would be the "right-to-left" model.
- Outside-to-tear duct: The reverse direction of the "tear duct-to-outside" model.
- Radial outside-to-inside.
- Radial inside-to-outside.

It is important to distinguish between left and right eye, and tear duct-to-outside and outside-to-tear duct because the eyelids tend to cover most of the iris on the side closer to the tear duct.

In this system, we first preprocess the full iris image to identify the iris area and determine pupil center, pupil radius, and limbic radius. In addition, eyelids and eyelashes are detected. These parameters are combined with the information available in the partial iris image to extract the partial iris pattern and to normalize the iris. The pupil may be contracted or dilated due to stimulation by light or other reasons (such as hippus, the natural continuous movement of the pupil). Accordingly, the distance between the pupillary and the limbic boundary would vary. As a result, the resolution of the same iris would change when taken at different times. To solve this problem, the partial iris must be normalized. The parameters such as the center and the radius of the pupil and the radius of the limbic boundary are obtained a priori from the full iris image. After these parameters are determined, the location of occluded iris patterns are zeroed and would not be used neither when generating the template nor for matching.

The experimental results show that a more distinguishable and individually unique features are found in the inner rings of the iris. As expected, the experimental results also show that the eyelids and eyelashes detrimentally affect the iris recognition results. There are minor differences between races, but this difference does not largely impact the iris recognition accuracy.

It is also observed that with the exploring of more percentage of the iris patterns, the increase in speed of the accuracy rate has been reduced. Especially, when the exploring of 45% iris patterns (from tear duct-to-outside), we can achieve very decent accuracy compared to full iris patterns (in rank 5 or rank 10 cases).

For surveillance, it is more likely that the eye away from the tear duct would be captured. This is the more challenging scenario, but the results show that it is still possible. The results show that a partial iris image can be used for human recognition when providing a ranked output, such as rank 5 or rank 10 system. Finally, the experimental results show that a partial iris image could be used for human identification (rank 1) with limited accuracy.

## 5 RESEARCH DIRECTIONS

The 1D iris recognition method differs from current approaches to iris recognition in several ways. First, it generates a 1D iris signature that is translation, rotation, and illumination invariant. The iris patterns or signatures generated by traditional methods are rotation dependent [6–13]. Circular rotation or special registrations are necessary for pattern matching/identification, and usually there is a limit regarding the angle of the eye tilt [1]. However, this method will relax this limitation since the signatures are rotation invariant. Since the generated iris signature does not have all the feature information, the recognition accuracy is not very high. In the future, the improvement to have more feature information in the signature could help to improve the recognition accuracy. In general, the recognition accuracy could be largely affected by the quality of iris images. Incorporating the quality measures in the iris recognition system could help to improve the accuracy.

## 1 INTRODUCTION

Advances in hyperspectral (HS) and multispectral (MS) sensing and imaging in the infrared (IR) spectrum have enabled numerous remote-sensing applications. These include military surveillance (i.e. target recognition, identification, and classification), medical imaging (i.e. medical diagnosis), and monitoring geographical terrain, only to name a few. Conventional HS/MS systems offer spectral information of a scene (target or an agent) in a spectral band by sensing a wide range of narrow segments of the IR spectrum in a spectral range of interest. This can be achieved by using a broadband IR detector in conjunction with dispersive optics (e.g. a bank of IR optical filters) that can be utilized to specify the spectral bands to be sensed. Alternatively, multiple sensors, each sensitive to a designated spectral range, can be employed to sense a wide spectral range. However, either one of these complex conventional methods is of relatively large physical size and high cost. Nanoscale and spectrally adaptable sensors are emerging as a highly desirable alternative to conventional MS/HS sensing strategies that feature simplicity through its single-detector nature (or array of identically fabricated detectors)

without requiring dispersive elements. To this end, a new class of IR photodetectors based on nanoscale epitaxial quantum dots (QDs) have recently been proposed and developed [1, 2]. A key feature of this technology is that it exploits intersubband transitions between quantum-confined energy levels in a self-assembled dots-in-a-well (DWELL) structure in an InAs/GaAs/$Al_XGa_{1-X}As$ semiconductor material system [3]. Potential advantages of this detector technology are low dark current, high operating temperature, and notably bias-controlled tunability [4]. The quantum-confined Stark effect applied to the system comprising dots in an asymmetric well results in a bias-dependent spectral response and also introduces a red shift (spectral shift) with significant spectral overlap [5] as the bias is varied in nominal range. Hence, a single photodetector can be operated as multiple detectors simply by applying different bias: the bias-dependent photocurrents of a single detector can be regarded as the outputs, resulting from spectrally overlapping bands. Recently, DWELL-based focal plane array (FPA) grown and processed at the Center for High Technology Materials (CHTM) at the University of New Mexico had successfully demonstrated multicolor sensing capability [6] in both midwave infrared (MWIR) and long-wave infrared (LWIR) regions. Figure 1 shows representative imagery showing the DWELL-based FPA's capability to sense MWIR and LWIR radiation.

In order to maximally exploit the features of bias-dependent and spectrally overlapping spectra from the DWELL photodetector, two sets of signal-processing algorithms were developed and tested to further bring about the following two extended enabling functionalities that are based on post-processing of data. The first is the capability for continuous spectral tuning [7–9], which enables a so-called *DWELL-based algorithmic spectrometer* and the second is the capability for application-specific, optimal hyperspectral feature selection, which, in turn, enables target recognition [10]. The rationale behind either one of these algorithms is to judiciously fuse multiple bias-dependent photocurrents from a single DWELL detector based on precise mathematical rules.

In this article, we report the principles, fabrication, and operation of the spectrally agile and bias-tunable DWELL photodetector. Device growth and processing are briefly reviewed, followed by results on device characterization. Device optimization for improving the DWELL's operating temperature is also described. In addition, two key post-processing strategies for maximal data exploitation are also reviewed and analyzed: the DWELL-based algorithmic spectrometer and hyperspectral feature selection for target recognition.

**FIGURE 1** Two-color image of a DWELL-based FPA in (a) MWIR (3–5 μm) and (b) LWIR (8–12 μm).

## 2 PRINCIPLE OF OPERATION FOR DWELL PHOTODETECTORS

A DWELL detector is a smart hybrid of conventional quantum well (QW) and QD infrared photodetectors. In a heterostructure, InAs QDs are embedded in InGaAs/GaAs multiple QWs as shown in Figure 2 [9]. Just as conventional QD detectors, a DWELL detector is inherently sensitive to normal-incidence radiation and photons. Lower dark current levels are expected since the ground state is lowered with respect to GaAs band edge. Longer intersubband relaxation times in a DWELL structure can achieve a relatively high detectivity [11, 12]. In addition, the reduced thermionic emission inherent in the DWELL technology leads to higher operating temperatures. Due to the quantum-confined Stark effect, a bias-dependent spectral response is evident depending upon the asymmetric electronic potential of a geometrically asymmetric DWELL structure. Two main attributes of this geometry are the shape of the dot and the different thicknesses of the QW above and below the dot, which together lead to variation of the local potential as a function of the applied bias. A DWELL detector could provide better control over the operating wavelength and nature of the allowable energy transitions (bound-to-bound, bound-to-quasi-bound, and bound-to-continuum (barrier)) as shown in Figure 3 [9]. All the DWELL devices considered in this article were fabricated and characterized at CHTM.

### 2.1 Brief Descriptions of Device Growth and Processing

The DWELL structures were grown by V-80 molecular-beam epitaxy (MBE) system, with an $As_2$ cracker source. An average of 2.4 monolayers of InAs dots were deposited on the sample with a rate of 0.053 ML/s. Then the dots were Si-doped at a level of $1–5 \times 10^{10}$ cm$^{-2}$. DWELL consists of 30 stacks of InAs/GaAs/AlGaAs heterostructures between two $n^+$ GaAs contact layers. DWELL detectors were then processed using standard contact-lithography, plasma-etching, and metallization techniques in a class 100

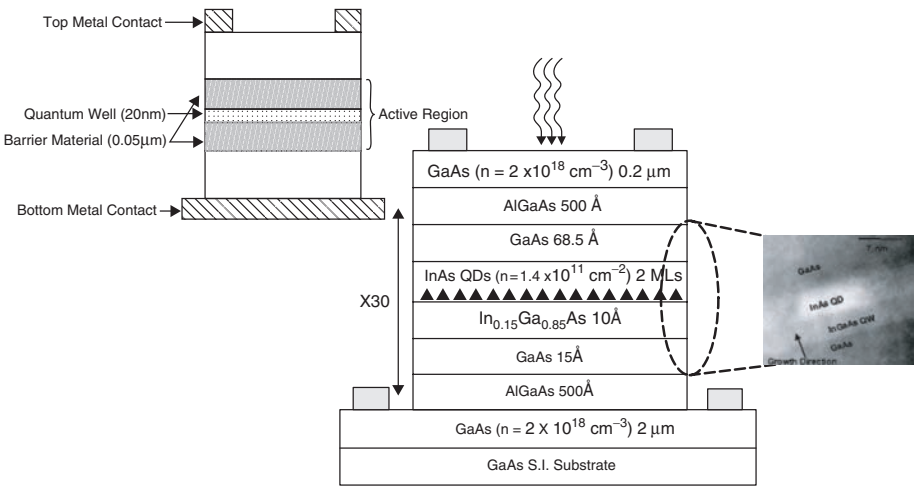

**FIGURE 2** General schematic of the DWELL heterostructure (top, left), example of the DWELL growth schematic (middle) and cross-sectional transmission electron microscopy (TEM) image (right) (adapted from Fig. 1 in Ref. 9).

clean-room environment. Each 400 μm square n-i-n mesas with top pixel apertures, ranging from 25 to 300 μm in diameter, were lithographically defined in the top metal contact [4, 9].

### 2.2 Device Characterization

Spectral response measurements were performed on single pixel InGaAs-DWELL detectors with a Nicolet 870 FTIR (Fourier transform infrared) spectrometer and a Keithley 428 current amplifier, which controls the electrical bias to the detectors. Multiple measurements of experimental photocurrents and dark currents are taken at different biases using a HP parameter analyzer. The bias-dependent spectral measurements and the corresponding experimental photocurrents of the DWELL detector are shown in Figure 4 [9]. Due to a red shift (spectral shift), there exists two different peaks at LWIR region, one around 9.5 μm with negative bias and the other at 10.5 μm with positive bias. However, the drawback of the current DWELL is the limited operating temperature because of the dominance of the dark current at higher device temperatures [9]. In Figure 5 [9], the spectral response of DWELL starts degrading remarkably as the operating temperature of the device exceeds 60 K. Also the working range of applied bias becomes narrower. Especially at 77 K, it is to be noted that no spectral variation is observed for the applied bias range. More details of the characterization can be found in Ref. 9.

### 2.3 Higher Operating Temperature DWELL ("Double DWELL")

Higher temperature operation is most crucial to reduce device size and cost since the required cooling system is bulky and expensive. By achieving up to near-room temperature levels, this DWELL photodetector can be more effective due to its tunability as compared to the current state of art detectors. To further increase the operating temperature, the present InAs quantum dots/InGaAs/GaAs/GaAs/AlGaAs DWELL growth structure is further modified by the increase in the shoulder of the GaAs well and the addition of shoulders on both sides of the InGaAs well, so it becomes the complete

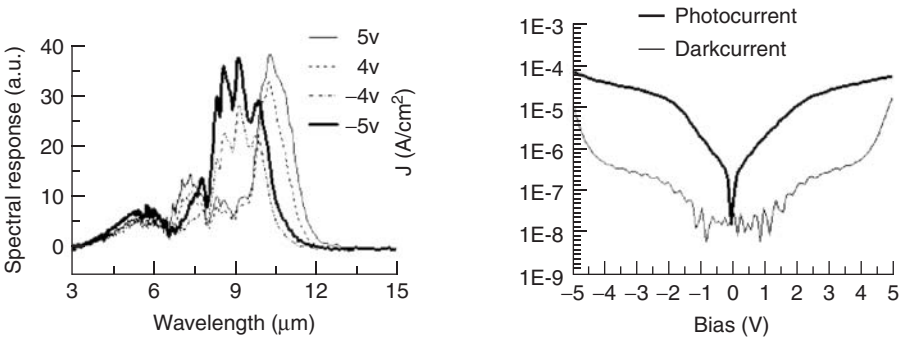

**FIGURE 4** Bias-dependent spectral responses of DWELL detector (left) and its photocurrent characteristic (right) (adapted from Fig. 6 in Ref. 9).

double DWELL (DDWELL) structure. The optimizations of the growth procedure and the processing technique can potentially lower the dark current level to obtain higher operating temperature of the device. In Figure 6 [11, 12], the bias-dependent DDWELL spectral response is observed until the device temperature of 120 K and the spectral shift are still present in LWIR. However, at 120 K, the device photocurrent is dominated by noise mainly due to the high dark current level.

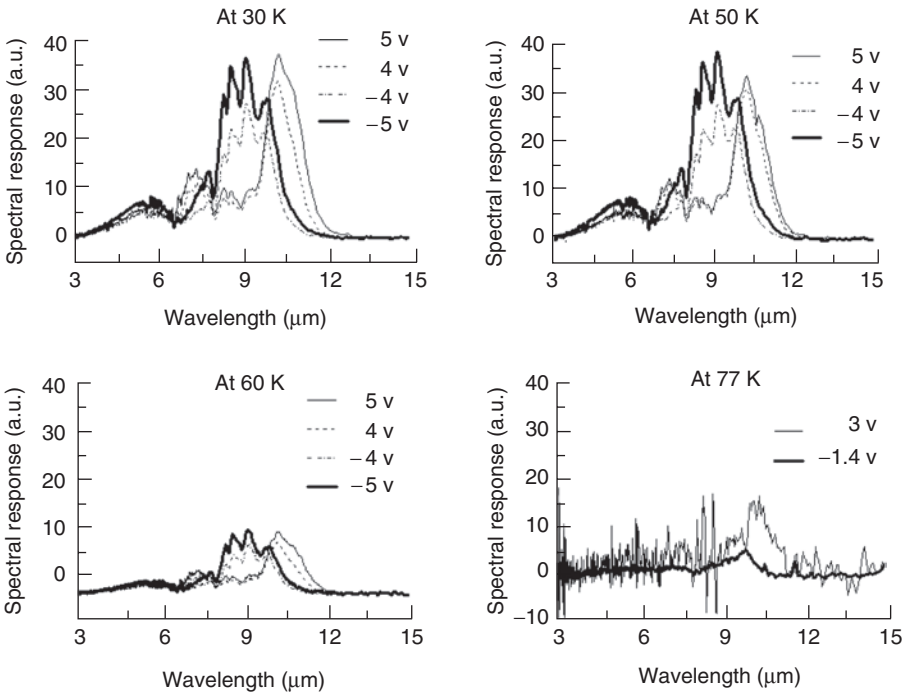

**FIGURE 5** Bias-dependent spectral responses of DWELL detector as a function of different operating temperatures at 30 K (top, left), 50 K (top, right), 60 K (bottom, left), and 77 K (bottom, right) (adapted from Fig. 7 in Ref. 9).

## 3 DESCRIPTION OF THE DWELL -BASED ALGORITHMIC SPECTROMETER

The concept of the spectral-tuning algorithm in conjunction with the DWELL-based detector is thoroughly reviewed here to describe the role of algorithmic spectrometer, drawing freely from our earlier published works [7, 8]. Assume that the object (target) of interest is illuminated by a black-body broadband radiation source and a DWELL detector probes the illuminated object applying different electrical biases, producing a group of bias-dependent photocurrents. The goal is to exploit these bias-dependent photocurrents to estimate (approximately reconstruct) the spectrum of the object of interest without the utilization of any physical dispersive optics or a spectrometer. The spectral estimation procedure is described as follows. First, a series of hypothetical, narrowband tuning filters, each with a prescribed center wavelength and transmittance, are defined by sweeping across the desired center wavelength of narrowband tuning filter in a spectral region of interest. Second, a set of superposition weights are calculated by estimating the spectrum of a DWELL detector with the choice of the tuning filters. Third, for each defined filter, the spectral reconstruction of object is performed by forming a weighted superposition of the DWELL spectral responses with predetermined superposition weights. With this step completed, the so-called "*synthesized photocurrent*", defined as the target reconstruction with weights, is shown to best approximate the ideal photocurrent obtained by sensing the same object of interest using an ideal broadband (with a spectrally flat response) detector

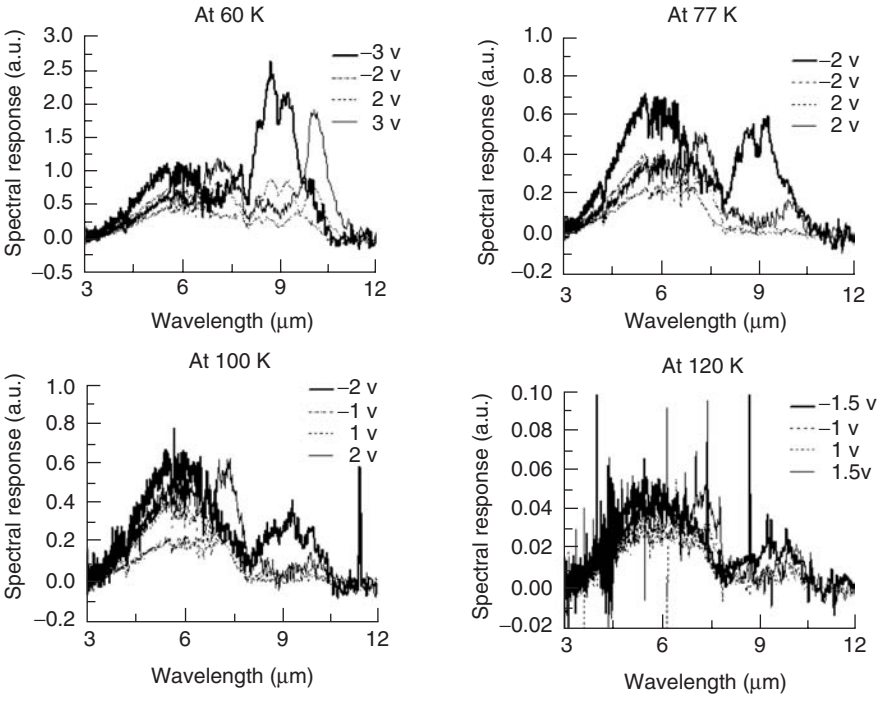

**FIGURE 6** Bias-dependent spectral responses of DDWELL detector as a function of different operating temperatures at 60 K (top, left), 77 K (top, right), 100 K (bottom, left), and 120 K (bottom, right) (adapted from Refs. 11, 12).

looking at the object through the spectral tuning filter. This approximation results in the minimization of the mean-square-error (MSE) between the synthesized photocurrent and the ideal response. Finally, the third step is repeated for every tuning wavelength and the spectrum is reconstructed within the prescribed wavelength range. In Figure 7 [9], the conventional spectrometer with an ideal broadband IR detector and a group of optical IR filters is schematically compared with the proposed algorithmic spectrometer for describing their functional equivalence.

### 3.1 Mathematical Description

Mathematically, the reconstructed target spectrum $\hat{I}_{\lambda_n}$ (Eq. (1) in Ref. 9) at a desired tuning wavelength $\lambda_n$ is formulated as

$$\hat{I}_{\lambda_n} = \sum_{i=1}^{k} w_{n,i} I_i \tag{1}$$

The weight vector, $\mathbf{w}_n = [w_{n,1}, \ldots, w_{n,K}]^{\mathrm{T}}$, is determined by computing the following expression (Eq. (18) in Ref. 8)

$$\mathbf{w}_n = [\mathbf{A}^{\mathrm{T}}\mathbf{A} + \Phi + \alpha\mathbf{Q}^{\mathrm{T}}\mathbf{A}^{\mathrm{T}}\mathbf{A}\mathbf{Q}]^{-1}\,[\mathbf{A}^{\mathrm{T}}\mathbf{r}_{\lambda_n}], \tag{2}$$

where $\mathbf{A}$ is a set of spectral responses of DWELL $= [\mathbf{R}_1, \ldots, \mathbf{R}_K]$ and each $\mathbf{R}_k = [R_k(\lambda_{\min}), \ldots, R_k(\lambda_{\max})]^{\mathrm{T}}$, ranging from a minimum value of $\lambda$ ($\lambda_{\min}$) to a maximum value of $\lambda$ ($\lambda_{\max}$). In addition, $\Phi$ is a diagonal noise-equivalent matrix whose $k$th diagonal entry is $\mathbf{R}_k{}^{\mathrm{T}}\mathbf{R}_k/\mathrm{SNR}_k{}^2$, where $\mathrm{SNR}_k$ represents the signal-to-noise ratio determined by the following formula (Eq. (3) in [9]),

$$\mathrm{SNR}_k = y_{p,k}/\sigma_{N,k}, \tag{3}$$

where $y_{p,k}$ is the experimentally averaged photocurrent (over 100 realizations) and $\sigma_{N,k}$ is the standard deviation of the dark current, also calculated empirically from the dark-current realizations. Then the remaining term named the *regularization term*, $\alpha\mathbf{Q}^{\mathrm{T}}\mathbf{A}^{\mathrm{T}}\mathbf{A}\mathbf{Q}$, limits spurious fluctuations in the approximation, where $\mathbf{Q}$ and $\alpha$ are the Laplacian operator and the regularization weight, respectively.

## 4 EXPERIMENTAL DEMONSTRATION OF ALGORITHMIC SPECTROMETER

Here we review an experimental application of the DWELL-based algorithmic spectrometer drawing from our earlier work reported in Ref. 9. Arbitrarily chosen targets in the LWIR region are considered and examined. First the spectral responses of the DWELL photodetector were measured at different biases varied between $-5$ and 5 V at a temperature of 30 K. Then the corresponding experimental photocurrent and dark current are obtained by illuminating the LWIR target with the FTIR source at each bias. As described in earlier section, measured spectral responses of the DWELL photodetector in conjunction with hypothetical, narrowband tuning filters determine the superposition weights in

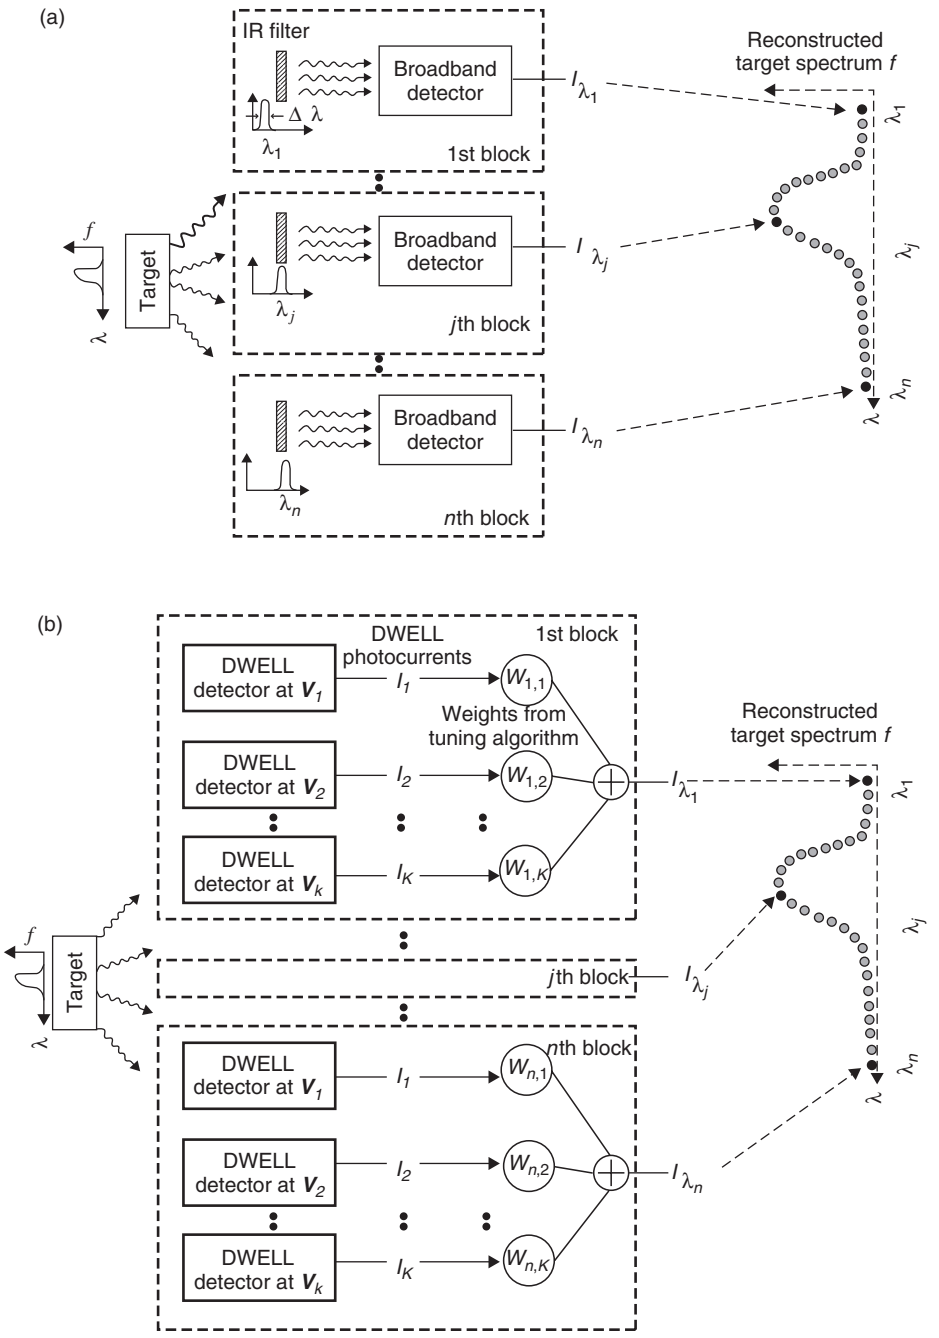

**FIGURE 7** (a) A conventional spectral sensing method using a standard broadband IR detector and a family of optical IR filters. (b) The proposed algorithmic-spectrometer equivalent of (a). Initially, several photocurrents (of the target spectrum $f$) are taken at different bias voltages $v_1 \ldots v_k$. Then, the measured responses at each bias are algebraically combined with predetermined weights $w_{i,n}$ that are used to match a desired filter centered at wavelength $n$. By changing the weights, the effect of different desired filters (similar to the ones used in (a)) is synthesized, albeit, without the use of any optical filters (adapted from Fig. 10 in Ref. 9).

a spectral region of interest. Then the experimentally obtained photocurrents are synthesized to give the weighted superposition representing each reconstructed point of the target at a desired tuning wavelength. The reconstruction results for four different target spectra, shown in Figure 8, are obtained by continuously tuning from 2.55 to 12.5 μm in steps of 0.05 μm. The solid curve is the true spectrum of target sensed by the standard broadband detector; whereas the dotted curve is the experimental reconstruction of algorithmic spectrometer incorporated with DWELL photodetector. The comparison of these two spectra clarifies the validation of algorithmic spectrometer. However, one limitation is evident that since the DWELL detector lacks its spectral information beyond 11.5 μm, the algorithmic spectrometer does not accurately reconstruct the long wavelength edge of target $f_2(\lambda)$ as shown in Figure 8(b).

## 5 REFINING THE ALGORITHMIC SPECTROMETER: REDUCTION OF REQUIRED BIASES AND HIGHER OPERATING TEMPERATURES

In an actual system, however, it may not be practical to use a large number of biases for operating the algorithmic spectrometer due to device limitations and the computational inefficiency as described later. Device limitations are related to the operation of the DWELL photodetector in which a reduction in the operating range of the bias is seen at high operating temperatures. With less biases required by the tuning algorithm, the

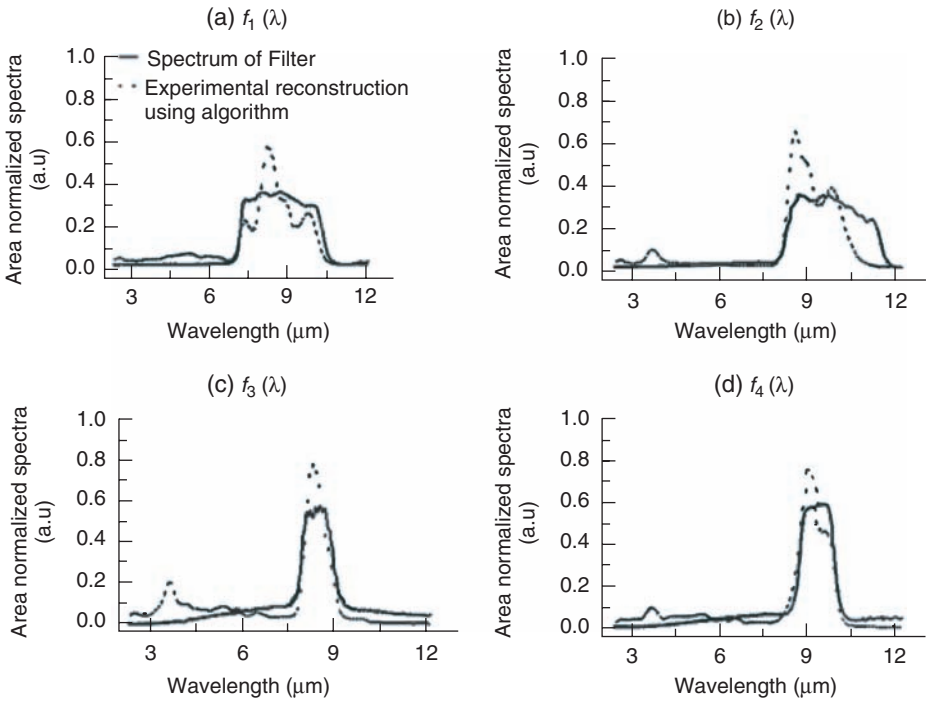

**FIGURE 8** Experimental reconstructions using algorithmic spectrometer incorporated with DWELL detector. Solid curves represent the actual responses of the targets and the dotted curves represent the reconstructed spectra using tuning algorithm (adapted from Fig. 13 in Ref. 9).

implementation of the algorithmic spectrometer simplifies, leading to increased speed, which may be suitable for near real-time applications. To this end, the algorithmic spectrometer is further refined by introducing the bias-selection scheme to reduce the number of required biases for acceptable target reconstruction. Bias-selection [13] is performed as follows: first, we find the threshold for the superposition weights, which can be predetermined from the analysis of the ordinary algorithmic spectrometer. Dominant weights are then selected while others are discarded based on the threshold.

Also, the DDWELL-based detector described earlier is used with this enhanced algorithmic spectrometer to test the performance against the detector operating temperature. Here we first measured the spectral responses of DDWELL detector for 30 biases available in the range between $-5$ and 5 V. The spectral measurement was repeated for different operating temperatures from 60 to 120 K. As illustrated in Figure 6, the operating bias range at 120 K is significantly reduced by the increase in device temperature, causing larger dark currents. Then one of LWIR targets described in Figure 8 was tested for a reconstruction using the algorithmic spectrometer with reduced number of biases; the minimum 10 biases originally from 30 biases were determined and required for achieving the reasonable target reconstruction. This algorithmic target reconstruction was repeated for incremental DDWELL operating temperatures (60, 77, 100, and 120 K). The results shown in Figure 9 are generally good at the device temperatures 60 and 77 K, yet at 100 K or above, the performance of algorithmic spectrometer is significantly degraded due to the lack of spectral information available from the DDWELL detector.

## 6 CANONICAL CORRELATION FEATURE SELECTION ALGORITHM AND ITS APPLICATION TO DWELL DETECTORS

Because of the capability to tune the quantum dot infrared photodetector (QDIP) responsivity continuously in its central wavelength and shape with the applied bias voltage, a single QDIP can be exploited as a multispectral or even hyperspectral IR sensor [8, 10]; the photocurrents measured at different operational biases can be viewed as outputs of different spectral bands. Unlike more traditional sensors, the spectral responsivities of QDIPs are broad $\sim$ μm and overlapping, thereby producing a high level of redundancy at the output photocurrents. Furthermore, the noise level at the photocurrents also varies continuously depending upon the bias applied, yielding band-dependent signal-to-noise ratio (SNR). These attributes of QDIP sensors necessitate the development of alternative methods for spectral feature-selection that will enable more efficient utilization of such sensors [10].

A novel, problem-specific spectral feature-selection algorithm termed the *Canonical Correlation Feature Selection* (CCFS) was rigorously developed for a general class of multispectral/hyperspectral sensors whose bands are both overlapping and noisy [10]. The approach is based on minimum mean-square-error (MMSE) criterion in conjunction with a canonical correlation (CC) analysis framework. The criterion ranks the best linear combinations of noisy and overlapping bands, termed *superposition bands*, guaranteeing minimal distances between each of the centers of the classes and their reconstructions in the space spanned by the sensor's bands [10]. In particular, for a given spectral pattern $p$, the algorithm selects an optimal superposition band, $f = \sum_{i=1}^{k} a_i f_i$, represented by the weight vector $\mathbf{a}^* = (a_1, \ldots, a_k)^T$, defined as solution of the constrained minimization

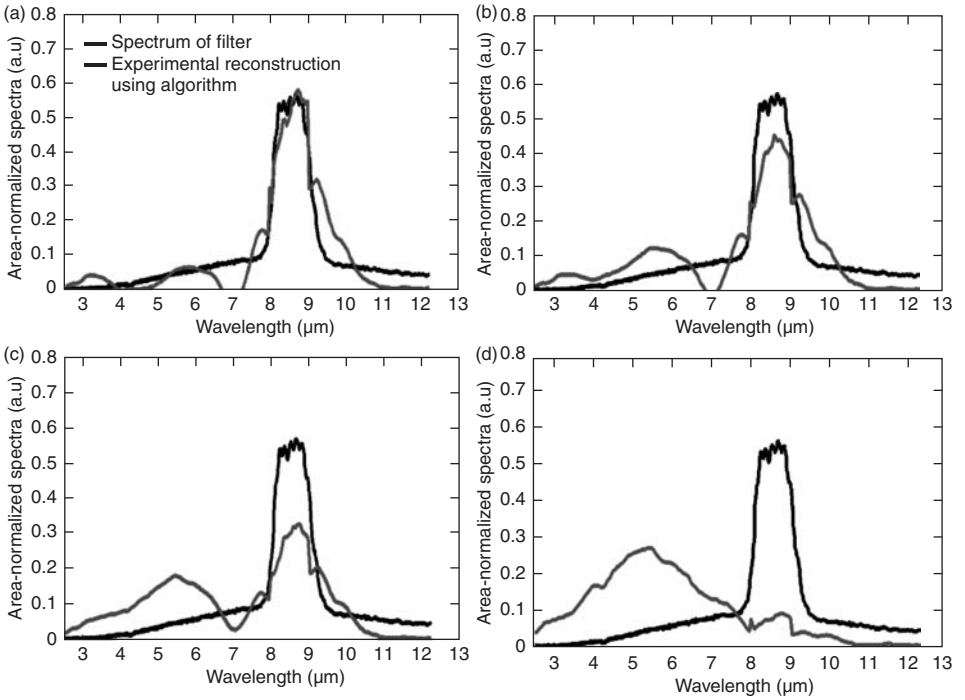

**FIGURE 9** Experimental reconstructions of a LWIR target using algorithmic spectrometer incorporated with DDWELL detector. Black curve represents the actual spectrum of the target and blue curves represent the reconstructed spectra with reduced biases (i.e. 10 biases) at different detector operating temperatures (a) 60 K, (b) 77 K, (c) 100 K and (d) 120 K (adapted from Ref. 12).

problem:

$$\mathbf{a}^* = \underset{\mathbf{a}\in R^K, \|f\|=1}{\arg\min} \; E\left[\left\| p - \sum_{i=1}^{k}\sum_{j=1}^{k} a_i a_j \left(\langle p, f_i\rangle + N_i\right) f_j \right\|^2\right] \tag{4}$$

where $N_i$ is the $i$th noise component associated with the sensor band $f_i$. The quantity

$$\tilde{I} = \sum_{i=1}^{k} a_i \left(\langle p, f_i\rangle + N_i\right) = \sum_{i=1}^{k} a_i I_i \tag{5}$$

is termed a *superposition photocurrent*, and it can be interpreted as the output photocurrent of the superposition band $f$. Moreover, the superposition photocurrent can be viewed as the optimal in an MMSE sense single spectral feature that can represent the spectral pattern $p$ in the space spanned by the sensor bands in the presence of noise.

The concept of optimal superposition band and photocurrent presented in Eq. (4) is then extended to a canonical feature-selection algorithm by utilizing the idea of the CC analysis [10]. Based on a computed sequence of principal angles $\theta_k$ between any two finite-dimensional Euclidean spaces, $U$ and V, the CC analysis yields the so-called *CC coefficients*, $\rho_k = \cos(\theta_k)$, between the two spaces. The first CC coefficient is computed

as $\rho_1 = \max_{i,j} \mathbf{u}_i^T \mathbf{v}_i$, where vectors $\mathbf{u}_i$, $i = 1, \ldots, m$, and $\mathbf{v}_i$, $i = 1, \ldots, n$, are unit length vectors that span the two spaces, respectively [10]. The two vectors for which the maximum is attained are then removed, and $\rho_2$ is computed from the reduced sets of the bases. This process is repeated until one of the remaining subspaces becomes empty.

When the inner product between two vectors is perturbed by additive noise as in the case of the photocurrent seen in Eq. (5), the CC analysis approach cannot be applied directly. A stochastic version of "principal angle" is introduced in Eq. (4) and used for ordering and selection of the optimal spectral features. The superposition band selection procedure described by Eq. (4) is repeated sequentially as many times as the number of the classes of interest, producing a canonical set of superposition bands. Following the general principle of CC analysis, at each stage, the algorithm excludes the class that has been selected in the prior stage from the search for the optimal direction and every superposition band is selected from a subspace of the sensor space that is in the orthogonal complement of the previously selected superposition directions.

Application of the CCFS algorithm to the problem of separability and classification analysis of seven rock classes [10] has demonstrated the efficacy of the proposed approach in a challenging remote-sensing task. A number of spectra of common rock samples in different grain size were selected from the Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) hyperspectral database to create training and two testing data sets. To extend the training and testing data sets, the endmebers in each rock-class were perturbed with different mixing materials, using a simple two-component linear mixing model [10]. QDIP spectral responses measured at different biases voltages varied in the range $-4.2$ to 2.6 V and at a temperature of 30 K were used to simulate the operation of a single-pixel, multispectral DWELL sensor.

In the presence of noise, for different SNR cases (10, 20, 30, and 60 dB) and using Bayesian classifier, the separability and classification results for the CCFS algorithm were compared with four different feature-selection strategies, each using seven spectral features. Here the number of selected superposition features is determined by number of classes of interest—seven. The first strategy was termed *deterministic CCFS* (DCCFS) and it employs the proposed CC feature-selection but without accounting for the photocurrent noise during the feature-selection process. In the second case, termed *noise-adjusted projection pursuit* (NAPP), seven features were extracted using the NAPP algorithm. The last two cases correspond to the classifiers that use seven QDIP and seven Multispectral Thermal Imager (MTI) bands.

From the results presented in Figure 10, right and left, we can conclude that embedding the noise statistics in the canonical feature-selection leads to a significant improvement in the classification. For the first three SNR cases (Fig. 10, right and left) the CCFS algorithm performs almost twice as good as the DCCFS algorithm. In the limiting case of a very high SNR, the performance of the CCFS and DCCFS algorithms becomes almost identical, as expected, and the classification error drops to 10–15%.

Comparison with the NAPP algorithm, as seen in Figure 10, shows that the CCFS algorithm outperforms the NAPP technique in the cases of low (10 dB) and high (60 dB) SNRs confirming further that CCFS offers enhanced robustness with respect to the photocurrent noise. These results indicate a great potential for operating QDIP sensors at higher temperatures, in the range 50–70 K, and thus leading to remote-sensing instruments with reduced size and cost.

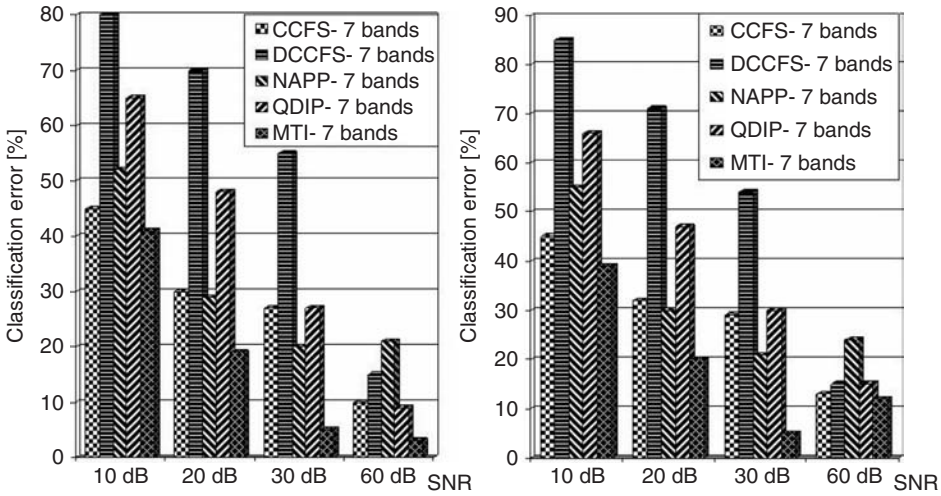

**FIGURE 10** Comparison in rock-type separation for CCFS, DCCFS, NAPP, QDIP bands and MTI bands in presence of noise with average SNR values of 10, 20, 30 and 60 dB. Left: Test Set-1. Right: Test Set-2 (adapted from Fig. 5 in Ref. 10).

# FINDING INADVERTENT RELEASE OF INFORMATION

ROHINI K. SRIHARI

*University at Buffalo, Buffalo, New York*

## 1 INTRODUCTION

Inadvertent release of information is an important aspect of homeland security. Traditional cybersecurity techniques can be used to safeguard unauthorized access to such information, that is, preventing unauthorized users from being able to even see such information. Intrusion detection is an example of such a cybersecurity technique. This

article approaches the problem from a different perspective, namely the content of the information. That is, assuming that the information was accessed through proper means, could a reader be able to gain information that was not meant to be released? A typical example of such a scenario is cross-domain information sharing, where a document classified at a higher level may be inadvertently released to users not authorized to see it. To prevent such situations, techniques that examine the content of the document must be deployed as a backup measure to traditional cross-domain information dissemination security measures. More subtle but equally catastrophic cases of inadvertent information release can occur with publicly disseminated information such as web pages. It is often the case that a document collection, such as a set of web pages, reveals interesting information other than what is explicitly stated. The hidden information may be a consequence of multiple sources and authors working independently, which may pose issues with respect to information security. Although the content on an individual page may be innocuous, inferences across multiple pages could lead to inadvertent information release. This article surveys different scenarios of inadvertent information release along with techniques to prevent such occurrences. It is important to note that in many cases, automatic techniques can be used to suggest instances of sensitive information; the final decision must be taken by a human reviewing the output.

## 2 BACKGROUND

Various approaches have been taken to address this problem depending on the particular scenario of inadvertent information release being considered. In order to fully appreciate the challenges to solving this problem, it is useful to first look in more detail at scenarios for sensitive information as well as different data sources that must be examined. This is followed by a discussion of relevant technologies to this problem.

### 2.1 Sensitive Information

Sensitive information can be explicitly marked on a document basis, or implicitly inferred. There are several definitions put forth for sensitive information by various government agencies, ranging from "information that if released, could pose threats to national security" to a more benign "information to be used on a need-to-know basis". One common source of inadvertent release of information is classified documents, those that have some security classification attached to either the entire document or individual paragraphs. These classifications typically restrict dissemination based on secret, top-secret, no-foreign, and so on, restrictions. This is referred to as *cross-domain dissemination*.

More subtle cases of sensitive information are manifested when no explicit marking is present. For example, a chart that shows the amount of expenditure due to security-related measures at various airports is interesting. Because of this, one could deduce that one airport is more vulnerable than another, a fact that could be exploited for harmful purposes. Similarly, by combining information from multiple announcements about an individual's scheduled public appearances, it may be possible to synthesize a very detailed schedule of his or her itinerary thus creating a potential security risk. Finally, detailed policy guidelines that are publicly debated can sometimes be mined for unintended intelligence such as the conditions for providing seats to (armed) off-duty air marshals.

### 2.2 Data Sources

There are several sources of information that can contribute to inadvertent information release besides explicitly classified material. An important source that must be examined in terms of homeland security interests is publicly accessible web pages. Since an organization attempts to disseminate useful information about its activities, websites often contain valuable and dynamically changing content. The problem can become even more complex due to web pages containing links to pages outside the organization. In such cases, it becomes extremely difficult to detect potential vulnerabilities. E-mail, due to its convenience and preferred mode of communication, is a prime source of inadvertent information release. It is important to consider not only the text within an e-mail (or other document), but also to examine any attachments. Attachments often contain charts and diagrams, which provide quantitative data that could be subjected to data mining and used for criminal intent. Multimedia presentations may reveal identities of key people or other background clues that could be considered sensitive.

### 2.3 Relevant Technologies

Several technologies are applicable to detecting inadvertent release of information. These include machine learning techniques [1], especially text categorization [2]. A text categorization system is trained on numerous examples of hand-annotated documents corresponding to different categories or classes. In order for the system to perform accurately, it must be trained on sufficiently representative and diverse examples. Various text categorization techniques may be utilized, ranging from simpler Naïve Bayes techniques to more sophisticated support vector machines.

Natural language processing (NLP), especially information extraction technology [3], may be used for more in-depth processing of textual content. While text categorization techniques use coarser representations of information content such as word frequencies (known as *bag-of-words* model), NLP techniques are able to detect finer-grained linguistic characteristics. Information extraction techniques are able to detect named entities corresponding to names of people, organizations, locations, and so on. Thus, they are useful in deriving measures of intrinsic information content. Information extraction systems are also able to extract key relationships between entities, for example, that a person is affiliated with a certain organization.

Data mining techniques [4] are useful in applications such as trend analysis. For example, by mining the numeric data associated with expenditure on fortification of the nation's telecommunication systems on a periodic basis, it may be possible to detect aging systems. Data mining techniques take large quantities of typically numeric data as input, and output significant patterns or correlations that are automatically detected. They can also be used to compare different data sets based on temporal or spatial changes.

Finally, state-of-the-art text mining techniques [5] can be used to make inferences between concepts across documents. These techniques were initially proposed for bioinformatics applications, including Swanson's research that discovered connections between fish oil and Raynaud's disease [6, 7]. Text mining techniques have been used in a wide variety of applications ranging from multidocument summarization to detecting aviation accident precursors. They are often based on statistical methods, including latent semantic analysis [8]. More recent text mining approaches use sophisticated machine learning methods based on probabilistic graphical models [9].

## 3 THREATS, CHALLENGES, AND SOLUTIONS

In this section, specific cases of inadvertent information release are discussed along with current approaches for detecting such scenarios.

### 3.1 Inadvertent Cross-Domain Release of Individual Documents

Classified documents are often restricted to certain types of information networks such as SIPRNet and JWICS in order to control restrictions on dissemination to the appropriate domains However, inadvertent release can occur through many channels, a common one being the e-mailing of such a document to an unauthorized person. Several techniques may be brought to bear to address such type of situations. The most obvious is technology related to cybersecurity for the specific purpose of security policy implementation and support. Recognizing that such techniques may not be sufficient, particularly when a document has been incorrectly marked, other techniques must be used as back-up measures. Chief among these are text categorization techniques that can automatically classify documents or individual paragraphs with the appropriate classification level by examining the content.

Although text categorization techniques are robust and can achieve the required levels of accuracy when sufficient training data is available, they have some weaknesses. Such techniques may not be sufficient to capture the intuitive notion that documents containing highly specific information about an individual (such as his contact information) or an organization may be sensitive. NLP techniques, specifically, information extraction techniques are capable of capturing this type of information. Finally, text categorization techniques may not perform well on documents containing charts and diagrams.

### 3.2 Inadvertent Release of Sensitive Information through Hidden Text

There have been cases reported of information being leaked through hidden text or metadata embedded in electronic documents such as Microsoft Word [10]. Examples of hidden text include text from other documents that are automatically opened, e-mail headers, names of document authors, and so on. A case in point was the accidental release of the names of four civil servants who worked on a controversial document related to Iraq in the United Kingdom; these names were part of the hidden text. In order to counter this, various measures are in place ranging from required checks for hidden data to mandated use of document formats such as portable document format (PDF).

### 3.3 Mining of Publicly Accessible Information by Intelligent Agents

This scenario concerns the use of intelligent agents to automatically visit and subsequently mine information from publicly available information such as websites [11]. Reference 12 gives the example of companies providing package tracking numbers over the internet to enable customers to track the status of their purchases. However, such information could be used by another company to gain competitive advantage. It is possible to use a web agent that queries the tracking site for packages through an automatically generated list of valid package numbers. This in turn may lead to valuable information about how the company routes packages, as well as the best business areas geographically, not to

mention actual identities of large accounts. It is not difficult to see how such technologies could pose threats to homeland security if the sites being monitored corresponded to merchant vessel cargo. Thus, the combination of publicly available information and intelligent data mining agents could lead to inadvertent information release.

Several techniques can be used to mitigate the impact of such threats. Organizations should routinely review their system logs to see who has been accessing their site, with the goal of spotting anomalous activity. Misleading information could intentionally be introduced in an attempt to thwart such predators. The lifetime of information should also be limited based on reasonable estimates of genuine use.

### 3.4 Dissemination of Sensitive Information across Multiple Documents

Open source document collections reflect diverse sources and authors; they often reveal interesting information other than what is explicitly stated. The goal of information analysts is to sift through these extensive document collections and find interesting links that connect facts, assertions, or hypotheses that may be otherwise missed. This is the most difficult scenario to handle, since the sensitivity of information is based on inferences across multiple documents. Reference 13 refers to this case of inadvertent information release as *unintended* (or *unapparent* in benign situations) *information revelation* (UIR). Figure 1 illustrates the overall framework for solving this problem. It is assumed that an off-line process has (i) processed a document collection of interest (e.g. a website consisting of hundreds or thousands of pages), (ii) extracted concepts contained in the documents based on an appropriate domain ontology, and (iii) generated a graphical representation of the content where nodes correspond to concepts or topics and edges correspond to associations between concepts. The task of a UIR toolkit is to examine sets of pages (corresponding to sets of important concepts) and generate alerts if inferences can be made that connect these concepts such that the information revealed crosses a threshold.

Although this seems like a hopelessly complex task, significant advances have already been made. Information analysts can use search engines to produce an incidence matrix of pages mapped to keywords or topics. This is illustrated in Table 1. Presumably, analysts are knowledgeable about which keywords or topics are important, and furthermore, which combinations of topics are particularly sensitive. On the basis of the matrix, they can manually inspect pages, or sets of pages, corresponding to key topics. Any page that could lead to inadvertent release of information is either removed or edited. Such a process was actually carried out by the FAA shortly after 9/11. In spite of modern technology such as search engines, the process can still be painstakingly laborious. Since there are many ways in which a particular topic can be expressed, it is necessary to map keywords (reflecting instances of a topic) into the topic category to which it best belongs. Recent advances in topic modeling [14] are very useful in performing this task in a data-driven manner: topic labels are manually assigned based on inspection of the set of keywords.

The UIR solution presented in [13] represents an automated solution to this problem whereby information analysts do not need to manually check multiple pages for potential inferences that could reveal sensitive information. This system focuses on detecting how concepts are linked across multiple text documents by generating an *evidence trail* explaining the connection. A traditional search involving, for example, two or more person names will attempt to find documents mentioning both these individuals. This system focuses on a different interpretation of such a query: what is the best evidence trail across

**TABLE 1 Topic-Document Incidence Matrix**

| Topic | URL1 | URL2 | . . . | E-mail1 | E-mail2 | . . . |
|---|---|---|---|---|---|---|
| Safety control | | | | | | |
| Crosswind correction, anomaly detection, directional control | X[a] | | | X | X | |
| Certification | | | | | | |
| Airworthiness certification, medical certification, and aviation medical examiners | X | X | | | X | |
| FAA regulations | | | | | | |
| Hazardous materials regulations and financial responsibility | | X | | X | | |

[a]X means that the indicated topic has occurred in the corresponding document (or web page, or email . . . ).

documents that explains a connection between these individuals? For example, all may be good golfers. A generalization of this task involves query terms representing general concepts (e.g. indictment and foreign policy). This system uses a hybrid text mining approach combining the robustness of information retrieval systems, with the granularity of information extraction systems. The corpus is first processed by an NLP system; a graphical representation of salient concepts and links between concepts is generated. Links between concepts are generated based on their participation in subject–verb–object relationships. Graph matching is first performed using the query concepts: this results in a matching subgraph where concept chains reflect virtual edges between nodes. Finally,

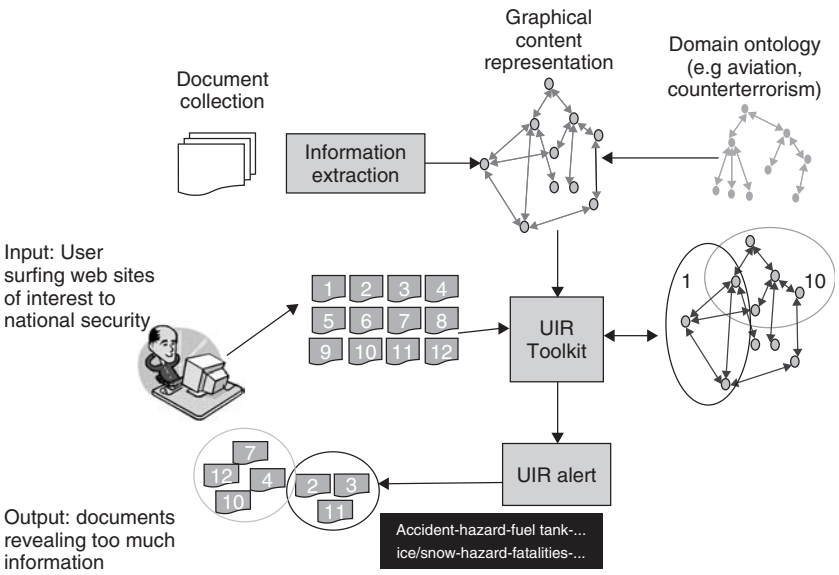

**FIGURE 1** General framework for system to detect inadvertent release of information.

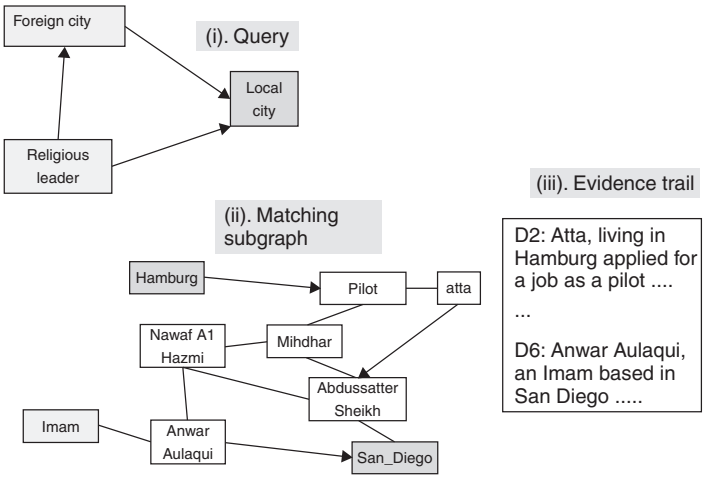

**FIGURE 2** UIR query and resulting evidence trail.

a graphical content model (based on topic and language models) is used to generate the evidence trail (i.e. set of sentences) corresponding to the matching subgraph. Since multiple subgraphs, and thus multiple evidence trails must be considered, a stand-alone evaluation system for evidence trails is used to rank the resulting evidence trails.

Figure 2 illustrates a query; it is based on a corpus of documents relating to 9/11. The analyst is looking for patterns involving a religious leader participating in some activity involving both US and foreign city. The query is simply a graph representing these three key concepts. Part (ii) of the figure shows the specific matching subgraph in the corpus based on the evidence trail shown in part (iii). The sentences are prefixed by the documents from which they are extracted. The subgraph in part (ii) is the corpus-specific match that is generated.

There are various criteria for ranking evidence trails, including (i) recency, (ii) most interesting, (iii) most plausible, and (iv) going through certain specified concepts. The primary focus is on finding chains that are *coherent* [15], that is, make sense, and *informative*. For example, if person A eats breakfast and person B also eats breakfast, then although eating breakfast is a valid connection, it is not of interest. On the other hand, if both of them have a liking for exotic spicy food from Southeast Asia, the connection starts to get more interesting. An alternate approach that could be used in the UIR problem that is specific to web pages (where URLs denote associations between concepts across pages) involving electricity analogs and information flows is discussed in [16].

There may be other instances of inadvertent release of information not covered here. However, the above categories cover the most significant classes of threats based on the sophistication of technology required to detect and defend against such scenarios.

## 4 FUTURE RESEARCH DIRECTIONS

Obviously, this is an open problem and requires significant research if risk of such threats to homeland security are to be mitigated. In general, there needs to be more work on automatic mapping of content to domain models to understand what information is reflected

in a collection of documents. It should be easy to visualize what type of information a set of documents contains, and its connection to other documents. This requires work on domain ontologies, as well as automatic mapping of content into these ontologies. The area of text mining is relatively new, and significant research is required, especially in drawing inferences across documents. Processing multimedia content, especially tables and figures is still in its infancy.

In order to make headway into this problem, a combination of content mining and usage mining techniques (see Further Reading on web mining) must be developed. Content mining has been discussed previously; usage mining reflects the sudden interest in a particular collection or sequence of information by parties of interest. Both these must be combined to both detect and prevent inadvertent release of information.

## 5 CONCLUSIONS

This article has examined various scenarios for inadvertent release of information. The problem is made difficult by the fact that there is no quantifiable metric for judging sensitive information, except for policy guidelines, along with the adage, "you know it when you see it". Document formats such as PDF have eliminated many of the previous risks due to hidden text or metadata; there is much more awareness for these types of risks now. Specific instances of inadvertent release, such as the accidental release of classified documents may have tractable solutions since the guidelines are governed by a classification system. Inadvertent release through data mining agents can also be limited by more careful monitoring of access to such information, along with modern technology such as "captchas", which are designed to prevent agent access. However, the most subtle forms of inadvertent information release that involve inferences across multiple pages may be very difficult to control. The problem is exacerbated through the links to pages outside the organization. Nevertheless, it is an important area to pursue since the results may not only impact national security but also have tremendous implications for areas such as bioinformatics and aviation security.

**Calvin Shipbaugh**, Arlington, Virginia, *High Consequence Threats: Nuclear*

**Brandon Sights**, Space and Naval Warfare Systems Center, San Diego, California, *Less Lethal Payloads for Robotic and Automated Response Systems*

**Stephan Singleton**, Center for Animal Health and Food Safety, University of Minnesota, St. Paul, Minnesota, *Livestock Agroterrorism and the Potential Public Health Risk*

**Barrett D. Slenning**, Department of Population Health and Pathobiology, College of Veterinary Medicine, North Carolina State University, Raleigh, North Carolina, *Foreign Animal Diseases and Food System Security*

**Edward Small**, Sacramento Metropolitan Fire District, Sacramento, California and FEMA Urban Search and Rescue Team, CA Task Force 7, Sacramento, California, *The Sensor Web: Advanced Technology for Situational Awareness*

**Diana K. Smetters**, PARC, Palo Alto, California, *Cyber Security Technology Usability and Management*

**Edward Smith**, Booz Allen Hamilton, McLean, Virginia, *Wireless Security*

**Gary R. Smith**, Logical Decisions, Fairfax, Virginia, *Qualitative Representation of Risk*

**David Solo**, Corporate Technology Office, Citigroup Inc., New York, New York, *Cyber Security for the Banking and Finance Sector*

**Murugiah Souppaya**, National Institute of Standards and Technology, Gaithersburg, Maryland, *Cyber Security Metrics and Measures*

**Rohini K. Srihari**, University at Buffalo, Buffalo, New York, *Finding Inadvertent Release of Information*

**John A. Stankovic**, University of Virginia, Charlottesville, Virginia, *Security of Distributed, Ubiquitous, and Embedded Computing Platforms*

**Stanley States**, Pittsburgh Water and Sewer Authority, Pittsburgh, Pennsylvania, *Surveillance Methods and Technologies for Water and Wastewater Systems*

**D. L. Stephens**, Pacific Northwest National Laboratory, Richland, Washington, *Radioactive Materials Sensors*

**Catherine H. Strohbehn**, Iowa State University, Ames, Iowa, *Risk Assessment, Risk Management, and Preventive Best Practices for Retailers and Foodservice Establishments*

**Makram T. Suidan**, University of Cincinnati, Cincinnati, Ohio, *Homeland Security and Wastewater Treatment*

**John Sullivant**, $S^3E$–Sisters Three Entrepreneurs Security Consultants Company, West Hollywood, California and Magallanes Associates International (MAI), Thousand Oaks, California, *Strategies for Protecting the Telecommunications Sector*

**Cheryl Surman**, General Electric Global Research Center, Niskayuna, New York, *Passive Radio Frequency Identification (RFID) Chemical Sensors for Homeland Security Applications*

**Ivan Susanto**, Chevron Corporation, San Ramon, California, *Industrial Process Control System Security*

**Manuel Suter**, Center for Security Studies (CSS), ETH Zurich, Switzerland, *Australia; Austria; Brazil; Canada; Estonia; Finland; France; Germany; Hungary; India; Italy; Japan; Republic of Korea; Malaysia; the Netherlands; New Zealand; Norway; Poland; Russia; Singapore; Spain; Sweden; Switzerland; United Kingdom; United States; European Union (EU); The Forum of Incident Response and Security Teams (FIRST); Group of Eight (G8); North Atlantic Treaty Organization (NATO); Organization for Economic Co-Operation and Development (OECD); United Nations (UN); and the World Bank Group*

**Andrew W. Szumlas**, Hamilton Sundstrand Corporation, Pomona, California, *A Tandem Mobility Spectrometer for Chemical Agent and Toxic Industrial Chemical Monitoring*

**Joseph A. Tatman**, Innovative Decisions, Inc., Vienna, Virginia, *Bayesian Networks*

**Lisa Theisen**, Contraband Detection, Sandia National Laboratories, Albuquerque, New Mexico, *Threat Signatures of Explosive Materials*

**Ken Thompson**, CH2M HILL, Englewood, Colorado, *Drinking Water Supply, Treatment, and Distribution Practice in the United States*

**Jimmy L. Tickel**, Emergency Programs Division, North Carolina Department of Agriculture and Consumer Services, Raleigh, North Carolina, *Foreign Animal Diseases and Food System Security*

**G. Loren Toole**, Los Alamos National Laboratory, Threat Reduction Directorate/Decision Applications, Los Alamos, New Mexico, *Interdependent Energy Infrastructure Simulation System*

**Edward T. Toton**, Toton, Incorporated, Reston, Virginia, *Defending Against Directed Energy Weapons: RF Weapons and Lasers*

**Wade R. Townsend**, U.S. Department of Homeland Security, Washington, D.C., *Vulnerability Assessment Methodologies for Interdependent Systems*

**Monique Mitchell Turner**, Center for Risk Communication Research, Department of Communication, University of Maryland, College Park, Maryland, *Risk Communication*

**Shawn S. Turner**, United States Marine Corps, Arlington, Virginia, *Risk Communication*

**Marc Vaillant**, Animetrics, Conway, New Hampshire, *2D-To-3D Face Recognition Systems*

**Luis S. Vargas**, Department of Electrical Engineering, University of Chile, Santiago, Chile, *Object-Oriented Approaches for Integrated Analysis of Interdependent Energy Networks*

**Ashok Veeraraghavan**, Center for Automation Research and Department of Electrical and Computer Engineering, University of Maryland, College Park, Maryland, *Knowledge Extraction from Surveillance Sensors*

**Kim-Phuong L. Vu**, Department of Psychology, California State University, Long Beach, California, *Human Sensation and Perception*

**William A. Wallace**, Rensselaer Polytechnic Institute, Troy, New York, *Network Flow Approaches for Analyzing and Managing Disruptions to Interdependent Infrastructure Systems*

**Anna E. Waller**, Department of Emergency Medicine, School of Medicine, University of North Carolina, Chapel Hill, North Carolina, *The North Carolina Biosurveillance System*

**Ronald A. Walters**, Pacific Northwest National Laboratory, Richland, Washington, *Biosurveillance Tradecraft; and Data Sources for Biosurveillance*

**Enoch Wang**, Intelligence Community, Washington, D.C., *Nano-Enabled Power Sources*

**Keith B. Ward**, Department of Homeland Security Science and Technology Directorate, Washington, D.C., *Sensing Dispersal of Chemical and Biological Agents in Urban Environments*

**Linda Warren**, Launch Consulting, Richland, Washington, *Emergency Response Planning for Drinking Water Systems*

**David M. Weinberg**, Practical Risk LLC, Rio Rancho, New Mexico, *Threats and Challenges to Homeland Security*

**Rand Whillock**, Honeywell International, Golden Valley, Minnesota, *Eye and Iris Sensors*

**Jack F. Williams**, Georgia State University, Atlanta, Georgia, *Terrorist Threat Analysis*

**Cecelia Williams**, Sandia National Laboratories, Albuquerque, New Mexico, *Carver + Shock: Food Defense Software Decision Support Tool*

**Henry H. Willis**, RAND Corporation, Pittsburgh, Pennsylvania, *Using Risk Analysis to Inform Intelligence Analysis*

**Mark Wilson**, National Institute of Standards and Technology, Gaithersburg, Maryland, *Cyber Security Education, Training, and Awareness*

**James M. Wilson**, Georgetown University Medical Center, Argus Research Operations Center, Imaging Science and Information Systems Center, Washington, D.C., *Biosurveillance Tradecraft*

**William Wilson**, North Dakota State University, Fargo, North Dakota, *Optimal Investments in Mitigating Agroterrorism Risks*

**Gordon Woo**, Risk Management Solutions, London, United Kingdom, *Terrorism Risk*

**Anthony D. Wood**, University of Virginia, Charlottesville, Virginia, *Security of Distributed, Ubiquitous, and Embedded Computing Platforms*

**Jon Woody**, Food and Drug Administration, Silver Spring, Maryland, *Carver + Shock: Food Defense Software Decision Support Tool*

**Ken Wright**, Depository Trust and Clearing Corporation, New York, New York, *Cyber Security for the Banking and Finance Sector*

**Lorna Zach**, Center for Human Performance and Risk Analysis, University of Wisconsin-Madison, Madison, Wisconsin, *Risk Assessment and Safety of the Food Supply*

**Thomas Zacharia**, Oak Ridge National Laboratory, Oak Ridge, Tennessee, *Ultra-scale Computing for Emergency Evacuation*

**Linfeng Zhang**, Iowa State University, Ames, Iowa, *Attack Traceback and Attribution*

**Rae Zimmerman**, Institute for Civil Infrastructure Systems (ICIS), New York University, Wagner Graduate School of Public Service, New York, New York, *Understanding the Implications of Critical Infrastructure Interdependencies for Water*

**Ludek Zurek**, Kansas State University, Departments of Entomology and Diagnostic Medicine and Pathobiology, Manhattan, Kansas, *Insects as Vectors of Foodborne Pathogens*
