The critical sectors and the protection policies for critical infrastructures are defined in the Security of Supply Act and in the Decree of the National Emergency Supply Agency (NESA) of 1992.[1] Based on these acts, the Finnish government sets official goals for the development of security of supply, which are updated every 5–6 years. The current governmental decision is from 2002, but there is already a proposal for a new decision, which is to be enacted in 2008 (the critical infrastructure will be defined in more detail, but the definition will include the same sectors as in 2002).[2]

Currently, the following infrastructures and services are deemed to be critical in Finland:

[1]The Security of Supply Act is the legal basis for ensuring supplies of various basic materials in the case of emergency situations. Based on this act, the National Emergency Supply Agency (NESA), a subordinate agency to the Ministry of Trade and Industry (now Ministry of Employment and the Economy), was founded in 1993 for the development and maintenance of security of supply. NESA is the national stock-holding agency of Finland.

- Energy Networks and Supply,
- Electronic Information and Communication Systems, including communication networks, IT systems (including SCADA systems), electronic mass media, and payment systems of banks and insurances,
- Transportation and Logistics Systems,
- Water supply and Other Municipal Utilities,
- Infrastructure Construction and Maintenance,
- Financial Services,
- Food Supply,
- Health Services,
- Print Media.

The government focuses on safeguarding society's critical infrastructure. The objective is to protect fundamental structures by using non-critical technology and organizations, even during disturbances and emergency situations. Accordingly, an essential aspect of safeguarding the technology is ensuring the system's ability to recover.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

### 2.1 Governmental Support for the Information Society

From the early 1990s on, the Finnish government has worked continuously on new programs aimed at promoting the Information Society, its infrastructure, and the protection of the infrastructure. On the basis of their reports, several ministries have produced action plans and provided funding for Information Society projects.

In 2005, the Finnish government issued a strategy resolution, which includes an Information Society Programme [1]. This program promotes the development of the Information Society in the areas of telecommunication infrastructure, digital television, citizens' skills to utilize the Information Society, research and development, and ICT in public administration and business.

As part of the implementation of this program, the government drafted the National Knowledge Society Strategy for 2007–2015 [2]. The vision of the strategy is "good life in information society", and accordingly, it aims to support the "transformation of Finland into an internationally attractive, human-centric and competitive knowledge and service society" [3].

As the previous strategies in regard to the information society, the National Information Society Strategy 2007–2015 emphasizes the security of networks so that citizens can trust the electronic services. In addition it highlights the importance of well-functioning infrastructures: "Information networks are dependent upon basic infrastructure, such as electricity supply. Security of supply in the information society is especially important in crisis situations" [4].

### 2.2 Strategy for Securing the Functions Vital to Society 2006

In order to ensure the security of critical infrastructures, the Finnish government issued the Strategy for Securing the Functions Vital to Society [5]. The strategy was first released in 2003 and was reviewed and updated in 2006 [6].

The strategy paper divides the vital functions into seven broad areas: management of government affairs, international activities, national military defense, internal security, functioning of the economy and infrastructure, the population's income security and capability to function, and psychological crisis tolerance.

Electronic information and communication systems are recognized as an important part of a well-functioning society. It is vital to secure electronic communication networks and their information security, to determine basic security levels for services and technical systems, and to ensure that the regulations on construction and maintenance of systems are observed. In addition, it is critical to coordinate the development of networks used by the authorities, to safeguard the state's information-processing capacity, and to provide guidelines for public electronic services, the public data administration, and information security. Among vital threats to society, the strategy paper lists threats to information and communication systems first.

### 2.3 Security and Defense Policy 2004

The Finnish government submits a Security and Defense Policy report to parliament every three or four years. The next report will be published in 2008. In 2004 [7], the report emphasized the growing importance of electronic information and communications technology systems for the functioning of modern society. It is no longer possible to shift to the use of manual reserve systems.

Along with the rest of society, criminals also use networks and systems. Therefore, specific chapters in this policy paper are devoted to combating cyber-crime and to securing society's electronic communications and information systems. According to the report, the capacity of the police for protecting information systems, telecommunication connections, and electronic transactions, as well as for combating cyber-crime, will be expanded. Cooperation between the police and the Finnish Communications Regulatory Authority (FICORA) will raise the level of information systems protection required in an open network environment.

The security level of communication networks is being increased. ICT used by major government agencies, security authorities, and vital industries are safeguarded by prioritization and by the construction of communication networks and data systems for special use. One example is Finland's Public Authority Network VIRVE.[3]

### 2.4 National Information Security Strategy

In 2001, the government set up an Advisory Committee for Information Security (ACIS) under the Finnish Communications Regulatory Authority (FICORA) as a point of contact for citizens, companies, organizations, and authorities on information security issues.

In 2002, ACIS released its "National Information Security Strategy Proposal" [8], which was approved by the government in 2003. The paper lists detailed policy objectives and measures to be implemented as well as the responsibilities of the various stakeholders. The priority areas of the strategy are to secure electronic services, to secure biometric identification, to protect critical infrastructure, to combat cyber-crime, to protect the national information assets, to enhance information security awareness by promoting

[3]Finland's Public Authority Network VIRVE, based on TETRA (Terrestrial Trunked Radio) technology, is being expanded by increasing the number of users. Among the user groups are fire and rescue services, police, border guards, customs, the military, and health services. http://www.virve.com.

the annual National Information Security Day, and to improve awareness in business enterprises.

The most visible result of the implementation of the strategy has been National Information Security Day on 11 February, held for the fifth time in 2008. The day promotes secure internet usage, particularly for schoolchildren and their parents. Another important result is the strengthening of the national Computer Emergency Response Team (CERT-FI) to give special service for actors in critical sectors in Finland.[2]

## 3 ORGANIZATIONAL OVERVIEW

In Finland, there are three major public agencies dealing with CIIP. The Finnish Communications Regulatory Authority (FICORA) promotes the Information Society, as well as technical regulation and standardizations; the National Emergency Supply Agency (NESA) analyzes threats and risk against critical (information) infrastructures; and finally, the Steering Committee for Data Security in State Administration (VAHTI) develops policy guidelines and practical guides for the security of information systems.

In addition, there are three important public-private partnerships in the field of CIIP: The National Emergency Supply Council (NESC), the Ubiquitous Information Society Advisory Board, and the Finnish Information Society Development Centre (TIEKE).

### 3.1 Public Agencies

***3.1.1 Finnish Communications Regulatory Authority (FICORA).*** The Finnish Communications Regulatory Authority (FICORA) [9] belongs to the Ministry of Transport and Communications. FICORA is a general administrative authority for issues concerning electronic communications and Information Society services. Its mission is to promote the development of the Information Society in Finland. The specific duty of FICORA is to safeguard the functionality and efficiency of the communications markets in order to ensure that consumers have access to competitive and technically advanced communications services that are affordable as well as of good quality.

FICORA's mission includes issuing technical regulations and coordinating standardization at the national level. It also oversees the protection of privacy and securing data in electronic communications. In addition, FICORA encourages national and international co-operation.

FICORA also ensures that telecommunications operators are prepared for emergencies. The operators must report significant information security incidents as well as any threats, faults, or disturbances in telecommunication networks and services to FICORA. FICORA checks the operators for compliance with the Communications Market Act and the Act on the Protection of Privacy in Electronic Communications and monitors compliance with the relevant technical regulations and standards. In pursuing this task, FICORA collects information from the operators and conducts inspections.

Finally, FICORA operates the CERT-FI (see the chapter on Early Warning and Public Outreach), which is tasked with the detection and resolution of data security infringements [10].

***3.1.2 National Emergency Supply Agency (NESA).*** The National Emergency Supply Agency (NESA) [11] is the cross-administrative operative authority for the security of

supply in Finland. NESA works under the auspices of the Ministry of Employment and the Economy. In addition, NESA serves to develop cooperation between the public and private sectors in the field of economic preparedness, in coordinating preparations within the public administration, and in developing and maintaining the security of supply.

NESA and the National Emergency Supply Council (NESC, see below) analyze threats and risks that may affect the critical infrastructure. NESA itself conducts research and finances research commissioned by outside organizations. NESA and NESC formulate plans and guidelines for public authorities and businesses with respect to the management and control of such threats and risks.

NESA has a growing role in securing the critical national infrastructure by developing and financing both technical backup systems and electromagnetic pulse (EMP)-secure premises for systems. Finland's vital communication and IT systems are located in the capital region. This is a risky concentration. Therefore, NESA owns two computer backup/colocation centers outside the capital region in order to secure society's critical IT systems in exceptional conditions.[2]

The National Fixed Line Telephone Backup Network is a digital, nation-wide separate network that was built to secure the lines of communication of vital public organizations, as well as other key subscribers, in exceptional situations and crises. The Ministry of Transport and Communications and NESA are jointly developing the network so that it can also secure other telecommunication services than voice services. NESA is involved in the development and maintenance of Finland's Public Authority Network VIRVE.

In addition, NESA has financed several projects to secure the communication and broadcast systems. These projects and activities are related to reserve systems, emergency and warning message broadcasting systems, and the construction of circuitous routes for critical nodes of networks.

In CIIP matters, NESA has participated in the preparation of European Programme for Critical Infrastructure Protection (EPCIP) and Critical Infrastructure Warning Information Network (CIWIN).[2]

***3.1.3 Steering Committee for Data Security in State Administration (VAHTI).*** The central government's data-security and information-management policies are steered and developed by the Ministry of Finance. Guidelines are developed by the Steering Committee for Data Security in State Administration (VAHTI) [12], a broad group of experts.

For the central government, the issue of data security includes a number of areas such as the use of the internet, data management outsourcing, remote work, e-mail, protection from viruses, personnel security, physical security, data communication security, and database security. The Ministry of Finance works in close cooperation with other ministries and agencies to support and facilitate cooperation in the development of e-government and electronic services in the state sector.

VAHTI has published an extensive collection of practical guides (some of them in English) for information system security. The guides are intended for the state administration, but they are also used by many private organizations.[2]

## 3.2 Public-Private Partnerships

***3.2.1 National Emergency Supply Council (NESC).*** Established in 1955, the National Emergency Supply Council (NESC, previously National Board of Economic Defense)

[13], under the auspices of the Ministry of Employment and the Economy, supports and assists NESA activities (see also chapter on Law and Legislation). NESC also plans and coordinates economic preparations for implementation in case of exceptional circumstances in Finland.

NESC is a network of committees consisting of the leading experts from both the public administration and the business world. Its tasks are to analyze threats against the country's security of supply, to plan measures to control these threats, and to promote readiness planning in individual industrial sites.

NESC's areas of responsibility include the Information Society, transport logistics, food supply, energy supply, health care services, financial services, and defense-related and other critical industrial sectors. NESC members include representatives of ministries, government agencies, the private business sector, and various industrial organizations. Approximately 800 people work within the NESC.

NESC has several planning bodies in the area of information infrastructure. They have prepared instructions and basic plans for the ICT sector as well as for other vital branches of the infrastructure. In addition, NESC studies and follows up on risks and threats to the critical infrastructure and security of supply. Databases and methods have been developed to support and improve the level of readiness to act in exceptional situations.

***3.2.2 Ubiquitous Information Society Advisory Board.*** The Ubiquitous Information Society Advisory Board [14] is a body with members from ministries, public administration, NGOs, and business life. Its task is to ensure that the National Information Society Strategy will be put into practice.

One of the six working groups in the board has the task of outlining a new national information security strategy and of coordinating its implementation. The working group's term of office will last from September 2007 to February 2011.[2]

***3.2.3 Finnish Information Society Development Centre (TIEKE).*** Since 1998, the Finnish Information Society Development Centre (TIEKE) [15] has been a key player in the development of the Information Society in Finland. TIEKE's goal is to create viable tools and expertise for use in the Information Society. Specifically, TIEKE's main focus is on the development of networking and interoperability.

TIEKE's membership includes more than 100 organizations and companies involved in the Information Society. The members operate in the areas of trade, industry, and public administration, and thus also serve individual citizens.

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 Computer Emergency Response Team Finland (CERT-FI)

FICORA's CERT-FI [10] group prevents, observes, and solves information security violations and gathers information on threats to information security. CERT-FI cooperates with national and international CERT actors and representatives of trade and industry. It is in contact with suppliers of equipment, networks, and software as well as with the police and other authorities.

CERT-FI receives notifications from telecommunications operators concerning information security incidents and threats. In addition, CERT-FI continuously follows up

current global events related to information security, security problems of information systems, security incidents, and responses to them.

In 2007, CERT-FI was contacted 2664 times. The information security helpline for customers operates during business hours, but the threats and incidents are supervised around the clock, seven days a week.

Starting in 2007, CERT-FI's manpower was substantially increased. CERT-FI now also provides special service for actors in critical sectors in Finland. The special service includes a 24/7 incident warning and handling service (available also via SMS and via the VIRVE Public Authority Network), personal advice, and focused product vulnerability warnings.

## 5 LAW AND LEGISLATION[4]

### 5.1 Bill for National Emergency Supply Council 2008 / Act on the National Board of Economic Defense 1960

The Act on the National Board of Economic Defense (NBED) (238/1960) [16] is the legal basis for the National Emergency Supply Council (NESC). It obliges the NBED to plan and organize activities needed to secure the economy and the livelihood of the population in exceptional situations. NBED has the legal right to obtain, from enterprises and other important actors, information that is necessary for performing its planning and organizational tasks.

In 2008, a bill for amendment of the Act on the National Board of Economic Defense was introduced to the parliament. According to the bill, the name of the board will be changed to National Emergency Supply Council (NESC). The board of directors will be shared with the National Emergency Supply Agency (NESA). The committee network and the legal jurisdiction will remain unchanged.

### 5.2 Emergency Powers Act 1991

In case of serious disturbances and in emergencies, public authorities need special powers to safeguard society's essential activities. The most important provisions are contained in the Emergency Powers Act (1080/1991). [17] In crisis situations, this law empowers the government to issue provisions concerning the critical infrastructures and other functions of society.

In 2008, a bill for amendment of the Emergency Powers Act was introduced to the parliament. Under the provisions of the bill, the conditions in which the emergency powers can be implemented are specified in more detail than in the existing act, in harmony with the new Constitution of Finland of 2000.[2]

### 5.3 Security of Supply Act 1992/2005

Critical infrastructure protection actions are based on both the Security of Supply Act (1390/1992) [18] and the Decree of the National Emergency Supply Agency (NESA)

[4]The official texts of Finnish legislation have been published in Finnish and Swedish. Some laws have an unofficial English translation. Unless otherwise indicated, we refer to the official texts.

(1391/1992). [19] The Finnish government specified the development of security of supply as one of the official goals for 2002. [20] The Security of Supply Act was amended in 2005 (688/2005). [21] The amendment refers to severe disturbances in otherwise normal circumstances (not only in crisis situations as defined in the Emergency Powers Act). The amendment emphasizes the securing of technical systems.

### 5.4 Penal Code

In the Finnish Penal Code, Chapter 38, Amendments 578/1995[22] and 540/2007 [23] specifically outlaw the endangering of information systems, and tampering with telecommunication systems.

### 5.5 Act on Television and Radio Operations 1998

This act (744/1998) [24] obliges television or radio broadcasters to ensure that they can continue transmitting with minimum disruption even in the exceptional circumstances referred to in the Emergency Powers Act. Additionally, broadcasters must transmit information from the authorities to the public if it is necessary to save human lives, protect property, or safeguard the functioning of society.

### 5.6 Act on Provision of Information Society Services 2002

This act (458/2002) [25] defines the rules of offering electronic services and the right of the authorities to limit the services if they constitute threats to consumers or to public security.

### 5.7 Communications Market Act 2003

This act (393/2003) [26] obliges the communications operators to ensure the functioning of their services, regardless of whether the disturbances occur during normal times, exceptional situations, or in times of crises. The act assures the telecommunications operators that any extra expenses incurred through such preparatory measures will be reimbursed to the operators by the National Emergency Supply Agency (NESA).

An amendment is being prepared which would specify the roles and authority of the Ministry of Transport and Communications and FICORA in detail, in accordance with the new Emergency Powers Act.

### 5.8 Act on the Protection of Privacy in Electronic Communications 2004

This Act (516/2004) [27] states that telecommunications operators or service providers must secure their services and inform the authorities about any violations. The operators or providers have the right to eliminate any programs that threaten information security. They may also limit or stop the traffic when necessary for the protection of information security.

The Amendment (198/2006) [28] obligates the operator also to transmit authority originated emergency SMS messages that are addressed to specified recipient groups.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Veli-Pekka Kuparinen, Ilkka Kananen, and Hannu Sivonen of the National Emergency Supply Agency who validated the content of this article.

## 1 CRITICAL SECTORS

All infrastructures that are vital to the maintenance of primary social and economic processes are considered critical sectors in France. These critical sectors are the following:[1]

[1]Decree No. 2006-212 dated 23 February 2006 on the protection of essential economic sectors. Information provided by an expert.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

- Finance,
- Industry,
- Energy,
- The work of the judiciary,
- Public Health,
- The work of national civil authorities,
- Electronic Communication, Audiovisual Media, and Information Technology,
- Transport Systems,
- Water Supply,
- Food,
- Space and Research,
- The Armed Forces.

A decree was issued in 2006 on the protection of essential economic sectors;[1] it aims to upgrade regulations pertaining to vulnerabilities by harmonizing the interagency state approach for analyzing hazards in terms of the nature of the threat, while expanding the list of issues to be taken into account and by including the flexible measures provided for within the framework of the Vigipirate plan.[2] Thus, each of the 12 essential economic sectors will include a national security directive for essential operators, who are in turn tasked with setting up their own operator security plan under the supervision of the ministry they are subordinated to; this plan is also intended for other major agencies to set up their own protection plans.

The French regulatory framework has been updated accordingly. Its approach is based on risk management and prevention/reaction plans. The national committee, the interdepartmental commission, and the defense and security delegates are encouraged to share information. The above-mentioned 12 sectors and the actors therein have to elaborate a national security directive, and all operators are instructed to refine the national security directive into an operator security plan for their specific context. For each critical point, the operators have to refine the operator security plan into particular protection plans, and the authorities are directed to elaborate an external protection plan.[3]

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

### 2.1 Government Action Program for an Information Society (PAGSI)

In August 1997, the prime minister of France designated the information and communication society as a priority for government action. The objective was to build an information society for all, to prevent a digital divide, and to help France catch up with other countries in terms of internet usage. Making government services available online has been the main goal of the formation of the Government Action Program for an Information Society (PAGSI) [1] (adopted at the meeting of the Inter-ministerial Committee

[2]Vigipirate is France's national security alert system. Created in 1978, it has since been activated three times, in 1995, 2000, and 2004. For more information, see: http://www.archives.premier-ministre.gouv.fr/raffarin_version2/information/fiches_52/plan_vigipirate_50932.html.

[3]Information provided by an expert.

for Information Society (CISI) in January 1998) [2]. In addition to the improvement of general public services, standardization, and training for civil servants, the action plan supported projects in the fields of education, culture, electronic commerce, and research and innovation, and established appropriate regulations for the safer use of information technologies and networks. Two of the main priorities of the action plan were managing the Security of Information Systems (SSI) and combating cyberthreats [3].

### 2.2 Expression of the Needs and Identification of Security Objects (EBIOS)

In 1997, the Central Information Systems Security Division (DCSSI) developed and published the first version of the guide Expression of the Needs and Identification of Security Objects (EBIOS). Since then, it has been regularly updated and expanded [4]. EBIOS outlines methodological tools for risk analysis concerning the security of information systems. The method allows for communication about information systems security within organizations and between the individuals concerned. The methodological framework of EBIOS consists of tools for apprehending the method, for training, and for contributing to its shared development [5].

### 2.3 State Information System Security Reinforcement Plan (2004–2007)

The director of the French Prime Minister's Office instructed the ministerial departments and the General Secretariat of National Defense to prepare a specific plan of action by October 2003 to "secure the main central and local governmental networks, and those used for vital infrastructure management" [6]. This plan of action was approved on 16 December of the same year. The so-called "State Information System Security Reinforcement Plan" had the following four objectives [5]:

- To secure communication channels for senior state officials; that is, to ensure, under all circumstances, the security of all protected communication means for the use of senior authorities, based on supervision under the direct control of state authorities;
- To secure government information systems; that is, to secure the new e-government functions in accordance with the Agency for the Development of Electronic Administration's (ADAE) [7] strategic e-government plan and guidelines, and to explain security policies;
- To set up operational capabilities to respond to computer attacks;
- To include the French information system security policy within the scope of the French security policy in the EU.

### 2.4 Plan RE/SO 2007

The Plan for a Digital Republic within the Information Society (Plan pour une République numérique dans la societé de l'information) was presented by the prime minister in 2002. Acknowledging the necessity and importance of information and communication technologies for French economic growth, employment, and overall "influence in the world", this plan aims at giving a new impetus to the information society by focusing on the efficient development and use of an ICT infrastructure. Specifically, it strives to simplify the rules governing the internet, to restore the trust of the users, and to clarify the responsibilities of all actors within the information society [8].

### 2.5 Defense and National Security Whitebook

In June 2008, French President Nicolas Sarkozy announced the most wide-ranging reform of the French armed forces since 1994. The Defense and National Security Whitebook (Défense et Sécurité nationale: Le Livre Blanc) [9] states that global terrorism poses the most virulent threat to the security of France and its citizens. The document outlines the French military strategy to face this challenge until 2020 [10]. It not only anticipates a major reduction in the personnel strength of the armed forces, but also simultaneously foresees a substantial increase in their funding. Funding for military intelligence, for example, will be doubled. These funds are intended to be used to strengthen satellite surveillance and ICT in general in order to prevent cyber-attacks. France also plans to develop offensive means to prevent cyber-attacks. Under the terms outlined in the whitepaper, up to 10,000 troops will be dedicated to the prevention of pandemics induced by chemical and biological attacks, and of cyber-attacks. The Defense and National Security Whitebook is scheduled to be discussed in the French parliament in June 2008 [11].

## 3 ORGANIZATIONAL OVERVIEW

In France, the secretary-general of national defense (SGDN) [12], a secretary attached to the Prime Minister's Office, bears complete responsibility for organizing CIP.

Furthermore, within the Ministry of Defense, the key organizations responsible for CIP/CIIP are the Central Directorate for Information Systems Security (DCSSI),[4] the Inter-Ministerial Commission for the Security of Information Systems (CISSI),[5] and the Advisory Office, whereas the Central Office for the Fight Against Hi-Tech Crime plays a leading role within the Ministry of the Interior.

As a public-private partnership, the Strategic Advisory Board on Information Technologies (CSTI) strives to bring together government officials, business and industry executives, and representative of the research and development community.

### 3.1 Public Agencies

***3.1.1 Secretariat-General for National Defense (SGDN).*** The secretary-general for national defense (SGDN) deals with national and international security affairs. The organization was first called into action with regard to information security for Y2K. A specific network of contacts among different bodies from the public and private sectors became involved under the coordination of the SGDN. The SGDN is directly subordinated to the French prime minister and assists the prime minister's office in the co-ordination of the preparation, implementation, and follow-up of the government's decisions regarding defense and security policy, including the security of information systems.

The SGDN also promotes and co-ordinates the activities between ministries involved in CIIP. This includes responsibility for the security of information systems (since 1996) and chairing the CISSI, as well as responsibility for the protection of classified and sensitive military information. The SGDN deals with the impact of the scientific and technical revolution on defense and security policy, focusing on securitization of information and communication technology relating to military as well as civilian matters. In this area, the SGDN works closely together with DCSSI.

[4]Direction centrale de la sécurité des systèmes d'information (DCSSI).
[5]Commission Interministérielle pour la Sécurité des Systèmes d'Information (CISSI).

***3.1.2 Central Directorate for Information Systems Security (DCSSI).*** The DCSSI was instituted by Decree No. 2001-693 of 31 July 2001 [13] under the authority of the SGDN. It succeeded the Central Information Systems Security Division as the state's focal center for Information Systems Security.

The DCSSI has two main objectives: To guarantee the security of the information systems of the French state (including critical infrastructures in times of crisis); and to create a trusted environment to promote and facilitate the development of the information society. The DCSSI's principal missions are [14]:

- To contribute to interdepartmental and international definitions of governmental policy as regards information security;
- To serve as a national regulatory authority for information security by issuing approvals, guarantees, and certificates for national information systems, encryption processes, and products used by public bodies and services; and by controlling information technology security evaluation centers (CESTI);
- To assist public services in information security (consult, audit, issue warnings, and conduct incident management, including crisis management);
- To develop scientific and technical expertise in the field of information security for the benefit of the administration and public services;
- To run training courses and increase awareness in information security (Information Systems Security Training Centre/CFSSI).

The DCSSI also administers the Security of Information Systems (SSI) website [15] and co-ordinates its activities. The SSI website comprises information on the Computer Emergency Response Team (CERTA) [16], information on regulation, certification, authorization, electronic signatures, and cryptography, and provides technical advice.

***3.1.3 Information Systems Security Training Center (CFSSI).*** Attached to DCSSI, the Information Systems Security Training Center's (CFSSI) [17] objectives are to increase awareness on information systems security and to train experts capable of designing, evaluating, and making recommendations on the following aspects of information systems security:

- Communications security,
- Protection against compromising viruses,
- Computer security.

The CFSSI continues training actions undertaken by the CESSSI (Center for Training and Advanced Studies on Information Systems Security) since 1986. It will become the central player in a network designed to increase awareness on information systems security problems and provide training in the various aspects of this area, for the benefit of all government authorities.

The CFSSI also develops partnerships with higher education and further training centers. The activities of the CFSSI and the education it provides are controlled and monitored by an improvement committee chaired by the secretary-general for national defense and composed of civil servants and military staff.

***3.1.4 Operational Center (COSSI).*** In order to defend governmental networks and information systems, the SGDN runs the Information System Security Operation center (COSSI) which, in addition to its general preventive tasks, coordinates the action of ministries and draws up protection and reaction measures. The centre also prepares and implements the Vigipirate plan against terrorist threats. COSSI operates around the clock, 365 days a year.[3]

***3.1.5 Central Office for the Fight Against Hi-Tech Crime.*** In May 2000, the Ministry of the Interior opened the Central Office for the Fight against Cyber-Crime [18]. It co-operates with Interpol and deals with unauthorized intrusions and crime in the field of information and communication technologies and supports legal investigations in this field. The Central Office has nationwide jurisdiction in this matter and works closely together with the national police as well as the private sector. It provides assistance to all agencies responsible for fighting computer crime, such as the police and gendarmerie, and sensitizes the actors.

### 3.2 Public-Private Partnerships

***3.2.1 Strategic Advisory Board on Information Technologies (CSTI).*** The Strategic Advisory Board on Information Technologies (CSTI) [19] was created in July 2000 at a meeting of the government committee on the Information Society. It is chaired by the French prime minister. The CSTI is composed of business and industry executives and leading representatives of the research and development community. It is responsible for recommendations to government concerning CIIP topics and the French contribution to the 6$^{th}$ European Framework Research and Development Program. The CSTI, in particular, has the following duties [20]:

- To communicate opinions and recommendations to the government on the studies and documents commissioned;
- To maintain a permanent dialog with representatives of industry and to improve co-ordination between private and public researchers (and the industry);
- To define national priorities and to select areas where more action is required;
- To provide general monitoring and warning services in the area of CIIP.

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 Computer Emergency Response Teams (CERTs)

In France, there are three different Computer Emergency Response Teams (CERTs), and each of them addresses a different constituency: CERT-RENATER, CERTA, and CERT-IST.

- CERT-RENATER [21], founded in 1993, specifically addresses research centers and academic institutions. CERT-RENATER gathers and provides information about information security and is dedicated to the membership of GIP[6] RENATER, the National Network of Telecommunications for Technology, Education, and Research;

[6]Groupement d'Intérêt Publique (Public Interest Group).

- The Computer Emergency Response Team CERTA [22] has been hosted by DCSSI since 2000. CERTA deals in particular with the French administration services. As a center of expertise, it evaluates CIIP threats and gives advice, issues warnings, and provides information on how to prevent, respond to, and handle an attack against information systems. High-level staff, mainly engineers, work at CERTA. The CERTA is part of the Central Directorate for the Security of Information Systems (DCSSI) and acts as the technical cell of the permanent operational center (ITSOC) operating around the clock, seven days a week. CERTA is also the expertise cell from COSSI;[3]
- CERT-IST (CERT-Industry, Services, and Tertiary) was launched in 1999 by Alcatel (a telecom company), CNES (the French Space Agency), France Telecom, and the TotalFinaElf energy group. It serves France's private sector as a contact point for security incident response. CERT-IST provides alerts and means of protection against computer attacks aimed at French enterprises. It also helps the association members with incident handling [23]. CERT-IST interacts with the French national security organizations SGDN and DCSSI, in conjunction with CERT-RENATER and CERTA [24].

### 4.2 Web Portal for Citizens and SMEs

In the wake of a prime ministerial decision to bring security to citizens and small and medium enterprises, the DCSSI has built a web portal dedicated to enduser computer security [25].

The prime minister's decision, which the portal serves to promote, consists of four main points:

- To coordinate the existing initiatives such as "internet sans crainte" (internet without fear);
- To keep citizens and SMEs informed about risks, recommendations, workarounds, and best practices;
- To alert citizens and SMEs when needed, and to provide timely and relevant information;
- To build and foster a contact network around the country.

## 5 LAW AND LEGISLATION

### 5.1 Penal Code 2004

Amended as Law no.2004-575 of 21 June 2004, entered into force on 23 June 2004.

- *Article 323-1.* Fraudulent accessing or remaining within all or part of an automated data processing system is punishable by a sentence not exceeding two years' imprisonment and a fine. Where this behavior causes the suppression or modification of data contained in that system, or any alteration of the functioning of that system, the sentence shall not exceed three years' imprisonment and a fine.

- *Article 323-2.* Obstruction or interference with the functioning of an automated data processing system is punished by a sentence not exceeding five years' imprisonment and a fine.
- *Article 323-3.* The fraudulent introduction of data into an automated data processing system or the fraudulent suppression or modification of the data that it contains is punished by a sentence not exceeding five years imprisonment and a fine.
- *Article 323-3-1.* Fraudulently, and without legitimate motive, importing, holding, offering, selling or making available any equipment, tool, computer program or any data designed or particularly adapted to commit one or more offences provided for by articles 323-1 to 323-3, is punishable by the sentences prescribed for offences in preparation or the one that carries the heaviest penalty [26].

Moreover, France ratified the Council of Europe Convention on Cybercrime on 10 January 2006.

## ACKNOWLEDGMENT

We acknowledge the contribution of the expert, Stanislas de Maupeou of the Secretariat-General for National Defense, who validated the content of this chapter.

# GERMANY

Manuel Suter and Elgin Brunner
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

The main assumption underlying CIP/CIIP in Germany is that both the government and society as a whole depend heavily on a secure infrastructure. Organizations or facilities

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

whose failure or impairment would cause a sustained storage of supplies, significant disruptions of public order, or other dramatic consequences for large parts of the population are defined as critical. According to the German constitution, it is the state's task to guarantee public security and order and to ensure that the population is provided with essential goods.

The following are the infrastructure sectors defined as critical in Germany: [1]

- Transportation and Traffic,
- Energy,
- Hazardous Materials,
- Telecommunications and Information Technology,
- Financial, monetary and insurance systems,
- Supply (including water supply, food supply, healthcare, emergency and rescue services),
- Government Agencies, Administration, and Justice,
- Media, research facilities, cultural property.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

In the past ten years, many activities have been undertaken that were directly or indirectly related to the issue of critical infrastructure protection. They emerged from inter-ministerial activities begun in 1997 at the initiative of the Federal Minister of the Interior, motivated in part by the study produced by the US President's Commission on Critical Infrastructure Protection (PCCIP). The events of 11 September 2001 added urgency to ongoing efforts and, as part of the campaign against terrorism, contributed to widening the scope of national activities and intensifying the international dialog.

In 2005, two key documents were presented:

- The National Plan for Information Infrastructure Protection (NPSI) [2], enacted by a cabinet decision of the federal government, and
- The Protection of Critical Infrastructures—Baseline Protection Concept [3], followed by the Protecting Critical Infrastructures—Risk and Crisis Management. A Guide for Companies and Government Authorities [4] in 2008.

These documents can be considered as initial milestones for a number of activities for establishing both CIIP and CIP processes throughout the country.

## 3 AG KRITIS

Initiated by the PCCIP report in the US, an inter-ministerial working group on critical infrastructures (AG KRITIS) was established in 1997 by the Federal Minister of the Interior. It consisted of the ministerial representatives, a steering committee, and a permanent office at the Federal Office for Information Security (BSI). The mandate of AG KRITIS was to:

- Describe possible threat scenarios for Germany;
- Conduct a vulnerability analysis of Germany's crucial sectors;
- Suggest countermeasures;
- Sketch an early-warning system.

The work of AG KRITIS [5] was an important basis for all further activities of public agencies in Germany.[1]

### 3.1 Situational Analysis of Threats and Hazards/CIP-Initiatives

CIP/CIIP activities were intensified after the events of 11 September 2001. The need for more coordinated CIP efforts was underpinned by lessons identified after the floods of the Danube, Oder, and Elbe rivers in the following years. The following sections provide summaries of CIP-related reports, recommendations, and activities. CIIP-related initiatives and reports are described in the next section.

***3.1.1 Comprehensive Report on Threats and Hazards.*** In March 2006, the Ministry of the Interior published a second comprehensive threat analysis for Germany [6]. The IT section in this report is founded on previous reports and continues to answer questions identified by the AG KRITIS work. Together with other national assets, information security is defined as crucial for the security of the German society and for the success of its economy.

***3.1.2 Kirchbach Report.*** The Kirchbach Commission, established in Saxony after the devastating flood of 2002, analyzed the overall structure of the German emergency protection system. Besides the focus on the flood disaster, the Kirchbach report provided a comprehensive analysis of existing facilities and recommendations for future capacities to secure information and communications technology in cases of emergency [7]. This disaster and the conclusions of the Kirchbach report triggered a broad range of measures in several ministries and agencies.

***3.1.3 Critical Infrastructure Protection—Baseline Protection Concept.*** The CIP baseline protection concept was developed in close cooperation between the Federal Ministry of the Interior (BMI), the Federal Office of Civil Protection and Disaster Assistance (BBK), the Federal Criminal Police Agency (BKA), and the private sector. It provides guidance for the analysis of potential hazards such as terrorist attacks, criminal acts, and natural disasters, as well as recommendations for companies on adequate protective measures [8].

***3.1.4 Protecting Critical Infrastructures—Risk and Crisis Management. A Guide for Companies and Government Authorities.*** The CIP baseline protection concept was complemented by a guideline Protecting Critical Infrastructures—Risk and Crisis Management. A Guide for Companies and Government Authorities [9], which was published in December 2007 and presented in January 2008. This guideline provides methods to support the implementation of risk management and crisis management in enterprises and government organizations and offers checklists and examples.

[1]The report of AG KRITIS was, however, never published. A draft version in German can be found in Ref. [5].

### 3.2 CIIP Initiatives

As already mentioned, the attacks in the US on 11 September 2001 lead to a considerable intensifying of activities in the area of CIIP as well.

***3.2.1 CIIP at the BSI.*** After 2001, several departments at the Federal Office for Information Security (BSI) were expanded and given additional tasks to support critical information infrastructure protection.

On its website, the BSI regularly updates information and practical advice on critical infrastructures [10].

In mid-2002, BMI and BSI commissioned a series of systematic infrastructure analysis studies on the influence of ICT on the CI sectors. The results of these studies, though unpublished, induced a number of further activities both in intensifying the dialog between public and private sectors and in developing and implementing CIIP-related strategies and policies, as described in the following subsections.

***3.2.2 National Plan for Information Infrastructure Protection (NPSI).*** The National Plan for the Protection of Information Infrastructures (NPSI), issued in 2005, is the federal government's umbrella strategy for a comprehensive approach to the protection of ICT and ICT-dependent assets [11]. It aims at strengthening IT security in the nation's IT-dependent infrastructures and at enabling swift responses to IT-related crises.

The NPSI pursues three strategic objectives:

- *Prevention.* protecting information infrastructures adequately;
- *Preparedness.* responding effectively to IT security incidents;
- *Sustainability.* enhancing German competence in IT security and setting international standards.

This strategy addresses public authorities as well as businesses and individuals. The NPSI announced two implementation plans, one for the federal administration and one for critical infrastructures, both of which were finalized in 2007 [12]. By cabinet decision, the implementation plan for the federal administration presents a mandatory IT security guideline. Implementing the designated measures will ensure a high level of IT security throughout the federal administration in a mid- to long-term perspective.

***3.2.3 CIP Implementation Plan.*** The CIP implementation plan [13] was prepared in close cooperation between representatives of critical infrastructure operators and service providers as well as experts from the federal administration. The plan aims at implementing measures that make it possible to bring the goals of operators in the private industry in line with the higher-level (safeguarding) interests of the community.

The plan addresses the need for measures that meet security requirements extending beyond the security and business continuity responsibilities within the enterprises, as well as the aim of encouraging industries to scrutinize their own security and risk management approaches.

This implementation plan also introduces a roadmap to the future: the following topics will be pursued in direct follow-up activities:

- Emergency and crisis exercises;
- Crisis response and management;

- Maintaining critical infrastructure services;
- National and international cooperation.

In future there will be regular reporting on progress and results, as well as updates of the implementation plan in response to progress and changes in the IT and threat environment.

***3.2.4 IT and Internet Security Situation in Germany.*** In order to provide general information on the IT security and internet security situation in Germany, the BSI started to publish a report on the IT Security Situation in Germany in 2005 (with a second edition following in 2007), which provides a survey of current threats to information and information systems, of the challenges to be met in order to secure information infrastructures, and of trends related to new information technologies and evolving threats. Furthermore, the BSI has started to issue a quarterly summary of the internet threat situation in 2007 [14].

***3.2.5 IT Security Guidelines.*** The IT Security Guidelines published by the BSI are intended to satisfy the needs of small and medium-sized businesses, summarizing the most important IT security measures in a compact overview that is intelligible to the non-expert. The focus is on organizational safeguards and on illustrating threats through practical examples [15].

### 3.3 E-Government Initiatives

The German e-Government initiative [16] aims to use modern information and communications technologies consistently in order to make administrative processes more efficient, and to facilitate an exchange between the business community, the public, and the administration. In short: e-Government should ensure that each agency within the federal administration is just one mouse click away for the citizen.

The BundOnline 2005 initiative—to make all suitable government services of the federal administration available to the public through the internet—was successfully concluded in August 2005.[2] The BSI had been tasked with developing the basic IT security components and with setting up the data security competence center. The BSI also published the e-Government Manual [18] covering all aspects of secure e-Government and presenting pragmatic approaches. In September 2006, the federal government initiated the E-Government 2.0 program for the further enhancement of e-Government services until 2010 [19].

As a related activity, Germany Online is the national e-government strategy pursued by the federal government, governments of federal states, and municipal administrations, initiated in 2003 [20].The goal was to establish a secure communications network for the entire German administration, and particularly for communication between the different state levels, i.e., the municipalities, the states, and the federal government. In June 2006, Chancellor Angela Merkel, together with the heads of the federal states' governments, adopted the Action Plan Germany Online, which was extended in June 2007 [21]. Among the six prioritized projects, the establishment of the communications infrastructure is the most relevant one from a CIIP perspective [21].

[2]For the final report, see [17].

### 3.4 International Collaboration

A joint initiative of the German Ministry of the Interior [22] and the US Department of Homeland Security [23] at the ministerial level in 2003 laid the groundwork for cooperation in several CIIP-related activities [24]. Among others, both parties agreed to foster regular consultations in international organizations in order to enhance multilateral cooperation. This bilateral initiative complements the already ongoing counter-terrorism efforts. As a mid-term result, the International Watch and Warning Network (IWWN) has been established, currently involving 15 participants from all continents.

Multilateral conferences such as the International Watch, Warning and Incident Response Workshop held in Berlin in October 2004, the International Watch and Warning Network Conference in Washington, D.C. in June 2006 (both co-hosted by the US and Germany), or the European IT security conference Innovation and Responsibility in Berlin during the German EU presidency 2007, with one of the six tracks dedicated to CIIP, have contributed to the development and improvement of methods for multinational cooperation. Furthermore, Germany is actively participating in efforts aimed at bringing forward the European Programme for Critical Infrastructure Protection (EPCIP) [25]. Germany's international CIIP activities also include participation in CIIP-relevant projects and working groups, such as the European SCADA and Control Systems Information Exchange (E-SCSIE) [26].

Moreover, Germany participates in efforts to identify, develop, and share CIIP good practice recommendations, e.g., the "Best Practices for Improving CIIP in Collaboration of Governmental Bodies with Operators of Critical Information Infrastructures" currently being discussed by the G8 High-Tech Crime Subgroup (HTCSG).

## 4 ORGANIZATIONAL OVERVIEW

Overall responsibility for, and coordination of, major CIP- and CIIP-related activities rests with the Federal Ministry of the Interior (BMI), together with several of its subordinated agencies, such as the Federal Office for Information Security (BSI) [27], the Federal Office of Civil Protection and Disaster Assistance (BBK) [28], the Federal Criminal Police Agency (BKA) [29], and the Federal Police (BPOL) [30]. For coordination within the ministry and the subordinated agencies, a task force for critical infrastructure protection (AG KRITIS) was established at the BMI in 2002. Strategy development and implementation are also coordinated with other federal ministries, especially the Federal Ministry of Economics and Technology [31], the Federal Chancellery [32], the Federal Ministry of Justice, the Federal Ministry of Foreign Affairs, the Federal Ministry of Defense, and other relevant agencies, such as the Federal Network Agency [33]. Furthermore, strategic partners from the private sector are consulted.

### 4.1 Public Agencies

***4.1.1 Federal Ministry of the Interior (BMI).*** As the government agency responsible for ensuring Germany's internal security, the Federal Ministry of the Interior (BMI) is closely involved with CIP/CIIP. This agency deals with and coordinates the relevant topics, such as physical protection within the context of civil protection and disaster response, threat prevention within the context of law enforcement, and all areas of IT and IT dependence. The authority in charge of IT-related issues with regard to CIIP

is Division IT 3 (Information Technology Security) under the Federal Ministry of the Interior's Chief Information Officer [34]. Responsibility for CIP resides with Division KM 4 (Critical Infrastructure Protection) [35].

***4.1.2 The Federal Office for Information Security (BSI).*** The Federal Office for Information Security (BSI), one of the agencies under the Federal Ministry of the Interior, plays an especially important role in CIIP. The BSI deals with all areas related to security in cyberspace and takes preventive action by analyzing IT weaknesses and developing protective measures, including the following:

- Security of applications and critical infrastructures,
- Security of networks (including CERT Bund, IT situation center, and IT crisis management center, and early warning systems),
- Cryptographic technology,
- New technologies (e.g., biometrics, RFID).

The BSI investigates security risks associated with the use of IT and develops preventive security measures. It provides information on risks and threats relating to the use of information technology and develops appropriate solutions. This work includes IT security testing and assessment of IT systems, including their development, in co-operation with industry. It also analyses developments and trends in information technology. The BSI's services address a broad audience: the federal administration as well as manufacturers, distributors, and private users of information technology [36].

Of special relevance in the CIIP context is the CERT-Bund 24-h on-call availability for the federal administration, and the operation of the IT situation center, where the IT threat situation is assessed on a continuous basis.[3]

***4.1.3 Federal Office of Civil Protection and Disaster Assistance (BBK).*** The Federal Office of Civil Protection and Disaster Assistance (BBK) was established on 1 May 2004 under the Federal Ministry of the Interior [37]. One of the main functions of this agency is information-sharing and resource allocation between the different levels of public authority in case of emergencies.

The BBK has a special focus on CIP.[4] It operates in close cooperation with the BSI and the Federal Network Agency (Bundesnetzagentur) in the field of CIIP. Moreover, contingency plans and appropriate measures are being developed according to case studies [38].

The BBK established the German Emergency Preparedness Information System (deNIS) as a special service for public authorities, emergency responders, and the general public [39]. For the public, deNIS provides general information about organizations and potential emergencies, and offers web links on emergency precaution and preparedness. For a closed user group of emergency responders and crisis management professionals, a secure and classified system called deNIS IIplus has been established [40].

Furthermore, on 1 October 2002, the Joint Reporting and Situation Center (Gemeinsames Melde- und Lagezentrum, GMLZ) took up operation with the objective of enhancing cooperation between federal, state, and local authorities as well as national,

[3]See also the chapter on Early Warning and Public Outreach.

[4]The BBK's main CIP-related output have been the publications on "Critical Infrastructure Protection—Baseline Protection Concept" and "Protecting Critical Infrastructures—Risk and Crisis Management". A Guide for companies and government authorities.

international, and supranational organizations in situations of severe damage and hazards. The tasks include continuous situation assessment; the receipt, acquisition, analysis, processing, coordination, and dissemination of information; and forecasts of damage progression in case of events. International request for emergency support from Germany will be handled through GMLZ.

***4.1.4 The Federal Criminal Police Agency (BKA).*** The Federal Criminal Police Agency (BKA) [41] is responsible in the first instance for prosecuting crimes against the internal or external security of the Federal Republic of Germany and crimes involving damage to or the destruction of critical infrastructures that could result in a serious threat to life, health, or the functioning of society. Further, the BKA is the central agency for investigating crimes involving information and communications technology.

***4.1.5 Federal Ministry of Economics and Technology (BMWi).*** With roughly 85 per cent of Germany's critical infrastructure being privately owned, the Federal Ministry of Economics and Technology (BMWi) [42] also plays a role, as its brief includes economic policy on the one hand, but also oversight over several CI sectors on the other (through the Federal Network Agency, see below). With regard to the energy sector, one of the BMWi's tasks is developing the framework for securing the energy supply. According to Article 87f of the German constitution, the BMWi is also responsible for ensuring the availability of adequate telecommunications infrastructure and services.

***4.1.6 Federal Network Agency.*** In July 2005, the Regulatory Authority for Telecommunications and Posts was renamed the Federal Network Agency for Electricity, Gas, Telecommunications, Post, and Railway. The Federal Network Agency is a higher federal authority within the scope of business of the Federal Ministry of Economics and Technology. The Federal Network Agency's task is to provide, by liberalization and deregulation, for the further development of the electricity, gas, telecommunications, and postal markets and, as of January 2006, of the railway infrastructure market as well [43].

***4.1.7 Other ministries involved.*** The Federal Ministry of Justice (BMJ) [44] is responsible for relevant legislation, in particular for ensuring that national laws comply with relevant EU legislation such as the EU Council Framework Decision on attacks against information systems [45].

The Federal Ministry of Defense (BMVg) [46] is involved in the context of its responsibility for national defense and for maintaining troop readiness and performance.

The Federal Chancellery plays a coordinating role at the ministerial level. Additional ministries with specific areas of responsibility are also involved in CIP.

Responsibilities are also shared among the agencies within the remit of the various ministries. The Federal Intelligence Service (Bundesnachrichtendienst, BND) and the Federal Office for the Protection of the Constitution (Bundesamt für Verfassungsschutz, BfV) provide important information regarding the threat situation and possible domestic targets.

## 4.2 Public-Private Partnerships

***4.2.1 CIP Implementation Plan.*** The latest example of public-private cooperation was the development of the CIP implementation plan (see chapter on Past and Present Initiatives and Policies), followed by a set of ongoing activities to actually implement measures.

***4.2.2 Germany Secure in the Web Campaign.*** The campaign Germany Secure in the Web (Deutschland sicher im Netz, DsiN) [47] is an initiative undertaken under the auspices of the Federal Minister of the Interior. Members include private enterprises as well as associations and non-profit organizations. Its main objective is to improve the security of both private and commercial IT users, to provide private users and small and medium-sized enterprises with a sound basis of information that encourages the use of, and confidence in, the internet and internet-based services, and to raise awareness of all relevant IT security issues. The association also targets children and adolescents specifically, with the objective of raising their awareness and that of their parents of IT-security related issues, but also to protect them from, and prevent them from accessing, criminal and abusive contents.

***4.2.3 Initiative D21.*** Launched in 1999, Initiative D21 [48] is the largest public-private partnership in Germany. This economic initiative also deals with information security. Initiative D21 is a neutral platform, independent of party allegiance and of individual industrial sectors. D21 has more than 200 participants from enterprises, associations, parties, political institutions, and other organizations. Initiative D21 pursues a steadily growing number of projects. Initiative D21 is organized into three subject areas (steering groups):

- Digital Integration,
- Digital Competence,
- Digital Excellence [48].

## 5 EARLY WARNING AND PUBLIC OUTREACH

### 5.1 CERT-Bund

The CERT-Bund unit was established on 1 September 2001 at the Federal Office for Information Security (BSI). CERT-Bund is a central contact point charged with protecting the security of data processes and networks of the federal public administration. CERT-Bund also offers some of its services to clients from the private sector. However, several services are only available to the federal administration (e.g., incident response) [49]. CERT-Bund's main tasks include warning and information-sharing, data collection, analysis and processing of information, documentation and dissemination, sensitization of IT decisionmakers, and cooperation with existing CERTs [50].

### 5.2 CERT-Network

The CERT-Verbund (CERT Network) is an alliance of German security and computer emergency teams [51]. The alliance provides a common base for cooperation between the teams and also allows the pursuit of the overarching objectives, namely to ensure the protection of national IT networks or to prepare for swift and coordinated reaction in case of larger IT security incidents.

### 5.3 IT Situation Center

The IT Situation Center collects, assesses, and summarizes information on the IT situation in Germany as a continuously updated situational picture. The processes of

gathering information and establishing an information exchange in cooperation with relevant partners, e.g., from critical infrastructures, are constantly being further developed. Procedures are emerging to share assessment results, including alerts and warnings, in a target-oriented way with a variety of audiences, including government agencies, critical infrastructure operators, and the general public.[5]

### 5.4 IT Crisis Response Center

To be prepared for national crisis situations affecting information infrastructures, Germany has established an IT Crisis Response Center as a non-standing organization located at the BSI, closely related to the IT situation center. Situational crisis indicators will activate IT crisis response functions to warn and alarm potentially affected parties and to develop countermeasures. Moreover, the center supports a coordination board for the IT security of the federal ministries in organizing timely responses to minimize and to contain damage, and to return swiftly to the safe and secure operation of affected information infrastructures [52].

### 5.5 Services for Citizens and SMEs

***5.5.1 Citizens' CERT (Bürger-CERT).*** The Citizens' CERT [53] project aims at informing and warning citizens and small enterprises of the threats stemming from worms, viruses, and security loopholes in IT systems not only rapidly and competently, but also from an explicitly neutral perspective and at no cost. The Citizens' CERT project was initiated jointly by the BSI and Mcert[6] in 2006. Since June 2007, Citizens' CERT has been maintained exclusively by the BSI. Every citizen can subscribe to the services of the Citizens' CERT project, which include technical warnings, a bi-weekly newsletter, and special editions of the newsletter. Thus, the project aims to make as many people as possible aware of the issues the importance of IT security [54]. For general information on IT security, there is a direct link to the website "BSI for the Citizen".

***5.5.2 BSI for the Citizen.*** The internet service "BSI for the citizen" [54] aims at providing easy-to-understand background information on IT security and the internet. The service offers guidance on how to surf the internet and use internet-based applications securely. For up-to-date warnings on new internet threats and a newsletter, users can follow a direct link to the Citizens' CERT webpage, which serves as a warning and information service for citizens.

## 6 LAW AND LEGISLATION

### 6.1 Telecommunications Act

First enacted in 1996, this act was revised in 2004 and last amended in 2007 [55]. Its purpose is to provide legal provisions for the liberalization and deregulation of the telecommunications market.

[5]Information provided by an expert.

[6]Mcert began as a CERT for SMEs in 2003 and suspended its services in June 2007, with key tasks being continued by Citizens' CERT and the initiative "Germany Secure in the Web" (see above).

### 6.2 Telecommunications and Media Act 2007

The Information and Telecommunications Services Act (Informations- und Kommunikationsdienste-Gesetz, IuKDG) of 1997 [56] was the starting point for the liberalization of the German telecommunications market [57]. The IuKDG and all related acts expired in 2007 with the enacting of the Telecommunications and Media Act (Telemediengesetz, TMG) [58].

### 6.3 Electronic Signature Act 2001

In May 2001, this act (which conforms to EU regulations) replaced the existing pioneer Digital Signature Act of 1997. The main purpose of the act is to define a framework for the handling of electronic signatures [59]. The act was last amended on 26 February 2007.

### 6.4 Penal Code

To implement the EU Council Framework decision on 2005/222/JHA of 24 February 2005 on attacks against information systems, the German penal code was amended on 7 August 2007, affecting §202a on data espionage, §202b on data interception, §202c on the preparation of data espionage and interception, §303a on alteration of data, and §303b on computer sabotage [60, 61].

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Susanne Jantsch and Monika John-Koch of the Federal Office of Civil Protection and Disaster Assistance, who validated the content of this chapter.

# HUNGARY

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

In 2005, Hungary welcomed the EU program for Critical Infrastructure Protection (EPCIP). Even though some policies in the field of CIP had already been implemented before, the EU program highly influenced the further development of Hungary's CIP and CIIP policies. Accordingly, the Hungarian definition of the concept of critical infrastructure corresponds to the definitions of the EU as formulated in the Green Paper of the EU Commission [1].[1] Critical Infrastructures, according to the Hungarian Green Book, are defined as interconnected, interactive, and interdependent infrastructure elements, establishments, services, and systems that are vital for the operation of the national economy and public utilities to maintain an acceptable level of security for the nation, individual lives, and private property, as well as concerning the maintenance of

[1]Cf. the article on the EU in this volume.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

the economy, the public health services, and the environment.[2] The CI sectors in the Green Book include the following:

- Information and Telecommunication Systems,
- Energy,
- Water Supply,
- Transport,
- Public Health,
- Food-Products Supply,
- Banking and Financial Sector,
- Industry,
- Government Institutions,
- Public Security and Homeland Defense.[2]

In addition, a legal definition has been agreed that includes e-communications and postal services among the nation's critical infrastructures. According to article 2, no. 11 of ministerial decree no. 27/2004 of the Ministry of Informatics and Communications on the National Alert Service of the Postal and Communications Sector and the Tasks of the Designated Service Providers, a critical information infrastructure can be "any object or service, including e-communications and informatics systems, of which inoperability or destruction can severely impair, either separately or in conjunction with other inoperable or destroyed critical infrastructure, national security, the life and property of citizens, the proper functioning of national economy and public services".[2]

## 2 PAST AND PRESENT INITIATIVES AND POLICY

The increasing importance of ICT in the Hungarian economy has prompted the government to increase its commitment to the security of information systems and networks in general and of CIIP in particular. These efforts were fostered by the EU, which has implemented various programs to strengthen the information society in its member states. Thus, Hungary has initiated different initiatives and policies aiming to promote the information society in recent years. This section presents the most important initiatives and policies with regard to CIIP and information security.

### 2.1 The National Security Strategy of the Republic of Hungary

The protection of important information systems and critical information infrastructures is an integral part of the National Security Strategy of the Republic of Hungary. The challenges of the information society and the vulnerabilities of the new communication technologies are explicitly mentioned as risk factors for the country [2].

The National Security Strategy also clearly points out the need for collaboration with international and private partners in the field of protection of information systems: "Successful protection [of information systems] requires close co-ordination with allies, as well as information and telecommunication providers and research centers" [3].

[2]Information provided by an expert.

On 18 December 2007 the National Security Cabinet of the government decided to establish a new Information Security Inspectorate (ISI), into whose jurisdiction CIIP will also fall, to issue new regulation on ISI, and to set up a coordination body for information security and CIIP. These tasks are to be fulfilled until the end of 2008.

### 2.2 The Hungarian Information Society Strategy

Despite of the rapid evolvement in the last years [4], internet penetration in Hungary is still relatively low, and the number of "digital illiterates" is considered to be too high. Hence, the focus of the strategy is the development of a modern society and a competitive economy based on a widespread usage of information and communication technologies.

The Information Society Strategy consists of two pillars: the introduction of information technologies into (economic) processes, and the implementation of public electronic services.

Information security and the protection of privacy are seen as essential parts of the development towards an information society, since the extent to with ICT is used is determined by the extent to which people trust new technology. The strategy therefore identifies IT security as a field of governmental intervention and highlights the necessity of regulatory, organizational, and technological measures.

### 2.3 The National Information Infrastructure Development Program (NIIF)

The National Information Infrastructure Development Program [5] was initiated to operate and advance the network of research bodies in Hungary. The program, which has been running since 1986, is the oldest and best established program for information and communication technology in Hungary. As a research program, the NIIF is essential for the development of the information society. By providing up-to-date information infrastructure for the academic and research community, the program introduces advanced network technology in Hungary.

The technical expertise of the NIIF and its broad network of national and international contacts are important for CIIP. The NIIF also operates a Computer Incident Response Team (CSIRT, see chapter on Early Warning and Public Outreach), and cooperates closely with other institutions involved in research on network security.

### 2.4 Security Evaluation and Certification Scheme

Based on international standards like the Common Criteria and the Common Evaluation Methodology [6], the Ministry of Informatics and Communications launched the Hungarian Information Security Evaluation and Certification Scheme (MIBETS) [7]. MIBETS assists in evaluating and testing the security of software.

In addition, the ministry introduced the Information Security Management Framework (MIBIK), which aims to evaluate security measures at the organizational level.

The current government scheme includes an updated version of the MIBETS and MIBIK, now jointly abbreviated as MIBA. Government IT systems must be in compliance with the recommendations of the scheme, and a supervisory body will begin operating within the Prime Minister's Office Electronic Government Center from the first half of 2008.

## 3 ORGANIZATIONAL OVERVIEW

After the parliamentary elections of April-May 2006, the organization of the government was restructured. With regard to CIIP and the development of the information society, the most important change was the integration of the Ministry of Informatics and Communication-which was the central body for questions related to information and communication technology-into the Ministry of Economy and Transport and the Prime Minister's Office. The major tasks of CIIP are now mainly allocated in different ministries:

- *Ministry of Economy and Transport [8].* As the ministry responsible for the maintenance and development of economic infrastructure—including the information infrastructure—the Ministry of Economy and Transport coordinates the various efforts in the field of CIP and CIIP;
- *Prime Minister's Office [9].* Through the Electronic Government Center [10], the Prime Minister's Office coordinates the efforts with regard to e-Government, as well as other CIIP-related issues;
- *Ministry of Defense [11].* This ministry is responsible for national security, including the security of information. In particular, it is responsible for protecting state secrets and public data;
- *Ministry of Justice and Law Enforcement [12].* The duties and responsibilities of this ministry include crime prevention and data protection. It controls the Public Administration and Central Electronic Public Services Office, which is the central body for all tasks relating to the provision of e-government services and the management of electronic records and documents.

Since information security and CIIP is a horizontal issue that cuts across the responsibilities of individual government departments, Hungary has established a number of inter-ministerial bodies dealing with these tasks. In addition, Theodore Puskás Foundation, which works as a public-private partnership, plays an important role in CIIP, since it operates the national Computer Emergency Response Team (CERT-Hungary).

### 3.1 Public Agencies

***3.1.1 The National Communications Authority (NCA).*** Based on the Electronic Communications Act of 2003, the National Communications Authority was established in 2004 as an independent regulatory body for communications. The NCA's main task is to support the development of the communications market and to ensure that every citizen has access to affordable and reliable communications services. The NCA constantly analyzes the market and exchanges information with national and international experts, and adapts its capabilities, methods, and operations accordingly.

The NCA is also responsible for the National Alert Service (NAS) in the postal and communication sectors, the operation of which has been outsourced to the CERT-Hungary Center of the Theodore Puskás Foundation (see chapter on Early Warning and Public Outreach). The NAS is based upon the co-operation of designated service providers who report the incidents affecting their services to the NAS. The main task of NAS is to gather and distribute these reports and to co-ordinate among service providers in case of

emergency in affected regions, most frequently in case of spring floods in North-Eastern Hungary.[3]

***3.1.2 The National Board for Communications and Information Technology.*** The National Frequency Allocation Board—the legal predecessor of the National Board for Communications and Information Technology [13]—was established in 1993 by the government as an independent consulting and recommendation-making body for the allocation of radio and television frequencies. Over the years, its jurisdiction has been expanded, and today, the board is engaged in the fields of information technology, telecommunication, and media.

Some of the members of the board are appointed by the government (e.g., the chairman, who is appointed by the President of the Republic), but there are also members appointed by scientific institutions and by the lobbies of the telecommunication companies. This heterogeneous composition ensures that the most important interests are represented, so that the board's recommendations are well-balanced.

The board elaborates drafts of laws and decrees related to IT or telecommunication and aims to foster the development of the information infrastructure.

### 3.2 Public-Private Partnerships

***3.2.1 Theodore Puskás Foundation.*** The Theodore Puskás Foundation [14] was established in 1992. It was co-founded by the government of Hungary and several distinguished institutions and businesses. It operates as a non-profit, public benefit organization. Its main objective is the dissemination of advanced technologies in Hungary. The foundation's activities include scientific research, consultations, and instruction in the field of information technologies.

In 2004, the Ministry of Informatics and Communication contracted the foundation to operate the national Computer Emergency Response Team (CERT-Hungary, see below), in consideration of its good reputation of the foundation and its research experiences in the field of information technology.

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 Computer Emergency Response Teams (CERTs)

In Hungary, there are three important CERTs. Each of them serves a different constituency.

***4.1.1 CERT-Hungary.*** CERT-Hungary [15] is the governmental and national CERT. It is operated by the Theodore Puskás Foundation and was established in 2005. In its function as governmental CERT, it aims to improve information security of public agencies and is responsible for the technical aspects of CIIP. In order to combat high-tech crime efficiently, CERT-Hungary has developed direct communication channels to the national police force, and closely collaborates with all other agencies involved in CIIP [7]. CERT-Hungary is an accredited member of all main CERT forums, and acts as a National Contact Point for incident-handling and CIIP-related issues.

[3]Information provided by the Hungarian experts involved.

Furthermore, CERT-Hungary offers also some free services for the public, in particular warnings about emerging threats and new vulnerabilities, and provides chargeable services for private companies, e.g., intrusion detection, security audits, or malware analysis. Finally, CERT-Hungary coordinates a SCADA working group, which is organized jointly by government agencies and the operators of SCADA networks.[3]

***4.1.2 Hun-CERT.*** Hun-CERT [16] is operated by the Computer and Automation Research Institute of the Hungarian Academy of Sciences (MTA SZAKI) [17]. It is sponsored by the Council of Hungarian Internet Service Providers (ISZT) [18] and mainly serves the interests of the members of the council. However, it is the intention of Hun-CERT to disseminate information on network security information among the general public.

Hun-CERT deals with all kinds of computer security incidents affecting Hungarian internet service providers. It supports system administrators in tackling these incidents. The level of support given varies according to the type and severity of the incident, the available resources of Hun-CERT, and the size of the affected community).

***4.1.3 NIIF-CERT.*** The NIIF-CSIRT (Computer Security Incidents Response Team of the National Information Infrastructure Development Program) [19] helps the members of the academic networks (NIIF and HUNGARNET) to handle all kinds of security incidents. The NIIF-CSIRT also disseminates important security-related information and warnings to its members.

### 4.2 Hungarian Financial Services ISAC

In 2007, with the coordination of CERT-Hungary, the Hungarian Financial Services ISAC (Information Sharing and Analysis Center) was formed, involving law enforcement, the Hungarian banking association, the Hungarian Financial Regulatory Authority, and individual banks, including the biggest commercial banks. The cooperation between the parties resulted in several exercises, an incident handling directory, and cooperation on a recommendation about IT security in online banking.[3]

### 4.3 Awareness Raising Programs

The www.biztonsagosinternet.hu project ("biztonsagos" means "safe") was launched by CERT-Hungary in May 2006 in order to provide a website for the general public with information on IT security in an easy understandable manner. The project is an adaptation of the German awareness-raising-program BSI für Bürger,[4] where the structure of the German model was adopted, and the texts were fitted to the Hungarian circumstances. The website gives advice for internet usage in general, and for e-shopping and e-banking in particular; it provides information on spam, viruses, and other threats to information security, and demonstrates how users can protect their privacy (with a special focus on child protection). Other awareness-raising programs include www.internethotline.hu and www.baratsagosinternet.hu. Both initiatives came into being as part of the Safer Internet Program—the first operating as an internet hotline for reporting harmful and illegal content, the other being the awareness node of Hungary.

[4]Cf. Country Survey Germany (in this volume).

The "e-Inclusion, be part of it!" [20] campaign was launched in December 2007. It aims to urge European governments and associations to give disabled people access to the advantages that the internet and information and communication technologies provide. The EU has issued three official calls since 2006 urging European governments to promote the advantages and digital opportunities of ICT for senior citizens, ill or disabled people, women (including those on maternity leave), minorities, or people living in rural areas of Hungary. Not only is Hungary's effort scant as far as the issue of inclusion in the information society is concerned. The majority of the Hungarian population are not aware of the advantages of the internet. The EU aims to change this situation by reducing the ratio of 'digital analphabetism' by half by 2010.

The Forum of Hungarian IT Organizations for Information Society (Inforum), together with other associations and firms, has announced plans to join the EU's initiative and is in the process of launching the e-Inclusion Year 2008, Hungary movement.

## 5 LAW AND LEGISLATION

### 5.1 Penal Code

The Hungarian Penal Code includes several sections that are of relevance with regard to CIIP.[5] Particularly important are Articles 300/C and 300/E.

*Article 300/C.* Criminal Conduct for Breaching Computer Systems and Computer Data: This article states that any person who gains unauthorized entry to a computer system shall be punished by imprisonment or community service. The punishment shall be more severe if the person alters, damages, or deletes data without permission, and particularly if the act is committed for financial gain.

*Article 300/E.* Compromising or Defrauding the Integrity of the Computer Protection System of Device: This article prohibits the creation, obtaining, and distribution of software, passwords, entry codes, or other data that can be used to gain access to a computer system or network illegally.

### 5.2 Act on Protection of Personal Data and Disclosure of Data of Public Interest

Enacted in 1992, the Personal Data Protection Act (Act LXIII, Article 10) [22] sets rules and safeguards regarding the processing of personal data by public and private bodies. Its application is controlled by the Parliamentary Commissioner for Data Protection and Freedom of Information.

### 5.3 Act on Electronic Commerce and Information Society Services

Adopted in 2001, this act implements an EU directive on electronic commerce. In doing so, it not only integrates the EU directive, but also makes use of the regulatory solutions included in the German (TDDSG, Mediendienststaatsvertrag) and US (Digital Millenium Copyright Act) legislation, especially in the sections relating to the liability of Information Service Providers (ISPs) and the notice-and-takedown procedure. The act governs the legal relationships of individuals, legal persons, and organizations for the

[5]For an overview on the cybercrime legislation of Hungary, see: [21].

purposes of e-commerce, in cases where the service is provided for or from the territory of Hungary [22].

### 5.4 Act on Electronic Signature

The Act on Electronic Signature [23] was adopted on 29 May 2001 and entered into force on 1 September 2001. It provides for legal recognition of electronic signatures (e-signatures) and electronic documents. Electronic documents and e-signatures are presumed to be admissible evidence in court and may not be challenged successfully based on the mere fact of their electronic form. An electronic document signed with an e-signature is deemed to be in compliance with a statutory requirement for a handwritten signature on a paper document. However, the act excludes family-related documents (e.g., marriage certificates and divorce decrees), and those documents must continue to be in paper form to have legal validity. Also, consumers are not obliged to accept the electronic format; if a consumer objects, a business firm must use paper documents. Hungarian government departments may elect to issue or accept electronic documents. Although all types of e-signatures are recognized, the digital signature enjoys most-favored status because it utilizes cryptographic methods resulting in a heightened degree of reliability and security.

### 5.5 Further Regulations with Regard to CIIP and Information Security

In addition to the acts mentioned above, there are several further acts and decrees referring to CIIP and information security to some extent:

- Act no. CXII of 1996 on financial institutions and enterprises has a separate section in §3B on the security requirements of IT systems within financial institutions and enterprises;
- Act no. LXXXV of 1998 on the establishment of the National Security Supervision Office (NSSO): The NSSO is to provide advice on security for personal, physical, document and information, and industrial purposes. The office is also in compliance with the security measures promulgated within NATO, with regard to classified information;
- Government Decree 180/2003 on the rules of procedures of NSSO. Chapter IV regulates the detailed procedures of electronic security supervision;
- Ministerial Decrees 24/2004 and 27/2004 of the Ministry of Informatics and Communications on the National Alert Service in the Postal and Communications Sector and the Designated Service Providers: Ministerial Decree 24/2004 obliges service providers to co-operate in the National Alert Service (NAS) of the Postal and Communication Sector. Decree 27/2004 sets the rules for the organization and operation of the NAS and gives a thorough list of definitions for CIIP (e.g., critical infrastructure, network security);
- Government Decree 84/2007 on the security measures of the Central Electronic Service System and adjoining systems: This decree states that the same security measures have to apply to all systems of the Central Electronic Service System (CESS), which include the government backbone, the government portal, the client portal, and all the services available through these gateways. The decree lists the

uniform requirements of IT security for the CESS and includes the IT catastrophe recovery plan. The Prime Minister's Office is the operator of the Central Electronic Service System.[2]

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Bence Birkás and Ferenc Suba of CERT, Lajos Muha of Dennis Gabor College, Barbara Locher of the Ministry of Economics and Transport, Peter Csokany of the National Communication Authority, and Csaba Sandor of the Electronic Government Center, who validated the content of this chapter.

# INDIA

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

In India, the following sectors are considered critical:

- Banking and Finance,
- Insurance,
- Civil Aviation,
- Telecommunications,
- Atomic Energy,
- Power,
- Ports,
- Railways,
- Space,
- Petroleum and Natural Gas,
- Defense,
- Law Enforcement Agencies.

These 12 critical sectors were identified by the National Task Force on Y2K a few years ago, taking into account the extent of penetration of information technology in these sectors and the impact that a disruption of any of these sectors would have [1].

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

In India, many efforts in the field of CIIP were triggered by the government's goal of making the country a leading knowledge-driven global economy by boosting IT and e-business. In 1998, the prime minister of India announced a drive to make India an IT superpower and one of the largest producers and exporters of software in the world within the next ten years. The government of India has recognized the potential of IT for

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

rapid national development [2]. Therefore, it has established a National Task Force on Information Technology and Software Development [3] and a Department of Information Technology (DIT) within the Ministry of Communications and Information Technology, also dealing with CIIP [4].

### 2.1 National Task Force on Information Technology and Software Development and Information Technology Action Plan

The Indian government has given top priority to developing an appropriate action plan for the country to emerge as a global leader in the field of IT. As a first step, the National Task Force on IT and Software Development [3] was set up by the then Prime Minister Atal Behari Vajpayee on 22 May 1998, under the chairmanship of the deputy chairman of the planning commission. This task force had a mandate to formulate the draft of a National Informatics Policy, including [5]:

- To recommend an appropriate institutional mechanism to implement this policy as a national mission with the participation of the central and state governments, industry, academic institutions, and society at large;
- To prepare a vision statement that will excite and energize the people of India, creating a faith in IT for personal and national growth. The task force will also suggest a strategy for the effective articulation and dissemination of that vision, so as to create an ethos, an ambiance, a mind-set, and a work culture that is consistent with the needs of the emerging knowledge-driven global civilization;
- To prepare a blueprint for the nationwide adoption of information technology, with a network of task forces at all governmental and non-governmental levels.

The IT Task Force submitted its first report in the form of an Information Technology Action Plan to the prime minister on 4 July 1998. The report contained a special section on IT for all by Year 2008, the centerpiece of which is a major national campaign called Operation Knowledge, focusing on spreading IT and IT-based education at all levels.[1]

The establishment of the Task Force is a clear indication that IT is an area where India wants to achieve global pre-eminence. It is hoped that IT, fostered by these government policies, will prove immensely useful in all areas of national economy—especially industry, trade, and services— and will contribute significantly to making India a global economic power.[1]

### 2.2 National e-Governance Plan (NeGP)

The government of India approved the National e-Governance Plan [7] (NeGP) on 18 May 2006. The plan lays the foundation and provides the impetus for long-term growth of e-governance within the country. The plan is intended to create the right government and institutional mechanisms, to set up the core infrastructure and policies, and to make the public administration more responsive to the needs of citizens and businesses.

[1]The IT Action Plan included, among others, the following measures: Ministries and departments to earmark 1-3 per cent of their budget for IT; IT literacy requirement for government/public-sector employment; software and IT to be treated as a priority sector by banks; zero tax on all IT products by 2002; internet access through cable TV; early introduction of IT legislation; networking of all engineering/medical colleges and universities before 2000 [6].

The NeGP has started to realize three important elements of the e-Governance Plan that form the core infrastructure for effective service delivery: Data processing centers, State Wide Area Networks (SWANs), and Common Services Centres (CSCs). In addition, the government announced in 2006 that it would enhance its efforts to bring a number of services online. Subsumed under the label 'E-District', these services are provided at the district level and serve as the primary interface between citizens and the government [8].

### 2.3 Core Group on Standards for e-Governance

Under the NeGP, standards for e-governance are crucial to ensure integration and interoperability of data and electronic applications. The Department of Information Technology (DIT) has therefore constituted a Core Group on Standards for e-Governance [9] to develop an institutional mechanism and processes, and to recommend key areas for standardization. Some of the priority areas for standardization are:

- Technical standards,
- Localization standards,
- Quality and documentation,
- Security standards,
- Metadata and data standards for various application domains.

An apex body has been constituted under the chairmanship of the secretary of the DIT with senior representatives from the government, the National Association of Software and Service Companies (NASSCOM) [10], the Bureau of Indian Standards (BIS), and others with a mandate to approve, deliver notification of, and enforce the standards formulated by various working groups and to ensure that they are in accordance with international practices.

The National Informatics Centre (NIC) [11] publishes whitepapers on all the desired standards, which serve as discussion papers for the working groups that develop the standards.[2] The working groups with representatives of the DIT, associations, industry, academia, and central and state governments, etc., are constituted with the approval of the DIT.

The standards approved by the apex body are released on the web by the Standardization Testing and Quality Certification (STQC) Directorate, an office attached to the DIT. The STQC further ensures conformance and certification (where required) of these standards. The e-Governance Division of the NIC and the STQC function in tandem with the e-Governance Programme Management Unit at DIT.[3]

[2]The National Informatics Centre (NIC) of the Department of Information Technology provides network backbone and e-governance support to the central government, state governments, administrations, districts, and other government bodies. It offers a wide range of ICT services, including a nationwide communication network for decentralized planning, improvement in government services, and greater transparency of national and local governments. The NIC collaborates closely with central and state governments in implementing IT projects.

[3]Information provided by an expert.

## 3 ORGANIZATIONAL OVERVIEW

In the Indian government, the National Information Board (NIB) is at the very top of the national information security structure. Directly linked to the NIB are the National Technology Research Organization (Technical Cybersecurity) and the National Information Security Coordination Cell (NISCC), which is part of the National Security Council Secretariat (NSCS). The NIB has instructed the NSCS to coordinate cyber-security activities across the country. The NISCC provides input for the consideration of the NIB. It works through the Sectoral Cyber Security Officers (SCOs).

Directly below the NIB are the Information Infrastructure Protection Centre (IIPC), followed by state cyber-police stations; and the Computer Emergency Response Team India (CERT-In), followed by state- and sectoral-level CERTs. Various ministerial coordinators of special functions are also situated at this level, as is the Development and Promotional Section of the Ministry of Communications and Information Technology (MOC).

As a public-private partnership initiative, the Indo-US Cyber Security Forum strives to discuss and implement increasing cooperation in high-technology between the two countries.

### 3.1 Public Agencies

***3.1.1 National Information Board (NIB).*** The establishment of the National Information Board (NIB) was recommended by a group of ministers. It consists of 21 members. The national security advisor is the chairman of the board, while the deputy national security adviser serves as its member secretary. The NIB acts as the highest policy formulation body at the national level and periodically reports to the Cabinet Committee on Security of the Government of India, headed by the Prime Minister. The NIB is at the very top of the information security structure [12].

***3.1.2 National Information Security Coordination Cell (NISCC).*** The NIB has charged the National Security Council Secretariat (NSCS) with coordinating cyber-security activities across the country, covering both the public and the private sectors. NISCC provides input to NIB for its consideration. It works through the Sectoral Cyber Security Officers (SCOs). There are 20 such SCOs in various ministries, where the senior officer holds the rank of a joint secretary or director. The NISCC deals with the following topics: CERT functions, research and development, encryption, laws, interception and early warning, cyber-crime, training, and international cooperation. It represents the government in international forums for cyber-security and issues related to large scale cyber-related incidents.[3]

***3.1.3 Ministry of Communications and Information Technology (MOC): Department of Information Technologies (DIT).*** The Department of Information Technologies (DIT) [13], part of the Ministry of Communications and Information Technology (MOC) [14], was established with the purpose of making India a leading IT nation by 2008. Through the DIT organization, the Indian government has undertaken several initiatives and strategies:

- The promotion of the internet and provision of IT infrastructure;
- The development of legislation;

- The support of IT education and development;
- The promotion of standardization, testing, and quality in IT;
- The establishment of an Information Security Technology Development Council (ISTDC);
- The creation of a National Information Security Assurance Framework;
- The establishment of Inter Ministerial Working Groups [15].

The Indian Computer Emergency Response Team (CERT-In) and the Controller of Certifying Authorities (CCA) are also DIT organizations. The Standardisation, Testing, and Quality Certification (STQC) Directorate and the National Informatics Centre (NIC) are also attached offices of the DIT [16].

The DIT has set up the following Inter Ministerial Working Groups on:

- Cyber-Security Education and Research;
- Cyber-Security Assurance and Awareness;
- Encryption Policy and PKI;
- Legislation and Forensics in Cyberspace;
- Critical Infrastructure Protection [17].

***3.1.4 Standardization, Testing and Quality Certification (STQC) Directorate.*** The Standardization, Testing, and Quality Certification (STQC) Directorate is an office attached to the DIT. The STQC provides quality and security assurance services that meet international standards to Indian companies and users. The STQC program has been in place for over three decades, and the STQC has positioned itself as a prime provider of assurance services to both the hardware and the software industry, as well as for users. The recent focus of the DIT on IT security, software testing and certification, and the assignment of a national assurance framework, has further raised the responsibility of the STQC as well as the expectations it must meet [18]. The STQC worked together with the US National Institute of Standards and Technology (NIST) to create a US standard for controls of Information Security, SP-800-53.

***3.1.5 Information Security Technology Development Council (ISTDC).*** The main objective of the Information Security Technology Development Council (ISTDC) is to facilitate, coordinate, and promote technological advancements, and to respond to information security incidents, threats, and attacks at the national level. ISTDC was established for the following functions [19]:

- To evaluate cyber-security project proposals, and to provide recommendations for further processing by DIT;
- To review on-going projects through monitoring committees and recommend any modification in scope, funding, duration, additional input, termination, and transfer of technology;
- To recommend follow-up action on completed projects concerning transfer of technology and the initiation of subsequent phases;
- To form project review and steering groups of projects approved and funded by the DIT.

### 3.2 Public-Private Partnerships

*3.2.1 Indo-US Cyber Security Forum.* In pursuance of the Indo-US Cyberterrorism Initiative announced by Indian Prime Minister Atal Behari Vajpayee and US President George Bush in Washington in November 2001, the first plenary session of the Indo-US Cyber Security Forum was held at the National Security Council Secretariat (NSCS) in India in April 2002. The second plenary meeting was held in Washington, D.C. in November 2004. This meeting resulted in the creation of five working groups on legal issues and law enforcement, research and development, emergency response and watch and warning, defense cooperation, and standardization. In 2005, the NSCS organized five seminars and a workshop with the help of the Confederation of Indian Industry (CII). There has also been some exchange of experts. In 2006, the third Plenary of the Indo-US Cyber Security Forum was held. The Confederation of Indian Industry, in consultation with its US counterpart, decided to set up an India Information Sharing and Analysis Center and an India Anti-Bot Alliance to raise awareness about emerging threats in cyberspace. CERT-In and the US national Cyber Security Division agreed to share expertise in artifact analysis, network traffic analysis, and exchange of information. The research and development group concentrates on hard problems of cyber-security, cyber-forensics, and anti-spam research [20].

The Indo-US Cyber Security Forum is a part of the Indo-US High Technology Group, a public-private partnership between India and the US established to discuss and implement ways and means of increasing cooperation between the two countries in high-technology areas.

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 Indian Computer Emergency Response Team (CERT-In)

The Indian Computer Emergency Response Team (CERT-In) [21] was established in January 2004 by the Department of Information Technologies (DIT) as part of the international CERT community. It has a mandate to respond to computer security incidents reported by the national computer and networking community as well as to create security awareness among Indian IT users. The main CERT is located in New Delhi, with backup in Bangalore. It has reactive as well as proactive functions [22]. CERT-In aims to become India's most trusted agency for responding to computer security incidents. In addition, CERT-In will also assist Indian IT users in implementing proactive measures to reduce the risks of security incidents.

Another five sector-specific CERTs have been set up: three for the army, air force, and navy; one for banking, known as FinCERT; and one for railways, known as RailCERT. It is anticipated that more CERTs will be established for the telecom and the power sectors.

CERT-In recently appointed a panel of IT security auditors, whose tasks will include vulnerability assessment and penetration testing of the computer systems and networks of various organizations of the government, critical infrastructure organizations, and in other sectors of Indian economy [23]. The auditors will assist CERT-In in assessing the information security risks. They will determine the effectiveness of information security controls over information resources and assets that support operations in the auditor organizations at their request [23].

## 5 LAW AND LEGISLATION

In the year 2000, the government of India enacted the Information Technology Act (IT Act) to provide a framework for the legal recognition of electronic commerce in India. The IT Act provides for the establishment of a public-key infrastructure in India and addresses issues of cyber-crime and the admissibility of digital evidence. It achieves this through various provisions and by way of amendments to other statutes, such as the Indian Penal Code 1860, the Indian Evidence Act of 1872, the Bankers' Books Evidence Act of 1891, and the Reserve Bank of India Act of 1934. The amendments relate to the inclusion of electronic records and other such computerized data alongside the traditional forms of documents.

### 5.1 Information Technology Act 2000 (IT Act)

The IT Act comprises 13 chapters, divided into 94 sections. The chapters relevant to the present discussion are: Chapter V (Secure Electronic Records and Secure Digital Signatures), Chapter VII (Digital Signature Certificates), Chapter IX (Penalties and Adjudication), Chapter XI (Offences), and Chapter XII (Network Service Providers Not To Be Liable In Certain Cases).

The IT Act provides a much-needed legal framework for electronic transactions in India. The National Association of Software and Service Companies (NASSCOM), the leading trade body and the chamber of commerce of the IT software and services industry in India, summarizes some of its key progressive features as follows [24]:

- From the perspective of e-commerce in India, the IT Act 2000 and its provisions contain many positive aspects. First of all, these provisions have approved e-mail as a valid and legal form of communication in India that can be duly produced and approved in a court of law;
- Companies are now able to carry out electronic commerce using the legal infrastructure provided by the act;
- The act bestows legal validity and sanction on digital signatures;
- The act allows companies to become certifying authorities that may issue digital signature certificates;
- The act allows the government to issue legal notifications on the internet, a first step towards e-governance;
- The act enables companies to file any form, application, or other document with any office, authority, body, or agency owned or controlled by the government in such electronic formats as may be prescribed by the government;
- The IT Act also addresses important issues of security that are critical for the success of electronic transactions. The act includes a legal definition of the concept of secure digital signatures that must undergo a security procedure as stipulated thereunder;
- The act offers companies a statutory remedy in case anyone should break into their computer systems or network and cause damages or copy data. The remedy provided by the act is in the form of monetary damages not exceeding 10 million rupees.

In order to resolve IT-related disputes in a focused and timely manner, the IT Act provides for the constitution of a Cyber Appellate Tribunal, which acts as a forum for

original jurisdiction on issues arising under the IT Act. Appeals from the tribunal can be made to the relevant state high courts.

Section 79 of the IT Act declares that network service providers shall not be liable for any third-party information or data made available by them if they prove that the offense or contravention was committed without their knowledge or that they had exercised all due diligence to prevent the commission of such an offense. This provision is crucial, as it is the only one under which a network service provider can claim a defense under the provisions of the act.

In order to further strengthen the scope and ambit of the IT Act, a committee has been set up comprising several experts in cyber-law and data protection who will review the act and make necessary changes to ensure that the existing lacunae in the law can be filled. These amendments are likely to deal with provisions concerning third-party liability, issues of privacy and data protection security, and the replacement of written signatures with digital signatures, among others.

## 5.2 IT Related Offenses Under the IT Act

Section 43 of the IT Act specifies acts committed without the permission of the owner or person in charge of a computer, computer system, or computer network that may cause damage by destruction, alteration, deletion, addition, modification, or rearranging of any computer resource. The offenses relate specifically to: (a) accessing or securing access to a computer, computer system, or computer network; (b) downloading, extracting, or copying of data or information from such computers, computer systems, or computer networks; (c) introducing or causing the introduction of any virus or computer contaminant; (d) disrupting or causing disruption to computers, computer systems, or computer networks; (e) damaging or causing to be damaged any computer, computer system, or computer network or any programs residing therein; (f) denying or causing denial of access by any person authorized to use the computer system or computer network; (g) assisting a person in contravention of the IT Act; (h) manipulating a computer for financial benefit.

Sections 65 through 74 of the IT Act contain provisions relating to various cyber-crimes.[3]

***5.2.1 Hacking and Tampering with Computer Source Code.*** The popular and notorious offense of hacking is dealt with under Section 66 of the IT Act. Hacking is defined as the act of destroying, altering, deleting, diminishing in value, or injuriously affecting the information residing in a computer resource, by any means. An essential element of this offense is the intention or knowledge on the part of the perpetrator of causing the wrongful loss. This provision is often viewed as a "catch-all" provision because of its broad wording, which could be potentially used to cover any IT crimes that are not covered by any other provision of the IT Act.

Tampering with computer source code has been made an offense under Section 65 of the act. This provision applies to offenders who alter, conceal, or destroy computer source codes.

The maximum punishment for both hacking and tampering with computer source code is three years' imprisonment and/or a fine of up to 200,000 rupees, or both.

***5.2.2 Breach of Confidentiality and Privacy.*** Section 72 of the IT Act deals with the penalty for breach of privacy and confidentiality. It applies to situations where individuals

who have gained access to any electronic record, book, register, information, document, or other material by virtue of powers conferred to them under the IT Act or related legislation make an unauthorized disclosure of the same.

Offenses relating to digital signatures, which include misrepresentation or suppression of material facts from the Digital Signature Certificate and publishing a digital signature for fraudulent purposes, are also covered under this section.

## 5.3 IT-Related Offenses under the Indian Penal Code

The Indian Penal Code of 1860 (IPC) is the statute governing criminal jurisprudence in India. With the enactment of the IT Act, specific provisions of the IPC dealing with offenses relating to documents and paper-based transactions were amended to include crimes conducted using electronic devices.

The amendments made to the IPC refer to the sections dealing with forgery, extortion, criminal breach of trust, criminal intimidation, and fraud.

***5.3.1 Forgery.*** The offense of forgery is covered by Section 463 of the IPC. It is defined as an act of creating false documents or electronic records for the purpose of causing damage or injury to the public or any person, or to commit fraud. A "forged document or electronic record" is defined under Section 470 as a document or electronic record that is false and has been forged either entirely or in part. The general offense of forgery is further classified into a range of individual offenses. These include forgery for the purpose of cheating or defaming another party; making, using, or possessing forged documents; and counterfeiting authentication marks and designs.

***5.3.2 Extortion.*** Such an offense involves one person dishonestly inducing another to deliver any property or valuable security by intentionally putting fear of injury in that person's mind. This offense is dealt with by the IPC under Section 383. When such crimes are committed electronically, they would be included within the purview of this section as well. Web-jacking and threatening e-mails are examples of extortion committed by an electronic medium.

***5.3.3 Criminal Breach of Trust.*** Section 405 of the IPC defines "criminal breach of trust" as any act whereby a person who has been entrusted with property, or with any power over any property, dishonestly misappropriates the property, makes wrongful use of the property, dishonestly disposes of that property, or induces any other person to do so.

***5.3.4 Criminal Intimidation.*** When a person threatens another or someone in whom such other person is interested with injury to their physical well-being, reputation, or property and causes them to commit or desist from actions against their free will in order to avoid the execution of such threats, this constitutes criminal intimidation. When such threats or intimidation occur through e-mails or other electronic means of communication, they are punishable under Section 503 of the Indian Penal Code. Threats of denial-of-service attacks, e-mail bombing, virus attacks, cyber-stalking, etc., can be used to intimidate a person and amount to criminal intimidation.

***5.3.5 Cheating.*** Section 420 of the Indian Penal Code deals with fraud cases. Under the section, whoever cheats and consequently dishonestly induces a person to deliver any property (to any other person), or to alter or destroy the whole or any part of a valuable

security, shall be punished. When fraud is committed with the use of a computer, as in the case of credit card fraud, money-laundering, or e-mail spoofing, it is punishable under the IPC.

### 5.4 Further Issues

***5.4.1 Data Protection.*** The only provision of the IT Act that currently addresses the issues of data protection and confidentiality is Section 72. To address the issue of misuse of personal information and data, India is currently in the process of reviewing the various clauses of the IT Act. In the absence of a specific law on data protection, appropriate principles, safeguards, and liquidated damages for breach would need to be built into a contract between relevant parties to ensure adequate remedies for data protection.

The Indian Contract Act of 1872 (Contract Act) codifies the way one enters into a contract, the execution of a contract, the implementation of its provisions, and the effects of breach of such contract. Contracts are among the best ways for foreign firms to protect their data and intellectual property while subcontracting work to India. The Indian Contract Act provides adequate safeguards to foreign companies, provided that both firms (Indian and foreign) agree to the contract. The companies subcontracting their work to India need to enter an exhaustive Service Level Agreement (SLA) with their vendor that covers various aspects of data security and confidentiality. This will help companies to safeguard against any fraud or misconduct.

***5.4.2 Copyright.*** The Indian Copyright Act of 1957 was amended in 1994–1995 to include penalties for any person who knowingly makes use of an illegal copy of a computer program. Such an act is punishable with a minimum imprisonment of seven days, although a sentence of up to three years can be imposed. The act further provides for fines of 50,000 to 2,000,000 rupees, a jail term up to three years, or both.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Subimal Bhattacharjee of Argus Integrated Systems and Luthra & Luthra, who validated the content of this chapter.

## 1 CRITICAL SECTORS

Since information and communication technologies (ICTs) play an important role in a number of critical sectors, the protection of critical information infrastructures is crucial

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

for the well-functioning of the Italian society. In consequence, there are several strategy and policy papers with regard to CIP and CIIP (see the section on Past and Present Initiatives and Policies). These documents define the critical sectors consistently, so that it is possible to specify the sectors that are deemed to be critical, even if there is no official register of the critical infrastructures of Italy:

- Banking and Finance,
- Public Safety and Order,
- (Tele-) Communication,
- Emergency Services,
- Energy Production, Transportation, and Distribution,
- Public Administration,
- Health Care Systems,
- Transportation and Logistics (Air, Rail, Maritime, Surface),
- Water (Drinking Water, Waste Water Management),
- Information Services and the Media,
- Food supply.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

There is no central unit in Italy devoted to defining CIP and CIIP policies and strategies: Various activities are assigned to ministries and public bodies in charge of the different critical sectors, as well as those responsible for public safety and security. In addition, a variety of coordination efforts have been undertaken:

- In order to create an inter-sectoral forum and to improve awareness on CIIP, a Working Group on Critical Information Infrastructure Protection was set up in March 2003 at the Department for Innovation and Technologies of the Presidency of the Council of Ministers. All ministries involved in the management of critical infrastructures are represented in the group, together with many Italian infrastructure operators and owners as well as various research institutes. The working group ended its activities after publishing the Report on Critical Information Infrastructure Protection: The Case of Italy in 2004;
- The Ministry of Communication has established a special working group to analyze the responsibilities and security requirements that CIIP imposes on communication infrastructure operators, and to analyze the dependencies of the latter on other critical infrastructures. This working group has issued the following guidelines with regard to CIIP: The Network Security of Critical Infrastructures (2005); Network Security: From Risk Analysis to Protection Strategies (2005); Guideline on Managing Local Emergencies (2006). With the publication of these guidelines, the working group ended its activities;
- In July 2005, to coordinate activities better and improve the protection of CII with respect to cyber-attacks, the Postal and Communications Police was identified as the unit responsible for law enforcement initiatives in this area;
- In 2006, a new body for the coordination of all ministries and agencies involved in CIP was established. This body, named Tavolo interministeriale di coordinamento

ed indirizzo nel settore della protezione delle infrastrutture critiche (Tavolo PIC)[1] is chaired by the Military Advisor to the President of the Minister's Council. Tavolo PIC is charged with coordinating all activities in the field of CIP and CIIP. It also serves as an international contact point;

- To improve the protection of critical information infrastructure against cyber-threats, the Ministry of the Interior established the National Anti-Cybercrime Center for the Protection of Critical Infrastructures (Centro Nazionale Anticrimine Informatico per la Protezione delle Infrastrutture Critiche, CNAIPIC) in 2008.

### 2.1 Report on Critical Information Infrastructure Protection: The Case of Italy

The Working Group on Critical Information Infrastructure, established as part of the Prime Minister's Office in 2003 to address CIIP, released the report Protezione delle Infrastrutture Critiche Informatizzate—La Realtà Italiana (Critical Information Infrastructures Protection: The Case of Italy) [1] in March 2004, offering a synthesis of its efforts. The document describes many elements of the Italian infrastructure, emphasizes their interdependencies, and suggests CIIP policy strategies. In particular, the Working Group suggests that full responsibility for the correct implementation of a survivability policy should remain with the individual owners and operators of critical infrastructure, while the government should be responsible for the definition of an overall policy to minimize interdependencies and cascading failures.

### 2.2 Guidelines for the Protection of Critical Information Infrastructures

The Institute for Information and Communication Technologies (ISCOM) of the Ministry for Communication has published several guidelines with regard to the security of ICT and the protection of critical information infrastructures. The guidelines are elaborated in close collaboration with various private organizations, most notably with the owners and operators of critical infrastructures. The following two guidelines directly address the security of information in critical infrastructures:

- The guideline The Network Security in Critical Infrastructures [2] highlights the importance of information infrastructures in Italy and identifies and analyzes the vulnerabilities and interdependencies of critical information infrastructures. The document also proposes best practices for the protection of critical infrastructures (e.g., certification of secure services), as well as organizational measures such as the creation of a crisis management group where stakeholders of all the critical infrastructures can be represented.
- The guideline Network Security: from Risk Analysis to Protection Strategies [3] describes the features of the information and communication network and its importance for contemporary society. In particular, the document addresses the topic of risk analysis and risk management with regard to ICT.

Other documents issued by the Ministry of Communication also deal with information security and risk analysis. They encompass analyses on the quality of communication

[1]Interministerial Coordination Platform and Contact Point for the Sector of Critical Infrastructure Protection.

networks; analyses on outsourcing in the field of information security; guidelines for local crisis management; and studies on the certification of secure ICT.[2]

## 3 ORGANIZATIONAL OVERVIEW

The main Italian government bodies dealing with CIIP are the Ministry of the Interior (Postal and Communications Police) and the Ministry of Innovation and Technologies. The Ministry of Communication is also involved in various activities to improve the security of information and communication networks.

In order to improve CIIP at all levels, the public agencies also collaborate closely with the private sector. The most important Public-Private Partnership in the field of CIP is the Association of Italian Experts for Critical Infrastructures (Associazione Italiana Esperti in Infrastrutture Critiche, AIIC) [5], an expert group of practitioners from both the public and the private sectors.

### 3.1 Public Agencies

***3.1.1 Ministry of Communication.*** The Ministry of Communication supervises postal and telecommunications services, acting as a regulator as well as implementing a policy of coordination, supervision, and control [6]. It is involved in the definition of security policies for communication. In 2004, ISCOM established a working group to analyze the different aspects of security in communication networks and the security requirements required in communication networks to guarantee an adequate level of services for critical infrastructures. The working group ended its activities in 2006.[3]

***3.1.2 Permanent Working Group on Network Security and Communications Protection.*** The Ministries of Communication, the Interior, and Justice established the Permanent Working Group on Network Security and Communications Protection in 1998 with a focus on criminal, legal, and economical aspects of communication services, such as the duration for which a provider should store communication data. Within this group, the Internet Subgroup deals with investigative and judicial matters related to the internet.

***3.1.3 Postal and Communications Police.*** In 1992, the Ministry of the Interior issued a directive assigning to the state police specific responsibilities for IT and telecommunications security that are in fact carried out by the Postal and Communications Police. The Postal and Communications Police is a flexible organization with a staff of around 2,000 highly trained officers, and placed at the peak of a structure involving 19 regional departments and 76 territorial sections. The Postal and Communications Police reviews communications regulations, studies new technical investigative strategies to fight computer crime, and coordinates operations and investigations for other offices. This police force also collaborates with other institutions—in particular, with the Ministry of Communication and the Privacy Authority—and with private operators who deal with communications. As the Italian contact point for the G8's computer crime offices,

[2]For an overview on the documents issued by ISCOM, see: [4].
[3]Information provided by an expert.

it is available at all times. This particular organizational aspect guarantees a quick, qualified, and efficient response [7] in the event of a threat or computer attack originating nationally or internationally.

The Postal and Communication Police Service also hosts and manages an emergency center at both the national and regional levels, in order better to deal with computer crimes against critical infrastructure and to conduct preventive monitoring activities on a technical and operational level. The center serves as a focal point for the evaluation of threats, thus providing adequate countermeasures to face such situations.

Article 7 bis of the Law n.155/2005 assigns the task of protecting national information infrastructures against cyber-crime attacks to the Postal and Communication Police Service. In order to perform this task, the aforementioned Centro Nazionale Anticrimine Informatico per la Protezione delle Infrastrutture Critiche (CNAIPIC) was established as a special unit of the Postal and Communication Police Service.[4]

***3.1.4 Ministry for Innovation and Technologies (MIT).*** The Ministry for Innovation and Technologies [8] has been delegated to act on behalf of the prime minister in the areas of technological innovation, the development of the Information Society, and related innovations for government, citizens, and businesses. This ministry has particular responsibility for network structures, technologies, and services, the development and use of information and communication technologies, and the fostering of IT and digital awareness and literacy, including through links with international and EU bodies that are active in the sector. The MIT has also been delegated to chair the Committee of Ministers for the Information Society and the Committee of Ministers for Joint Satellite Navigation Initiatives.

The Department for Innovation and Technologies (DIT) is the department of the Presidency of the Council of Ministers that provides support to the minister of innovation and technologies. It serves to coordinate ministerial policies for the development of the Information Society and to promote innovation in public offices and among citizens and businesses [8].

***3.1.5 National Technical Committee for ICT Security in the Public Administration.*** On 16 October 2002, the Ministry for Innovation and Technologies and the Ministry of Communication created the National Technical Committee for ICT Security in the Public Administration. The establishment of this new committee followed from the Directive on ICT Security for the Public Administration, which enacts EU recommendations with the important initial aim of achieving compliance with a set of minimum security standards. The Technical Committee can therefore be seen as the operative arm of the new national IT security policy [8]. It was constituted in July 2002 with support from the Ministry for Innovation and Technologies and the Ministry for Communications [9].

The committee aims to attain a satisfactory security level in information systems and digital communications, in compliance with international standards, in order to guarantee the integrity and reliability of the information. It prepares strategy proposals concerning computer and telecommunications security for the public administration. In particular, it develops:

[4]Information provided by an Italian expert.

- The National Emergency Plan for the Security of Information and Communication Technologies in the Public Administration. The committee annually verifies its state of progress, and proposes corrective measures if required;
- The ICT security national organizational model for the public administration. The committee monitors its level of activation and application.

Furthermore, the committee formulates proposals for regulating certification and security assessment, as well as certification criteria and guidelines for ICT security certification in the public administration, on the basis of national, sectoral, and international norms of reference.

Finally, the committee elaborates guidelines for agreements with the Ministry of Public Administration for training public employees in ICT security. Among other proposals, the group is tasked with establishing the Computer Emergency Response Team (CERT) for the Public Central Administration (CERT-PA, now GovCERT.it, which has also assumed the role of coordinating the CERTs of the other parts of the public administration). It will have a central Early-Warning System operating around the clock.

In March 2004, the National Technical Committee on ICT Security published a preliminary proposal for the National Security Plan and an organizational model. Guidelines were suggested for building an organizational infrastructure to coordinate and support public offices at the national level, and the most urgent areas of action for putting the process on track were identified [8].

***3.1.6 National Center for Informatics in the Public Administration (CNIPA).*** The Authority for IT in the Public Administration (AIPA), founded in 1993, was transformed into the National Center for Informatics in the Public Administration (CNIPA) in 2003 [10]. CNIPA is supervised by the Ministry of Innovation and Technologies, and its head is nominated by the Council of Ministries. It addresses central and local administrations, especially the elements responsible for IT systems in the public administration. The main task of CNIPA is to promote modern information technologies in the Italian public administration, to establish standards and methods, to deal with security issues, and to make recommendations and technical regulations in the field of IT for public administration [10]. CNIPA published a comprehensive guide on the protection of personal data in 2001.

## 3.2 Public-Private Partnerships

***3.2.1 Association of Italian Experts for Critical Infrastructures (AIIC).*** The Association of Italian Experts for Critical Infrastructures [5] is a not-for-profit-organization that aims "to support an interdisciplinary and inter-sectoral culture for the development of strategies, methodologies, and technologies supporting the correct management of Critical Infrastructure during periods of crisis, in case of exceptional events, and during terrorist attacks or natural disasters" [11]. The AIIC comprises public as well as private members.

In order to raise awareness of information security and critical infrastructure protection, the association publishes periodical newsletters on national and international developments in the field of CIIP and provides information on strategies and policies as well as on recent scientific findings on its website.

## 4 EARLY WARNING AND PUBLIC OUTREACH

A variety of Computer Emergency Response Teams (CERTs) is currently active in Italy. They are all devoted to the development of IT security and to supporting organizations in increasing their level of security with respect to cyber-threats.

- *CERT-IT.* The Italian Computer Emergency Response Team was founded in 1994 as a non-profit organization. It is mainly supported by the Department of Informatics and Communications (DICO) at the University of Milan [12]. CERT-IT is a member of the Forum of Incident Response and Security Teams (FIRST). It promotes research and development activities in security systems, provides information about computer security, and has an expert team for handling computer incidents [13];
- *GovCERT.it.* [14] This initiative was planned by the National Technical Committee on Computer and Telecommunications Security to help public administrations to improve their level of ICT security by providing an early-warning service on cyber-threats;
- *GARR-CERT.* [15] The GARR Network Computer Emergency Response Team assists the users of the GARR Network (Gestione Ampliamento Rete Ricerca—the Italian Academic and Research Network) in implementing proactive measures to reduce the risk of computer security incidents and in responding to such incidents when they occur;
- *CERT Difesa.* [16] The CERT of the Ministry of Defense assists its users in protecting ICT networks and disseminates information about ICT security.

The Ministry of the Interior, together with the Postal and Communication Police, is also active in early-warning activities. These agencies continuously monitor cyberspace to discover criminal or malicious behavior in order to provide adequate countermeasures. Moreover, specific protocols have been established to prevent incidents and to manage and share information as well as criminal evidence.

## 5 LAW AND LEGISLATION

Italy has specific laws and ministerial decrees devoted to CIP and CIIP. In the early 1990s, a new law related to computer crimes was introduced (Law 547 of 23 December 1993) that gave more power to investigators in the evidence-collection phase and allowed computer and telecommunication intercepts. Italy was one of the first European countries to adopt such legislation, mainly due to the incidence of new crimes in the areas of computer fraud, forgery, data corruption, computer misuse, unauthorized interceptions of computer communications, and sabotage. The great attention given to such crimes is underscored by the fact that computer intrusions are treated as domestic property violations.

The innovative concept of High-Tech Crime, which had already enjoyed currency in the Italian penal legislation for different types of offenses, was introduced with Law 547. According to Article 420 of the Italian Penal Code (attempt to damage public utilities systems), actual damage or destruction to the systems are not required for such activities to constitute an offense; the mere intention suffices. Such cases will be prosecuted even if the attempt was unsuccessful.

Other relevant laws include:

- Legislative Decree 518, enacted on 29 December 1992 and modified by Law 248 (18 August 2000), a legislative decree against illicit ICT piracy;
- Law 547, enacted on 23 December 1993, a comprehensive and integrated law against ICT crimes;
- Law 675, enacted on 31 December 1996, a law governing personal data protection, integrated by subsequent legislation (DPR 318/1999, Law 325/2000, Legislative Decree 467/2001, and Legislative Decree 196/2003);
- Legislative Decree 374/2001, changed into Law 438/2001, a law devoted to improving law-enforcement instruments and to combating terrorism. Law 374/2001 was transformed into Law 438/2001 after 11 September 2001, so that now, crimes committed in Italy are liable to prosecution even if they are directed against a foreign state or against a multilateral institution.
- Article 7 bis of Law 155/2005 defines the authority of the Postal and Communication Police Service to carry out undercover investigations and preemptive interceptions both for the protection of critical infrastructures and for countering terrorist acts committed by means of new technologies.

### 5.1 Privacy Law

Part of Article 15 of Law 675/96 [17] (the Privacy Law) deals with the organizational issues that the use of IT systems raises. By establishing a duty to store data in a way that minimizes the risk of loss and prevents unauthorized access (including access inconsistent with the reasons given for the original acquisition and processing of such data), Article 15 requires data holders to update their security to keep up with technical advances and changes in the methods of infiltration.

Consequently, not only should the minimum measures established by Presidential Decree 318/99 be strictly implemented and observed, but all appropriate additional measures should also be taken and regularly updated to match technical progress.

A New Privacy Code, which contains specific requirements for the protection of personal data online, has been in force since July 2003 [18].

### 5.2 Italian Penal Code

Penal Code Article 615 ter: Unauthorized Access to Computers or Telecommunication Systems: Any person who enters a computer or telecommunication system protected by security measures without authorization, or remains in it against the expressed or implied will of the authority that has the right to exclude them, shall be sentenced to imprisonment not exceeding three years.

The imprisonment is from one until five years:

1. if the crime is committed by a public official or by an officer of a public service, through abuse of power or in violation of the duties concerning the function or the service, or by a person who practices—even without a license—the profession of a private investigator, or by abusing the authority of a system operator;
2. if, in order to commit the crime, the culprits use violence against assets or people or if they are manifestly armed;

3. if the deed causes the destruction or damage of the system or the partial or total interruption of its operability, or the destruction or damage of the data, information, or programs contained in it.

If the crimes listed in the first and second paragraphs concern computer or telecommunication systems of military importance, or of importance to public order or public security, or civil defense, or any public interest whatsoever, the penalty is one to five years and three to eight years of imprisonment, respectively. In the case provided for in the first paragraph, the crime is only liable to prosecution after an action by the plaintiff; the other cases are prosecuted ex officio.

Penal Code Article 615 quater: Illegal Possession and Diffusion of Access Codes to Computer or Telecommunication Systems:

Whoever, in order to obtain a profit for themselves or for another or to cause damage to others, illegally gets hold of, reproduces, propagates, transmits, or delivers codes, key-words, or other means for accessing a computer or telecommunication system protected by safety measures, or whoever provides information or instructions for the above purpose, will be punished by imprisonment not exceeding one year and a fine.

Penal Code Article 615 quinquies: Diffusion of Programs Intended to Damage or to Disrupt a Computer System:

Whoever propagates, transmits, or delivers a computer program—written by themselves or by another party—with the aim and the effect of damaging a computer or telecommunication system, the data or the programs contained therein or pertinent to it, or achieving the partial or total interruption or an alteration in its working, will be punished by imprisonment not exceeding two years and a fine [19].

# JAPAN

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

The critical infrastructures of Japan are defined in the Action Plan on Information Security Measures for Critical Infrastructures that was issued by the Information Security Policy Council in 2005: "Critical infrastructures are formed by business entities providing highly irreplaceable services and are essential for people's social lives and economic activities. If an infrastructure's function is suspended, reduced or unavailable, people's social lives and economic activities will be greatly disrupted" [1]. The paper lists the following ten sectors that are deemed to be critical:

- (Tele-) Communication,
- Government and Administrative Services,
- Finance,
- Civil Aviation,

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

- Railways,
- Logistics,
- Electricity,
- Gas,
- Medical Services,
- Water.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

The government of Japan, based on the Action Plan of the Basic Guidelines Toward the Promotion of an Advanced Information and Telecommunications Society of 1998,[1] has been steadily promoting policies contributing to the advancement of information technology and telecommunications in Japan [2].

The Comprehensive Strategy on Information Security, released in 2003 by the Ministry of Economy, Trade, and Industry (METI) was the next step of the policy development process. In this document, ICT-related risks and threats confronting the Japanese society were explicitly considered from a national-security perspective [3].

In 2005, the First National Strategy on Information Security was issued. This is now the most important policy paper and provides the basis for all other guidelines and action plans related to CIIP and information security [4].

### 2.1 The First National Strategy on Information Security

In October 2003, the Information Security Committee of the METI published the Comprehensive Strategy on Information Security [5]. This document was the starting point for the development of a national strategy on information security, because it highlighted the need for a comprehensive approach to bring about and improve a highly reliable Information Society in Japan. Most importantly, the Comprehensive Strategy called for a clear definition of responsibilities within the government and promoted the development of a dedicated organization for information security within the Cabinet Secretariat.

In 2005, the propositions of the Comprehensive Strategy were implemented. A council and an organization were established within the Cabinet Secretariat (the Information Security Policy Council (ISPC) and the National Information Security Center (NISC)), and a new national strategy was elaborated. This strategy, called The First National Strategy on Information Security—Towards the Realization of a Trustworthy Society [6], is a mid- and long-term strategy formulating clear goals for the years 2006–2008. The Information Security Policy Council issued separate implementation plans for each of these three years [7].

In general, the strategy aims to make Japan an advanced nation in the field of information security. Most importantly, the strategy aims to establish a new public-private partnership model to improve information security. Thus, the strategy defines the roles of government, critical infrastructures, businesses, and individuals, and the measures that need to be implemented by these actors:

[1]Decision of the Advanced Information and Telecommunications Society Promotion Headquarters (9 November 1998).

- Central and local governments are required to define best practices for information security and implement these practices in their agencies. By defining and implementing standards for information security, the government shall increase the overall ability to respond to emergencies, including cyber-attacks;
- Critical infrastructures must ensure stable provision of their services. The major step to prevent disruptions of critical infrastructures is the development of so-called Capabilities for Engineering of Protection, Technical Operations, Analyses, and Response (CEPTOAR; for more detail, see the chapter on Organizational Overview) for each major sector. The Action Plan on Information Security Measures for Critical Infrastructures defines the strategy for critical infrastructures in more detail;
- Businesses need to implement information security standards and measures that are promoted by government agencies. Security audits and third-party evaluation systems shall be promoted;
- Individuals: the government aims to raise awareness of information security among users of IT services by improving information security education and by promoting user-friendly services.

The second version of the Comprehensive Strategy is being discussed as of March 2008.[2]

### 2.2 Action Plan on Information Security Measures for Critical Infrastructures

In 2000, the Cabinet Secretariat released a Special Action Plan on Countermeasures to Cyber-Terrorism of Critical Infrastructure [8], which was replaced in December 2005 by the Action Plan on Security Measures for Critical Infrastructures [9], published by the ISPC as an amendment of The First National Strategy on Information Security.

The new plan includes definitions of critical infrastructure elements and threats, safety standards for information security, information-sharing systems in public-private partnerships (PPP), interdependency analyses, and exercises. In particular, the plan emphasizes the importance of PPPs. The plan therefore aims to establish within each critical sector so-called Capabilities for Engineering of Protection, Technical Operation, Analysis, and Response (CEPTOAR, see the chapter on Organizational Overview).

In addition, the Action Plan provides for analyses of interdependencies and cross-sectoral status assessments of the critical infrastructures. For this purpose, various cross-sectoral exercises are projected. Such exercises shall be implemented in every fiscal year, based on concrete threat scenarios corresponding to the assumed threats.

### 2.3 Standards for Information Security Measures for the Central Government Computer Systems

In order to achieve a sector plan for improving the information security level of the whole government, the ISPC has issued the Standards for Information Security Measures for the Central Government Computer Systems. The standards formulated by the ISPC represent the nominal level of information security in government agencies. The NISC inspects and evaluates the actual levels and compares them with the standards. In that way, it is possible to formulate recommendations for each government agency [10].

[2]Information provided by an expert.

## 3 ORGANIZATIONAL OVERVIEW

Within the Japanese government, the Cabinet Secretariat is the main actor in the field of CIIP and information security in general. In 2005, the ISPC and the NISC were established within the Cabinet Secretariat. These two organizations are now the focus of CIIP policies in Japan.

In addition, the METI, the National Police Agency (NPA), and the Ministry of Internal Affairs and Communications (MIC) assist the Cabinet Secretariat and play major roles in the field of CIIP.

As a private-public partnership initiative, the so-called CEPTOAR (Capabilities for Engineering of Protection, Technical Operation, Analysis, and Response) are designed to serve the purpose of information-sharing between government and the private sector.

### 3.1 Public Agencies

***3.1.1 Cabinet Secretariat and IT Strategic Headquarters.*** The IT Strategic Headquarters, which includes all ministers and private-sector experts, was established in July 2000 within the cabinet in order to promote comprehensive measures for making Japan an internationally competitive IT nation. At the same time, the IT Strategy Council, consisting of 20 opinion leaders, was established in order to study the issue strategically and by combining private-public partnerships [11]. In January 2001, the Strategic Headquarters for the Promotion of an Advanced Information and Telecommunications Network Society (IT Strategic Headquarters) was launched under the provisions of the Basic Law on the Formation of an Advanced Information and Telecommunications Network Society (IT Basic Law), with the prime minister as its director-general, and including all cabinet members and opinion leaders from the private sector as members, to serve as a new base for joint government and private-sector promotion of IT policies [12].

***3.1.2 Information Security Policy Council (ISPC).*** The ISPC, set up in May 2005, is chaired by the chief cabinet secretary and forms part of the IT Strategic Headquarters with members from various ministries as well as private-sector experts. It plays a central role in developing and reviewing the information security strategies and policies. Thus, the ISPC has the following tasks:

- To develop and review strategies with regard to information security;
- To undertake proactive and retrospective assessments of information security policy, based on the basic strategy;
- To develop safety guidelines for information security that are uniform throughout government;
- To recommend information security policies based on the government-wide safety guidelines.

***3.1.3 The National Information Security Center (NISC).*** The NISC was launched in April 2005 as Japan's central implementing body for IT security issues. It collaborates closely with the ISPC and pursues the following tasks:

- Planning government-wide fundamental strategies for information security policy;
- Promoting comprehensive measures on information security concerning government organizations;
- Supporting these government organizations in an appropriate way when information security incidents occur;
- Strengthening the information security of critical infrastructures;
- Reinforcing information-sharing systems;
- Implementing cross-sector cyberspace exercises;
- Creating an international strategy and promoting relationships with other countries.

***3.1.4 Ministry of Economy, Trade and Industry (METI).*** The METI is responsible for planning and implementing various information policies under the guidance of the IT Strategic Headquarters. In particular, METI deals with e-commerce, e-government, data protection, and research and development related to IT [13]. In order to enhance the IT industry competitiveness in Japan, METI promotes policies that improve information security in companies.

***3.1.5 National Police Agency (NPA).*** The NPA [14] has long been committed to maintaining computer and network security and investigating cyber-crimes. Traditionally, it has done this via its High-Tech Crime Prevention Department. In 1999, a new program was established to help fight high-tech crime. The High-Tech Crime Technology Division (HTCTD) was set up in the Information-Communications Bureau, and a National Police Agency Technology Center was created as the technical heart of the division. In April of 2004, the National Police Agency established the HTCTD in each Prefectural Information-Communications Department in order to enhance the capacity for technological support [15].

Additionally, the National Police Agency is committed to creating a monitoring and emergency response service to prevent and minimize the spread of large scale cyber-related incidents, as well as to arrest so-called cyber-terrorists. One branch of this service consists of mobile technical teams, or Cyber Forces. These technical computer-security teams are stationed throughout Japan, and the Cyber Force Center acts as their command center. It monitors internet security around the clock and collects and analyzes relevant information. It is also equipped with facilities for a wide range of research and development, as well as for personnel education and training.

***3.1.6 Ministry of Internal Affairs and Communications (MIC).*** The MIC [16] is responsible for creating the fundamental national infrastructure of Japan, including information and communications. In order to realize “secure and safe” communications as a social infrastructure, MIC promotes various policies that reinforce information security in the three categories of “Network”, “Terminal System and Equipment”, and “Person”.

The MIC publishes an annual White Paper on Information and Communications in Japan [17]. In each edition, a special chapter deals with privacy protection as well as information security. The aim is to strengthen public-private partnership cooperation to ensure information security. Moreover, the MIC conducts research related to fundamental technologies related to measures against cyber-attacks and other network security issues

and to the protection of personal information in the field of ICT, and carries out measures to upgrade emergency information functions in the telecommunications area.

The 2007 White Paper deals with ways to achieve a ubiquitous network society (u-Japan) by 2010 that allows connection to networks anytime, anywhere, by anyone, and enables an easy exchange of information. The MIC outlined the future of such a society and summarized the necessary policies as the u-Japan Policy, which is based on the four principles "ubiquitous", "universal", "user-oriented", and "unique". Among these, "ubiquitous" (connects everyone and everything) plays the key role [18].

### 3.2 Public-Private Partnerships

***3.2.1 Capabilities for Engineering of Protection, Technical Operation, Analysis, and Response (CEPTOAR).*** Public-private partnerships are an important part of CIIP policies in Japan. The Comprehensive Strategy on Information Security of 2003 already contained suggestions for cooperation between the national government and private enterprises [19]. The First National Strategy on Information Security and the Action Plan on Security Measures for Critical Infrastructures substantiated this requirement. They formulate the need for implementation of CEPTOAR within each critical infrastructure sector.

The latter serve the purpose of information-sharing between the government and the private sector. The CEPTOAR receive information from the Cabinet Secretariat (via the presiding ministries and agencies) and provide this information to their corporate members that operate critical infrastructures [9].

In order to enable information sharing between government agencies and private companies, the NIPC issued a "traffic light" protocol for information sharing: information can be classified as red (not to be disseminated), amber (need-to-know restriction), green (can be shared among all persons concerned), or white (can be made public) [20].

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 National Incident Response Team (NIRT)

The National Incident Response Team (NIRT) has been part of the IT Security Office of the Cabinet Secretariat since April 2002 [21], and is in charge of the first response to cyber-incidents as the Japanese government CERT. Based on the Action Plan for Ensuring e-Government's IT Security (adopted on 10 October 2001 by the IT Security Promotion Committee), NIRT comprises 17 computer security experts from both the government and the private sector and has the following tasks [22]:

- To understand incidents correctly: To collect and analyze the related information or intelligence and make forecasts on possible future damage;
- To develop technical countermeasures for mitigation and recovery, and to prevent reoccurrence: To analyze countermeasures and to organize concrete remedies to be implemented by the ministries and agencies;
- To assist in response: To provide help-desk service for ministries and agencies, as well as response support when required;
- To collect and analyze information or intelligence in order to make predictions and provide effective incident response;

- To supply expertise, knowledge, and information to government organizations;
- To improve the necessary expertise.

### 4.2 Japan Computer Emergency Response Team Coordination Center (JPCERT/CC)

JPCERT/CC [23] is an independent non-profit organization acting as a national point of contact for the other Computer Security Incident Response Teams (CSIRTs) in Japan. Since its establishment in 1992, the center has been gathering information on computer incidents and vulnerabilities, issuing security alerts and advisories, and providing incident responses as well as education and training to raise awareness of security issues. JPCERT/CC coordinates with network service providers, security vendors, government agencies, and industry associations, and is a member of the Forum of Incident Response and Security Teams (FIRST; see the survey on FIRST in this volume).

### 4.3 Asia Pacific Computer Incident (Emergency) Response Team (AP-CIRT/APCERT)

The aim of the Asia Pacific Security Incident Response Coordination (AP-CIRT) is to foster close collaborations among the CIRTs (Computer Incident Response Teams) in the region.[3] In February 2003, its name was changed to Asia Pacific Computer Emergency Response Team (APCERT), and it continues to carry out its mission, which is to maintain a trusted contact network of computer security experts to improve the region's awareness and competency in relation to computer security incidents [25].

### 4.4 Telecom Information Sharing and Analysis Center Japan (Telecom-ISAC Japan)

Telecom-ISAC Japan [26] is an independent organization established as Japan's first ISAC (Information Sharing and Analysis Center) in July 2002. Telecom-ISAC Japan works to improve information security by various means such as collecting, analyzing, and sharing incident information, providing timely countermeasures and best practices, and coordinating/collaborating with related organizations, based on mutual cooperation between a wide variety of members in the information and telecommunications industry, such as ISPs, carriers, and manufacturers.

### 4.5 Cyber Force

The Cyber Force, a section within the police, gathers data on the internet around the clock and looks for evidence of cyber-crime. When the Cyber Force detects an unusual phenomenon, it provides critical infrastructure operators with security information to prevent cyber-terrorism and conducts vulnerability tests. Additionally, the Cyber Force will give operators of critical infrastructures advice on how to limit the damage from such an incident and how to recover their services safely, and to find the cause of the incident [27].

[3] See the membership list: [24].

### 4.6 @police

The National Police Agency has a security portal site, @police, whose purpose is to prevent large-scale cyber-related incidents or keep them from spreading by quickly providing information gathered by the police on information security. Moreover, @police makes efforts to increase security awareness among internet users. Therefore, it provides a wealth of diverse content in order to help as many people as possible improve their security. Special online security courses, examples of internet crimes and how to avoid them, quick security checks, and information on security holes are provided for the benefit of private PC users as well as server administrators [28].

### 4.7 Ministry of Economy, Trade and Industry (METI)

METI has responded to security breaches in cooperation with JPCERT/CC and the Information Technology Promotion Agency (IPA) since 1990. Around that time, it also began releasing reports on computer viruses and unauthorized access and started to gather information about damage caused by computer viruses and disseminating it to the public immediately after the incident [29].

## 5 LAW AND LEGISLATION

### 5.1 Unauthorized Computer Access Law 1999

The Unauthorized Computer Access Law No. 128 of 1999 prohibits acts of unauthorized computer access (Article 3) as well as acts that facilitate unauthorized computer access (Article 4).

Article 3 covers acts such as:

- Facilitating a specific use that is restricted by an access control function, by entering via a telecommunications line another person's identification code into a specific computer that controls access;[4]
- Facilitating a specific use that is restricted by an access control function, by entering via a telecommunications line any information (excluding an identification code) or command that can evade the restrictions of that access control function for that specific purpose;
- Facilitating a specific use that is restricted by an access control function, by operating a computer whose specific use is restricted by an access control function installed on another specific computer that is connected, via a telecommunication line, to that specific computer, by entering via a telecommunications line any information or command that can evade the restriction concerned.

Article 4 makes it illegal to provide another person's identification code relating to an access control function to a person other than the access administrator for that access control function, or to the authorized user for that identification code, while indicating

[4]To exclude such acts conducted by the access administrator who has added the access control function concerned, or conducted with the approval of the access administrator concerned or of the authorized user for that identification code.

that it is the identification code for a specific computer's specific use, except where such acts are conducted by the access administrator, or with the approval of that access administrator or of the authorized user.

Moreover, the Japanese Penal Code, Article 258, makes it illegal to damage documents or electronic-magnetic records in public or private use [30].

### 5.2 Act on Electronic Signatures and Certification Business 2000

The Act on Electronic Signatures and Certification Business No. 102 of 2000 aims to promote the distribution of information by electromagnetic forms and information processing by ensuring easy use of electronic signatures, and thereby to contribute to the improvement of citizens' quality of life and the sound development of the national economy, by providing the presumption of authentic establishment of electromagnetic records, the accreditation system for designated certification businesses and other necessary matters, with respect to electronic signatures [31].

### 5.3 Basic Law on Formation of an Advanced Information and Telecommunication Network Society 2001

The purpose of the IT Basic Law, which entered into force on 6 January 2001, is to promote measures for forming an advanced information and telecommunications network society where citizens can enjoy the benefits of ICT. Its measures include (Articles 16–24) the formation and expansion of advanced ICT networks; the promotion of fair competition; increasing IT user skills and development of expert human resources; reform of regulations and facilitation of e-commerce through appropriate protection; promotion of e-government and digitalization of administration; assuring security and reliability for networks and the protection of personal data; promotion of creative research and development; and international cooperation [32].

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Mika Shimizu of East-West Centre, Tomoko Makino and Tohru Nakao of the Ministry of Internal Affairs and Communications, and Yoshihiro Sato and Toshihiko Suguri of the National Information Security Center, who validated the content of this chapter.

# REPUBLIC OF KOREA*

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

The critical information and communication infrastructure plays a crucial role in providing public safety and stable services that are essential for everyday life. In Korea, the following sectors are counted among the critical infrastructures that are heavily dependent on information and telecommunication technologies.

- E-Government and National Government Administration,
- National security,
- Emergency/Disaster Recovery Services,
- National Defense,
- Media Service, e.g., Broadcasting Facilities,
- Financial Service,
- Gas and Energy, e.g., Power Plants,
- Transportation, e.g., Subways and Airports,
- Telecommunication [1].

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

Report on the status of the Critical Information Infrastructure (2001)
e-Korea Vision (2006)
Cyber Korea 21 (1999)
Mid- to Long-Term Roadmap for Information Protection (2005)
Basic Strategy for Ubiquitous Information Security (2006)

*The Country Survey of the Republic of Korea 2008 was reviewed by Heung Youl Youm, Professor at the Department of Information Security Engineering of Soonchunhyang University.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

### 2.1 Report on the Status of the Critical Information Infrastructure

In 2001, the Korean Information Security Agency (KISA) published a Report on the Status of the Critical Information Infrastructure. The scope of the research was:

- To provide technical consulting for critical information infrastructure management agencies to perform a risk assessment and establish safeguards;
- To evaluate the security and confidentiality of internet data centers;
- To assign information-security consultants for information infrastructure.

These efforts resulted in a model and guidelines for vulnerability analysis and assessment of critical information infrastructures, including a protection guide and protection measures; a vulnerability analysis and assessment model; a guide to risk computation; asset classification; threat classification; and vulnerability analysis. In addition, technical consulting was provided for the former Ministry of Information and Communication [2] now the Korea Communications Commission.

### 2.2 e-Korea Vision 2006

In April 2002, the Ministry of Information and Communication published its third master plan for Informatization Promotion for the years 2002–2006, called e-Korea Vision 2006 [3], in consultation with the Korean Informatization Promotion Committee [4]. It followed the first master plan of informatization promotion devised in 1996 and the second, called Cyber Korea 21, drawn up in 1999. e-Korea Vision focuses on "Ensuring Safety and Reliability of Cyberspace" to strengthen the security of the critical information infrastructures. Government policies relevant to the vision paper include the following:

- Identifying critical information infrastructures that are important for national security and the economy, systematic analysis of vulnerabilities and preparation for protective plans, and establishment of cooperation between the public and private sectors in order to prevent cyber-attacks and intensify response measures;
- Reinforcement of real-time warning systems to fight against hacking and viruses and strengthening international cooperation, because cyber-terrorism is intrinsically transnational;
- Developing information security technologies and training new information security experts to meet the changing needs of the information security environment;
- Strengthening cooperation between the government and the private sector for a sound and healthy cyberspace;
- Devising plans to establish information ethics that enable a secure cyberspace, and encouraging voluntary regulation of the private sector in terms of online information circulation.

With the designation of major information and communication facilities as critical to the national defense and the economy, the government plans to conduct a systematic analysis of their weaknesses and implement strong security measures to protect these facilities. The government has established an Information Sharing and Analysis Centre (ISAC) for each area of the government and the financial and information sectors. In addition, standards have been developed for information security technologies, together with an evaluation methodology for information security systems [5].

### 2.3 Basic Strategy for Ubiquitous Information Security

The downside of the information revolution is seen in the growing number of cyber-attacks on the internet, infringement of private information, and spam. According to a vision called u-Korea, based on the four principles "ubiquitous" (connects everyone and everything), "universal", "user-oriented", and "unique", the resulting damage would not be limited to individuals, but would affect the whole society and its economy, and even pose a threat to the life and property of its citizens. Therefore, a new framework of information protection is required that takes the new virtual ubiquitous environment into account.

In May 2005, the Ministry of Information and Communication issued a report on the Mid- to Long-Term Roadmap for Information Protection dealing with the security of high-technology infrastructures and the establishment of reliable systems for new IT services. In particular, the report presents a phased roadmap from 2005 to 2008 for the prevention of attacks on the internet, advanced response measures, reinforced protection of privacy, improvement of the legal system regarding information protection, and the training of a specialized force [6].

In December 2006, the Ministry of Information and Communication established the Basic Strategy for Ubiquitous Information Security. The strategy aims to strengthen the global competitiveness of Korean industries; improving the existing legal and regulatory system, and promoting research and development in the field of ICT. It defines four specific policy goals: [7][1]

- *Secure infrastructures.* developing a more efficient incident response system, minimizing threats, protecting critical infrastructures from cyber-attacks;
- *Privacy Protection of users.* privacy protection of location information, protection of biometric and healthcare information, protection of personal information and personally identifiable information;
- *Trusted IT services and devices.* developing authentication and ID management systems, developing techniques for making IT services secure, providing a base for secure electronic transactions;
- *Clean internet environment.* preventing the dissemination of illegal and harmful traffic on the internet, spreading a culture of security, raising users' awareness.

## 3 ORGANIZATIONAL OVERVIEW

In general, all governmental organizations and their subsidiary organizations are in charge of CIIP.

The National Cyber Security Center (NCSC) coordinates the efforts of these departments and agencies. In the field of cyber-crime investigation and prevention, the Internet Crime Investigation Center (ICIC) under the authority of the Supreme Public Prosecutors' Office plays a central role. The Electronics & Telecommunications Research Institute has the leadership in developing technology and providing support to protect critical information infrastructure. The Ministry of Public Administration and Security, the Korea Communications Commission (the former Ministry of Information and Communication), and the Korea Internet Security Center (KISC; KrCERT/CC) within the Korean

[1]Information provided by an expert.

Information Security Agency (KISA) are undertaking efforts to foster a culture of safe internet and telecommunication networks.

In addition, the structure of government organization was changed in February 2008. According to new regime plan, the Ministry of Information and Communication was abolished, and its functions in the area of information security were transferred to several ministries: the Ministry of Public Administration and Security, the Ministry of Knowledge and Economy, and the Korea Communication Commission. Therefore, the Ministry of Public Administration and Security, the Korea Communications Commission, and the Ministry of Knowledge and Economy have begun sharing CIIP-related responsibilities in Korea.

As a public-private partnership, the national Information Security Alliance (NISA) strives to improve information security by fostering information exchange between governmental agencies, enterprises, and research institutes. The Financial Information Security Alliance has members from banks and insurance companies and strives to implement international information protection policies. The Information Security Practice Alliance is an initiative fostering information protection activities in the private sector, and the Korea Information Security Industry Association (KISIA) is an exchange platform for the information security industry.

### 3.1 Public Agencies

***3.1.1 Ministry of Public Administration and Security (MOPAS).*** As a result of the government restructuring, the Ministry of Public Administration and Security (MOPAS), a government department that is responsible for electronic-government and public administration services, began to play a primary role in information security tasks including CIIP-related missions in March 2008. The informatization strategy office, which is part of MOPAS, is responsible for information security matters in the private sector. It pursues the following tasks:

- Establishing an information security policy for private sector;
- Ensuring the protection of users' privacy;
- Dealing with electronic authentication;
- Cultivating a sound internet culture for the public and private sectors [8].

***3.1.2 Korea Communications Commission (KCC).*** As a result of the government restructuring in February 2008, the Korea Communications Commission (KCC), a government department that is responsible for establishing the policy for communications and digital broadcasting, began to play a primary role in tasks of the network security in March 2008. It pursues the following tasks:

- Establishing a network security policy;
- Ensuring the protection of internet users' privacy [9].

***3.1.3 National Cyber Security Center (NCSC).*** The government established the National Cyber Security Center (NCSC) [10] in February 2004. It not only coordinates the efforts of the Korean governmental departments and agencies in charge of CIIP, but is also a platform that brings together the private, public, and military sectors to fight

cyber-threats. This is based on the understanding that cooperation among all sectors is crucial for the effective prevention of cyber-attacks as well as for the minimization of damage. The NCSC operates under the auspices of the National Intelligence Service (NIS) and is the central point of government for identifying, preventing, and responding to cyber-attacks and threats in Korea. NCSC performs the following tasks:

- Overall management of national cyber-security by working out plans and guidelines to improve national cyber-security systems, as well as providing support for strategic committee meetings;
- Publishing national cyber-security manuals, security guidelines, and analysis reports, and collecting, analyzing, and distributing information on cyber-threats;
- Detecting and responding to cyber-threats, issuing warnings and information on cyber-incidents, and developing cyber-security technology;
- Preventing the spread of cyber-attacks, providing support for recovery procedures, and establishing and managing pan-governmental working groups for prompt response measures;
- Promotion of cooperation among international and domestic IT security organizations;
- Education and public relations regarding cyber-security issues.

In addition, NCSC operates early-warning services (see the chapter on Early Warning and Public Outreach) [11].

***3.1.4 Internet Crime Investigation Center (ICIC).*** The Supreme Public Prosecutor's Office and the Seoul District Public Prosecutor's Office have established the Internet Crime Investigation Center (ICIC) [12] to deal more effectively with internet-related crimes. The ICIC monitors crime trends such as hacking, the spread of viruses, fraud in electronic commerce, and infringement of privacy. In doing so, it develops more effective response measures and new investigative methods to crack down on cyber-crimes. Moreover, to maximize its investigation capacity, it maintains close cooperation with international and domestic organizations. The ICIC is operated by a high-tech crime investigation team of the Central Investigation Department and performs the following tasks:

- Intensive and systematic monitoring of cyber-crime trends;
- Collecting reports on cyber-crimes;
- Developing effective investigation methods;
- Improving the legal system in the field of cyber-crime;
- Around-the clock monitoring system to respond to high-tech crime.

***3.1.5 Korea Information Security Agency (KISA).*** The Korea Information Security Agency (KISA) [13], affiliated with the Korea Communications Commission (the former Ministry of Information and Communication), was established in 1996 to create a safe, reliable information environment in Korea by reacting effectively to various acts of electronic infringement and intrusion. KISA is devoted to enhancing the security and reliability of electronic transactions by developing and supplying cryptographic algorithms. In addition, KISA has supported the development of information security in

Korea through evaluations of IT-security products, IT-security education, public awareness campaigns, information security policy, and research and standardization in support of the legislative framework. In January 1998, KISA became a member of the Forum of Incident Response and Security Teams (FIRST; for more information on FIRST, see the FIRST chapter in this volume).

KISA opened the Korea Certification Authority Central in 1999, and the Personal Information & Privacy Protection Center in 2000. In addition, the Korea Information Security Industry Support Center (KISIS) was established under KISA in 2001. The Korea Internet Security Center (KISC, KrCERT/CC) [14] was founded in 2003 (see the chapter on Early Warning and Public Outreach), the Korea Spam Response Center (KSRC) also in 2003, and the Korea IT Security Evaluation Center (KISEC) [15] began its work in 2004.

In accordance with the Information Infrastructure Protection Act and the Act on Promotion of Utilization of Information and Communication Network and Data Protection, which became effective as of July 2001, KISA acquired additional duties such as the analysis and evaluation of the vulnerabilities of the critical information infrastructure, and the certification of information security management systems.

KISA includes an Information Infrastructure Protection Division with a CIIP Planning Team, a Critical Infrastructure Security Management Team, and the Korea Certification Authority Central Team, providing:

- Vulnerability analysis and assessment, including technical consulting and vulnerability analysis for facilities designated as CII;
- Security technology service for CII, including technical consulting for CII management agencies to establish safeguards and help in computer system recovery;
- Certification for information security management systems, including certifying integrated information security management systems, as well as technical and physical safeguards [16].

***3.1.6 Electronics and Telecommunications Research Institute (ETRI).*** The Information Security Research Division, a part of the Electronics and Telecommunications Research Institute (ETRI) [17], is developing advanced technologies in the area of information security for the private sector in Korea and supporting rapid industrialization of those technologies to resolve impediments to the emergence of the Information Society such as malfunctions of the Broadband Convergence Network infrastructure, the exchange of unsound and harmful information, and leaking of personal information, all of which are obstacles to the creation of a knowledge-based society. It aims to establish leadership in information security technology in order to approach the ideal of a secure u-Korea (see the chapter on the Past and Present Initiatives and Policies). This division focuses on four major research areas: Network Security, Ubiquitous Security, Biosecurity, and Security Chipset Technology.

The National Security Research Institute (NSRI), an affiliated research institute of ETRI [18], is managed by the Ministry of Science and Technology [19]. NSRI contributes to the public welfare by developing technology for protecting critical information infrastructures and enables the government to exercise information sovereignty by providing national security technology and policies required to protect the country and public organizations from cyber-attacks. NSRI deals with: [20]

- Developing technology to deal with cyber-terror and cyber-attacks, and for evaluating information protection systems, as well as to ensure the reliability and viability of governmental and military critical information infrastructures;
- Raising awareness of CIIP and giving seminars;
- Analyzing weaknesses in the government, public, and military sectors;
- Supporting Korea's e-Government strategy for information protection;
- Demonstration projects in the area of information protection for governmental organizations.

***3.1.7 Information and Telecommunication Infrastructure Protection Committee.*** The Information and Telecommunication Infrastructure Protection Committee, which is chaired by the viceminister for State Affairs of the Prime Minister's Office [21] and whose members are appointed by the chiefs and chairpersons of central administrative organizations, reviews items related to critical information infrastructures. The chairperson of the Information and Telecommunication Infrastructure Protection Committee can set up the Joint Working Group for Security Incident Response in order to provide emergency measures, technological support, and recovery procedures in the case of a large-scale security incident [22]. This committee was established in accordance with Article 3 of the Critical Information Infrastructure Protection Act. However, the Ministry of Public Administration and Security in May 2008 announced plans to abolish this committee.

### 3.2 Public-Private Partnerships

***3.2.1 National Information Security Alliance (NISA).*** The National Information Security Alliance (NISA) was established in September 2002 to improve information security by facilitating information exchange, presenting policies, and concentrating pan-governmental efforts. The alliance consists of 22 major governmental organizations, such as the Ministry of National Defense, the Ministry of Public Administration and Security, and the Korea Communications Commission, as well as information security officials from 17 public enterprises, communication network providers, the Korea Information Security Industry Association, research institutes, and experts from industry and academia. One main aspect of NISA's work is the executive meeting of chairpersons of the National Information Security Alliance, the Public Enterprise Information Security Alliance, and the Industrial-Educational-Research Information Security Alliance as a way of improving cooperation, while guaranteeing the autonomy of each of these actors within the alliance [23].

***3.2.2 Financial Information Security Alliance.*** The Financial Information Security Alliance was established in October 2002 to protect financial information security systems from cyber-terror and hacking, and to implement changes in international information protection policies such as the Banking Industry Technology Secretariat (BITS). The alliance has 87 members (20 banks, 27 security corporations, 30 insurance companies, and ten non-bank financial institutions). The Financial Information Security Alliance develops information protection standards and policies for the financial sector, as well as assessments and certifications. It also performs research in the field of information security and provides education.[1]

***3.2.3 Information Security Practice Alliance.*** The Information Security Practice Alliance was set up in July 2002 as a way of voluntarily increasing information protection activities in the private sector, in cooperation with various security companies and associations and with the help of the KISA. KISA has introduced a variety of projects in order to promote information protection campaigns with voluntary efforts from the public.[1]

***3.2.4 Korea Information Security Industry Association (KISIA).*** The KISIA was established in July 1998 as a platform for nurturing the information security industry (KISA has more than 150 members). Moreover, KISIA became a corporation in 2004 in accordance with Section 2 of Article 59 of the Act on Telecommunication Network Usage Promotion and Information Protection. It proposes measures to improve the legal system relevant to information security, trains specialized forces in the field, does joint research on innovative technology, analyzes market trends to understand the status of information security industry and to make plans, solves IT problems of the industry, reflects the opinions of members on governmental policies, promptly shares information with related authorities through an integrated system, provides support for participating in information security seminars or expositions, and promotes joint research with governmental or other related organizations [24].

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 National Cyber Security Center (NCSC)

The National Cyber Security Center (NCSC) takes preventive measures against cyber-threats. It also analyzes collected information on IT security, traffic, and capacity, using the service networks of numerous organizations, including government high-speed networks. Moreover, NCSC issues color-coded cyber-threat warnings (“green”, “blue”, “yellow”, “orange”, and “red”). It also distributes various security guidelines and information on worms and viruses, security news, cyber-incidents, and security technology to the private, public, and military sectors.[2] Furthermore, if a cyber-incident takes place, NCSC staff is dispatched to the site to investigate its cause and swiftly restore the system. The NCSC staff also examines the security of systems to prevent similar incidents in advance. Besides, the security center has organized a response team alliance dealing with national cyber-attacks, and is installing an emergency contact system for affected organizations [26].

### 4.2 Korea Internet Security Center (KISC, KrCERT/CC)

The Korean Internet Security Center (KISC, also called the Korea Computer Emergency Response Team Coordination Center, or KrCERT/CC), established in 2003, aims at raising the technical capability for the protection of critical network infrastructure in order to create a safe internet and communication network. KISC develops effective countermeasures against hacking and viruses, such as cyber-attack countermeasure methodology and attack tools. KISC is organized into five major teams:

[2]For example, the NCSC issues the “NCSC Monthly”, which contains information about incidents, cyber-threat trends, response activities, and analysis results [25].

- Incident Analysis Team,
- Response Coordination Team,
- Hacking Response Team,
- Spam Response Team,
- Botnet Response Team,
- Network Monitoring Team.

KISC responds to threats against IT networks and has built cooperation systems with relevant organizations in order to immediately handle incidents. As a member of FIRST, KISC does its utmost to fulfill its duties in cooperation with international organizations. The tasks of KISC (KrCERT/CC) are as follows:

- Technological support to prevent cyber-incidents;
- Analysis of cyber-incidents, analysis of malicious codes and their destructive power, and development of response and recovery measures;
- Analysis of network traffic and the status of the internet, monitoring of vulnerabilities at the national and the international levels;
- Analysis of the latest hacking tools and development of response measures;
- Receiving reports on spam, making improvements to the legal system, and analyzing domestic as well as international trends;
- Reinforcing cooperation with international CERTs;
- Dealing with phishing, activating CERTs, and raising awareness in the private sector [27].

### 4.3 Information Sharing and Analysis Center (ISAC)

In 2001, the first Korean Information Sharing and Analysis Center (ISAC) was established, after regulations were enacted according to Article 16 of the National Information Infrastructure Protection Act. The aim of ISACs is to prevent cyber-attacks on critical information infrastructures by sharing information on incidents with other companies and with the authorities concerned.[3]

In Korea, there are three ISACs, each of them addressing businesses of a different sector:

- The KS-ISAC (Korean Security Information Sharing and Analysis Center) was the first ISAC in Korea. It offers a database on cyber-incidents, vulnerabilities, and patches, shares information with relevant organizations outside the ISAC, and provides information online; [28]
- The KF-ISAC (Korea Financial Information Sharing and Analysis Center) was established in 2002 within the Korean Financial Telecommunication and Clearings Institute (KFTC). It provides various information security services to the participating members, especially customized for the Korean banking industry. The most important services are information security reports; real-time monitoring and warning services; information security checks for core systems; and education and training services [29];

[3]The first ISACs were established in the US (see country survey on the United States in this volume).

- The Korean Telecommunication ISAC was also established in 2002. It aims to provide its members with the opportunity to share proper information on incidents and to exchange experiences and insights. The ISAC gathers and disseminates information obtained from different sources, such as CERTs or other information-security associations [30].

## 5 LAW AND LEGISLATION

### 5.1 Information Security Promotion Systems

Information-security promotion systems in Korea can be divided into national cyber-security systems, e-Government security systems, critical information infrastructure systems, and private information security systems. With respect to the national cyber-security system, the National Cyber Security Management Regulation was issued by a presidential directive on 31 January 2005, which regulates cyber-security organizations such as the National Cyber Security Strategy Council or the National Cyber Security Center. Meanwhile, for e-Government security systems, the Act on Promotion of Electronic Administration for e-Government, enacted on 28 February 2001, regulates matters of information protection as well as e-Government.[1]

### 5.2 Digital Signature Act 1997

The Digital Signature Act was enacted by Korea Parliament on July 1997 and revised on 31 December 2005 [31].[1] The purpose of the Digital Signature Act is to endow electronic documents with an equal level of legal validity as paper documents and to regulate basic matters related to achieving reliability, protect consumer rights, and implement policies, and thus to promote electronic commerce, with a view to creating a legally predictable environment in which the private citizens can make secure transactions in the Information Age. It contains provisions on "definition of digital signature", "licensed certification authority", "public-key certificate", "security and trust for certification service", and "electronic certification policy", etc. Responsibility for implementing this act has resided with the Ministry of Public Administration and Security since March 2008.

### 5.3 Act on Promotion of Utilization of Information and Communication Network and Information Protection 1999

The Act on Promotion of Utilization of Information and Communication Network and Information Protection was enacted on 1999 and revised on December 2007 [32].[1] The purpose of this act is to promote the use of information and communications networks, to protect users' personal information when they are using information and communications services, and to construct an environment within which users can safely use information and communications networks. It consists of many articles governing the utilization of digital documents through relay servers, protection of personal information, protection of juveniles in information and communication networks, securing the safety of information and communications networks, and other issues. Responsibility for implementing this act has been shared by the Ministry of Public Administration and Security, the Korea Communication Commission, and the Ministry of Knowledge and Economy since March 2008.

### 5.4 Act on Private Information Protection of Public Organizations 1994

The Act on Personal Information Protection by Public Organization, enacted in 1994 and revised in 1998, aims to ensure the adequate performance of public duties and to protect the rights and interests of users by protecting personal information processed by computers [33].[1]

### 5.5 Critical Information Infrastructure Protection Act 2001

The ministerial meeting on the prevention of large scale cyber-related incidents in February 2000 decided to pass a law covering comprehensive and systematic information infrastructure protection and countermeasures against so-called cyber-terrorism. The Critical Information Infrastructure Protection Act was enacted in January 2001 and revised in December 2007. It serves as a fundamental law protecting critical information infrastructure from various cyber-incidents. A critical information infrastructure was defined as a public or private network that carries information relevant to national security and safety or information of high financial value. The critical ICT infrastructure can also be defined physically as the whole network or a part of the network that exchanges information of high significance. This law consists of many articles defining the critical information and communication infrastructure, outlining protective measures and responses against cyber incidents, defining the work of the information security consulting agency, and specifying legal responsibilities and penalties. It outlines the government framework for critical information infrastructure protection. It directs the affairs of the Critical Information Infrastructure Protection Committee, the Working Group for Security Incident Response, and other central administrative organizations. Moreover, protection measures, prevention and response, technical support, development of technologies, international cooperation, and penalties for cyber-crimes are addressed [34]. Responsibility for enforcing this act has rested with the Ministry of Public Administration and Security since March 2008.

In addition, the Act on Private Information Protection of Public Organizations, the Act on Promotion of Electronic Administration for e-Government, and the Resident Registration Act in the public sector, as well as the Act on Promotion of Utilization of Information and Communication Network and Information Protection in the private sector deal with private information security systems [35].[1]

### 5.6 e-Commerce Framework

As electronic transactions and commerce across long distances become more common due to the development of ICT networks, a legal framework has been established regarding electronic signatures and their certification, in order to secure the safety and reliability of electronic documents that are drawn up by data processing systems and then transferred, received, or saved. The Digital Signature Act and the e-Commerce Framework Act regulate certification of electronic signatures, and the Act on Promotion of Electronic Administration for e-Government governs the use of digital signatures in the public administration [36].[1]

### 5.7 Protection of Telecommunication Networks and Information Systems

As attacks on telecommunication networks and information systems increase in the public and private sectors, the need for a systematic national-level protection system has

become urgent. The Framework Act on Information Promotion, the Critical Information Infrastructure Protection Act, the Act on the Promotion of Utilization of Information and Communication Network Utilization and Information Protection, the e-Commerce Framework Act, the e-Government Act, the Act on Trade Automation Promotion, the Act on Industrial Infrastructure, and the Freight Distribution Promotion Act have been passed to protect telecommunication networks and information systems [37].

### 5.8 Cyber-Attacks

The following laws and regulations are applied in order to prevent national and social loss arising from hacking, viruses, denial-of-service (DoS) attacks on telecommunication networks as well as other information systems, and theft or forgery of information:

- Article 28 of the Critical Information Infrastructure Protection Act imposes a penalty for attacks on critical information infrastructures;
- Article 62 of the Act on the Promotion of Utilization of Information and Communication Network Utilization and Information Protection outlaws attacks on telecommunication networks and violations of a duty to protect secret information;
- Article 25 of the Act on Trade Automation Promotion, as well as Sections 2 and 4 of Article 54 of the Freight Distribution Promotion Act, may also apply.

In addition, there are provisions in the national criminal legislation dealing with computer crime [37].

## ACKNOWLEDGMENT

We acknowledge the contribution of the expert Heung Youl Youm of Soonchunhyang University, who validated the content of this chapter.

*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

In Malaysia, the following sectors are regarded as making up the national critical infrastructure [1]:

- Financial Sector,
- Water and Sewerage,
- Communications and Media,
- Energy,
- Health and Emergency Services,
- Industry,
- Central Government,
- Government Services,
- Transportation,
- Military.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

National IT Agenda (NITA)
National Information Technology Council (NITC) Strategic Agenda
e-Secure Malaysia 2005 International Conference

### 2.1 National IT Agenda (NITA) and NITC Strategic Agenda

Malaysia launched the National IT Agenda (NITA) in 1996 as part of a major strategy to prepare the nation for the challenges of the information age. The agenda contains an outline for a national framework aimed at ensuring a balanced IT development for Malaysia, its infrastructure, and the applications found within. According to NITA, for this

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

effort to succeed, Malaysia requires greater trust and faith in the use of information and communication technology (ICT), which can be fostered through enhanced ICT security [2]. The launch of NITA provided the foundation and framework for the utilization of information and communication technology to transform Malaysia into an information and knowledge society.

Besides NITA, the National Information Technology Council (NITC) (see the chapter on Organizational Overview) formulated the NITC Strategic Agenda, a strategy involving a more participatory governance structure with active partnership between the public, private, and community-interest sectors. The Strategic Agenda includes concepts such as e-Community, e-Public services, and e-Economy. It is based on the assumption that knowledge and information will be the most valuable assets in the new economy [3].

### 2.2 e-Secure Malaysia 2005 International Conference

A major information security event, e-Secure Malaysia 2005, took place in September 2005 in Kuala Lumpur. It consisted of two conferences and an exhibition targeted at security professionals, solution providers, policy makers, corporate decision makers, and government officials. The event was jointly organized by various government agencies such as the Ministry of Science, Technology and Innovation (MOSTI); the Ministry of Energy, Water and Communications (MEWC); the Malaysian Communications and Multimedia Commission (MCMC); the National ICT Security and Emergency Response Centre (NISER); and the Malaysian Administrative Modernisation and Management Planning Unit (MAMPU). The conference focused on the following topics: Computer Emergency Response Teams (CERTs) and incident response; critical infrastructure protection; network and application security; security management and strategy; and knowledge-sharing [4].

## 3 ORGANIZATIONAL OVERVIEW

The Malaysian Communications and Multimedia Commission (MCMC) has a coordinating role. The Malaysian Administrative Modernization and Management Planning Unit (MAMPU) administers security issues in the public sector. The Police Cyber Crime Unit is responsible for investigation and prevention of commercial cyber-crime. The Ministry of Science, Technology and Innovation (MOSTI) holds wide-ranging responsibilities concerning national ICT policy and security, while it is the objective of the Ministry of Energy, Water and Communications (MEWC) to protect the infrastructure.

As a public-private partnership, the Information Sharing Forum (ISF) strives to bring together various ICT stakeholders in order to jointly address Malaysian information and network security issues.

### 3.1 Public Agencies

***3.1.1 Malaysian Communications and Multimedia Commission (MCMC).*** The MCMC [5] is a statutory body established in 1998 in accordance with the national policy objectives set out in the Communications and Multimedia Commission Act[1] and

[1]This act created a new regulatory body, the MCMC. Cf. [6].

in the Communications and Multimedia Act (CMA).[2] The MCMC oversees the new regulatory framework for the converging industries of telecommunications, broadcast, and online activities. This includes the development and enforcement of access codes and standards. The MCMC ensures information security and the integrity and reliability of the network of Malaysia, identified as one of the ten national policy objectives in the CMA. Together with the police, the MCMC has enforcement powers for offences relating to network security in the CMA. In June 2002, MCMC hosted a workshop on Information and Network Security and the Protection of Critical Infrastructure [7]. In response to a proposal by the Malaysian prime minister in 2005, an initiative called IMPACT (an International Multilateral Partnership Against Cyber-Terrorism, set up by the Malaysian government) was recently launched. The first inaugurating IMPACT summit took place in Kuala Lumpur in May 2008 under the auspices of MCMC.

***3.1.2 Malaysian Administrative Modernization and Management Planning Unit (MAMPU).*** Security issues in the public sector are administered by the Malaysian Administrative Modernization and Management Planning Unit (MAMPU) [8]. Within MAMPU, the ICT Security Division also operates as Computer Emergency Response Team (GCERT) for the government [9]. In the field of e-Government, MAMPU developed the ICT Strategic Plan in 2003 to provide citizens and businesses with enhanced access to government information and services. The Public Sector ICT Strategic Plan outlines the guidelines for implementing the public sector's ICT requirements, frameworks, and the core areas to be strengthened [10]. The MAMPU is also the host of the Government ICT Security Command Center, a project designed to monitor cyber-threats to the network system and to public ICT. The aims of this project include the provision of periodic scanning of vulnerabilities and assets, the detection of security breaches, and forecasting and warning of cyber-attacks [11].

The current information security measures provided by MAMPU fall under three categories:

- *Proactive measures.* Providing ICT security documents such as an ICT security policy framework for the public sector; ICT incident reporting mechanisms; and best practices;
- *Recovery measures.* Ensuring the continuous function of critical business in the event of disruption; advice on how to upgrade patches; and warnings of virus attacks;
- *Continuous measures.* Monitoring, enforcement, policy review and improving ICT security management.

***3.1.3 Police Cyber Crime Unit.*** The Royal Malaysia Police has established a Technology Crime Investigation Unit under the Commercial Crime Investigation Division of the Criminal Investigation Department. The investigation officers in this unit investigate and take preventive action against commercial crime involving computers and internet-related

[2]This act set out a new regulatory licensing framework for a convergent communications and multimedia industry. For example, it covers fraudulent use of network facilities or services and interceptions of communications [6]. See the chapter on Law and Legislation.

crimes. The police has also established a forensic computer laboratory to assist officers investigating computer crime [12].

***3.1.4 Ministry of Science, Technology and Innovation (MOSTI).*** Under a recent restructuring, the Ministry of Science, Technology and Innovation (MOSTI) took over responsibility from the former Ministry of Energy, Communication and Multimedia (MECM) for the following areas:

- Formulation and implementation of national policy on ICT;
- Formulation and implementation of national information security policy;
- Encouraging research and development and commercialization of ICT;
- Development and promotion of ICT industries [13].

Following the restructuring, the secretariat of the National Information Technology Council (NITC) (see the chapters on Past and Present Initiative and on Early Warning and Public Outreach) was transferred to MOSTI. The ICT Policy Division within MOSTI was established on 1 March 2005 with five units, namely the Policy and Strategic Unit, the ICT Technology Studies Unit, the Assessment and Monitoring Unit, the ICT Acculturation Unit, and the NITC Secretariat [13].

At an NITC meeting in April 2006, agreement was reached on a Malaysian National Cyber Security Policy (NCSP), and the National ICT Security and Emergency Response Center (NISER) was assigned to carry out the function of the national cyber-security agency. In March 2007, NISER was given additional mandates and renamed CyberSecurity Malaysia. And in August 2007, CyberSecurity Malaysia was officially launched by the prime minister. It has been operating autonomously since then under the heading of the MOSTI [14] (see the chapter on Early Warning and Public Outreach).

***3.1.5 Ministry of Energy, Water and Communications (MEWC).*** The Ministry of Energy, Water and Communications (MEWC) was established in March 2004 and manages the nation's energy, communications (infrastructure), and postal services, as well as water supply. MEWC develops and formulates strategic and innovative policies, a self-regulatory framework, and an effective management system. One of its objectives is to ensure a secure and reliable supply and provision of energy, water, and communications services [15].

### 3.2 Public-Private Partnership

***3.2.1 Information Sharing Forum (ISF).*** The Information Sharing Forum (ISF) was formed in June 2004 by the Malaysian Communications and Multimedia Commission (MCMC). It brings together various Internet Service Providers (ISP) and other agencies—namely, CyberSecurity Malaysia, the ICT Security Division of MAMPU, and the Malaysian Technical Standards Committee—to address Malaysian information and network security issues. Apart from encouraging cooperation between different network owners, operators, and other agencies, this forum enables the sharing of experience and expertise for the benefit of the Malaysian network infrastructure. Moreover, it aims at elaborating guidelines and best practices.The ISF meets every month and is chaired by the MCMC. It also hosts a newsgroup where members interact and debate on issues before each ISF meeting [16].

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 Malaysian Computer Emergency Response Team (MyCERT)

In March 1997, the Malaysian Computer Emergency Response Team (MyCERT) was launched [17]. Over the years, MyCERT has provided assistance to many Malaysians in handling ICT security incidents. During this period, there was an increase in national awareness of ICT—in particular, of the fact that ICT security issues encompass a much broader scope than previously envisaged. Purely technical measures, such as firewalls, are not sufficient for tackling security threats. The government of Malaysia realized that the growing number and variety of ICT applications and devices produced by suppliers lacking fundamental security precautions had created a strong need for a trusted ICT security center to support not only reactive measures, but also proactive measures in ICT security. To this end, MyCERT provides a point of reference for the internet community to deal with computer security incidents and methods of prevention. It strives to reduce the probability of successful attack and lowering the risk of consequential damage. MyCERT has the following functions:

- Providing an expert point of reference on network and security matters;
- Reporting security incidents and facilitating communication to resolve security incidents;
- Disseminating security information, including system vulnerabilities and defense strategies;
- Acting as a repository of security-related information, acquiring patches, tools, and techniques;
- Educating the public with regard to computer security in Malaysia [18].

### 4.2 From the National ICT Security and Emergency Response Center (NISER) to Cyber Security Malaysia

The National ICT Security and Emergency Response Center (NISER) [14] was formed by the National Information and Communication Technology Council (NITC) to address e-Security issues and to act as Malaysia's CERT. NISER evolved from what was originally the Malaysian Computer Emergency Response Team (MyCERT) in March 1997. As mentioned earlier (see the chapter on Organization Overview, section on MOSTI), the transformation process of NISER into CyberSecurity Malaysia, through the adoption of the Malaysian National Cyber Security Policy, started in 2006. It was given additional mandates and officially launched by the prime minister in 2007 [14]. Thus, NISER's role was elevated as it became Cyber Security Malaysia. Today, CyberSecurity Malaysia exists as the national reference and specialist center for cyber-security under the purview of MOSTI. CyberSecurity Malaysia was formed as a one-stop coordination center for all national cyber-security initiatives with the aim to

- Reduce the vulnerability of ICT systems and networks;
- Nurture a culture of cyber-security among users and critical sectors;
- Strengthen Malaysian self-reliance in terms of technology and human resources.

With the advent of CyberSecurity Malaysia, the country has been striving towards overcoming cyber-threats and to build a safer and more secure cyberspace. The services offered by CyberSecurity Malaysia include computer emergency response, digital forensics, security assurance, security management and best practices, and training and outreach [19]. Therefore, CyberSecurity Malaysia offers services to private and public entities such as research in vulnerability detection, intrusion detection, and computer forensic technology. It is also a member of the Forum of Incident Response and Security Teams (FIRST) (see the chapter on FIRST in this volume) and APCERT (the Asia Pacific Computer Emergency Response Team). Through collaboration with other agencies, it provides specialized ICT security services and continuously identifies possible gaps that could be detrimental to national security [20]. CyberSecurity Malaysia fosters mutual co-operation, information-sharing, and expert assistance among the different government agencies involved. The integrative purpose of CyberSecurity Malaysia is to reduce the vulnerability of ICT systems and networks, to nurture a culture of cyber-security amongst users and critical sectors, and to strengthen Malaysian self-reliance in terms of technology and human resources [21].

## 5 LAWS AND LEGISLATION

The Malaysian government has passed a number of laws relating to cyberspace since 1997 to provide a comprehensive legal framework that encompasses the security of information and network integrity and reliability, for the benefit of society at large as well as the business sector in particular.

### 5.1 Computer Crimes Act 1997

Part II, Offences

3 (1) A person shall be guilty of an offence if

(a) he causes a computer to perform any function with intent to secure access to any program or data held in any computer;
(b) the access he intends to secure is unauthorized; and
(c) he knows at the time when he causes the computer to perform the function that is the case.

(2) The intent a person has to have to commit an offence under this section need not be directed at—

(a) any particular program or data;
(b) a program or data of any particular kind; or
(c) a program or data held in any particular computer.

(3) A person guilty of an offence under this section shall on conviction be liable to a fine or to imprisonment not exceeding five years or to both [22].

### 5.2 Communications and Multimedia Act (CMA) 1998

An Act to provide for and to regulate the converging communications and multimedia industries, and for incidental matters.

Part 1—Preliminary Section 3.

Objects (1)

The objects of this Act are (a) to promote national policy objectives for the communications and multimedia industry; (b) to establish a licensing and regulatory framework in support of national policy objectives for the communications and multimedia industry; (c) to establish the powers and functions for the Malaysian Communications and Multimedia Commission; and (d) to establish powers and procedures for the administration of this Act.

(2) The national policy objectives for the communications and multimedia industry are—(a) to establish Malaysia as a major global centre and hub for communications and multimedia information and content services; (b) to promote a civil society where information-based services will provide the basis of continuing enhancements to quality of work and life; (c) to grow and nurture local information resources and cultural representation that facilitate the national identity and global diversity; (d) to regulate for the long-term benefit of the end user; (e) to promote a high level of consumer confidence in service delivery from the industry; (f) to ensure an equitable provision of affordable services over ubiquitous national infrastructure; (g) to create a robust applications environment for end users; (h) to facilitate the efficient allocation of resources such as skilled labour, capital, knowledge and national assets; (i) to promote the development of capabilities and skills within Malaysia's convergence industries; and (j) to ensure information security and network reliability and integrity.

(3) Nothing in this Act shall be construed as permitting the censorship of the Internet [23].

## 1 CRITICAL SECTORS

Using the so-called Quick Scan method[1] and in consultation with the industry and government, it was determined in 2002 that the Netherlands' critical infrastructure comprises 11 sectors and 31 critical products and services [1]. That result was adjusted in the ensuing risk analysis phase. Since April 2004, the list comprises 12 critical sectors and 33

*This chapter was reviewed by Eric Luiijf, TNO Defense, Security and Safety; Williët Brouwer, Programme Manager Critical Infrastructure Protection, Ministry of the Interior; and André Griffioen, Deputy Programme Manager Critical Infrastructure Protection, Ministry of the Interior.
[1]For more information on "Quick Scan", see the chapter on Past and Present Initiatives.

critical products and services. Infrastructures are deemed critical if they constitute an essential, indispensable service for society, and if their disruption would rapidly bring about a state of emergency or could have adverse societal effects in the longer term. In the Netherlands, critical sectors (and products and services) include the following: [2]

- Drinking Water Supply,
- Energy (Electricity, Natural Gas, and Oil),
- Financial Sector (Financial Services and the Financial Infrastructure, both Public and Private),
- Food (Food Supply and Food Safety),
- Health (Urgent Health Care/Hospitals, Sera and Vaccines, Nuclear Medicine),
- Legal Order (Administration of Justice and Detention, Law Enforcement),
- Public Order and Safety (Maintaining Public Order, Maintaining Public Safety),
- Retaining and Managing Surface Water (Management of Water Quality, Retaining and Managing Water Quantity),
- Telecommunications (Fixed Telecommunication Network Services, Mobile Telecommunication Services, Radio Communication and Navigation, Satellite Communication, Broadcast Services, Internet Access, Postal and Courier Services),
- Public Administration (Diplomatic Communication, Information Provision by the Government, Armed Forces and Defense, Decision-making by Public Administration),
- Transport (Mainport Schiphol, Mainport Rotterdam, Main Highways and Waterways, Rail Transport),
- Chemical and Nuclear Industry (transport, storage, and production/processing).

The Critical Information Infrastructure (CII) of the Netherlands consists mainly of the internal supporting infrastructure of critical sectors like the energy, transport, and financial sectors, and is supported by a set of services delivered by the telecommunications and energy sectors (fixed telecommunication, mobile telecommunication, internet access, electricity).

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

In the Netherlands, CIP/CIIP is perceived increasingly as a crucial issue of national security. Since the end of the 1990s, several efforts have been made to manage CIP/CIIP better. The early initiatives and policies were aimed at information security in general, because there was no clear definition of critical infrastructures. This changed with the Critical Infrastructure Protection Project, which started in 2001 and formulated dedicated policies for CIP and CIIP.

### 2.1 Early Efforts to Protect Information and Communication Infrastructure

***2.1.1 The Digital Delta.*** The publication The Digital Delta of June 1999 offered a framework for a range of specific measures regarding government policy on information and communications technology (ICT) for the next three to five years [3]. This memorandum noted the increasing importance of ensuring the security of information systems

and the communications infrastructure, and of mastering the growing complexities of advanced IT applications [4].

***2.1.2 Defense Whitepaper 2000.*** Likewise, the increasing importance of ICT is also explicitly mentioned in the Dutch Defense Whitepaper 2000: "Given the armed forces' high level of dependence on information and communication technology, it cannot be ruled out that in the future attempts will be made to target the armed forces in precisely this area" [5].

***2.1.3 Infodrome Initiative & BITBREUK.*** In March 2000, the key essay BITBREUK (English version In Bits and Pieces) was published by the government-sponsored think-tank Infodrome to stimulate the discussion on the need to protect CII.[2] The essay offered an initial vulnerability analysis and postulated a number of hypotheses for further discussion and examination by the Dutch authorities in co-operation with the appropriate national public and commercial organizations [6]. In mid-2001, this document was used as a starting point for a so-called 24-hour cabinet session. This was a 24-hour workshop with a selected group of experts that created a manifesto on CI/CII issues (KWINT-manifest) with a set of recommendations for all political parties. These recommendations provided the basis for the KWINT program to improve information security.

***2.1.4 KWINT Report and KWINT Program.*** The report entitled Kwetsbaarheid op Internet—Samen werken aan meer veiligheid en betrouwbaarheid (KWINT),[3] written by Stratix Consulting/TNO[4] for the Ministry of Transport, Public Works, and Water Management (V&W), was completed in 2001. The report concluded that the Dutch internet infrastructure was extremely vulnerable. Final recommendations were made on policy measures with regard to awareness and education, coordination of incidents, protection, and security. The report concluded that the measures should be realized within a public-private partnership framework, while the government should play a facilitating and coordinating role [7].

The findings and recommendations of this report triggered the formation of an interdepartmental working group of members of the Ministries of Economic Affairs, Defence, Finance, the Interior, Justice, and Transport (Telecom and Post Directorate).[5] As a result, the KWINT government memorandum Vulnerability of the Internet was endorsed by the cabinet on 6 July 2001. It includes a set of recommendations for action. The government-wide computer emergency response team, GOVCERT.NL, was established, and a malware-alerting service for Small and Medium Enterprises (SMEs) and the public was set up [8]. Other KWINT tasks were given to the Platform Electronic

[2]Infodrome was a think-tank founded in 1999 and sponsored by the Dutch government that served a threefold objective: (1) to develop an understanding of the social implications of the information revolution (this requires the gathering of empirical, quantitative knowledge and data on IT-related developments, and a systematic analysis thereof), (2) to stimulate social awareness of the importance of having a government policy that meets the requirements of the information society, and (3) to examine the priorities given by parties and interest groups to activities (public or private) undertaken in relation to the information society. This requires an understanding of the political and social value of knowledge, experience, and insights. The Infodrome project ended in 2002.

[3]Vulnerability of the Internet –Working Together for Greater Security and Reliability.

[4]TNO is the Netherlands' Organization for Applied Scientific Research.

[5]The Telecom and Post Directorate (DGTP) became part of the Ministry of Economic Affairs as of 1 January 2003.

Commerce in the Netherlands (ECP.NL), the public-private platform for e-commerce in the Netherlands.

The KWINT Program 2002–2005 was especially targeted towards the protection and safe use of the internet. The 2005 report to the Dutch parliament recognizes the need to address the security of ICT that is used across critical sectors. The dependency and vulnerability of Supervisory, Control, and Data Acquisition (SCADA), for instance, is a cross-sector ICT area that will be analyzed in detail.

***2.1.5 Veilige Elektronische Communicatie (VEC).*** The successor of the KWINT program is called Veilige Elektronische Communicatie (VEC).[6] The program started in January 2006 and will run for at least three years. The program is designed as a public-private partnership under the responsibility of the Ministry of Economic Affairs. It aims to raise general awareness of information security and will implement a pilot project to support SMEs in the fight against cybercrime [9].

## 2.2 The Critical Infrastructure Protection Project

In early 2002, the Dutch government initiated the critical infrastructure protection project Protection of the Dutch Critical Infrastructure,[7] with the objective of developing an integrated set of measures to protect the infrastructure of government and industry, including ICT [10]. The project includes four steps: 1) A quick-scan analysis of the Dutch critical infrastructure to identify products and services vital to the nation, the (inter-) dependencies of these products and services, and underlying essential processes; 2) stimulation of a public-private partnership; 3) threat and vulnerability analysis; and 4) a gap analysis of protection measures.

To identify sectors, products, and services comprising the national critical infrastructure, a Quick-Scan Questionnaire was developed. Dutch government departments used this questionnaire in early 2002 to make an inventory of all products and services that they regarded as vital, including the underlying processes and dependencies. In June 2002, an analysis of the collected information was presented in a working conference with key representatives of both the public and the private sectors. The initial results were augmented and refined in 17 workshops with the vital public and private sectors. In parallel, damage experts evaluated the potential damage impact of loss or disruption of vital products and services [11].[8]

In April 2003, the findings of the Quick Scan, performed in close collaboration with the Netherlands Organization for Applied Scientific Research (TNO), were published by the Ministry of the Interior and Kingdom Relations [12].[8] The following main conclusions were drawn from the Quick Scan results:

[6]Safe Electronic Communications.

[7]Bescherming Vitale Infrastuctuur.

[8]To determine the elements of the national critical infrastructure, the Dutch approach aims to distinguish between products and services vital to the nation and those that are "merely" very important. Under this method, a product or a service is defined as vital if it "provides an essential contribution to society in maintaining a defined minimum quality level of (1) national and international law and order, (2) public safety, (3) economy, (4) public health, (5) ecological environment, or (6) if loss or disruption impacts citizens or the government administration at a national scale." By measuring criticality according to a predefined minimum level of acceptable quality in vital services to society, the approach shifts the problem of defining "vital" or just "very important" elements to the political level. It is the government that must determine the level of damage impact that is acceptable to society.

- The Dutch government and industry now have a clear understanding of the critical products and services that comprise the Netherlands' critical infrastructure, and of their (inter-) dependencies;
- The direct and indirect vitality of critical products and services has been elaborated;
- It became clear that actors responsible for critical products and services only have a limited understanding of other critical products and services that depend on them, and of the extent of this dependence [13].[8]

The next steps concerning the strengthening of the Netherlands' CIP/CIIP included pinpointing the vital nodes for each of the critical services, risk and vulnerability analyses for each critical sector, scenarios to test the effectiveness of CIP/CIIP measures, and an international exchange of CIP/CIIP information and coordination [14].[8] In addition, the CIP project has been established as a regular policy file under the responsibility of the Ministry of the Interior and Kingdom Relations. In 2005, the ministry outlined the Report on Critical Infrastructure Protection for the attention of the Dutch parliament. The report contained a review of the achievements of the CIP Project and defined a new set of actions [15].

- *Intensifying critical infrastructure security policy.* CIP is a collective task, and it is important that all relevant stakeholders pull together to improve the security of national infrastructures. Therefore, a Strategic Board for CIP (Strategisch Overleg Vitale Infrastructuur, SOVI) was created (for more information, see the chapter on Organizational Overview);
- *Analyzing CIP dependency.* Fostering cross-critical sector communication is also the goal of the CIP Dependency project. Critical sectors must be able to get in touch with each other—not only to determine the extent of the crisis, but also to assess its likely duration. The project is underway and will determine whether the affected critical sectors will have to take additional measures in order to guarantee continuity;
- *Improving protection of critical infrastructures against human threats.* Protection against willful disruptions of vital services is a high priority. Such attacks may be conducted by hackers, activists, frustrated employees, ordinary criminals (who are motivated by financial gains), and terrorists. In order to prevent such attacks, cooperation between law enforcement units, the intelligence services, CERTs, and private parties is indispensable. The National Advisory Centre Critical Infrastructures (NAVI) [16] provides a platform for mutual exchange among these organizations;
- *Awareness-raising.* Scenario exercises will be implemented involving distribution plans for CI products/services in the event of scarcity of supply, both at the national and regional levels.

Progress reports on these activities were published in 2006 and 2007 [17].

### 2.3 National Security Strategy and Work Programme 2007–2008

In order to cope with emerging risks, the Dutch cabinet has drawn up a National Security Strategy and Work Programme for the years 2007–2008 [18]. The strategy defines the goals of Dutch security policy, analyzes and assesses threats and risks, and develops methods for strategic planning. The strategy pursues an all-hazard approach and aims to provide for a more coordinated and integrated approach to national security [19].

Accordingly, the strategy will serve as a framework for the future protection policies for critical infrastructures [20]. The document states that there are many potential threats to the country and that each of these threats puts a strain on national security. National security is conceived as being under threat when vital interests of the Dutch state and society are harmed to the extent that society can become destabilized. These vital interests, and examples thereof, include the following: [21]

- *Territorial security.* The threat or occurrence of (terrorist) attacks on Dutch soil;
- *Economic security.* The breakdown of overseas trade or an ICT malfunction;
- *Ecological safety.* An environmental disaster or disruption of the drinking water supply;
- *Physical safety.* A dyke breach or epidemic;
- *Social and political stability.* Tension between various ethnic groups.

In the Netherlands, national security encompasses both breaches of security by intentional human actions (security) and breaches due to disasters, system or process faults, human failure, or natural anomalies such as extreme weather (safety).

The new approach aims at allowing signals of potential threats to be identified at an earlier stage, by systematically linking information streams and cross-referencing developments (e.g., to what extent will energy requirements change if summers become warmer and more air conditioning and refrigerators are needed). The strategy formulates a method of weighing various interests and strives to prioritize among them [21]. Clearly, critical infrastructure protection is intimately linked with the National Security Strategy and planning. One of the capabilities named to be strengthened according to the national risk assessment (part of this programme) is business continuity [22].

In 2008 one of the issues addressed within the National Security Strategy is ICT failure. A project called "ICT-verstoring" was initiated in which relevant private and public parties co-operate in a government-wide analysis and risk assessment of ICT. In this project, short, medium, and long-term ICT threats to the Netherlands are identified and analyzed in terms of their likelihood and potential impact. The insights gained from this process are used to assess whether preventative capabilities and preparation are sufficient to cope with these threats.

## 3 ORGANIZATIONAL OVERVIEW

Responsibility for the Dutch CI and CII lies with various actors and involves public and private sectors as well as several ministries, including the Ministry of the Interior and Kingdom Relations, the Ministry of Economic Affairs, the Ministry of Transport, Public Works, and Water Management, the Ministry of Housing, Spatial Planning, and the Environment, and the Ministry of Health, Welfare and Sport. The General Intelligence and Security Service is also involved in protecting information security in the Netherlands.

Moreover, public-private partnerships play a crucial role in CIP and CIIP in the Netherlands. As mentioned above, the KWINT program and the Critical Infrastructure Protection Project are both based on public-private collaboration. The KWINT program led to a flurry of policy recommendations that are elaborated in further detail in the public-private partnership Platform Electronic Commerce in the Netherlands (ECP.NL). These recommendations refer to awareness-raising, research and development, alarm and incident response, and the integrity of information.

Public-private co-operation within the project Critical Infrastructure Protection Project gained further importance with the official establishment of the Strategic Board for CIP (SOVI). With regard to the protection of critical information infrastructures, the National Continuity Consultation Platform Telecommunication (NCO-T) is of special interest, because it enables public-private collaboration between the government and telecommunication companies on continuity planning and crisis response. Furthermore, the National Advisory Centre Critical Infrastructures is an initiative of the government striving to enhance information exchange on security issues between critical sectors, critical sector enterprises, and government agencies. Finally, the National Infrastructure against Cyber-Crime is a cyber-crime information-sharing model organized as a private-public partnership program.

### 3.1 Public Agencies

***3.1.1 Ministry of the Interior and Kingdom Relations (BZK).*** First of all, the Ministry of the Interior and Kingdom Relations (MoI) is responsible for the general C(I)IP policy, the co-ordination of the national activities across all sectors and responsible ministries, and international policy (e.g., EPCIP) and co-ordination. Additionally, the MoI is responsible for the protection of government information infrastructures (government CIIP), national emergency management, and the CIP aspects of emergency response services. The national emergency management includes the National Crisis Centre (NCC), which is in charge of co-ordination activities at the policy level in case of emergencies and disasters with a nation-wide impact.

***3.1.2 Ministry of Economic Affairs (EZ).*** Some other key C(I)IP areas are the responsibility of the Ministry of Economic Affairs (EZ). EZ is responsible for C(I)IP coordination with the private sector in the areas of energy and telecommunications, including the internet [23]. Other parts of the same ministry are responsible for CIP/CIIP policies regarding the private industry, including SMEs.

***3.1.3 Ministry of Transport, Public Works, and Water Management (V&W).*** The Ministry of Transport, Public Works, and Water Management (V&W) [24] is responsible for the public-private C(I)IP co-ordination for the critical infrastructures related to transport (road, rail, air, harbors, and inland shipping) and water management as well as the biochemical quality of the surface water.

***3.1.4 Ministry of Housing, Spatial Planning, and the Environment (VROM).*** The Ministry of Housing, Spatial Planning, and the Environment (VROM) [25] is responsible for public-private co-ordination of the C(I)IP activities of the chemical and nuclear industries, as well as the potable water infrastructure.

***3.1.5 Ministry of Health, Welfare and Sport (VWS).*** The Ministry of Health, Welfare, and Sport (VWS) [26] is responsible for the public-private coordination of the C(I)IP activities of the health sector.

***3.1.6 General Intelligence and Security Service (AIVD).*** The General Intelligence and Security Service (AIVD) [27] is a division of the Ministry of the Interior and Kingdom Relations and is tasked with protecting the information security and vital sectors of Dutch

society [28]. The AIVDs focus shifts in accordance with social and political changes. One of its tasks is to uncover forms of improper competition, such as economic espionage, that could harm Dutch economic interests. Another task is foreign intelligence. In the interests of national security, it will carry out investigations abroad, though only in the non-military sphere. The AIVD is responsible for analyzing potential and likely threats to the Dutch CI sectors.

### 3.2 Public-Private Partnerships

***3.2.1 Platform Electronic Commerce in the Netherlands (ECP.NL).*** The Platform Electronic Commerce in the Netherlands (ECP.NL) [29] has been tasked by the Ministry of Economic Affairs with setting up a public-private partnership program to implement the action guidelines of the KWINT Memorandum.

The objective of the KWINT program focused on the following aspects: continuity of the internet infrastructure in the Netherlands, viruses, denial-of-service attacks, hacking, transparency of internet services, integrity and confidentiality of information, and misuse by personnel. As the KWINT program expired in 2005, ECP.NL established the Digibewust program (Digital Awareness) [30] in order to improve awareness of information security.

***3.2.2 National Continuity Plan for Telecommunications (NACOTEL) and National Continuity Forum Telecommunications (NCO-T).*** The National Continuity Plan for Telecommunications (NACOTEL) was established in 2001 in order to structure the contingency policy and crisis management in the telecommunications sector. The public-private partnership included BT (IT-services), Enertel, KPN Telecom, Telfort, Orange, T-Mobile, and Vodafone—as well as the Ministry of Economic Affairs. NACOTEL was based on voluntary cooperation. The participants discussed possibilities to strengthen the security of the telecommunication sector. The building of trust was a central goal of the process. However, it became apparent that effective crisis management could not be achieved solely on a voluntary basis of cooperation. During crisis situations, it is possible that individual operators need to implement actions that run contrary to their interests. This analysis led to the decision to make participation in the public-private partnership mandatory for all operators of critical telecommunication services [31]. Therefore, NACOTEL was dissolved in February 2006 and replaced by the National Continuity Consultation Platform Telecommunications (NCO-T) [32].

***3.2.3 Strategic Board for CIP (SOVI).*** The Strategic Board for CIP (Strategisch Overleg Vitale Infrastructuur, SOVI) was established in September 2006 as a dedicated public-private partnership for critical infrastructure protection. All critical sectors are represented in the strategic board, which meets two or three times a year. In 2007, the SOVI initiated a study on the electric power dependency of the various critical sectors and their resilience and ability to cope with longer duration power outages. It investigated issues such as secondary dependencies (e.g., dependency of various sectors on diesel oil for back-up generators) and the way in which these are prioritized amongst the critical sectors. It also studied the question of which related arrangements already exist or have yet to be made.

***3.2.4 Nationaal Adviescentrum Vitale Infrastructuur (NAVI).*** The Dutch Nationaal Adviescentrum Vitale Infrastructuur (National Advisory Centre Critical Infrastructures,

NAVI) [33] was initiated by the Dutch government as part of the CIP action plan discussed above [34]. In 2006, the Dutch parliament agreed to its business plan for 2006–2009 [35]. NAVI has knowledge and expertise about the security of critical infrastructures and aims to exchange these with the critical sectors, critical sector enterprises, and government agencies. It builds upon its links within the government and critical sectors, such as current information provided by the AIVD and the Dutch National Coordinator for Counterterrorism (NCTb) [36].

NAVI offers various services to its constituency such as support for risk analysis as well as security advice. NAVI's modus operandi is derived from the (physical security aspect) of the UK's Centre for the Protection of National Infrastructure (CPNI). It has established sector-specific information exchanges between critical sectors and government functions. NAVI offers various services such as a front office and advisory function for critical infrastructure enterprises, good practices, and an international contact desk (information and good practices exchange with other nations and the EU). NAVI offers products such as risk analyses and risk methodologies, critical sector-specific threat scenarios, security methodologies, and advice.[9]

***3.2.5 Nationale Infrastructuur ter bestrijding van CyberCrime (NICC).*** The National Infrastructure against Cybercrime (NICC) was established in 2006 as a three year program [37]. The NICC infrastructure consists of several components: a contact point, a reporting unit, trend-watching, monitoring and detection, information distribution, education, warning, development, knowledge sharing, surveillance, prevention, termination, and mitigation. The NICC further strengthens this infrastructure by hosting the Cybercrime Information Exchange, where public and private organizations share sensitive information, and by developing and supporting practical projects and trials that both solve concrete problems and generate knowledge about cybercrime.

The Cybercrime Information Exchange information-sharing model is based on the one designed by the UK's Centre for the Protection of National Infrastructure (CPNI). The NICC Information Exchange function can be pictured as following a 'flower' model. The heart of the flower is made up of government bodies, like the police, intelligence services, GOVCERT.NL, and the NICC itself. Critical infrastructure sectors and some other major industrial communities that heavily rely upon ICT can be thought of as being the petals of the flower. The different sectors chair their own petal, decide which parts of the meeting can be attended by the government bodies, and decide which information is sharable outside their sector 'petal'. The confidentiality of their exchanged information is maintained by an agreed set of rules on dissemination that follow the Traffic Light Protocol.

Many of the recognized information infrastructure sectors take part in a 'petal': The financial sector; providers of drinking water, energy, and telecommunication; Schiphol Airport; Rotterdam harbor; large enterprises/multi-nationals; and the rail sector.

One of the 2007 activities was the analysis of the information security posture of the SCADA and other process control systems in the Dutch drinking water sector. As a result, a SCADA security good practices document has been developed [38].

It is expected that the NICC will receive new instructions in a successor program from mid-2009. The information exchanges will either continue under another public-private partnership entity or be merged with the NAVI activities that are oriented more towards physical security.[10]

[9]Information provided by an expert.
[10]Information provided by the country expert.

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 SURFCERT (part of SURFnet)

SURFCERT, formerly known as CERT-NL, is the Computer Emergency Response Team of SURFnet, the internet provider for institutes of higher education and for many research organizations in the Netherlands. SURFCERT handles all computer security incidents involving SURFnet customers, either as victims or as suspects. SURFCERT also disseminates security-related information to SURFnet customers on a structural basis (e.g., by distributing security advisories) as well as on an incidental basis (distributing information during disasters) [39].

## 5 GOVCERT.NL

A computer emergency response team for government departments (CERT-RO) was established in June 2002. In February 2003, it was renamed GOVCERT.NL [40]. It is operated under the responsibility of the Ministry of the Interior and Kingdom Relations (MoI). The GOVCERT.NL team is co-located and co-operates with Waarschuwingsdienst.nl (Alert Service) [41], a website and initiative provided by the Ministry of Economic Affairs/Directorate-General for Energy and Telecom (EZ/DGET). The Waarschuwingsdienst is responsible for issuing alerts and advice memoranda to the public and SMEs about viruses, Trojan codes, and other malicious software. Warnings are disseminated to the public via e-mail, web services, and SMS. The Waarschuwingsdienst was founded in early 2003 and is funded by the Ministry of Economic Affairs.

## 6 LAW AND LEGISLATION

### 6.1 Penal Code

The Penal Code prohibits attacks against (non-ICT) CI (e.g., sabotage and interference with water management systems, electricity, the railway network, etc.).

### 6.2 Computer Crime Laws

The second version of the Dutch computer crime law has been under development since 1999. It was delayed because of the need to adapt it to the European Cybercrime Convention, and several anti-terror measures have been included in this new national law. The Computer Crime Law II was introduced in September 2006, with some articles taking effect from September 2007 onwards [42].

### 6.3 Telecommunications Law

This law states the requirements that must be met by public telecommunication operators regarding the capacity, quality, and other properties of the services offered (e.g., free access to the 112 emergency number), as well as regulations with respect to safety and privacy precautions regarding their network and services.

### 6.4 Criminal Code, Articles 138a and 138b

In summary, Article 138a states that any person who intentionally and unlawfully accesses an automated system for the storage or processing of data, or part of such a system, is guilty of a breach of computer peace and shall be liable to a term of imprisonment not exceeding six months or a related fine [43] if they breach security by technical intervention with the help of false signals or a false key, or by acting in a false capacity.[10]

An unauthorized person penetrating an automated system who copies the contained, processed, or transferred information for their own use or use by a third party may be punished with a maximum of four years imprisonment. The same holds for someone using public telecommunications means for accessing an automated system with the purpose of own gain or gain of a third party or for unauthorized access to an automated system of a third party.

In summary, Article 138b states that whoever deliberately and without authorization disrupts an automated system by sending information to that system shall be punishable with no more than one year's imprisonment.

The penal aspects of disrupting various critical infrastructure services have been described in specific articles of penal law for electric power, railway systems, and water management, and are covered by a cybercrime law article that raises the penalties when the safety or even the lives of people are threatened, or when people are actually injured or die.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Eric Luiijf of TNO Defense, Security and Safety, and Williët Brouwer and André Griffioen of Ministry of the Interior, who validated the content of this chapter.

# NEW ZEALAND*

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

Critical information infrastructure protection (CIIP) in New Zealand is about the protection of infrastructure necessary to provide critical services. "Critical services are those whose interruption would have a serious adverse effect on New Zealand as a whole or on a large proportion of the population, and which would require immediate reinstatement" [1]. New Zealand's critical sectors comprise the assets and systems required for the maintenance of [1]:

*The Country Survey of New Zealand 2006 was reviewed by Richard Byfield and Mike Harmon, Centre for Critical Infrastructure Protection (CCIP). For this edition, the authors have thoroughly updated the New Zealand country survey by referring to open-source material.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

- Emergency Services,
- Energy (including Electricity Generation and Distribution, and the Distribution of Oil and Gas),
- Finance and Banking,
- Governance (including Law and Order and National and Economic Security),
- Telecommunications and the Internet,
- Transport (including Air, Land, and Sea).

The various critical sectors depend on each other. Most systems assume the continuity of power and telecommunications infrastructures and make extensive use of networked information technology in their management and control systems.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

The New Zealand government's Defence Policy Framework is a crucial document illustrating that CIIP is a key objective of the country's overall security policy. The Centre for Critical Infrastructure Protection (CCIP) [2] addresses the cyber-threat aspects of that objective.

### 2.1 CIIP within the Defence Policy Framework

New Zealand's government promotes a comprehensive approach to security and aims to protect and maintain the country's physical, economic, social, and cultural security. In the government's Defence Policy Framework of June 2000, critical infrastructure protection is identified as one of the key objectives: "[ . . . ] to defend New Zealand and to protect its people, land, territorial waters, Exclusive Economic Zone, natural resources and critical infrastructure" [3].

### 2.2 Report on Protecting New Zealand's Infrastructure from Cyber-Threats

New Zealand's State Services Commission's e-Government Unit released the report Protecting New Zealand's Infrastructure from Cyber-Threats [4] on 8 December 2000. The report deals with the protection of New Zealand's critical infrastructure from cyber-crime and other IT-based threats. The report assessed levels of risk due to IT-based threats in finance and banking, transport, electric power, telecommunications and the internet, oil and gas, water, and critical state services that support national safety, security, and income [5]. The report made several recommendations such as [6]:

- The establishment of a New-Zealand-based security-monitoring and incident-handling organization;
- Harmonization of computer-crime legislation with that of other nations (e.g., Australia, the US, Britain, and Canada);
- Adoption of specific IT security standards;
- Establishment of an ongoing cooperation program between owners of critical infrastructure and the government.

### 2.3 Report Towards a Centre for Critical Infrastructure Protection (CCIP)

The Centre for Critical Infrastructure Protection was established in February 2001. The process of the center's development is traceable within the documents addressed below [7]. On 11 June 2001, the report Towards a Centre for Critical Infrastructure Protection (CCIP) was issued by the e-Government Unit [8]. Following the previous National Information Infrastructure Protection (NIIP) report of December 2000, it recommended that the government establish a centre for critical infrastructure protection. The argument was that the dependence of citizens and businesses on various infrastructure services, the vulnerability of IT systems, and the risks and possible damage caused in case of failure were increasing. Therefore, measures had to be taken to ensure that infrastructure operators and government agencies were kept up to date on vulnerability and threat information: "The CCIP is proposed as an insurance measure in that it mitigates, for a low cost, a risk of a large loss" [9].[1]

### 2.4 Manual on Security in the Government Sector

The Interdepartmental Committee on Security issued a comprehensive and detailed manual in 2002 called Security in the Government Sector [10], which took into account the Australian/New Zealand Standard AS/NZS ISO/IEC 17799:2001 Information Technology—Code of Practice for Information Security Management, which deals with possible sources of threats to information and ways to counter them. The manual's security guidelines are mandatory for government departments, ministerial offices, the New Zealand Police, the New Zealand Defence Force, the New Zealand Security Intelligence Service, and the Government Communications Security Bureau (GCSB). In the manual, the government requires that information important to its functions, its official resources, and its classified equipment be adequately safeguarded to protect the public and national interests and to preserve personal privacy.

Furthermore, the manual proposes that overall responsibility for security should rest with a manager, the designated Departmental Security Officer (DSO). That person's duties should include formulating and implementing the general security policy and common minimum standards within the organization, issuing instructions on security, and serving as liaison with the secretary of the Interdepartmental Committee on Security (ICS), the New Zealand Security Intelligence Service (NZSIS), and the GCSB for any special advice [11].

### 2.5 Security Policy and Guidance Website

The security policy and guidance website [12] provides information on the government's activities in the area of information security. This website acts as a focal point for the publication of government information about security standards, procedures, and resources.

### 2.6 Standards New Zealand (SNZ)

Standards New Zealand (SNZ) [13] promotes several standards specific to New Zealand, as well as a host of joint Australian/New Zealand and international standards. AS/NZS ISO/IEC 17799 Information Security Management provides an overview of factors to be considered and included in the protection of information and information systems.

[1]For more information about the CCIP, see the chapter on Organizational Overview.

## 3 ORGANIZATIONAL OVERVIEW

Among the public agencies concerned and involved with CIIP in New Zealand are the Domestic and External Security Group (DESG), the Officials Committee for Domestic and External Security Co-ordination (ODESC), the Interdepartmental Committee on Security (ICS), the Centre for Critical Infrastructure Protection (CCIP), the Government Communications Security Bureau (GCSB), and the e-Government Programme.

As public-private partnerships, the New Zealand Security Association (NZSA) tries to engage representatives of both sectors in a dialog, as does the Computer Society Special Interest Group on Security (NZCS SigSec).

### 3.1 Public Agencies

***3.1.1 The Domestic and External Security Group (DESG).*** The main actor in charge of formulating New Zealand's security policy, including CIIP, is the Domestic and External Security Group (DESG), which co-ordinates central government activities aimed at protecting New Zealand's internal and external security, including intelligence, counter-terrorism preparedness, emergency and crisis management, and defense operations. The DESG director provides timely advice to the prime minister on issues affecting the security of New Zealand, including policy, legislative, operational, and budgetary aspects. DESG is the support secretariat for the Officials Committee for Domestic and External Security Co-ordination [14].

***3.1.2 Officials Committee for Domestic and External Security Co-ordination (ODESC).*** The Officials Committee for Domestic and External Security Co-ordination (ODESC) is chaired by the prime minister and makes high-level policy decisions on security and intelligence matters, including policy oversight in the areas of intelligence and security, terrorism, maritime security, and emergency preparedness. ODESC comprises chief executives from the Ministry of Foreign Affairs and Trade, the Ministry of Defence and the Defence Force, the New Zealand Security Intelligence Service, the Government Communications Security Bureau, the police, the Ministry of Civil Defence and Emergency Management, the Treasury, and others when necessary [14].

***3.1.3 Interdepartmental Committee on Security (ICS).*** The Interdepartmental Committee on Security (ICS) [12] is a sub-committee of the Officials Committee for Domestic and External Security Co-ordination (ODESC). It formulates and coordinates the application of all aspects of security policy and sets common minimum standards of security and protection that all government organizations must follow. In addition, the ICS provides detailed advice on information security matters to government and other organizations or bodies that receive or hold classified information [15].

***3.1.4 Centre for Critical Infrastructure Protection (CCIP).*** The Centre for Critical Infrastructure Protection (CCIP) [2] was established in 2001 to provide advice and support to public and private owners of CI, in order to protect New Zealand's critical infrastructure from cyber-threats.

In the early stages of CCIP planning, the location of the new center was constrained by the need to give private-sector companies the confidence that their sensitive commercial and security information would be adequately safeguarded, as well as by the need to provide a secure environment to provide adequate protection for intelligence information

that the CCIP had to be able to access. It was stated that "Overseas experience shows that the center should not be part of a law-enforcement agency, since this might reasonably focus on the pursuit of offenders, to the detriment of rectifying damage and of confidentiality" [16].

The Government Communications Security Bureau was finally given the responsibility for this effort, based on cost-effectiveness as well as its significant IT security skills and its culture of security [16, 17]. Furthermore, the e-Government Unit acknowledged that the CCIP requires timely access to classified intelligence, among other sources, in order to provide the best chance of a successful threat warning [18].

Hence, the CCIP is located within the Government Communications Security Bureau and has three main tasks [19]:

- To provide a round-the-clock watch and warning advice to owners and operators of critical infrastructure and to the government;
- To investigate and analyze cyber-attacks against critical national infrastructure; and
- To work with national and international critical infrastructure agencies to improve awareness and understanding of cyber-security in New Zealand.

Whereas the CCIP provides coordination, support, and advice on the ways in which information security can be maintained and improved, owners of critical infrastructures in the public and private sectors remain responsible for the security of their own systems [20].

***3.1.5 Government Communications Security Bureau (GCSB).*** In 1977, the Combined Signals Organization was replaced by the current signals intelligence agency, the GCSB, which is a civilian organization. Its chief executive reports directly to the prime minister. The GCSB gives advice and assistance to New Zealand government departments and agencies concerning the security of information-processing systems [21].

One of the GCSB's tasks is to ensure the integrity, availability, and confidentiality of official information through the provision of Information Assurance (IA) services to departments and agencies of the New Zealand government, and to contribute to the protection of the critical infrastructure from IT threats [22]. The New Zealand Security of Information Technology (NZSIT) publications are therefore produced as guidelines for New Zealand government organizations in support of securing and protecting IT systems and associated information and services [23].

***3.1.6 e-Government Programme.*** The e-Government Unit [24] was established in July 2000 within the State Services Commission (a department of the New Zealand Public Service). The responsibilities of the e-Government Unit, as defined by the cabinet, included, first, the development of an overarching e-government strategy; second, to facilitate the uptake of the e-government vision by government agencies; third, to coordinate collaboration in identifying opportunities across government agencies; fourth, the unit is responsible for providing policy advice to the minister of State Services in relation to e-government; and finally, it is in charge of monitoring progress toward achieving the e-government vision [25]. In April 2001, the work of the new unit resulted in the publication by the government of New Zealand's first e-government strategy. The strategy was updated in December 2001, in June 2003, and most recently, in November 2006. The latest version, called Enabling Transformation, reflects changes in the IT environment. The strategy paper covers the following areas [26]:

- It clarifies what the goal of transformation means for service delivery and collaboration;
- It matches the measurement of success to the indicators for the development goals for state services;
- It confirms the key role of collaboration, standards, and interoperability;
- It provides an updated high-level outline of the work undertaken across the government;
- It establishes a new goal for the way in which the government uses technology by 2020.

### 3.2 Public-Private Partnerships

***3.2.1 New Zealand Security Association (NZSA).*** The New Zealand Security Association (NZSA) [27] was formed in 1972. It represents licensed and certificated persons providing services to government departments, state-owned enterprises, businesses, and private users. The NZSA has two member groups: Corporate members, who are individuals or companies engaged in the security industry, and associate members, who are individuals or companies involved or interested in security, although security is not at the core of their business operations. Members of the latter category include government departments, insurance companies, airlines, banks, food distributors, area health boards, oil companies, etc. [28]. Among the NZSA's main objectives are [29]:

- To set minimum operating standards for members, and to develop and approve codes of practice;
- To co-operate with the police, government departments, and other organizations and agencies concerned with the safekeeping of people, property, and information in New Zealand;
- To provide information and advisory services, education, and training.

***3.2.2 Computer Society Special Interest Group on Security (NZCS SigSec).*** The New Zealand Computer Society's Special Interest Group on Security (NZCS SigSec) [30] is a forum for networking with others with an interest in IT security from within and outside government. The group meets quarterly for a presentation and networking [31].

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 AusCERT

AusCERT[2] is the national Computer Emergency Response Team for Australia. It also provides significant support to New Zealand organizations. It is one of the leading CERTs in the Asia/Pacific region; it provides prevention, response, and mitigation strategies for members [32].

AusCERT was founded as a commercial CERT for Australia before the New Zealand Centre for Critical Infrastructure Protection (CCIP) was formed. The CCIP has a working relationship with AusCERT, but also provides an early-warning service and a moderated mailing list through its website. Moreover, CCIP Vulnerability Alerts are posted daily

[2]See also the Country Survey on Australia in this volume.

on the CCIP website and contain a summary of a vulnerability or patch deemed important by its operations center for general public release [33].

Several commercial organizations—including the New Zealand company Co-logic—also provide vulnerability alerts filtered and tailored for their customers [34].

## 5 LAW AND LEGISLATION

### 5.1 Crimes Amendment Act 2003: Crime Involving Computers

The Crimes Amendment Act came into force in October 2003. It includes four new offenses relating to the misuse of computers and computer systems. These offenses are:

- Accessing a computer system for a dishonest purpose (Section 249);
- Damaging or interfering with a computer system (Section 250);
- Making, selling, or distributing or possessing software for committing a crime (Section 251);
- Accessing a computer system without authorization (Section 252).The terms "access" and "computer system" are defined in Section 248.

The first two offenses carry a range of penalties depending on the seriousness of the offense, with a maximum of seven and ten years' imprisonment respectively, while the remaining offenses carry a maximum penalty of two years' imprisonment.

The Section 249 offense involves accessing a computer system directly or indirectly, either to obtain a benefit for oneself or to cause loss to another person, or with intent to do so. The essential element of the crime in either case is dishonesty or deception (which is separately defined in Section 240(2)).

The Section 250 offense involves intentional or reckless destruction, damage, or alteration of a computer system. In the most serious case, if this is done by a person who knows or ought to know that danger to life is likely to result, the section provides a maximum penalty of ten years' imprisonment. In cases where a person damages, deletes, modifies, or otherwise interferes with or impairs any data or software without authorization, or causes a computer system to either fail or deny service to any authorized users, the maximum penalty is seven years' imprisonment.

The key element of the Section 251 "sale, supply, or distribution" offense is that the person must either know that a crime is to be committed, or must promote the software in question as being useful for the commission of a crime, knowing that or being reckless as to whether it will be used for such a purpose. In the case of the "possession" offense, the key element is intention to commit a crime.

In practice, the more significant of these two offenses is likely to be Section 252, which in effect makes computer "hacking" a criminal offense. The offense is simple unauthorized access, whether direct or indirect, to a computer system, knowing that or being reckless as to whether one is unauthorized to access that computer system.

Sections 253 and 254 contain qualified exemptions in respect of the Section 252 offense for the New Zealand Security Intelligence Service and the Government Communications Security Bureau respectively, where those organizations are acting under the authority of (in the case of the NZSIS) an interception warrant or (in the case of the GCSB) a computer access authorization issued under Section 19 of the GCSB Act 2003 [35].

## 1 CRITICAL SECTORS

In April 2006, the Commission for the Protection of Critical Infrastructures in Norway submitted a report to the Ministry of Justice and the Police that defined the critical infrastructures of Norway as follows: "Critical infrastructures are those constructions and systems that are essential in order to uphold society's critical functions, which in

*The country survey of Norway was reviewed by Stein Henriksen, Norwegian National Security Authority; Håkon Styri, Norwegian Post and Telecommunications Authority; Einar Oftedal, Norwegian National Security Authority; and Lene Bogen Kaland, Norwegian National Security Authority and National Information Security Coordination Council.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

time safeguard society's basic needs and the feeling of safety and security in the general public" [1].

Based on this definition, the commission identified the critical sectors, distinguishing between critical infrastructures and critical societal functions. A societal function is critical when it is indispensable for covering society's basic needs. These "critical societal functions" are themselves dependent on different infrastructures, some of which are deemed to be critical. The criticality of infrastructures is assessed according to three criteria: dependency (a high degree of dependency on other infrastructures implies criticality), alternatives (few or no alternatives imply criticality), and tight coupling (a high degree of linkages to other infrastructures implies criticality).

Using these criteria, the commission identified the following critical infrastructures:

- Electrical Power,
- Electronic Communication,
- Water Supply and Sewage,
- Transport,
- Oil and Gas,
- Satellite-based Infrastructure [2].

These critical infrastructures provide the basis for the following critical societal functions:

- Banking and Finance,
- Food Supply,
- Health Services, Social Services, and Social Security,
- Police Services,
- Emergency and Rescue Services,
- Crisis Management,
- Parliament and Government,
- Judiciary,
- Defense,
- Environment Surveillance,
- Waste Treatment [2].

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

Over the past few years, and as a result of technological developments, there has been an increased focus on CIIP. CIIP has been regarded as a security issue in Norway since the end of the 1990s. In fact, CIIP was placed on the political agenda by the government commission on "A Vulnerable Society". Moreover, US policy has been an important trigger in putting CIIP on the political agenda in Norway as a political, security, and economic issue.[1]

[1]Information provided by an expert.

### 2.1 Policy Statements

In 1998, the State Secretary Committee for ICT [3] formed a subcommittee with a mandate to report on the status of ICT vulnerability efforts in Norway. Furthermore, the importance of CIIP is also stressed by the Defense Review 2000 and the Defense Policy Commission 2000.[1] In the aftermath of attacks in the US on 11 September 2001, the government considered it necessary to increase national safety and security, particularly within civil defense, in the Police Security Service, and in emergency planning within the health sector [4].

### 2.2 Report A Vulnerable Society

The governmental commission on A Vulnerable Society was established by royal decree on 3 September 1999. It was active from 1999 until 2000. The findings gave important input to the national planning process.[1] The commission's task was to study vulnerabilities in society with a broad perspective. The mandate was to assess the strengths and weaknesses of current emergency planning, to assess priorities and tasks, and to facilitate increased awareness, knowledge, and debate about vulnerabilities.

The government commission identified several focus areas. One of these was CI [5]. In its green paper A Vulnerable Society [6], the commission placed great emphasis on the significance of ICT for the vulnerability of society in general. The commission, in what was probably its most controversial proposal, recommended that responsibility for safety, security, and emergency planning should be concentrated in a single ministry [6]. Furthermore, a strategy based on the following pillars was proposed [6]:

- Partnership between the public and private sectors;
- Promotion of information exchange,
- Establishment of an early-warning capacity,
- Harmonization and adjustments of laws and regulations,
- Public responsibility for CIP.

### 2.3 ICT Vulnerability Project

The ICT Vulnerability Project was an interdepartmental group commissioned by the Ministry of Trade and Industry in 1999. The project collaborated with the government commission on A Vulnerable Society, and the two groups coordinated their findings on ICT vulnerabilities [7]. In the ICT Vulnerability Project, each sector authority evaluated the risks linked to specific functions in that sector. A common feature of these evaluations is that each individual sector operation is dependent on its own ICT user systems as well as on the public telecommunications services. Therefore, robust access to telecommunications seems to be very important to most sectors. The telecommunications services are dependent on ICT. This project resulted in the publication of the National Strategy for Information Security in 2003.

### 2.4 Safety and Security of Society

On 5 April 2002, the Ministry of Justice and the Police presented its 17$^{th}$ report on the Safety and Security of Society to the Norwegian Storting (parliament). The report

is a comprehensive statement of the government's proposals regarding the reduction of vulnerabilities in modern society and measures to increase safety and security in the future. It states that when assessing the vulnerability of society, it is important to "consider the consequences of lapses in CI, such as a lapse in the distribution of power or a lapse in telecommunication" [8]. The recommendations laid the basis for new government measures, including most importantly the formation of the new Directorate for Civil Protection and Emergency Planning (DSB) in 2003 [9].

### 2.5 National Guidelines to Strengthen Information Security, 2007–2010

The Norwegian government published a national strategy for securing ICT systems in Norway in June 2003 [10].[2] The strategy involved all aspects of ICT security, ranging from security for individuals, businesses, and the daily activities of the government to the security of IT-dependent critical infrastructure. As a result of the recommendations of the strategy, the NorCERT, NorSIS, and KIS organizations were established (for more information on these organizations, see below in the chapters on Organizational Overview and Early Warning and Public Outreach). In 2007, this was supplanted by the National Guidelines to Strengthen Information Security, 2007–2010.

These guidelines state three overriding targets for the work in the field of information security:

- Resilient and secure critical infrastructures and support systems for critical societal functions;
- A good security culture guiding the development and use of information systems and sharing of electronic information;
- High competence and a focus on research about information security.

Based on these three targets and on present security challenges, 11 objectives have been identified that will form the basis of concrete measures by the National Information Security Coordination Council (KIS):

- Increased protection of ICT infrastructures critical to society;
- Review of legislation for information security;
- Categorization of information and information systems;
- Implementing risk and vulnerability analyses;
- Awareness-raising and sharing of knowledge;
- Rapid and coordinated warning and incident management;
- Promoting use of standards and certifications;
- Increasing focus on R&D, education, and development of competencies in the area of information security;
- Establishing a coordinated scheme for identity management;
- Coordinating and developing Norwegian international participation;
- Continued development of the National Information Security Coordination Council [10].[2]

[2]This strategy proposed several initiatives for improving security based on the "OECD Guidelines for the Security of Information Systems and Networks".

### 2.6 Report on the Protection of Critical Infrastructures and Critical Societal Functions in Norway

This report was issued in April 2006 by the Commission for the Protection of Critical Infrastructure for the attention of the Ministry of Justice and Police and represents the most recent analysis of CIP and CIIP in Norway. It is a comprehensive assessment on how critical infrastructures and critical societal function are protected in Norway and analyzes the impact of recent evolvements (emergence of new threats, shifts in the ownership of infrastructures, reorganizations within the government) on CIP and CIIP.

As mentioned above, the report starts by defining critical sectors and critical societal functions and clarifies the concepts of threats, risks, vulnerabilities, prevention, etc. Furthermore, it provides an overview on the situation in all critical sectors and functions [11].

The report also contains various recommendations to improve the protection of critical infrastructures. The commission highlights the importance of coordinating the various CIIP efforts and recommends that the Ministry of Justice and Police assume leadership with regard to this task [12].

### 2.7 An Information Society for All

The report "An Information Society for All" was issued in December 2006 by the Ministry of Government Administration and Reform. The purpose of the report is to show the state of affairs in the ICT sector, and to invite debate on challenges and the way ahead. Chapter 9, dealing with ICT security, describes a number of security measures necessary to achieve secure ICT infrastructures. The report also clarifies responsibilities among several ministries—both in relation to preventive security work and responsibilities during a crisis [13].

## 3 ORGANIZATIONAL OVERVIEW

In Norway, the ministry or authority that has responsibility for an area during peacetime or non-crisis times also has responsibility during times of crisis and war. This system also applies to CIIP. The coordinating authority on the civilian side is the Ministry of Justice and Police. The overall authority for ICT security is the Ministry of Government Administration and Reform, which took over this task from the Ministry of Trade and Industry, while the Ministry of Defense is responsible on the military side. The Ministry of Transport and Communications has responsibility for the communication sector in Norway, including all related security issues. The directorates and authorities that are responsible for handling the various aspects of CIIP on behalf of the ministries are answerable to the respective ministries [14].

In order to promote public-private partnerships, the National Information Security Coordination Council (KIS) cooperates with the private sector.

### 3.1 Public Agencies

***3.1.1 Directorate for Civil Protection and Emergency Planning (DSB).*** The Directorate for Civil Protection and Emergency Planning (DSB) was established on 1 September 2003, replacing the former Directorate for Civil Defense and Emergency Planning and the Directorate for Fire and Electrical Safety. The DSB is subordinate to the Ministry

of Justice and Police, and its main task is to serve as a center of resources and expertise for emergency contingency planning. The DSB is a point of contact between the central authorities and regional commissioners during disasters occurring in peacetime.

To ensure adequate preparedness measures in the community, the DSB devotes considerable efforts to ensure that all Norwegian municipalities carry out risk and vulnerability analyses. The DSB works to ensure that activities involving preparedness responsibilities lead to the implementation of internal control systems to ensure the quality of emergency planning at local government level. The DSB also supervises the planning efforts in the ministries and offices of the regional commissioners. In the context of CIIP, the DSB coordinates and carries out research on vulnerabilities and the protection of critical assets in cooperation with other actors [9].

***3.1.2 Norwegian National Security Authority (NSM).*** The Norwegian National Security Authority (NSM) [15] was established on 1 January 2003 and coordinates preventive IT-security measures. It controls the level of security, e.g., of central and local public administration, and monitors private suppliers of goods and services to the public when the products or services concerned are security-sensitive. The NSM also develops technical and administrative security measures and issues threat evaluations and vulnerability reports. The Ministry of Defense funds and administers the NSM. Moreover,

- The NSM hosts SERTIT [16], the public Certification Authority for IT Security in Norway.
- The NSM operates NorCERT (see chapter on Early Warning and Public Outreach).

***3.1.3 Norwegian Post and Telecommunications Authority (NPT).*** The Norwegian Post and Telecommunications Authority (NPT) [17] is an autonomous administrative agency under the Norwegian Ministry of Transport and Communications, with monitoring and regulatory responsibilities for the postal and electronic communications markets in Norway. The NPT is responsible for contingency planning regarding the public electronic communications infrastructure.

***3.1.4 The National Information Security Coordination Council (KIS).*** The National Information Security Coordination Council (KIS) was established in May 2004 [18]. It is chaired by the Ministry of Government Administration and Reform and consists of representatives from six ministries, the Prime Minister's Office, and ten different directorates. KIS has no authority to make decisions, but provides a platform for discussions and advises ministries and government agencies in topics related to ICT security, national security (interests), critical information infrastructure, common standards, working methods for ICT security, risks, and vulnerabilities.

KIS will have a central role in the implementation of the national guidelines to strengthen information security by [18]:

- Keeping track of the implementation of measures in different areas of responsibility;
- Identifying cross-sectoral challenges in information assurance that have to be followed up;
- Pushing for the implementation of measures of a cross-sectoral nature.

The KIS will be in close dialog with the private sector, local government, and others that may be impacted by the guidelines during the implementation of measures.

### 3.2 Public-Private Partnerships

In reaction to the report A Vulnerable Society, public-private initiatives have been established to enhance early-warning capabilities, e.g., NorCERT and NorSIS. In addition, there are sectoral co-operation bodies within sectors such as electric power, finance, oil, and telecommunications. KIS co-operates with the private sector in the further development of the guidelines. Representatives of the private sector are invited to participate in working groups when required.

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 NorCERT

The Norwegian Computer Emergency Response Team (NorCERT) was formally established in January 2006 as an operational department of the NSM and is the national CERT for Norway. NorCERT consists of two integrated sections [19]:

- The Warning System for Digital Infrastructure (VDI) was established in 2000 by the government. VDI intended to enable security professionals to chart the extent of the threat to vulnerable information infrastructure through the use of a national monitoring system to collect data on emerging threats. Since 2006, VDI has been an integrated part of NorCERT.
- The Incident Handling Section is responsible for incident handling and coordination, including vulnerability handling and artifact handling.
- Together, these two sections manage the Operation Center, where they maintain an up-to-date view of current cyber-threats and day-to-day operational matters.

Apart from early warning and incident-handling, NorCERT also serves as a point of contact for similar organizations abroad and shares information with other response teams regarding emerging threats.

### 4.2 UNINETT CERT

The Computer Emergency Response Team of the UNINETT (the academic research network) [20] was already formed in 1995. Its constituency consists of the Norwegian state universities, colleges, and research and development institutions. The team was created to contribute to better internet security for UNINETT member institutions, and to serve as a focal point for security issues regarding UNINETT member institutions [21]. The basic duty of UNINETT CERT is to provide assistance on handling and investigating incidents involving one or more members of the constituency, but it also collaborates with NorCERT to improve overall information security [21].

### 4.3 Norwegian Center for Information Security (NorSIS)

The aim of the Norwegian Center for Information Security (NorSIS) is to improve the overall level of information security in Norway. Its primary target groups are SMEs and the public authorities. NorSIS engages in the following activities:

- Making the public aware of the importance of information security by means of training and information;

- Compiling guidelines and tutorials for users;
- Establishing an overall awareness towards information security.

The NorSIS has its own web page [22] offering news, advice, and guidance. In addition, the NorSIS helps to disseminate information during serious incidents.

### 4.4 Norwegian Post and Telecommunications Authority

The Norwegian Post and Telecommunications Authority (NPT) has responsibility for contingency planning related to the public telecommunications infrastructure. Its area of responsibility includes the following tasks:

- Considering investment in measures designed to increase the robustness of the telecom networks;
- Conducting inspections to see that the required measures are implemented;
- Creating awareness, improving expertise, and offering guidance to operators, users and other players (courses, seminars, company visits, establishment of forums of expertise, etc.);
- Arranging joint exercises and developing cooperation between the operators of telecom networks.

Electronic communications providers who provide essential electronic communications services to users who have socially critical functions must notify the NPT of significant operational and technical problems that could reduce or have reduced the quality of services.

The establishment of the nettvett.no portal [23] in April 2005 is one example of the NPT's instructional undertakings within the security area. This portal provides information about the secure use of the internet.

## 5 LAW AND LEGISLATION

There are a number of regulations concerning information assurance and critical infrastructures, distributing responsibility onto several bodies. The most pertinent and overriding regulations concerning CIIP in Norway are:

- *The Security Act.* [24] This act applies to the protection of objects and information from incidents threatening security.
- *The Electronic Communications Act.* [25] This act applies to activity connected to the transmission of electronic communications and the associated infrastructure, services, equipment, and installations.
- *Personal Data Act.* [26] This act applies to the processing of personal data wholly or partly by automatic means, and other processing of personal data that is part of or intended to form part of a personal data filing system.

In addition to these, there are sector-specific regulations. Most Norwegian public and private bodies are subject to relevant regulations issues by various authorities. The national guidelines to strengthen information security will, inter alia, focus on making regulations about information assurance more consistent and user-friendly.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Stein Henriksen of the Norwegian National Security Authority, Håkon Styri of the Norwegian Post and Telecommunications Authority, Einar Oftedal of the Norwegian National Security Authority, and Lene Bogen Kaland of the Norwegian National Security Authority and National Information Security Coordination Council, who validated the content of this chapter.

# POLAND*

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

According to expert opinion, Poland perceives those physical and cyber-based systems as critical infrastructures that are essential to the minimum required operations of the economy and the government. They include the following sectors:

- Telecommunications,
- Energy,

*The Country Survey of Poland was reviewed by Tomasz Prz1da, Polish Internal Security Agency, Micha3 M3otek, Polish Ministry of Interior and Administration, and Miros3aw Maj and Krzysztof Silicki, NASK/CERT Polska, Poland.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

- Banking and Finance,
- Transportation,
- Chemical Industry,
- Water and Sewage Systems,
- Private and governmental emergency services [1].

In the same expert document, information and communications systems are more specifically defined as key assets within the overall realm of critical infrastructures. Therefore, among other things, it is recommended that the control systems be enhanced and prioritization plans be developed for ensuring cybersecurity.

## 2 INITIATIVES AND POLICY

It was officially acknowledged in Poland in 2000 that access to information has become increasingly significant for the economy and social life, and therefore the Polish government seeks to use means of communication to support the economy and to improve the public standard of living. These government activities were in response to the Polish parliament's resolution of 14 July 2000 on building the foundation of an Information Society in Poland, which underlines that modern technologies, services and applications of telecommunication, communication, and multimedia services may be a catalyst for economic growth, increase the competitiveness of the economy, create jobs, foster the development of the democratic state and its regions, assist in education and health care, and improve access to cultural goods [2]. As a consequence of this acknowledgement, several initiatives have been launched. On the one hand, these initiatives mainly fall into two categories—the development of the Polish Information Society (ePolska) and the application of elements of the Information Society to the public administration (e-government). On the other hand, issues related to the protection and security of information and its infrastructure are addressed exclusively within a single research and development organization, the Polish data networks operator and Research and Academic Computer Network (NASK). The latter are addressed in the early warning and public outreach section of this chapter.

## 3 ePOLAND

In reaction to the above-mentioned parliamentary resolution on building the foundations for a Polish Information Society, the Council of Ministers adopted two relevant documents in 2001: A strategic publications called Aims and Directions of the Information Society Development in Poland and a paper on practical aspects called Action Plan for the Information Society Development in Poland for the years 2001–2006—ePoland [3]. The strategic document had been prepared by the State Committee for Scientific Research in cooperation with the then Ministry of Telecommunications. It set out the following priorities: [4]

- Universal access to information;
- Information technology education;

- Changes in employment structure;
- Law and offences in the information and communications field;
- Electronic documents and commerce;
- Public procurement;
- Information technology implementation in the administration;
- Information and communication technology market development;
- Science and culture.

The Action Plan ePoland, oriented more towards practical applications, followed the European action plan eEurope—an Information Society for All that was issued by the European Commission in May 2000 [5]. The ePoland program [6] deals with a number of issues connected with the implementation of the Information Society, taking into consideration developments and realities in Poland. An absolute precondition for realizing the aims enshrined in the program is broadband, universal, affordable, and safe access to new electronic communication networks. In practical terms, ePoland comprises the following aims: Preparing society for rapid technological changes in the social and economic sphere due to the emergence of the Information Society, education of adults in the area of information technologies, and the promotion of professions connected with the application of these technologies. It foresees the adaptation of the legislative framework to the standards of rapid technological progress and the information age. Moreover, the ePoland action plan is to be compatible with the requirements of the electronic economy. This could be achieved by introducing legal regulation on electronic signatures, electronic transactions means, legal protection of databases, providing universal access to information technology, and electronic commerce. An additional advantage for the development of the Information Society in Poland is identified in the implementation of an electronic procedure in public procurement, facilitating online access to public administration, enhancing the participation of small- and medium-sized enterprises in e-commerce, and the elaboration of models for digital media in Poland.

In 2003, the ePolska action plan was updated in preparation for its adoption on 13 January 2004 by the Council of Ministers. Called ePoland—The Strategy on the Development of the Information Society in Poland for the years 2004–2006, it identifies information technology as a key challenge for Poland and specifies three priorities in order to achieve the goal of becoming a competitive knowledge-based economy and improving the quality of life of citizens: [7]

- Common access to electronic content and services;
- The development of valuable content and services accessible via the internet;
- The ability to use them.

The official projection of the prospects of the Information Society in Poland in the middle range perspective is contained in the document entitled The Proposed Direction of the Information Society Development to the year 2020, which was issued in late 2004. The document focuses on the prioritization of various aspects of public life in the context of Information Society development, and on the problem of ICT infrastructure as a factor shaping the overall framework of development opportunities [8].

### 3.1 E-government

The second pillar of Polish Information Society policies concerns the government's use of ICT and accessibility of government services. One of the government's most important programs for integration of information technology is the summary plan for communications technology development and its application in government administration, drawn up by the Ministry of the Interior and Administration [9]. In July 2003, the government accepted a draft bill on the "informatization of the public administration". The bill creates a legal framework for the monitoring and coordination of the various informatization projects of the public administration and specifically aims at the following: [10]

- To ensure compatibility of public IT systems and registries;
- To establish a legal framework for the development of e-government in Poland;
- To attain budgetary savings thanks to better coordinated spending on IT projects and to shift a number of public services to electronic platforms;
- To enhance the efficiency of the public administration and increase the quality of its services.

The bill empowered what was then the Ministry of Scientific Research and Information Technology (now the Ministry of Science and Higher Education) to audit all public IT systems for their appropriateness and viability and to establish mandatory standards for the exchange of documents and information between various public institutions. Moreover, the bill opens a way for citizens to deliver various public documents electronically.

Common access to e-government services is conditional on providing all citizens with internet access, or at least establishing a network of public internet access points. These projects have not been finished yet. In March 2005, the then Ministry of Science and Information Technology published a statement on "the comparative position of Poland in basic categories of e-government services". Among various services delivered by the public administration via internet, two basic categories can be pointed out based on the target group of the specific service: government to citizen (G2C)—with its reverse (C2G) services—and the second one, government to business (G2B) and reverse (B2G) services. Poland ranks low in the overall European comparison [11].

### 3.2 National Foresight Program

The Polish National Foresight Program was initiated in early 2003 by the then Ministry of Science and Information Technology. It is conceived as a method of building a vision for the medium- and long-term development of scientific and technical policy, its directions, and priorities, and is being implemented at the initiative of the Ministry of Science and Higher Education. An initiatory group of high-ranking experts was responsible for the definition of the foresight areas. The program's scope of realization covers three research areas: sustainable development, security, and information and telecommunications technologies. The latter area is to be coordinated by the Polish Ministry of Science and Higher Education [11] and centers on five major issues:

- Access to information;
- ICT and the society;

- ICT and education;
- e-Business;
- New media.

The foresight program is organized and managed by a coordination consortium, the conceptual work is done by different expert panels, and partnership institutions give scientific and analytical support [12].

## 4 ORGANIZATIONAL OVERVIEW

Within the Polish government, two ministries have responsibilities that impinge upon the country's information infrastructures and their protection—the Ministry of Science and Higher Education and the Ministry of the Interior. As a public-private partnership, the Polish Competence Center for eGov and eEdu [13] strives to provide a platform to bring together the public sector and the IT companies.

### 4.1 Public Agencies

In January 1991, the Parliament of the Republic of Poland passed an act creating the State Committee for Scientific Research (KBN). This governmental body was responsible for the science and technology policy of the state. Following the Council of Ministers' regulation of 18 March 2003, the Committee for Scientific Research was integrated into the newly founded Ministry of Science and Information Society Technologies. For the first time in the history of the Republic of Poland, a governmental body responsible for the country's information technology was created. After the parliamentary elections in 2005, the Ministry of Education and Science was established through the merger of the Ministry of National Education and Sport and the Ministry of Science and Information Technology. In mid-2006, the next reorganization resulted in the creation of the Ministry of Science and Higher Education [14].

***4.1.1 Ministry of Science and Higher Education.*** The main player and the coordinating body for science and technology policies is the Ministry of Science and Higher Education, which is involved in all policies relating to information infrastructures and their protection. Until November 2005, it was called the Ministry of Science and Information Technology. Its responsibilities relating to critical information infrastructures include:

- IT infrastructure, networks, and systems of the public administration;
- The establishment of IT standards for the public administration;
- Supervision and support of IT projects in public, central, and local administrations;
- Education and vocational training in Information Technology standards;
- The development of an Information Society in Poland;
- International cooperation within the IT sector and participation in EU programs [15].

The establishment of this ministry (and of its immediate predecessor) created a single coordinating institution for all state policies on informatization, it advises other ministries and institutions on informatization strategies, and it ensures the compatibility of national public IT systems and the economic viability of new informatization projects. Moreover,

the national foresight program Poland 2020 is also located under the auspices of the Ministry of Science and Higher Education.

***4.1.2 Ministry of the Interior and Administration.*** The Ministry of the Interior and Administration is crucial insofar as it is responsible for the national IT infrastructure, the national teleinformation system, and the national information administrative systems. These responsibilities are handled by the Department of Information Technology Development on the one hand, and through the Department of Teleinformational Infrastructure on the other hand. Both these departments are located at the Undersecretariat of State [16]. The latter is mainly in charge of maintenance of IT systems of the ministry, with particular attention given to security and availability of all processed data. Moreover, its responsibilities include[1]

- Supervision of the teleinformation networks used by government entities for accessing the state registries, planning, developing, and coordination of all IT networks of the ministry;
- Acting as an administrator of the government communication systems, including radio communications and also isolated systems;
- Fulfillment of tasks regarding the Polish Local Domain of the TESTA network and communication center of all the units of the ministry, including supervision and coordination in regard to isolated TESTA SIS/VIS networks;
- Supervision and maintenance of the Public Key Infrastructure (PKI) of the ministry as well as coordination of all tasks regarding digital signatures;
- Building and implementation of a special communication infrastructure for all public security and rescue forces;
- Maintaining continuity of all infrastructure considered essential for the state teleinformation systems and government communication;
- Prevent internal and external threats through securing the above-mentioned infrastructures.

Overall, the Ministry of the Interior and Administration is responsible for digitizing the public administration, developing the Information Society, and protecting it from exploitation of its vulnerabilities.

## 4.2 Public-Private Partnerships

***4.2.1 The Polish Competence Center for eGov and eEdu.*** The Polish Competence Center for eGovernment and eEducation was founded in February 2005 by four partners, including the Fraunhofer Institute for Open Communications FOKUS (Berlin), the Poznan Supercomputing and Networking Center (Poznan), the Foundation for Economic Education (Warsaw), and Witold Sartorius, the designated head and CEO of the center. It is currently run by the Foundation for Economic Education as a consortium and plans to become an incorporated not-for-profit company in Poland. The competence center aims at being an independent and trustworthy platform to bring the public sector, as a potential qualified customer, together with the IT companies to initialize successful and innovative IT projects with additional and significant cost saving and revenues for the partners.

[1]Information provided by an expert.

Therefore, the center supports and coaches partners and public sector clients during the whole process of preparing, organizing, and financing eGov and eEdu projects and brings them to the final implementation stage.

This includes tasks related to technology, organization and re-organization, as well as financial engineering in bigger and smaller projects. The center acquires, checks, tests, shows, and promotes modern IT and software solutions for the public sector and education. It has close links with Polish government bodies at both the ministerial and local levels. Moreover, the center also addresses projects in support of small and medium enterprises. The center's activities are driven by the belief that the strategic planning and realization of cost-effective IT solutions is the key to success for the Polish administration and public sector. Therefore, it aims at bringing the respective relationships to the next level by creating public-private institutional partnerships focused on the promotion of internet business solutions for the local governments. To this end, the competence center cooperates with a variety of programs and initiatives such as, among others, ePolska, the Cisco networking Academy Program, and the Polish education portal Interkl@sa [17].

## 5 EARLY WARNING AND PUBLIC OUTREACH

As mentioned earlier, the concerns of information infrastructure protection in Poland are mainly addressed by one particular organization—the Polish data networks operator NASK.

### 5.1 NASK Polska

NASK connected Poland to the internet in 1991. Since 1993, it has been a research and development organization and the leading Polish data networks operator. It offers telecommunications and data solutions to business, administration, and academic customers. Its service packages comprise broadband internet access, corporate networks, data transmission, collocation and hosting, videoconferencing, and network security services. NASK also carries out scientific and research activities in cooperation with the faculty of electronics and information technology at the Warsaw University of Technology—in particular, its cooperation with the Institute of Control and Computation Engineering led to the establishment of a biometric laboratory—and it is a member of many international organizations and associations including the Forum of Incident Response and Security Teams (FIRST) (see the survey on FIRST in this volume), the Council of European Top Level Domain Registries (CENTR), the Trans-European Research and Education Networking Association (TERENA), and the European IP Networks (Réseaux IP Européens, RIPE). Moreover, NASK is the Polish national registry of internet names in the.pl domain. The Polish Computer Security Response Team (CERT Polska), a part of the NASK organization, is very much engaged in information infrastructure protection and security issues [18].

### 5.2 CERT Polska

The Polish Computer Emergency and Response Team that is now called CERT Polska was formerly known as CERT NASK and was established in March 1996 by the NASK director. Its goals include:

- To provide a single trusted point of contact in Poland for the community of NASK customers and other networks in Poland to deal with network security incidents and their prevention;
- To respond to security incidents in networks connected to NASK and networks connected to other Polish providers reporting security incidents;
- To provide security information and warning of possible attacks in cooperation with other incident response teams all over the world.

The CERT Polska team registers all requests, alerts, and incoming and outgoing information and provides statistical data and reports on registered incidents. It also provides help for sites that have security problems, and supplies current information about security problems and solutions for dealing with them [19]. CERT Polska itself points out that the creation and maintenance of a computer security and incident response team benefits the government in many respects. Four of its areas of activities in particular contribute to critical infrastructure protection: Early warning and alerting, centralized security management, security response, and auditing [20]. CERT Polska signed a cooperation agreement on IT security with the Information Security Department of the Polish Internal Security Agency in July 2004 [21]. It also organizes a highly respected annual conference under the auspices of NASK. The SECURE conference series, organized since 1997, brings together company and IT managers; specialists in information system, network, and database security; and telecommunications and data network users who are interested in security issues. Co-sponsored by ISSE (Information Security Solutions Europe), ENISA (European Network and Information Security Agency) and the Polish Ministry of the Interior and Administration, SECURE is Europe's largest conference on data communications safety [22].

### 5.3 CERT GOV PL

On 1 February 2008, the Internal Security Agency established the government's computer incident response team (CERT GOV PL). Its goals include ensuring and developing the ability of public administration units to defend themselves against cyber-threats, in particular against attacks on the infrastructure consisting of IT systems and networks, the disruption or destruction of which might to a large extent threaten the life and health of people, national heritage, and the environment, or result in considerable financial losses and disrupt the operation of the state.

The goals of the CERT GOV PL include [23]:

- Creating a policy concerning cyber-defense;
- Coordination of the information workflow among the above-mentioned entities with reference to cyber-threats;
- Detection and recognition of, and response to cyber-threats;
- International cooperation concerning cyber defense;
- Playing an oversight role in relation to all national institutions, organizations, and units within governmental departments concerning cyber-defense;

The main objectives of the CERT GOV PL are:

- Collecting information concerning the current security status and threats to the critical IT infrastructure;
- Responding to IT security incidents, in particular the ones concerning the national critical IT infrastructure;
- Post-incident computer forensics;
- Establishing the policy for defense of the cyberspace of the Republic of Poland;
- Training sessions and raising awareness of the topic;
- Consulting and advising with reference to cyber-security.

### 5.4 ARAKIS-Gov

In 2004, ARAKIS-gov, a distributed internet-based early-warning system developed and maintained by CERT Polska (NASK) in cooperation with the Information Security Department of the Polish Internal Security Agency, was accepted as the most important system for ensuring the protection of the Polish critical information infrastructure. The goal formulated for this project is to create a real early-warning system that can detect a new threat, analyze the exploit, and create a description of a new attack.[1] Therefore, data from various sources, such as firewalls, darknets, honeypots, and anti-virus systems are correlated in order to detect emerging threats against the Polish network (also, notably, against governmental institutions), to detect new attack patterns, to monitor differences between attacks observed in Poland and in other countries, to gather statistical data, and to aid in general incident-handling activities. ARAKIS also provides a public dashboard showing a snapshot of network activity observed by the system. In the form of a polar chart, the alerts as generated by the ARAKIS system over the last 24 hours are plotted [24].

### 5.5 PIONIER-CERT

This incident response service entity is responsible for incident-handling in an academic network environment. The main purpose of this initiative is to establish a single point of contact for all security incidents occurring in the constituency of PIONIER, which consists exclusively of Polish academic research institutions [25]. In order to assist system administrators in handling the technical and organizational aspects of incidents, the overall process of incident response is divided into three main stages: incident triage, incident co-ordination, and incident resolution. The incident resolution is performed in a very limited range, and is in fact limited to special cases with a potential significant impact on PIONIER's constituency. The actual range of activities in such cases may cover removing vulnerability, restoring a system that has been compromised, or providing direct technical support while collecting evidence where criminal prosecution or other disciplinary actions are being considered [26].

## 6 LAW AND LEGISLATION

Relevant legislation as concerns the protection of data and information in Poland consists of Articles 267 to 269 of the penal code. These three articles regulate the respective crimes of

- Unauthorized access to information (267);
- Destruction, alteration, deletion, or damaging of information (268);
- Destruction, alteration, deletion, or damaging of information with particular significance for national defense, transport safety, the operations of the government, or other state authority or local governments (269).

These crimes are defined as being of increasing gravity, and the punishments range from two, three, to eight years respectively [27].

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Tomasz Przda of the Polish Internal Security Agency, Michał Młotek of the Polish Ministry of Interior and Administration, and Krzysztof Silicki and Mirosław Maj of NASK/CERT Polska, who validated the content of this chapter.

# RUSSIA

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

During the last few years, Russia has made significant progress in improving its information infrastructure. The national security and economic welfare of the Russian Federation depends to a substantial degree on ensuring information security, a dependence that will increase in future with technological progress.

The information security is determined by the protection of national interests in the information field. The content of those interests can be inferred from the Information Security Doctrine of the Russian Federation and include the state's guarantee of human rights in the information field, IT support of the state policy of the Russian Federation, development of a domestic information industry, and the protection of information and of

information and communication systems in the various areas of public life. The critical sectors subject to critical information infrastructure protection are the following:[1]

- Economy,
- Domestic and Foreign Policy,
- Science and Technology,
- State Information and Communication Systems,
- Defense,
- Justice,
- Disaster Response.

The Information Security Doctrine of the Russian Federation reflects the G8 Okinawa Charter of the Global Information Society [1], which was prepared in the year 2000. However, in the Russian Information Security Doctrine, the specific social and economic circumstances and long-term reforms of the Russian Federation as well as its experience with terrorist attacks were taken into consideration.[1] In Russia, information assurance includes not only (technical) information security, but also the safeguarding of state secrets.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

In 2008, the president of the Russian Federation approved two documents, including Strategy for the Development of Information Society in Russia and Measures for Ensuring the Information Security of the Russian Federation in the Field of Information and Communication Systems use for International Information Exchange.

Earlier, the Russian government had approved the federal program The Development of United Information Environment for Education (2001–2005) (2001), the Concept for the Use of Information Technologies in the Federal State Organizations (2004), a federal program entitled Electronic Russia (2002–2010) (2005), and a federal program entitled National Technological Basics 2007–2011 (2007).[1]

### 2.1 Information Security Doctrine of the Russian Federation

The Information Security Doctrine [2] of the Russian Federation, adopted on 9 September 2000, is an extension of the National Security Concept [3] (approved by the President on 10 January 2000) intended to strengthen state policy regarding information security. Its aim is to help formulate legal, methodological, technical, and organizational provisions for information security in Russia and to assist the development of specific programs for this purpose. The doctrine defines the context of the nation's interests in the information sphere and assesses information threats to citizens, society, and the state. The doctrine is very comprehensive in scope and ranges over many policy areas, from data protection, personal privacy, copyright, and computer misuse (hacking) to state secrets, access to information, and the functioning of the media [4].

Russian information security is defined in the doctrine as "the state of protection of its national interests in the information sphere defined by the totality of balanced interests of

[1]Information provided by an expert.

the individual, society, and the state." Russia views both public opinion and the national information systems as integral parts of its concept of information security [5]. Moreover, the Russian government considers the uncontrolled spread of foreign media in Russia to be a threat to Russian information security and, as a result, intends to "strengthen" the Russian media [6].[2,3]

The doctrine is legally based on Russian federal laws on security, state secrets, the protection of information, and participation in international information exchange. The document is divided into four major chapters, covering 11 sections. The four main chapters are:

- *Information security.* This chapter defines the Russian Federation's national interests in the information sphere, referring to constitutional rights, to IT support for state policy, to the development of the information industry, and to the security of information against unauthorized access. Moreover, internal and external sources of threats to Russia's information security are identified. The doctrine acknowledges frankly that just like private monopolies and organized crime, government policy and legislation can also pose a threat. Aggressive foreign corporations and international terrorists are mentioned as major foreign threats. In the domestic arena, the critical state of the national industry as well as the under-development of the legal framework can constitute a barrier to full exploitation of information technology, particularly where e-commerce is concerned. Finally, the chapter discusses the state of information security in the Russian Federation and objectives for amending it. The deteriorating safety of data constituting state secrets is identified as a major problem;
- *Methods of ensuring information security.* This chapter covers legal, organizational-technical, and economic methods for information security. Moreover, it describes a number of features of information security in various spheres, such as the economy, domestic policy, foreign policy, science and technology, information and telecommunication systems, defense, law enforcement, and emergency situations. Finally, it mentions international cooperation in the field of information security such as banning information warfare, supporting information exchanges, coordinating law enforcement activities, and preventing unsanctioned access to confidential information;
- *The main provisions of the state policy for ensuring information security, and priority measures for implementing it.* This chapter lays out—at a high level of abstraction—the policy of the government, ranging from observing the constitution to supporting the development of new technologies. The chapter suggests provisions for information security, such as developing guidelines for federal institutions. In addition, the document mentions priority measures for implementing the rule of law, an increase in the efficiency of state leadership, programs providing access to information archives, educational measures, and a system for harmonizing standards in the field of computerization and information security are mentioned;

[2]This aspect of Putin's doctrine has been criticized by journalists, who fear restrictions on freedom of opinion and speech.

[3]The Information Security Doctrine claims to protect the interests of the individual, society, and the state in the information sphere. In fact, however, the main focus lies on the government's and society's interests in this field, and the document stresses the possible external threats to information security coming from abroad. Among these, the document mentions the dominance of certain states in the information sphere, foreign policy issues in the economic, military, and intelligence fields, and the exclusion of Russia from the information market by other states.

- *Organizational basis of ensuring information security.* This chapter describes the functions of the system of information security, as well as the organizational elements and actors of Russia's information security system, including the president, the Federation Council of the Federal Assembly, the State Duma of the Federal Assembly, the government of the Russian Federation, the Security Council, and other federal executive authorities, presidential commissions, judiciary institutions, public associations, and citizens.

An area of obvious emphasis is the creation of a legal base for information security. The laws on the Constitution of the Russian Federation, State Secrecy, Information, Computerization, and Information Protection, Participation in International Information Exchange, and Essentials of Legislation of the Russian Federation on the Archive Collection of the Russian Federation and Archives are specifically mentioned. Legal instruments constitute one of three approaches to information security mentioned in the doctrine—the other two being organizational-technical and economic measures. Furthermore, the document stresses the threat of attacks against Russia's information infrastructure and the threat of foreign governments using information warfare techniques against Russia. In addition, special attention is given to the development of telecommunication systems, the integrity of information resources, space-based reconnaissance, and electronic-warfare facilities [7].

## 2.2 Electronic Russia

The idea of Electronic Russia [8] appeared in early 2001, when the Ministry of Economic Development and Trade was elaborating a strategic development plan for Russia up to the year 2010. The program is based on the notion that in order to reduce the country's economic lag, it is necessary to develop the hi-tech sector, where it would be possible to reach a higher productivity level than in the raw-materials sector. None of this would be possible without computers and powerful ICT [9].[4]

Involving various ministries[5] and coordinated by the Ministry of Telecommunications and Informatization (which became the Ministry of Information Technologies and Communication in 2004), Electronic Russia 2002–2010 is the core IT program that will lay the groundwork for a more efficient economy and public administration through mass implementation of information and telecommunications technology [10]. It is also designed to facilitate by technological means the advancement of civil institutions by

[4]All cities in Russia with populations over 30,000 should soon be connected to the country's "fiber-optic backbone", although the connections to individual homes and offices can still be relatively primitive. Many thousands of villages in Russia still do not have a single telephone line, so it will be many years before some of the more sparsely populated areas can hope to have a fully operational telecommunications infrastructure. Many options are under consideration to provide this infrastructure, including satellite delivery. The Electronic Russia plan seeks to deliver an increasing number of government services online, and to alleviate some of the heavy bureaucratic burden on Russia's citizens and businesses. It will then be possible to perform tasks such as tax filing and business registration online. The country's vast geographic area and the financial difficulties of the education system have encouraged Russian planners to seek creative solutions to the provision of education throughout the country. The delivery of a wide range of distance-learning packages via the internet is seen as a potentially effective solution to this problem, which the Electronic Russia plan seeks to explore.

[5]Ministry of Economic Development and Trade, Ministry of Education, Ministry of Industry, Science and Technologies, Aviation and Space Agency, Federal Agency of Government Communications and Information with the President, Agency on Systems Management.

securing the right of citizens to unrestricted information access, and by expanding IT training opportunities for specialists and qualified users [11].

Electronic Russia has a nine-year planning horizon and addresses four key areas:

- Regulatory environment and institutional framework;
- Internet infrastructure;
- e-Government;
- e-Education.

The main objective of Electronic Russia is to increase the efficiency of the economy, to improve management in the public sector, and to enhance self-government by applying information and communication technologies. In order to reach this goal, the following tasks are addressed:

- To create effective legislation governing ICT;
- To ensure open communication and interaction between the state bodies, agencies, and companies by applying state-of-the-art ICT technologies;
- To create conditions for more extensive and more effective use of ICT in the economic and social spheres;
- To provide up-to-date computer training for professionals;
- To create incentives for the development of an independent press and media by employing ICT in their professional activities;
- To develop the infrastructure of telecommunication networks, as well as access to electronic libraries, archives, databases of scientific and technical information for citizens, state-owned organizations, and educational institutions;
- To support the establishment of e-commerce for state procurement and other commercial activities of the state [12].

In 2006, the government of the Russian Federation modified some of the aims and tasks of this program. The main aim of the Electronic Russia program has initially been restricted to increasing the quality of the public administration through implementation of information and telecommunications technology in government bodies, in order to increase the skills of the state employees in their use of IT and the quality of the state's services for citizens. Now Electronic Russia has a four-year planning horizon and addresses mainly e-Government issues.

The main objective of Electronic Russia is to increase the efficiency of management in the public sector by applying information and communication technologies. In order to reach this goal, the following tasks are addressed:

- Formulating standards and proposals related to the use of information and communication technologies in state governance;
- Providing for effective interaction between different bodies through information and communication technologies and integration of the state information systems;
- Providing for effective interaction between the state authorities, citizens, and organizations through information and communication technologies;
- Application of the information systems to control the activities of state authorities;

- Creation of software and technical solutions to support the activities of state authorities;
- Monitoring the program's implementation.

One of the regional branches of the Electronic Russia Program is the city program Electronic Moscow [13]. This program, announced on 24 December 2002, aims to strengthen Moscow's role as the information industry center of Russia. The program is based on the city's powerful telecommunication infrastructure—the Moscow Fiber Optic Network. The issues addressed by e-Moscow include the creation of a normative and legal basis for the information society; a more efficient city management, based on e-Government; developing the urban economy and overcoming information inequality within the city; building an interoperability framework; and integrating all existing ICT projects of the municipal authorities [14].

### 2.3 International Cooperation

International cooperation is an important component of the Russian Federation's efforts in the field of ensuring information security. Russia's international cooperation in ensuring information security has two distinctive features: International competition for technological and information resources and for dominance in the markets has increased, and the world's leading economies have achieved a growing technological lead that allows them to build up their potential for information warfare. Russia views this development with concern, as it could lead to a new arms race in the information sphere and raises the threat of foreign intelligence services penetrating Russia through technical means, such as a global information infrastructure. Therefore, the main areas of the Russian Federation's international cooperation in the field of information security are: [15]

- Banning the development, proliferation, and application of instruments of information warfare;
- Ensuring the security of international information exchange, including the security of information being transmitted via national telecommunications channels;
- Coordinating the activities of law-enforcement bodies worldwide for preventing computer crime;
- Preventing unauthorized access to confidential information in international banks, telecommunications networks, and information support systems that are indispensable for maintaining global trade; and sharing information with international law-enforcement organizations fighting transnational organized crime, international terrorism, the spread of narcotics and psychotropic substances, the illegal trade in arms and fissile materials, and human trafficking;
- Active participation of Russia in all international organizations active in the field of information security, including standardization and certification.

In accordance with UN General Assembly Resolution No. 58/32 of 8 December 2003, a group of government experts on international information security was organized, chaired by a Russian representative [16]. The group of government experts includes representatives of 15 countries.[6] Furthermore, the Russian government has special

[6]United Kingdom, China, Russia, France, Belarus, Brazil, Germany, India, Jordan, Malaysia, Mali, Mexico, South Korea, and South Africa.

partnerships with the state members of the Shanghai Cooperation Organization (SCO)[7] and with the state members of the Collective Security Treaty Organization (CSTO)[8] in the sphere of information security.

## 3 ORGANIZATIONAL OVERVIEW

The main organizations responsible for information security in Russia are the Security Council of the Russian Federation, the Federal Security Service of the Russian Federation (FSB), the Federal Guard Service of the Russian Federation, the Federal Technical and Export Control Service, and the Ministry of Information Technologies and Communications.

As far as public-private partnerships are concerned, the Russian Association of Networks and Services (RANS) strives to contribute to the development of norms for the implementation and use of secure IT, while PRIOR, as a national public initiative, aims at uniting public, private, and non-profit organizations directed at developing the Russian Information Society.

### 3.1 Public Agencies

***3.1.1 Security Council of the Russian Federation.*** The Security Council of the Russian Federation [17] is appointed by the president in accordance with the constitution and the Federal Law on Security. It is responsible for ascertaining Russia's national interests related to information and defines information resources that must be defended. The Security Council defines conceptual approaches to national security [3]. It drafts policy proposals on defending the vital interests of individuals, society, and the state against internal or external threats. The Security Council also coordinates the elaboration of a strategy for the Russian Federation's information security, and helps the president to carry out his constitutional duties in defending human and civil rights, as well as Russia's sovereignty, independence, and territorial integrity [18].

***3.1.2 Federal Security Service of the Russian Federation (FSB).*** According to its statute, the FSB [19] is a federal agency of the executive branch of government with a mandate to safeguard the security of the Russian Federation. This includes defending and protecting the state borders of the Russian Federation, as well as its internal waterways, territorial waters, exclusive economic zone, and continental shelf and their natural resources, and safeguarding the information security and the main areas of activity of agencies of the Federal Security Service, as defined in the laws of the Russian Federation [20].[9]

As far as technical support is concerned, the FSB has its own research institute specializing in information technologies. It carries out technical information assessments, particularly regarding criminal cases [20]. It is also responsible for tracking cases of cyber-terrorism [21]. The FSB Computer and Information Security Directorate

[7]In addition to Russia, these include: China, Kazakhstan, Kyrgyzstan, Tajikistan, and Uzbekistan.
[8]In addition to Russia, these include: Armenia, Belarus, Kazakhstan, Kyrgyzstan, Tajikistan, and Uzbekistan.
[9]Text of the "Statute on the Federal Security Service of the Russian Federation and Structure of the Federal Security Service Agencies". Approved by presidential edict no. 960 of 11 August 2003, signed by V. Putin, President of Russian Federation.

(Directorate-R) was established in October 1998. The Directorate's main tasks are counterintelligence and the fight against cyber-crime. Since undergoing a minor reform in September 2004, the FSB has a changed structure. The Computer and Information Security Directorate is part of its counterintelligence service [22].

Among the fundamental objectives of the FSB in the field of information security are the planning and implementation of state and scientific-technical policy in the sphere of information security; the organization of support for the cryptographic and technical engineering security of information and telecommunications systems; and protecting state secrets as well as systems of encrypted, classified, and other special types of communications in the Russian Federation and in its institutions abroad. Another function is to certify equipment for the protection of information, telecommunications systems, and networks, as well as technical devices for the detection of electronic surveillance in buildings and technical equipment, in accordance with federal law. Moreover, it certifies special technical equipment for the covert collection of information and technical equipment to safeguard the security and (or) protection of information, and defines the basic guidelines of the activity of the agencies of the Federal Security Service in these areas. Finally, it regulates the development, production, sale, use, export, and import of encryption (cryptographic) equipment, telecommunications systems, and networks protected by encryption systems [23].

***3.1.3 Federal Guard Service of the Russian Federation.*** According to its statute, the Federal Guard Service of the Russian Federation is a federal body of the executive branch of government with a public mandate to shape state politics and legal regulations, as well as to conduct monitoring and surveillance to ensure the safety of the president of the Russian Federation, the chairman of the government of the Russian Federation, and other important public figures. An additional structure—the Special Communication and Information Service—was added in August 2004 as a result of the administration reform of the Federal Guard Service of the Russian Federation [24].

Until 2004, the Federal Agency for Government Communications and Information (FAPSI) [25] was the main responsible body for information security. FAPSI was abolished in 2003 and its functions distributed between the Federal Security Service (FSB) and the Federal Guard Service of the Russian Federation. FAPSI was responsible for ensuring the security of communications [26]; the cryptographic and technical security of encrypted communications; intelligence-gathering activities; and providing information to higher bodies of authority. The agency also fought domestic criminals, foreign intelligence services, and engaged in other forms of information warfare; and it monitored information security in the financial sector. FAPSI was a strategic asset and oversaw information security on this level for the Russian Federation. It developed the technological basis not only for the country's administrative system, but also for the command-and-control system of the armed forces [27].

***3.1.4 Federal Technical and Export Control Service.*** The Federal Technical and Export Control Service was formed in August 2004.[10] The Federal Technical and Export Control Service's activities are guided by the president of the Russian Federation and come under the jurisdiction of the Ministry of Defense. The Federal Technical and Export Control Service is an executive body dealing with the following issues:

[10]Edict no. 314" of the president of the Russian Federation of 9 March 2004 on the System and Structure of Federal Executive Bodies.

- Ensuring information security in ICT systems that are important for the state's and society's security;
- Countering foreign technical espionage on the territory of the Russian Federation;
- Ensuring the protection of the state's classified information and other data by restricting access and preventing technical leaks and unauthorized access;
- Export control.

***3.1.5 Ministry of Information Technologies and Communications.*** The Ministry of Information Technologies and Communications is a branch of the federal government that implements state policy and oversight in the telecommunications sector. Among many other tasks, the ministry, together with other parts of the federal government, takes measures aimed at the restoration of the information and communication networks of the Russian Federation in emergency situations. It develops and implements a scientific-technical strategy for information security. The ministry also coordinates efforts to develop the national IT infrastructure [28].

## 3.2 Public-Private Partnerships

For many years, information security problems in Russia were only studied and addressed in a timely fashion for the protection of state secrets in military, governmental, or other state-related automated systems. Thus, over time, a situation developed in which very specific commercial-sector problems went unresolved because of the absence of such a sector [29]. At present, the development of commercial IT security products in the Russian market is prospering, yet it is sometimes limited by financial restrictions and the shortage of IT specialists.

Genuine public-private co-operation in the field of information security remains rather limited when compared to efforts in other countries. This is a result of the fact that for many (especially small and medium-sized) businesses in Russia, information assurance is not the most pressing problem. But both sides—private and public—are currently changing their stance, making more cooperation a much likelier prospect [30].

***3.2.1 Russian Association of Networks and Services (RANS).*** The Russian Association of Networks and Services (RANS) [31] is a public and governmental organization. RANS is developing norms and legal documents for the implementation and use of secure IT. The establishment of RANS was initiated by the Ministry for Information Technologies and Communications of the Russian Federation in 1994. At present, RANS has 122 members from all over Russia including universities, scientific institutions, ministries, legal and insurance companies, operators, ISPs, vendors, and users. RANS has several committees and workgroups on main topics covering the internet, security and privacy, wireless communications, education and training, and IP telephony. One of its working groups monitors standards.

The main activities of RANS are: [32]

- Assisting the development of the internet in Russia;
- Establishing a predictable, informative, non-contradictory, and clear legal environment for internet activities;
- Creating and realizing projects and programs aimed at the development of networks, systems of data transmission, telematic services, and information safety;

- Integration and coordination of the interests of users, producers, and operators of information and telecommunication systems;
- Integration of Russian information and telecommunication systems into the European and global infrastructure;
- Organization of conferences and exhibitions; publishing activities, and professional development.

In the sphere of information security, the program of RANS covers: [33][11]

- The creation and development of the PKI and information security concept in Russia;
- The preparation of a draft law on electronic digital signatures;
- The preparation of proposals in co-operation with the Ministry for Internal Affairs for the prevention of illegal activities in the telecommunication networks;
- Creating a hierarchical PKI Infrastructure, managed by the Federal Cryptographic Body.

***3.2.2 PRIOR.*** PRIOR [34] is a national public initiative that unites public, private, and non-profit organizations. Through its activities, this initiative aims to supplement the existing state and non-governmental programs and projects directed at developing an Information Society and a knowledge economy in Russia. PRIOR recognizes the importance of participating in the major development programs, including those of the state. These include the Federal Program Electronic Russia for the Years 2002–2010, the municipal program Electronic Moscow, the program Electronic Saint Petersburg, and others.

PRIOR's major project is creating the Russia Development Gateway [34], which is envisioned as an environment for partner interaction and collaboration to reach common goals as well as a means of integrating expert knowledge in the development field. It is an unprecedented coalition of equal partners instead of the traditional Russian hierarchical system.

PRIOR is a volunteer association of organizations and individuals who have pooled their efforts and resources in order to provide mutual informational, technological, consulting, financial, organizational, and other types of support to reach common goals. These goals include e-Governance, e-Business, the networked society, distance learning, digital libraries, and strengthening international, national, and local projects and initiatives through effective dissemination of best practice knowledge and experience.

Among others, PRIOR's aims are: [34]

- To assist in developing the legal base of the Information Society, the infrastructure of information processing, and communications channels;
- To serve as an effective national system for applying innovations;
- To educate and train qualified knowledge workers;
- To provide relevant local information content and services;
- To establish a unified methodological and terminological base regarding the Information Society and the knowledge economy;

[11]Other major projects are in the fields of telecommunications, e-business, and education and training.

- To give Russian users access to best-practice solutions and know-how and to assist in the implementation of partnership-based programs and projects aimed at development through ICT.

## 4 EARLY WARNING AND PUBLIC OUTREACH

The Russian Information Security Doctrine mentions the development of some early-warning mechanisms: "In these specific conditions, information security is ensured, among other things, by developing an effective system of monitoring critical objects whose malfunction may give rise to emergency situations and prediction of emergency situations" [35].

### 4.1 Russian Computer Emergency Response Team (RU-CERT)

The Russian Computer Emergency Response Team (RU-CERT) [36] was founded in 1998 and is maintained by the Russian Institute for Public Networks (RIPN) [37]. RU-CERT is part of the RBNet Network Operation Center (NOC) [38]. RBNet was established to provide internet services for science and high school communities in Russia. RBNet is a project funded by the Russian government under the responsibility of the RIPN.

RU-CERT provides computer-incident prevention and response services for RBNET users. The initial goal of the RU-CERT project was the coordination of efforts in the Greater Moscow area in their fight against hackers, primarily "script kiddies" who used stolen dial-up passwords and caused considerable material damage. However, it quickly became clear that service providers prefer to solve all problems independently and hide the results of their anti-hacker efforts from the public. It was subsequently decided to change the scope of its activity and to create an organization like the US CERT for Russia.

### 4.2 Governmental Scientific Support

One of the important factors determining the state outreach policy in the field of the ensuring information security is scientific support. The coordination of the activities of Russian scientific organizations in this field has been entrusted on the Institute Information Security Issues (IISI) [39] of the Moscow State University and the Academy of Cryptography of the Russian Federation (which deals with technical aspects of such problems).

## 5 LAW AND LEGISLATION

The legal framework for information security in Russia includes three main parts: the legal insurance of information security, the legal insurance of the security of information infrastructure and the legal insurance of the legal status of the information security's subjects.

The legal framework for information security is based on the Law of the Russian Federation on Mass Media, the Federal Law on Advertising, the Federal Law on Countering Extremist Activity, the Federal Law on Political Parties, the Code of Administrative

Offences of the Russian Federation. It is also governed by a number of other legal acts such as the Law of the Russian Federation On State Secrets [40], the Basic Principles of the Legislation of the Russian Federation on the Archive Fund of the Russian Federation and Archives [41], and the Federal Laws On Information, Informatization and Information Protection [42], which focus mainly on the use of information resources, information access rights, and information protection in the sense of preventing unauthorized access to documented information that may cause damage to government bodies or any other holder of information resources. Moreover, the Law of the Russian Federation on Legal Protection of Computer Programs and Databases [43] protects the content of computer programs and databases.

The legal framework for the security of information infrastructure is based on the Federal Law on Communications [44], which also covers communication network management in emergencies [45]. A number of other laws [46] have been adopted, and work has begun on implementing them and preparing draft laws regulating social relations in the information sphere [15]. The government hopes that the new federal Electronic Digital Signature (EDS) Law [47] will serve as a tool for regulating the field of information security. The law provides for recognizing the EDS as being legally equivalent to a physical personal signature. Specifically, the EDS Law protects the rights of persons who use EDS in their electronic data exchange. As part of enforcing this law, the government has been working to put into place a network of EDS authentication centers that will help enforce the law and derive regulations. The new Russian Law on Technical Regulation [48] also offers a new definition of the concept of security [49]. It states that "security is a condition in which intolerable risk of harm is absent". Furthermore, Article 7 of this law states that "technical regulations taking into account the degree of risk of harm establish minimum necessary requirements for ensuring, among others, electrical security."[12]

The legal provision on the status of the subjects of information security is based on the Constitution of the Russian Federation, the Criminal Code of the Russian Federation, the Law of the Russian Federation on Mass Media, and other legal acts that consolidate norms ensuring the rights of citizens, organizations, and state bodies in their information-related activities.

### 5.1 Russian Criminal Code 1996/2004

The number of cyber-attacks against enterprises, organizations, and citizens is growing at a stable pace. According to information from the Main Administration for Special Technical Measures of the Russian Ministry of Internal Affairs, the number of computer-related crimes committed in Russia has increased by almost 150 per cent over the previous years [50].

The Russian Criminal Code of 1996 (revised in 2004) provides for the punishment of the following crimes related to breaches of computer security: [51] Unlawful access to lawfully protected computer information; development of computer programs or introduction of changes into existing computer programs that are known to lead to unsanctioned destruction, blocking, modification, or copying of information; disruption of the operation of the computer, the computer system, or its networks, and likewise the use or

[12]Interestingly, before 2003, documents issued by Russian state organizations on information security did not include the word "risk".

dissemination of such programs or discs containing such programs; and violation of the rules of use of a computer, computer system, or network by a person having access to this computer, computer system, or network.

The Criminal Code of the Russian Federation now includes articles establishing penalties for types of crimes that had not been defined previously. Chapter 28 of the code, Crimes in the Computer Information Sphere, consists of three articles outlining the penalties for unlawful access to computer information (Article 272); for the creation, use, and dissemination of malicious computer programs (Article 273); and for violations of rules for the operation of computers, computer systems, and networks (Article 274) [52].

## ACKNOWLEDGMENT

We acknowledge the contribution of the expert, Anatoly Streltsov of Lomonosov Moscow State University, who validated the content of this chapter.

# SINGAPORE

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

New security threats that have emerged in the post-11 September 2001 era emphasized the need for closer cooperation between the military and homefront agencies in Singapore. Immediately after the attacks in the US in 2001, the homefront agencies undertook a review of the vulnerabilities and strengths of Singapore's national critical infrastructures from the following sectors:

- Banking and Finance,
- Information- and Telecommunications,
- Energy,
- Water,
- Transportation,
- Health [1].

Since 2002, the critical infrastructures of these six sectors have been reviewed and assessed, and remedial plans were implemented. However, infrastructure protection policies in Singapore are not limited to these sectors, but have been expanded to the following sectors:

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

- Food supply,
- Aviation Security,
- Maritime Security.[1]

Even though these sectors have been at the focus of the most recent efforts to prevent terrorism, they do not represent the totality of Singapore's critical infrastructure. Other sectors may well be included in future protection efforts.

## 2 INITIATIVES AND POLICY

Singapore adopted the internet comparatively early. According to the Network Readiness Index by the World Economic Forum, Singapore was the most network-ready country in 2004–2005 [3]. In spring 2005, the Singaporean government presented a comprehensive "Infocomm Security Masterplan" for the years 2005–2007 that is part of the country's national security strategy to address cyber-security and cyber-terrorism [4].

### 2.1 National Emergency System (NEST)

Since the mid-1980s, Singapore has planned and developed its homefront preparedness efforts along the lines of a total defense concept. The Ministry of Home Affairs (MHA) has brought various ministries and emergency authorities together to integrate homeland preparedness plans. Since 2001, the MHA has boosted its efforts and developed a robust National Emergency System (NEST) for national security, while the Singapore Armed Forces are in charge of external defense. NEST is a comprehensive system encompassing civil security, civil defense, the provision of essential services, and the smooth operation of the economy during an emergency. It also ensures the provision of essential services and commodities such as water, power, health services, telecommunications, food, and fuel to the public [5].

### 2.2 National Critical Infrastructures Assurance (NCIA) Program

As announced in 2002 [6], the Singapore government has set up a National Critical Infrastructure Assurance (NCIA) project to carry out an in-depth assessment of the vulnerabilities of the nation's critical national infrastructures and of necessary measures to reduce these vulnerabilities. The project involves consultation and partnership between the government agencies and the private sector. The National Infocomm Security Committee (NISC) supports the NCIA program.

### 2.3 The Fight Against Terror—Singapore's National Security Strategy

In August 2004, the government's National Security Coordination Centre released a document entitled The Fight Against Terror—Singapore's National Security Strategy [7], according to which security standards in crucial areas such as aviation security, maritime security, land transport security, border control, and critical infrastructure protection have been raised in Singapore [8]. In response to terrorist attacks in the US

[1] Cf. [2].

and based on the recommendations of the National Critical Infrastructure Assurance Committee, Singapore has initiated several measures to protect its physical critical infrastructure and key installations, including prominent public places, power stations, and transportation and water supply networks [9].

### 2.4 Infocomm Security Masterplan

In response to cyber-threats such as hacking, virus attacks, and cyber-terrorism, the deputy prime minister announced the three-year Infocomm Security Masterplan (2005–2008) in February 2005. He said that as Singapore's economy would continue to rely heavily on ICT, securing the information and communication environment would be critical. The government would thus set aside S$38 million (about US$23 million) over the next three years to build capabilities in managing cyber-threats and enhancing the security of cyberspace.

The master plan was developed through a multi-agency effort led by the Infocomm Development Authority of Singapore (IDA) under the guidance of the National Infocomm Security Committee (NISC), and is the result of extensive private and public collaboration. Companies and government agencies provided feedback and input through surveys and focus group discussions [10]. It was discovered that businesses have difficulty formulating and complying with IT security policies and best practices, as they lack the necessary professionals and experience.

The Infocomm Security Masterplan has two main aims:

- To maintain a secure IT environment for the government, businesses, and individuals. This involves raising awareness of risks, cyber-threats, and appropriate security measures among internet users and businesses. Two planned key projects to secure these three sectors are the National Authentication Infrastructure, which will develop reliable and robust authentication means to curb identity theft and promote more secure e-services, and the Business Continuity Readiness Assessment Framework. They will measure the effectiveness of government agencies' business continuity plans;
- To defend Singapore's critical infrastructure from cyber-attacks. The master plan also outlines strategies to develop national capabilities, to enhance security technology research and development, and to improve the resilience of critical information infrastructure.

Finally, a Common Criteria Certification Scheme and a set of international standards on security are planned [11].

The Infocomm Security Masterplan 2005–2008 will be replaced by a new five-year master plan in 2008. The new plan will build on existing efforts and will perpetuate the collaborative approach to ensure information security in Singapore [12].

## 3 ORGANIZATIONAL OVERVIEW

The Infocomm Development Authority of Singapore (IDA) is the chief technology office of the Singapore government covering planning, policy formulation, regulation, and cooperation with the private sector in the field of ICT. The National Infocomm Security

Committee (NISC) and the Technology Crime Division (TCD) within the Singapore Police Forces also play important roles in the field of CIIP.

In addition, the government of Singapore has recognized the importance of public-private partnerships to secure critical information infrastructures. In his speech on the occasion on the launch of the Infocomm Security Masterplan, Peter Ho, the then chairman of the National Infocomm Security Committee, emphasized the need for collaboration: "The cyber-threat landscape is constantly changing. No single organization can deal with these changes alone. Instead, collaboration among infrastructure owners, operators and government must take place. This is because separately, each of us sees only a small part of the picture and may not comprehend the full scale of malicious activities involved" [13].

Accordingly, Singapore has implemented different initiatives to foster public-private collaboration in the field of information security. The second part of this section lists the most important among them with regard to the protection of critical information infrastructure.

### 3.1 Public Agencies

***3.1.1 Infocomm Development Authority of Singapore (IDA).*** IDA is a statutory board of the Singapore government that was formed in 1999 as the result of a merger between the National Computer Board (NCB) and the Telecommunications Authority of Singapore (TAS). The aim was to have a single agency for integrated planning, policy formulation, regulation, and industry development of the ICT sector.[2] IDA operates under the Ministry of Information, Communications, and the Arts (MICA).

Among IDA's main responsibilities are fostering a competitive IT industry in Singapore, preparing residents for living and working in the "New Economy", supporting the delivery of citizen-centric e-Government services, and building and operating the government's IT infrastructure [14]. IDA sets ICT standards and regulations and supports the private sector in implementing security measures.

IDA's Infocomm Security Division (iSec) plays a central role in establishing and implementing a solid IT security infrastructure for Singapore's national ICT infrastructures. iSec monitors the implementation of ICT security measures and practices for the whole public sector. Moreover, iSec conducts awareness-raising programs for the public and the private sector as well as individuals. For instance, in 2001, IDA initiated a year-long public-awareness campaign that aimed to educate users from the public and private sectors as well as the general public about safe computing practices [15].

***3.1.2 National Infocomm Security Committee (NISC).*** The National Infocomm Security Committee (NISC) was set up to formulate policies and strategic direction for cybersecurity at the national level. With members from various government agencies, it is a platform for the government to institutionalize considered policies and mandate strategic initiatives in IT security. It comprises representatives from the Ministry of Home Affairs, the Ministry of Defence; the Ministry of Information, Communication and the Arts; the Ministry of Finance; the DSO National Labs; and the Defence Science and Technology Agency (DSTA). IDA serves as the secretariat for this committee [16].

[2]Among other entities, IDA supports the Information Technology Standards Committee (ITSC), the National Trusts Council (NTC)—an industry-led council to build confidence in e-Commerce, and the Public Key Infrastructure (PKI) Forum Singapore.

***3.1.3 Technology Crime Division (TCD) within the Singapore Police Force.*** Within the Singapore Police Force (SPF), the Criminal Investigation Department (CID) is the primary investigation agency in Singapore for all criminal matters [17]. The Technology Crime Division (TCD) is part of the CID. TCD provides specialized investigative and forensic services in addition to training the entire police force in investigating high-tech crime. Its scope of operation goes beyond computer crime and includes traditional crimes committed with the use of technology, such as encrypted mobile devices, the internet, and even wireless platforms. In order to prepare the nation for crimes of the future, the approach adopted by TCD is also to build capabilities through research, alliance-building, and education [18].

### 3.2 Public Private Partnership

***3.2.1 Critical Infocomm Infrastructure Surety Assessment (CII-SA).*** The Critical Infocomm Infrastructure Surety Assessment project was established in 2006 to assess the security readiness of Singapore's critical information and communications infrastructure. The project is led by the IDA, and provides a platform for owners and operators of CII to work together and ascertain the adequacy of their protection measures [19].

***3.2.2 Information Technology Standards Committee (ITSC).*** Volunteer members from the industry, supported by the Productivity and Standards Board (PSB) and IDA, established the industry-led Information Technology Standards Committee (ITSC) [20] in 1990. It is a neutral platform for interested industry and government parties to convene to agree on technical standards. To this end, the ITSC organizes workshops and seminars on various topics.

***3.2.3 Governmentware Seminar.*** The annual Governmentware IT Security seminar series began in 1991. The seminars are organized by the IT Command of the Internal Security Department (ISD) of the Ministry of Home Affairs (MHA). Since 2002, the Institute of Public Administration and Management (IPAM) of the Civil Service College has been the MHA's organizing partner. The lectures are also open to an audience from outside the public sector. The first seminar, organized by ISD for civil service participants, was held in the wake of urgent concerns about virus attacks against the PCs of government users. The Governmentware seminars alert participants to the latest security threats posed by emerging technology and advanced hacking techniques. Private-sector IT security industry experts are invited to participate and share their knowledge [21].

## 4 EARLY-WARNING APPROACHES

### 4.1 Singapore Computer Emergency Response Team (SingCERT)

The Singapore Computer Emergency Response Team (SingCERT) [22] is responsible for the detection, resolution, and prevention of security-related incidents on the internet. SingCERT also issues advisories and alerts about incidents. It maintains a website and a hotline for reporting and dissemination of advisories. SingCERT was initially established in October 1997 as a program of IDA, in collaboration with the Centre for Internet Research at the National University of Singapore (NUS).

SingCERT provides the following services:

- Broadcasting alerts, advisories, and security patches;

- Promoting security awareness through security courses, seminars, and workshops;
- Collaborate with vendors or other CERTs to find solutions to security incidents.

SingCERT is also a founding member of the Asia Pacific Security Incident Response Coordination Working Group (APSIRC-WG). The APSIRC-WG is staffed by volunteers from the national Incident Response Teams (IRTs) of Japan, Korea, and Singapore and aims to promote collaboration with other international IRTs and security groupings, such as the Forum of Incident Response and Security Teams (FIRST). Furthermore, APSIRC-WG provides assistance to countries in the region that would like to establish their own IRTs [22].

### 4.2 National Cyberthreat Monitoring Centre (NCMC)

Under the Infocomm Security Masterplan, the National Cyberthreat Monitoring Centre (NCMC) as a national resource to safeguard Singapore's cybersecurity and to provide focused tracking of cyber-threats. Besides the round-the-clock monitoring of critical networks, the centre will provide regular in-depth analysis of cyber-threats by incorporating information from all available sources. The NCMC will provide latest trends in cyber-threats, allowing the authorities to better respond to, and even preempt future attacks [23].

## 5 LAW AND LEGISLATIVE ACTION

### 5.1 Computer Misuse Act 1993/1998

The Computer Misuse Act (CMA) was first enacted in 1993 and first amended in 1998. It is aimed at protecting computers, computer programs, and information stored in computers from unauthorized access, modification, use, or interception. The CMA also applies to any person, irrespective of physical location, who hacks into computers located in Singapore, and to any person in Singapore who hacks into computers outside Singapore.

The 1998 amendments also address newer forms of cyber-crime (such as Trojan horses, password trafficking, or denial-of-service attacks). The amended CMA also provides enhanced penalties for computer crimes proportionate to the potential and actual harm caused. The amendment gives the police the legal authority to gain access to computer material, including encrypted material [24].

### 5.2 Computer Misuse (Amendment) Act 2003

The amendment to the Computer Misuse Act in 2003 allows the minister to authorize any person or organization to take necessary measures to prevent or counter any threat to a computer system that can affect the national security, essential services, defense, or foreign relations of Singapore. This is part of the government's efforts to establish a robust defense against cyber-attacks.

As in many other countries, Singapore's essential and critical services such as water, electricity, gas, telecommunications, and transportation are increasingly dependent on computer networks and information systems. Terrorists and criminals can exploit this dependence. Any attack on the critical infrastructure and essential services will severely disrupt the economy and threaten the national security.

Furthermore, with an increasingly computer-literate population and widespread availability of user-friendly hacker tools, more people around the world now have the necessary skills to carry out cyber-attacks. Hackers and computer viruses can flood network connections, steal or tamper with information, and disrupt essential services.

Section 15A of the Computer Misuse Act allows the minister to authorize any person or organization to take necessary measures to prevent or counter any threat that may endanger the national security, essential services, defense, or foreign relations of Singapore. The new Section 15A would be invoked to deal with situations of an outright cyber-attack, or in cases where specific intelligence has been received of an imminent cyber-attack against Singapore's critical infrastructure.

The powers given to the minister under Section 15A may not be used indiscriminately. The measures are aimed at preventing or countering any threat to a computer or computer service, or to any class of computers or computer services. The powers would be invoked only to avert threats that may endanger national security and essential services, such as any service directly related to the communications infrastructure, the banking and finance sectors, and the defense and foreign relations of Singapore. The powers under the new Section 15A would not be invoked to prevent or investigate a criminal offence that does not threaten the national security or essential services. Singapore's security agencies will also be required to satisfy the minister that the cyber-threats are imminent before the powers provided by Section 15A can be invoked [25].

### 5.3 Electronic Transactions Act 1998

The Electronic Transactions Act (ETA) was enacted in 1998 to provide a legal infrastructure for electronic signatures and electronic records, and to ensure predictability and certainty for electronic contracts. The ETA establishes the supporting legal infrastructure for the Public Key Infrastructure (PKI). The ETA addresses the following issues:

- Commercial code for electronic commerce transactions;
- Use of electronic applications and licenses for the public sector;
- Liability of service providers;
- Provision for a PKI.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts of the Ministry of Home Affairs who validated the content of this chapter.

# SPAIN

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

For a long time, Spain's critical sectors had not been exhaustively defined by the Spanish government. On 7 May 2007, the State Security Secretariat approved the so-called National Plan for the Protection of the Critical Infrastructures (Plan Nacional de Protección de las Infraestructuras Críticas). This plan defines the critical infrastructures as "those installations, networks, services, physical equipment, and information technologies whose interruption or destruction would have a grave impact on the health, security, or economic wellbeing of the citizens or on the efficient functioning of the state institutions and of the public administration".[1] Moreover, the plan includes a list of 12 strategically critical sectors. These are:[2]

- Chemical Industry,
- Nuclear Industry,
- Investigative installations,
- Centers of Power,
- Space,
- Energy sector,
- Telecommunications,
- Transportation,
- Water supply,
- Alimentation,
- Financial Sector,
- Public Health.

[1]Information provided by an expert. Translation by the author.

On 12 June 2007, Congress in a plenary session unanimously urged the government to put together a catalog with an exhaustive list of the national critical infrastructures within six months [1]. This classified catalog was elaborated and now contains 3,500 critical installations all over Spain [2]. Moreover, the catalogue is designated to become the basis of information for the European Program for Critical Infrastructure Protection (EPCIP) and will be constantly updated.

The Department of the Interior's General Directorate for Infrastructures and Security Equipment (Dirección General de Infraestructuras y Material de la Seguridad) is tasked, among other responsibilities, with securing the information and communications systems and data systems [3].

## 2 PAST AND PRESENT INITIATIVES AND POLICY

The main Spanish initiatives and policies in the area of information infrastructure and security occur along a two-pronged strand and focus on the opportunities and positive challenges created by the current developments in information and communications technologies.

### 2.1 Information Society Action Plan

In 1999, the Spanish government launched a strategic initiative for the development of the Information Society corresponding to the insight that Spanish society and the country's economy as a whole would benefit from the capacity to adopt the Information Society's technological innovations and to exploit the opportunities thus created.

The very first step of this initiative was the adoption of INFO XXI: La Sociedad de la Inform@ción para todos[3] in January 2000, a project that aims at building the Information Society of Spain. It consists of several structured programs and action steps to help stimulate the development of the Information Society in Spain. The first Action Plan INFO XXI (2000–2003) intends to establish the coordination of public administration initiatives by achieving three major objectives [5]:

- To stimulate the telecommunications and information technologies sector and complete the liberalization process within this sector by fostering competition;
- To enhance e-Government;
- To foster inclusive access to the Information Society.

In July 2003, the successor plan for the further development of the Information Society, called España.es, was adopted by the Spanish government to replace the INFO XXI plan. Covering the two-year period of 2004–2005, it is partly based on the recommendations of an expert commission on the Information Society and pursues two main objectives: to stimulate Information Society services in the population and to improve the infrastructure, contents, and services. The three strategic axes of the new action plan are as follows [6]:

- To foster the availability of contents and services that are most likely to stimulate demand;

[3]This document is accessible in its entirety [4].

- To improve the accessibility of Information Society services in the broadest sense, by offering public access points and developing training and communication;
- To connect small and medium-sized enterprises to enable them to fully take advantage of the benefits of e-Business.

To deliver on these objectives, the plan comprises six areas of action divided into two categories: vertical actions targeting specific segments of society such as the public sector (administración.es), education (educación.es), or small and medium-sized enterprises (pyme.es), and horizontal actions covering the whole population, accessibility and inclusion (navega.es), contents (contenidos.es), and communication and marketing (comunicación.es) [7].

In November 2005, the Spanish cabinet adopted the latest successor plan, the so-called Plan Avanza, which forms part of a broader program, Ingenido2010. The latter is aimed at giving new impetus to research and development investment in Spain. Plan Avanza focuses in particular on the investments needed for the ongoing development of the Information Society [8]. Plan Avanza has three major domains of activity including digital citizenship, small and medium-sized enterprises, and local entities. The element of information and communications security within all three domains is the jointly maintained anti-virus early-warning center (Centro de Alerta Temprana sobre Virus y Seguridad Informática) [9].

### 2.2 E-Government Action Plan

Jointly launched in 2003 by the Ministries of Science and Technology and of Public Administration, the Spanish e-Government action plan initially had the objective to enhance the drive towards electronic public services with a "short sharp shock". Therefore, a bunch of measures was implemented organized around the following four strategic areas [10]:

- Facilitating access to electronic services for all citizens (with the introduction of the electronic ID card, and the development of public access points to the internet);
- Developing interactive and transactional services that meet users' needs in terms of need, accessibility, and sophistication (starting with the improvement of the central e-government portal administracion.es);
- Enabling data and information interchange between administrations, both at the central level and with regional and local administrations;
- Supporting the internal change and re-engineering efforts of public administrations (coordination of developments, technical assistance, and reorganization of supporting structures).

In October 2004, this plan was updated to become the Public Administration Technological Modernization Plan 2004–2007 aiming to "connect administrations and connect people" while reducing bureaucracy, simplifying procedures, and eliminating unjustified delays [11]. Therefore, an electronic system for the secure interchange of data between administrations was to be put in place. In January 2006, the national e-Government initiatives were once again updated to boost the transition of the country's national public administration into cyberspace by offering a full range of on-line services

to Spanish citizens. A new new key element of the latest plan, called MODERNIZA, is a wide-ranging law on e-Government (see the chapter on Law and Legislation). MODERNIZA covers the period from 2006 to 2008 and consists of 16 measures to be implemented with the aim of achieving a huge step towards e-Government in Spain. The new law, for example, establishes citizens' electronic access to all public administration services and their right to submit electronic documents and signatures for official purposes. Other measures in the action plan repeated earlier calls for the distribution of electronic ID cards, the online availability of 800 new administrative forms, the conversion of 100 services to cyberspace, and a progressive introduction of electronic payment of public fees and royalties. The government is also creating an integrated network of information points and a single one-stop-shop web portal service for citizens to replace more than 500 different websites.

## 3 ORGANIZATIONAL OVERVIEW

The various aspects of Spanish critical information infrastructure policies mainly come under the auspices of the Ministry of Industry, Tourism, and Trade; the Ministry for Public Administration; and the Ministry of the Interior.

There are two State Secretariats under the administration of the Spanish Ministry of Industry, Tourism, and Trade: the State Secretariat of Tourism and Trade and the State Secretariat of Telecommunications and for the Information Society. The State Secretariat of Telecommunications and for the Information Society, in turn, is in charge of two General Directorates—the General Directorate of Telecommunications and Information Technologies (Dirección General de Telecomunicaciones y Tecnología de la Información—DGTTI) and the General Directorate for the Development of the Information Society (Dirección General para el Desarrollo de la Sociedad de la Información—DGDSI) [12].

Three initiatives under the auspices of the Ministry for Public Administration are particularly important as regards Spain's information and communication infrastructure and its security. These are the e-Government Council, its Technical Committee, and the so-called technimap project.

The Police Services and the National Center for the Protection of the Critical Infrastructure operate under the auspices of the Ministry of the Interior.

The two main public-private partnership initiatives include the Information Society and Telecommunications Analysis Center, called Enter, and the Spanish Electronics, Information Technology, and Telecommunications Industries Association, AETIC.

### 3.1 Public Agencies

***3.1.1 General Directorate for the Development of the Information Society.*** The General Directorate for the Development of the Information Society was created by Royal Decree 1554 of 25 June 2004. Article 9 of this decree defines a set of 20 functions and jurisdictions for the general directorate, distributed among the following Sub-Directorates [13]:

- Sub-Directorate for access to the information society;
- Sub-Directorate for companies of the Information Society;

- Sub-Directorate for the services of the Information Society;
- Sub-Directorate for audiovisual tools.

The DGDSI maintains multiple services [14] ranging from Plan Avanza over the provision of ICT technologies to small and medium-sized companies, universities, and the public, to the extension of broadband access and a program for the promotion of technical research. Other departments address a variety of international cooperation programs, e-Government, a range of Information Society services, and information security. The latter comes under the jurisdiction of the Antivirus Early Warning Center (Centro de Alerta Temprana sobre Virus y Seguridad Informática—CATA) [15].

***3.1.2 General Directorate of Telecommunications and Information Technologies.*** The General Directorate for Telecommunications and Information Technologies is in charge of six Sub-Directorates and is organized into 11 sections [16]. It offers manifold services [17], electronic forms [18], and access to legislation relating to telecommunications [19]. Most importantly, several so-called advisory councils and commissions are organized and convened by the DGTTI, including the following three bodies in particular. First, the Advisory Council of Telecommunications and of the Information Society is composed by delegated members of the different administrative units including the national government the autonomous administrations, and the local administrative authorities. Furthermore, representatives of the industrial and commercial sectors, of the telecommunications services providers, of the sectoral trade organizations, and delegates of the educational sector make up this advisory body. The main function of the Advisory Council is to study, deliberate, and advise the government on an informed basis concerning matters of IT policy [20].

Second, the Special Study Commission for the Development of the Information Society has the task of analyzing the consequences of implementing the Information Society for both small and medium-sized companies and for Spanish society in general. It is tasked with issuing written recommendations. It is composed of eminent members who are acknowledged experts in their respective professional fields, both technological and academic.

The third and most wide-ranging council is the Interministerial Commission of the Information Society and of the New Technologies in Spain, which was created with the objective of elaborating, developing, and evaluating the government's strategic initiatives relating to the Information Society and information technology. More precisely, the commission's tasks include:

- To collate a catalog of all activities undertaken by the various ministerial departments and other public entities regarding the Information Society;
- To elaborate and propose to the government a strategic initiative for the development of the Information Society, including objectives, priorities, and an agenda for implementation;
- To evaluate the tools considered for use in the strategic initiative, and to submit an annual report to the Council of Ministers;
- To propose guidelines to the government on the position to be adopted by Spain in the most relevant international forums and bodies in this field;
- To promote the diffusion of the strategic initiative and its tools within Spanish society.

The commission is to carry out its functions through specialized working groups. It is chaired by the Minister of Science and Technology, and its secretary is the General Director for the development of the Information Society. The list of the participating members is composed by representatives of 15 different ministerial secretariats [21].

***3.1.3 Red.es.*** Besides the two General Directorates described above, the State Secretariat of Telecommunications and for the Information Society manages two public entities—the red.es office and the Telecommunications Market Commission—as well as an autonomous organism, the State Agency for Radiocommunications [22]. On the same organizational level as the two General Directorates, the red.es office aims to promote the development of the Information Society through the execution of the programs defined in Plan Avanza; to analyze efforts pertaining to the Information Society by means of the Spanish Telecommunications and Information Society Observatory; to offer advice and specific support to the national government; and it is responsible for handling registrations of domain names under the country-code top level domain .es for Spain [23].

The various programs of red.es aim to promote digital inclusion and ameliorate the quality of services, to enhance the digitalization of the educational sector through the allocation of ICT infrastructures, to support the provision of digitalized public services both for citizens and for companies, to enhance broadband infrastructures, and to raise awareness of security mechanisms that generate confidence in ICT and digital content. The Observatory of red.es analyses the activities of the ICT sector and pursues the development of Plan Avanza for convergence among the autonomous regions and of Spain with Europe. The red.es office advises the Spanish government by submitting studies and reports to the various administrative bodies and by assisting the implementation of e-Government [24].

***3.1.4 The e-Government Council.*** Among the bodies of the Ministry for Public Administration is the e-Government Council (Consejo Superiór de Administración Electrónica). In 2005, it replaced the Council for Informatics and for the Promotion of e-Government, which had replaced the first incarnation of this body—the Council for Informatics—two years before. The task of this council is to prepare, elaborate, develop, and apply the government's IT policies and strategies [25]. It has seven main areas of activities, including statistical services, the promotion of telecommunications in the administration, the enhancement of the quality and productivity of the services, international activities, IT cooperation between the different levels of the administration, organization, and human resources.

Moreover, the council is assigned with the task of elaborating a security policy in collaboration with the National Cryptology Center of the National Intelligence Center for the development of information and communication security measures and systems security [26]. Under this header, it has developed tools for ICT security; issued publications on security criteria, standardization, and conservation of information and communications [27]; and published documentation on methodology for risk analysis and management [28] in information systems—the latest version of which dates from June 2006. The council operates as a plenum, has a permanent commission that is responsible for coordinating the technical support supplied by various bodies under the jurisdiction of different ministries, and its activities are sub-divided into ministerial commissions (Comisiones Ministeriales de Administración Electrónica).

***3.1.5 Technical Committee for the Security of Information Systems and Personal Data Processing.*** The Technical Committee for the Security of Information Systems and Personal Data Processing (Comité Técnico de Seguridad de los Sistemas de Información y Tratamiento Automatizado de Datos Personales—SSITAD) [29] is responsible for cyber-security and for supporting the e-Government Council's task of elaborating a Spanish information security policy. The main task of this committee is to unify activities related to information systems security among all government departments. In order to achieve this objective, the SSITAD defines common information security policies and procedures, provides advice and training, and fosters general awareness. It also works on the adoption of international and European regulations in information systems security [30]. The committee exercises its functions in plenary sessions and also in four ad-hoc working groups. These are responsible, respectively, for personal data protection, the elaboration of directives for information systems security, the evaluation and certification of information systems security, and the use of electronic, information, and telematics technology in the government [31].

***3.1.6 TECNIMAP.*** Tecnimap [32] is a conference that brings together ICT experts from various areas of the public administration, the main companies in the field, and other experts. It aims at creating a space to exchange experiences, ideas, and projects in the field of information technologies and public services. The first conference was held in 1989 (Madrid). The 2007 conference, the tenth one, was organized in association with the Ministry of Public Services, the Government of the Principality of Asturias, and the Gijón City Council, and was held from 27 to 30 November. Over 5,000 participants, 250 enterprises, and representatives of 100 media outlets attended the event. Round tables and workshops were held for four days, during which interesting subjects relating to new technologies and e-administration were discussed.

The 2007 conference also included an opportunity to observe the latest projects developed by the public administration, and a forum was held at which citizens presented their opinions and suggestions. This conference discussed legal issues related to public access to the public administration using IT and other emerging issues.

***3.1.7 The Police Services.*** Under the auspices of the Ministry of the Interior, both the Policía Nacional and the Guardia Civil deal with cyber-crime. The national police operates through the Information Technology Crime Unit (Unidad de Investigación de la Delincuencia en Tecnología de la Información), and the Guardia Civil hosts a High Technology Crime Department (Departamento de Delitos en Alta Tecnología). The National Police Department and the General Judicial Police Department have an emergency service for cyber-crime. This citizen/police contact service allows the police to act rapidly and efficiently to prevent cyber-crime. The 24-hour alert system is active in the areas of cyber-crime, child pornography and telecommunications fraud [30].

***3.1.8 National Center for the Protection of the Critical Infrastructures.*** An organization that is more generally concerned with the protection of critical infrastructures is the National Center for the Protection of the Critical Infrastructures (Centro Nacional de Protección de Infraestructuras Críticas—CNPIC), which was established on 2 November 2007 under the responsibility of the State Security Secretariat of the Ministry of the Interior [33]. This agency is responsible for leading, coordinating, and supervising the

protection of the national critical infrastructures. The Ministry of the Interior had previously elaborated the antiterrorism prevention and protection plan as well as the national plan for the protection of the critical infrastructures, and had forged the agreement by the Ministerial Council of 2 November 2007 that established the CNPIC. Moreover, the State Security Secretariat is also responsible for the application of the National Plan for the Protection of the Critical Infrastructures, for the coordination of Spain's policies with the requirements of the EU, and for the elaboration of consistent best practice procedures. More specifically, the tasks of CNPIC include:[2]

- The maintenance and updating of the national security plan for the critical infrastructures and of the catalog;
- The collection, analysis, integration, and evaluation of the information furnished by the public institutions, police services, and strategic sectors;
- Threat assessment and risks analysis concerning strategic installations;
- The design and establishment of information, communication, and alert mechanisms;
- Coordination with the respective programs of the EU.

### 3.2 Public-Private Partnerships

***3.2.1 The Information Society and Telecommunications Analysis Center/ENTER.*** The Information Society and Telecommunications Analysis Center (Centro de Análisis de la Sociedad de la Información y las Telecomunicaciones) called ENTER is a public-private partnership designated as a center for providing information and analysis on the Information Society from the perspective of digital conversion. It brings together private companies and public institutions.[4] ENTER is structured into four functional units of analysis, including a technology section, an economic section, a societal section, and a regulations section. These four units supply data to a shared knowledge management system. Moreover, ENTER disseminates knowledge on the Information Society, which it holds in a database [35] and in an extensive collection of documents [36].

***3.2.2 AETIC.*** The Spanish Electronics, Information Technology and Telecommunications Industries Association (Asociación de Empresas de Electrónica, Tecnologías de la Información y Telecomunicaciones de España, AETIC) is a non-profit organization representing Spanish companies from the electronic, IT, and telecommunications sectors. AETIC collaborates with various arms of the public administration, including with the Presidential Office, the Ministry of Industry, Tourism, and Commerce, and with the Ministry of Public Administrations.[5] This collaboration between AETIC and the public administrations is mainly guided by the desire to protect the general interests of the industries that AETIC represents to the government at all levels [38].

## 4 EARLY WARNING AND PUBLIC OUTREACH

***4.0.1 A ntivirus Early-Warning Center.*** The Antivirus Early-Warning Center (Centro de Alerta Temprana Antivirus, CATA) became operational in 2001 and is located

[4]For a list of its members see: [34].
[5]For a full list of the ministries that AETIC collaborates with, see: [37].

under auspices of the Ministry of Industry, Tourism, and Trade's Secretariat of Telecommunications and for the Information Society.

It supplies users with current first-hand information about computer viruses, information system vulnerabilities, and identified security loopholes. The center collaborates with numerous public bodies at all levels as well as with ministries, universities, and private entities such as the large internet service providers and the producers of anti-virus programs [39]. The center aims to assure the security of data transmitted by means of electronic devices. Therefore, it provides an information platform for IT experts and users [40]. The services offered by the center are structured into four groups. First, the virus-warning group provides effective virus warnings and background information. Second, CATA issues reports about the emergence of new viruses, and collates statistical reports on electronic traffic between particular Spanish investigation centers and universities searching for virus incidents. Third, users can use a search engine to find information about known viruses within the center's databases, including advice on how to deal with virus incidents. And fourth, CATA provides preventive recommendations, FAQs, a virus encyclopedia, a list of the criteria applied, and a documentation center with all relevant information [41].

***4.0.2 CERT of the National Cryptology Center.*** The CERT-CNN (Equipo de Respuesta ante Incidentes de Seguridad Informática de Centro Criptológico Nacional de España) is dedicated to enhancing the level of security of the information systems of the public administrations of Spain. Its mission is to warn about and respond to security incidents, and to help the public administrations rapidly and efficiently in the case of emerging security threats that affect their information systems. The CERT-CNN, which resides within the National Intelligence Center, furnishes information services such as warnings about new threats and vulnerabilities, provides investigation reports and conducts awareness-raising campaigns, and offers support and coordination services for incident resolution [42]. CERT-CNN is member of the global Forum for Incident Response and Security Teams (FIRST) (see the survey on FIRST in this volume).

***4.0.3 RedIRIS.*** In 1988, the National Plan for Research and Development initiated a special program called IRIS for the interconnection of computer resources (Interconexión de los Recursos InformáticoS) of universities and research centers [43]. In 1991, when the first stage was finished, IRIS became what RedIRIS is today: the national academic and research network, which is still funded by the National Plan for Research and Development and was managed from 1994 to 2003 by the Scientific Research Council [44]. Since January 2004, RedIRIS has become a department within Red.es, but has preserved its autonomy. About 250 institutions are connected to RedIRIS today [45].

***4.0.4 I RIS-CERT.*** IRIS-CERT is the security service of RedIRIS', and is dedicated to the early detection of security incidents affecting RedIRIS centers, as well as the coordination of incident handling in cooperation with these centers. Proactive measures are constantly being developed, including timely warning about potential emerging problems, technical advice, and training. IRIS-CERT also provides incident handling coordination for the rest of the .es domains. IRIS-CERT has been a member of FIRST since 1997 and contributes to CSIRT Coordination in Europe [46].

## 5 LAW AND LEGISLATION

### 5.1 Spanish Penal Code

Three sections of the Spanish penal code in particular apply to cyber-crime. These in include Article 197 On the Discovery and Revealing of Secrets, Articles 248, 264, 256, and 270 On Fraud, and Article 273 On Crimes Involving Corporate Property [47]. No specific cyber-crime laws have been passed yet, but the Ministry of the Interior is preparing a proposal for cyber-crime laws in order to amend several articles of the penal code.

### 5.2 Law on Citizens' Electronic Access to Public Services

On 20 June 2007, the Spanish Congress adopted[6] a new law on electronic access of citizens to public services (Ley de Acceso Electrónico de los Ciudadanos a los Servicios Públicos). This law recognizes the right of citizens to communicate with the public administrations by electronic means and states the obligation of the administrations to guarantee this right. The most notably innovations introduced by the new law are:

- New rights for citizens vis-à-vis the public administrations;
- The creation of the position of a "users' advocate" (Defensor del usario de la administración electrónica)
- The obligation of public administrations to implement these regulations by 2009;
- Access to e-Government services is to be ensured from everywhere and at all times.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts of the Directorate of the Center for the Protection of National Infrastructure who validated the content of this chapter.

## 1 CRITICAL SECTORS

Sweden does not yet have an official definition of CII or CIIP. However, CIIP can be understood as the protection of essential electronic information services, such as IT systems, electronic communications, and radio and television services. CIIP has not only a technical, but also a human aspect. The following are regarded as critical information infrastructure sectors:[1]

- Air Control Systems,
- Supervisory Control And Data Acquisition (SCADA) systems in use within water, transport, and industry,
- Financial Systems,
- National Command Systems,
- Telecommunication Systems,
- The Internet.

Disruption of any of these systems would have immediate serious consequences for society.

[1]Information provided by the country experts.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

CIIP issues have been on the political agenda in Sweden for many decades. Measures to increase the robustness and security of critical national infrastructures have been implemented since World War II. The vulnerability problems associated with society's increasing dependence on IT and information infrastructures were identified early on as a matter of national security. In addition, management of IT-related vulnerabilities has been discussed since the early 1970s. The present Swedish CIIP policy is derived from these historical developments and from some more recent initiatives described below. The CIIP area in Sweden is currently in a transformative phase. The functions and responsibilities of governmental agencies are under review.

### 2.1 Commission on Vulnerability and Security

Following a decision on 23 June 1999, the Swedish government authorized the minister for defense to appoint a special investigator to head a commission of inquiry, with a mandate to analyze and submit proposals for a more integrated approach to civil defense and emergency preparedness planning [1]. The findings and proposals of the Commission on Vulnerability and Security, as presented in May 2001, have been a most important step in the implementation of a new structure for defense and emergency preparedness planning in Sweden.

The commission suggested several strategic measures for improving the general stability of critical technical infrastructure.[2] In its final report, the commission also proposed measures specifically designed to enhance information assurance and improve protection against information operations. The commission's view was that the central government must assume responsibility in these areas. At the same time, the commission emphasized that all managers and system owners are responsible for securing their own systems against computer intrusions and other types of IT-related threats. The role of the government should be to support these activities and to provide functions and facilities that exceed the financial capabilities of other sectors in society. In 2005, it submitted its final report to the Swedish government [3].

### 2.2 Bill on Swedish Security and Preparedness Policy

In March 2002, the government presented its first bill on Swedish security and preparedness policy. The bill was, to a large extent, based on the findings and proposals of the Commission on Vulnerability and Security.

The bill presented the government's framework for a new planning system to prepare for major societal crises and for activities related to a potential threat of war. Furthermore, the bill gave an account of how the crisis management structure would be strengthened. All of this has implications for the security of critical infrastructures in general, and of critical information infrastructures in particular.[3]

[2]Such as cross-sector activity, security standards, Computer Emergency Response Teams, a coordinating body for IT security, an information security technical support team, an intelligence and analysis unit, research and development, international cooperation, a system for the certification of IT products, and more [2].
[3]Information provided by expert of SEMA.

### 2.3 Information Security Policy proposals by the Committee on Information Assurance

The Swedish government on 11 July 2002 instituted the Committee on Information Assurance in Swedish Society. The committee's brief was to present an assessment of information protection requirements in critical sectors of society, and to make a proposal on organizational matters of the Swedish signals protection service.

After monitoring the implementation of the information assurance measures, the Committee on Information Assurance in Swedish Society has presented its proposal for a national strategy on information assurance [4] and also an organization plan [5]. The committee's proposal was processed by the government by March 2006.

### 2.4 SEMA action plan for information security

In January 2007, the Swedish Emergency Management Agency (SEMA) was commissioned by the government to prepare a proposal for a plan of action for implementing and administering the nation's strategy for information security. The plan was submitted to the government in April 2008 and consists of 47 proposed measures. The following four areas have been designated as priorities.[1]

- Improved sector-wide and cross-sectoral work is needed for civil information security. All-embracing directives for the field of information security applying to all government agencies should be prepared. At the same time, sector-specific responsibility must be clarified. Furthermore, there must be opportunities to provide practical recommendations to other civil sectors;
- A fundamental security level must be established for information security. Such a basic level is a prerequisite for being able to secure the information assets that have become increasingly fundamental for both trade and industry and the public sector;
- Society must be able to deal with extensive IT-related disturbances and emergencies. An operative national coordinating function should therefore be established;
- There are competence deficiencies in the field of information security at all levels of society. The rapid development also implies that competence deficiencies on the part of individual users have increasingly greater consequences. For this reason, several proposals are submitted that jointly constitute a broad program to raise competence in the field.

The plan of action proposes measures that address the problems reported in SEMA's annual situational assessment. The proposed measures also take into consideration, among other things, the Commission on Information Security's report Secure Information; the government bill for improved emergency preparedness; and the committee directive for a new agency with responsibility for emergency preparedness and security matters.[1]

### 2.5 Organizational Overview

Swedish government agencies report to their respective ministries, but are formally subordinated only to collective cabinet decisions. The various agencies and organizations in charge of CIIP are presented below under the heading of the ministry they are affiliated with, including the Ministry of Defense; the Ministry of Industry, Employment and Communication; and the Department of Justice.

The bill on Swedish security and preparedness policy contains a few changes of tasks and responsibilities for the actors within the area of information assurance. The bill relates to other issues beyond CIIP. The Committee on Information Assurance in Swedish Society has evaluated the CIIP work and suggested the changes to be introduced in the bill. The suggested changes are presented in the following chapter in connection with each actor. Importantly, in 2009, SEMA and other agencies will be replaced by a new agency called the Swedish Civil Contingencies Agency (SCCA) that will report to the Ministry of Defense; hence, there will be major changes in the overall CIIP system.

The public-private partnership initiatives in Sweden currently include SEMA's efforts to promote interaction between the public and the private sector, the Industry Security Delegation (NSD), and the Swedish Information Processing Society (DFS).

## 2.6 Public Agencies

***2.6.1 The Swedish Civil Contingencies Agency (SCCA).*** As of 1 January 2009, a new national government agency will be established with an all-encompassing task with regard to civil contingencies, that is to say, its work will cover the whole spectrum of contingencies from everyday road traffic accidents, fires, chemical emergencies, power cuts, and other technical failures to even more serious emergencies such as bomb threats and other hostile attacks, epidemics, natural disasters, and war. The responsibilities of this new agency will include information security. SEMA's current work on CIIP will be expanded, and the new agency will be given the authority to issue binding regulations.

The English designation of this new authority will be the Swedish Civil Contingencies Agency (SCCA), and it is being formed from three existing national government authorities, all of which will be closed down at the end of 2008, namely SEMA, the Swedish Rescue Services Agency (SRSA), and the National Board of Psychological Defence (SPF).

Within the Cabinet Offices, cross-departmental work is being performed on ways to implement the findings of the SEMA action plan and to reform CIIP in Sweden further.[1]

***2.6.2 The Swedish Emergency Management Agency (SEMA).*** The Swedish Emergency Management Agency (SEMA) [6] is responsible for the co-ordination of national information assurance at the policy level. This includes analyses of the development of society and the interdependency of critical societal functions. The agency further promotes interaction between the public and private sectors and coordinates and initiates research and development in the area of emergency management. It also has overall governmental responsibility for information assurance in Sweden. The Information Assurance and Analysis Department at SEMA manages these tasks. Its main activities include:

- Maintaining an updated overall picture of society's information security in terms of threats, vulnerabilities, protective measures, and risks; once a year, it presents an annual assessment of information assurance in Sweden to the government;
- Hosting various forums in order to develop a common national culture of information assurance. Certain forums are solely intended for the private sector or the public sector, respectively, while there are also combined forums for the public and private sectors;
- Developing public-private partnerships;

- Gathering, analyzing, and disseminating open-source information related to information assurance;
- The development of preventive IT security recommendations (consistent with ISO/IEC 17799) to support the IT security activities of other organizations;
- Initiating research and development in the area of different important societal systems and summarizing the respective risk and vulnerability assessments;
- Managing the Board of Information Assurance;
- Participating as a member in several international forums.

In its guidelines for emergency planning for 2006 and 2007 and in its annual report on information security in Sweden for 2008, SEMA points out that there is much work to be done to raise standards of information security in Sweden to an acceptable level. SEMA also reiterates the importance of protecting the nation's critical infrastructures. Dealing with the risks of technical collapses in electricity, telecom, and IT systems that are vital for society must be given priority, according to SEMA.[4] As far as the critical infrastructure (especially the technical infrastructure) is concerned, actions designed to mitigate the consequences of serious emergencies are given priority over preventive measures with the purpose of increasing robustness.[4]

SEMA recently conducted a case study on the topic of large-scale internet attacks. The study was prompted by the attacks that Estonia was subjected to in 2007. The study aims to analyze how Sweden would handle a similar attack [7].

***2.6.3 SEMA/Information Assurance Council.*** The Information Assurance Council was established to support SEMA's activities in the area of information assurance. This council will create a network of skilled experts from a variety of important organizations in the area. The council replaced the earlier Cabinet Office Working Group on Information Operations [8]. The council's primary assignment is to assist the senior management of SEMA by supplying:

- Information about trends in research and development in the area of information assurance;
- Suggestions and viewpoints concerning the direction, prioritizing, and realization of SEMA's activities in the area of information assurance.

***2.6.4 SEMA/Agency Cooperation Forum.*** The SEMA/Agency Cooperation Forum consists of seven agencies, and the main task of this forum is to secure the information assets of Swedish society in order to obtain a certain level of confidentiality, integrity, and availability. This is done through information exchange and cooperation. The focus areas of this group are:

- Strategy and regulatory framework;
- Technical and standardization issues;
- Information assurance issues at the national and international levels.

***2.6.5 The Swedish Defense Materiel Administration (FMV) and the Certification Body for IT Security (CSEC).*** The Swedish Defense Materiel Administration (FMV) [9] is the procurement agency for the armed forces. The FMV has been involved in the

[4]Information provided by the country expert.

area of IT security evaluations since 1989, performing in-house evaluations of equipment intended for use by the armed forces.

In the summer of 2002, the FMV was tasked by the government with establishing a national scheme for the evaluation and certification of IT security products to be used within Swedish governmental organizations. The certification body is now established as an independent entity within the FMV and is known as the Swedish Certification Body for IT Security (CSEC). Its work includes the production of quality manuals, descriptions of responsibility, descriptions of processes for licensing of evaluation laboratories, rules for implementation of certificates, and training of certification staff and evaluation companies [9].

***2.6.6 FRA / Information Security Technical Support Team.*** The Information Security Technical Support Team is associated with the Swedish National Defense Radio Establishment (FRA) [10], which is the Swedish signals intelligence organization. It is a civilian agency directly subordinated to the Ministry of Defense. The Information Security Technical Support Team consists of 20 experts in the field of IT security. The team is specifically intended to support:

- National crisis management where IT-security qualifications are required;
- Identification of individuals and organizations involved in IT-related threats against critical systems.

On request, the team supports the Swedish authorities, agencies, and state-owned corporations that are responsible for critical functions in Swedish society with IT-security expertise and services. The customized services consist of penetration tests, forensic computer investigations, source code analysis, audits, risk analyses, etc. The team co-operates on a regular basis with the national and international IT security community.

The changes suggested by the Committee on Information Assurance in Swedish Society concerning FRA are:

- Technical responsibility for coordination in the field of information security;
- Responsibility for signals protection;
- Creation of a group that can support initiatives in national crises with an IT component and in the case of related threats to important public systems.

***2.6.7 The Swedish Armed Forces.*** The Swedish Armed Forces [11] must be able to quickly respond to different types of threats and risks. The Swedish parliament has therefore decided to develop the armed forces according to the concept of network-based defense. This places a great demand on the information infrastructure in terms of availability and security. The armed forces are therefore heavily involved in research and development in areas such as IT security and information infrastructures.

The Swedish Military Intelligence and Security Service handles operational IT security in the armed forces during peacetime. In addition, the National Communications Security Group (TSA) offers advice and inspections of cryptographic systems to Swedish defense organizations and industries.[1]

***2.6.8 Center for Asymmetric Threat Studies (CATS).*** The National Center for IO/CIP Studies (CIOS) is now broadening its perspective from Information Operations (IO) to include terrorism, e.g., cyber-terrorism. In order to do so, the center's name has been

changed to "Center for Asymmetric Threat Studies (CATS)" [12]. CATS is located at the Swedish National Defense College [13]. It conducts research and policy development in the fields of CIIP, IO (Information Operations), PSYOPS (psychological warfare), and CIP. Research at CATS is funded by the Ministry of Defense and the Swedish Emergency Management Agency (SEMA).

***2.6.9 The Swedish Defense Research Agency (FOI).*** The Swedish Defense Research Agency (FOI) [14] focuses on research and development in the fields of applied natural sciences and political sciences, such as security policy analysis. At the Division of Defense Analysis, the Critical Infrastructure Studies Unit (CISU) research group is carrying out a long-term research program on CIP sponsored by SEMA, in cooperation with Systems Analysis and IT Security – another FOI department. This department has acquired a deep knowledge of commercial and military IT systems and applications.

***2.6.10 The Swedish National Post and Telecom Agency (PTS).*** The Swedish National Post and Telecom Agency (PTS) is a government authority that monitors all issues relating to ICT and postal services. One of its key tasks is to ensure the development of functioning postal and telecom markets. Within the PTS, the Department of Network Security is responsible for security issues concerning ICT.

The Department of Network Security is tasked with monitoring developments related to security issues and with implementing measures to reduce the threats to ICT from sabotage and terrorism. Emergency measures are planned in consultation with the ICT operators, the Swedish armed forces, and other agencies. As an example, critical nodes in the ICT structures are hardened, and all nodes that are crucial for running the ".se" domain autonomously have been installed within Sweden's borders. The Swedish IT Incident Center (see chapter on Early Warning and Public Outreach) is associated with this department.

***2.6.11 The Swedish National Police Board (NPB).*** The Swedish National Police Board (NPB) [15] is the central administrative and supervising authority of the police service. The NPB administers the National Criminal Police and the Swedish Security Service. Within the NPB, the IT Crime Squad has expert knowledge in investigating IT crime. This group supports the local Swedish police departments in IT crime investigations, participates in the education of parts of the judicial system, and assembles and communicates information about IT crime. The Internet Reconnaissance Unit is linked to this squad.

Additionally, the Swedish Security Service (SÄPO) has the fundamental duty of preventing and detecting crimes against the security of the realm. SÄPO is engaged in four main fields: protective security (including personal protection), counter-espionage, counter-terrorism, and protection of the constitution. Whenever IT-related criminal activity touches upon these fields, the Swedish Security Service is involved.

## 2.7 Public-Private Partnerships

***2.7.1 SEMA's Private Sector Partnership Advisory Council and Board of Information Assurance.*** SEMA promotes interaction between the public sector and the private sector, and works to ensure that the expertise of non-governmental organizations (NGOs) is taken into account in emergency management.

There are two advisory councils connected to SEMA: the Private Sector Partnership Advisory Council and the Board of Information Assurance.

SEMA has two forums for sharing information between private and public actors in the area of information assurance. The two established forums in the area of Supervisory Control And Data Acquisition (SCADA) and the financial sector. In these forums, the actors share information about threats and vulnerabilities in order to learn from each other. This concept is largely based on the British model for Information Exchange (IE).[5]

***2.7.2 The Industry Security Delegation (NSD).*** The Industry Security Delegation (NSD) [16] is part of the Confederation of Swedish Enterprise [17], whose objective is to increase cooperation between enterprises, organizations, and authorities, and to promote comprehensive views on vulnerability and security issues. The overall goal of this network structure is to enhance security and risk awareness among the general public and in the business sector. The NSD arranges courses in information assurance as well as crisis and risk management to help its members improve security.

***2.7.3 The Swedish Information Processing Society (DFS).*** The Swedish Information Processing Society (DFS) [18] is an independent organization for IT professionals with 32,000 members. The DFS owns the SBA brand of security products (the abbreviation stands for SårBarhetsAnalys, or "vulnerability assessment" in Swedish), which are focused on risk analysis and information security. SBA is regarded as the de-facto Swedish standard.

## 3 EARLY WARNING AND PUBLIC OUTREACH

### 3.1 PTS/The Swedish IT Incident Centre (SITIC)

In May 2002, the Swedish government tasked the Swedish National Post and Telecom Agency (PTS) with establishing the Swedish IT Incident Centre (SITIC) [19]. The center was officially opened on 1 January 2003 and can be considered to be the Swedish government CERT. SITIC supports national activities for protection against IT incidents by:

- Operating a system for information exchange on IT incidents between both public and private organizations and SITIC;
- Rapidly communicating to the public information on new problems that can disrupt IT systems;
- Providing information and advice on preventive measures;
- Compiling and publishing incident statistics as input to the continuing improvements of preventive measures.

## 4 LAW AND LEGISLATION

### 4.1 The Swedish Penal Code (SFS 1962:700)

The Swedish Penal code, in Chapter 4, Section 9 c, states that any person who, in cases other than those defined in Section 8 and 9, unlawfully obtains access to a recording for automatic data processing or unlawfully alters or erases or inserts such a recording in a

[5]Information provided by an expert.

register, shall be sentenced for breach of data secrecy to a fine or imprisonment for no more than two years, unless the deed is punishable under the Criminal Code or the 1990 Protection of Trade Secrets Act. A recording in this context includes even information that is being processed by electronic or similar means for use through automatic data processing (Law 1998:206). Attempts and preparations to do so shall be punished as stated in Chapter 23 of the Criminal Code, unless the completed act would have been regarded as a petty crime. A proposal for amendments of the Act of the Penal Code has been presented. According to the draft, denial of service attacks (DoS) will be made a criminal offence.

Other important legal texts in Sweden in this context are the Personal Data Act (SFS 1998:204) and the Electronic Communications Act (SFS 2003:389).

### 4.2 The Electronic Communications Act (SFS 2003:389)

In its report, the Commission on Vulnerability and Security [20] concluded that there was a need for legislative amendments in order to support the proposals with respect to IT security and protection against information operations. A particular need for legislative amendments is seen in the following areas:

- Statutory and administrative provisions relating to the activities of local authorities and national administrative boards during major crises;
- The possibility of reallocating resources in the health services during major crises;
- Stricter safety regulations and more effective supervision of the power supply sector.

The government has decided to review the legislation relevant to CIIP and emergency management.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Linda Englund and Jan Lundberg of the Swedish Emergency Management Agency, who validated the content of this chapter.

## 1 CRITICAL SECTORS

Since the end of the Cold War, risks and vulnerabilities involving information and communications technologies have become a growing issue in the Swiss debate on security policy. The high density of information and communication technology (ICT) in Switzerland's public and private sectors offers a high potential for vulnerabilities. Critical

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

Infrastructure Protection (CIP) in general and the protection of information infrastructures in particular are therefore of high relevance for Swiss security policy.

In July 2007, the Federal Council approved the First Report to the Federal Council on the Protection of Critical Infrastructures, submitted by an interdepartmental working group under the lead of the Federal Office for Civil Protection (FOCP) [1]. This report defines critical infrastructures as "those infrastructures whose disruption, failure, or destruction would have a serious impact on the public health, the environment, the political affairs, the security, and the economic and social well-being of a population" [2]. The report defines the following ten sectors:

- Public Administration,
- Chemical Industry,
- Energy,
- Waste Disposal,
- Financial Services,
- Public Health,
- Information and Communication Technology,
- Water and Food,
- Public Safety, Rescue and Emergency Services,
- Transport [3].

These ten sectors are further divided into 31 sub-sectors. In May 2008, the working group launched a project to define criteria to identify critical elements and parts of the Swiss infrastructure.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

Since the end of the 1990s, several important steps have been taken in Switzerland to improve the management of CIIP. Strategic exercises and new threats such as the Millennium Bug have highlighted the importance of information assurance. From the beginning, the private sector was involved in the development of policies for information assurance and CIIP.

### 2.1 Strategic Leadership Exercise

Two strategic exercises were crucial for the development of Swiss protection policies in the field of information security:

- A key experience, and in fact the impetus for many later steps in Switzerland, was the Strategic Leadership Exercise in 1997 (SFU 97).[1] The exercise dealt with the revolution in information technologies and related challenges to modern society, politics, economics, and finance, as well as to other critical sectors [5]. The exercise

[1]This exercise was organized by a unit of the Swiss Federal Chancellery called "Strategische Führungsausbildung" (SFU), which is now called "Federal Crisis Management Training" (CMT). The unit is responsible for the periodical training of federal decision makers [4].

revealed that Switzerland's CI was facing new threats. For the first time, the idea of developing an early-warning system for threats to information security was raised.

- After a two-year planning process, the Strategic Leadership Training in 2001 conducted the three-day exercise INFORMO 2001. The goals were to review the information assurance process established after 1997 and to train a newly-established Special Task Force on Information Assurance.

### 2.2 Information Assurance Policy

The first Concept of Information Assurance was elaborated by the Information Society Coordination Group (ISCG) in 2000. It recommended the establishment of a crisis management system of a special task force on "Information Assurance" [6]. This strategy of the Swiss Federal Council was accompanied by a large number of parliamentary initiatives and was further developed.

In December 2001, the Swiss Federal Strategy Unit for Information Technology (FSUIT) presented a four-pillar model for information assurance in Switzerland [7]. Since then, the Swiss CIIP policy has been based on the following four pillars:

- *Prevention.* Suitable preventive measures must be implemented to limit the number of incidents;
- *Early recognition.* Dangers and threatening situations have to be recognized as early as possible to provide the necessary defensive measures or to avoid particularly vulnerable technology. The Reporting and Analysis Center for Information Assurance (MELANI) is the main actor in this field.
- *Crisis management.* The effects of disruptions on society and the state must be kept to a minimum. The major actors in charge for this are the Special Task Force on Information Assurance (SONIA), together with MELANI and the Federal Office for National Economic Supply (NES), which includes the ICT Infrastructure Unit.
- *Technical problem solution.* The technical causes of the disruption must be identified and corrected. This area is covered by MELANI together with the experts in charge in the private sector.

It is a tenet of Swiss information assurance policy that all four of the above pillars, or principles, must be taken into account to achieve a complete and strong system of CIP/CIIP.

### 2.3 Risk Analysis: InfoSurance and the Federal Office for National Economic Supply (NES)

The InfoSurance Foundation (see the chapter on Organizational Overview) started its work in 2002 with the initiation of a nation-wide risk analysis covering various sectors and branches such as telecommunications, finance, energy (electricity), emergency and rescue services, transportation and logistics, and health care. The risk analysis focuses on interdependencies of information infrastructures both within and between the various sectors and on potential preventive measures that can be derived from the analysis. Since 2004, the NES has been responsible for working out and reworking the risk analysis in cooperation with the private-sector experts.

### 2.4 Report on Critical Infrastructure Protection

Based on a first analysis—which was requested by the Control Delegation of the Federal Assembly—on the protection and safety of critical infrastructures in Switzerland, the Federal Council decided in 2005 to launch an interdepartmental CIP project. The FOCP was mandated to establish a working group that includes all relevant federal agencies.[2] It is the goal of the working group to improve the collaboration between all offices involved with CIP and ultimately to establish a national CIP strategy together with the private sector.

In 2007, the FOCP submitted a first report on CIP in Switzerland to the Federal Council [8]. The report was developed in close cooperation with all relevant federal agencies. It represents a first major step towards the elaboration of a national strategy. It establishes a common understanding of the problem in that it clarifies key concepts and identifies the critical infrastructure sectors relevant for Switzerland. It highlights threat scenarios from natural and technical hazards to violent and armed conflicts. It further defines the need for future action in the area of CIP. The appendix lists previous CIP activities and compares policies on international level, and highlights former and ongoing CIP developments of the relevant federal agencies.

The FOCP will submit a follow-up report to the Federal Council in spring 2009 and will elaborate a national CIP strategy by 2011.[3]

## 3 ORGANIZATIONAL OVERVIEW

The issue of CIP/CIIP involves agencies from different departments as well as the cantonal and local governments. The first part of this section provides an overview of the most important federal agencies. In the second part, the most important public-private partnerships are listed. Switzerland has a long-standing tradition of public-private collaboration. Historically, this is due to the tradition of part-time service in a strong militia system, both in the military and in politics. Accordingly, there are several important public-private partnerships in the field of CIP and CIIP (those partnerships with an early-warning function are listed in the section on Early Warning and Public Outreach).

### 3.1 Public Agencies

***3.1.1 Federal Office for Civil Protection (FOCP).*** The Federal Office for Civil Protection (FOCP) [9] is part of the Federal Department of Defence, Civil Protection, and Sports (DDPS). It supports the cantons and municipalities—which bear the principal responsibility for civil protection services in the intervention phase—in their efforts in that regard. As the responsible federal agency in the areas of both manmade and natural disasters, the FOCP ensures cooperation between the federation, the cantons, and the municipalities. The legal underpinnings of civil protection, especially the explicit aim of "protecting the population and its vital resources", are of particular relevance to critical infrastructure protection.[4]

[2]Currently the working group comprises 23 offices from all seven federal departments, including the Federal Chancellery. The working group usually meets four times a year. Its work is supported by sub-working groups where the actual CIP projects are conducted (information provided by an expert).

[3]Information provided an expert.

[4]Art. 2, Federal Law of Civil Protection.

In the field of CIP, the FOCP was therefore mandated in 2005 to coordinate the CIP interagency activities. As mentioned above, the FOCP established a working group and issued a first report for the attention of the Federal Council, summarizing the current state of work of the working group. A national CIP strategy will be elaborated by 2011.

***3.1.2 Federal Strategy Unit for Information Technology (FSUIT).*** One of the main bodies on CIIP in Switzerland is the Federal Strategy Unit for Information Technology (FSUIT) [10]. It is part of the Swiss Federal Department of Finance (FDF). The FSUIT reports to the FDF and is charged with producing instructions, methods, and procedures for the federal administration's information security. It collects data on incidents within the Swiss federal government and is responsible for the Special Task Force on Information Assurance (SONIA) and for the Reporting and Analysis Center (MELANI). The FSUIT itself runs the Swiss Government Computer Emergency Response Team GovCERT.ch (see the chapter on Early Warning and Public Outreach).

***3.1.3 Federal Office of Communications (OFCOM).*** The Federal Office of Communications (OFCOM) [11] is the main regulatory body in the field of telecommunications and ICT in Switzerland. The OFCOM studies various aspects of the information revolution. It includes consumer protection and management of the frequency spectrum as well as conformity assessment rules in the telecommunications equipment area. The OFCOM deals with risks affecting the information society, such as the formation of a new two-tier society, information overload, and the resulting inability to analyze problems and make decisions, and new opportunities for the manipulation of information of a technical, political, or economic nature.

***3.1.4 Federal Office for National Economic Supply (NES).*** The Federal Office for National Economic Supply (NES) [12], which includes the ICT Infrastructure Unit (see below, in the section on Public-Private Partnerships), reports to the Swiss Federal Department of Economic Affairs. Its main task is to ensure that the Swiss population is able to obtain vital goods and services at all times. The NES provides governmental support when the private sector is unable to resolve supply problems of vital goods and services on its own. However, measures to ensure a steady flow of supplies to the national economy would only be undertaken if the free-market system were seriously disrupted. In the four pillars of the Swiss information assurance policy, the NES plays an important strategic role in the fields of prevention and crisis management.

***3.1.5 Federal Office of Information Technology and Telecommunication (FOITT).*** The Swiss Federal Office of Information Technology, Systems, and Telecommunication (FOITT) [13] is part of the Swiss Federal Department of Finance. Its responsibilities include security and emergency preparedness for the federal administration's information systems on an operational level.

***3.1.6 Coordination Unit for Cybercrime Control (CYCO).*** Citizens can report suspected internet crimes, including unlawful access to IT systems, spreading of computer viruses, destruction of data, and similar offenses to the Swiss Coordination Unit for Cybercrime Control (CYCO) [14], which is part of the Federal Office of Police (fedpol). The offenses reported are then forwarded to the respective national or foreign prosecution authorities. CYCO also scans the internet for criminal content and is responsible for in-depth analysis of cyber-crime. In addition, CYCO collaborates closely with MELANI.

### 3.2 Public-Private Partnerships

***3.2.1 InfoSurance Association.*** InfoSurance was established as a foundation in 1999 by a number of companies with the support of the Swiss government. Today, it is an association that aims to increase awareness of the information assurance issue and to establish networks of cooperation among various players from both the public and the private sectors. The association aims at creating a closely-linked network that promotes the organizational and structural conditions for recognizing and analyzing Switzerland's growing dependency on information technologies and the associated risks. The target group of InfoSurance consists of SMEs, and the focus lies on prevention [15].

***3.2.2 Federal Office for National Economic Supply (NES): ICT Infrastructure Unit (ICT-I).*** Another important public-private partnership is the NES. It works in close cooperation with the private sector as well as with cantonal and municipal authorities. The federal government has requested that the NES deal with all prolonged disruptions of the information and communications infrastructure affecting the whole of Switzerland (ICT Infrastructure Unit, ICT-I) [16]. The NES also conducts sector-specific risk analysis in cooperation with the private-sector experts involved. These analyses were formerly conducted by the InfoSurance association.

***3.2.3 CLUSIS.*** The non-profit association CLUSIS (Club de la sécurité des systèmes d'information—Suisse) [17] has existed in Switzerland since 1989 and represents about 230 members, including Swiss public administrations, IT suppliers, providers, banks, industries, consultants, etc. CLUSIS organizes seminars related to information security practices and technologies, issues whitepapers and publications, and is involved in education. The aim is to provide networking opportunities for their members and to share experiences. CLUSIS mainly covers the French- and Italian-speaking parts of Switzerland.

## 4 EARLY-WARNING APPROACHES AND PUBLIC OUTREACH

In addition to the public-private partnerships listed above, collaboration between government agencies and private companies is also essential for early warning and public outreach.

### 4.1 The Reporting and Analysis Center for Information Assurance (MELANI)

On 29 October 2003, the government decided to create a center for CIIP that would collect information on the security of the IT infrastructure, especially of the internet. This new center, called the Reporting and Analysis Center for Information Assurance (MELANI) [18], has been operational since October 2004 and is now the core of the Swiss CIIP early-warning system. It plays a role in all four pillars of the Swiss information assurance policy (prevention, early warning, crisis management, and technical problem solution) and is the central office for CIIP in Switzerland. In addition to its own investigations, it depends on close cooperation with the public and private sectors.

It is designed as a cooperative undertaking between the Federal Strategy Unit for Information Technology (FSUIT) and the Federal Office of Police (fedpol). These two partners of MELANI have the following main tasks [19]:

- The FSUIT is responsible for strategic issues and the management of MELANI. Since 1 April 2008, it has also run the Swiss government's Computer Emergency Response Team (GovCERT.ch). GovCERT.ch is MELANI's technical competence center, and is responsible for dealing with technical incidents, in particular concerning the internet and computer operating systems;
- The fedpol operates the MELANI analysis center and is responsible for collecting, condensing, and presenting operational information from different sources in the public and private sectors.

MELANI offers warnings and advice for the broader public via a website, but also runs a special program for the owners and operators of critical infrastructures. For members of the so-called "closed constituency" MELANI organizes workshops, disseminates detailed warnings, and operates a 24/7 help-desk. The "closed constituency" of MELANI can be described as a dedicated public-private partnership for CIIP.

The cooperation between the involved partners as well as the conceptualization of MELANI as a public-private partnership has proven to be successful. By pooling existing resources, new threats to information security can be confronted effectively and effectively. On 24 January 2007, the Federal Council decided definitely to establish MELANI as a federal office for information assurance [20].

### 4.2 Special Task Force on Information Assurance (SONIA)

The Special Task Force on Information Assurance (SONIA) [21] is also directed by the FSUIT. SONIA is a crisis-management organization and constitutes the core element of the third pillar of the Swiss information assurance policy, namely damage limitation. Its main task is to advise the Swiss Federal Council and senior management representatives from the private sector in crisis situations and to act as a link between the public and private sectors. SONIA would be activated after a breakdown in the information and communication infrastructure that resulted in (massive) disruptions in CI. Unlike MELANI, it is not a permanent body, but would only be convened for damage limitation in genuine crises.

SONIA is mainly supported by the following organizations:

- The ICT Infrastructure Unit of NES, to raise awareness and to give guidance in threat and risk analysis, and to establish contacts among the experts in charge in the private sector;
- MELANI, as a provider of reliable information about a possible imminent threat and its consequences, and as an information base in case of a crisis [22].

## 5 LAW AND LEGISLATION

### 5.1 Swiss Penal Code

A number of articles in the Swiss Penal Code are of relevance in the context of CIIP:

- Article 143 (unauthorized procurement of data);
- Article 143 bis (unauthorized access to a computing system): This article states that any person who, by means of a data transmission device, gains unauthorized access

to a computing system belonging to others that is specially protected against access by the intruder shall be punished by imprisonment or a fine if a complaint is made;[5]

- Article 144 (damage to property): The article states that any person who damages, destroys, or renders unusable any property belonging to others shall be punished by imprisonment or a fine if a complaint is made;[5]
- Article 144 bis (damage to data): The article states that any person who alters, deletes, erases, or renders unusable data stored or transferred by electronic or similar means without authorization shall be punished by imprisonment or a fine if a complaint is made;[5]
- Article 147 (fraudulent use of a computer): The article states that any person who, with the intention of unlawfully obtaining financial rewards for himself or another, interferes with an electronic procedure through the unauthorized use of data shall be punished by community service of up to five years or imprisonment.[5]

Switzerland's laws against virus creation and the use of malicious software in general are widely applicable. However, the structure of the Swiss legal system makes prosecution difficult, due to the complexities of different laws (comprising laws on both the federal and cantonal level) and law enforcement procedures.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts of the Federal Office for Civil Protection, the Reporting and Analysis Center for Information Assurance, and the Federal Office for National Economic Supply, who validated the content of this chapter.

# UNITED KINGDOM

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 CRITICAL SECTORS

In the United Kingdom, the critical national infrastructure (CNI) comprises those key elements of the national infrastructure that are crucial to the continued delivery of essential services to the UK. Without these key elements, essential services could not be delivered and the UK could suffer serious consequences, including severe economic damage, grave social disruption, or even large-scale loss of life [1]. Many of the critical

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

services that are essential to the well-being of the UK depend on IT and are provided by both the public and private sectors. Nine sectors are considered to deliver "essential services". These are outlined below:

- Communications (Data Communications, Fixed Voice Communications, Mail, Public Information, Wireless Communications),
- Emergency Service(Ambulance, Fire and Rescue, Coastguard, Police),
- Energy(Electricity, Natural Gas, Petroleum),
- Finance(Asset Management, Financial Facilities, Investment Banking, Markets, Retail Banking),
- Food(Produce, Import, Process, Distribute, Retail),
- Government and Public Services (Central, Regional, and Local Government; Parliaments and Legislatures; Justice; National Security),
- Public Safety (Chemical, Biological, Radiological, and Nuclear (CBRN) Terrorism; Crowds and Mass Events),
- Health (Health Care, Public Health),
- Transport (Air, Marine, Rail, Road),
- Water (Mains Water, Sewerage).

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

The UK government aims to protect the CNI from both two kinds of threats: physical attacks against physical installations and electronic attacks against computers or communications systems [2]. It has therefore developed a National Information Assurance Strategy. Another important field of action is data security. In reaction to a data security incident in 2007, the government has elaborated data security guidelines.

### 2.1 National Information Assurance Strategy

The UK Cabinet Office produces and maintains the National Information Assurance Strategy [3]. This was first produced in 2003 by the Central Sponsor for Information Assurance (CSIA), a unit within the Cabinet Office, and aims to provide ongoing assurance to the government that the risks to information systems and the information they hold are appropriately managed. The CSIA, with partner organizations, coordinates and sponsors work programs to deliver the strategy's recommendations.

Information assurance (IA) is defined as the confidence that information systems will protect the information they carry and will function as they need to, when they need to, and under the control of legitimate users. The CSIA has a lead role in helping governments to improve IA. That involves the following tasks:

- Enabling the government to deliver public services through the appropriate use of information and communications technology (ICT);
- Strengthening the UK's national security by protecting information and information systems at risk of compromise;
- Enhance the UK's economic and social well-being as the government, businesses, and citizens realize the full benefits of ICT.

Most importantly, the strategy recognizes that within an increasingly interdependent and interconnected information infrastructure, the government must concern itself with the confidentiality, availability, and integrity of all information systems [3].

### 2.2 Government Data Security

Following a data security incident in November 2007, the prime minister asked the Cabinet Office to review data handling procedures in all government departments. An interim report was presented to parliament on 20 December 2007, and the final report is expected in 2008. The government has already accepted a number of recommendations in the interim report to bring about greater transparency, increased monitoring, improved guidance, and better mandatory training.[1]

A number of other reviews are being conducted across the UK government that will have an effect on data security measures. The Poynter Review [4] is looking into the specific incident of the loss of child benefit data at HM Revenue & Customs (HMRC)[2] and is expected to report in 2008 [5]. In October 2007, before the HMRC-incident, the government had already identified the need to do more to protect the data it controls, and the prime minister commissioned the independent Walport/Thomas review on the use of information in both the public and private sectors. The review is expected to report in the first half of 2008. The Burton report, looking at data losses in the Ministry of Defence, is also due to be published in 2008.[1]

## 3 ORGANIZATIONAL OVERVIEW

In the UK, the main responsibility for CIIP lies with the home secretary [6]. However, a number of other departments play a role in the protection of the various CNI sectors and contribute resources and expertise to the UK CIIP effort. These contributions are coordinated by the Centre for the Protection of the National Infrastructure (CPNI) [7]. CPNI was formed on 1 February 2007 from the merger of the National Infrastructure Security Co-ordination Centre (NISCC) and the National Security Advice Centre (NSAC).

CIIP policy is developed and delivered by several government departments and bodies including CPNI, the Central Sponsor for Information Assurance (CSIA), the Civil Contingencies Secretariat (CCS), the Cabinet Office Security Policy Division, the Home Office, and the Government Communications Headquarters (GCHQ).

Responsibility for the provision of advice on physical protection to the CNI is shared between CPNI, the Security Service, and the police. CSIA is in charge of the UK's broader information assurance strategy, which deals with all aspects of the Information Society. The coordination of the government's contingency and emergency response effort (regardless of the cause of the disruption) is the responsibility of the CCS (part of the Cabinet Office).

Furthermore, there are several public-private partnerships in the field of CIIP. The government collaborates closely with the private sector. The CPNI shares information with the owners and operators of CNI in so-called Information Exchanges.

[1]Information provided by an expert.

[2]Her Majesty's Revenue & Customs (HMRC) is responsible for collecting the bulk of tax revenue and paying tax credits and child benefits. See: http://www.hmrc.gov.uk/. For more information on the incident, see: http://www.infosecurity-magazine.com/news/071121_hmrc_bamford.html.

### 3.1 Public Agencies

***3.1.1 Centre for the Protection of National Infrastructure (CPNI).*** Since 1 February 2007, the Centre for the Protection of National Infrastructure (CPNI) has worked to protect the UK's CNI from both physical and electronic attack. CPNI provides integrated (combining information, personnel and physical) security advice to the businesses and organizations that make up the national infrastructure. Through the delivery of this advice, it protects national security by helping to reduce the vulnerability of the national infrastructure to terrorism and other threats.

CPNI advice is targeted primarily at the critical national infrastructure (CNI)—the key elements of the national infrastructure that are crucial to the continued delivery of essential services to the UK. Recommendations are drawn from the expertise, knowledge, and information of the organizations that contribute to its work. CPNI sponsors research and works in partnership with academia, other government agencies, research institutions, and the private sector to develop applications that can reduce vulnerability to terrorist and other attacks and reduce the impact when attacks take place. CPNI also has special access to intelligence and information about terrorism and other threats, and this informs its advice and priorities.

CPNI shares information, such as warnings of specific threats and vulnerabilities, with its CNI partners so that operators can install suitable defenses, and offers periodic assessments of the nature of the threat from electronic attack. This information on vulnerabilities and alerts is disseminated by the Combined Security Incident Response Team (CSIRTUK) [8]. together with GovCertUK (part of GCHQ) [9].

CPNI works with vendors and researchers to co-ordinate the release of vulnerabilities in a controlled way, so that fixes are in place before the software weaknesses are publicly disclosed. This work enhances the understanding of the potential impact of vulnerabilities.

CPNI's advice is provided to national infrastructure organizations in a variety of ways, including:

- Face-to-face advice through teams of sector-based and specialized, highly experienced advisers;
- Training;
- Online information;
- Written advisory products.

CPNI advice is integrated across the physical, personnel, and information security disciplines both in response to user requirements and derived from expert knowledge about how to make the national infrastructure less vulnerable. Its closest relationship, which has been built up over many years, is with those organizations that operate the key elements on which essential services depend.

CPNI discharges its responsibilities through government departments that have overall responsibility for ensuring that appropriate steps are taken to improve protective security within their sectors. They are also in charge of the identification of critical infrastructure within their sectors in consultation with CPNI and sector organizations. The following departments and agencies have responsibility for sectors or sub-sectors of the CNI:

- Cabinet Office (government and public services),
- Communities and local government (emergency services),

- Department for Business, Enterprise and Regulatory Reform (communications, energy),
- Department for Environment, Food and Rural Affairs (food supply, water),
- Department for Transport (emergency services, transport),
- Department of Health (emergency services, health),
- Food Standards Agency (food safety),
- HM Treasury (finance),
- Home Office (emergency services),
- Maritime and Coastguard Agency (emergency services).

CPNI also works closely with the police. It has a particularly strong partnership with the police National Counter Terrorism Security Office (NaCTSO) [10], which is co-located with CPNI, and the nationwide network of specialist police Counter Terrorism Security Advisers (CTSAs) that they co-ordinate. NaCTSO and the CTSAs support CPNI in the delivery of advice to critical sites within the national infrastructure.

***3.1.2 Civil Contingencies Secretariat (CCS).*** The Cabinet Office Civil Contingencies Secretariat (CCS) [11] was established in July 2001 and reports to the prime minister through the prime minister's security adviser. The CCS works in partnership with government departments, the devolved administrations of Scotland and Wales, and key stakeholders to enhance the UK's ability to prepare for, respond to, and recover from emergencies.

The aim of the CCS is to improve the UK's resilience to disruptive challenges by working with others inside and outside government on the anticipation, preparation, prevention, and resolution of threats. Its current objectives are:

- To make sure that the government can continue to function and deliver public services during a crisis. To work with departments and the wider Cabinet Office to make sure that plans and systems are in place and cover the full range of potential disruption;
- To ensure improved resilience of the government and the public sector, and to support ministers in developing policy;
- To lead horizon-scanning activity to identify and assess potential and imminent disruptions. To build partnerships with other organizations and countries to develop and share best practice in horizon-scanning and knowledge of the UK's critical networks and infrastructure;
- To improve the capability of all levels of government, the wider public sector, and the private and voluntary sectors to prepare for, respond to, and manage potential challenges.

Like all Cabinet Office Secretariats, the CCS supports ministers collectively. In times of national crisis, it supports the Civil Contingencies Committee, which manages and exercises arrangements to handle national crises in the Cabinet Office Briefing Room (COBR) to deliver an integrated government response.

The Emergency Planning College is an integral part of the CCS. It has a key role to play in the development and promulgation of the UK's resilience doctrine, and in the development of cross-organizational communities to deliver it.[1]

### 3.2 Public-Private Partnerships

***3.2.1 CPNI's Public-Private Partnerships.*** In addition to the assurance advice that it provides to specific CNI companies, the Centre for the Protection of the National Infrastructure (CPNI) actively promotes information-sharing. Based on the assumption that the sharing of information about the risks facing networks is beneficial to both government and industry, CPNI works with its CNI partners in Information Exchanges. These aim to create a mechanism through which one company can learn from the experiences, mistakes, and successes of another, without fear of exposing company sensitivities to competitors and the media.

The success of Information Exchanges is based on the personal trust of representatives sharing information in a confidential meeting. In face-to-face meetings, CPNI helps to build a trusted community with a common interest. Each member organization can have a maximum of two representatives. Substitutes are not permitted, as a stranger turning up at a meeting would inhibit the sharing of sensitive information.

Warning Advice and Reporting Points (WARPs) are another way for an organization to share information from which lessons can be abstracted and shared with the CPNI. A WARP is a community-based service where members can receive and share up-to-date advice on information security threats, incidents, and solutions. Currently, there are WARPs for local governments, public services, businesses, and voluntary and international organizations [12].

***3.2.2 Other Private-Public Partnerships.*** There is a wide range of private-sector organizations that work with the public sector to promote information assurance. These include:

- The Information Assurance Advisory Council [13];
- The British Computer Society,
- The Internet Security Forum,
- The National Computing Centre,
- The Internet Watch Foundation,
- The Confederation of British Industry,

## 4 EARLY WARNING AND PUBLIC OUTREACH

### 4.1 Combined Security Incident Response Team (CSIRTUK)

CPNI runs a Computer Emergency Response Team (CERT) for its partners in the private sector who operate elements of the national infrastructure. This service, which advises on how to manage the response to incidents and produces advisories on security matters, is called the Combined Security Incident Response Team (CSIRTUK). CSIRTUK receives,

reviews, and responds to computer security incident reports, providing advisories and related activity for its CNI partners [8].

An important part of risk management is to learn from the experiences of others, and national infrastructure organizations can contact CSIRTUK about potential security vulnerabilities, incidents, or events, whether they be electronic, physical, or personnel-related. Information received is treated confidentially and, if necessary, particular details that would identify individuals or organizations are removed so the information can be incorporated into generic security advice. In this way, valuable experience can be shared to help others.

By enhancing the traditional CERT role to cover holistic advice—including physical, personnel, and electronic issues—CSIRTUK provides a central point for reporting security incidents and for receiving advice and guidance.

### 4.2 GovCertUK

The Communications-Electronics Security Group (CESG), the national technical authority for Information Assurance within GCHQ [15], has the lead responsibility within the government for providing IA advice to public-sector organizations. This role includes providing an emergency response capability to public-sector organizations that may require technical support and advice during periods of electronic attack or other network security incidents. CESG therefore runs the GovCertUK, which assists public-sector organizations in the response to computer security incidents and provides advice to reduce exposure to threat [16].

Together, CSIRTUK and GovCertUK have replaced the Unified Incident Reporting and Alert Scheme (UNIRAS), which has been the UK government CERT in the past.

### 4.3 Ministry of Defence Computer Emergency Response Team

The UK Ministry of Defence Computer Emergency Response Team (MODCERT) is responsible for information security within the Ministry of Defence. It is a member organization of both the international Forum of Incident Response Security Teams (FIRST, see the chapter on FIRST in this volume) and the Trusted Introducer (TI) [17] scheme, both of which provide a mechanism for sharing information on computer security incidents among the communities concerned. MODCERT [18] consists of a central co-ordination center and a number of monitoring and reporting centers, Warning, Advice, and Reporting Points (WARPs), and incident response teams. It also works closely with GovCertUK and CSIRTUK.

### 4.4 GetSafeOnline

GetSafeOnline, designed to educate the public about IT security, is the result of collaboration between the government and private-sector companies. The website has been available since October 2005 and offers comprehensive advice on safe internet use for home users and for micro-businesses about how to protect computers, mobile phones, and other devices against electronic attack. The aim of this free service is to reduce occurrences of ID theft, viruses, and spam by educating internet users and helping them to protect themselves and their computers from online threats [19].

## 5 LAW AND LEGISLATION

The UK has created a legal framework to protect information systems. This includes a number of pieces of legislation. These are outlined below.

- Telecommunications (Fraud) Act 1997: This act amends the Telecommunications Act 1984 to make further provision for the prevention of fraud in connection with the use of a telecommunication system;
- Data Protection Act 1998: This act regulates the processing of information relating to individuals, including the obtaining, holding, use, or disclosure of such information;
- Electronic Communications Bill 2000: This Bill makes provision to facilitate the use of electronic communications and electronic data storage. It also makes provision for the modification of licenses granted under Section 7 of the Telecommunications Act 1984; and for connected purposes;
- Terrorism Act 2000: This act relates to terrorism. It makes temporary provision for Northern Ireland about the prosecution and punishment of certain offences, the preservation of peace, and the maintenance of order. It also makes the deliberate interference with or disruption of electronic systems a criminal act;
- Police and Justice Act 2006: This act makes provision for a range of items relating to policing, crime, and disorder. It also amends the Computer Misuse Act 1990.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts of the Center for the Protection of National Infrastructures who validated the content of this chapter.

## 1 CRITICAL SECTORS

In the US, critical infrastructures are defined according to the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT ACT) Act of 2001, section 1016e: "[ ... ] the term 'critical infrastructure' means systems and assets, whether physical or virtual, so vital to the United States that the incapacity or destruction of such systems and assets would have a debilitating impact on security, national economic security, national public health or safety, or any combination of those matters" [1].

Based on this definition, Homeland Security Presidential Directive 7 (HSPD-7), issued on December 2003, identified 17 critical infrastructures and key resources (CI/KR) and delineated the roles and responsibilities for the protection of these sectors. The most recent policy plan (the National Infrastructure Protection Plan, issued in 2006) [2] and the current strategy for Homeland Security (issued in 2007) [3] both reconfirm the HSPD-7 list of 17 critical sectors and the corresponding assignment of responsibilities. However, the list of critical infrastructures and key resources is not meant to be final and conclusive—HSPD-7 states that the Department of Homeland Security (DHS) "shall [...]

evaluate the need for and coordinate the coverage of additional critical infrastructure and key resources categories over time, as appropriate" [4]. In March 2008, the DHS announced the establishment of the critical manufacturing sector as the 18th CI/KR sector. While further changes and additions are still possible, the following sectors are currently defined as critical infrastructures and key resources:

- Information Technology,
- Telecommunications,
- Chemicals,
- Commercial Facilities,
- Dams,
- Commercial Nuclear Reactors, Materials, and Waste,
- Government Facilities,
- Transportation Systems (including Mass Transit, Aviation, Maritime, Ground/Surface, and Rail and Pipeline Systems),
- Emergency Services,
- Postal and Shipping Services,
- Agriculture and Food,
- Public Health and Healthcare,
- Drinking Water and Waste Water Treatment Systems,
- Energy, including the Production Refining, Storage, and Distribution of Oil and Gas, and Electric Power (except for commercial nuclear power facilities),
- Banking and Finance,
- National Monuments and Icons,
- Defense Industrial Base,
- Critical Manufacturing.

## 2 PAST AND PRESENT INITIATIVES AND POLICIES

There have been several efforts since the 1990s to manage Critical Infrastructure Protection (CIP) and Critical Information Infrastructure Protection (CIIP) better in the US, and CIIP still plays an important role in the overall US security strategy. The 2007 Strategy for Homeland Security highlights the importance of CIIP for the nation's safety and security: "Many of the Nation's essential and emergency services, as well as our critical infrastructure, rely on the uninterrupted use of the Internet and the communications systems, data, monitoring, and control systems that comprise our cyber infrastructure. A cyber attack could be debilitating to our highly interdependent CI/KR and ultimately to our economy and national security" [5].

Whereas traditionally, national security has been recognized as the responsibility of the federal government and is underpinned by the collective efforts of the military, the foreign policy establishment, and the intelligence community with respect to defense, homeland security in general— and CIIP in particular—is viewed as a shared responsibility that requires coordinated action across many sectors [6]. In consequence, a multitude of actors is involved with CIIP. In order to ensure coordination among all relevant stakeholders, the US government has developed various initiatives and policies.

### 2.1 Presidential Commission on Critical Infrastructure Protection (PCCIP)

Based on the recommendations of the Critical Infrastructure Working Group (CIWG), President Bill Clinton set up the Presidential Commission on Critical Infrastructure Protection (PCCIP) in 1996, the first national effort to address the vulnerabilities of the information age.

The PCCIP included representatives from all relevant government departments as well as from the private sector. The PCCIP presented its report to the president in October 1997 [7]. The commission's most important decision was to foster cooperation and communication between the private sector and the government. The commission no longer exists, as its functions have been reallocated per HSPD-7.

### 2.2 Presidential Decision Directives (PDD) 62 and 63

Clinton followed the recommendations of the PCCIP and issued Presidential Decision Directives (PDD) 62 and 63 in May 1998 [8]. Those directives established policy-making and oversight bodies making use of existing government agency authorities and expertise. PDD-63 set up groups within the federal government to develop and implement plans to protect government-operated infrastructure, and called for a dialog between the government and the private sector to develop a National Infrastructure Assurance Plan [8].

### 2.3 National Plan for Information Systems Protection

On 7 January 2000, Clinton presented the first comprehensive national plan for CIIP—focusing on securing the cyber-components of critical infrastructures, but not the physical components—called Defending America's Cyberspace. National Plan for Information Systems Protection Version 1.0—An Invitation to a Dialogue [9]. This plan reinforced the perception of cyber-security as a responsibility shared between the government and the private sector.

### 2.4 Homeland Security Executive Orders

In the aftermath of attacks in the US on 11 September 2001, President George Bush signed two executive orders (EO) affecting CIP. With EO 13228, entitled Establishing the Office of Homeland Security and the Homeland Security Council and issued on 8 October 2001, the Office of Homeland Security was established, headed by the assistant to the president for homeland security [10]. One of the functions of the assistant to the president is to coordinate efforts to protect the country and its CI from terrorist attacks. The EO further established the Homeland Security Council, which advises and assists the president in all aspects of homeland security.

The second executive order, EO 13231 Critical Infrastructure Protection in the Information Age, established the President's Critical Infrastructure Protection Board. The board's responsibility is to "recommend policies and coordinate programs for protecting information systems for critical infrastructure" [11]. Finally, the EO also established the National Infrastructure Advisory Council (NIAC), a presidential advisory committee of owners and operators of the nation's critical infrastructures [11].

### 2.5 Homeland Security Presidential Directive/HSPD-7

On 17 December 2003, Bush released Homeland Security Presidential Directive/HSPD-7, which supersedes PDD 63 of May 1998, and any presidential directives issued prior to this HSPD-7.

This new directive established a national policy for federal departments and agencies to identify and prioritize US critical infrastructure and key resources and protect them from terrorist attack. It identified the government agencies responsible for coordinating the protection of specific critical infrastructure sectors. A key element of this directive is the designation of federal sector-specific agencies that are charged with collaborating with specific elements of the private sector.

Also, HSPD-7 required that by July 2004, the heads of all federal departments and agencies develop plans for protecting the physical and cyber critical infrastructure and key resources that they own or operate, including identification, prioritization, protection, and contingency planning [12].

Finally, HSPD-7 designated the secretary of homeland security as "the principal Federal official to lead, integrate, and coordinate implementation of efforts among Federal departments and agencies, State and local governments, and the private sector to protect critical infrastructure and key resources" [12].

### 2.6 National Strategies

The National Strategy for Homeland Security was released in July 2002 and established the base for CIP and CIIP in the US. On February 2003, the White House released two presidential national strategies that are follow-on documents to the National Strategy for Homeland Security, namely the National Strategy to Secure Cyberspace and the National Strategy for Physical Protection of Critical Infrastructure and Key Assets.

***2.6.1 National Strategy for Homeland Security.*** In July 2002, the Office of Homeland Security issued the National Strategy for Homeland Security [13] to secure the US from terrorist attacks. It provides direction to the federal government departments and agencies that have a role in homeland security. One of the six "critical mission areas" identified in the strategy is protecting critical infrastructure and key assets.

In October 2007, President Bush issued an updated version of the Strategy for Homeland Security [14]. The protection of critical infrastructures and key resources is maintained as a central element of the strategy. In reference to the National Infrastructure Protection Plan (see below), the strategy defines 17 critical sectors and key resources, each with cross-cutting physical, cyber, and human elements.

***2.6.2 National Strategy to Secure Cyberspace.*** The National Strategy to Secure Cyberspace (NSSC) [15] recognizes that securing cyberspace is an extraordinary challenge that requires a coordinated effort from all parts of society and government. It defines cyberspace as an "interdependent network of information technology infrastructures" and depicts cyberspace as the nervous system or control system of society. Its main aim is to set national policies to engage US citizens in securing the portions of cyberspace they own, operate, control, or with which they interact. The NSSC therefore outlines an initial framework both for organizing and prioritizing national efforts in combating cyber-attacks committed by terrorists, criminals, or nation-states, while highlighting the role of public-private engagement.

Consistent with the National Strategy for Homeland Security, the strategic objectives of the NSSC are:

- To prevent cyber-attacks against the national CI;
- To reduce the national vulnerability to cyber-attacks;
- To minimize damage and recovery time from cyber-attacks.

The strategy recognizes that, as owners and operators of much of the internet infrastructure, the private sector is best equipped and structured to respond to cyber-threats. Therefore, public-private engagement will take a variety of forms and will address awareness, training, technological improvements, vulnerability remediation, and recovery operations.

***2.6.3 The National Strategy for the Physical Protection of Critical Infrastructures and Key Assets.*** The National Strategy for the Physical Protection of Critical Infrastructures and Key Assets [16] states that the CI sectors of the US provide the foundation for national security, governance, economic vitality, and "the American way of life". Its main aim is to reduce the nation's vulnerability to acts of terrorism by reducing the vulnerability of national critical infrastructure and key assets to physical attack. An attack on the nation's critical infrastructures and key assets could not only result in large-scale human casualties and property destruction, but also damage the national prestige, morale, and confidence, as experienced in the 11 September 2001 attacks. As a result, the following strategic objectives are considered:

- To identify and assure the protection of those infrastructures and assets that are deemed most critical in terms of national-level consequences for public health and safety, governance, economic and national security, and public confidence;
- To provide timely warning;
- To assure the protection of other infrastructures and assets that may become terrorist targets over time.

By pursuing these objectives, coordinated action is required on the part of federal, state, and local governments, as well as the private sector and concerned citizens. The Department of Homeland Security (DHS) provides overall cross-sector coordination in this new organizational scheme, acting as the primary liaison and facilitator for cooperation among federal agencies, state and local government, and the private sector. Cross-sector initiatives should be fostered in the areas of planning and resource allocation, in information-sharing, in personnel security (including background checks where appropriate) and awareness, in research and development, and in modeling, simulation, and analysis.

## 2.7 National Infrastructure Protection Plan (NIPP) and Sector-Specific Plans (SSP)

The National Infrastructure Protection Plan (NIPP) [17] was issued by the DHS in June 2006. It provides an overall framework for existing and future programs and activities for the protection of critical infrastructures and key resources. The NIPP defines three different protection policies: deterrence of the terrorist threat, mitigation of vulnerabilities,

and mitigation of potential consequences. In addition, it specifies key initiatives; lists the public and private actors involved in CIP; sets milestones and targets that are to be achieved; and provides a risk management framework for critical infrastructures.

One of the key elements of the NIPP is that it formalizes the institution of public-private partnerships in the field of CIP and CIIP. Each sector is supposed to create a sector coordinating council for policy coordination and designate an operational entity (such as Information Sharing and Analysis Centers, ISACs) for information sharing. Likewise, the government is to form a Government Coordinating Council and sector-specific agencies for coordinating efforts on specific sectors. This collaboration takes place through the Critical Infrastructure Advisory Council framework, which provides legal protections for this collaboration.

The NIPP gives special consideration to the cyber dimension of critical infrastructure protection. Cybersecurity is addressed in two ways: first, as a cross-sector element that needs to be considered in all sectors; and second, as a major component of the IT sector's responsibility in partnership with the telecommunications sector.

The responsibility of the IT sector is further outlined in the Sector-Specific Plan for Information Technology [18], which was published in May 2007. Sector-Specific Plans (SSPs) complement the NIPP and provide the means by which the NIPP is implemented across all critical infrastructure and key resource sectors. The SSP for the IT sector was developed collaboratively by all relevant public and private actors in the field. The plan outlines the implementation of the NIPP risk management framework; establishes sector-specific goals and objectives; aligns initiatives to meet the goals and objectives; and describes roles and responsibilities.

### 2.8 National Strategy for Information-Sharing

The Strategy for Homeland Security, the National Infrastructure Protection Plan (NIPP), and the Information Technology Sector-Specific Plan all emphasize the importance of information-sharing between different sectors as well as between the government and the private sector. Various organizations and initiatives have been established to enable information-sharing within and among sectors. The National Strategy for Information Sharing [19], which was published in October 2007, builds upon the existing efforts and provides guidelines for sharing information to protect critical infrastructures. The strategy clearly highlights the need to share information with those who need it, rather than to conceal information. It states that "the exchange of information should be the rule, not the exception" [20].

## 3 ORGANIZATIONAL OVERVIEW

In the early days, two agencies had primary responsibility for coordinating US CIP policy: The Critical Infrastructure Assurance Office (CIAO), which used to be part of the Department of Commerce, and the National Infrastructure Protection Center (NIPC), formerly a division within the Federal Bureau of Investigation (FBI). However, in accordance with the various presidential directives discussed above and the creation of the DHS, the functions of the CIAO and the NIPC have been absorbed by the DHS.

Today, DHS coordinates the governmental CIP efforts. However, within the different sectors, various agencies are deeply involved in CIP, for instance as sector-specific

agencies (the National Infrastructure Protection Plan assigns the responsibility for CI/KR protection activities to different federal departments) [21]. Thus, while this section focuses on agencies and offices with a coordinative task (and as a result, mainly on DHS offices), this does not mean that other government agencies are no longer involved in CIP.

## 3.1 Public Agencies

***3.1.1 Department of Homeland Security (DHS).*** The attacks of 11 September 2001 provided the impetus to restructure the overall organizational framework for the protection of homeland security, including CIP and CIIP. In March 2003, 23 federal agencies, programs, and offices were merged to become the Department of Homeland Security (DHS) [22]. The DHS coordinates the efforts of several federal, state, and local governments and encompasses a variety of agencies for all different tasks related to homeland security [23]. Within the DHS, the agencies dealing with CIP and CIIP are affiliated with the National Protection and Programs Directorate, which focuses on the reduction of physical and virtual risks to homeland security [24]. The following two offices are dedicated to deal with CIP and CIIP:

***3.1.2 Office of Infrastructure Protection (OIP).*** The Office of Infrastructure Protection (OIP) [25] coordinates the different sectoral efforts to protect critical infrastructures and key resources (CI/KR). Its functions include:

- Leading a robust organizational framework to facilitate the identification, prioritization, coordination, and protection of critical infrastructures/key resources (CI/KR);
- Developing and maintaining the National Infrastructure Protection Plan (NIPP);
- Coordinating and assisting the vulnerability assessments of all 18 CI/KR sectors in the US and communicating standards to the infrastructure owners/operators and key stakeholders;
- Ensuring the maintenance of a CI/KR sector governance and information-sharing framework;
- Collecting data, analyzing risks to CI/KR, and providing government and private-sector stakeholders with a means of prioritizing resource allocation and assistance;
- Establishing and maintaining international programs and relationships that promote a global culture for the protection of CI/KR.

***3.1.3 Office for Cybersecurity and Communications (CS&C).*** The Office of Cybersecurity and Communications (CS&C) [26] coordinates with the private sector on identifying threats, managing risks and improve situation awareness. In order to be prepared for catastrophic incidents that could damage or even destroy the ICT-network, CS&C has implemented three programs:

- The National Communications System (NCS) [27] has the mission to ensure national security and emergency communication for the federal government under all circumstances.
- The National Cyber Security Division (NCSD) [28] works collaboratively with private, public, and international partners to protect the information infrastructure. It does so by building and maintaining response systems (e.g., US-CERT, see the

chapter on Early Warning and Public Outreach) and by working with security partners to develop and implement risk management programs for cyber-risks in critical infrastructures.

- The Office of Emergency Communications (OEC) [29] develops, implements, and coordinates interoperable and operable communications for emergency response at all levels of government.

***3.1.4 US Department of State.*** With respect to the formulation of an international CIP program in the US, the Department of State has overall statutory authority to conduct foreign affairs, and therefore takes the lead in the interagency process of coordinating international CIP matters. The Department of State collaborates closely with the Department of Defense (DoD) to develop and implement international initiatives designed to encourage allied nations to enhance the security of those critical infrastructure and key resources on which the US military depends for its operations [30].

***3.1.5 Congressional Focus.*** Both Houses of Congress have created bodies to focus on CIIP issues. Within the Committee on Homeland Security in the House of Representatives [31], the following subcommittees deal with questions related to CIP and CIIP:

- Subcommittee on Transportation Security and Critical Infrastructure Protection;
- Subcommittee on Emerging Threats, Cybersecurity, and Science and Technology;
- Subcommittee on Emergency Communications, Preparedness, and Response;
- Subcommittee on Intelligence, Information Sharing, and Terrorism Risk Assessment.

Within the Senate Committee on the Judiciary [32], the Subcommittee on Terrorism, Technology, and Homeland Security has oversight of laws related to government information policy, electronic privacy, security of computer information, and the Freedom of Information Act [33]. The House Government Reform Committee [34] has similar, but not identical, jurisdiction.

The Senate Homeland Security and Government Affairs Committee [35] has overall jurisdiction, for the Senate, on most homeland security issues, including critical infrastructure protection. Its Subcommittee on Federal Financial Management, Government Information, and International Security has jurisdiction on matters related to cyber-security.

***3.1.6 Government Accountability Office (GAO).*** The Government Accountability Office (GAO) [36] is the investigative arm of Congress. It is an independent and nonpartisan body that studies federal government spending and helps to improve the performance and ensure the accountability of the federal government. Congress often asks the GAO to study the programs and expenditures of the federal government. The GAO has released several reports and testimonies addressing critical infrastructure protection and information security. For example:

- In July 2004, the GAO reported on Critical Infrastructure Protection and Improving Information Sharing with Infrastructure Sectors. In this report, the GAO recommends that the DHS proceed with the development of an information-sharing plan that defines roles and responsibilities and establishes appropriate policies for interacting with ISACs and the various stakeholders involved [37].

- In May 2005, the GAO reported on Information Security: Emerging Cybersecurity Issues Threaten Federal Information Systems, addressing the problems of spam, phishing, and spyware and the resulting security risks to federal information systems [38].
- In May 2005, the GAO reported on Critical Infrastructure Protection: Department of Homeland Security Faces Challenges in Fulfilling Cybersecurity Responsibilities. The following issues were identified as key challenges facing the DHS: achieving organizational stability; gaining organizational authority; overcoming hiring and contracting issues; increasing awareness about cyber-security roles and capabilities; establishing effective partnerships with stakeholders and sharing information with these stakeholders [39].
- In May 2005, the GAO report Information Security: Federal Agencies Need to Improve Controls over Wireless Networks advised federal agencies to implement various controls, including policies, practices, and tools, to secure their wireless networks [40].

***3.1.7 Defense Community.*** In May 2007, the DoD published the Sector-Specific Plan for the Defense Industrial Base as input to the National Infrastructure Protection Plan of 2006 [41]. The Defense Industrial Base (DIB) includes the DoD, the US government, and the private sector companies that design, produce, deliver, or maintain military weapon systems, subsystems, components, or parts to meet military requirements. The DIB does not include commercial communication and information infrastructure, which are addressed by the respective Sector-Specific Plans.

Nevertheless, the information infrastructure is of course crucial for the DoD. The latter has therefore established information assurance programs in the Office of the Assistant Secretary of Defense for Networks and Information Integration (OASD/NII) [42] that are headed by a Chief Information Officer of the DoD.

***3.1.8 Computer Crime and Intellectual Property Section (CCIPS).*** The Computer Crime and Intellectual Property Section (CCIPS) of the Criminal Division of the Department of Justice is responsible for implementing the department's national strategies in combating computer and intellectual property crimes worldwide. The Computer Crime Initiative is a comprehensive program designed to combat electronic penetration, data theft, and cyber-attacks on critical information systems. CCIPS prevents, investigates, and prosecutes computer crimes by working with other government agencies, the private sector, academic institutions, and foreign counterparts [43].

## 3.2 Public-Private Partnerships

The cornerstone of US CIP policy is active cooperation between the public and private sectors. The President's Commission on Critical Infrastructure Protection (PCCIP) concluded that "the need for infrastructure protection creates a zone of shared responsibility and potential cooperation for industry and government" [44]. Since then, public-private partnerships and information-sharing between public and private sectors have been central for CIP efforts in the US. This section provides an overview on the most important organizations and programs for public-private partnerships in the field of critical infrastructure protection and cybersecurity.

***3.2.1 DHS Interagency Committees.*** As the leading department for CIP, it is one of the DHS's main tasks to facilitate partnership efforts between the government and the private sector. The two following interagency committees within the DHS are responsible for coordination and supervision of partnership efforts:

- The National Infrastructure Advisory Council (NIAC) [45] advises the President on the security of the critical infrastructure sectors and their information systems. The council is composed of a maximum of 30 members appointed by the President from private industry, academia, and state and local government;
- Critical Infrastructure Partnership Advisory Council (CIPAC) [46] was established in 2006 to facilitate effective coordination between federal infrastructure protection programs with the infrastructure protection activities of the private sector and of state, local, territorial, and tribal governments. CIPAC's membership encompasses representatives from the individual sector coordinating councils as well as from federal, state, local, and tribal governmental entities;
- The president's National Security Telecommunications Advisory Committee (NSTAC) is a CEO-level advisory committee on telecommunications issues.

***3.2.2 Protected Critical Infrastructure Information Program (PCIIP).*** The Protected Critical Infrastructure Information Program (PCIIP) aims to protect certain information shared by the private sector from being disclosed under the federal Freedom of Information Act. Under this program, only people who are trained and certified as PCII-compliant can receive protected critical infrastructure information. The program's goal is to encourage private-sector companies to voluntarily share information so that the DHS and other federal, state, and local analysts can:

- Analyze and secure critical infrastructure and protected systems;
- Identify vulnerabilities and develop risk assessments;
- Enhance recovery preparedness measures [47].

***3.2.3 Information Sharing and Analysis Centers (ISACs).*** Today, most critical infrastructure industry sectors have established their own Information Sharing and Analysis Center (ISAC). Private-sector ISACs are membership organizations managed by the private sector. Each ISAC has a board of directors that determines its institutional and working procedures. The function of an ISAC is to collect, analyze, and share security, incident, and response information among ISAC members and with other ISACs, and to facilitate information exchange between the government and the private sector. The following list gives an overview of the most mature ISACs with regard to CIIP:

- The IT-ISAC started operations in March 2001. Members include 20 major hardware, software, and e-commerce firms, including Microsoft, Intel, CA, Symantec, CSC, IBM, Oracle, Ebay, EWA-IIT, Harris, Hewlett Packard, BAE Systems, IT, and VeriSign, Inc. The ISAC is overseen by a board made up of members, and its operations center is managed by Internet Security Systems; [48]
- The telecommunications industry has established an ISAC through the National Coordinating Center (NCC). Each member firm of the NCC monitors and analyzes its own networks. Incidents are discussed within the NCC, and members decide

whether the suspect behavior is serious enough to report to the appropriate federal authorities; [49]

- The electric power sector has created a decentralized ISAC through its North American Electricity Reliability Council (NERC). Much like the NCC, the NERC monitors and coordinates responses to disruptions in the nation's supply of electricity [50]. The government and industry work together in the NERC to ensure the resilience of the electricity infrastructure in case of potential physical and cyberspace attacks; [51]
- A number of the nation's largest banks, securities firms, insurance companies, and investment companies have joined in a limited liability corporation to form a Financial Services Information Sharing and Analysis Center (FS/ISAC); [52]
- In addition to the individual sector ISACs, several ISAC leaders have convened as an ISAC Council [53]. This council strives to strengthen the relationship between the ISAC community and government, and to solve problems common to all ISACs.

***3.2.4 InfraGard.*** InfraGard is a partnership between industry and the US government as represented by the FBI. The InfraGard initiative was developed to encourage the exchange of information by members of the government and the private sector. With help from the FBI, private-sector members and FBI field representatives form local chapter areas. These chapters set up their own boards to share information among their membership. This information is then disseminated through the InfraGard network and analyzed by the FBI [54].

***3.2.5 National Cyber Security Alliance (NCSA).*** The National Cyber Security Alliance (NCSA) is a cooperative effort between industry and government organizations to foster awareness of cyber-security through educational outreach and public awareness. Its goal is to raise citizens' awareness of the critical role that computer security plays in protecting the nation's internet infrastructure, and to encourage computer users to protect their home and small-business systems [55]. It offers computer security advice and tools for private users as well as small businesses on its website. The NCSA is sponsored by a variety of organizations.

***3.2.6 Partnership for Critical Infrastructure Security (PCIS).*** The Partnership for Critical Infrastructure Security (PCIS) [56] grew out of initiatives outlined in Presidential Decision Directive 63 (PDD 63) as a means to coordinate CIP efforts across critical infrastructure sectors. In October 2005, the National Infrastructure Advisory Council (NIAC) recommended that the PCIS serve as the cross-sector coordinating mechanism, as part of the DHS partnership model. Today, the PCIS serves that role, and its membership consists of the leaders of the various sector coordinating councils. The PCIS works to develop joint policies to secure CI and examines cross-sector issues.

***3.2.7 The Cross Sector Cyber Security Working Group (CSCSWG).*** The Cross Sector Cyber Security Working Group (CSCSWG)[1] serves as a forum to bring together representatives of the government and the private sector to address risk collaboratively across the CI/KR sectors. In this function, it replaces the National Cyber Security Partnership [57], which was the forum for cross-sector coordination until 2005.

The CSCSWG is co-chaired by the industry and the government. It focuses on strategic cross-sector cybersecurity issues such as:

[1]The information on CSCSWG was provided by the US expert involved.

- Identifying opportunities to improve sector coordination around cyber security issues and topics (e.g., the internet, control systems);
- Considering the policy implications of cross-sector cyber dependencies and interdependencies; and
- Providing a conduit for sharing the group's products and findings with the sectors through their Sector Coordinating Council (SCC), Information Sharing and Analysis Center (ISAC), and Sector-Specific Agency (SSA) representatives.

***3.2.8 Institute for Information Infrastructure Protection (I3P).*** The Institute for Information Infrastructure Protection (I3P), managed by Dartmouth College, is a consortium of leading national cyber-security institutions, including academic research centers, government laboratories, and non-profit organizations. Founded in September 2001, the institute's main role is to coordinate a national cyber-security research and development program and to help build bridges between academia, industry, and the government. The I3P identifies and addresses critical research problems in CIIP and opens information channels between researchers, policy-makers, and infrastructure operators [58].

## 4 EARLY WARNING AND PUBLIC OUTREACH

Information-sharing is one of the driving factors behind effective early-warning networks. Many entities focused on information-sharing are also engaged in early-warning activities.

### 4.1 CERT Coordination Center, Carnegie Mellon University

The Computer Emergency Response Team Coordination Center (CERT/CC) is the oldest and still one of the most important early-warning programs in the field of information security. It is a federally funded research and development center operated by Carnegie Mellon University. It was established in 1988 after the Morris worm crashed 10 per cent of the world's internet systems. CERT/CC acts as a coordination hub for experts during security incidents, and works to prevent future incidents.

The CERT/CC acts through several mechanisms. First, its experts research and assess network vulnerabilities and develop risk assessments. Second, they disseminate information to the public through regular security alerts and presentations to the public. Finally, members of the CERT/CC participate in various security groups to improve internet security and network survivability. The CERT/CC is a primary contributor to the US-CERT [59].

### 4.2 US-CERT

On 15 September 2003, the Department of Homeland Security, in conjunction with the CERT Coordination Center (CERT/CC) at Carnegie Mellon University, announced the creation of the US-CERT. The US-CERT works with the National Cyber Security Division (NCSD) of the IAIP to prevent and mitigate cyber-attacks and to reduce vulnerabilities to cybernetic attacks. Together, they have set up the National Cyber Alert System, a trusted warning system offered by the government to help home users and technology experts. It sends e-mails about major virus outbreaks and other internet attacks as they occur, along with detailed instructions to help computer users protect themselves.

The US-CERT initiative is designed to help accelerate the nation's response to cyber-attacks and vulnerabilities. The initiative also enables the DHS to provide expanded analysis, warning, and response coordination [60].

### 4.3 Federal Bureau of Investigation (FBI)

The 1997 PCCIP Report stated that efforts were required to establish a system of surveillance, assessment, early warning, and response mechanisms [61]. The FBI was chosen to serve as the preliminary national warning center for infrastructure attacks and to provide information on law enforcement and intelligence. Under PDD 63, the National Infrastructure Protection Center (NIPC) as part of the FBI was given responsibility for developing analytical capabilities to provide information on changes in threat conditions and newly identified system vulnerabilities, as well as timely warnings of potential and actual attacks [62]. The NIPC, as discussed above, was incorporated into the DHS, but the FBI still retains its responsibilities for addressing cyber-crime.

### 4.4 Information-Sharing and Analysis Centers (ISACs)

The Information Sharing and Analysis Centers (ISACs) serve as an early warning and situational awareness capability by providing a forum for members to report information on threats, vulnerabilities, and incidents. ISACs then collate the information, as well as information they receive from other sources, analyze it, and issue warnings and alerts to members. Many ISACs, such as the IT-ISAC, for example, now distribute information more broadly throughout the sector, beyond its own individual membership (see the chapter on Organizational Overview).

### 4.5 OnGuardOnline.gov

OnGuardOnline.gov provides practical recommendations from the federal government and the technology industry to help users be on guard against internet fraud, to secure their computers, and to protect their personal information. The comprehensive website has tips, articles, videos, and interactive activities. The Federal Trade Commission (FTC) maintains OnGuardOnline.gov with contributions from various government departments, including the DHS [63].

## 5 LAW AND LEGISLATION

### 5.1 Federal Advisory Committee Act (FACA) 1972

One obstacle to fully implementing a robust public-private partnership is the 1972 Federal Advisory Committee Act (FACA). The FACA (Public Law 92-463, 5 U.S.C., App) was enacted by Congress in 1972. Basically, this act is designed to prevent any person or company (or groups of them) from having undue influence in government decision-making. Its purpose was to ensure that advice rendered to the executive branch by the various advisory committees, task forces, boards, and commissions formed over the years by Congress and the president be both objective and accessible to the public. The act not only formalized a process for establishing, operating, overseeing, and terminating these advisory bodies, but also created the Committee Management Secretariat, whose task it is to monitor and report executive branch compliance with the act [64].

In the field of CIP/CIIP, the delicate issue is that CIP is based on partnership with the DHS, which requires meetings. If these meetings are open to the public and subject to other government restrictions, the industry will be unwilling to be frank or overly commit itself, since businesses would be putting sensitive information in the public domain.

In the US, the challenge has been to ensure that the private sector and its representatives have the opportunity to provide comments and input on CIP policy without violating FACA considerations. One solution to this is found in Section 871 of the Homeland Security Act, which gives the Secretary of Homeland Security the authority to create FACA-exempt advisory panels. Secretary Chertoff used the authority granted to him in Section 871 to create a FACA exempt organization to work on CIP issues. This is the Critical Infrastructure Partnership Advisory Council referred to earlier.[2]

### 5.2 Computer Fraud and Abuse Act (CFAA) 1986

In the US, legislative awareness of computer crimes grew dramatically in the early 1980s as computers became increasingly important for the conduct of business and politics. The Computer Fraud and Abuse Act (CFAA) of 1986 was the conclusion of several years of research and discussion among legislators [65]. It established two new felony offenses of unauthorized access to "federal interest" computers[3] and unauthorized trafficking in computer passwords. Violations of the CFAA include intrusions into government, financial, medical, and "federal interest" computers.

The Computer Abuse Amendments Act of 1994 expanded the 1986 CFAA to address the transmission of viruses and other harmful code. The measures provided by this act were further tightened on 26 October 2001 by the USA PATRIOT anti-terrorism legislation.[4] Violations of the CFAA are investigated by the National Computer Crimes Squad at the FBI and supported by its Computer Analysis and Response Team (CART), a specialized unit for computer forensics.[5]

### 5.3 Homeland Security Act 2002

Much of the federal legislation concerning CIP/CIIP was written before the emergence of "cyber-threats". Thus, it is questionable whether a timely and efficient response would be possible under the existing legal frameworks at both federal and state/local levels [66].

While the overall act established the Department of Homeland Security (DHS), Title II of the Homeland Security Act (of 2002) specifically addresses information analysis and infrastructure protection. It transferred the various agencies (like CIAO, NIPC, and others mentioned above) into the DHS, and established the categories of information to which the secretary of homeland defense has access. In order to adequately protect the nation,

[2]Information provided by a US expert involved.

[3]"Federal interest computers" are defined as two or more computers involved in a criminal offense, if they are located in different states.

[4]"Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act". For the full-text version, see: http://www.cdt.org/security/usapatriot/011026usa-patriot.pdf. Privacy and civil liberty advocacy groups have expressed concern over the USA PATRIOT Act and a number of other legislative developments.

[5]http://www.fbi.gov/hq/lab/org/cart.htm. Of further importance is also the recent enactment of the Gramm-Leach-Bliley (GLB) Act and the regulations for implementing it, which address privacy concerns by setting forth a range of requirements to protect customer information. For the text of the GLB Act, see: http://www.ftc.gov/privacy/privacyinitiatives/glbact.html.

the secretary has access to certain intelligence analysis, infrastructure vulnerabilities, and any "raw" data that the president discloses to the secretary.

### 5.4 Freedom of Information Act (FOIA)

CIIP is an important issue in the US, primarily because many of the critical sectors are regulated by the government, but controlled by private entities. As part of the regulation, the private entities must regularly file reports and disclose sensitive information to the government. This could place such information in jeopardy, since under the Freedom of Information Act (FOIA), the public can request such information from the government. However, a FOIA exemption was included in the Homeland Security Act of 2002. Any information regarding critical infrastructures (including security systems, warnings, or interdependency studies) is exempt from disclosure.

After the attacks of 11 September 2001, the Federal Energy Regulatory Commission (FERC) removed certain information from its website and its public reading room. This included detailed maps and other information about electric power facilities and natural gas pipelines. Although exempt from FOIA procedures, this information had traditionally been open and available to anyone who requested it. In February 2003, the FERC ruled that individuals wanting access to this information would have to apply for it. The application requirements include identification information, and take into account the necessity or purpose of accessing the information. Access is granted on a case-by-case basis, and only to individual applicants.

***5.4.1 Critical Infrastructure Information Act: Procedures for Handling Critical Infrastructure Information.*** The Homeland Security Act of 2002 contained a provision called the Critical Infrastructure Information Act, which was designed to encourage the private sector to share information voluntarily with the DHS. In April 2003, the DHS released regulations for the implementation of this program, which the DHS has named the Protected Critical Infrastructure Information Program (PCIIP) [67]. These regulations, which were authorized in the Homeland Security Act of 2002, provide rules for the receipt, care, and storage of critical infrastructure information, the maintenance of security and confidentiality, and methods for dealing with proprietary or business-sensitive information. The basic concept of the regulations again underscores the fundamental principles of public-private partnership. Their goal is to encourage the private sector to share sensitive security information with the DHS without fear that the information will be made public. It stipulates that business-sensitive information that businesses voluntarily submit to the DHS may be labeled CII and exempted from disclosure under the FOIA. Under this program, CII that the DHS shares with state and local governments would be protected from state laws pursuant to the Freedom of Information Act. The final rules implementing this program have not yet been issued. This change in the law has potentially broad effects and requires a change of culture, as disclosure of information held by the government has traditionally been favored in the US.

### 5.5 Terrorism Risk Insurance Act 2002

The Terrorism Risk Insurance Act of 2002 is a new law that creates a federal program for public and private compensation for insured losses resulting from acts of terrorism. All commercial insurance providers must offer terrorism risk insurance, and the federal

government agrees to underwrite some of the losses in the event that a terrorist event takes place. Under this law, an act of terrorism includes any act of violence against elements of the infrastructure [68]. This could include catastrophic network assaults as well as physical attacks.

# EUROPEAN UNION (EU)

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 INTRODUCTION

The European Union is a key player at the international level concerning information assurance. CIIP, the Information Society, and information security are considered key issues. Therefore, the EU has launched initiatives and research programs to study various

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

aspects of the information revolution and its impact on education, business, health, and communications.

The terrorist attacks in Madrid in 2004 and London in 2005 have highlighted the risk of terrorist attacks against European infrastructures in a broader sense. The damage or loss of a piece of infrastructure in one state may have negative effects on several others, and on the European economy as a whole. The following chapter gives a short overview of important steps taken by the EU in the field of CIP and CIIP [1].

## 2 CRITICAL SECTORS

The Communication of the Commission of the European Communities (EU Commission) on Critical Infrastructure Protection in the Fight Against Terrorism, adopted on 20 October 2004, provides a definition of critical infrastructures (CI), enumerates the critical sectors identified, and discusses the criteria for determining potential CI. In the Communication, CI are defined as follows: "Critical infrastructures consist of those physical and information technology facilities, networks, services and assets which, if disrupted or destroyed, would have a serious impact on the health, safety, security or economic well-being of citizens or the effective functioning of governments in the Member States. Critical infrastructures extend across many sectors of the economy and key government services"[2].

In the follow-up publication of the EU Commission, the Green Paper on a European Program for Critical Infrastructure Protection (Green Paper on EPCIP) [3], CIIP is defined as: "The programs and activities of infrastructure owners, operators, manufacturers, users, and regulatory authorities which aim at keeping the performance of CII in case of failures, attacks or accidents above a defined minimum level of services and aim at minimizing the recovery and damage. CIIP should therefore be viewed as a cross-sector phenomenon rather than being limited to specific sectors. CIIP should be closely coordinated with CIP from a holistic perspective" [3].

The Green Paper on EPCIP identifies the following critical sectors and their products and services:

- Energy (Oil and Gas Production, Refining, Treatment and Storage, including Pipelines; Electricity Generation; Transmission of Electricity, Gas, and Oil; Distribution of Electricity, Gas, and Oil),
- Information and Communication Technologies (ICT) (Information System and Network Protection; Internet; Provision of Fixed Telecommunications; Provision of Mobile Telecommunications; Radio Communication and Navigation; Satellite Communication; Broadcasting),
- Water (Provision of Drinking Water; Control of Water Quality; Stemming and Control of Water Quantity),
- Food (Provision of Food and Safeguarding Food Safety and Security),
- Health (Medical and Hospital Care; Medicines, Serums, Vaccines, and Pharmaceuticals; Bio-Laboratories and Bio-Agents),
- Financial System (Payment Services/Payment Structures (private); Government Financial Assignment),
- Public and Legal Order and Safety (Maintaining Public and Legal Order, Safety and Security; Administration of Justice and Detention),

- Civil Administration (Government Functions; Armed Forces; Civil Administration Services; Emergency Services; Postal and Courier Services),
- Transport (Road Transport; Rail Transport; Air Traffic; Inland Waterways Transport; Ocean and Short-Sea Shipping),
- Chemical and Nuclear Industry (Production and Storage/Processing of Chemical and Nuclear Substances; Pipelines of Dangerous Goods (Chemical Substances),
- Space and Research [4].

Although most infrastructures are owned and operated by the private sector, the EU Commission declared in its Communication 574/2001 of 10 October 2001: "The reinforcement of certain security measures by the public authorities in the wake of attacks directed against society as a whole and not at the industry players must be borne by the State. The public sector has therefore a fundamental role to play too" [5].

To determine the criticality of an infrastructure is a complex task. The EU Commission suggests that the following three factors be taken into consideration when identifying potential critical infrastructures:

- *Scope.* the loss of a critical infrastructure element is rated by the extent of the geographic area (international, national, provincial/territorial, or local) that could be affected by its loss or unavailability;
- *Magnitude.* the degree of the impact or loss can be categorized as "none", "minimal", "moderate", or "major". Among the criteria for assessing the potential magnitude of an incident are: public impact (number of citizens affected, loss of life, medical illness, serious injury, evacuation); economic impact (GDP effect, significance of economic loss and/or degradation of products or services); environmental impact (effect on the public and the environment); interdependency (with other critical infrastructure elements); and finally, political impact (confidence in the ability of the government to cope);
- *Effects of time.* this criterion ascertains at what point the loss of an element could have a serious impact (e.g., immediately, within 24 to 48 hours, within one week).

However, in most cases, psychological effects also need to be taken into consideration [6].

## 3 INITIATIVES AND POLICIES

The European Commission plans to launch a policy initiative on Critical Communication and Information Infrastructure Protection (CIIP) in 2008 [7]. The aim is to ensure an adequate and consistent level of protective security and the resilience of critical information infrastructure throughout the European Union. This initiative will be part of the broader framework of the European Programme for Critical Infrastructure Protection (EPCIP) [8] and managed independently by the Information and Media Directorate-General (DG INFSO) [9]. This initiative is the latest development since the European Council recognized the vulnerability and interdependency of underlying infrastructures in June 2004 and asked the Commission and the member states to prepare an overall strategy on critical infrastructure protection.

In response to this request, the Commission issued a Green Paper on the EPCIP in November 2005 [8]. It was followed, in December 2006, by a proposal for a directive of the Council on the identification and designation of European Critical Infrastructure and the assessment of the need to improve their protection [10].

In parallel, the Commission's strategy [11] for a secure information society stressed that critical infrastructures are also becoming increasingly dependent on the security of their respective information systems. The strategy was acknowledged by a Council Resolution [12], and the creation of an environment enhancing the reliability, resilience, and robustness of communication networks and information systems was promoted by the Council. The main activities undertaken so far by the European Union are addressed below.

### 3.1 Study for the Commission on the Availability and Robustness of Electronic Communication Infrastructures (ARECI)

In preparation for this new action area, Lucent Technologies carried out a study for the Commission on the Availability and Robustness of Electronic Communication Infrastructures (ARECI). The study makes ten recommendations for key actions to be taken by the European Commission, member states, and the private sector to improve the reliability, resilience, and robustness of the underlying infrastructures. These recommendations include the areas of emergency preparedness, priority communications on public networks, formal mutual aid agreements, critical infrastructure information-sharing, inter-infrastructure dependencies, integrity and trusted operation of the supply chain, unified European voice standards, interoperability testing, vigorous ownership and partnering deals, and discretionary European expert best practices. The report was presented in January 2007. Stakeholders were invited to comment on its findings, and contributions were discussed in June 2007 [13].

### 3.2 Green Paper on a European Programme for CIP (EPCIP)

The EC Communication on CIP in the Fight Against Terrorism mentioned above discusses the EU Commission's efforts in the field of CIP and proposes additional measures to strengthen existing instruments, mainly by the establishment of a European Programme for Critical Infrastructure Protection (EPCIP). On 24 November 2005, the EU Commission published a "Green Paper on a European Programme for Critical Infrastructure Protection" [14], which outlines options to enhance prevention, preparedness, and responses in protecting the EU's critical infrastructure. The Green Paper provides options on how the EU Commission may respond to the EU Council's request to establish an EPCIP and a Critical Infrastructure Warning Information Network (CIWIN), and constitutes the second phase of the consultation process that began with the Commission Communication on CIP that was adopted in October 2004.

The Green Paper addresses such key issues as:

- EPCIP's protection aim;
- Key principles;
- The type of framework needed;
- Definitions and a comprehensive list of EU Critical Infrastructures (ECI);
- ECI versus National Critical Infrastructures (NCI);

- The role of CI owners, operators, and users;
- The role of CIWIN, and the evaluation and monitoring of critical infrastructure (interdependencies).

The options presented by the Green Paper on EPCIP are a combination of measures and should be seen as complementary measures to current national efforts.

### 3.3 Critical Infrastructure Warning Information Network (CIWIN)

In order to facilitate the exchange of information on shared threats and vulnerabilities within the EU, the EU Commission is setting up the Critical Infrastructure Warning Information Network (CIWIN). This EU network aims at helping member states, EU institutions, and owners and operators of critical infrastructure to exchange information on shared threats, vulnerabilities, and appropriate measures and strategies to mitigate risk in support of critical infrastructure protection.[1] The precise determination of the nodes of this network is still an open issue and will most likely include authorities at various levels.[2]

The EU Commission suggested the following three possible options for the development of the CIWIN in its Green Paper:

- The CIWIN could take the shape of a forum limited to the exchange of CIP ideas and best practices in support of CI owners and operators;
- The CIWIN could be a rapid alert system (RAS) linking member states with the EC;
- CIWIN could be a multi-level communication and alert system with two distinct functions: a rapid alert system (RAS) linking member states with the EU Commission, and a forum for the exchange of CIP ideas and best practices.

Regardless of the option finally chosen, the CIWIN will complement existing networks and not duplicate them [16].

### 3.4 European Network and Information Security Agency (ENISA)

The European Network and Information Security Agency (ENISA) [17] was created on 14 March 2004. By deciding on 5 June 2003 to set up ENISA as a legal entity, the EU reinforced its efforts to enhance European coordination on information security.

ENISA aims at ensuring a high level of network and information security within the community. Thus, the agency contributes to the development of network and information security for the benefit of the citizens, consumers, enterprises, and public-sector organizations of the EU. This work also contributes to the smooth functioning of the Internal Market.

The agency assists the EU Commission, the member states, and, consequently, the business community in meeting the requirements of network and information security, including present and future EU legislation. ENISA ultimately serves as a center of

[1]The US has a similar system, known as the Critical Infrastructure Warning Information Network (CWIN), which has been operational since 2003. http://www.gao.gov/new.items/d05434.pdf [15].
[2]Information provided by an expert.

expertise both for member states and for EU institutions to seek advice on matters related to network and information security.

ENISA's work programs included several deliverables. It has created a Who is Who Directory on Network and Information Security [18] with contact information for authorities acting in the field of network and information security in the member states. ENISA has also published an Inventory of CERT Activities in Europe [19] and issues a quarterly newsletter. In addition, ENISA organizes workshops for outreach and dissemination of good practices in the member states. Moreover, ENISA defines customized information packages, including good practices for specific target groups (e.g., SMEs and home users). Finally, ENISA has created a network of liaison officers that helps ENISA to exchange information and cooperate on a day-to-day basis with member states [17].

ENISA's latest work program for 2008 is entitled Build on Synergies—Achieve Impact [20], and was released in November 2007. It focuses on increasing the agency's impact in network and information security based on cooperation with relevant stakeholders. The Work Programme has been developed in a new approach of setting priorities in closer cooperation with all stakeholders. It also introduces three new key elements by defining so-called Multi-annual Thematic Programmes (MTP). The current three MTPs cover the following topics [21]:

- Improving resilience in European e-Communication networks;
- Developing and maintaining cooperation models;
- Identifying emerging risks for creating trust and confidence.

It offers an overview of ENISA's activities, including awareness-raising and promotion of best practices, and enhancing cooperation. ENISA is aware of the importance of its role and supports the strategy of the European Commission. In an effort to maximize the impact of its activities, the agency strives to leverage existing synergies and initiatives at the national and European levels and will follow a more focused impact-oriented approach [22].

## 4 RESEARCH AND DEVELOPMENT

### 4.1 Information Society Technologies (IST) FP6 and FP7

The overall objective of the IST (Information Society Technologies) efforts within the EU's Sixth Framework Program (FP6) was to contribute directly to realizing European policies for the information society as agreed at the Lisbon European Council of 2000, the Stockholm European Council of 2001, and the Seville European Council of 2002, and as reflected in the eEurope Action Plan. The IST component of FP6, which ran from 2002 to 2006, aimed at ensuring European leadership in the generic and applied technologies at the heart of the knowledge economy. The IST research efforts within FP6 reinforced and complemented the eEurope 2005 objectives. In this EU research program, IST had the first priority in terms of funding [23]. Among the strategic objectives of IST FP6 were: A global dependability and security framework; semantics-based knowledge systems; networked business and government; e-Safety for road and air transport; e-Health; cognitive systems; embedded systems; improving risk management; and e-Inclusion. As in the preceding FP5, the focus of these projects was mainly on technical issues, whereas

policy aspects (such as organizational aspects, ethical questions, etc.) concerning CIIP were hardly discussed and somewhat undervalued in the strategic objectives.

Under FP7, which began in 2007 and runs until 2013, the EU Commission wishes to identify topical areas of interest that are continued after the end of FP6, as well as new and emerging topics, including space and security [24]. While the EU has been funding research into ICTs since 1986, the Seventh Research Framework Programme is the largest yet [25]. This is due to the commitment that Europe must master both the development and use of ICTs to generate economic growth required to fund its social model and protect its environment and quality of life [23]. More specifically, the objective of ICT research under the EU's FP7 is to improve Europe's competitiveness at all levels by focusing on the following three key areas of ICT [26]:

- Productivity and innovation, by facilitating creativity and management;
- Modernization of public services, such as health, education and transport;
- Advances in science and technology, by supporting cooperation and access to information.

CORDIS is the official portal for participating in FP7 and subsequent related developments in European science and technology [27].

### 4.2 European Security Research Programme (ESRP)

The goal of European security research is to make Europe more secure for its citizens while increasing its industrial competitiveness. By co-operating and coordinating efforts on a European scale, the EU can better understand and respond to risks in a constantly changing world [28]. For projects in the field of security research, the following priority missions were identified:

- Optimizing the security and protection of networked systems;
- Protecting CI against terrorism (including bio-terrorism and incidents involving biological, chemical, and other substances);
- Enhancing crisis management (including evacuation, search and rescue operations, control, and remediation);
- Achieving interoperability and integration of systems for information and communication;
- Improving situation awareness (e.g., in crisis management, anti-terrorism activities, or border control) [29].

Furthermore, the EU Commission set up the European Security Research Advisory Board (ESRAB) on 1 July 2005. ESRAB was attached to the EU Commission and could be consulted on any questions related to the content and implementation of the European Security Research Program. ESRAB carried out its work in full awareness of the European policy context, in particular of the research and development activities carried out at the national level and in support of European research policy initiatives [30]. ESRAB published its final report on 22 September 2006 and ceased its activities on 31 December 2006 [31]. In this report, it recommended the creation of the European Security Research and Innovation Forum (ESRIF) to foster greater dialog and a shared

view of European security needs [32]. In the following, the creation of ESRIF was announced at the 2nd European Conference on Security Research in March 2007, and the forum was established as a public-private dialog in security research in September of the same year.

The main objective of ESRIF is the development of a mid- and long-term Joint Security and Research Agenda that will link security research with security policy-making and its implementation [33]. Based on the understanding that research and public-private partnerships have a role to play in protecting critical infrastructures, the aims of the ESRIF program are [34]:

- To bring together all the relevant stakeholders in order to discuss issues of cross-cutting and common concern;
- To identify proposals for forming a strategic security research and innovation agenda, involving national and European stakeholders, laying out a shared and clear view of European security research needs and priorities; and
- To share ideas, views, and best practices in order to make better use of existing capabilities and to enhance the use of technology in security-related domains.

One main focus of ESRIF is critical information protection. ESRIF is supposed to present a Joint Research Agenda towards the end of 2009, when the forum will be terminated.

### 4.3 Critical Information Infrastructure Research Co-ordination (CI2RCO)

The EU has set up a task force[3] to explore the measures taken by its 25 member states to combat (cyber-) threats against critical infrastructure. As part of the EU's CI2RCO (Critical Information Infrastructure Research Coordination) project, announced in April 2005, the task force aims to identify research groups and programs focusing on IT security in critical infrastructures, such as telecommunications networks and power grids. The scope of the cooperation goes beyond the EU; the task force also wants to include the US, Canada, Australia, and Russia. The CI2RCO project was a Co-ordination Action co-funded under the IST FP6. The main objectives of the CI2RCO project are [35]:

- To encourage a coordinated Europe-wide approach for research and development on CIIP;
- To establish a European Research Area (ERA) on CIIP as part of the larger IST strategic objective of integrating and strengthening the ERA in terms of dependability and security.

CI2RCO focuses on activities and actions across the EU-25 and associate candidate countries. Among other information, the CI2RCO website features the European CIIP Newsletter and upcoming events in the area of CIIP [36].

[3]The European task force includes the Fraunhofer Institute for Secure Information Technology (FhG-SIT); the German Aerospace Center (DLR); the Industrieanlagen-Betriebsgesellschaft (IABG) company; the Italian National Agency for New Technologies, Energy and the Environment (ENEA); the Netherlands Organization for Applied Scientific Research (TNO); the Ecole Nationale Supérieure des Télécommunications; and consulting firm Ernst Basler+Partner.

### 4.4 Service and Software Architectures, Infrastructures, and Engineering

In its Research Framework Programme 7, the European Commission will also provide substantial funding for research into service and software architecture, infrastructure, and engineering. This objective integrates research activities in the areas of services, software, grid, and virtualization technologies [37]. The challenge in achieving pervasive and trusted network and service infrastructures is to look at the converged communication and service infrastructure that will gradually replace the current internet, mobile, fixed, and audiovisual networks. The objective of this research project integrates and builds on the achievements of related work from the IST Programme in FP6. The integrated research effort aims at bringing in world-class participants including European industry, small- and medium-size enterprises, universities, and research institutes, each of which are to contribute their specific skills to ensure success [38].

## 5 LAW AND LEGISLATION

In its legislation on CIIP, the EU went back to the basic principles already enshrined in European law, particularly with regard to the confidentiality of communications and the legal conditions for interception, traffic data retention, legality of content, or intellectual property [39].

### 5.1 Data Protection Directive 1995

The Data Protection Directive (95/46/EC) [40] provides a regulatory framework to guarantee the secure and free movement of personal information across the national borders of EU member countries, and also establishes a baseline of security controls protecting this information [41]. The Data Protection Directive requires that any third country to which data is transferred provide "adequate" data protection.[4]

### 5.2 Directive on Electronic Signature 1999

In to the area of e-Commerce, the Directive on Electronic Signatures (1999/93/CE) [42] has been duly incorporated into the national legislation of member states. This directive outlines requirements for certificates, certification service providers, and secure signature-creation devices, and provides recommendations for secure signature verification. The directive recognizes the potential variety of technologies used to generate signatures, but does not establish detailed technical standards or propose best practices. It also lays the groundwork for the international recognition of certificates.

### 5.3 Directive on Privacy Protection in the Electronic Communications Sector 2002

Directive 95/46/EC has been complemented by Directive 97/66 [43] on the protection of personal data in the field of telecommunications and, of even greater relevance, by the EU Directive on Privacy Protection in the Electronic Communications Sector (2002/58/CE) [44].

[4]Cf. the US Safe Harbor Arrangement as a streamlined process for US companies to comply with the directive, developed by the US Department of Commerce in consultation with the EU. http://www.export.gov/safeharbor/.

The directive clarifies policies on spamming, electronic data collection, and retention by requiring the member countries to adopt legislation providing data confidentiality, limiting the traffic data storage, and providing exceptions for reasons of national security. Moreover, the directive specifies that traffic data is to be deleted or depersonalized as soon as it is no longer needed for sending or preparing invoices, but nonetheless allows member states the possibility "of adopting legislative measures providing for the retention of data for a limited period" [45]. These measures must be "appropriate or proportionate, within a democratic society, to safeguard national security, defense, public security, and the prevention, investigation, detection and prosecution of criminal offences or of unauthorized use of electronic communication systems" [45].

### 5.4 Framework Directive 2002

The objective of the Framework Directive (2002/21/EC) [46] is to establish a harmonized framework for the regulation of electronic communications networks and services. It lays the foundation in the form of horizontal provisions serving the other measures: the scope and general principles, basic definitions, general provisions on the national regulatory authorities, the new concept of significant market power, and rules for granting certain indispensable resources such as radio frequencies or rights of way.

### 5.5 Council Framework Decision on Attacks Against Information Systems 2005

The European Council Framework Decision on attacks against information systems (2005/222/JHA) [47] of February 2005 aims to strengthen criminal judicial cooperation on attacks against information systems by developing effective tools and procedures. The criminal offences punishable under the framework decision are: illegal access to information systems, illegal system interference (the intentional serious hindering or interruption of the functioning of an information system by inputting, transmitting, damaging, deleting, degrading, altering, suppressing, or rendering inaccessible computer data) and illegal data interference. The member states will have to make provisions for such offences to be punished by effective, proportionate, and dissuasive criminal penalties. To enhance cooperation, the member states must establish operational points of contact that are available 24 hours a day and seven days a week.

### 5.6 Directive on Data Retention 2006

In March 2006, the European Parliament and the Council enacted the Directive on the Retention of Data processed in connection with the provision of public electronic communication services or of public communications networks (2006/24/EC, following Commission proposal COM(2005)0438).[5] The directive is designed to harmonize

[5]This directive amends Directive 2002/58/EC: http://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=OJ:L:2006:105:0054:0063:EN:PDF. Member states had to transpose the requirements of the Directive into national laws by 16 September 2007; however, a grace period of 18 additional months is available. Until 15 March 2009, each member state may postpone application of the Directive to the retention of communications data relating to internet access, internet telephony, and e-mail. Any member state that intends to make use of this provision must notify the Council and the Commission to that effect by way of a declaration. The following member states have made such a declaration postponing application for differing lengths of time: the Netherlands, Austria, the United Kingdom, Estonia, Cyprus, Greece, Luxembourg, Slovenia, Sweden, Lithuania, Latvia, the Czech Republic, Belgium, Poland, Finland, and Germany.

member states' national legislation on the retention of telephone and e-mail data for investigating, detecting, and prosecuting serious crime, as defined by each member state in its national law. The directive applies to traffic and location data on both legal entities and natural persons and to the related data necessary to identify the subscriber or registered user. It does not apply to the content of electronic communications, including information consulted using an electronic communications network. Member states must ensure that communications providers retain communication data for periods of not less than six months and not more than two years from the date of the communication. The measures, drafted by the United Kingdom after the London terrorist bombings in July 2005, require companies to keep a wide range of data, including incoming and outgoing phone numbers; the duration of phone calls; data that can be used to trace fixed or mobile telephone calls; information about text messages; IP addresses, which identify a computer's coordinates on the internet; login and logoff times; and details of e-mail traffic—but not the actual content of communications.[6] Details of connected calls that are unanswered, which can be used to send signals to accomplices or to detonate bombs, will also be archived where that data exists. Independent authorities will be designated to monitor the use of the data, which will have to be deleted at the end of the period unless it is kept for anti-terror investigation purposes.[7]

No later than 15 September 2010, the European Commission is required to submit an evaluation of the application of the Directive and its impact on economic operators and consumers, taking into account further developments in electronic communications technology and the statistics provided to the Commission with a view to determining whether it is necessary to amend the provisions of this Directive, in particular with regard to the list of data and the periods of retention.

### 5.7 Treaty of Lisbon 2007

The Treaty of Lisbon, signed by the heads of state or government of the 27 member states in Lisbon on 13 December 2007, which was scheduled to enter into force on 1 January 2009 in order to reform the EU's constitutional framework, includes provisions for the protection of personal data.[8] The treaty reaffirms the "right to the protection of personal data" (Art. 16 B of the Treaty of Lisbon). Moreover, it states that the European Parliament and the Council shall lay down the rules relating to the protection of individuals with regard to the processing of personal data by EU institutions, bodies, offices, and agencies, and by the member states when carrying out activities that fall within the scope of EU law, and the rules relating to the free movement of such data. Compliance with these rules

[6]The following categories of data must be retained with regard to fixed network telephony and mobile telephony, as well as internet access, e-mail, and internet telephony (see Article 5 of the Directive): (a) data necessary to trace and identify the source of a communication; (b) data necessary to trace and identify the destination of a communication; (c) data necessary to identify the date, time and duration of a communication; (d) data necessary to identify the type of communication; (e) data necessary to identify the communication device; (f) data necessary to identify the location of mobile communication equipment.

[7]Each member state must designate a supervisory authority to be responsible for monitoring the application within its territory of the provisions adopted by the member states regarding the security of the stored data (see Article 9 of the Directive). Those authorities may be the same authorities as those referred to in Article 28 of Directive 95/46/EC. The supervisory authority must act with complete independence.

[8]Full text of the Treaty of Lisbon (also known as "the Reform Treaty"): http://europa.eu/lisbon_treaty/full_text/index_en.htm.

shall be subject to the control of independent authorities. As an annex, the Declaration on Article 16 B of the Treaty on the Functioning of the European Union (No. 20) states that whenever rules on the protection of personal data could have direct implications for national security, due account will have to be taken of the specific characteristics of the matter. The Declaration on the Protection of Personal Data in the Fields of Judicial Cooperation in Criminal Matters and Police Cooperation (No. 21) acknowledges that specific rules on the protection of personal data and the free movement of such data in the fields of judicial cooperation in criminal matters and police cooperation may be necessary because of the specific nature of these fields.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Marcelo Masera of the Institute for the Protection and Security of the Citizen Joint Research Centre and Martin Wählisch of Humboldt University Berlin, who validated the content of this chapter.

# THE FORUM OF INCIDENT RESPONSE AND SECURITY TEAMS (FIRST)

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 INTRODUCTION

FIRST is the global Forum for Incident Response and Security Teams. The organization is widely recognized as a global leader in incident response and brings together a variety of Computer Security Incident Response Teams (CSIRTs) from government, commercial, and education organizations. FIRST aims to foster cooperation and coordination in incident prevention, to stimulate rapid reaction to incidents, and to promote information-sharing among members and the community at large. FIRST's vision is that membership should enable incident response teams to respond more effectively to security incidents by providing best practices, tools, and trusted communication with member teams. FIRST's mission statement, which was originally adopted in 1995 and reissued in an updated version in June 2003, holds that FIRST is an international confederation of trusted CSIRTs that cooperatively handle programs to prevent computer security incidents. Moreover,

- FIRST members develop and share technical information, tools, methodologies, processes, and best practices;
- FIRST encourages and promotes the development of quality security products, policies, and services;
- FIRST develops and promulgates best computer and security practices;
- FIRST promotes the creation and expansion of incident response teams and membership from organizations around the world;

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

- FIRST members use their combined knowledge, skills, and experience to promote a safer and more secure global electronic environment [1].

## 2 FIRST HISTORY

FIRST was formed in 1990 in response to the occurrence of major incidents—a computer security incident known as the "internet worm", which brought the internet to its knees in 1988, and the "WANK worm", which highlighted the need for better communication and coordination in 1989. Since that time, it has continued to grow and evolve in response to the changing needs of incident response and security teams and their constituencies. By now, most companies rely on the internet in their daily business transactions. Incident response and security teams continue to form around the globe, covering the growing range of constituencies and member teams of FIRST, including entire countries as well as multi-national organizations and teams from educational and commercial establishments, vendors, the government, and the military [2].

## 3 ORGANIZATION

FIRST consists of a network of individual CSIRTs that work together voluntarily to deal with computer security problems and their prevention. It operates under a formal Operational Framework that describes the governing principles and operating rules for the organization [3]. FIRST exercises no authority over the organization and operation of individual member teams. The general coordination of FIRST activities is provided by the Steering Committee, the Board of Directors, and the Secretariat. Every year, FIRST holds general meetings where members are expected to be represented and the Steering Committee members are elected. In order to address specific topics, special meetings can be called by the chair of the Steering Committee.

There are two types of participants in FIRST. The full members represent organizations that assist an information technology community or another defined constituency in preventing and handling computer-related incidents. Liaison members are individuals or representatives of organizations other than incident response or security teams that have a legitimate interest in and value to FIRST [4].

## 4 GLOBAL INITIATIVES

FIRST is the only worldwide global CSIRT forum, and its members are experts from across the field and from all over the world. With its global scope and its heterogeneous character, FIRST supports and collaborates with existing initiatives to communicate with CSIRT members. As a global umbrella organization, it strives to bring together a wide variety of collaborative and cooperative approaches of the multiple disciplines involved in computer and network security incident response [5].

Mainly, FIRST's global initiatives are introduced in Special Interest Groups (SIG) and in the Corporate Executive Programme (CEP). SIGs exist to provide a forum where FIRST members can discuss topics of common interest to the incident response community. A SIG is a group of individuals composed of FIRST members and invited parties, typically coming together to explore an area of interest or specific technology

area, with the goal of collaborating and sharing expertise and experiences to address common challenges. SIGs generate papers and publications for the industry covering their area of interest. While these papers and publications are distributed by FIRST, they do not represent the official position of the FIRST members, or of FIRST itself [6].

In June 2005, the board and membership of FIRST agreed to fund and establish a unique Corporate Executive Programme (CEP). The aim of the CEP is to bring together cross-functional senior executives with responsibility for decision-making in their organizations. The program caters for heads of departments in HR, finance, operations, technology, security, sales and marketing, research, logistics, legal affairs, and other key business disciplines in all sectors—public and private—across all global regions. The program aims to provide an environment where business leaders can fully appreciate the nature of future threats and risks that global organizations will be facing in the years ahead [7].

# GROUP OF EIGHT (G8)*

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 INTRODUCTION

Since 1995, the Group of Eight (G8) has become increasingly involved in issues relating to cyber-crime, the Information Society, and Critical Infrastructure Protection. At the

*The Group of Eight Survey of 2006 was reviewed by Harry Hoverd, Home Office, UK. For this edition, the authors have thoroughly updated the Group of Eight survey by referring to open-source material.

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

Halifax summit in 1995, a group of senior experts was set up with the task of reviewing and assessing existing international agreements and mechanisms to fight organized crime. This G8 Senior Experts Group took stock extensively and critically before drawing up a catalog of 40 operative recommendations. These recommendations were approved at the G8 summit in Lyon in 1996. The G8 Senior Expert Group, known since then as the Lyon Group, was the first international political forum to fully recognize the significance of high-tech crime. The Lyon Group has since developed into a permanent multi-disciplinary body with numerous specialized sub-working groups. Since October 2001, the Lyon Group meetings have been held together with the Roma Group dealing with combating terrorism (Lyon/Roma Group) [1].

A further important stage for the G8 and CIP/CIIP came in spring 2000. On 15–17 May 2000, government officials and industry participants from G8 countries and other interested parties attended the G8 Paris Conference on Dialogue Between the Public Authorities and Private Sector on Security and Trust in Cyberspace [2]. The aim was to discuss common problems and to find solutions associated with high-tech crime and the exploitation of the internet for criminal purposes. The G8 member states were convinced that a dialog between governments and the private sector was essential in the fight against the illegal or prejudicial use of ICT, and they agreed on defining a clear and transparent framework for addressing cyber-crime [2].

## 2 OKINAWA CHARTER ON GLOBAL INFORMATION SOCIETY

The Okinawa Charter on Global Information Society was published in July 2000 [3]. The charter states that ICT is one of the most potent forces shaping the 21st century, enabling many communities to address social and economic challenges with greater efficiency. One of the key principles and approaches of the charter is that international efforts to develop a global Information Society must be accompanied by coordinated action to foster a crime-free and secure cyberspace. In this respect, the Okinawa charter refers to the OECD Guidelines for Security of Information Systems.[1] Moreover, in the Okinawa Charter, the G8 asked both the public and private sectors to make efforts to bridge the international information and knowledge gap.

## 3 G8 PRINCIPLES FOR PROTECTING CRITICAL INFORMATION INFRASTRUCTURES

G8 members met in Paris in March 2003 for the first multilateral meeting devoted to CIP/CIIP. Top-level experts from G8 member states, together with the major CIP/CIIP operators (e.g., France Telecom for France) came together to define common principles for the protection of vital CI/CII [4]. The 11 clearly defined CIIP principles were adopted on 5 May 2003 by the G8 justice and interior ministers. They cover the following topics [5]:

- Countries should have emergency warning networks regarding cyber-vulnerabilities, threats, and incidents;
- Countries should raise awareness to facilitate stakeholders' understanding of the nature and extent of their CII, and the role each must play in protecting them;

[1] See the survey on the OECD in this volume.

- Countries should examine their infrastructures and identify interdependencies among them, thereby enhancing protection of such infrastructures;
- Countries should promote partnerships among stakeholders, both public and private, to share and analyze information on their critical infrastructure in order to prevent, investigate, and respond to damage to or attacks on such infrastructures;
- Countries should create and maintain crisis communication networks and test them to ensure that they will remain secure and stable in emergency situations;
- Countries should ensure that data availability policies take into account the need to protect critical information infrastructures;
- Countries should trace attacks on critical information infrastructures and, where appropriate, disclose the results to other countries;
- Countries should conduct training and exercises to enhance their response capabilities and to test continuity and contingency plans in the event of an attack on the information infrastructure, and should encourage stakeholders to engage in similar activities;
- Countries should ensure that they have adequate substantive and procedural laws, such as those outlined in the Council of Europe Cybercrime Convention of 23 November 2001, and trained personnel to enable them to investigate and prosecute attacks on critical information infrastructures, and to coordinate such investigations with other countries as appropriate;
- Countries should engage in international cooperation, when appropriate, to secure critical information infrastructures, including by developing and coordinating emergency warning systems, by sharing and analyzing information regarding vulnerabilities, threats, and incidents, and by coordinating investigations of attacks on such infrastructures in accordance with domestic laws;
- Countries should promote national and international research and development and encourage the application of security technologies that are certified according to international standards.

With the adoption of these principles, the G8 member states suggested that the emergence of a new "security culture" should encourage them to strengthen international co-operation, to implement the best professional practices in the field of computerized surveillance and alert, to conduct common exercises to test the reaction capabilities in case of incidents, to make other countries aware of the problems, and to invite them to adopt the same main courses of action [6]. The 11 principles are intended to guide national responses to CIIP. However, to this end, it is crucial that the principles be communicated to all parties concerned.

The essential elements of the principles of protecting CII were adopted by the 78th United Nations General Assembly [7]. Resolution 58/199 of January 2004, entitled "Creation of a global culture of cyber security and the protection of critical information infrastructures", is complemented by the annex Elements for Protecting CII, which is based on the 11 principles defined by the G8 in 2003 [8].

The G8 justice and home affairs ministers (the ministerial meeting of the Lyon/Roma Group) met in Washington in May 2004 and endorsed Best Practices for Network Security, Incident Response and Reporting to Law Enforcement. This guide assists network operators and system administrators in responding to computer incidents [9].

## 4 HIGH-TECH CRIME SUB-GROUP ACTIVITIES

One of the sub-groups of the Lyon Group, called the High-Tech Crime sub-group, deals with issues concerning CIIP. The sub-group's goal for CIIP work is to find a way to protect the infrastructure that G8 countries are dependent on, and to provide a more unified approach to multinational companies that deal with a number of G8 countries for setting up an international information-sharing mechanism. Furthermore, the High-Tech Crime sub-group is active in a number of areas, including:

- A CIIP handbook of national contact points. This International CIIP Directory is compiled and maintained by CPNI (UK),[2] and its scope is limited to national governmental organizations. The directory is not available publicly, commercially, or to industry (except on government business);
- CIIP conferences;
- A summary of domestic legal frameworks and avenues of co-operation for addressing illegal internet content;
- Best practice for law enforcement in addressing criminal misuse of wireless networks [10];
- A summary of countries' national legislation regarding law enforcement treatment of encrypted evidence and current trends in criminal use of encryption;
- A standard template for making and responding to requests for 24/7 high-tech investigative assistance;
- A work plan for tackling viruses, worms, and other malicious code.

During its presidency of the G8 for the year 2005, the UK defined the improvement of international co-operation in the field of CIIP as a main objective.

From 15–17 June 2005, a meeting of the justice and home affairs ministers was held in Sheffield. On the basis of this meeting, the justice and home affairs ministers published a communiqué on CIIP. The communiqué refers to the Unified Response Tabletop Exercise hosted in New Orleans by the G8 High-Tech Crime sub-group in May 2005, where various experts in law enforcement, watch and warning, and industry met to find solutions to challenges in the field of CIIP. The communiqué also outlines areas where further action is required:

- To continue to enhance communication and information-sharing between watch and warning organizations and law enforcement agencies;
- To ensure that all G8 countries have, and encourage other countries to develop, watch and warning organizations able to detect vulnerabilities and threats;
- To ensure that law enforcement agencies can quickly respond to serious cyber-threats and incidents;
- To continue and strengthen cooperation with the private sector;
- To continue to conduct national and multinational training and exercises.

At the same meeting in Sheffield in June 2005, the High-Tech Crime sub-group released a further paper on Best Practices for Law Enforcement Interaction with Victim-Companies During a Cyber-Crime investigation [11].

[2]See the country survey on the UK in this volume.

## ACKNOWLEDGMENT

We acknowledge the contribution of the expert, Harry Hoverd of the Home Office, United Kingdom, who validated the content of this chapter.

# NORTH ATLANTIC TREATY ORGANIZATION (NATO)

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 INTRODUCTION

Critical Infrastructure Protection remains one of the key areas of work of the Civil Emergency Planning in the North Atlantic Treaty Organization (NATO). The Ministerial

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

Guidance for NATO Civil Emergency Planning (CEP) for 2007–2008 includes several references to critical infrastructure protection, while the Updated Civil Emergency Planning Action Plan for the improvement of civil preparedness against possible chemical, biological, radiological, and nuclear (CBRN) attacks includes several action items related to the CIP field of work. In line with the Concept Paper approved in 2003, the Senior Civil Emergency Planning Committee (SCEPC) and its eight Planning Boards and Committees (PB&Cs) will continue to examine critical infrastructure protection from a functional perspective, and to provide integrated contributions from the areas of expertise of all Planning Boards and Committees.

## 2 CIVIL COMMUNICATION PLANNING COMMITTEE (CCPC)

The Civil Communication Planning Committee (CCPC) is responsible for reviewing existing and planned electronic public and non-public communications infrastructures, services, associated facilities, postal services, and any related services with a view to determining their ability to meet the requirements of all vital users (civil and military) during emergencies. Recommendations are made to nations, taking into consideration new and emerging technology, national legislation and arrangements, and the role of international organizations in this field.

The CCPC has published a number of documents and studies on civil communications infrastructures, such as

- Critical telecommunications infrastructure protection;[1]
- CEP consequences of disruption of critical postal infrastructure;[2]
- New risks and threats to civil telecommunications;[3]
- CEP requirements for coordinated national telecommunications regulatory measures;
- New risks and threats to the postal services.[4]

In addition, the CCPC has contributed to the "North Atlantic Council's Action Plan on Cyber Defense", such as:

- CEP consequences of the introduction of the Computer Emergency Response Teams (CERTs)/CEP regarding cyber-attacks and information warfare on critical civil communication infrastructure;
- Identification and assessment of the interdependencies of other critical infrastructures on civil communication networks;
- Impact of Information Society developments and related opportunities for NATO CEP.

[4]NATO document: EAPC(CCPC)D(2003)1.

The Bucharest Summit declaration of 2008 in its paragraph 47 states that "NATO remains committed to strengthening key Alliance information systems against cyber attacks. We have recently adopted a Policy on Cyber Defence and are developing the structures and authorities to carry it out. Our Policy on Cyber Defence emphasis the need for NATO and nations to protect key information systems in accordance with their respective responsibilities; share best practices, and provide a capability to assist Allied nations, upon request, to counter a cyber attack. We look forward to continuing the development of NATO's cyber defence capabilities and strengthening the linkages between NATO and national authorities".[5] On 15 May 2008, at the initiative of Estonia, top military commanders from seven NATO countries and the Allied Command Transformation signed an agreement to create a Cooperative Cyber Defense Center in Tallinn. The cyber-attacks on Estonia in 2007 highlighted for the first time the potential vulnerability of NATO countries, their institutions and societies, an even NATO itself to disruption by penetration of their information and communication systems.[6] The goal of NATO policy and of the center is to assist allied countries as needed in protecting their critical communication and information networks [1].

## 3 CIVIL PROTECTION COMMITTEE (CPC)

The work of the Civil Protection Committee (CPC) in the CIP field started in 2001, when an Ad Hoc Group (AHG) on CIP was established. One of the first tasks of this AHG was to conduct a mapping survey of critical infrastructure. Nations were invited to indicate how they were structurally organized to deal with critical infrastructure protection, and to give indications about their state of readiness in terms of planning and infrastructure mapping.[7] Based on this initial mapping, definitional and conceptual work was undertaken by the AHG on CIP, resulting in a Critical Infrastructure Protection Concept Paper, approved by the SCEPC on 6 November 2003.

The Concept Paper not only proposed a way for work to be carried out by the CPC in this field, but also contained a road map detailing immediate, mid-term, and long-term actions. Also attached were a scenario to further explain the concept and a glossary of frequently-used CIP terms.

In 2005, the CPC conducted a seminar on the theme of Critical Infrastructure Protection (CIP)—Education, which aimed to raise awareness of the importance of CIP. The primary results expected from the seminar were sets of teaching points that could form part of a CIP course curriculum and recommendations for next steps regarding the CIP concept. The AHG is considering ways to develop further training and education activities on the basis of the seminar outcomes.[8]

Among other training activities, the CPC in 2007 organized a table-top exercise attended by representatives of more than 20 NATO, Euro-Atlantic Partnership Council (EAPC), Mediterranean Dialogue (MD), and Istanbul Cooperation Initiative (ICI)

[5]Bucharest Summit Declaration Issued by the Heads of State and Government participating in the meeting of the North Atlantic Council in Bucharest on 3 April 2008. http://www.summitbucharest.ro/en/doc_201.html.
[6]For more information about these incidents, see the chapter on Estonia.
[7]NATO document: EAPC(CPC)N(2002)6.
[8]Information provided by an expert.

countries and by representatives of NATO Military Authorities. The exercise aimed at increasing the understanding of:

- The vulnerabilities of and interdependencies between various critical infrastructures, including energy-related critical infrastructures;
- The bottlenecks that arise in decision-making at the national and international levels;
- The best practices in disaster response with regard to CIP.

In early 2008, the AHG was reorganized. Its work priorities over the next two years will be to update the Road Map and, if needed, the Concept Paper; to set up an information exchange tool to be used by different civil emergency planning stakeholders and to step up the work on addressing CIP interdependencies.[8]

## 4 INDUSTRIAL PLANNING COMMITTEE (IPC)

In 2003, an Industrial Planning Committee (IPC) seminar in Slovakia was attended by senior officials and representatives from EAPC governments, industry, and trade. The aim of the seminar was to examine industrial interdependencies and resulting vulnerabilities, and to discuss potential preventive and/or consequence-management measures. These issues were introduced by plenary presentations, including two case studies—a Canadian paper on industrial interdependencies and a Slovak case study on aspects of electricity, water, gas, and chemical utilities. Other presentations looked at

- Preventive measures for the protection of critical infrastructure;
- The military experience in infrastructure protection in France;
- Protecting critical infrastructure during disasters.

Following this initial seminar, and based on a questionnaire circulated in April 2003[9] and replies to it,[10] the IPC agreed to develop a guide containing criteria for identifying critical infrastructure in industry and the energy sector, and to compile active and passive methods of critical infrastructure protection. The IPC also established an Ad-Hoc Working Group on Energy CIP (AHWG) for appropriate action. The group agreed that energy-related CI consists of three main infrastructures:

- Systems of electricity generation, transmission, and delivery;
- Systems of natural gas production, transmission, and delivery;and
- Systems of oil production, transportation, refining, and delivery.

The IPC initially concentrated on the protection of critical electricity infrastructure. In 2005, it held a seminar on the topic of Protection of Electricity-Related Critical Infrastructure against Security Related Hazards". Subsequently, in October 2006, the IPC

[9]NATO document: EAPC(IPC)N(2003)6.
[10]NATO document: EAPC(IPC)WP(2003)2.

Vital Resources Seminar on Energy Critical Infrastructure Protection was held. Drawing on the discussions and recommendations of the seminar, the committee has compiled a collection of best practices on the protection of energy CIP as well as on the protection of electricity CIP. In 2007, the IPC seminar addressed the issue of CIP related to gas deliveries. A collection of best practices on protecting critical gas-related infrastructures is currently being drafted.[8]

The Bucharest NATO Summit Declaration states in Paragraph 48: "We have noted a report 'NATO's Role in Energy Security', prepared in response to the tasking of the Riga Summit. Allies have identified principles which will govern NATO's approach in this field, and outlines options and recommendations for further activities. Based on these principles, NATO will engage in the following fields: information and intelligence fusion and sharing; projecting stability; advancing international and regional cooperation; supporting consequence management; and supporting the protection of critical energy infrastructure" [2].

## 5 FOOD AND AGRICULTURE PLANNING COMMITTEE (FAPC)

The Food and Agriculture Planning Committee (FAPC) looks at the impact of CIP on food, agriculture, and water production. In particular, the FAPC looks at threats, risks, and vulnerabilities affecting the water sector. In doing so, the FAPC has chosen a multi-disciplinary training approach, which will make better use of the wealth of knowledge of all NATO experts by bringing them together to work on this subject under exercise conditions. Other planning boards and committees, particularly the Transport and Telecommunications Committees, work jointly with the FAPC.

## 6 CIVIL AVIATION PLANNING COMMITTEE (CAPC)

The Civil Aviation Planning Committee (CAPC) has begun identifying critical infrastructure vulnerabilities and possible protective measures in the area of civil aviation. While the protection of airports, equipment, and resources is primarily a national responsibility, the Civil Aviation Working Group has discussed minimum standards that can help to make national efforts more effective. Any large-scale military deployment would require the transport capabilities of the civil aviation sector and the related infrastructure elements, which together with the air traffic control network, the power grid, fuel supplies, and supporting surface transportation are essential parts of NATO's deployment capability.

## 7 PLANNING BOARD FOR INLAND SURFACE TRANSPORTATION (PBIST)

The Planning Board for Inland Surface Transportation (PBIST) has conducted exploratory and definitional work on problems that may result from attacks on critical inland surface transport infrastructure. A PBIST report emphasizes that the civilian transport infrastructure is considered an attractive target, as global trade depends heavily on transportation.[11]

[11] NATO document: EAPC(PBIST)D(2003)8.

The report aims to reach conclusions on threats to the inland transport infrastructure, characteristics of likely targets, possible protective measures, and the potential role of the PBIST.

## 8 PLANNING BOARD FOR OCEAN SHIPPING (PBOS)

At the behest of the NATO Council and the SCEPC, the Planning Board for Ocean Shipping (PBOS) continues to serve as the NATO focal point for advice and assistance on the protection of civilian maritime assets against acts of terrorism. This work includes: monitoring the work and activities of other international bodies, gathering and exchanging information from international and national sources, and providing advice and assistance as necessary.

## 9 COORDINATION

Overall responsibility for coordinating CIP work lies with the SCEPC. However, on the initiative of the CPC, representatives of the Planning Boards & Committees (PB&Cs) meet on a regular basis to discuss various issues related to CIP. These meetings are an opportunity for all PB&Cs to present work that is under way and/or planned within their respective areas of interest, in addition to fostering closer cooperation and coordination.

## 10 SPECIAL REPORT TO THE NATO PARLIAMENTARY ASSEMBLY 2007

Lord Jopling from the United Kingdom was nominated Special Rapporteur and delivered a report on the protection of critical infrastructures [3] to the NATO Parliamentary Assembly in the 2007 annual session. This report strives to outline the critical infrastructure policies of NATO and also of its individual member countries. It collects the various definitions, highlights their commonalities and differences, and tries to attribute responsibilities by identifying the CIP stakeholders and the sectoral policies including CIIP; energy security, civil aviation security, and port security.

## ACKNOWLEDGMENT

We acknowledge the contribution of the expert, Denisa-Elena Ionete of Civil Emergency Planning, NATO Headquarters, who validated the content of this chapter.

# ORGANIZATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT (OECD)*

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 INTRODUCTION

The Organisation for Economic Co-operation and Development (OECD) has a long history and expertise in developing policy guidance for the security of information systems and networks, including critical information infrastructures. The OECD is also committed to the fight against cyber-crime; notably, it fights against the use of malicious software. The OECD produces analytical reports, statistics, and policy guidance (declarations and recommendations) to help governments and businesses develop consistent policies to strengthen information security, to raise public awareness about the importance of information security for the internet economy, and, more broadly, to develop a culture of security across society. There is a consensus among the member countries that secure and reliable (information) infrastructures and services are a necessary requirement for trustworthy e-Commerce, secure transactions, and personal data protection. This is the main reason why the OECD Working Party on Information Security and Privacy (WPISP) promotes a global approach to policy-making in these areas to help build trust online [1]. In addition, the Committee for Information, Computer and Communications Policy (ICCP) analyzes the broad policy framework underlying the e-Economy, information infrastructures, and the Information Society [2].

## 2 OECD GUIDELINES FOR THE SECURITY OF INFORMATION SYSTEMS AND NETWORKS: TOWARDS A CULTURE OF SECURITY

The attacks of 11 September 2001 in the US marked a turning point for the OECD's efforts for information security and CIIP. In order to improve measures against cyber-crime, computer viruses, and hacking, the OECD drew up new guidelines. At its 1037th session on 25 July 2002, the OECD Council adopted the new Guidelines for the Security of Information Systems and Networks: Towards a Culture of Security [3]. The guidelines are not binding. However, they are the result of a consensus between OECD governments

*The OECD Survey of 2008 was reviewed by Anne Carblanc, OECD.

and of discussions involving representatives of the information technology industry, business users, and civil society [4]. The OECD invites governments in other countries to adopt a similar approach to CIIP. Furthermore, the private-sector representatives are asked to improve security in their own environment and to provide security information and updates to the users. The individual users are urged to be more aware and responsible, and also to take the best preventive measures possible to decrease the risks to CI/CII. The OECD Guidelines include the following complementary principles at the policy and operational levels [5]:

1. *Awareness.* Participants should be aware of the need for security of information systems and networks and of options to enhance security;
2. *Responsibility.* All participants are responsible for the security of information systems and networks;
3. *Response.* Participants should act in a timely and co-operative manner to prevent, detect, and respond to security incidents;
4. *Ethics.* Participants should respect the legitimate interests of others;
5. *Democracy.* The security of information systems and networks should be compatible with the essential values of a democratic society;
6. *Risk assessment.* Participants should conduct risk assessment;
7. *Security design and implementation.* Participants should incorporate security as an essential element of information systems and networks;
8. *Security management.* Participants should adopt a comprehensive approach to security management;
9. *Reassessment.* Participants should review and reassess the security of information systems and networks and make appropriate modifications to security policies, practices, measures, and procedures.

## 3 OECD GUIDELINES FOR THE PROTECTION OF CRITICAL INFORMATION INFRASTRUCTURES

In 2008, the OECD Council plans to adopt a Recommendation on the Protection of Critical Information Infrastructures (CII).[1] This document highlights the relevance of the Security Guidelines to CII. It provides guidance on national policies and proposes ways to improve international cooperation for the protection of CII. The guidance derives from best practices identified in an OECD comparative study of CII policies in seven countries.

The recommendation identifies the need for strengthened international cooperation to address cross-border issues, given the importance of the internet as a global infrastructure. It also identifies the need for a national operational infrastructure security capability, a willingness and ability to share information, close cooperation with the relevant parts of the private sector, and a strong culture of security in the face of rapid technological growth and consequential social changes. The recommendation therefore calls on member

[1]The expression CII used in the OECD recommendation refers to those information networks and systems the failure of which would have a serious impact on the health, safety, security, and economic well-being of citizens, or the effective functioning of government or the economy. The adoption of this document was planned for the OECD Ministerial Meeting on the Future of the Internet Economy in Seoul, Korea, 16–18 June 2008. http://www.biac.org/members/iccp/mtg/2008-06-seoul-min/seoul2008 ministerial documents.asp.

countries to adopt a common approach in a number of areas to enable progress on some of these issues. Further, although the recommendation is addressed to governments, it stresses the need for collaboration with the private sector.

The OECD recommendation is timely. First, critical infrastructures are increasingly interdependent and reliant on the effective functioning of information and communication technologies. For example, the monitoring and control systems of power grids and hydroelectric power plants are often dependent on the functioning of underlying internet protocol-based networks. Further, most industrial control systems that monitor and control critical processes are now increasingly being connected directly or indirectly (through corporate networks) to the internet and therefore face a new set of threats. Also, as shown in the OECD-APEC Analytical Report on Malware [6], there is increasing malicious activity online, which adversely affects all internet users and activities, and unfortunately, critical information systems have not proven immune to this phenomenon.[2]

## 4 CULTURE OF SECURITY WEBSITE

In December 2003, the OECD launched the Culture of Security website as part of the organization's initiative to promote a global culture of security. The site primarily provides member and non-member governments with an international information-exchange tool on initiatives to implement the OECD Security Guidelines. The OECD website provides an overview of [7]:

- OECD work in the area of security of information systems and networks since the adoption of the Security Guidelines in 2002;
- National implementation initiatives: Activities in various countries to apply the OECD Security Guidelines at the national level;
- Selection of practical tools: Countries are developing various useful tools to encourage awareness, education, and individual responsibility;
- International co-operation: Action taken by governments and international organizations at the regional or international levels to co-operate among themselves and/or with other participants.

## 5 OECD FORUMS AND WORKSHOPS

Other OECD efforts concerning CIIP included the OECD-APEC Global Forum on Policy Frameworks for the Digital Economy, held in Honolulu in January 2003, and the OECD Global Forum on Information Systems and Network Security, which was convened in Oslo in October 2003 [8]. The Honolulu Forum emphasized the importance of the security of information systems and networks, as well as the need for the OECD to implement the OECD Security Guidelines. Furthermore, it emphasized the importance of preparing for the World Summit on the Information Society (WSIS) in December 2003 in Geneva (Switzerland). Many Asia-Pacific Economic Cooperation (APEC) member countries were invited to the Oslo conference due to an agreement made in Honolulu

[2]Information provided by an expert.

to increase co-operation between the OECD and APEC. This was another major step towards international and transnational management of CIIP efforts.

Among the main intended policy impacts of the Oslo Forum were:

- Raising awareness of the importance of secure information systems and networks for safeguarding critical infrastructures, as well as business and consumer information;
- Increasing knowledge of the OECD Security Guidelines;
- Encouraging the development and the promotion of security architectures that effectively protect the information systems of organizations;
- Exploring the use of technology and security standards in safeguarding IT infrastructures.

In September 2005, an OECD-APEC Workshop on Security of Information Systems and Networks was held in Seoul (South Korea). Topics discussed included spyware, reaching out to SMEs and individuals, promoting effective global incident response (e.g., the roles of governments and CERTs/CSIRTs), emerging security threats and the technologies being developed to address them, as well as the role of research and development, and finally, a comparison of legislative and policy approaches to improve the management and security of information systems and networks [9].

In March 2006, the OECD together with the US National Science Foundation held a workshop on The Future of the Internet in Paris. The event marked the beginning of the project on the future of the internet by the OECD Committee for Information, Computer and Communications Policy (ICCP) [10]. Following up on this workshop, in 2007, the OECD again co-organized a workshop together with the US National Science Foundation on the Social and Economic Factors Shaping the Future of the Internet. The goal of this second workshop was the discussion of strategic directions for the future of the internet, from both the technological and the policy viewpoints [11].

From 16–18 June 2008, ministers, business leaders, technical experts, academics, and civil society representatives from the 30 OECD countries and more than 15 other economies will meet in Seoul, Korea, to discuss the Future of the Internet Economy and agree new ways to improve global dialog, co-ordination, and co-operation on policies and practices to form an enabling environment for the internet economy.

Strengthening the security of the internet and other information systems and networks, including CII, will be one of the key issues addressed at the ministerial meeting.

## ACKNOWLEDGMENT

We acknowledge the contribution of the experts, Anne Carblanc and Peter Lübkert and Laurent Bernat of the Organization for Economic Cooperation and Development, who validated the content of this chapter.

# UNITED NATIONS (UN)

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 INTRODUCTION

Issues related to CIIP have been discussed by the United Nations (UN) and its system of organizations since the end of the 1980s. However, formal CIIP efforts are a more recent phenomenon. Several initiatives have since been undertaken towards better work coordination. Among these are initiatives taken by UN institutions, several UN resolutions, and the results of the World Summit on the Information Society (WSIS).

## 2 UN INSTITUTE FOR DISARMAMENT RESEARCH (UNIDIR)

An important first step was the organization of a workshop in July 1999 by the UN Institute for Disarmament Research (UNDIR) in Geneva. The main topic was how to better

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

achieve worldwide information security and assurance in a global digital environment. In this context, a variety of issues, such as the Revolution in Military Affairs (RMA) and the proliferation of offensive tools for attacking information systems and networks, were discussed in Geneva. There was consensus among the participants that the vulnerability of national and international information infrastructures to cyber-attacks was increasing, and that international cooperation had to be improved in order to meet this challenge. One other conclusion was that the issue of CIIP is not only of military or strategic importance, but that it is mainly a political, economic, and social issue [1]. Hence, it is crucial to achieve cooperation between public and private actors as well as between nations.

## 3 UN GENERAL ASSEMBLY RESOLUTIONS

In December 2000 and 2001, the 55th and 56th UN General Assemblies issued Resolutions 55/63 and 56/121 on "Combating the criminal misuse of information technologies" [2]. This was another important step in the efforts of the UN concerning CIIP. These resolutions emphasize in particular that the Commission on Crime Prevention and Criminal Justice is intended to make law enforcement more efficient and effective. Furthermore, the importance of cooperation among countries and between the public and private sectors was stressed once again. The resolutions also mention the Convention on Cybercrime of the Council of Europe and the work done by the G8 as crucial milestones in the international field [2].

In December 2002, the 57th UN General Assembly issued Resolution 57/239 on the "Creation of a global culture of cyber-security" [3]. This resolution emphasizes that effective cyber-security not only requires action at the governmental level, but must be supported throughout society. Therefore, it points out the different actors responsible in the field of cyber-security, namely, governments, businesses, and other organizations, as well as individual owners and users of information technologies. The resolution further recognizes once more the importance of international cooperation. The annex outlines nine complementary elements required to create a global culture of cyber-security. They range from awareness of the need for security of information systems and networks, to identifying adequate action in the field of CIIP (taking into account ethical and democratic principles), to security management and reassessment [3].

In December 2003, the 28th UN General Assembly issued Resolution 58/199 on the "Creation of a global culture of cyber-security and the protection of critical information infrastructure" [4]. This resolution points out the increasing links among most countries' critical infrastructure and the growing number and variety of threats facing them. The resolution's annex outlines 11 principles for protecting CII, which are based on those adopted by the G8 Justice and Interior Ministers in Paris in 2003. The UN General Assembly invites member states and international organizations to consider these principles for protecting CII, as well as to share their best practices and measures that could assist other actors in their efforts to achieve cyber-security. Furthermore, the resolution asks that these principles be taken into account in preparations for the second phase of the World Summit on the Information Society (WSIS) in Tunisia in November 2005. Finally, the UN General Assembly outlines the necessity of involving the developing and the least developed countries in CIIP, which means that the transfer of information technology and capacity-building efforts need to be strengthened [4]. In the subsequent years, the UN General Assembly regularly adopted a resolution on the "Developments

in the field of information and telecommunications in the context of international security" [5]. Referring to the earlier resolutions, the member states are repeatedly called upon to promote further the consideration of existing and potential threats in the field of information security, as well as possible measure to limit the threats emerging in the field. Moreover, the secretary-general, with the assistance of a group of experts (to be established by 2009), is requested to continue to study existing and potential threats in the sphere of information security and possible cooperative measures to address them.

In 2005 and 2006, two subsequent resolutions on WSIS were adopted. The first one urges member states to support and actively contribute to the success of the Tunis Summit, as well as its aims and goals. The second one requests that the Economic and Social Council (ECOSOC) oversee the system-wide follow-up of the Geneva and Tunis outcomes of the summit [6]. Furthermore, it proclaims an annual World Information Society Day (17 May) and calls for an overall review of the implementation of the summit outcomes in 2015.

## 4 UN ICT TASK FORCE

The establishment of the UN ICT Task Force in November 2001, in response to a request by the UN ECOSOC, was a further important step. The task force was mandated to mobilize worldwide support for attaining the Millennium Development Goals with the use of ICT. In April 2004, a seminar on "Policy and security issues in information technology" was held at the UN Headquarters. Part of the seminar series was on policy awareness and training in information technology, organized by the ICT Task Force and the UN Institute for Training and Research (UNITAR) [7]. In 2005, the task force published a guide called "Information Insecurity—A Survival Guide to the Uncharted Territories of Cyber-Threats and Cyber-Security" [8]. This publication depicts the problem of information insecurity in general, and provides possible solutions for prevention and response to security incidents (including standards and best practices). Moreover, it attempts to create a greater awareness about the growing dangers of cyber-hooliganism, cyber-crime, cyber-terrorism, and cyber-war, which are inherent aspects of the new opportunities (both positive and negative) that have been opened up by new information technologies [8].

## 5 THE WORLD SUMMIT ON THE INFORMATION SOCIETY (WSIS)

Recognizing that confidence and security in the use of information and communication technologies (ICT) are the main pillars of the information society, the first phase of the World Summit on the Information Society (WSIS) in December 2003 urged governments, in cooperation with the private sector, to consider legislation that allows for effective investigation and prosecution of misuse and strengthens institutional support at the international level. As a result, a number of recommendations were made in the WSIS Geneva 2003 first phase Declaration of Principles and Plan of Action [9] that relate to building confidence and security in the use of ICTs and promoting a global culture of cyber-security.

The outcomes of the second phase of the WSIS, held in Tunisia in November 2005, are summarized in the Tunis Agenda and Tunis Commitment. All governments, according to the Tunis Agenda [10], should have an equal role and responsibility in internet governance, but must also ensure the internet's stability, security, and continuity. The

document calls for enhanced cooperation to enable all governments to carry out these responsibilities, including the development of globally applicable principles on public policy issues associated with the coordination and management of critical internet resources.

The Tunis Agenda also recognizes the need for "national action and increased international cooperation to strengthen security while enhancing the protection of personal information, privacy and data." It underlines "the importance of the security, continuity and stability of the Internet, and the need to protect the Internet and other ICT networks from threats and vulnerabilities". It further emphasizes "the need for a common understanding of the issues of Internet security, and for further cooperation to facilitate outreach, the collection and dissemination of security-related information and exchange of good practice among all stakeholders on measures to combat security threats, at national and international levels" [11].

In a resolution passed on 28 July 2008, entitled Follow-up to the World Summit on the Information Society and Review of the Commission on Science and Technology for Development (CSTD) [12], ECOSOC indicated how it would oversee the system-wide follow-up of the summit outcomes, as requested by the Tunis outcomes. To this end, ECOSOC decided that CSTD would assist the council as the focal point in the system-wide follow-up of WSIS. It was agreed that this would entail a strong development orientation and that the Commission would be strengthened in its substantive capacity through the effective and meaningful participation of member states in its work. While preserving the inter-governmental nature of the commission, ECOSOC decided that CSTD should make use of the successful multi-stakeholder approach that was pioneered by WSIS. During the two sessions of 2007 and 2008, the deliberations of CSTD therefore were (and remain) open not only to NGOs in consultative states with ECOSOC, but also to other interested NGOs and civil society entities who were accredited to WSIS [13].

## 6 INTERNATIONAL TELECOMMUNICATION UNION (ITU)

At the WSIS, world leaders entrusted the International Telecommunication Union (ITU) [14] with the leading role in coordinating international efforts on cyber-security. As the sole facilitator for the action line related to Building Confidence and Security in the Use of ICT (WSIS Action Line C5) [15], the ITU launched the Global Cybersecurity Agenda (GCA) in May 2007 to provide a framework within which the international response to the growing challenges to cyber-security can be coordinated and addressed [16]. GCA benefits from the advice of a High-Level Experts Group (HLEG) [17] comprising more than one hundred (100) world-renowned specialists in cyber-security from governments, industry, international organizations, research organizations, and academia. The HLEG was established to advice the ITU secretary-general on concrete measures and strategies to address global challenges in the five work areas of the GCA:

- Legal Measures,
- Technical and Procedural Measures,
- Organizational Structures,
- Capacity-Building,
- International Cooperation.

In 2007 and 2008, the ITU carried out significant standardization work in security architecture, encryption and authentication, and information security management systems:[1]

- Three new recommendations on cyber-security were approved by ITU: Overview of cyber-security; vendor-neutral framework for automatic notification of security related information and dissemination of updates; and guidelines for telecommunication service providers for addressing the risk of spyware and potentially unwanted software.
- Three new recommendations on countering spam were approved by ITU: Technical strategies on countering spam; technologies involved in countering e-mail spam; and a technical framework for countering e-mail spam.
- Two new draft ITU recommendations have been submitted for the approval process: Countering IP multimedia application spam; and requirements for global identity management trust and interoperability.
- Twenty-eight more security recommendations were approved by ITU, as of June 2008, in areas including: directory services, authentication, security architecture, security management, tele-biometrics, peer-to-peer communication security, and secure mobile data communication.
- An ITU Study Group leads the identity management (IdM) work and has made four ongoing draft recommendations, which cover topics such as: data models, interoperable frameworks, interchange frameworks, and entity authentication assurance. In addition to the above-mentioned topics, new issues such as a trusted service provider identifier (T-SPID) were introduced into discussion.
- Significant progress has been made on the security aspects of IPTV. The first IPTV security recommendation is expected to be completed by September 2008.

In addition, the ITU has launched the ICT Security Standards Roadmap [18], an online database that provides information about existing ICT security standards and works in progress in key standards development organizations.

The ITU is also engaged in direct assistance to member states (particularly developing countries) building cyber-security capacities through a number of different activities. To this end, the ITU is developing a national cyber-security framework to coordinate national efforts, provide technical assistance, and organize capacity-building cyber-security forums. The ITU is also working with partners from the public and private sectors on specific cyber-security and Critical Information Infrastructure Protection development initiatives to assist developing countries in awareness and self-assessment, capacity-building, and expanding watch, warning, and incident response capabilities. Some relevant deliverables include the ITU National Cybersecurity/CIIP Self-Assessment Toolkit [19], which aims to assist governments in enhancing their cyber-security and address CIIP requirements; the Botnet Mitigation Toolkit [20]; as well as toolkits on the establishment of CERTs/CSIRTs, and promoting a culture of cyber-security. Other ITU initiatives to assist developing countries include the development of anti-spam legislative surveys, assessment activities of national cyber-crime legislations, and research on the financial aspects of network security, malware, and spam.[1]

# THE WORLD BANK GROUP

MANUEL SUTER AND ELGIN BRUNNER
*Center for Security Studies (CSS), ETH Zurich, Switzerland*

## 1 INTRODUCTION

The growing incidence of computer and cyber-crime has a particularly strong bearing on the financial sector. In view of the growing amount of financial data stored and transmitted online, the ease of computer intrusions has added to the severity of the problem. Therefore, the World Bank Group has taken several steps over the last few years to face the challenges of information security, especially in developing countries [1].

## 2 THE GLOBAL INFORMATION AND COMMUNICATION TECHNOLOGIES DEPARTMENT (GICT)

The Global Information and Communication Technologies Department (GICT) [2] promotes access to information and communication technologies in developing countries. It serves as the World Bank Group's core department for research, policy, investment, and programs related to ICT in developing countries. The GICT's aim is to expand access to a range of information infrastructure networks and support the development and application of information technologies to reduce poverty and improve people's lives. Linked to this mission are three goals aimed at [3]:

- Accelerating the participation of developing countries in the global information economy;
- Spreading the benefits of these technologies through increased competition and private investment in information infrastructure;
- Fostering sustainable economic and social development through innovative technologies, with a special emphasis on the need of the poor in developing countries.

Moreover, the World Bank Group's ICT sector strategy is based on four pillars [3]: The broadening and deepening of sector and institutional reform, the improvement of

Reprinted with permission from Elgin M. Brunner and Manuel Suter. **International CIIP Handbook 2008/2009, Series Editors**: Andreas Wenger, Victor Mauer and Myriam Dunn Cavelty, Center for Security Studies, ETH Zurich.

access to information infrastructure, the support of human capacity to exploit ICT, and the support of ICT applications across a broad range of sectors.

The GICT group consists of six teams including [4] the office of the director, the strategy and business development team, the telecom and media division, the portfolio and technology division, the public sector policy and operations division, and the Information for Development (infoDev) Program [5].

## 3 INFORMATION TECHNOLOGY SECURITY HANDBOOK

The Information Technology Security Handbook [6], funded by the infoDev Program, provides technology-independent best practices and recommendations in the field of IT security. The handbook was published in 2003 and, as the technology evolves, the accompanying website [7] provides updates as appropriate. The book addresses private users of IT, small and medium-sized organizations, government, and technical administrators, especially in developing countries. The handbook is based on the premise that use of ICT is on the rise, while the knowledge of IT security practices is lagging behind.

After a general introduction to IT security, the Information Technology Security Handbook deals with topics such as [8]:

- *Security for individuals.* keeping personal computers, data and operating systems, and applications secure; malicious software; securing services over networks; tools to enhance security; and the role of encoding and encryption;
- *Security for organizations.* risk evaluation and mitigation; planning; organizational security policy and personnel security; security outsourcing; mobile risk management; and best practices;
- *Information security and government policies.* various arrangements for protecting government systems; laws and legislation; and government policy in promoting better security in the private sector;
- *IT security for technical administrators.* physical security; information security; identification and authentication; server security; network security; attack and defenses; and detecting and managing break-ins.

## 4 THE WORLD BANK'S E-SECURITY/E-FINANCE EFFORTS

The World Bank published a report on Electronic Security: Risk Mitigation in the Financial Transactions in June 2002, building on previous papers that identified e-security as a key component to the delivery of e-finance benefits. This paper and its technical annexes identify and discuss eight key pillars for a secure electronic environment [9].

In January and May 2004, a follow-up publication was published, entitled Technology Risk Checklist [10]. This World Bank publication describes 13 layers of e-security, covering both hardware and software pertaining to network infrastructures. These layers cover risk management, policy management, cyber-intelligence, access controls and authentication, firewalls, active content filtering, intrusion detection systems (IDS), virus scanners, encryption, vulnerability testing, systems administration, incident response plans (IRP), and wireless security [11]. In 2005, two further documents were published by the World

Bank's e-security/e-finance section on the dangers emanating from BOTs–Cyber Parasites [12] and on the issue of Money Laundering in Cyberspace [13].

# CYBER SECURITY

# CLASSES OF VULNERABILITIES AND ATTACKS

PASCAL MEUNIER
*Purdue University CERIAS, West Lafayette, Indiana*

## 1 INTRODUCTION

The analysis of the nature of flaws, vulnerabilities, weaknesses, and the attacks they enable has fascinated computer scientists. A better understanding of vulnerabilities and attacks can be achieved by grouping them based on common properties and similarities. Many groups and "types" are commonly discussed in computer security texts and secure programming materials. These popular classifications usually capture a defect or a weak technology that enables attacks or present an appealing, succinct, and useful point of view for discussing vulnerabilities. It is common to refer to the set of vulnerabilities that enable attack scenario X as "X vulnerabilities", for example, "cross-site scripting (XSS) vulnerabilities". Sometimes the name of a technology is used instead of the name of an attack, for example, "format string vulnerabilities". However, the popular vulnerability types suffer from many defects, such as ambiguities and overlapping classifications. A single vulnerability may belong to several popular types simultaneously or at different times, when the analysis is performed from a different point of view or from a different level of abstraction. A systematic grouping can achieve the status of a scientific classification if it meets rigorous criteria, such as reproducibility, objectivity, and lack of ambiguity. First, popular classifications are reviewed and their usefulness discussed. Then, scientific taxonomies and other systematic efforts are discussed. Finally, the advantages of using ontologies instead are presented.

As a side effect of these classifications, there have been various attempts at defining vulnerabilities and flaws. A software vulnerability has been defined as "an instance of an error in the specification, development, or configuration of software such that its execution can violate the security policy" [1]. This definition of vulnerability is close to the definition of a flaw in [2]. For the purposes of this article, a flaw defines or implies what should have been done to prevent policy violations; it is a problem at a higher level of abstraction that may potentially enable several different attacks and create various vulnerabilities. For example, a flaw such as missing input validation may result

in memory management problems such as a buffer overflow vulnerability, an integer overflow vulnerability resulting in a call "malloc(0)", or improper memory access through the indexing of inexistent elements in an array. The same flaw could also cause violations of invariants in the design, such as negative payments or corrupted prices. Because there may be several different ways in which to avoid a vulnerability, flaws can be a vague concept. There have been many attempts to classify vulnerabilities by the flaws that enabled them, so both classes of vulnerabilities and classes of flaws are discussed in the same section.

## 2 POPULAR VULNERABILITY CLASSIFICATIONS

Popular vulnerability classifications fail to meet scientific criteria; yet they can be useful and powerful descriptions of what went wrong. For example, in the book "19 deadly sins", Howard et al. use a mix of several different popular classifications [3]. As a result, the theme of each section is easy to understand and can be effectively and succinctly described. However, it is possible to find examples or contrive vulnerabilities that could fit in more than one section at once, and others that would fit in none.[1] It has also been argued that taxonomies should be judged on whether they are useful, instead of whether they are scientifically correct [2]. In this article, classifications aiming first for usefulness are called *popular classifications* to distinguish them from attempts to meet the rigorous scientific criteria for taxonomies established across disciplines. Popular classifications may have different goals from scientific taxonomies, such as educational, conceptual, and tool use.

### 2.1 Classification by Exploitability

Exploitability can be difficult to establish, therefore including a criterion that is difficult to observe or deduce correctly is not a good idea. Yet the concept is useful and exploitability is often debated, so this section presents the classification of vulnerabilities depending on whether they are latent, potential, or exploitable. A latent vulnerability consists of vulnerable code that is present in a software unit and would usually result in an exploitable vulnerability if the unit was reused in another software artifact. However, it is not currently exploitable due to the circumstances of the unit's use in the software artifact; that is, it is a vulnerability for which there are no known exploit paths. A latent vulnerability can be exposed by adding features or during the maintenance in other units of code, or at any time by the discovery of an exploit path. Coders sometimes attempt to block exploit paths instead of fixing the core vulnerability, and in this manner only downgrade the vulnerability to latent status. This is why the same vulnerability may be found several times in a product or still be present after a patch that supposedly fixed it.

A potential vulnerability is caused by a bad programming practice recognized to lead to the creation of vulnerabilities; however, the specifics of its use do not constitute a vulnerability. A potential vulnerability can become exploitable only if changes are made to the unit containing it. It is not affected by the changes made in other units of code.

[1]This is not a criticism of the book, which meets its goal of providing "a simple list of those security issues that are most important" [3]. It was not intended to provide complete, scientific coverage.

For example, a vulnerability could be contained in the private method of an object. It is not exploitable because all the object's public methods call it safely. As long as the object's code is not changed, this vulnerability will remain a potential vulnerability only.

Vendors often claim that vulnerabilities discovered by researchers are not exploitable in normal use. However, they are often proved wrong by proof-of-concept exploits and automated attack scripts. Exploits can be difficult and expensive to create, even if they are only proof-of-concept exploits. Claiming unexploitability can sometimes be a way for vendors to minimize bad press coverage, delay fixing vulnerabilities, and at the same time discredit and discourage vulnerability reports.

### 2.2 Classification by Software Development Life Cycle (SDLC) Phase

Taxonomies of this kind attempt to categorize vulnerabilities according to when they were introduced in the software life cycle. Classically, six phases are recognized: feasibility study, requirements definition, design, implementation, integration and testing, and operations and maintenance. At a basic level, this classification groups the above phases into three groups: design (first 3 phases), implementation (phases 4 and 5), and operation and maintenance. It was suggested that the timing of reviews could be decided based on the phase in which a vulnerability type could be introduced [4].

The design and implementation distinction is particularly appealing to computer scientists who want to argue the correctness of an algorithm, protocol, or model in theory separately from an implementation that may be subject to unfavorable limitations or mistakes resulting in vulnerabilities. For example, a vulnerability may be due to a bad algorithm being chosen during design phases. Another may be due to a bad implementation of a correctly chosen algorithm, and therefore the vulnerability was introduced at some point during the implementation phases of the program.

It was also suggested to classify vulnerabilities into design, implementation, and configuration vulnerabilities [5]. However, "configuration" vulnerabilities are a narrower category than all the vulnerabilities introduced during operation and maintenance. This difference could be resolved if maintenance is considered as reoccurring design and implementation phases, and if emergent vulnerabilities are considered to be design vulnerabilities at the level of the system.

Even though operation and maintenance are often seen as a single phase from a timeline point of view, they differ in how they can introduce vulnerabilities. Vulnerabilities introduced during operation are usually configuration issues, although some also emerge due to interactions with an unexpected or changed environment, including other installed software and operating system (OS) version, kernel modules and libraries, or unexpected or virtual hardware. Vulnerabilities can be introduced during maintenance to fix bugs or modify functionality. The difference is that maintenance changes the code, whereas operation does not. So, five classes have been proposed: analysis, design, implementation, deployment, and maintenance [6].

The difficulty with the above classifications is that there are usually many levels of abstraction at which to view complex systems, in addition to the choice of the number of phases. What is a design problem may be viewed as an implementation problem or an operation problem at another level, and *vice versa*. This can make some comparisons across projects difficult. Therefore, this classification is subject to an abstraction level that needs to be specified. For the sake of auditing vulnerabilities, reasonable and

useful but fuzzy definitions are provided in [4]. The time of introduction of a vulnerability in the software development life cycle (SDLC) has been used as a taxonomic characteristic [6–8], but was later shown to fail scientific requirements [1, 9]. Some flaws can be introduced at multiple points in the SDLC, so although linking a vulnerability to a specific SDLC phase can be an interesting consideration, it is not always applicable.

This kind of classification may also be useful when reviewing software development processes in a software development firm. The details of the classification are then dependent on the specific software engineering model adopted. Therefore, there can be as many taxonomies of this kind as there are software engineering development models. This makes the comparison and discussion of vulnerabilities across development models difficult.

### 2.3 Classification by Genesis

The premise of this classification is that the reasons and ways flaws are introduced into a system can provide insight into their prevention or detection. This classification differentiates first between intentional and inadvertent flaws. Intentional flaws are further divided into malicious and nonmalicious ones [2, 7]. However, whether the programmer maliciously introduced the vulnerability or not and in general the programmer's intent are in practice impossible to determine after the fact, and therefore the classification is not objective and not specific [1]. Truly, the programmer's intent is irrelevant (and unknowable) to a security researcher analyzing the consequences of released vulnerable code, but that is not the purpose of this classification. The genesis classification helps understand how some flaws could be prevented or caught during development. For example, tools attempting to catch inadvertent flaws were successful [2]. This classification is, therefore, more an aid for strategic thinking and design than something directly applicable to collections of flaws.

### 2.4 Classification by Location in Object Models

These classifications attempt to categorize vulnerabilities according to which model object or "entity" they belong to. Examples are classifying vulnerabilities using the ISO open systems interconnect (OSI) reference model for networking [10]. This model defines seven distinct layers, so a vulnerability could in theory be classified according to which layer it belongs to. In reality, some vulnerabilities depend on the specific interactions between two or more layers or objects, so this kind of taxonomy is not always applicable.

Similarly, attempts to differentiate whether a vulnerability was due to an OS or an application were unsuccessful (CVE-1999-0144). This was because a configuration option of the OS could prevent it from happening, whereas others argued that well-behaved programs should not need that kind of OS configuration. This difficulty can be encountered whenever the vulnerability relates to ill-defined responsibilities. The classification may then change depending on the perception of the responsibilities and is therefore subjective. For example, currently the security of web browser plug-ins and scripting engines is considered their own problem. However, as web browsers mature, the better browsers should limit the security risks posed by vulnerable plug-ins and malicious scripts, in a manner similar to OSs limiting what processes can do.

### 2.5 Classification by Affected Technology

Format string vulnerabilities in the "C" programming language are an example of a vulnerability type identified by the underlying technology. The implementation of polyvariadic functions in "C" is such that called functions have no way of knowing how many arguments were passed. Attacker-controlled format strings can exploit both that limitation and format string functionality, for example, to write data at arbitrary locations in memory by using the "%n" format specifier. Depending on the format string supplied, the result of the attack can be (i) a crash by trying to access inexistent memory or memory allocated to another process (denial of service); (ii) the formatted strings contain unexpected data, possibly exposing confidential data, or adding incorrect or malicious information; or (iii) the process comes under the control of the attacker (compromise).

Metacharacter vulnerabilities happen in technologies where some characters have a special significance, for example, syntactic. Metacharacters are often used to separate data and commands in dynamic query languages. "SQL injection" and "LDAP injection" are examples of subcategories of metacharacter vulnerabilities. Character encoding issues are other examples of a subcategory, inasmuch as special metacharacters indicate special encodings (e.g. URL "percent" encoding).

Resource exhaustion vulnerabilities happen when limited computer resources can be abused maliciously in a way that limits the functionality of the system, possibly resulting in a denial of service. Examples are SYN-flood attacks[2] resulting from the transmission control protocol (TCP) protocol requiring memory for every connection request; memory leaks (specific to languages without garbage collection); and algorithmic complexity issues where an attacker is able to trigger worst-case behaviors in vulnerable algorithms.

Although the name of the affected technology is a useful and descriptive reference, there are many vulnerabilities that do not relate directly to a specific technology. For those that do, the usefulness of the classification is limited in cases where the flaw enabling the vulnerability has a weak or no relationship to the technology; the identification may not always help understand the properties and causes of the vulnerability. Therefore, this classification scheme is not universally useful.

### 2.6 Classification by Errors or Mistakes

Errors known to have led to vulnerabilities have been categorized by their cause, the nature of their impact, and the type of change or fix made to remove the error [11]. A similar type of classification is used often in "19 Deadly Sins", with categories such as "use of weak password-based systems" and "failing to store and protect data securely" [3]. Another example is the "double-free" memory management mistake.

This has educational value, especially when the mistake can be abstracted and applied to new situations. Unfortunately, there are situations in which any of several changes in different code locations, modules, or even different programs altogether can fix a vulnerability or at least block the known exploitation paths. Therefore, as a classification, it can be ambiguous.

### 2.7 Classification by Enabled Attack Scenario

Sometimes the set of vulnerabilities that enable a specific kind of attack is highly descriptive and fairly precise. For example, "XSS" is an attack scenario and "XSS

[2]SYN-flood attacks are remote denial-of-service attacks; see CERT advisory CA-1996-21.

vulnerabilities" are vulnerabilities enabling the injection of scripting code into content served to web browsers. They enable other attacks, but "XSS vulnerabilities" capture a unique common property and is a useful and succinct reference. It should be noted that many XSS vulnerabilities, but not all, are the result of metacharacter handling vulnerabilities.

On the other hand, referring to "denial-of-service vulnerabilities" is not useful because denial of service is the consequence of an attack, and not an attack scenario, and can be achieved in many disparate ways, for example, buffer overflows and format string vulnerabilities.

A classification of vulnerabilities in network protocols proposed by Pothamsetty and Akyol [12] is interesting because it offers simultaneously a "test" or attack taxonomy and countermeasures. Even though the mistakes ("vulnerability classes") are presented first, it is evident that they are defined based on the attacks they enable. This kind of enumeration is likely to be proved incomplete as a new kind of attack may be uncovered in the future. However, it may still be useful in practice. The categories are

1. clear text communication
2. nonrobust protocol message parsing
3. insecure protocol state handling
4. inability to handle abnormal packet rates
5. vulnerability arising from replay (RP) and reuse (RU)
6. protocol field authentication
7. entropy problems.

The "test" or attack techniques are[3]

1. packet sniffing (PS)
2. protocol field fuzzing (PFF)
3. protocol field spoofing (PFS)
4. packet flooding (PF)
5. Replay
6. Reuse
7. packet size variation (PSV)
8. packet number variation (PNV)
9. out-of-sequence packets and out-of-range values
10. special and reserved packets (SRPs)
11. information retrieval[4]
12. communication initiation (CI)
13. communication termination (CT)
14. encryption and random number check (EC).

[3]The attack techniques have been reordered to roughly match the order of the vulnerability types.
[4]This refers to checking the protocol for exposures, not vulnerabilities.

### 2.8 CLASP Classification

CLASP (comprehensive, lightweight application security process) is a set of activities aiming to improve security [13]. It uses a classification focused on enumerating errors, but simultaneously includes conditions resulting from mistakes, as well as events. It has the following categories at the top level:

- *Range and type errors.* This includes the "write-what-where condition" as well as buffer overflows and "format string problems".
- *Environmental problems.* This includes events such as the failure of a random number generator.
- *Synchronization and timing errors.* For some reason this includes statistical attacks. It also includes "capture-replay", the vulnerability to which is usually a protocol flaw.
- *Protocol errors.* This includes using a broken or risky cryptographic algorithm.
- *General logic errors.* This is a catchall that includes things as diverse as using a "noncryptographic" random number generator or too few parameters being passed to a function (e.g. format string issues in "C").

Although the list of things that can go wrong is interesting, this classification has several flaws from a scientific perspective. A vulnerability may simultaneously be classified in several categories at once, for example, if several mistakes are linked to the vulnerability simultaneously, if a mistake results in a condition, or if an event triggers a condition. This classification is inconsistent when used at different abstraction levels. For example, when considered at a low level, a problem may be due to an integer overflow problem. At a higher abstraction level, it may become the failure of a random number generator. Also, similar issues, for example, cryptographic issues, are not grouped together. This may not matter in practice, as the goal of this classification is to discuss which kinds of vulnerabilities may be found during various activities.

### 2.9 Seven Kingdoms

This classification of software security errors has the following eight top levels [14]:

1. input validation and representation
2. API abuse
3. security features
4. time and state
5. error handling
6. code quality
7. encapsulation
8. environment (this category is mostly composed of configuration issues, that is, issues that do not belong in the first seven).

This classification simultaneously includes causes, consequences, and bad practices. Therefore, a vulnerability can belong to several categories simultaneously or be classified differently depending on the abstraction level used. The API abuse category, while

an appealing concept, is especially ambiguous and conflicting with other categories. It harbors issues that could arguably be classified as input validation problems, such as a buffer overflow vulnerability caused by not performing input validation on potentially malicious names returned by a reverse domain name service (DNS) call [14]. Its main strength is that it makes sense when discussing the detection rules used by code scanning software. It can also help educating and conveying to programmers secure programming concepts, such as being aware of the rules involved ("contract") when calling a given API.

### 2.10 Classification by Disclosure Process

Vulnerabilities for which there are written exploits, before they become publicly known, are zero-day (also known as *0-day*) vulnerabilities. Some variations in usage refer to vendor knowledge instead of public knowledge. Before public disclosure, zero-day vulnerabilities may be sellable on black markets or some security companies (e.g. iDefense's "vulnerability challenges"). "Private" 0-days refer to vulnerabilities and exploits shared by small groups. So, 0-day vulnerabilities can be secret, private, or disclosed.

Following the disclosure of a 0-day vulnerability, owners of the vulnerable systems may be able to take actions to mitigate the issue or to detect compromises. Simultaneously, more attackers are informed of new ways to attack systems. Vendors may have to scramble to produce patches that will protect their clients; if the vendor already knew about the vulnerability, they may take less time to produce the patch.

Knowing whether a vulnerability is a 0-day or not has ethical implications, for a security researcher, which will influence the disclosure process. In responsible disclosure, vendors are notified first and given some time to fix the vulnerabilities before they are made public [15]. If a vulnerability is being exploited, that is, it is a 0-day, then there is an ethical justification for giving less or no advance notification at all to the vendor.

### 2.11 Configuration Issues, Exposures, System Vulnerabilities, "Proper" Vulnerabilities

For the purposes of this article, a system is a combination of interacting software and hardware, which may be located on one or several machines, and that performs a set of tasks as a whole. The definition of vulnerabilities with reference to a security policy [1] is especially appropriate for system vulnerabilities. System vulnerabilities may exist even if a system is composed of software artifacts all with correct designs and all perfectly implementing their design. This may be due to misconfigurations (e.g. the presence or execution of software contrarily to policy), designs that are inappropriate for the system, or emergent properties due to the combination and interactions of software artifacts designed separately. Flaws in various subsystems can combine to produce a vulnerability. This is the realm of compositional security. In particular, systems can be vulnerable to emergent abusive behavior attacks, in which legitimate acts can be combined to violate a policy [16].

The analysis of system vulnerabilities cannot proceed simply from the analysis of the code or design of a subsystem in isolation, but should reference the violated security policy and be accompanied by a description of the relevant interactions with other software artifacts. Different security policies that are appropriate given different environments in different organizations may result in two different lists of vulnerabilities for copies of

the very same system. The security policy is defined externally to the system, and is not an intrinsic property; therefore, system vulnerabilities are not intrinsic properties of systems.

Sometimes, the reasonable expectation that there is a relevant policy deployed somewhere is sufficient for the discussion of a system vulnerability, but the generic terms of that policy should be defined explicitly for the discussion. The MITRE common configuration enumeration (CCE) effort aims to identify configuration issues by finding examples of a relevant "reasonable" policies, such as hardening configuration guides for OSs [17].

"Proper" vulnerabilities are apparent when a specific software artifact is compared to its requirements and design (explicit or implied) at the time of its creation. It can be argued that the design and design goals of a software artifact are intrinsic properties of the artifact, because they remain the same regardless of where, how, when, or by whom the software is used. The examination of software artifact vulnerabilities can therefore be performed with less information than needed with system vulnerabilities, while being more objective and reproducible, because it is grounded in technical facts proper to the artifact. However, this can become subjective if some aspects of the design are guessed by the researcher. The MITRE common vulnerabilities and exposures (CVE) effort gives unique identifiers to software artifact vulnerabilities [18].

Understanding the difference between system vulnerabilities and software artifact vulnerabilities is useful when practitioners and academics attempt to communicate. A practitioner may argue that a system is not vulnerable due to a configuration that blocks attacks, while the academic will point out that a vulnerability remains (and could get exposed again). Likewise, a practitioner may consider a system to be vulnerable due to a service running and exposing excess information when it should not, in violation of a policy. In this situation, the academic may lose interest because the violated policy is "arbitrary", that is, orthogonal to the design of all of the software artifacts.

Exposures are information leaks that may aid an attacker, but do not directly violate the design goals of a software artifact. This distinction was at the origin of the name change of the CVE from "common vulnerabilities enumeration" to "common vulnerabilities and exposures" in order to be inclusive of unexpected exposures. As the CVE effort matured and the CCE effort was introduced, the CVE focused on exposures that were not part of the design of a software artifact. Exposures that can be easily prevented without disabling a useful feature are handled by the CCE.

Some vulnerabilities can be examined as both system and software artifact vulnerabilities; consider CVE-1999-0997. This vulnerability arose due to the interactions between the FTP server software "wu-ftpd" with the ftp conversion option enabled and compression programs such as tar. This can be discussed from the point of view of a system vulnerability, because it appears through the combination and interactions of various software artifacts. It can also be considered a software artifact vulnerability because wu-ftp was designed to work with compression programs through the conversion option. A difficulty in creating such programs is that a design can be suddenly invalidated by the introduction of a new feature in an interacting product or by the introduction of a new product that supports unexpected features.

## 3 POPULAR ATTACK CLASSIFICATIONS

Popular attack classifications often use a mix of ambiguous classifiers such as the origin, goal, mechanism, and motivation of an attack, and suffer from a perspective ambiguity.

The purpose of an attack may be clear to the attacker, but can appear as something else to the defender. The DARPA 1999 IDS evaluation program used these five types [19]:

1. *Probe (or surveillance).* This category applies to activity meant to gather information.
2. *Denial of service.* This is really the consequence of an attack.
3. *R2L (remote to local).* Unauthorized access from a remote machine.
4. *U2R (user to root).* Unauthorized transition to root for an unprivileged user.
5. *Data.* This is meant to represent attacks whose goal is to obtain and extract ("exfiltrate") confidential files from a system.

Failed or misunderstood attacks could be put in the probe category by a defender. An attack that may have been meant to be a probe by an attacker may result in a denial of service, accidentally or not. Denial of service can also be the consequence of a failed R2L or U2R attack. Data attacks can also be R2L or U2R attacks, so an attack can be simultaneously classified into two categories [19]. These categories are not complete, as they do not include U2U (user to user) attacks or take into account new attacks, for example, attacks aimed at other users of the system by planting malicious links or scripts (e.g. XSS attacks) or misinformation. Nevertheless, this classification was useful and appropriate for the IDS evaluation, given attacks with known goals.

### 3.1 Web Application Security Consortium Threat Classification

The web application security consortium (WASC)'s threat classification has the following top classes:

1. *Authentication.* This identifies the authentication mechanisms attacked (targets).
2. *Authorization.* This identifies the authorization mechanisms attacked (targets).
3. *Client-side attacks.* This really is a technology type classifier, in this case used to identify a target.
4. *Command execution.* This is a goal.
5. *Information disclosure.* This is a consequence.
6. *Logical attacks.* This contains as a subclass denial-of-service attacks, which is a consequence. Other subclasses describe mistakes or attacks against access control mechanisms (which were covered in class 2).

In conclusion, this classification uses inconsistent types of classification criteria at the same level, which leads to ambiguities, as an attack can be classified in several categories at once.

### 3.2 Classification by Transactional Attack Scenario

A transactional attack scenario describes how the attack operates on the basis of transactions between the participants. Examples are RP attacks, man-in-the-middle, and the strictly defined XSS attacks that involve a third-party host. Eavesdropping is another

transactional attack scenario that simply requires listening and passively gathering information. It can be carried out by listening to incidentally leaked signals (lights of light emitting diodes (LEDs), sounds of typing on keyboards, monitor radiation) or to network or wireless (including Bluetooth) transmissions (also known as "sniffing"). These attack classifications are most useful when studying the security of communication protocols.

### 3.3 Impact

The impact of the attack on the confidentiality, integrity, and availability of targets has been used by the common vulnerability scoring system (CVSS) with levels of "none", "partial", and "complete". These coarse levels indicate the impact of the worst attack enabled by a vulnerability [20]. As the worst attack scenario may not be known yet (perhaps it is enabled only in some circumstances), this classification may be subject to change as more information is found, contrary to the goal of the CVSS to use this as an invariant in the scoring system.

### 3.4 Attack Language

Attack instances can be described as a series of steps to achieve an unauthorized result [5]. This includes the tool used, the vulnerability targeted, events comprised actions and targets, and finally an (at least attempted) unauthorized result. Tool categories are as follows:

- Physical attack.
- Information exchange. This includes social engineering attacks (see below).
- User command.
- Script or program. This includes trojan horses (see below).
- Autonomous agent. This includes viruses and worms (see below).
- Toolkit. This includes rootkits (see below).
- Distributed tool.
- Data tap. This is the monitoring of energy leakage through an external device. This includes light (videos, pictures, blinking LEDs), variations in power consumption, sounds of keys being pressed, radio waves, and so on, which may reveal information.

The events and characteristics of an attack instance provide information useful for identification and comparison. However, the language itself does not define a classification. Although the language is flexible and avoids committing to a specific classification scheme, analyzing and storing detailed information about every instance is expensive and unwieldy.

### 3.5 Classification of Attacks on Human Interactions

Human interactions can be exploited as part of an attack or preattack recon. Human beings may not be the final target of the attack, but are being used by deceptive means. "Social

engineering" is a powerful descriptor of an attack that involves tricking human beings. Subclasses of social engineering attacks include "phishing", which involve exploiting ambiguities in user interfaces (usually in emails pointing to fake websites). "Pretexting" is a form of fraud used to collect password, host, or account information from naïve employees or to instruct them to perform actions that will give the attacker access or weaken systems. Social engineering attacks can also be physical ("in person") by the use of disguises and body language. Some of these attacks are assisted by malicious code (see trojans) in "free" software or "lost" media.

### 3.6 Classification of Malicious Code

The classification of the malicious code used in an attack can be useful to understand the attack. However, for the sake of objectivity, code should be classified from its behavior alone, without needing to know that it was created with malicious intent (maliciousness may be inferred later, however). Indeed, benevolent viruses have been discussed before [21]. An attempt to create a benevolent worm, the Welchia worm, backfired [22], so intent can be largely irrelevant. The classification of viruses as a subclass of Trojan Horse is objectionable [6], since a virus may replicate without needing to deceive users by appearing as another code entity (e.g. boot sector viruses or macroviruses in formats supporting macroscripting). It makes more sense to consider the need to deceive users separately from self-replicating aspects. According to the criteria proposed in [23], it is more useful and desirable to consider "primitive" classifiers that can each be answered by yes or no. Possible definitions of various aspects of malicious code include the ones listed below.

1. *Attack code.* Attack code aims at exploiting vulnerabilities, and is commonly found in the form of attack scripts or proof-of-concept exploits. Worms are another example of attack code. Malicious code is not necessarily an attack code, but its mere presence may imply that the system was compromised by a prior attack. Malicious code resident on a victim computer and performing an undesirable function, such as spyware, rootkits, or backdoors, is to be differentiated from attack code that exploits vulnerabilities.
2. *Parasitic code.* Parasitic code is a code that is attached or included in another document or executable and violates its integrity. Intended or original properties of the document or executable must be identifiable in order to determine the presence, nature, and extent of the parasite. Parasitic code is not necessarily an attack code.
3. *Backdoors (also known as "Trapdoor".* [7]*).* A backdoor is code bypassing policy-approved user authentication mechanisms. Backdoors are usually hidden, hard to discover, and inserted and used for malicious purposes. For example, a remote user may issue commands as root through a previously installed backdoor. Some backdoors are created by programmers for reasons of convenience (e.g. remote maintenance), and so the original intent may not be malicious. However, backdoors that violate security policies must be considered malicious based on their behavior alone as discussed above. Remote access mechanisms operating within policy are not to be confused with backdoors.
4. *Trojans.* Code that gets executed by deceiving a user is a trojan (the deception aspect implies maliciousness, even if it is a mild prank). Trojans can carry and be

the initial entry mechanism for malicious code of another nature (e.g. a backdoor or keylogger).

5. *Self-propagating code.* Self-propagation can occur in two modes:
   (a) Viruses are parasitic and are spread by means of finding new host files (documents or executables) that will presumably also get read and run later. Macro viruses refer to viruses carried by documents which can carry "macros", essentially a scripting capability which blurs the boundary between data and code.
   (b) Worms spread on their own, by duplicating their code to other systems and respawning their processes.
6. *Spyware.* Spyware is a code that reports user activities and system information to "unauthorized" parties (who is "unauthorized" may depend on perspective). An example is an "unauthorized" keylogger. Spyware could also take "interesting" forms such as being a virus and reporting when a certain type of document is opened.
7. *Logic-/time-triggered code.* This is an extraneous code that is not part of the expected function of a software artifact and remains dormant until very specific activation conditions are met. If it can then perform attacks, it is a "bomb" [7]. If not, and it simply exposes humorous (at least to some) content, it is considered an "Easter egg". Some digital rights management ("DRM") codes that violate a security policy, for example, while trying to aggressively enforce a licensing agreement, could be considered triggered code.
8. *Rootkit.* A rootkit is a set of software artifacts that attempts to conceal its existence and execution (and possibly that of other malicious software as well) from the rest of the OS, other processes, or security tools, and consequently from users and administrators. Typically, a rootkit subverts or replaces the utilities included with an OS for the purposes of hiding a compromise and a backdoor. A rootkit may include attack code as one of its components and may resist removal.
9. *Distributed code.* Distributed code has coordinated copies of itself on many hosts. By acting in a coordinated fashion, the distributed code attempts goals that would likely be unreachable for a single copy. The coordination mechanism may be the reception of commands or interactions between copies or with a controller. Blindly following specially crafted rules of conduct may also result in the overall desired behavior. Worms have been known to include a time bomb for attacking a predetermined target at a given time, resulting in a distributed attack.

## 4 SCIENTIFIC CLASSIFICATIONS

Scientifically correct taxonomies of vulnerabilities and attacks are difficult to create due to the requirements that they separate elements of a group into subgroups (taxa) that are mutually exclusive. The crucial problem in designing a taxonomy is to identify and organize appropriate taxonomic characters, also known as features, attributes, or characteristics. The taxonomic characteristics must have the following properties [1]:

1. *Objectivity.* Values must be based on an observable property of the object.

2. *Determinism.* There must be a clear and explicit procedure to follow so that there is no possibility of misclassification.
3. *Repeatability.* Values must be selected reproducibly by different people.
4. *Specificity.* The selected value must be unique and unambiguous.

Finally, the taxonomy must be exhaustive and useful for a broad audience. Many attempts have been made at classifying vulnerabilities and attacks, but most do not meet the above requirements. A typical error seen in the classifications previously discussed is to use different types of taxonomic characteristics at the same level. This leads to ambiguities or nonsensical questions similar to asking "whether something breathes air or has eyes".

Vulnerabilities are conceptual entities, not objects or lines of codes; this is an additional challenge to their understanding and classification, because desirable taxonomic characters should be observable without speculation. They exist at several different conceptual and abstraction levels; many vulnerabilities may exist simultaneouslyat several levels. In addition, the notions of cause or effect suffer from the problem that vulnerabilities may depend on several mishaps in a sequence of events. A "buffer overflow" may have been caused by an "integer overflow" issue. An off-by-one miscalculation resulting in an NUL-termination problem may enable the joining of two string buffers, which then provides sufficient space for a format string attack to be successful (CVE-2001-0609). There is also a possible decoupling of the coding mistake versus the exploit location. An overflow may first occur in a heap buffer, but become (more easily) exploitable when the string is copied to a buffer of the same size on the stack (CVE-2006-0855); in this case, the second copy is justifiably "correct". Information about vulnerabilities is often incomplete and revealed progressively, which may change the "dominant" or primary aspect of the vulnerability or its "cause" as more details are learned.

Taxonomies that use criteria oriented toward defining what programmers, designers, and architects have done incorrectly (implying what they should or could have done) have had fatal flaws [24–27]. The reasons why these taxonomies are incorrect were previously analyzed [1, 9]. Intuitively, this can be understood because there are vulnerabilities whose exploitation could have been prevented or fixed by any of several different ways and mechanisms; therefore, the classification of the vulnerability by the prevention measure or error is ambiguous. Typically, these measures also involve different concepts and levels of abstraction. This situation is even expected when a vulnerability arises from an underspecified API [2].

Taxonomies also have a domain of validity and purpose, or scope and viewpoint, for example, web services [28]. The specific data used to classify vulnerabilities depend upon the specific goals of the classification [23]. However, the scope and the taxonomic criteria should be technical in nature to avoid speculation [23]. The classification of environmental assumptions proposed by Krsul [1] has limited usefulness, because the definition of its scope requires knowing the distinction between a designer misunderstanding the environment and making a simplifying assumption about it. This may be difficult to decide, even in retrospect; it is not objective. So, it is not sufficient that taxonomic characteristics inside the taxonomy have the properties defined above; the scope of the taxonomy should also possess them.

### 4.1 Classification by Violated Program Invariant

Most vulnerabilities can be expressed in the form of an assumption, explicit or implicit, that did not hold [1]. Some assumptions can be expressed as program or unitwide invariants, others specifically as preconditions and postconditions to algorithms, functions. All these properties need to hold true for the program to be correct. Some can be explicitly tested, for example, by using "assert" statements. Some invariants that are not tested or stated can be discovered by dynamic analysis [29].

Buffer overflows are primarily the result of violating the invariant that data should only be read or written to within the space allocated for it. They are very common in "C" because the programming language makes the preservation of that invariant difficult and error-prone. As a result, "buffer overflow" is a common vulnerability type that could belong to a taxonomy where vulnerabilities are classified by violated invariant or assumption. Such taxonomies have the potential to be very powerful and precise. Unfortunately, many assumptions are made unknowingly, and they tend to be unique, which results in a high cardinality of "types". For these reasons, it is not useful to try to express all vulnerabilities as violated assumptions or violated program invariants. However, the explicit specification of invariants in programming languages such as Spark, where they get verified, can be quite useful in avoiding vulnerabilities [30].

## 5 ENUMERATION OF ATTACK AND VULNERABILITY TYPES

As an alternative to producing a rigorous taxonomy from the top down, efforts have tried to tackle the enumeration of all known attack and vulnerability types from a very low level. These enumerations in effect form both test cases and requirements for successful taxonomies. Because of their high cardinality nature, it is impossible to list the enumerated types in this article. The following is merely an introduction to these efforts, pointing out their useful properties.

### 5.1 Plover

The preliminary list of vulnerability examples for researchers was an MITRE effort grouping CVE issues by low-level types of weaknesses [31]. It has been superseded by the common weakness enumeration (CWE) (see below). This was the first attempt to build an "a posteriori" classification, that is, bottom-up ("a priori" classifications are built top down, from a theoretical standpoint).

### 5.2 Common Weakness Enumeration (CWE)

The CWE is an MITRE-driven effort to produce a "standard dictionary of software security weaknesses" [32]. The CWE attempted to be a community effort by enlisting industry, academia, and government. Amongst many benefits, it should allow the verification of coverage claims made by software security tool vendors and service providers [32]. At the top level, the CWE contains "location", "genesis", and "time of introduction" classifiers, which can be used independently, as is applicable and as knowledge permits.

The "genesis" classifier is subject to the limitations and objections noted before. The subcategories for the time of introduction classifier are very detailed, considering events such as bundling and porting. Because the subcategories are flat, a high level of knowledge is required to match the high level of detail in order to make a correct choice. Otherwise, classifications will be biased toward more generic-sounding categories such as "design" or "implementation".

The "location" classifier is subdivided into environment, configuration, and code. Configuration issues are not further expanded upon, and should be the subject of further research (cf. the MITRE CCE effort), especially when configuration options are so complex as to require their own language (is it code then?). The code subcategories are subject to the criticisms appropriate to the classifications borrowed by the CWE. It is, however, very interesting to see how the PLOVER examples were mapped to those classifications.

### 5.3 Common Attack Pattern Enumeration and Classification (CAPEC)

Common attack pattern enumeration and classification (CAPEC) describes attack patterns and relates them to weaknesses in the CWE. It includes "not only weaknesses directly related to the attack but also those whose presence can directly increase the likelihood of the attack succeeding or the impact if it does succeed" [33]. The CAPEC schema description is a work performed under contract for the Department of Homeland Security, and is therefore public.

Attack patterns aim to represent aggregate abstract information about similar attacks: "An attack pattern is a general framework for carrying out a particular type of attack, such as a method for exploiting a buffer overflow or an interposition attack that leverages certain kinds of architectural weaknesses" [34]. As such, they are a form of attack classification.

## 6 ONTOLOGIES AND FUTURE RESEARCH

The definition of a common language for computer security is an important step toward being able to describe and communicate vulnerability and attack knowledge [5]. Seacord and Householder observe that the classical taxonomy approach has not worked well in security and suggest "a structured approach to classifying security vulnerabilities". They do this by describing vulnerabilities and exploits as things with properties [35], which resemble part of an ontological approach to the problem.

Vulnerabilities are concepts, and many taxonomies attempt to link them to more concepts. Ontologies are models of reality in the form of a highly structured system of concepts, including their properties. So, in reality, these "taxonomies" are attempts at creating partial ontologies. They present a reduced ("flattened") or simplified view of the accumulated knowledge, and may be appropriate for limited, specific purposes, as defined by their scope and goals. To completely and accurately represent, transmit knowledge, and discuss vulnerabilities and attacks, proper ontologies are required.

Common ontologies address a clearly defined but restricted domain. The wider the domain, the more difficult the task may be. Upper ontologies are applicable across a wide

range of domain ontologies, but are difficult to create. One reason why an upper ontology may succeed where taxonomies failed is that ontologies can be more flexible and complex. Ontologies may allow an object to belong to several classes at once, because partitions are not necessarily disjoint. Also, through the use of relations (e.g. "part-of") they may allow multiple "memberships" or inheritances to represent complex cases. It is believed that an upper ontology created this way could have simpler "views" (e.g. subsets of the relations and concepts) appropriate to particular domains or applications. In practice, a number of regular ontologies with smaller domains could be created before the task of an upper ontology is addressed. They would also be easier to use. The development of such ontologies is left for future research.

# AUTHENTICATION, AUTHORIZATION, ACCESS CONTROL, AND PRIVILEGE MANAGEMENT

DAVID FERRAIOLO, RICK KUHN, AND VINCENT HU
*National Institute of Standards and Technology, Gaithersburg, Maryland*

## 1 INTRODUCTION

Homeland security applications present a number of cutting-edge challenges for access control and privilege management because they necessarily entail the integration of physical and information technology (IT) system access controls. Airports, industrial plants, and many other critical infrastructure domains have physical assets that could, in the wrong hands, result in significant loss of life. To get a sense of the problem space, consider the following incidents:

- *Sewage release.* In 2000, an employee of an Australian company that develops industrial control software used a wireless connection to illegally access the control system for a sewage treatment plant, causing eventually the release of 264,000 ga of raw sewage [1].
- *Air traffic control and emergency services.* In 1997, an attacker disabled a critical telephone switch through a dial-up modem, shutting down tower control and air traffic transmission at an airport in Worcester, Massachusetts. Telephone service was disabled for a nearby town also [2].
- *Train derailment.* In January, 2008, a 14 year old in Lodz, Poland took over the control system for city trains, derailing four and injuring several people [3].

None of these incidents would have occurred if access control had worked properly, and the potential for terrorist attacks, beyond the damage described above, should be clear. This article reviews access control models, with their underlying processes of authentication and authorization, and how various models are used in privilege management.

## 2 AUTHENTICATION AND AUTHORIZATION

Authorization and authentication are fundamental to access control. They are distinct concepts but often confused. Part of the confusion stems from the close relationship between the two; proper authorization in fact is dependent on authentication. Authentication can be defined as verifying the identity of a user, process, or device, often as a prerequisite to allowing access to resources in a system, whereas authorization is granting or denying access rights to a user, program, or process.

Authentication determines if a user's claimed identity is legitimate. Every computer user is familiar with passwords, the most common form of authentication. Less common forms of authentication include biometrics (e.g. fingerprint readers) and smart cards. Authentication is a process of determining who you are, whereas authorization determines what you are allowed to do. Authorization refers to a yes or no decision as to whether a user is granted access to a system resource.

## 2.1 Authentication Technology

An extensive collection of authentication methods and products is available on the market, ranging from simple and nearly universal approaches, such as passwords, to sophisticated biometric devices. Each method has its own strengths and weaknesses, and the strongest authentication may require more than one approach. A password can be guessed; a key can be lost; and face recognition systems have a significant false positive rate, so using only one of these authentication methods may not provide an acceptable level of security. This is why banks require both cards and personal identification numbers (PINs) to access automatic teller machines (ATMs) rather than only a password, or only a key or card. If the card were lost, a thief would have to guess the PIN in only three tries to beat the authentication system.

Authentication is based on one or more of three factors: (i) something you know, such as the password, PIN, or lock combination; (ii) something you have, such as a smart card, ATM card, or key; (iii) a physical characteristic, "something you are", such as a fingerprint or retinal pattern, or a facial characteristic.

Careful design can provide strong authentication at low cost, as with the ATM example above. Fraudulent ATM transactions have consistently been a fraction of 1% of volume throughout the industry for many years. The problem of authentication continues to be an active field of research as new products and methods appear each year. In this section, we review some of the most significant techniques for human and computer system authentication.

***2.1.1 Personal Authentication.*** Authenticating a user to a computer system requires one or more of the factors given in the introductory section above.

*2.1.1.1 Passwords.* Passwords (something you know) are clearly the most common form of authentication, since they provide adequate security for many applications and are easy to set up. However, it is important to keep in mind that with sufficient time, or a sufficiently large number of accounts, an attacker will inevitably be able to guess a working password if users are able to choose arbitrary passwords. One recent study [4] found the following 10 most commonly used passwords, so an attacker trying words from this list across several thousand accounts would be almost certain to succeed: password, 123456, qwerty, abc123, letmein, monkey, myspace1, password1, blink182, (user's first name). A variety of guidelines for choosing and managing strong passwords can be found at government and industry organizations, such as National Institute of Standards and Technology (NIST)'s Publication 800-114 [5].

*2.1.1.2 Smart Cards and Other Tokens.* Token-based authentication schemes can improve authentication security by requiring the user to possess a physical token (something you have) that the system can recognize as belonging to a particular user.

ATM cards are the most widely used example. Tokens typically contain information that is physically, magnetically, or electrically coded in a form that can be recognized by a host system. More sophisticated tokens, for example, smart cards, contain one or more integrated circuits, which can store and, in some cases, process information. Token-based systems reduce the threat from attackers who attempt to guess or steal passwords, because the attacker must either fabricate a counterfeit token or steal a valid token from a user in addition to knowing the user's password. Even smart cards provide no guarantees however, as several sophisticated systems have been demonstrated to have weaknesses that make them vulnerable to counterfeiting [6, 7].

*2.1.1.3 Biometrics.* Biometric characteristics are being used increasingly for authentication, as technology costs come down. Biometrics includes a variety of human characteristics and can be roughly divided into two clusters: static and dynamic. Static biometrics are relatively fixed: fingerprint, face, handprint, iris, and DNA. Dynamic biometrics include active characteristics of a user: signature, voice, typing speed and rhythm, and others.

- Fingerprints—well known and used since the nineteenth century, fingerprints are often assumed to be a foolproof method of user authentication, and many computers are supplied with built-in fingerprint readers. However, effective means of defeating fingerprint readers, even with live sensing, are well known [8].
- Iris scanners—base authentication on pattern recognition algorithms applied to an image of a user's eyes. Iris recognition is quite accurate, with an average current false match rate of 0.001 and false nonmatch rate of 0.0122–0.03847. In other words, only one in a thousand imposters would fool the system, but roughly 1–4% of legitimate users will be rejected [9]. Some methods of defeating iris recognition under controlled conditions have been demonstrated.
- Facial recognition technology is not as well developed as other biometric methods but has advanced rapidly. The best systems achieve a false acceptance rate of 0.001 and a false reject rate of 0.01 on very high resolution images in controlled conditions [10], but results are much worse in less controlled situations. Different applications may use one or more of the following settings: single still image, multiple still image, uncontrolled conditions, and different types of 3D images.
- Keystroke dynamics attempts to recognize users based on measurements such as time between key presses for various pairs of keys, the length of time the keys are down, and the speed of typing letter combinations. These measurements are used as input to pattern recognition algorithms to distinguish among possible users. Error rates are significantly higher than other biometrics, but keystroke dynamics can be used covertly for user recognition, or combined with other methods to provide relatively high strength authentication [11].
- Other biometric authentication technologies include hand geometry, walking gait, and signature recognition. Commercial implementations of these methods have not developed to the degree of other biometrics.
- The Biometric Consortium has information on a wide range of technologies and biometric standards at: http://www.biometrics.org/. Additional resources are maintained by the US Department of Defense: http://www.biometrics.dod.mil/. Evaluations of commercial and research biometric product accuracy are conducted by NIST: http://biometrics.nist.gov/

***2.1.2 Web Authentication.*** Computer-to-computer authentication is very different from the case where one end of the communication is a human and the authentication methods take full advantage of a machine's storage and computational power. Hypertext transfer protocol (HTTP) basic authentication [12] provides a standard format to send user login ID and password for authentication of users at a website. Because it assumes that transmissions from the user to the website are secure, encryption is not used. Thus, basic authentication should be considered very weak, but for applications with minimal security requirements it may be an acceptable solution.

HTTP digest authentication [12] is a stronger authentication method for web browsers. Digest authentication protects authentication information from packet sniffers and makes it possible to avoid storing a clear-text password. Timestamps can also be used to prevent replay attacks. However, digest authentication relies on an algorithm (MD5) that has never been approved by the US Government because of known weaknesses. Implementation is complicated by the fact that the standard contains options that may allow operation in a reduced security form, either an obsolete variant of digest authentication or the weaker basic authentication.

### 2.2 Authentication Standards

Standards are important in any mature field of IT, but are particularly critical for authentication because of the need for interoperability among products. The primary US standards body dealing with IT standards is the International Committee on Information Technology Standards (INCITS) [13], which operates under the auspices of the American National Standards Institute (ANSI).

Active groups within INCITS that are relevant to authentication include the M1 biometrics group and B10 identification cards and related devices. INCITS M1 includes the following: M1.2, biometric technical interfaces, develops standards for secure transfer of stored data between systems; M1.3, biometric data interchange formats, addresses standardization of content and representation of biometric data exchange formats; M1.4, biometric profiles, deals with profiles for biometric-based verification and identification of transportation workers, border management, and point of sale; M1.5, biometric performance testing and reporting, is standardizing performance metrics, testing, and result reporting for biometrics; M1.6, cross jurisdictional and societal issues, covers standards related to societal aspects of biometric implementations. INCITS B10—identification cards and related devices working group covers standards for international or interorganizational exchange of biometric data.

Security standards and practices are also promulgated by the NIST [14], a consortium that develop industry-specific standards, such as the Payment Card Industry Standards Council [15], and Internet Engineering Task Force (IETF) [16] for internet protocol standards, including web applications.

## 3 ACCESS CONTROL AND PRIVILEGE MANAGEMENT

Authentication and authorization mechanisms are the building blocks that must be integrated into a coherent access control policy. The ability to enforce access control policies is a critical capability of most modern day enterprises. Policies are enterprise requirements that specify how access is managed and who, under what circumstances, may

access what information. Among other issues, security policy enforcement is instrumental in preventing the unauthorized disclosure of sensitive data, protecting the integrity of vital data, mitigating the likelihood of fraud, and ultimately enabling the secure sharing of information. The ability to enforce access control policy can be of great economic and mission importance. Although access control is often specified in terms of limitations or protections, the ability of an organization to enforce access control policy is what ultimately enables the sharing of greater volumes of data and resources to a greater and more diverse user community.

Access control policies are enforced through a mechanism consisting of a fixed system of functions and a collection of access control data (reflecting the configuration of the mechanism) that together map a user's access request to a decision whether to grant or deny access. Included in the access control data is the set of permissions—each indicating a user's potential to perform an operation (e.g. read and write) on object or resource. Regarding a specific mechanism, permissions are not individually specified, but instead permissions are organized in terms of, and mapped (through administrative operations or a predefined set of rules) onto a set of user, subject (processes), and recourse attributes, pertaining to a specific type or class of policy. Also common to access control mechanisms is a requirement to store and authenticate user identities. From an authenticated identity, an access control mechanism is able to establish a security context (activate a specific identity, groups or other attributes) as a basis for granting or denying user and process access requests to resources managed under the control of the mechanism at hand. Operationally access control mechanisms compute a series of decisions based on the specifics of the access control data, and ultimately enforce policy based on those decisions.

To understand management issues and solutions requires a basic understanding of the underlying access control models and approaches that are implemented in today's commercially available products. Although a large number of access control models have been proposed in an attempt to solve real-world access control policy issues, today's operating systems (OSs) are limited to the enforcement of instances of discretionary access control (DAC) and simple variations of role-based access control (RBAC) policies, and to a far lesser extent, instances of mandatory access control (MAC) policies. Each of these models is described below.

### 3.1 Discretionary Access Control (DAC)

DAC [17] is a means of restricting access to objects based on the identity of users or the groups to which they belong, or both. Controls are discretionary in the sense that the object's "owner" has control permission to grant access permission to the object for other subjects. Perhaps the most common approach to representing and administering DAC policies is through the use of access control lists (ACLs). Each object is associated with an ACL that stores the users and the user's approved operations for the object. The list is checked by the access control system to determine if access is granted or denied.

The principal advantage of ACLs is that they make it easy to review the users who have access to an object, as well as the operations that users can apply to the object. In addition, it is easy to revoke access to an object by simply deleting an ACL entry. These advantages make ACLs ideal for implementing policies that are object oriented, such as the policy of DAC. Another advantage is that the lists need not be excessively long, if groups of users with common accesses to the object are attached to the object instead of

the group's individual members. A serious disadvantage of DAC is that it is inherently unsafe because users can give away access to others, and the organization cannot control the propagation of the information beyond the owner.

### 3.2 Mandatory Access Control (MAC)

MAC [17] policies remove the user's ability to give away access rights, by controlling access at an organization level. With regard to this policy, security levels are assigned to users, with subjects acting on behalf of users, and to objects. Security levels have a hierarchical and a nonhierarchical component. For instance, the hierarchical components might include "unclassified" (U), "confidential" (C), "secret" (S), and "top-secret" (TS) whereas the nonhierarchical components may include "NATO" and "NUCLEAR". The security levels are partially ordered under a dominance relation, often written as "$\geq$". For example, TS $\geq$ S $\geq$ C $\geq$ U and S (NATO, NUCLEAR) $\geq$ S (NUCLEAR) $\geq$ S. The security level of the user, often referred to as the *user's clearance level*, reflects the level of trust bestowed to the user and must always dominate the security levels that are assigned to the user's subjects. The security levels that are assigned to objects, often referred to as the *object's classification level*, reflect the sensitivity of the contents of the objects. Access control decisions are made in accordance with the following two properties:

- *Simple security property.* A subject is permitted read access to an object if the subject's security level dominates the security level of the object.
- *Star property.* A subject is permitted write access to an object if the object's security level dominates the security level of the subject.

Satisfaction of these properties prevents users from being able to read information that dominates (i.e. is above) their clearance level. The simple security property directly supports this policy, never allowing a subject to read information that dominates the invoking user's clearance level. The star property supports the MAC policy indirectly, by disallowing subjects from writing information of level $x$ into a container (contents of an object) that could be subsequently read by a subject with a security level that is dominated by $x$. Intuitively, the star property prevents high information from ending up in a low container where a low user could read it.

### 3.3 Role-Based Access Control

In an attempt to streamline authorization management, RBAC models [18, 19] and more recently an RBAC standard [20] have been developed. When deployed, RBAC features offer greater administrative efficiency as well as the ability to intuitively administer and enforce a wide range of commercial access control policies. In RBAC, permissions are associated with roles, and users are made members of roles, thereby acquiring the role's permissions. The implementation of this basic concept has been shown to greatly simplify access control management. Roles are centrally created for the various job functions in an organization, and users are assigned roles based on their responsibilities and qualifications. As such, users can be easily reassigned from one role to another. Users can be granted new permissions as new applications and systems are incorporated, and permissions can be revoked from roles as needed. For example, if a user moves

to a new function within the organization, the user can simply be assigned to the new role and removed from the old one, whereas in the absence of the RBAC, the user's old privileges would have to be individually located, revoked, and new privileges would have to be granted. This includes the specification of duties, responsibilities, and qualifications. For example, the roles that an individual associated with a hospital can assume include doctor, nurse, clinician, and pharmacist. Roles in a bank include teller, loan officer, and accountant. Roles can also apply to military systems; for example, target analyst, situation analyst, and traffic analyst are common roles in tactical systems. An RBAC policy bases access control decisions on the functions a user is allowed to perform within an organization. The users cannot pass access permissions on to other users at their discretion. This is a fundamental difference between RBAC and DAC.

### 3.4 Policy Enforcement Issues

Although DAC and RBAC mechanisms dominate the marketplace, they can be weak in their ability to enforce policy. Consider an RBAC policy where only a user in the role of doctor can read medical records. While reading a medical record, nothing prevents the doctor, or a Trojan horse embedded in the doctor's application, from making a copy of the record to a file that is accessible by a user that is not a doctor. As stated above, today's OSs are limited to the enforcement of instances of DAC, RBAC, and MAC policies. As a consequence, there exist a number of important policies (orphan policies) that lack a commercially viable OS mechanism for their enforcement.

### 3.5 Application-Level Mechanisms

To fill policy voids, policies are routinely accommodated through the implementation of access control mechanisms at the application level, often independent of any underlying OS access control mechanism. Examples include database management systems, enterprise calendars, and time and attendance. Although not normally considered in the realm of access control, e-mail and workflow management systems provide access control services as well. E-mail provides for the reading of messages and attachments, through the discretionary distribution of objects, and workflow provides the reading and writing of specific documents for a prescribed sequence of users. Essentially, any application that requires a user's authentication implements some form of access control. Applications can aggravate identity and privilege management problems, and also undermine policy enforcement objectives. For instance, although a file management system may narrowly restrict access to a specific file, chances are the contents of that file can be attached to or copied to a message and mailed to anyone in the organization or the world.

## 4 INTEROPERABILITY ISSUES

Access control mechanisms come in a wide variety of forms, each with their individual method for authentication, access control data constructs for expressing and managing policy, and functions for making access control decisions and enforcement of policies. Although standardized access control models and specifications may prescribe a strategy for achieving uniform policy support at some level of discourse, they should not be confused with a method for affording interoperability. This is because models and

specifications can and often are implemented in different ways, and thus result in different access control mechanisms. For example, the standard for DAC can be successfully met through the implementation of protection bits, ACLs, or capability lists [21], and consequently each implementation will result in a dramatically different mechanism. Deploying a multitude of heterogeneous systems results in a lack of interoperability. Although this may not be a problem for systems that can adequately operate independently of one another, access control mechanisms clearly do not fall into this category of systems. Users with vastly different credentials have a need to access resources protected under different mechanisms, and resources that are protected under different mechanisms differ vastly in there sensitivity, and therefore accessibility. This lack of interoperability in today's access control paradigm introduces significant privilege and identity management challenges.

In an attempt to enforce global policies, an enterprise has two choices—either procedurally coordinate the administration of access control data among relevant mechanisms or deploy an enterprise security management product. Enterprise security management products attempt to overcome interoperability problems through centralized policy specification and local decision making and enforcement. However, in the end, enterprises are limited to the weak enforcement of fairly simple global policies. This is because the space of enforceable policies is restricted to those policies that can be derived through administrative techniques (manual or automated) alone and are otherwise bound by the decision-making and enforcement functions of the underlying mechanisms. For instance, although simple RBAC policies may be configured and globally enforceable over mechanisms that provide user identity and group structures [18], no administrative technique can be applied over these mechanisms to enable the enforcement of a MAC policy. Even these simple policies cannot be truly globally enforced. For instance, users are now accustomed to being able to copy the content of an object that is protected under one mechanism and paste the content into a second object protected under a different mechanism. In today's paradigm, there does not exist a means to enforce access control policies over such actions. Furthermore, application-level access control mechanisms have the potential to undermine global policies. Although a global policy may restrict user access to information under one policy or another, nothing may stop a user from attaching an otherwise-protected object to an e-mail message and sending the message to an unauthorized user, or prevent a sender from inadvertently routing sensitive data to an unauthorized recipient through a workflow application.

## 5 EMERGING SOLUTIONS

To solve the interoperability and policy enforcement problems of today's access control paradigm, NIST (in part under sponsorship of the Department of Homeland Security) has developed an access control standard, referred to as the *policy machine ( PM )* [22]. Its objective is to provide a unifying framework to support not only current OS and application polices but also a host of orphan polices for which no mechanism yet exists for their viable enforcement. The PM requires changes only in its data configuration in the enforcement of arbitrary and organization-specific, attribute-based access control policies.

A comprehensive reference implementation of PM features has been under development during the past 2 years. Demonstrated benefits now include the following:

- *Policy flexibility.* Virtually any collection of attribute-based access control policies can be configured and enforced (e.g. DAC, multilevel security (MLS), Chinese wall,

user controlled (UCON), and object-based separation of duty (SoD)). In addition, basic application services can be provided through PM configuration to include those services offered by workflow management, e-mail, and database management applications.

- *Policy combinations.* Resources (objects) regardless of their type can be selectively protected under one or more currently configured policies (e.g. DAC only, or DAC and RBAC combined).
- *Comprehensive enforcement.* All user access and subject (process) access requests, and all exchange of data to and from and among applications, between sessions, all exportation of data outside the bounds of the PM can be uniformly controlled under the protection policies of the objects of concern (e.g. "copy and paste", e-mail, workflows, granting access, file management, and writing to devices and ports).
- *Assurance.* Configuration strategies can render malicious application code harmless and prevent unlawful leakage of data, all enforcement could be implemented at the kernel level, and attributes are automatically and minimally assigned to sessions (least privilege) to fit a user's access requests (as opposed to a user's need to select attributes or a user's session provided with all attributes of the user).

The features described above could be provided through a number of PM architectural deployments to include its implementation within a single-OS environment. Our reference implementation provides centralized policy configuration and decision making with local OS enforcement. This PM deployment affords still additional benefits as listed below:

- *Single enterprise-wide scope of protection.* One administrative domain versus policy management on an OS-by-OS and application-by-application basis. Access control policies are uniformly enforced over resources that are physically stored on a multitude of heterogeneous systems.
- *True single sign on.* By virtue of the PM's single scope of control, and a personal object system (POS) that includes the ability to reference and open any resource accessible to a user (e.g. e-mail messages, work items, files, records and fields within records), eliminates the need for a user to authenticate to a multitude of applications and hosts.
- *Logical access.* Any accessible resource could be securely accessed through any PM-compliant OS with access to an application to process the resource.
- *Minimized OS vendor support.* To be PM compliant, all an OS vendor needs to do is implement a standard set of enforcement functions (i.e. PM authentication, user resource presentation, session management and reference mediation), and does not need to be concerned with the management of access control data or the execution of access control decisions.

With the PM's advantages over the existing access control paradigm, coupled with a minimum investment on the part of OS vendors, there exists a strong business argument in favor of the adoption of the PM. Moreover, the features that provide these benefits are native to the PM and as such are afforded without the deployment and expense of less effective privilege management, provisioning, identity management, or synchronization products.

## 1 HONEYPOT ESSENTIALS

Honeypots and honeynets are well known to security processionals. Newly developed honeynet techniques and technologies are a hot topic in information security. However, the amount of technical information available on their setup, configuration, and maintenance is still sparse as are qualified people with the capability to run them, interpret the activity, and make security recommendations. Higher-level guidelines, such as a need and business case determination, are similarly absent. In addition, honeypot risks, such as legal authority and ethical use, need to be fully evaluated prior to honeynet deployments. In this article, we present a brief introduction to honeynet technologies, a short word on ethical and legal considerations, and then describe four of the most productive honeynet technologies.

What is a honeypot? Lance Spitzner, a founder of Honeynet Project [1] defines a honeypot as "a security resource whose value lies in being probed, attacked or compromised". Thus, a goal of such a masochistic system is to be compromised and abused. Hopefully, each time a honeypot goes up in smoke, the researcher learns a new technique. For example, you can use a honeypot to find new rootkits, exploits, or backdoors before they become mainstream.

The term *honeynet*, originated by the Honeynet Project, means a network of honeypots. The configuration of the honeypots is specific to the network and services architecture of the environment you are defending. Further the honeynet is configured so that if a honeypot is compromised, the attacker cannot use that system to attack systems in your production network or external systems. Details of this configuration are described in Section 3.1. In some configurations, the system software of the honeypots is slightly modified (in the same manner as a rootkit works) to help monitor activity and

encrypted communication of attackers. The Honeynet Project defines such honeypots as "high-interaction" honeypots, meaning that attackers interact with a fully functional deception system exactly as they would with a real victim machine. On the other hand, various honeypot and deception daemons are "low interaction", since they only provide an illusion to an attacker. These systems only hold attacker attention for a short time. Examples of low-interaction honeypots include, Honeyd [2], Specter [3], and KFSensor [4]. Such honeypots have value as an early attack indicator collecting statistical data, and collecting malware, but do not yield in-depth information about the attackers.

Honeypots can further be separated into client and server honeypots. Client honeypots or "honeyclients" masquerade not as a legitimate server, but as a legitimate client system, such as a web surfer. A honeyclient might be compromised when trying to connect to a malicious or compromised server. Honeyclients are perfect for collecting web-deployed malware and web exploits.

What are some of the common sense prerequisites for running a honeynet? First, security basics should be covered. If your firewall crashes or your IDS misses attacks, you are clearly not yet ready for a honeypot deployment. Running a honeypot also requires advanced knowledge in computer security, network, platform, and application levels. Obviously, the compromised honeypot systems (whether client or server) should not be allowed to attack other systems.

The Honeynet Project defines guidelines on data control (capability required to control the network traffic flow in and out of the honeynet in order to contain the blackhat actions within the defined policy) and data capture (defines the information that should be captured on the honeypot systems for future analysis, data retention policies, and standardized data formats) for the deployed honeynet. They distill the above ideas and guidelines into a well-written document "Honeynet Definitions, Requirements, and Standards" [5].

The deployment of honeynets must be carefully planned and guidance sought to ensure that legal requirements are followed. Do you have the authority to monitor network traffic? What requirements exist for the data contained within the network packets? What must be done if your honeypots are actually attacked? If the attacker then engages in illegal activity using your honeypots, are you liable?

## 2 HONEYPOT RISK; LEGAL AND ETHICAL ISSUES

Running a honeypot incurs some risks. There are many laws, in virtually all nations that cover a person's expectation of privacy and the culpability incurred when your systems are involved in a cyber crime. Despite the risks, running the honeypot is an exciting and educational experience, which also contributes to a state of the art in information security.

What are some of the legal issues typically associated with running a honeypot?

Liability risk is the most common issue. Can you get sued if an attacker uses your honeynet to attack other, possible sensitive, systems? Given that there is very little case law, it is still too early to decide how significant this is. However, the more freedom is given to the attacker for the sake of creating a realistic "production-like" environment, the more risk of such liability is present.

The privacy and handling of the data captured is also a concern. The data packet may contain communications from unknowing bystanders or sensitive data (such as credit card or other personal information). Proper safeguards must be used to ensure that this type of

data is protected from disclosure. A bizarre issue that is sometimes brought up is whether the honeypots infringe upon the rights (such as the privacy right) of the hackers? While this sounds truly preposterous, the cases where burglars sued the victims who wounded them while defending their property are no less ridiculous—and they actually happened!

Richard Salgado, former senior counsel for the Department of Justice's computer crime unit, investigated some of the legal issues related to honeynet operation. He did confirm that "There are some legal issues here, and they are not necessarily trivial, and they're not necessarily easy." For example, in one of his media interviews [6], Mr Salgato mentioned a case where "an accused kidnapper who was using a cloned cell phone sued for the interception of the cell phone conversations and won."

The discussion of the legalities of deploying honeynets can be a very long one. The specific legal restrictions of the implementer's nation or province must be well understood. As the primary focus of this article is to describe emerging honeynet technologies, the reader should review the material available specifically covering legal issues on the Honeynet Project website [7] as well as other publications [8, 9].

## 3 HONEYNET TECHNOLOGIES

Honeynet technologies have matured over the last 9 years to a collection of sophisticated architectures that enable a relatively safe deployment of honeypots in the traditional high-interaction format to the new Global Distributed Honeynet (GDH) or as a honeyclient. The high-interaction honeypot is the most recognized honeynet technology. The latest version, generation III, brings the latest in ease of deployment, data control and capture, and analysis.

### 3.1 Generation III Honeynet

The generation III honeynet consists of an architecture where the honeypots reside behind a data control and capture device called a *honeywall*. The honeywall is a data link layer (layer 2) proxy. The software for the Honeynet Project honeywall is distributed on a bootable CD and is currently built using a CentOS kernel. This layer 2 proxy intercepts all inbound and outbound packets and uses a variety of mechanisms including rate limiting, selective dropping, and "bit-flipping," to mitigate the risk of a honeynet being used to exploit or scan yours or other's networks.

As shown in Figure 1, the honeywall is placed between the honeynet and the rest of the network. The organizations production systems (for example, e-mail or web services), shown as Production 1 and 2, are placed in front of the honeywall. The honeywall uses a combination of Snort [10] and Snort-inline to log and, where necessary, scrub incoming and outgoing packets. A detailed communication flow for a honeywall is shown in Figure 2.

In most cases, the packets coming into the honeynet through the honeywall are allowed to pass unchallenged to the honeypots. Only packet capture is done on the honeypot facing NIC. Outbound packets are subject to rate limiting (implemented in IP tables) and analysis by the Snort-inline process. The rate limiting of outbound activity is based on protocol and number of packets and can be specified in the scripts that start IP tables.

The task of data control and protecting the production and internet hosts from attacks originating from your honeypots is handled by the Snort-inline process. This process

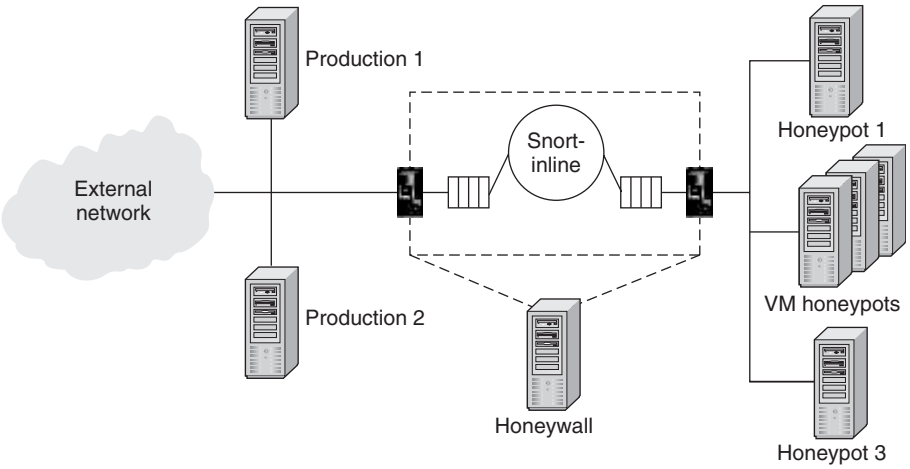

**FIGURE 1** Honeynet architecture.

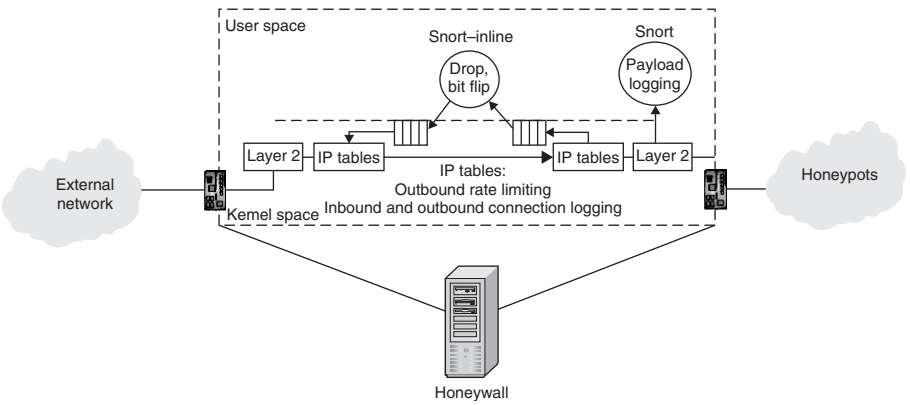

**FIGURE 2** Honeywall connection detail.

receives packets from the IP table queuing feature and matches the packets against a modified Snort rule set. If the packet matches a rule, either the packet could be allowed to continue (not likely) or be simply dropped, or Snort-inline could slightly modify the outbound packet's payload thereby rendering the exploit impotent when it reaches its intended target. Using the last approach, it is less likely that the attacker will become discouraged and move on.

Data Capture is accomplished as described above by the Snort process on the internal interface. Additionally a host-based technology called *Sebek* [11], logs all attacker activity on the honeypot and sends it to the honeywall for capture. The original version of Sebek was based on the Adore rootkit. The current version of Sebek replaces the read() function in the system call table in the 2.4 Linux kernel with a read() that is configured to copy all data that it sees into a packet and sends it to a server that collects Sebek packets as well as the normal processing handled by the read() function. Using this method not only captures all activity by the attacker on the honeypot, but also any data that was

once encrypted between the honeypot and the attacker's SSH server. Sebek also allows data to be sent covertly out of the honeypot without being observed by the attacker. This is accomplished by bypassing the TCP/IP stack (and the corresponding raw socket interface) and sending the Sebek data packets directly to the network device driver using the transport protocol UDP.

While Sebek provides a tremendous opportunity to record everything an attacker does, it is not invisible. Just as we are using attacker techniques by modifying the kernel functions for the purpose of monitoring, an attacker could determine the build of the OS on the honeynet and compare the various kernel functions known to be used by Sebek (most commonly through an MD5 checksum) and determine that he is on a honeypot. While this might be true and the attacker would probably leave, we have still gained a tremendous amount of information about the attacker—including the fact he is *not* a script kiddie. There are other detection mechanisms for honeypots and Sebek that can be found; the first one published is known as *NoSEBrEak* [12].

### 3.2 Global Distributed Honeynet (GDH)

Until last year, the deployment of honeynets was very geographically constrained. The GDH project is an attempt to develop, deploy, operate, and analyze data based on a worldwide network of honeynets. GDH was developed and led by David Watson of the UK Honeynet Project. The idea is to set up at different network locations an identical honeypot sensor system and store all collected information in a central database. Each GDH node consists of different components:

- virtual honeywall for data capture and data control;
- virtual Nepenthes honeypot for automated malware collection;
- one or more high-interaction honeypots running in a virtual machine.

All honeypot components are executed within virtual machines such that the whole honeynet can be deployed on one physical machine. Besides needing only a limited amount of hardware for running a GDH node, this approach has the additional advantage of the administration and system maintenance of the honeypot being easier. Setting up a new node only requires booting from a GDH CD-ROM, which automatically sets up the base platform on the system.

The whole honeynet is structured in a star-based network model with many GDH nodes and one central GDH data server. Each day all collected information, such as raw network data, IDS log files, and binary samples of malware, is transferred from each sensor node to the central data server. This enables a central correlation and analysis mechanism and all reports about malicious activities are generated based on this data.

The full GDH sensor system was operated for a period of 3 months between March and May 2007 with 11 GDH nodes. This GDH phase one was an attempt to test the whole infrastructure in a real-world environment. More than 730 million network packets were captured during this period, resulting in more than 122 GB of raw network data. In total, about 300,000 unique source IP addresses were observed at all honeypot sensors and this shows that such a global network of honeypots can collect quite a lot of information about network-based attacks. Furthermore, about 670,000 brute force attacks against SSH servers could be observed and 1680 malware samples were collected with the virtual Nepenthes honeypots.

Besides these automated attacks, several attacks by blackhats were also observed and lot of information about the typical tools, tactics, and motives of the attackers were collected. The major incidents observed include, for example:

- Polish cyber crime botnet used to attack other system with distributed denial-of-service (DDoS) attacks
- Brazilian group of blackhats who attacked web applications
- Romanian group of blackhats who are specialized in SSH brute force compromises.

The GDH phase one demonstrated the ability to successfully deploy and operate a globally distributed, standardized honeynet with identical sensor nodes at each location. The whole operation has also demonstrated that large scale distributed data collection and analysis are complex and time-consuming efforts, but the collected data compensates the effort since a lot of data about blackhat attacks were collected. In the future, the basic design of a GDH will be refined and adopted to new threats observed in the wild. The goal is to continuously operate a global network of both low- and high-interaction distributed honeynets based on current honeynet technology. Such a system can then be used to study and analyze current events and threats against systems connected to the Internet. The whole infrastructure can also be used as a test bed to study current honeynet technology in a real-world environment.

### 3.3 Honeyclients

One of the new research areas for Honeynet technologies is the honeyclient. Honeyclients, which are sometimes also called *client honeypots*, are the opposite of server honeypots. The main idea is to simulate the behavior of humans and then closely observe whether or not the honeypot is attacked. For example, a honeyclient can actively surf websites to search for malicious web servers that exploit the visitor's web browser and thus gather information of how attackers exploit clients. Another example are honeyclients that automatically process e-mails by clicking on attachments or following links from the e-mail and then closely observing if the honeypot is attacked. The current focus in the area of honeyclients is mostly based on the analysis of web client exploitation, since this attack vector is often used by blackhats in order to compromise a client.

Honeyclients also have another advantage: honeyclients initialize every analysis and thus control the maximum number of possible attacks. It is possible that a server honeypot may not be attacked for weeks or even months, or it is also possible that the honeypot is attacked occasionally by many attackers at the same time. In general, it is not possible to predict how frequently attacks will occur on a honeypot, and therefore the analyses get more complicated.

Honeyclients can also be classified as high-interaction or low-interaction honeyclients. High-interaction honeyclients are usually real, automated web browsers on real operating systems which interact with websites like real humans would do. They log as much data as possible during the attack and allow a fixed time period for an attack. Since they provide detailed information about the attack, high-interaction honeyclients are in general rather slow and not able to scan broad parts of the web. Low-interaction honeyclients, on the other hand, are often emulated web browsers, usually webcrawlers, which have no or only limited abilities for attackers to interact with. Low-interaction honeyclients often

make use of static signature or heuristics-based malware and attack detection tools and thus lack the detection of zero-day exploits and unimplemented attack types.

For all available honeyclients, a common general architecture or process chain, which consists of three serial steps depending on each other, can be observed. At first, a queue is filled with objects to analyze. Second, a honeyclient draws targets from the queued objects. Third, the collected information about the object is analyzed regarding their maliciousness. Several examples of different kinds of honeyclients and first results obtained with these tools are provided in the following paragraphs.

The HoneyMonkey project is a web browser (Internet Explorer) based high-interaction honeyclient developed at Microsoft Research in 2005 [13]. The HoneyMonkey architecture consists of a chain of virtual machines with different flavors of the Windows operating system in various patch levels. Starting with a fully unpatched system, the Monkey Controller initiates a so-called "monkey" program that browses previously scheduled websites. The monkey opens the website and waits for a predefined time. After the time-out, the virtual machine is checked for signs of a successful intrusion. If an attack is detected, the website is revisited with the next machine having a higher patch-level in the pipeline. During their research in May/June 2005, the researchers found that unpatched Windows XP SP1 systems could be exploited by 752 different URLs and a fully patched Windows XP SP2 had no exploits. They also claim to have detected a zero-day exploit in July 2005.

Capture [14] is a high-interaction honeyclient developed at the Victoria University of Wellington, New Zealand. Capture has two functional areas in its design, namely, a Capture client and a Capture server. The clients are hosting the actual high-interaction honeypotclient on a virtual machine, whereas the server coordinates and controls the clients. Capture concentrates on three aspects of high-interaction honeyclients:

- Capture is designed to be fast. State changes on the clients are triggering malicious actions in real time to the server.
- Capture is designed to be scalable. The central Capture server can control numerous clients across a network
- Capture supports different clients. The current version supports the three web browsers Firefox, Opera and Internet Explorer.

The server takes a URL as input and distributes it to one of the honeyclients in a round-robin fashion while controlling the clients in means of starting and stopping them. The clients report back any state changes: each client monitors its own state for changes on the file system, registry, and processes while browsing a website. An exclusion list for known, benign system changes are used to identify a nonmalicious state change; any other operation triggers a malicious classification of the web server and sends this information to the Capture server. Since the state of the client has been changed, the client resets its state to a clean state and retrieves new instructions from the server. If no state change was detected, the client requests new instructions from the server and continues its browsing without resetting. An interesting feature in development is to support nonbrowser clients, such as multimedia players and Microsoft Office applications.

### 3.4 Low-Interaction Malware Collectors

Several low-interaction honeypots were developed in the last few years to automatically capture binary copies of autonomous spreading malware. The basic idea of each of these

honeypots is to emulate an actual vulnerability. If a honeypot thus emulates a vulnerability and behaves like a vulnerable system, the malware will be tricked into thinking that the machine can actually be compromised and attacks the honeypot. By analyzing the received attack data and sending back packets that emulate an actual exploitation phase, the honeypot can collect enough information to acquire a binary copy of the malware.

One of the well-known honeypots from this area is Nepenthes [15]. Nepenthes is a low-interaction honeypot which aims at capturing malicious software artifacts that spread in an automated manner, like for example, worms or bots. The tool is based upon a very flexible and modularized design. The core—the actual daemon—handles the network interface and coordinates the actions of the other modules. The actual work is carried out by several modules, which register themselves in the Nepenthes core, and currently there are several different types of modules:

- Vulnerability modules emulate the vulnerable parts of network services. In total, this honeypot emulates more than 20 different vulnerabilities, corresponding to commonly exploited network services.
- Shellcode parsing modules analyze the payload received by one of the vulnerability modules. These modules analyze the received shellcode, an assembly language program, and extract information about the propagating malware from it.
- Fetch modules use the information extracted by the shellcode parsing modules to download the malware from a remote location.
- Submission modules take care of the downloaded malware, for example, by saving the binary to a hard disc, storing it in a database, or sending it to antivirus vendors.
- Logging modules log information about the emulation process and help in getting an overview of patterns in the collected data.

With the help of Nepenthes, it is possible to collect a large number of malware binaries, which spread autonomously. For example, during an 8-week measurement study between December 2006 and January 2007 a Nepenthes sensor running on about 16,000 IP addresses in parallel was able to collect more than 2500 unique malware samples [16]. The uniqueness is determined by the MD5 hash of each binary: two binaries that have the same MD5 hash are considered to be the same malware. Other operators of low-interaction malware collectors report a similar amount of malware collected with these honeypots [17].

# DETECTION OF HIDDEN INFORMATION, COVERT CHANNELS, AND INFORMATION FLOWS

NEIL F. JOHNSON AND PHIL A. SALLEE
*Booz Allen Hamilton, McLean, Virginia*

## 1 INTRODUCTION

The oldest form of protecting information is to conceal its existence—hide it. Numerous methods for hiding information have been developed through the years, ranging from physical concealment of objects which are "hidden in plain sight" to high-tech methods for covert communications in digital media. Some examples of hiding information include hidden tattoos, covered writing, invisible inks, microdots, grille and null ciphers, code words, digital signatures, covert channels and spread-spectrum communications, to name but a few [1–5].

Steganography is used to conceal the existence of hidden messages within seemingly innocuous carriers. Common techniques in digital steganography usually camouflage the intended message within another object or media, referred to as either the *cover* or *carrier*. By far, the most common steganography tools embed information within image files. However, hidden information can be embedded within nearly any type of digital media or information flow. Research also extends beyond digital media such as DNA [6–8], chemical compounds [9], and circuit boards [10–12]. The focus in this article is on digital steganography: hiding in electronic files and media.

Covert channels, though not necessarily designed for communication, provide a means to communicate through the misuse of another mechanism, typically a shared resource. Such a mechanism can be exploited to convey information from a higher (more secure) environment to a lower (less secure) environment [13]. Human ingenuity and the availability of shared resources provide a variety of resources for communications. For example, convicted spy Robert Hanson would signal to his counterparts that information could be picked up by placing a chalk mark on a park sign: no mark, no information. In a digital world, signaling takes place in 0s and 1s.

Any organization or individual requiring secret communication will employ whatever technology is at their disposal to achieve the perceived secrecy. As a result, there is practically no limit to the variety of steganography implementations that may be developed. Inherent redundancy in many digital media formats provides ample storage space for hidden information. Examples of potential carriers include text [14–16], audio [17–19], image (the majority of steganography research), video [20–22], and hidden file systems [23, 24]. Research and techniques also exist for exploiting network packets and protocols to establish covert channels for communication in information flows [25–38]. Figure 1

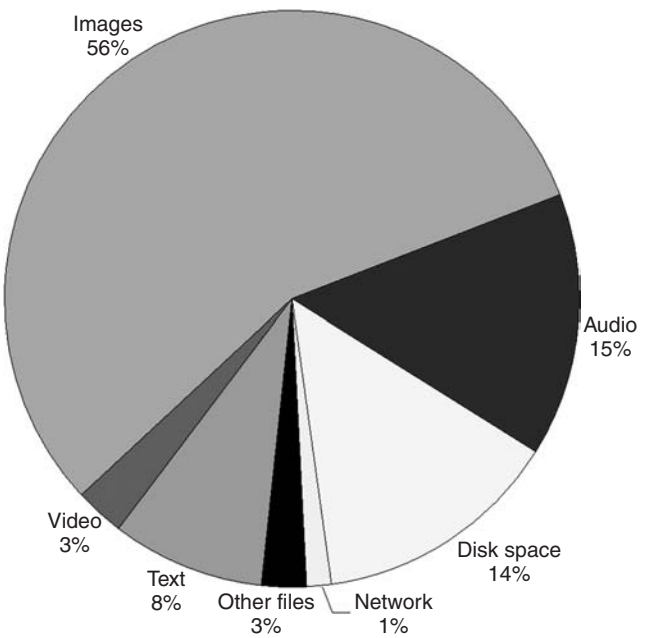

**FIGURE 1** Chart illustrates the observed distribution of media type supported as carriers for hidden information through steganography-related software development from 1992 through 2007.

illustrates the general distribution of media types used as carriers for hidden information by publicly available steganography software.

With the growth of the Internet, the introduction of new digital media formats, and increased concerns over privacy and security, tools and methods for protecting individuals and their information continue to expand. Each year reveals growing interest in steganography as new tools are developed, new research papers are published, and the number of academic research programs and conferences dedicated to the subject of hiding digital information continue to increase. Research efforts on the subject span the globe, and hundreds of new steganography-related software programs are released each year on the Internet. Some of these tools are academic in nature as student projects, others are malicious utilities designed to circumvent security mechanisms, and others are commercially marketed. Some steganographic products are marketed to the public with claims of protecting personal information or encourage the use of steganography where cryptography may be scrutinized.

## 2 SCIENTIFIC OVERVIEW

While many steganography tools and academic papers still focus primarily on the imperceptibility of the hidden information, the most current art in steganography takes into account the potential for statistical steganalysis. Likewise, research efforts in steganalysis quickly respond to new steganography methods and techniques as they are presented. Steganography and steganalysis research efforts form a cat and mouse game that continually advances the state of the art—similar to that of cryptography and cryptanalysis.

Both cryptography and steganography may be used to secure information. However, the two address differing requirements. Cryptography secures information by scrambling it, thus rendering a message unintelligible. Yet, cryptographic data may still be observed in state or in transmission. If an encrypted message is intercepted, the interceptor knows the text is an encrypted message.

Steganographic security is obtained by keeping the very existence of the embedded message from being discovered—essentially camouflaging information so that any observable data or communication does not appear out of the ordinary. The steganography has failed if an observer can determine that a hidden message exists. Like cryptography, however, really good steganography is challenging to design. Detectable signatures can easily be introduced during the embedding process. Consequently, relying solely on "security by obscurity" (concealing the details of the encoding/decoding algorithm) is considered highly inadvisable. Strong steganography, like cryptography, relies on academic peer review to identify potential weaknesses.

### 2.1 Hiding Information

Assume a digital carrier, $C_{\{p,h\}}$. $C_p$ is the perceptual portion of the carrier and any manipulation to this portion will be readily noticeable. $C_h$ is the portion of the carrier that falls below the perceptual threshold and manipulation to this portion will not be readily noticed. If the construct of $a + b$ denotes a composition of $a$ and $b$, then the carrier may be represented as $C_{\{p,h\}} = C_p + C_h$. The size of $C_h$ depends upon the properties of the carrier, complexity of the data hiding process, and the need to balance constraints of imperceptibility versus robustness (survivability of the embedded data to some level of distortion).

If the operation $e \rightarrow f$ represents a process for hiding data $e$ into $f$, then a representation of the embedding process is $m \rightarrow C_h = C'_h$, where the message (m) is hidden in the imperceptible component $C_h$ of the carrier $C$. The resulting modified carrier is in the form of $C'_{\{p,h\}} = C_p + C'_h$ and is perceptually indistinguishable from $C_{\{p,h\}}$. The resulting $C'_{\{p,h\}}$ contains the hidden message and is referred to as the *steganogram* or *stego-media* (images may be referred to as stego-images, audio as stego-audio, etc.).

A common method for hiding data in digital carrier is to manipulate the bits that have the least impact to the observable carrier if changed. In 24-bit images such as bitmap (BMP) or audio files such as PCM WAVs, the *least significant bits* (LSBs) provide an instance of the $C_h$ portion in these carriers. Table 1 illustrates the impact of changing the LSBs of the color cells. Changing three bits of data has no visual impact. In fact, changing the lowest four bits of the color block also has little visible impact to this color. Therefore some bits can be used to embed any data we want without significantly changing the image [39]. Research examining image color reduction based on human vision limitations [40] inspired others to experiment with data hiding techniques and develop steganography tools [41].

A 24-bit image that is 1024 by 768 pixels in size yields 2,359,296 (1024*768*3) bytes of image data from the pixels. Changing only the LSBs permits storage capacity of 294,912 bytes. This article, with the figures and tables would fit with room to spare in such an image—(escaping detection is an altogether different matter). Many steganography tools that embed in BMP images or WAV audio files hide data using this type of technique.

The compressed formats GIF and JPEG are more prevalent on the Internet than BMP files. GIF images have only up to 256 colors and use only one byte to represent an image pixel. This byte is a pointer to a color table (palette) that is used to paint the colors of the image to the screen. Changing the LSB of one of these pointer bytes changes the position being pointed to in the color palette. If neighboring colors are distant, then changing the LSB will have visible difference on the resulting stego-image [39, 42]. To avoid this, steganography developers have investigated ways of arranging image palettes so that near colors are closer [43], or reconstructing new palettes [41] so that LSB manipulation is less visible.

**TABLE 1 Illustrates the Impact of Changing the LSBs of the Color Cells. Changing Three Bits of Data has No Visual Impact. In Fact, Changing the Lowest Four Bits of the Color Block Also has Little Visible Impact to This Color. We Can Clearly See that Some Bits Can be Used to Embed any Data We Want without Significantly Changing the Image**

| | Color | | Color Values |
|---|---|---|---|
| Original | | Red:<br>Blue:<br>Green: | 11000000 (192)<br>11000000 (192)<br>11000000 (192) |
| Only LSBs changed | | Red:<br>Blue:<br>Green: | 1100000*1* (193)<br>1100000*1* (193)<br>1100000*1* (193) |
| HALF the image data changed | | Red:<br>Blue:<br>Green: | 1100*1111* (207)<br>1100*1111* (207)<br>1100*1111* (207) |

Because JPEG images are highly compressed, the pixel data is not as readily available for manipulation. Therefore, manipulation to JPEG images occurs most commonly in the DCT compression coefficients. However, given a process to decode and re-encode coefficients within the JPEG format, the process of hiding data within DCT coefficients can be performed similarly to changing LSBs of pixels in a BMP file.

Early methods for steganography follow the simple LSB embedding technique described. As research progressed and methods for detecting hidden data became published, techniques for hiding became more elaborate. Researchers began combining cryptographic techniques—scrambling and diffusing the hidden messages across the cover media to make the message recovery more difficult if detected. Later techniques consider properties of the cover media and try to mimic the expected statistics of bits that are manipulated within the cover, or attempt modeling other characteristics of the cover media so embedded messages are more difficult to detect [44–52]. Each of these improvements in data hiding prompted related research for detection [42, 50, 53–65].

## 3 COUNTERMEASURES

Countermeasures to hidden communications fall into two general categories: detection and disruption. Steganalysis involves analyzing steganography algorithms, techniques, and their output to devise methods to detect the presence of the hidden data and, if possible, extract the data to reveal the hidden message. Alternatively, one may be more interested in protecting legitimate communications and disrupting potential covert communications by rendering the hidden data unusable.

### 3.1 Countermeasures: Detection

The basis of detecting hidden information involves making observations similar to forensic analysis of files and systems. These observations aid in determining whether applications were used to hide information, or if any media contains hidden data. Such observation includes the examining of media to look for indicators of manipulation by various steganographic tools, and may lead to the development of new *steganalysis* techniques. Two types of signatures emerge when investigating hidden information. *System Signatures* are residual artifacts on computer systems that result from the installation, execution, or removal of tools that hide information [39]. *Steganographic Signatures* are detectable distortions that occur in the carrier media when the carrier is manipulated to conceal the hidden data [39, 42].

The identification of steganographic signatures generally requires extensive experimentation with various products that provide information hiding capabilities. Stego-media is compared with the original carrier media to determine what properties or characteristics change when data is hidden. Such experimentation is also useful in determining the capabilities and limitations of data hiding methods (i.e. the breaking points), as well as discovering signatures that may be leveraged for more rapid detection. Distortions that take the form of repeatable patterns and provide reliable indication that a steganography tool has been used are often referred to as *hard signatures*. The Steganalysis Research Center (SARC) produces forensic and steganalysis tools that look for system signatures and hard signatures in stego-media [66].

Hard signatures do not provide a complete solution to the steganalysis problem, however. Developing a database of signatures requires time, and the growth in the number of steganography applications exceeds the current discovery of steganographic signatures provided in forensic and steganalysis tools. Additionally, not all hiding techniques produce such patterns. In some cases, distortions caused by a steganographic method may simply violate the expected structure of the carrier media to a degree that allows for some uncertainty as to the cause of the distortion. Here, steganalysists must rely on *soft signatures*, based on statistical anomalies in the stego-media to identify potential data hiding.

To address the rapid growth in steganography tools and techniques, other detection methods need to be employed. Research is progressing in the area of *blind detection*, which does not rely on specific knowledge of a steganography technique, and holds the promise of detecting even previously unknown steganography applications. Most academic research in steganalysis is currently pursuing approaches for statistical and blind detection [50, 53–58, 61–65]. Wetstone Technologies produces a steganalysis suite for investigations to perform detection of system signatures (Gargoyle) and assist investigators in discovering stego-media based on statistical analysis [67]. Other researchers have also made attempts at producing steganography detection techniques with mixed results [64].

Both hard and soft signature approaches to detecting stego-media have merit. However, the volume of emerging steganography methods and tools is a hindrance in producing hard signatures for them all. Blind and Statistical detection methods are generally limited in accuracy, due to the intrinsic variability and unpredictability of media content as well as variations due to lossy compression, transcoding, and processing. Even relatively small false alarm rates can overwhelm analysts working with large data sets. Combining features and signatures may help investigators to make better determinations and reduce false alarms.

### 3.2 Countermeasures: Disruption

In some cases, preventing data leakage may be of greater importance than detecting the presence of hidden data. In this case an *active warden* may manipulate suspect media or traffic in an attempt to render any embedded data unusable. Revisiting the steganography system of $C'_{\{p,h\}} = C_p + C'_h$, the warden may also manipulate $C'_h$ to change, overwrite, or remove any embedded data without noticeable distortion to $C'_{\{p,h\}}$. From the warden's view point, as long as the portion or simulation of $C_h$ is below the perceptual level, then a $C_h''$ exists that is of the warden's choosing and prevents the hidden information from being passed [3]. Researchers have investigated using such approaches in multimedia (images, audio, video) [42, 61, 69–73] and as countermeasures to hiding in network traffic and covert channels [31, 38, 74–80].

Some disruption attacks can be defeated. The Stirmark tool was developed to test the robustness of watermarking algorithms by applying various distortions to images [71]. In [81], however, authors described a generalized countermeasure against the distortion attacks executed by Stirmark, demonstrating the ability to recover previously unreadable watermarks from distorted images.

## 4 RESEARCH AND DEVELOPMENT TRENDS

### 4.1 Research Trends

Application development and academic research in digital steganography and steganalysis started gaining momentum during the 1990s and has steadily increased in depth and breadth since. The first academic conference on the subject, the International Information Hiding Workshop, was held in Cambridge, UK, in 1996 [82]. Conferences in information hiding share venues and ideas with research in related areas including anonymity and privacy, cryptology, computer security and forensics. Continued research in information hiding takes inspiration from many other fields as well, including signal detection theory, information theory, signal processing, computer vision, and machine learning. Although having different end goals, digital watermarking is closely related to steganography as a type of information hiding and the two have developed alongside one another with many shared ideas and techniques. Research in both areas has focused on expanding information hiding concepts to address many different types of digital media and signals, and also in the sophistication of the techniques employed and their ability to conceal and reveal information using statistical methods.

The earliest academic research in digital steganography focused primarily on hiding from view, that is, a human observer, in a variety of digital formats. Common techniques of this era included modifying LSBs of a carrier signal, or hiding in specific bit-planes of binary values [39, 83]. Images provided an attractive carrier, with a relatively large capacity for hiding information, and BMPs were an easy target for manipulation due to their simple format. Later, academic research in image steganography shifted to hiding in DCT coefficients in the more popular JPEG format [47, 51, 52], and eventually also in the wavelet transform domain [84]. Hiding in text gained early interest before images were prevalent in e-mail attachments, and while the Internet was still in its infancy. Text embedding techniques included whitespace manipulation, such as line and word spacing [16], and synonym replacement [14, 15]. Other media formats were also exploited, including audio [17, 19] and internet protocols [28, 30, 35].

Early approaches to digital steganalysis included visualization techniques, and histogram tests such as the Chi-squared attack, which demonstrated weaknesses in LSB steganography [42, 65]. In response, steganography algorithms were designed to avoid detection by these specific attacks, and the focus shifted toward resisting statistical detection rather than avoiding human observation. For example, LSB methods were replaced by $\pm 1$ additive embedding [85], and in DCT coefficients by reduction in magnitude [51] and histogram preservation [47]. As steganography improved in sophistication, research in steganalysis quickly responded, focusing primarily on specific attacks to counter known steganography algorithms [59, 60].

Theoretical research has focused on the possibility of provably secure steganography. Taking inspiration from cryptology and information theory, Cachin introduced the concept of epsilon-security for steganography based on the similarity between the true cover and embedded cover distributions in terms of information theoretic divergence measures [86]. A link was recognized between compression and steganography that later served as inspiration for model-based techniques [49, 50, 87]. Some work has also considered the maximum capacity of secure steganographic embedding [49, 88]. Drawing from the

computer vision and natural scenes communities, other research has looked at statistical differences of image steganography as compared to the statistics of natural scenes [89], with obvious implications to steganalysis.

Out of these early starts in digital steganography, some recent trends emerged. Steganography methods began to focus less on avoiding specific attacks and more on preserving the statistical properties of the cover media, and reducing the number of required changes to the media. For example, matrix-embedding techniques provide a means to reduce the number of changes required to hide information, by trading off capacity for a given sized cover. Also, model-based techniques use statistical models of the cover media to preserve the modeled cover statistics more accurately and efficiently [49, 50, 90, 91]. Some more recent steganography techniques dynamically adapt to the characteristics of the cover media. For example, these techniques may identify locations with higher variability that are considered more suitable for embedding data. A significant advancement in this regard is known as informed embedding, which uses side information about the media that is not preserved or passed to the receiver in order to improve the quality and undetectability of the resulting stego-object [44, 92].

Similarly, steganalysis methods began to focus more on modeling the properties of cover media, as well as the results of steganographic embedding. Most notable in this regard is the advancement of general, or universal, steganalysis methods, which use machine learning and classification techniques such as Support Vector Machines (SVMs) to detect steganography based on exemplars rather than specific knowledge of the algorithms being detected. Taking inspiration from computer vision, SVMs were trained using image wavelet statistics [55–57], and later, calibrated features computed in the DCT domain [61, 62]. Future work in this area continues to improve the features that are useful for detecting steganography and explore classification techniques.

### 4.2 Development Trends

Relatively few developers of steganography-related tools appear to incorporate advances published in related academic research. Those that do, introduce methods in an attempt to reduce the detectability of the hidden content. Thus, as research and development in the academic arena continues, the sophistication of available steganography software continues to improve. For example, many applications now incorporate cryptographic methods to encrypt data prior to embedding, or select pseudo-random locations within the digital carriers to hide their data.

Between 1992 and 2004, interest in steganography exploded at a near exponential rate. The most significant jump in software releases that claim to provide steganographic capabilities appear from 2001 to 2002. This growth may be due, in part, to the security and threat frenzy following the 9/11 attacks in 2001. Shortly after the attacks, some authors of steganography tools abandoned their wares while others were driven by curiosity, growing markets, and the desire for privacy protection in a seemingly ever pervasive world. Figure 2 illustrates the trend of steganography-related tools released each year from 1992 through 2007 [93]. Due to the increasing volume of tools being released each year and the fact that some products are released for time, it can be difficult to accurately depict the overall size of this market. As of the writing of this text, over 3000 tools are identified by the authors representing over 1500 software titles. Keeping track of steganography-related tools can be complicated when multiple authors select the same name for their application. For example, over 40 software titles from more

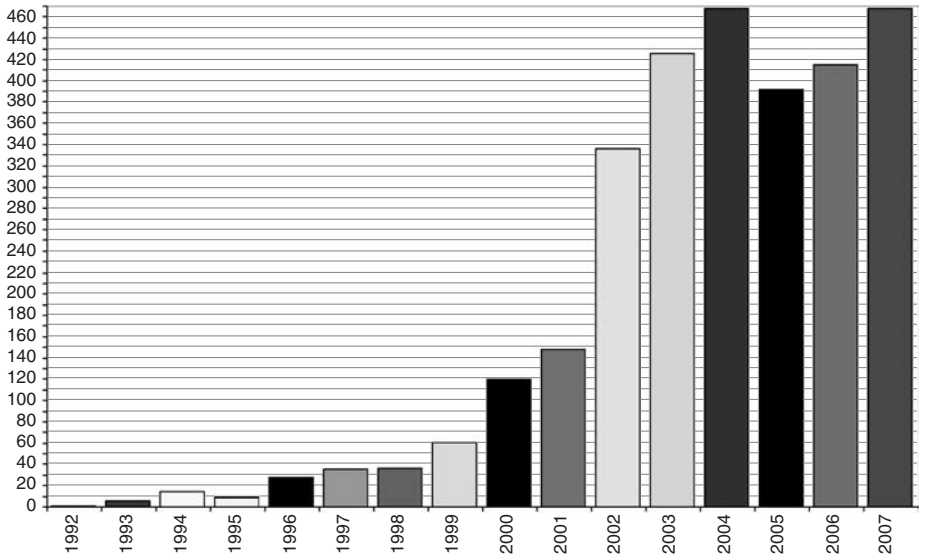

**FIGURE 2** Chart illustrates the overall observed trend of steganography software development from 1992 through 2007 [93].

than 30 authors are variants of the words "steganography" or "steganographie". Other popular steganography tool names include variants of steg, stego, stegano, camouflage, hide, invisible, and stealth.

Steganography research and application development takes place around the globe. Observing research publications and software releases, the top 10 countries with active steganography-related research are (in alpha order) Canada, China, France, Germany, India, Italy, Japan, Russia, United Kingdom, and the United States. A number of steganography applications are multinational, meaning that collaborative software development occurs between individuals from multiple countries. International academic researchers and hacker organizations typically pool talent from multiple countries.

## 5 CRITICAL NEEDS ANALYSIS

Information hiding techniques pose a threat to national security and law enforcement through the potential loss of secrets or intellectual property and as possible distribution and communication channels for coordinating illicit activities. An investigator or analyst must find ways to analyze information that cannot be readily apparent and must seek subtleties that may suggest hidden information. It is not sufficient for investigators to have tools and techniques for handling password-protected files, but must also be involved in locating and recovering data hidden within seemingly innocuous carriers [69, 70].

Traditional perimeter security mechanisms such as firewalls, intrusion detection systems, and virus scanners are ill-equipped to handle media that may contain hidden information. Some tools available to forensic investigators/analysts are useful at examining slack space on storage devices or matching hash sets for known applications. However, many common forensic tools do not specifically detect the presence of steganographic

content in potential carriers. Hash sets are available as part of the National Software Reference Library (NSRL) Project. This project collects and compiles digital signatures of software to produce a reference data set (RDS). The RDS includes signatures of applications including steganography tools and hacking scripts [94].

## 6 RESEARCH DIRECTIONS

The ease in use and abundant availability of steganography tools has authorities concerned about the trafficking of illicit material, or coordination of terrorists' plots via web page images, audio, video, and other transmissions over the Internet. Methods of message detection and understanding the thresholds of current technology are continually under investigation. The success of steganography is dependent upon selecting the proper mechanisms. However, a stego-medium that seems innocent may actually broadcast the existence of embedded information upon further investigation. As long as the need exists for covert communications, development of information hiding techniques will continue. Systems to recover seemingly destroyed information and steganalysis techniques will be useful to authorities in computer forensics, digital traffic analysis, cyber-warfare, and counterterrorism.

Steganographic implementations, through the development of open source or commercial products, are generally behind the ideas and methods published in the research community. Many tools continue to use only basic methods at attempting to hide information. However, research continues to improve and hundreds of applications are released each year. The sheer volume of emerging steganography methods and tools requires innovative and accurate approaches to steganalysis. Being able to detect unforeseen techniques requires continued research. Research efforts continue to push the technological envelope, and staying abreast of such research is increasingly important. Technical publications and conferences provide the best window to the evolution of information hiding techniques from the open source and around the world. For a list of relevant proceedings from the International Information Hiding Workshop see the Further Reading List.

# ATTACK TRACEBACK AND ATTRIBUTION

YONG GUAN AND LINFENG ZHANG
*Iowa State University, Ames, Iowa*

## 1 INTRODUCTION

With the growth of the Internet, cyber attacks happen every day and everywhere. It is very important that we trace back and attribution the real attackers. In this article, we discuss the current techniques in cyber attack traceback. We focus on the present schemes in Internet Protocol (IP) spoofing traceback and stepping stone attack attribution. Furthermore, we introduce the traceback issues in Voice over Internet Protocol (VoIP), botnet, and anonymous systems.

## 2 SCIENTIFIC OVERVIEW

With the phenomenal growth of the Internet, more and more people enjoy and depend on the convenience of its provided services. The Internet has spread rapidly to almost all over the world. Up to December 2006, the Internet has distributed to over 233 countries and world regions, and has more than 1.09 billion users [1]. Unfortunately, the wide use of computer and Internet also has opened doors to cyber attackers. There are different kinds of attacks that an end user of a computer or Internet has to face. For instance, there may be various viruses on the hard disk, there may be several backdoors opened in the operating system, and there may be a lot of phishing e-mails in his/her mailbox, and so on. According to the annual Computer Crime Report of Computer Security Institute (CSI) and the US Federal Bureau of Investigation (FBI) released in 2006 [2], cyber attacks cause a lot of money losses each year.

When we face the cyber attacks, we can detect them and take countermeasures. For instance, an intrusion detection system (IDS) can help detect the attacks; we can update operating systems to close the potential backdoors; we can install antivirus software to defend many known viruses. Although in many cases we can detect attacks and mitigate their damages, it is hard to find who the real attackers are. However, if we cannot trace back to the attackers, they can always conceal in the dark and launch their attacks. If we have the ability to find the attackers and give them desired punishment, we believe this may help reduce the attacks we face every day significantly.

Why is the traceback difficult in computer networks? One reason is that today's Internet is stateless. There are too much data in the Internet to record them. For example, a typical router only forwards the passed packets and does not care where they are from; a typical mail transfer agent (MTA) just relays e-mails to the next agent and never minds who the sender is. Another reason is that today's Internet is almost an unauthorized

environment. Alice can make a VoIP call to Bob and pretends to be Carol; an attacker can send millions of e-mails out using anybody's e-mail address and that individual's mailbox will be bombarded by millions of replies. According to the two main reasons, there are two kinds of attacks that are widely used by attackers and also of interest to researchers all over the world. One is IP spoofing and the other is stepping stone attack. Each IP packet header contains the source IP address. Using IP spoofing, an attacker can change the source IP address in the header to a different machine and thus avoid traceback. Figure 1 shows an example of distributed denial of service (DDoS) attack using IP spoofing. In stepping stone attack, the attack flow may travel through a chain of stepping stones (intermediate hosts) before it reaches the victim. Therefore, it is difficult for the victim to know where the attack comes from except that she or he can see the attack traffic from the last hop of the stepping stone chains. Figure 2 shows an example of stepping stone attack.

In the following section, we first introduce the existing schemes to trace back IP spoofing attacks and then discuss current work on stepping stone attack attribution.

## 2.1 IP Traceback

In this part, we review major existing IP traceback schemes that have been designed to trace back to the origin of IP packets through the Internet. We roughly categorize them into four primary classes:

1. Active probing [3, 4];
2. ICMP traceback [5, 6];
3. Packet marking [7–11];
4. Log-based traceback [12–15].

***2.1.1 Active Probing.*** Stone [4] proposed a traceback scheme called *CenterTrack*, which selectively reroutes packets in question directly from edge routers to some special tracking routers. The tracking routers determine the ingress edge router by observing from which tunnel the packet arrives. This approach requires the cooperation of network administrators, and the management overhead is considerably large.

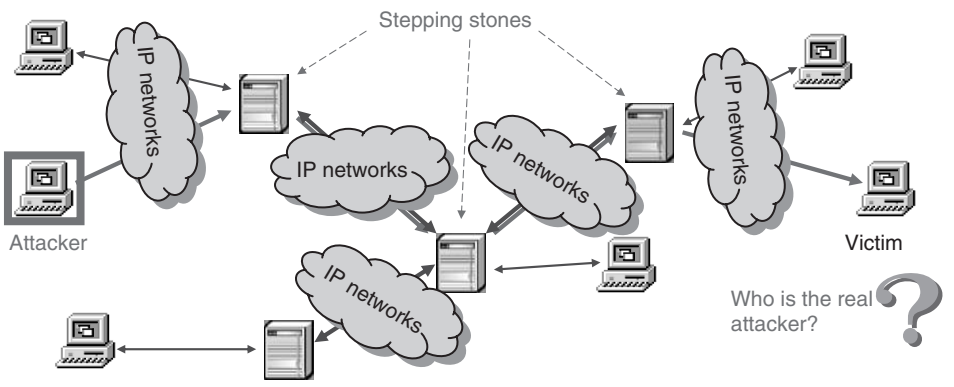

**FIGURE 1** Example of stepping stone attack.

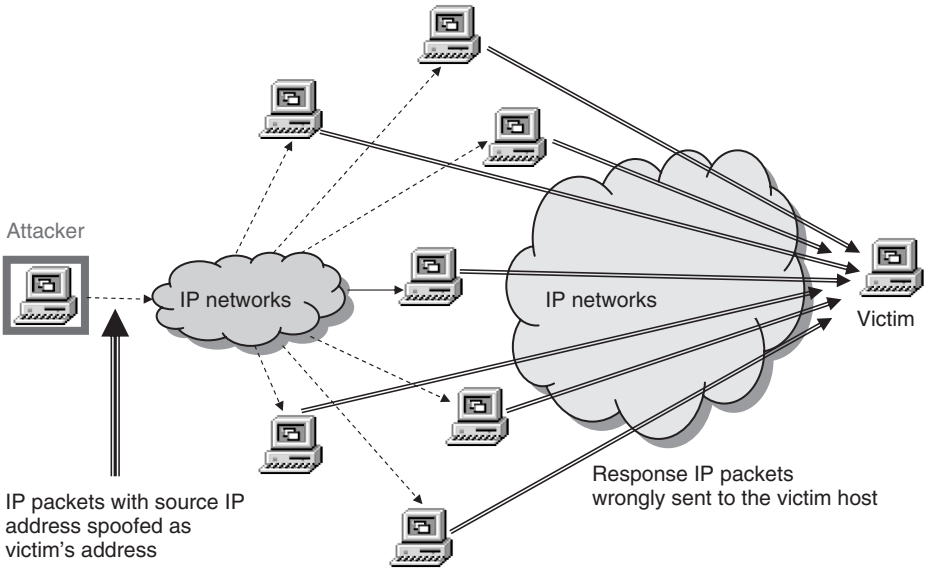

**FIGURE 2** Example of distributed denial of service (DDoS) attack using IP spoofing.

Burch and Cheswick [3] outlined a technique for tracing spoofed packets back to their actual source without relying on the cooperation of intervening internet service providers (ISPs). The victim actively changes the traffic in particular links and observes the influence on attack packets, and thus can determine where the attack comes from. This technique cannot work well on distributed attacks and requires that the attacks remain active during the time period of traceback.

***2.1.2 Internet control message protocol (ICMP) Traceback (iTrace).*** Bellovin [5] proposed a scheme named *iTrace* to traceback using ICMP messages for authenticated IP marking. In this scheme, each router samples (with low probability) the forwarding packets, copies the contents into a special ICMP traceback message, adds its own IP address as well as the IP of the previous and next hop routers, and forwards the packet either to the source or destination address. By combining the information obtained from several of these ICMP messages from different routers, the victim can then reconstruct the path back to the origin of the attacker.

A drawback of this scheme is that it is much more likely that the victim will get ICMP messages from routers nearby than those farther away. This implies that most of the network resources spent on generating and utilizing iTrace messages are wasted. An enhancement of iTrace, called *Intention-Driven iTrace*, was proposed in [6]. By introducing an extra "intention bit", it is possible for the victim to increase the probability of receiving iTrace messages from remote routers.

***2.1.3 Packet Marking.*** Savage et al. [10] proposed a *probabilistic packet marking* (PPM) scheme. Thereafter, several other PPM-based schemes have been developed [8, 9, 11]. The baseline idea of PPM is that routers probabilistically write partial path information into the packets during forwarding. If the attacks are made up of a sufficiently large number of packets, eventually, the victim may get enough information by combining a

modest number of marked packets to reconstruct the entire attack path. This allows victims to locate the approximate source of attack traffic without requiring outside assistance.

*Deterministic packet marking* (DPM) scheme proposed by Belenky and Ansari [7] involves the marking of each individual packet when it enters the network. The packet is marked by the interface closest to the source of the packet on the edge ingress router. The mark remains unchanged as long as the packet traverses the network. However, there is no way to get the whole paths of the attacks.

Dean et al. [8] proposed an *algebraic packet marking* (APM) that reframes the traceback problem as a polynomial reconstruction problem and uses techniques from algebraic coding theory to provide robust methods of transmission and reconstruction. The advantage of this scheme is that it offers more flexibility in design and more powerful techniques that can be used to filter out attacker generated noise and separate multiple paths. However, it shared similarity with PPM in that it requires a sufficiently large number of attack packets.

***2.1.4 Log-based Traceback.*** The basic idea of log-based traceback is that each router stores the information (digests, signature, or even the packet itself) of network traffic through it. Once an attack is detected, the victim queries the upstream routers by checking whether they have logged the attack packet in question or not. If the attack packet's information is found in a given router's memory, then that router is deemed to be part of the attack path. Obviously, the major challenge in log-based traceback schemes is the storage space requirement at the intermediate routers.

Matsuda et al. [13] proposed a hop-by-hop log-based IP traceback method. Its main features are logging *packet feature* that is composed of a portion of the packet for identification purpose, and an algorithm using data-link identifier to identify the routing of a packet. However, for each received packet, about 60 bytes data should be recorded. The resulted large memory space requirement prevents this method from being applied to high-speed networks with heavy traffic.

Although today's high-speed IP networks suggest that classical log-based traceback schemes would be too prohibitive because of the huge memory requirement, log-based traceback becomes attractive after Bloom filter-based (i.e. hash-based) traceback schemes were proposed. *Bloom filters* were presented by Burton H. Bloom [16] in 1970, and have been widely used in many areas, such as database and networking. A Bloom filter is a space-efficient data structure for representing a set of elements to respond membership queries. It is a vector of bits that are all initialized to value 0. Then each element is inserted into the Bloom filter by hashing it using several independent uniform hash functions and setting the corresponding bits in the vector to value 1. Given a query whether an element is present in the Bloom filter, we hash this element using the same hash functions and check if all the corresponding bits are set to 1. If any one of them is 0, then undoubtedly this element is not stored in the filter. Otherwise, we would say that it is present in the filter, although there is a certain probability that the element is determined to be in the filter whereas it is actually not. Such false cases are called *false positives*. The space efficiency of Bloom filters is achieved at the cost of a small acceptable false-positive rate. Bloom filters were first introduced into IP traceback area by Snoeren et al. [15]. They built a system named *source path isolation engine* (SPIE) that can trace the origin of a single IP packet delivered by the network in the recent past. Therefore, SPIE can trace an attack even when it finishes using a single packet. They demonstrated that the system is effective, space-efficient, and

implementable in current or next-generation routing hardware. Bloom filters are used in each SPIE-equipped router to record the digests of all packets it received in the recent past. The digest of a packet is exactly several hash values of its nonmutable IP header fields and the prefix of the payload. However, the inherent false positives of Bloom filters caused by unavoidable collisions restrain the effectiveness of these systems. To reduce the impact of unavoidable collisions in Bloom filters, Zhang and Guan [17] propose a topology-aware single packet IP traceback system, namely TOPO. The router's local topology information, that is, its immediate predecessor information is utilized. The performance analysis shows that TOPO can reduce the number and scope of unnecessary queries and decrease false attributions significantly. When Bloom filters are used, it is difficult to decide their optimal control parameters a priori. They designed a k-adaptive mechanism that can dynamically adjust parameters of Bloom filters to reduce the false-positive rate.

Shanmugasundaram et al. [14] proposed a *payload attribution system* (PAS) based on a *hierarchical Bloom filter* (HBF). HBF is such a Bloom filter that an element is inserted several times using different parts of the same element. Compared with SPIE, which is a packet digesting scheme, PAS uses only the payload excerpt of a packet. It is useful when the packet header is unavailable.

Li et al. [12] proposed a Bloom filter-based IP traceback scheme that requires an order of magnitude processing and storage cost less than that of SPIE, thereby being able to scale to much higher link speed. The baseline idea of their approach is to sample and log a small percentage of packets and 1-bit packet marking is used in their sampling scheme. Therefore, their traceback scheme combines packet marking and packet logging together. Their simulation results showed that the traceback scheme can achieve high accuracy, and scale well to a large number of attackers. However, as the authors also pointed out, because of the low sampling rate, their scheme is no longer capable to trace one attacker with only one packet.

### 2.2 Stepping Stone Attack Attribution

Ever since the problem of detecting stepping stones was first proposed by Staniford-Chen and Heberlein [18], several approaches have been proposed to detect encrypted stepping stone attacks.

The ON/OFF-based approach proposed by Zhang and Paxson [19] is the first timing-based method that can trace stepping stones even if the traffic were to be encrypted. In their approach, they calculated the correlation of different flows by using each flow's OFF periods. A flow is considered to be in an OFF period when there is no data traffic on a flow for more than a time period threshold. Their approach comes from the observation that two flows are in the same connection chain if their OFF periods coincide.

Yoda and Etoh [20] presented a deviation-based approach for detecting stepping stone connections. The deviation is defined as the difference between the average propagation delay and the minimum propagation delay of two connections. This scheme comes from the observation that the deviation for two unrelated connections is large enough to be distinguished from the deviation of connections in the same connection chain.

Wang et al. [21] proposed a correlation scheme using interpacket delay (IPD) characteristics to detect stepping stones. They defined their correlation metric over the IPDs in

a sliding window of packets of the connections to be correlated. They showed that the IPD characteristics may be preserved across many stepping stones.

Wang and Reeves [22] have presented an active watermark scheme, which is designed to be robust against certain delay perturbations. The watermark is introduced into a connection by slightly adjusting the IPDs of selected packets in the flow. If the delay perturbation is not quite large, the watermark information will remain along the connection chain. This is the only active stepping stone attribution approach.

Strayer et al. [23] presented a state-space algorithm that was derived from their work on wireless topology discovery. When a new packet is received, each node is given a weight that decreases as the elapsed time from the last packet from that node increases. Then the connections on the same connection chain will have higher weights than other connections.

However, none of these previous approaches can effectively detect stepping stones when delay and chaff perturbations exist simultaneously. Although no experimental data is available, Donoho et al. [24] have indicated that there are theoretical limits on the ability of attackers to disguise their traffic using evasions for sufficiently long connections. They assumed that the intruder has a maximum delay tolerance and used wavelets and similar multiscale methods to separate the short-term behavior of the flows (delay or chaff) from the long-term behavior of the flows (the remaining correlation). However, this method requires the intrusion connections to remain for long periods and the author never experimented to show the effectiveness against chaff perturbation. These evasions consist of local jittering of packet arrival times and the addition of superfluous packets.

Blum et al. [25] proposed and analyzed algorithms for stepping stone detection using ideas from Computational Learning Theory and the analysis of random walks. They achieved provable (polynomial) upper bounds on the number of packets needed to confidently detect and identify stepping stone flows with proven guarantees on the false positives, and provided lower bounds on the amount of chaff that an attacker would have to send to evade detection. However, their upper bounds on the number of packets required were large, whereas the lower bounds on the amount of chaff needed for attacker to evade detection were very small. They did not discuss how to detect stepping stones without enough packets or with large amounts of chaff, and did not show experimental results.

Zhang et al. [26] proposed and analyzed algorithms which represent that those attackers cannot always evade detection only by adding limited delay and independent chaff perturbations. They provided the upper bounds on the number of packets needed to confidently detect stepping stone connections from nonstepping stone connections with any given probability of false attribution.

Although there have been a lot of stepping stone attack attribution schemes, there is a lack of comprehensive experimental evaluation of these schemes. Therefore, there are no objective, comparable evaluation results on the effectiveness and limitations of these schemes. Xin et al. [27] designed and built a scalable test bed environment that can evaluate all existing stepping stone attack attribution schemes reproducibly, provide a stable platform for further research on this area, and be easily reconfigured, expanded, and operated with user-friendly interface. This test bed environment has been established in a dedicated stepping stone attack attribution research laboratory. An evaluation of proposed stepping stone techniques is currently underway.

## 3 RESEARCH AND FUNDING DATA

From early 2004, Intelligence Advanced Research Projects Activity (IARPA) (formerly, Disruptive Technology Office (DTO)/Advanced Research and Development Activity (ARDA)) supported seven groups from universities and industries on stepping stone attack attribution. Table 1 shows their topics, affiliations, and the names of principal investigators.

The group from North Carolina State University utilizes timing-based watermarking to trace back stepping stone attacks. They proposed schemes to handle repacketization of the attack flow. Wang from George Mason University proposed a "centroid-based" watermarking scheme to detect attack flows with chaff. The group from Iowa State University proposed the first effective detection scheme to detect attack flows with both delay and chaff perturbations. A scheme named *datatick* is proposed, which can handle significant packet merging/splitting and can attribute multiple application layer protocols (e.g. X-windows over secure shell (SSH), Windows Remote Desktop, virtual network computing (VNC), and SSH). A scalable test bed environment is also established, which can evaluate all existing stepping stone attack attribution schemes reproducibly.

The group from Johns Hopkins University demonstrates the feasibility of a "post-mortem" technique for traceback through indirect attacks. The evidence in memory and other sources is collected and characterized to attribute the attacks. The group from Telcordia Technologies proposed a scheme that reroutes the attack traffic from noncooperative networks to cooperative networks, such that the attacks can be attributed. The BBN's group integrates single packet traceback and stepping stone correlation together. A distributed traceback system called *FlyTrap* is developed for uncooperative and hostile networks. A group from Sparta integrates multiple complementary traceback approaches and tests them in Tor anonymous system.

National Science Foundation supports a research project named "Tracing VoIP Calls through the Internet" led by Xinyuan Wang from George Mason University. The objective of this project is to investigate how VoIP calls can be effectively identified and traced

**TABLE 1 DTO/ARDA-Funded Projects on Stepping Stone Attack Attribution**

| Research Topic | Affiliation | Principal Investigator |
|---|---|---|
| Tracing attacks through noncooperative networks and stepping stones with timing-based watermarking | North Carolina State University | Douglas Reeves |
| Advanced watermark tracing through stepping stones and uncooperative networks | George Mason University | Frank Wang |
| Stepping stone attack attribution in noncooperative IP networks | Iowa State University | Yong Guan |
| Johns Hopkins applied physics laboratory presentation | Johns Hopkins University | S. Lee |
| RapidTrace: rapid traceback of cyber attacks | Telcordia | Rajesh Talpade |
| FlyTrap: a practical traceback system for sparse and uncooperative deployment | BBN | Timothy Strayer |
| Tracing attacks through noncooperating networks | Sparta | Richard Edell |

in the Internet and to develop efficient tracing methods with sound scientific foundation. Wang et al. introduced their watermarking technology in stepping stone attack attribution into VoIP attribution and showed VoIP calls still can be attributed [28].

Strayer et al. have been supported by US Army Research Office in their research on how to attribute the attackers using botnets. Their approach for detecting botnets is to examine flow characteristics such as bandwidth, duration, and packet timing looking for evidence of botnet command and control activity [29].

## 4 CRITICAL NEEDS ANALYSIS

Although large scale cyber terrorism seldom happens, some cyber attacks have already showed their power in damaging homeland security. For instance, on October 21, 2002, all the 13 Domain Name System's (DNS) root name servers sustained a Denial of Service attack [30]. Some root name servers were unreachable from many parts of the global Internet due to congestion from the attack traffic. Till now, we do not know who the real attacker is and what his/her intention is.

Besides the Internet itself, many sensitive institutions, such as the US power grid, nuclear power plants, and airports, may also be attacked by terrorists if they are connected to the Internet, although they have been carefully protected physically. If the terrorists want to launch large scale attacks targeting these sensitive institutions through the Internet successfully, probably they have to try several times. If we only sit there and do not fight back, they finally can find our vulnerabilities and achieve their evil purpose. However, if we have the ability that attributes to the source of the attacks, we can detect and arrest them before they succeed.

Although there have been a lot of traceback and attribution schemes on IP spoofing and stepping stone attacks, there still have a lot of open issues in this area. The biggest issue is the deployment of these schemes. Many schemes (e.g. packet marking, log-based traceback) need the change of IP on each intermediate router. Many schemes need a lot of network monitors placed all over the world. These are very difficult to be implemented in current Internet without the supports from government, manufactures, and academics. It is necessary to consider traceback demands when designing and deploying next-generation networks.

## 5 RESEARCH DIRECTIONS

There are still some open problems in attack traceback and attribution.

### 5.1 Vo-IP Attribution

Like the Internet, the VoIP also provides unauthorized services. Therefore, some security issues existing in the Internet may also appear in the VoIP systems. For instance, a phone user may receive a call with a qualified caller ID from his/her credit card company, so he/she would answer the critical questions about social security number and date of birth, and so on. However, this call comes actually from an attacker who fakes the caller ID using a computer. Compared with a public switched telephone network (PSTN) phone or mobile phone, IP phone lacks monitoring. Therefore, it is desirable to provide schemes that can attribute or trace back to the VoIP callers.

### 5.2 Botnet Traceback

A botnet is a network of compromised computers, or bots, commandeered by an adversarial botmaster. Botnets usually spread with virus and communicate through the internet relay chat (IRC) channel. With the army of bots, the bot controllers can launch many attacks, such as spam, phishing, key logging, and denial of service. Now, more and more scientists are interested in how to detect, mitigate, and trace back botnet attacks.

### 5.3 Traceback in Anonymous Systems

Another issue is that a lot of anonymous systems, such as Tor, exist all over the world [31]. Tor is a toolset for anonymizing web browsing and publishing, instant messaging, IRC, SSH, and other applications that use the transmission control protocol (TCP) protocol. It provides anonymity and privacy for legal users, and at the same time, it is a good platform to launch stepping stone attacks. Communications over Tor are relayed through several distributed servers called *onion routers*. There are more than 800 onion routers all over the world so far. Since Tor may be seemed as a special stepping stone attack platform, it is interesting to consider how to trace back attacks over Tor.

# CYBER FORENSICS

MARCUS K. ROGERS
*Purdue University, West Lafayette, Indiana*

## 1 INTRODUCTION

The field of forensics or criminalistics in general has received a great deal of attention over the last few years. The popular media's obsession with anything forensic related has also resulted in increased attention by the scientific and information technology communities. The judiciary has also increased its scrutiny of the field, as judges and lawyers are struggling with the concept of digital or electronic evidence. The very nature of evidence has evolved from being primarily document based to being digital or electronic based. It has been estimated that in the next few years, 80% of all criminal investigations will contain digital evidence (DE). This prediction seems realistic as electronic documents have replaced paper documents in most business environments.

The media attention has also prompted many private sector consulting companies and academia to focus on this area of criminalistics. The introduction of these two communities to the field has resulted in some interesting challenges and uncovered various issues within the field. However, the private sector and academia have also been important factors in the rapid evolution that cyber forensics is currently undergoing.

The current article is divided into three main sections: scientific overview, critical needs analysis, and research directions. More explicitly, the article looks at the development of this new forensic discipline, with specific attention on its historical development, and current state. The discussion will examine the context of digital forensic science (DFS) and cyber forensics/DE, emerging standards and process model(s), current and near term issues and challenges, and finally future directions for the field.

Limitations on the size of the article precludes an in-depth discussion of many of the subtopics, but those interested with specific topics are directed to the further readings section. It is important that it is understood that the deliverablility of this article is to provide a high-level overview of the field.

## 2 SCIENTIFIC OVERVIEW

DFS is the umbrella category to which cyber forensics or DE investigation belongs [1–5]. DFS encompasses what has historically been considered computer forensics (media analysis) as well as multimedia such as audio, video, and imaging technology (IT) [1, 4, 6, 7]. DFS has been defined as follows:

> The use of scientifically derived and proven methods toward the preservation, collection, validation, identification, analysis, interpretation, documentation and presentation of DE derived from digital sources for the purpose of facilitating or furthering the reconstruction

> of events found to be criminal, or helping to anticipate unauthorized actions shown to be disruptive to planned operations [8].

DFS is a forensic science and as such the underlying foundation is no different than other forensic or criminalistics fields. As a forensic science, the admissibility of evidence and the presentation of findings or results in a court of law (e.g. civil, criminal, regulatory, and administrative) is its primary consideration.

In the United States, the American Academy of Forensic Science (AAFS) oversees all forensic sciences, and this governing body is what the courts look to in order to determine the status of a forensic science field. In order to be officially recognized by the AAFS, DFS has been further subdivided into the following [1]:

- digital evidence (DE)
- imaging technology (IT)

The rationale for the subdivision is based on the notion that DE and IT require different and distinct skills sets, knowledge, and abilities. The subdivision has led to the creation of two bodies in the United States to deal with the maturation and acceptance of these new fields of study as follows. The Scientific Working Group on Digital Evidence (SWGDE) and the Scientific Working Group on Imaging Technology (SWGIT). As the name connotes, the SWGDE has the responsibility for DE that encompasses computer forensics (also known as *media analysis*), network/distributed forensics, and code analysis.

The focus of this article is on the DE side of DFS and will not include any discussion related to IT. However, it should be noted that IT and DE are converging and it is expected that in the not too distant future the separation of these two areas/domains will be artificial, as DE will cover both the domains.

### 2.1 Current State

Cyber forensics is defined as follows:

> The scientific examination of electronic data in such a way that the information can be used as evidence in a court of law [9].

This definition is based on the traditional use of the term *forensics*. In the realm of cyber security, cyber forensics is often mistakenly confused of being synonymous with incident response and general investigations such as root cause analysis. Strictly speaking, while incident response, root cause analysis, and cyber forensics are investigative in nature, incident response and root cause analysis have a lower standard of proof. Many organizations will use the cyber forensics process model to aid in general investigations where legal action is not initially anticipated (either civil or criminal). These organizations understand that by using the highest standard of proof as a threshold, this ensures that, if at a later date legal action is desired, there will be fewer issues (e.g. inadmissibility of evidence).

Cyber forensics includes the same processes as DFS and treats a system, network, or storage device as a witness, storage container, or victim/corpse. Cyber forensics is the

marriage of science, technology, and engineering (STEM disciplines) with law and the legal justice system [10–12].

At its most basic level cyber forensics focuses on the three As of acquire, authenticate and analyze DE [13]. *Acquire* refers to acquiring evidence in a manner that does not alter the scene or the potential evidence (or at the very least minimizes the contamination). Authenticate means to prove that the evidence has fidelity and integrity (in the case of a forensic image), and is a true representation of the state and nature of the DE. The most common method of authentication is by using a hashing algorithm (e.g. MD5, SHA 256)—discussed later. *Analyze* refers to examining and interpreting the data/evidence and then drafting a report (either oral or written).

In conjunction with the three As is the concept of chain of custody of evidence. It is vital that the entire life cycle of the DE be documented and accounted for. Chain of custody of evidence is tantamount to the who, what, when, where, how, and why of the evidence, from its initial identification to its ultimate disposition (e.g. destruction or return). If any part of the "chain" is broken or brought into question, the admissibility and/or weight of the evidence becomes questionable and/or significantly diminished [3, 14–16].

According the Digital Forensic Research Workshop (DFRWS) [5, 17, 18], there are at least three different communities that have a vested interest in cyber forensics. These communities consist of Law Enforcement, Military, and Private Sector. Cyber forensics was historically the domain of law enforcement (including military law enforcement). In fact, the term computer forensics came from the law enforcement community in the earlier 1980s.

As society has become more dependent on technology and the Internet, DE and electronic trails have become more commonplace. This has led to the military being interested in cyber forensics for purposes of national security and information warfare. The military soon realized that the same process models and tools used for traditional law enforcement DE investigations could be used for intelligence gathering.

The private sector's interest in cyber forensics stems from the ubiquity of technology in the workplace and/or the fact that electronically stored information (ESI) plays a vital role in various civil litigations (e.g. Intellectual Property (IP) law suits, wrongful terminations, and regulatory investigations). The private sector has also discovered that offering consulting services in the area of DE investigations is lucrative. The reasons for this service line are varied and include the belief that despite law enforcement having the longest history with DE, they are ill prepared and/or trained to conduct complicated investigations. There is also the very real desire to protect organizations from unwanted publicity that can occur if law enforcement is officially involved.

Recently, a fourth community has been added to the model. Educational institutions are starting to play a vital role in education and training, curriculum development, and both applied and basic research in this area. With the public popularity of forensics, academia sees the potential for increased enrollment and funding opportunities. Academy also plays a vital role in basic and applied research in this field—which is discussed in a subsequent section.

Unfortunately, the goals of the four communities are not necessarily congruent. Law enforcement is concerned with the investigation and prosecution of criminals and the military is concerned with protecting national security, gathering intelligence, and attacking the enemy's technology, while protecting its own. The private sector is concerned with

profit, protecting its investors, getting its infrastructure back up and running in the event of an attack or breach. Academia is concerned with education, training, and research. These sometimes mutually exclusive goals have led to conflicts and a lack of uniformity within the scientific discipline.

Cyber forensics is a relatively immature field. The more traditional forensic sciences such as questioned document analysis and latent fingerprint analysis have been around for several hundreds of years. As was stated earlier, cyber forensics can trace its beginnings to the 1980s in North America and to about the same time period in the United Kingdom.

Historically, vendors have dominated the area of cyber forensics. As previously stated, the field originated with law enforcement. Few, if any, law enforcement officers dealing with DE had basic or advanced degrees in computer science or engineering. This resulted in a dependency on vendors to develop tools to allow law enforcement to conduct their investigations [4, 5]. There was little, if any, oversight on the vendors and the investigators were completely dependent on the vendors to ensure that the tools worked correctly. Although this may have been sufficient in the past, this dependency has become very problematic (Section 3). It is now the job/mandate of academia to develop the theoretical framework for tool development and the investigators to articulate the functional requirements of the tools; all the while keeping in mind the fundamental rule of forensics—admissibility of the derived evidence.

At the time of writing, there was no definitive process model for conducting the actual acquisition, authentication, and analysis [5–7, 17, 19, 20]. Several academic papers have been written and organizations, such as SWGDE, National Institute of Justice (NIJ), US Secret Service (USSS), International Association of Computer Investigative Specialists (IACIS), the High Technology Crime Investigators Association (HTCIA), Royal Canadian Mounted Police (RCMP), Canada, and Association of Chief Police Officers (ACPO) United Kingdom, have released white papers, technical reports, and guidelines. However, there are varying degrees of consensus among these groups as to what is the best approach from an investigative, admissibility of evidence, and scientific perspective. The ever-changing nature of technology also makes it extremely difficult to adapt any sort of static approach for gathering DE.

The closest approach to a consensus can be found in the work of the International Organization on Computer Evidence (IOCE) and SWGDE, whom have released a set of six high-level principles for dealing with DE [1]:

1. When dealing with DE, all of the general forensic and procedural principles must be applied.
2. Upon seizing DE, actions taken should not change that evidence.
3. When it is necessary for a person to access original DE, that person should be trained for the purpose.
4. All activity relating to the seizure, access, storage, or transfer of DE must be fully documented, preserved, and available for review.
5. An individual is responsible for all actions taken with respect to DE while the DE is in their possession.
6. Any agency, which is responsible for seizing, accessing, storing, or transferring DE is responsible for compliance with these principles.

Principle 2 is considered one of the most basic axioms, and yet even this is coming under increasing scrutiny and debate given the fact that cyber forensics is moving away from dealing primarily with static systems (turned off) or storage devices, to live systems that are very dynamic. Although it is relatively easy to adhere to the second principle with systems that are static, it is impossible not to change the state and nature of the scene and possible evidence, when gathering evidence from a system that is turned on and running processes.

With a static system, an investigator can use a hardware write blocker to protect the suspect storage device from being written to or changed, while acquiring an image or collecting pieces of evidence. The hardware write blocker is a physical bridge device that sits between the investigators system and the suspect storage device and physically blocks any commands to the suspect device that could modify or change the device. It essentially turns the suspect device into a physical read only device (much like the old write protect tabs on floppy disks). The hardware write blocker is quickly replacing software write blockers that operated at the BIOS and Interrupt level (INT13 or Extended INT13). With modern drives and operating systems, the BIOS is often no longer responsible for managing input output (IO) requests, thus the software write blockers are often bypassed and prone to failure resulting in changes to the suspect device, and possible contamination and/or destruction of evidence (both inculpatory and exculpatory).

Live system and memory analysis present unique problems. With a system turned off, any potential evidence that may have been in the volatile memory is lost, although, depending upon the operating system and the user defined settings, the swapfile or virtual memory (pagefile) is accessible and may contain remnants of important data. With live systems, the memory is intact, any network shares are still mounted, and cache information is available. The conundrum arises from the fact that in order to collect and interpret the data in a meaningful (human readable) way, an application has to be run on the system. This causes a change in the memory as a running application or tool uses the memory, and thus changes the state and nature of the very thing it is trying to collect. Despite this issue, the limitations of the tools, lack of protected memory space, and virtualization of storage devices, makes the examination, collection, and analysis of live systems and memory an investigative reality.

## 2.2 Cyber Forensics Process Model

The exact process of conducting a cyber forensics investigation is dependent upon various factors such as the context of the investigation, the technology in question, type of storage device and file system, technical knowledge of the suspect, and legal considerations. For the sake of simplicity, only a generic process model is discussed.

Once the cyber forensic process has been initiated, the first phase deals with the proper identification of the physical and digital crime scene, and potential evidence or likely containers of potential evidence (e.g. workstations, external peripherals, network storage, and log files).

Once the proper identification has been completed, the evidence must be collected in a manner that minimizes the alteration to both the physical and digital crime scene. This may include photographing the physical scene, obtaining forensic images of the systems,

storage devices, and so on. (A forensic image is a bit stream image that captures all data from the entire physical storage; from sector 0 to the last sector.)

Once the evidence has been collected, it needs to be preserved and its integrity needs to be maintained. This is often accomplished by using protected media (i.e. write once) or read only file image formats (e.g. EnCase E0). A digital hash functional (e.g. MD5 and SHA1) is then calculated from the original and the image copy and compared. If the totals match, it is assumed that the image copy is an exact copy of the original. This calculated and stored hash total can be used to further prove that nothing was changed on the image at a later date.

The collected evidence is then examined and analyzed to determine what has happened (sometimes referred to as *root cause analysis* in incident response situations) and answer the appropriate investigative questions. In most cases, the original evidence is never examined; the investigator works from a copy (investigative copy) of the forensic image (library copy). This further ensures the integrity of the original evidence. Various tools are used to abstract the evidence and assist in the interpretation of what is discovered.

The final phase consists of creating a report that summarizes the process that was followed, the evidence identified and collected, and the investigative findings. This report may include both factual and speculative findings. The report should be written for a nontechnical audience and be free from acronyms and jargon. A glossary is often used to assist readers with technical terms.

## 3 CRITICAL NEEDS AND ISSUES

As a relatively new discipline, cyber forensics has its fair share of issues, hurdles, and critical needs. Some of these are generic and common to all forensic sciences (e.g. changing case law and rules pertaining to admissibility of evidence, scientific expert witness testimony considerations). However, others are unique to cyber forensics and are artifacts of the dynamic nature of technology and scientific advances. For simplicity sake, the issues can be broken down into the following categories: education and training, technology and tools, research and scholarship, policies and processes, and at the center, legal requirements (Figure 1).

### 3.1 Education and Training

The demand for properly educated and trained investigators and scientists has outpaced the supply. Formal education and training in cyber forensics has only come about in the last few years. The tremendous demand for all levels of individuals to deal with DE has resulted in an increased interest by the various education institutions ranging from vocational schools and private colleges (offering associate degrees) to tier 1 doctoral granting universities. Programs of study can be found in criminal justice departments, management, computer science, engineering, and technology departments, as well as in law schools, and law and society departments. This academic plurality has some very serious unanticipated consequences for the discipline. One serious consequence is the lack of standards for curricula development. This has resulted in a situation in which the

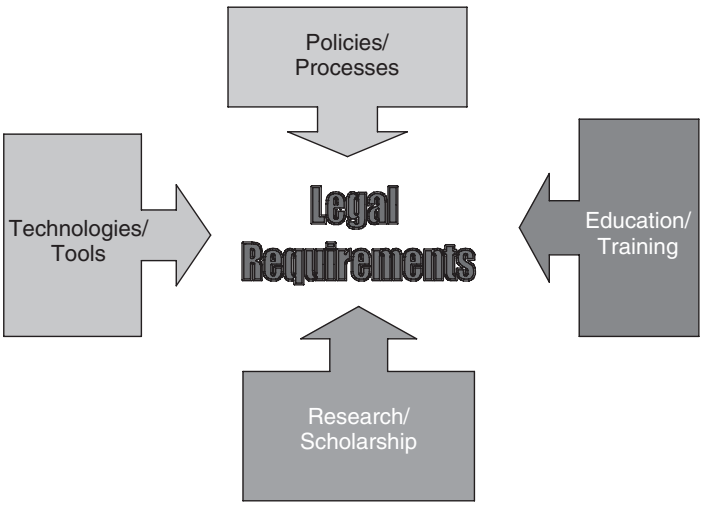

**FIGURE 1** Cyber Forensic Issues.

judiciary is confused as to who has the proper credentials and who is properly qualified in the scientific discipline. The severity of this problem has prompted the AAFSs in conjunction with the Forensic Science Education Program Accreditation Commission (FEPAC) and the NIJ to begin development of a national strategy for accrediting cyber forensic academic programs. The accreditation will be similar to accreditation program that was developed for the traditional forensic sciences (e.g. biology, physics, and chemistry).

While accreditation may address the educational issues, the training issue has still not been addressed. There is no one "gold" standard for practitioners of cyber forensics. At the time of writing, there were approximately eight different professional certifications in cyber forensics, and at least 12 bodies claiming to be the "legitimate" certification and accreditation body. The certifications range from vendor/tool specific to law enforcement only. Some of these bodies grant the credentials based on extensive hands on testing, while others are based solely on the individual's resume and history of cases investigated.

This lack of standards in training is unacceptable and negatively impacts the maturation of the discipline. In an attempt to address this, a national certification body for cyber forensics is being formed. This body will oversee the testing and proficiency requirements and accreditation of training programs. It will not offer any training itself in order to maintain a neutral posture. This model is consistent with the Boards developed by the other forensic sciences, and thus it will allow an individual to effectively be Board Certified in cyber forensics (it is anticipated that the certification will be in a specific specialty such as digital crime scene analysis and small-scale devices).

The emerging requirement in the United States that crime laboratories be accredited by the American Society of Crime Lab Directors/Laboratory Accreditation Board (ASCLD/LAB) in all areas of criminalistics, including DE (ca. 2003), has increased the pressure for educational and training standards. The ASCLD/LAB has specific educational, training, and proficiency requirements for individuals handling DE. These

requirements should form the basis for the development of standards for certification and possibly the development of a recognized common body of knowledge (CBK) or corpus of knowledge for cyber forensics. It should be noted that ASCLD/LAB is being harmonized with the ISO/IEC 17025 General Requirements for the competence of calibration and testing laboratories. This mapping to an ISO will assist in the internationalization of standards.

### 3.2 Technology and Tools

The field of cyber forensics is inextricably tied to technology. Given the fact that technological advances are continuing at an unheralded pace, keeping up with the changes is a major issue for the field [3, 21]. Even the most basic process of identification has been complicated by changes in technology. Currently, digital storage devices come in a plethora of sizes (both in terms of storage capacity and footprint). Storage media ranges from devices the size of dimes to thumb drives, watches, digital media devices, personal digital assistants (PDAs), cell phones, digital video recorders (DVRs), gaming systems, smart refrigerators, and black boxes in automobiles. The unconventional nature of these devices makes the chances of DE being overlooked much higher. These devices have also pushed the very method of storage from magnetic based (e.g. hard drives) to solid state and flash memory. The move from magnetic to solid-state storage also has a large impact on the notion of data permanence and data wiping (solid-state memory has the capacity for true one-button data destruction and/or wiping).

The continual upgrading of operating systems and file systems such as Microsoft Vista and Apple Leopard negatively affects the ability of the current tools to create forensics images, interpret the file system structure, and locate potential evidence. A case in point is Apple's HFS+ file system. Most current cyber forensics tools have problems creating accurate forensic images of HFS+ drives, and cannot interpret the structure in a manner that allows the investigator to visually examine the system. The current process requires the investigator to perform a string or keyword search on the raw data structure; a very time-consuming process.

Other issues include the data carving of multimedia files, dealing with large volumes of data (e.g. plus 1 TB storage, network area storage—NAS), multifile system devices (e.g. Intel Core 2 Duo using Windows NTFS and Apple HFS+), proprietary file systems on unique devices (e.g. cell phones), and virtualization (e.g. virtual computer images, fiber channel drives, cluster computing, and grids). This is obviously not an exhaustive list, but it illustrates the problems of keeping up with such a dynamic entity as technology. The more traditional forensics sciences are somewhat resistant to this problem as the elements they are concerned with are static (e.g. fingerprints, blood, and DNA).

### 3.3 Research and Scholarship

As was stated earlier, it is only recently that there has been formal and widely published research in the area of cyber forensics. If one examines the history and development of the other forensic sciences, it can be seen that their origin was derived from basic scientific research and development efforts. These fields tested the theories, which resulted in a body of research and the discovery that the methods, tests, results, and findings could be

extended to a forensic capacity; the science drove the forensics. This has not been the case with cyber forensics. The dearth of empirically sound research makes it difficult to defend the development of tools and techniques. Most tools currently in use and introduced before the courts are little better than black boxes whose internal structure, error rate, and true functionality are either unknown or if known by the vendor, not released to the community. (In some documented cases, the claims by the vendors were found to be incorrect and/or misleading.) Such glaring areas of uncertainty are unacceptable; especially when people's freedom if not their very lives may be hanging in the balance. The field of cyber forensics needs to reach out to the various scientific disciplines that comprise the field and formally develop a common body of scientific knowledge and basic theory. This corpus must then drive future development, testing and evaluation of hypotheses, processes, and tools.

A corollary to the late arrival of research is the problem of defining the scientific community for cyber forensics. As it currently stands, cyber forensics is an amalgam of various disciplines and is truly eclectic, with no one really owning the field. Adding to the problems is the reality that there are currently only a handful of what can be considered peer reviewed and refereed journals and conferences. In order for the discipline to mature scientifically, oversight by the scientific community is crucial.

As with anything related to research and scholarship, funding is very important. The newness of cyber forensics, coupled with its multidisciplinary nature has resulted in inadequate funding and confusion over which funding entity should have jurisdiction over the area. Is this a computer science problem, a legal justice problem, or a social science problem? It is anticipated that the government funding agencies will recognize that the answer to the preceding question is yes, it is all of these and thus funding needs to come from various sources. It is only through increased funding levels that research, development, and scholarship will continue.

### 3.4 Policies and Process

Tied to the issues of the lack of a unified CBK and changing technology is a lack of consensus on standard processes and procedures to follow. The field as a whole has shied away from checklists or even well-defined process models [5, 6, 17]. Although several models have recently been defined, none have become the "gold standard". In a field that is so dynamic, the development of anything more than principles and/or axioms may not be feasible. This has been readily apparent with the shift from dealing with static systems and devices to live analysis and acquisitions requiring the need for volatile memory examination while minimizing the degree of contamination [22].

Most organizations have yet to appreciate the importance of DE despite its ubiquitous nature in today's business environment. Notwithstanding some movement in recent years toward having standard policies related to information assurance and security, policies focusing on the capacity to conduct DE investigations are rarely found. It is speculated that the recent changes to the US Federal Rules of Civil Procedure specifically targeting ESI and discovery will prompt businesses and organization to be more proactive with their policies. [It is also anticipated that (ESI) discovery will result in systems that have a built-in forensics capability that will be embedded at the operating system or kernel level.]

### 3.5 Legal Requirements

Like other forensic sciences, cyber forensics must satisfy the courts that the procedures, processes, tools, and protocols are sufficient to allow for the admissibility of derived evidence [23].

A further legal hurdle in the United States is the ability of expert witnesses in area of cyber forensics to satisfy the federal and state admissibility requirements for novel scientific evidence. The current Federal Rules of Evidence (FRE) Section 702—*Daubert* considerations require that the tools, techniques, or procedures have been tested are generally accepted by the scientific community, have undergone peer review, and have a known or knowable error rate [24]. Although these four considerations are intended to assist judges (acting as gate keepers) in filtering out testimony based on pseudo or junk science, the field of cyber forensics as it currently stands is unable to satisfy any of the four criteria.

### 3.6 Critical Needs Analysis

Although cyber forensics tends to be discussed solely in the realm of criminal or civil investigations, it also plays a role in counterterrorism, critical infrastructure protection, and information warfare [18, 25]. Terrorist organizations, hostile foreign governments, and organized crime have all embraced technology as a tool to conduct business. Most industrialized countries depend on technology and the Internet for the smooth operation of their critical infrastructures (e.g. telecommunications, healthcare, banking and finance, power—hydroelectric and oil/gas, transportation). The ability to effectively and efficiently investigate and conduct a root cause analysis is paramount not only for law enforcement, but also for counterterrorism efforts. Several countries including the United States have included cyber terrorism and organized attacks against technology in discussions with weapons of mass destruction such as chemical, biological, and nuclear [26, 27]. Others consider attacks of this nature to be more along the lines of weapons of mass disruption and emphasize both direct and indirect impacts (e.g. disruption of first responder communications).

The view that technology will be used simply as a target or victim for terrorists is myopic at best. The terrorists (both foreign and domestic) and organized crime groups rely on technology such as computers and the Internet in order to communicate, gather intelligence, recruit followers, raise money, conduct marketing and propaganda, and conduct day-to-day business operations. The assumed anonymity fits perfectly into the shadow world of both terrorism and organized crime, and can make it difficult for counterterrorism efforts. In some cases, the lines between terrorists (both single cell and traditional organizations) and criminals have become very blurred. Organized crime groups operating in countries that formerly comprised the USSR are a hybrid of highly trained military and intelligence people, criminals, and arguably terrorists. It is artificial and naive to talk in terms of distinct and mutually exclusive categories when it comes to domestic and international deviant/criminal use of technology.

The best counterterrorism weapons include the gathering of timely intelligence and the transformation into meaningful information. The tools, processes, and technologies used for traditional digital investigations come into play here as well. Real-time data taps, the ability to pinpoint trends in large volumes of data, detecting and defeating crypto and steganography, data recovery, and source identification are all prime examples of the

synergy between computer forensics and counterterrorism/intelligence gathering. Open source and commercial developers are now starting to undertake development efforts that will extend the capabilities of their tools from traditional criminal or civil investigations to intelligence gathering, counterespionage, and counterterrorism.

## 4 RESEARCH DIRECTIONS

As was alluded to throughout the various sections, there are many areas that require further research in order to deal with both the current and near term issues and challenges. These are not necessarily relevant to digital investigations alone; solutions to these challenges will also assist in homeland security and counterterrorism efforts.

One of the biggest challenges is the ability to deal with large volumes of data. In the next few years, the storage capacity on servers and workstations is expected to surpass the multiterabyte range and potentially be in the petabyte range. Solutions to the issue of volume will likely be based on the commercial data mining approaches, but this will require more efficient algorithms, multiprocessing, and true multithreading. The use of cluster computing may also factor into the solution.

Closely related to the problem of the volume of data to search is the ability to search or carve data from the physical storage device, independent of the file system itself. Data carving for images (e.g. GIF, ART, JPEG, and BMP) is a common approach for most investigators today, but the current tools are inefficient, have issues with false positive rates, and cannot be extended to other multimedia formats such as MP4, MPEG, and Quicktime. Newer tools need to be developed that can identify files using more sophisticated file signature algorithms (e.g. fuzzy logic based and neural networks) and be more efficient and effective at carving multiple classes of file types, including multimedia.

As operating system developers/vendors are looking at implementing encrypted file systems, defeating encryption (crypt analysis) will be a real challenge. There is not much sense making a forensic image of a storage device, if the original is encrypted at the file system level. Solutions to this problem may need to leverage cluster computing to run brute force attacks against the encryption keys. Other solutions may look for backdoors, trapdoors, or flaws in the implementation of the encryption. (This is the current approach to defeating encrypted file systems.) These newer encrypted devices may also necessitate better methods for conducting live system analysis where the data is live and in clear text (i.e. nonencrypted).

The ability to forensically image and conduct a forensically sound analysis and examination of a live system and live memory is becoming more important today and will be even more critical in the future. This increase in importance is due to the phenomena of virtualizing storage and operating systems themselves. Virtual storage devices and the data they contain can be lost once a system is shutdown (e.g. fiber channel drives, and SAN). The size of random access memory (RAM) capacity on systems is exceeding 16 GB. The old method of pulling the power cord form the wall to turn a system off is now counterproductive as entire operating systems can be run in volatile memory. (To say, nothing of the paged data that is lost when the power is terminated.) Once shared RAM becomes more common, powering a suspect system off will be the exception as opposed to the norm.

Although these are a subset of the challenges facing the field, progress in any of these alone will greatly benefit investigative and homeland security efforts. The dynamic nature of technology will continue to be problematic for cyber forensics, but as long as the field is vigilant in its efforts at keeping an eye on the advances that are on the horizon, the problem is not insurmountable.

## 5 SUMMARY

The field of cyber forensics has become an important part of the general area of information assurance and security. Although cyber forensics is primarily focused on the identification, collection, analysis, and examination of DE, its tools can be extended to assist in counterterrorism and homeland security initiatives.

As our society becomes more and more dependent on technology, the ability to quickly and accurately deal with DE will become increasingly important. Despite the issues and challenges faced by this developing scientific area, cyber forensics is a crucial investigative tool in the fight against crime and terrorism.

# CYBER SECURITY POLICY SPECIFICATION AND MANAGEMENT

SUSAN K. HINRICHS
*University of Illinois at Urbana-Champaign and Network Geographics, Inc., Champaign, Illinois*

## 1 INTRODUCTION

According to the Oxford English Dictionary, policy is defined as "a course or principle of action adopted or proposed by an organization or individual". The policy defines how things should be, but it does not get into the details of how that principle of action should be enforced. Consider an organizational policy that states that employees may not use e-mail for personal correspondence. The policy defines a general goal that will not change frequently, but how that goal gets enforced may change over time. Perhaps initially it is enforced by procedure. The employees are informed that they are not to use e-mail for personal use, and the system administrator periodically spot checks the e-mail queues for personal mail. The system administrator may later deploy a tool to automate the detection of personal mail. By separating policy from enforcing mechanism, the longer term goals and constraints driving the organization are clear. The enforcing mechanisms are then free to evolve over time to best enforce the policy goals. Most organizations today use these high level natural language policies to drive all aspects of their operation from human resources to financial practices to security. If the natural language security policy could be formalized, a computer program could use the policy to directly provision a security architecture and guide or validate its operation. This chapter discusses policy in greater detail and examines how formal policies have been used in several technology domains.

## 2 WHAT IS POLICY?

The term policy has been used in quite a few diverse projects and products over the years, making the term itself somewhat ambiguous. It is applied to both high level natural language policies and very low level statements that could also be seen as device configuration. In reality, policy is a continuum from the broad natural language guiding principles to the device-specific configurations. Morris Sloman's policy group at the Imperial College London has formalized the policy refinement hierarchy [1]. See Figure 1 for an example refinement hierarchy. The policy statements at the top of the hierarchy are very broad and too ill defined to be formally analyzed, but perhaps these policies are intuitively understandable to the executive responsible for setting the organization's policy. At each level of the refinement hierarchy, one formalizes some aspect of the policy, potentially creating multiple versions from the previous level, for example refining the policy for one site versus another or refining the policy for one technology (networking)

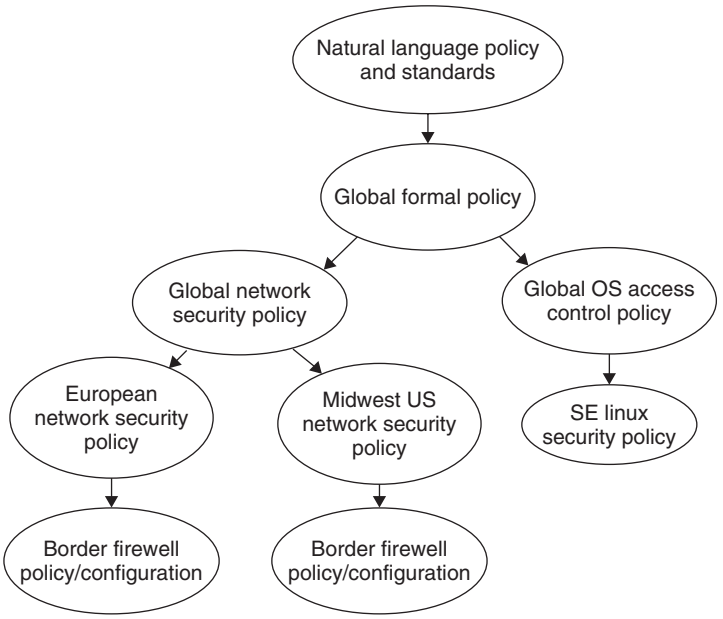

**FIGURE 1** Example of a policy refinement hierarchy. In this case the high level organizational policy is refined by technology area and then site.

versus another (operating system). At the lowest level of the refinement hierarchy is a policy that could be used to directly control enforcing devices. At the higher levels of the hierarchy, there are more general policies that could be used to direct global validation of a security implementation.

With a formal security policy, one can build tools to directly control the way security devices operate. Such a policy-based management tool can generate native configuration for the security device, or newer security devices can be developed that operate on the formal security policy directly. Most policy management tools can be mapped into the policy management architecture defined by the Internet Engineering Task Force (IETF) [2] shown in Figure 2. The policy enforcement point (PEP) is the mechanism that enforces the policy (e.g. a firewall device or an authentication system). The policy decision point (PDP) works on the policy to determine how the PEPs should operate. The PDP will also take input on restrictions specific to the environment like topology or maximum available resources to interpret the policy appropriately for the specific implementation. The PDP may generate the configuration for the PEP from the policy, or using a protocol like COPS [3], the PEP may query the PDP for operational guidance as needed.

By operating on a global policy, the system administrator can be freed from the details of the device-specific view and better keep the higher level goals of the policy in mind. The policy may describe goals that must be enforced by a set of devices, and the policy management tool can control and coordinate the operation of these enforcing devices. Even when operating at a device-specific level, the policy can shield the user from the necessary but infrequently changing vendor-specific details of the enforcing device.

If such a global policy-based management is not feasible, the presence of a formal high level policy can be beneficial for policy validation and compliance checking. The enforcing devices may be configured directly by different administrators, but a validation tool

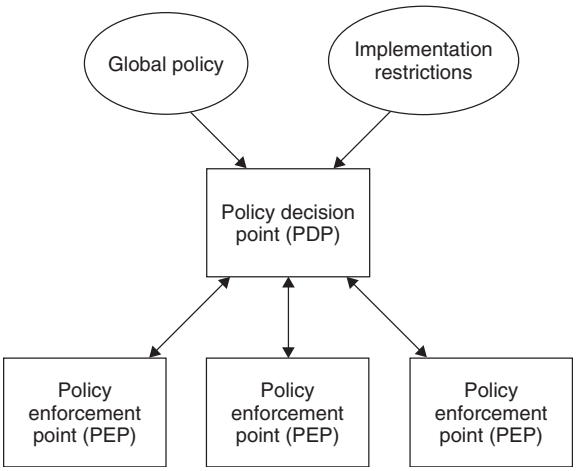

**FIGURE 2** The workflow of the policy management architecture suggested by the IETF. The policy management tool acts as the policy decision point (PDP). It operates on the formal policy and a set of implementation restrictions to create device-specific operational information used by the policy enforcement points (PEPs).

could use the formal high level policy to drive validation of the current implementation. Figure 3 shows the flow of such a policy-based validation tool. The administrator may have a new version of the device configuration. Before deployment the new configuration can be evaluated against sets of policy-based constraints to ensure that the configuration changes do not violate policy. Auditors may also use policy-based constraints to test whether the policy specifications of the client match their deployed configurations.

### 2.1 Conflict Resolution

One issue that appears with all nontrivial formal policy systems is that of conflict resolution. In any real environment, there are conflicting policies that guide operation. An organization may want to provide a easy to use web interface to encourage new customers, but the organization must also ensure that their infrastructure has sufficient authentication and auditing to avoid fraudulent customers. These two goals are necessarily conflicting. At the implementation level, one group may require HTTP communication with a particular server, but another group may need to prohibit all communication with that server to avoid potential conflict of interest contamination.

The policy language could force the user to clarify all conflicts through ordered lists or policy priorities, and this is the approach taken with most currently deployed policy tools. While this approach is straightforward to implement, it pushes complexity back onto the user. Some early firewall devices tried to use "best match" languages to eliminate conflicts between firewall rules, but the meaning of "best match" was either vague or did not always match the user's expectations. More recent work with autonomic network management [4] adds a ratification policy to enable the administrator of a specific system to describe how conflicting policies should be resolved. For example, some aspects of the high level policy may not apply in the particular environment (e.g. Windows policies in a Linux environment). The ratification policies are meta policies that are defined against the operation of other policies rather than the operation of the managed devices.

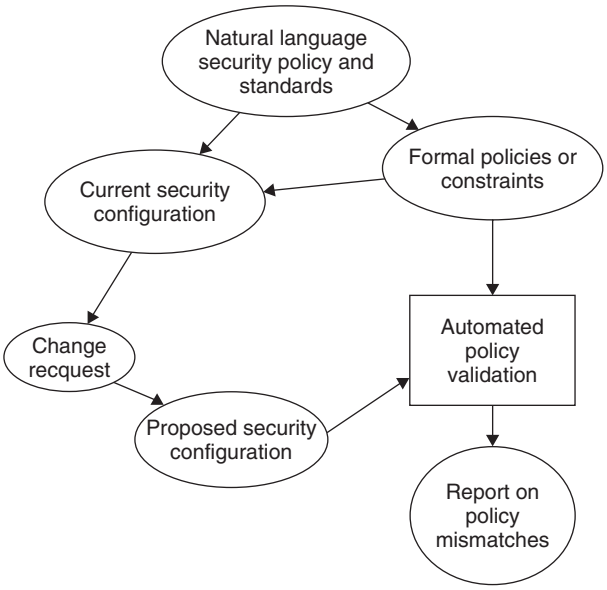

**FIGURE 3** The workflow of a policy validation tool. It takes a formal policy description and a proposed enforcing device configuration. The policy validation tool builds a model of the new configuration and determines whether there are mismatches between the formal policy and the new operational model.

## 2.2 A Policy Example

To make this policy definition discussion more concrete, consider the following broad organizational security policy.

> Partners should only be given access to a specific set of partner servers and only necessary communication protocols should be permitted. Partner traffic must be appropriately authenticated and encrypted.

This policy can be refined into a network security policy that describes where traffic can flow and where it must be encrypted. Ultimately, this formal security policy will direct the provisioning of the appropriate enforcing devices (firewalls, intrusion protection systems, tunnel routers, etc.). The broad organizational security policy can also be refined into a set of policies that define allowable cryptographic algorithms and parameters for the IPSec tunnels. This policy set will be used at run time to negotiate mutually agreeable tunnel parameters for the organization and its partners.

For this example, assume there are more specific natural language policies and standards which enumerate the partner IP networks and internal partner services addresses. The standards also state that the protocols HTTP and secure shell (SSH) are necessary for partner communication and declare that the deep inspection or state-full analysis performed by most of today's enterprise firewalls is sufficient for the broader policy's analysis requirements.

The system administrators can create and maintain configurations for the security enforcing devices directly from the natural language policies and standards. However, as the environment changes, the human mapping between the natural language security

policies and the real configurations may diverge, particularly when dealing with change requests for other policy goals that have unintended consequences. Consider the following scenario.

The system administrator is told to give FTP access to the sensitive document repository machine to machines from network 192.168.1.0/24. Say the configuration writer accidentally mistyped the mask so access was allowed from 192.168.1.0/23. If 192.168.0.0/24 was a partner network, this seemingly unrelated change causes a conflict between the security implementation and the policy on partner communication.

In this scenario the supposedly unrelated changes will affect how the security policy with respect to partner communication will be implemented. It is unlikely in reviewing these unrelated change, the IT personnel will think to check for policy requirements that "should not" be affected by the current change. This error may not be caught until the next audit cycle. In the meantime, some partners have access to a sensitive internal machine that is not indicated by policy.

## 3 PROVISIONING POLICY TOOLS

In the example partner policy, a formal network security policy can be used to provision or validate the network enforcing devices. The formal policy directs a relatively static set of rules for resource allocation or access control. The configuration can be generated from a single policy or a set of policies that can be resolved at configuration or provisioning time. In contrast, other systems can delay policy resolution until runtime via a negotiation protocol. This section discusses tools developed for manipulating provisioning policies.

### 3.1 Network Security Policy Tools

Although the specifics of network security vendor configuration languages differ, they all configure operations on the same basic packet model, which is *"specify a packet and describe what happens to it"*. Thus, it is possible to parse configurations and place the functional configuration information into a common network security model. Guttman [5] first described a technique for parsing router access control lists (ACLs) and building a packet flow model. Others [6, 7] have followed up on this work to parse in network configurations and build higher level packet handling modules. This work provides the basis for a wide variety of network security management and validation tools.

### 3.2 Network Security Policy Management

A number of commercial and research groups have developed network security management tools that present a common security management model and generate the appropriate device-specific configuration to implement the desired model. The architecture of these tools map into the general IETF policy management architecture shown in Figure 2. Cisco Secure Policy Manager [8] and Solsoft [9] both present a global policy model. The user defines the network architecture and identifies the location of the configurable security enforcing devices in that architecture as the implementation restrictions, and he then defines a global policy of desired traffic flows, tunnels, and so on. The management tool acts as the PDP and generates the appropriate configurations for the enforcing points to enforce the global policy.

Some management tools present a rule table interface and use a variety of multi-assignment techniques to share policy rules to multiple enforcing devices, for example Checkpoint, NetScreen Security Manager, Cisco Firewall MC, and Cisco Security Manager. In the research space Bartel et al. [7] created Firmato, a toolkit for creating management tools for different vendors' devices.

Presenting the security implementor with a higher level policy-based management model is a good solution to keep security policy and implementation in sync. By raising the security implementor up a level of abstraction and enabling him to express his requirements globally, he is working at a level closer to the natural language security policies. However, for a variety of technical and social reasons these policy-driven configuration generation solutions have not gained wide acceptance in the network security domain.

In general, the problem with the policy-driven configuration is that it is an all-or-nothing solution. Some aspects of the configuration may map very well to the high level policy, but perhaps other aspects of the configuration are easily done by someone with expertise in the configuration language. Some people in the organization may be comfortable working with the policy language, but others are more comfortable with the command line. In general it is hard to have a configuration that is sometimes configured from policy generation and sometimes through direct human editing [10], because the changes at the lower level may not consistently map into the model at the higher abstraction layer.

### 3.3 Network Security Policy Validation

Today organizations rely on a combination of manual configuration review and network scanning to ensure that configuration changes to the network security implementation are still consistent with the guiding security policy. In many organizations, network security changes are only allowed within a particular change window each week. No configuration change can be deployed until it has been reviewed by the key IT staff with the hope that multiple eyes will catch potential problems.

Many organizations also use network traffic scanners such as *nmap* and *nessus* to probe the newly deployed configuration to ensure that only the expected traffic is passed. Based on the guiding security policy the IT staff can determine what and where to scan and review the scanning logs to see if there are any surprises. Generally, the scanning checks are made after the configuration changes are deployed in the production network. If the changes are extreme or an organization is very security conscious, they may deploy the changes in a similar network in an isolated lab and perform the scans in the lab before deploying the changes on the production network.

Although these solutions catch many potential problems, it is desirable to have a more precise understanding of how the network will behave once the proposed changes deployed without going through the trouble of setting up a separate lab or opening up the organization to a potential vulnerability window on their production network. A number of groups have started to look at configuration validation in addition to direct management. Such validation tools fit into the workflow as shown in Figure 3. Al-Shaer and Hamed [11] and Wool [12] have cataloged sets of possible conflicts that arise in today's common linearly ordered access lists. Al-Shaer and Hamed and a number of commercial products (e.g. Netscreen and Cisco Firewall MC) have tools to perform rule conflict analysis which examines access lists or rule lists and presents conflicts within

the lists. This conflict analysis identifies rules within the same list that could be matched by the same packet. Some conflicts will occur in most ordered access lists, because there are narrow permit rules followed by broader deny rules, but the conflicts are a good place to focus a configuration review. Typos and other development errors will result in unexpected conflicts as indicated in the example error scenario for the partner policy.

Mayer et al. [13] have developed a firewall analyzer that augments the Firmato query engine to generate an exhaustive report of how all possible packets will be handled by a device configured with a specific configuration. This exhaustive report removes any ambiguity from trying to understand how the packets will be processed. This report can be performed without actually configuring the device or passing any traffic. The user can then review the report to understand how any particular packet will be processed.

InfoSecter [14] is another tool that addresses the network security policy validation. In addition to identifying conflicts between rules within the same configuration, it evaluates a configuration against a set of formal policy constraints which are written as conditions that test packet attributes (e.g. source and destination address, and service) and specify desired actions. The condition describes how sets of packets should be treated in the operational environment. The constraint analysis compares the policy constraint against the processing model built from the proposed device configuration and determines if there are sets of packets where the configuration model and the policy constraint differ on the specified action (e.g. permit, encrypt, proxy, or deny). In the case of the FTP configuration change described in the example policy section, the constraint analysis would catch the mismatch with existing policy and alert the IT staff before the proposed configuration is even deployed.

Multiple policy constraints can be defined, and there is no need to specify ordering or other conflict resolution for the policy constraints as would be needed for policy management. This is beneficial when multiple groups of people have policy concerns about the operation of a specific PEP. Consider a firewall that is managed by the IT team. Traffic to the accounting team and the engineering team passes through this device, and each team has its own unique policy concerns. As the firewall configuration evolves, the accounting and engineering teams could independently run their own reviews and scans on each newly deployed change to the firewall, but this would require too much time and expertise on the part of the nonprovisioning teams. Instead, by encoding their concerns in formal policy constraints, the IT team could automatically check their policy constraints on each proposed new configuration.

### 3.4 Operating System Policy Tools

Operating systems that provide mandatory access control (MAC) use policy to define the access rules. The MAC rules are not embedded in the representation of the objects (files) or subjects (processes). The Bell LaPadula MAC policy [15] that is implemented by most multilevel systems does not present a configurable policy. Rather, the administrator can adjust security levels of the subjects and objects to change access control decisions, but the rules or policy against which these levels are evaluated is fixed. However, the type enforcement MAC policy used by SELinux [16] is directly configured by the system administrator. This gives the system administrator a great deal of freedom to implement almost any MAC model, but the policy can grow to be very complex with this increased expressibility.

SEEdit developed by Hitachi provides a graphical interface to edit the SELinux type enforcement policy on a device. It attempts to address the policy creation and management complexity by providing the policy writer with a higher level view of the type enforcement policy. The editor also presents information about common building blocks and macros used to create the policy.

The SELinux type enforcement language provides a basic validation mechanism in the form of the neverallow statement. With this statement, the policy writer can assert that a particular subject (or domain) should never have the specified access to a particular object (or type). For example, the policy writer may want to specify that the guest user should never gain direct access to the objects of type system configuration.

Tresys has created Apol to provide higher level analysis of the type enforcement policy. Apol gives the user the ability to query the policy to determine the allowed information flow, for example which subjects can access which objects. One problem with this and similar higher level SELinux policy analysis tools is that they operate on the raw policy. The policy writer is working with a policy that refers to M4 macros in an attempt to have some form of modularity and reusability. The types that are presented by Apol may have been generated by one of the M4 macros and so are not directly meaningful to the policy writer.

MulVal [17] is a tool that validates access control policy against a formal model built from system configuration. The tool builds a system model from operating system access control information, known system vulnerabilities, and network connectivity. With this formal system model, MulVAL validates whether a formal system policy is accurately enforced. The paper describes results against a network of Red Hat linux devices. The tool was later applied to networks of well-managed Windows devices and revealed numerous exploitable access control flaws. Thus, by defining the system in terms of global access control via policy, the tool was able to take care of the details of validation in a rather complex system.

## 4 CONTRACTUAL OR NEGOTIATING POLICY

Another style of policy has been developed, which does not require configuration time resolution. Rather the infrastructure is aware of the policy and the system entities introduce policies which are resolved at runtime as needed. The policies are like contracts, and the infrastructure provides negotiation protocols to resolve conflicts at run time. The IPSec policy of acceptable cryptographic parameters from the partner example is a very simple example of such a contractual policy.

The Security Assertion Markup Language (SAML) [18] is a more sophisticated example of this type of policy. With SAML statements a user can coordinate between one identify provider and one or more service providers. The service providers can share an identity proof assuming they trust the identify provider. The SAML statements coordinate this sharing. Thus the user can sign on once and pass his validated identity to multiple service providers (that all trust the identity provider).

Similarly the web services security policy (WS-Policy) [19] is a language of assertions which are used to control the run time operation of the web services security infrastructure. For example, a user of a web service may have an associated WS-Policy statement that indicates that he wants to use at least 128 AES encryption with communicating with

a service. The Web Server may have an associated policy that places restrictions on what it needs to be convinced of a user's identity.

In the research space, trust negotiation has been breaking new ground in implementing policy constraints on identity proofs [20]. It is desirable to initiate communication with entities that the user has not previously directly registered with, for example a shopper. The shopper may want some proof that the shopping site is legitimate. Similarly, the shopping site wants to know that the shopper has a good credit rating. The shopper may hold some certificates that show he has a valid credit card and a good credit rating. The shopping site may have certificates that show it is in good standing with the better business bureau. Some of the certificates may be sensitive, and the entities may not want to exchange all certificates up front. Trust negotiation gives a framework for a controlled exchange of information. Policies describe what each entity needs to know to trust the other side. Policies also control how much information an entity is willing to reveal about himself and to whom.

## 5 SUMMARY

Without a strong tie between an organization's high level policy and their operational stance organization is very likely to have a mismatch between policy and operation at some point. This mismatch will expose the organization to insecure states, e.g., too much access, too weak encryption, or too little authentication. By introducing formal policies to fill out the policy refinement hierarchy, one can deploy tools to automatically tie policy to operations via policy management or policy validation. By relying on tools and infrastructures to automatically control devices from policy, an organization has a more direct path from organizational policy to operation. Changes at a more abstract policy level are easier to reconcile with an organization's goals and guiding constraints.

Policy-aware technologies still face many technical hurdles. Accurate and usable conflict resolution will continue to be a difficult problem. The conflict resolution sophistication continues to grow with the evolution of the ratification policies and constraint systems (borrowing technology from artificial intelligence (AI) and type systems). The more dynamic environments of negotiating policies will present even greater problems in reasoning about all possible ways a policy can be enforced.

The benefits of using policy to direct and validate system operation will drive the resolution of these technical hurdles. The computer is well-suited to keeping track of the details in a formal model, and the policy-driven program is less likely to introduce errors (via typos or mismatches between devices) than direct human operation would introduce. As our systems become more complex and control more critical functions, the need for policy driven systems becomes even more important to operate secure and reliable systems.

# MULTILEVEL SECURITY

CYNTHIA E. IRVINE
*Naval Postgraduate School, Monterey, California*

## 1 INTRODUCTION

Multilevel security (MLS) refers to policies and techniques where the sensitivity of the information is immutably bound to an equivalence class. (One can think of *equivalence classes* as subsets of a set where there is no overlap or intersection among the subsets. For example, pens could be subdivided into red pens, blue pens, black pens, green pens, and so on. Information might be subdivided into *CRITICAL* and *NONCRITICAL* information or *PUBLIC* or *PROPRIETARY* information.) The active entities that access the information are also statically associated with equivalence classes. On the basis of the relationships between the equivalence classes, rules determine whether and with what rights an active entity can access the information. The mandatory policies associated with MLS can apply to integrity as well as confidentiality. Specific models and mechanisms have been developed to support MLS in computer systems. Requirements for multilevel secure systems span the private sector, the government, and the military.

## 2 BACKGROUND

Most organizations maintain information that is either protected or openly available. In government, information often is categorized as either classified or unclassified. Within

the context of classified information, various levels of information sensitivity may be established based upon the damage caused should that information become accessible to adversaries. The more grievous the damage resulting from unauthorized access, the more sensitive the information. For example, the recipe for Uncle Joe's secret sauce may be considered critical to the continued well being of a producer of barbeque sauce: it must neither be revealed to competitors, nor should be corrupted by changing the proportions of the ingredients. Physical documents containing sensitive information are protected through a variety of physical and procedural controls. Computer systems introduce new challenges.

Throughout the 1960s, as multiprocessing computer systems evolved, it became evident that the separation provided by the resource management mechanisms of typical operating systems was insufficient to prevent highly sensitive information from becoming accessible to unauthorized individuals. These controls were so inadequate that instead of utilizing the power of multiprocessing, classified information processing was conducted separately. At times, this meant that those with classified tasks had to wait until after hours, when the system could be dedicated to processing the sensitive information. Following the completion of the classified tasks, the system was purged of all sensitive information and restored to unclassified activity. This is what is called *periods processing*. If the amount of classified processing merited the additional expense, a *dedicated system* might be allocated to sensitive tasks.

Both these approaches were insufficient to meet the requirements of organizations that depended upon rapid access to information for military command and control. Periods processing could result in unacceptable delays and dedicated systems incurred both the expense of additional equipment and a high cost of ownership in terms of system maintenance and support personnel. If simultaneous processing at several classification levels, such as *CONFIDENTIAL*, *SECRET*, and *TOP SECRET*, was required, then the resources for either periods processing or dedicated systems could be inadequate. In addition, these approaches could be wasteful if the computing resources allocated to particular classification levels were underutilized.

In organizations where access to a broad spectrum of information is required for making informed decisions, the temporal and spatial separation of information with various sensitivities afforded by periods processing and dedicated systems was more than inconvenient: it could mean the difference between victory and defeat, life or death. Those at the management level wanted computer systems that would mimic the kind of access to information possible when using physical documents: timely simultaneous access to both classified and unclassified information, by properly authorized individuals.

MLS addresses these requirements. To understand MLS, it is necessary to understand the nature of the policies to be enforced, the challenges associated with enforcement of those policies in automated systems, how multilevel systems and networks are implemented, current approaches to MLS systems, and emerging technologies for MLS systems.

## 3 MULTILEVEL SECURITY POLICIES

Security policies are embodied in the laws, procedures, and rules used to manage and protect information. In general, policies reflect an organization's requirements for information confidentiality, integrity, and availability. MLS is applicable to both confidentiality and integrity policies. An organization may use labels to associate a particular

sensitivity level with particular piece of information, and people are vetted for access to sensitive information through checks that result in some form of authorization. For example, extensive and costly background checks are required to vet individuals as sufficiently trustworthy to merit access to *TOP-SECRET* information. Individuals lacking appropriate authorization will be unable to access any sensitive information, whereas those with many or high authorizations have access not only to nonsensitive information but also to highly sensitive information. MAC policies are policies that are both global in scope and persistent in time; users cannot override the policy during normal use. Sometimes mandatory policies are called *nondiscretionary* policies; the two terms are equivalent. In contrast, *discretionary access control* policies permit modification of the rules pertaining to access to information: a run-time interface is provided through which properly authorized users may modify policy. Consequently, it is up to the discretion of the individual to determine who will have access to information. A test for determining whether a policy is mandatory or discretionary is to examine the punishment associated with its violation [1]. Disclosure of state secrets can result in prison or firing squads, whereas violation of discretionary policy may only result in a reprimand.

*Sensitivity levels* are identifiers for equivalence classes of information and are based upon the secrecy and integrity attributes of the information. The choice of equivalence classes is up to the organization. For a private enterprise, the sensitivity levels might be *PROPRIETARY* and *PUBLIC*, whereas a military organization might choose *SECRET*, *CONFIDENTIAL*, and *UNCLASSIFIED*. Consider a few examples.

In a large company, only personnel in the *PRODUCT-RESEARCH* group may have access to *PRODUCT-RESEARCH* information, whereas only personnel in *CORPORATE-STRATEGY* group may access the *CORPORATE-STRATEGY* for next year. Information on the company web pages is *PUBLIC* and is readable by anyone, although the company is likely to restrict write access to its webmasters and system administrators. Management determines the membership of the respective groups. Lipner provided a discussion of the applicability of MAC policies in the commercial sector [2] and concluded that a very large number of labels would be required when many enterprises were involved. Military organizations may organize classified information into *TOP SECRET*, *SECRET*, and *CONFIDENTIAL* levels, and all nonsensitive information is *UNCLASSIFIED*. Individuals are given background checks and are assigned clearances such as *TOP SECRET* and *SECRET*.

There may be a hierarchical relationship between the major equivalence classes. For example, a user cleared for *TOP SECRET* is able to access *TOP SECRET*, *SECRET*, and *UNCLASSIFIED* information. In the corporate example, everyone in *PRODUCT-RESEARCH* may be allowed to access both *SHIPPING* and *PUBLIC*. Often an organization may impose further granularity on its access controls by imposing a mandatory *need-to-know* policy. Additional metadata is associated with both subjects and objects to reflect mandatory need-to-know policies. For example, an individual cleared for *TOP SECRET* may be vetted for access to information that is in special compartments such as *Imagery Intelligence* (*IMINT*), *Signals Intelligence* (*SIGINT*), and *Human Intelligence* (*HUMINT*). Such labels are commonly used by the intelligence community where the work of analysts is compartmented so that individuals have access only to the information required to do their job. These mandatory policies reflect a requirement to enforce the notion of least privilege [3]. Figure 1 shows both a hierarchical ordering of access classes and classes created from combinations of noncomparable attributes. For a mandatory confidentiality policy, information is allowed

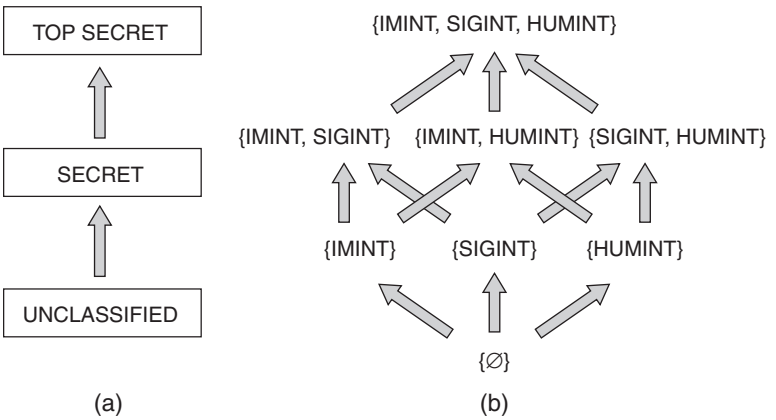

**FIGURE 1** A hierarchical ordering of classes is shown in (a). In (b), a set of noncomparable classes is depicted. Arrows show the allowed direction of information flow.

to flow from lower classification levels or combinations to higher ones. In the latter, any classes may receive information from classes with attributes that are a subset of its own.

A common misconception is that MLS applies only to the enforcement of mandatory confidentiality policies. MLS may also be used to enforce mandatory integrity policies. The semantics of integrity are as follows. If information is of high integrity, then it must not be corrupted by low integrity information. However, adding high integrity information to low integrity information does no harm, although there is no real improvement unless the low integrity information is somehow cleaned up. For example, the Royal Observatory at Greenwich, England, is a reliable and high integrity source for astronomical time, while an amateur sundial might be a relatively low integrity time source. Thus high integrity information should be readable by everyone, whereas low integrity information should be confined and readable within quarantine-like processes. Note that processing of high integrity information by low integrity software, whether being executed by a high integrity process or not, lowers the integrity of that information [4].

The sensitivity labels form a set of equivalence classes that can be organized according to the information flow intended in the system. Denning showed that these equivalence classes can be represented mathematically with respect to the flow of information via read and write operations [5]. This work demonstrated that all mandatory policies could be simply combined and that the resulting sensitivity classes could be easily compared with one another.

For both the corporate and the military examples, the policy regarding access to information is inflexible with respect to location. Even though the corporation may have offices across the world, only *PRODUCT-RESEARCH* group personnel may handle *PRODUCT-RESEARCH*; and, analogously, military access to *TOP-SECRET* information requires a *TOP-SECRET* clearance regardless of the location. These policies are also temporally inflexible. Information marked as *PRODUCT-RESEARCH* does not become *PUBLIC* at certain times of the week while it is marked *PRODUCT-RESEARCH* the rest of the time, just as the classification of information designated *TOP SECRET* does not become *UNCLASSIFIED* just for the weekends. Thus, we say that mandatory policies are *global* and *persistent*.

The global nature of MAC policies does not dictate that all components of a multilevel system, whether individual machines or elements of a highly distributed network, must enforce all policies. The system may be organized so certain components only process information at a single classification level and need not be required to enforce mandatory policy. Such components are *single level*.

In practice, certain information once highly classified may after some time be downgraded and released to the public. Certain situations may require the rapid *regrading* of selected intelligence information so that it is available to operational personnel. This might occur during military operations or in disasters involving first responders who are typically not cleared for access to sensitive information. Similarly low integrity information may be analyzed and judged qualified for use in a high integrity context. For example, integrity regrading might take place in the creation of software for a manned space mission. Initially, the software might be labeled *DEVELOPMENT*, but following proper analysis, it could be upgraded to *MANNED_FLIGHT*. These examples illustrate that the notion of persistence is not absolutely rigid; however, the processes used to regrade information, whether procedural or automated, must be carefully controlled.

Two techniques are commonly used to enforce mandatory policies. The first is physical and the second, logical. Enforcement of mandatory policies in a context without computers involves only individuals and documents. Individuals who have been properly vetted to handle sensitive documents are trusted to ensure that the sensitive information contained in those documents is not transferred to documents with inappropriate sensitivity markings. Organizations go to great lengths to ensure that corrupted insiders or spies do not cause the release of sensitive information. Physical protection can ensure that sensitive information is accessible only within confined spaces. Locks and guards ensure that only authorized individuals enter the sensitive enclave, and logging of entry and exit to the space as well as check-in and check-out of information while in the space deter malicious insiders. Special construction methods may protect the enclave from eavesdropping technologies.

Because an *organizational security policy* may be stated in very general terms, its translation to a form that can be implemented in computer systems results in an *automated security policy* [6]. This articulation of the policy permits access to information to be described in terms of the active and passive entities of the system. Ultimately this translates to execution of an instruction by the CPU that accesses resources managed by the system.

The active system entities, *subjects*, access information contained in passive entities, *objects*. Subjects are not the cleared individuals themselves, but generally are processes that execute software [7]. Subjects are surrogates for users who may be either administrators or normal users. The mechanism that implements and enforces the MAC policy exports subjects and objects at its interface. The enforcement mechanism binds a sensitivity level, either implicitly or explicitly, to each subject and object.

### 3.1 Confinement

In the world external to computers, individuals use their judgment to ensure that only authorized individuals have access to information. Subjects within a computer are programs in execution. Programs do not exercise judgment and thus may violate the intended policy if they are programmed to do so. An example of this problem is a *Trojan Horse*, that is, clandestine malicious software placed within an application. While the user

innocently uses the application, the Trojan Horse abuses the user's privileges to cause unauthorized information flow so that it may be accessed by unauthorized individuals.

To better appreciate the Trojan Horse problem, consider a system that enforces a discretionary policy using access control lists (ACLs). Each process has a binding to the individual upon whose behalf it is running, and a separate ACL is associated with each file and directory. Each ACL contains a list of individuals and their access rights to the object.

Suppose that Alice has *PRODUCT-RESEARCH* information in the file called *research-stuff* and that the ACL on *research-stuff* allows read and write access only to Alice and Bob, who are both members of the *PRODUCT-RESEARCH* team. Elmo is in the shipping department and has a file called *shipping-stuff* with an ACL that allows anyone in the company to have read and write access to it. In theory, Alice could use her computer to read information out of *research-stuff* and write it into *shipping-stuff*, but Alice is a good employee and would not do this. What Alice does not know is that her program, *research-SW*, contains a Trojan Horse. While she uses *research-SW* in the normal course of her job, it is clandestinely writing *PRODUCT-RESEARCH* information to Elmo's file, as illustrated in Figure 2. Elmo, a corporate spy, will sell this information to competitors who are stealing the intellectual property of Alice's company in order to dominate the marketplace. Of course, since a system enforcing discretionary access controls has a run-time application programming interface that may change the policy, it is possible that the Trojan Horse in research-SW might change the ACL on research-stuff, thereby allowing direct read by Elmo. However, the first approach is somewhat preferred as it is less likely to be detected by an auditing mechanism.

Integrity Trojan Horses are also possible. In this case, an integrity Trojan Horse would write to a high integrity object. An example of an integrity attack might be modification of critical avionics information on a commercial aircraft.

In an automated system, the mandatory policies can be enforced in a way that will prevent Trojan Horses from causing unauthorized information flows. Thus, unlike the world of people with judgment and paper, that of subjects and objects is constrained by rules that thwart attempts to violate policy.

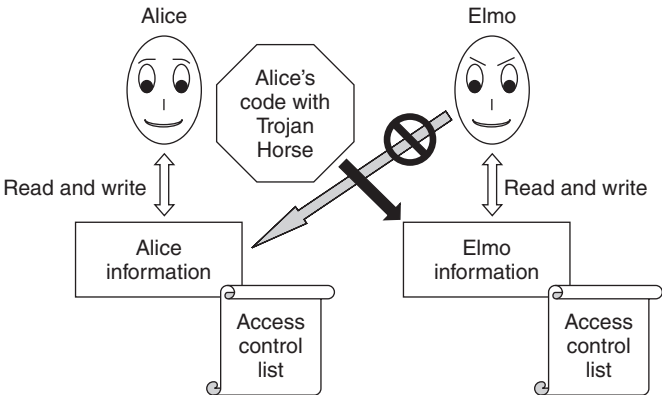

**FIGURE 2** A Trojan Horse executing in Alice's code is able to write to Elmo's information, thus circumventing Alice's intent to block Elmo's read access to her information.

Users set their session level before starting work on an MLS system. This sets the label on any subjects that will act on behalf of the user. Normally these subjects are single level. The systems' objects possess immutable labels indicating a single sensitivity level. Subjects may have access to objects with labels different from their session levels, but in the case of confidentiality they are neither authorized to read from objects that are more sensitive, nor permitted to write to objects less sensitive than the current session level. The former rule reflects the laws and practices imposed in the world of people and paper, whereas the latter is imposed specifically to prevent either accidental or malicious flow of information from high to low sensitivity. This is called *confinement*, and in formal security policy models is called the *confinement-property* (also called the **-property*) [8]. The rules for enforcement of integrity policies have an opposite symmetry. Subjects are permitted to read information of higher integrity and to write to low integrity objects, but they may not read low integrity information or write to higher integrity objects.

Mathematical models allow precise articulation of the properties to be enforced when mandatory policies are required. The Bell and LaPadula model [9] provides a formal representation of a mandatory confidentiality policy and the Biba model describes a mandatory integrity policy [9]. Figures 3 and 4 illustrate the rules of the Bell and LaPadula and Biba models, respectively.

The SeaView model was the first to illustrate that a single set of equivalence classes could be used to enforce combined secrecy, integrity, and least privilege policies in a system with mandatory controls [10]. The least privilege policy, implemented using protection rings [11], addressed process-internal integrity. Extensions to this work have been presented in the context of multilevel secure smart cards [12].

### 3.2 Supporting Policies

In an operational system, there must be a binding between the real user and the subjects acting on behalf of the user [3]. First, a user must be identified to the system, and then the user must be authenticated to the system by presenting something that only come from that user. This might involve a password, token, biometric factor, or some combination of these.

Once logged in, the user must set a session level. To accomplish this, the password file might be augmented to contain the maximum sensitivity level, such as a clearance,

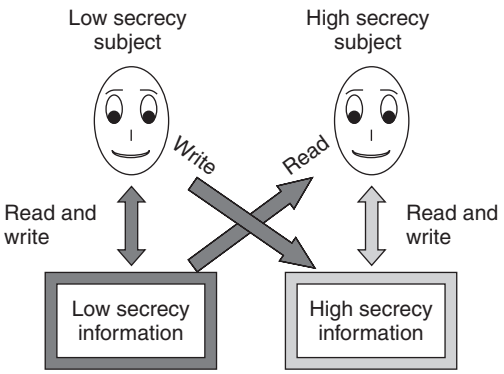

**FIGURE 3** High confidentiality subjects have read access to low confidentiality information; at the same time mandatory policy prohibits the flow of high information to low.

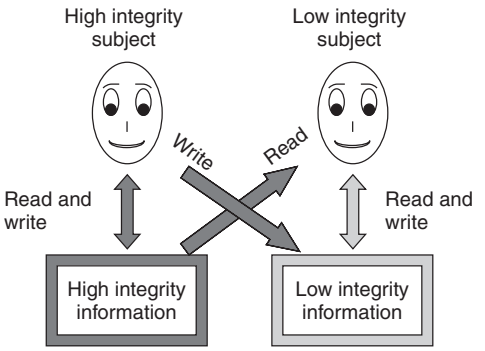

**FIGURE 4** Mandatory integrity policies prevent corruption of high integrity information by low integrity subjects, while low integrity domains benefit from high integrity information.

at which the user can work. Although this maximum sensitivity level might be possible, users may wish to work at lower levels and must select a *session level*. For example, Jane, who is cleared to *TOP SECRET*, could select any one of the following session levels for her current session: *TOP SECRET*, *SECRET*, or *UNCLASSIFIED*. Suppose the user logs on at *SECRET*, then, when a subject is instantiated on behalf of the user, one of its attributes will be the user's current session level, for example, *SECRET*.

The implementation of an identification and authentication policy requires a *trusted path*. The idea behind the trusted path is that the user is trustworthy, as is the identification and authentication mechanism. So, both the system and the users require an unforgeable connection that assures the user protected communication with the trusted system that communication is with the user and not a man-in-the-middle or some other malicious entity. Users invoke the trusted path using a *secure attention key*: a single key or some special combination of keys designated solely for the purpose of establishing a trusted path.

Since the attributes bound to subjects acting on behalf of users are the basis for access control decisions, it is clear that a well-defined identification and authentication policy is essential for multilevel systems.

Audit provides a record of security-relevant events. If bound to a rule-checking mechanism, audit may provide alerts of impending security violations. Policies must be established to determine what should be audited. For example, one might choose to audit all accesses to a particular object, but to no others; all activity on the system could be audited; the activities' subjects at a particular sensitivity level might be recorded; the use of selected system calls could be audited; and so forth. It is important to audit the activities of the security administrator and other trusted individuals so that a record of security-critical activities can be maintained. Also, good audit reduction tools are needed, otherwise voluminous audit records are not likely to be particularly useful.

In systems enforcing mandatory policies, the management of labels and the labeling of information being transferred into and out of the system should be reflected in supporting policies. For example, there may be a requirement that all printed documents contain markings in their headers and footers indicating whether the document is CORPORATE-STRATEGY or PUBLIC.

System support is also required for the enforcement of administrative policies, such as user account management and security configuration, including the configuration of mandatory sensitivity levels.

### 3.3 Trusted Subjects

To perform many of the tasks associated with supporting policies as well as to provide functionality such as regrading, systems enforcing MLS must support subjects that have the ability to both read and write to a label range that spans multiple sensitivity levels [13]. Trusted subjects do not violate the MLS policy, but are explicitly part of the system and adhere to a relaxed MLS policy. To ensure that the information flows resulting from the actions of trusted subjects are not in violation of the intent of the overall system policy, the code executed by these subjects must be analyzed for possible incorrect or malicious execution. As a result of this analysis, we can say that they are trustworthy [14]. A challenge associated with the design and analysis of trusted subjects has been the modeling of their correct behavior [15].

Trusted subjects execute at the login interface to allow each user to set a session level and create untrusted, single-level subjects at that session level. They are also used by security administrators to set the levels associated with single-level devices. For multilevel devices where the sensitivity level of incoming or outgoing information can require the use of explicit sensitivity labels, trusted subjects ensure that correct label-to-information bindings occur. Another service performed by trusted subjects is in regrading information. Many organizations enforce mandatory policies; however, operationally, they also require mechanisms where exceptions to these policies may be implemented. For example, consider a system that encrypts information before transmitting it on the network. The process of encryption can transform bits that represent proprietary sensitive information into bits that represent no information and, thus, can be seen by anyone. In essence, encryption is *downgrading* the information, viz., changing its sensitivity level from high to low. Modern systems may require additional downgrading functions that move certain information from high networks or repositories to low ones. A downgrader or *guard* will consist of a trusted subject that is able to read information from a high sensitivity level, for example, TOP SECRET, and write that information to an object at a lower sensitivity level, for example, SECRET.

Sometimes sensitive information is scanned for certain critical words that are then expunged from the data. This is called *sanitization*. A danger in downgrading systems is *steganography* [16]. Steganography, the art of hidden writing, involves a secret encoded by malicious code in seemingly innocuous data so that it is not visible to the casual observer. Clearly, filtering and regrading must be conducted using systems for which there is a very high confidence that only the correct actions will be taken.

Note that in the regrading example given above, the labels on the subjects and objects are immutable. A trusted subject does not change the label of the object, but rather reads the information from the source object and writes it to a destination object that has a different sensitivity level. This is an example of *tranquility*. Because of its lower complexity, label tranquility for both subjects and objects has been considered to be an essential aspect of highly trustworthy implementations of MLS policies.

The construction of *trusted systems* represents one of the great challenges in security modeling and engineering. Underlying operating system controls are used to enforce mandatory policies on its processes and, at the same time, permit *trusted* applications to be subject to relaxed mandatory constraints.

## 4 ENFORCEMENT OF MULTILEVEL SECURITY POLICIES

When constructing an MLS system, several approaches are possible. Threats will determine system requirements, which include those that specify functionality and those that determine its trustworthiness.

### 4.1 Design Approaches

To enforce policy using physical mechanisms, one must construct a separate single-level network for each sensitivity level. All users must be authorized for the sensitivity level of the network and all information created and managed in that network must be considered to be at the network's sensitivity level. The advantages of single-level systems or networks include the ability to identify and manage the access to information in a manner that is easy to understand. An isolated network may be maintained in a special facility and only authorized users may be granted access to the premises. Although costly, extremely critical information may warrant the protection afforded by isolated networks and systems.

In the case of physically isolated systems, users must either move from room to room to access different networks or they may have multiple systems on the desktop. The latter can lead to clutter and confusion. The user could use a keyboard, video, mouse (KVM) switch to minimize consumption of desktop space; however, multiple processors are still required and the possible advantage of simultaneously seeing information at different sensitivity levels is lost.

If nonsensitive information can be moved to networks of higher sensitivity, but without a highly trustworthy binding of sensitivity labels associated to the information, the users cannot distinguish nonsensitive from sensitive information. Also, to share nonsensitive information with individuals having lesser authorizations, users must go back to the nonsensitive system. If a user wishes to transmit nonsensitive information directly from the more sensitive enclave, complex procedures including automated guards are required, and the possibility of steganography [16] and other techniques for clandestine information hiding must be addressed.

Logical isolation depends upon an underlying mechanism that enforces the security policy. Because mandatory policies can always be characterized by comparisons between equivalence classes, it is possible to construct a relatively simple mechanism to determine whether a particular subject may have access to a given object. Systems that enforce logical isolation can provide users with a coherent view of all information at or below their sensitivity level. They also allow users to log into the system at any sensitivity level at or below their maximum authorization or clearance. Thus, from a single system, an authorized user is able to both access company proprietary information when logged in at *PROPRIETARY* and the Internet when logged in at the *PUBLIC* sensitivity level.

### 4.2 Threats to MLS Systems

The critical nature of information to be protected in MLS systems requires that threats to correct policy enforcement be carefully examined before system development. This

allows requirements to be elicited that will ensure threats are eliminated as part of a carefully articulated system life cycle process.

Threat analysis reveals that there are two broad classes of threats: *developmental threats* and *operational threats* [17]. Developmental threats include the introduction of flaws into the system through mistakes in design and implementation and through deliberate system subversion. The former introduces exploitable flaws, whereas the latter introduces trapdoors.

Operational threats occur when the system is in use. Adversaries can include malicious insiders as well as external activities. The mechanisms that have been designed into the system are intended to counter operational threats; however, system security also depends upon adequate user and administrator training, as well as good configuration management and system maintenance. Constructive techniques counter developmental threats, and systems must be designed and implemented so that operational threats are addressed.

A large number of failures in policy enforcement result from the presence of unspecified functionality in systems, for example, vulnerabilities in the form of system flaws and unintended artifacts that permit an adversary to bypass the policy enforcement mechanism of a system. These failures in design and implementation can be exploited by adversaries intent on gaining system privileges for the purpose of avoiding the constraints of the protection mechanism. Flaws range from inadequate bounds checking of interface parameters to pathological interactions between synchronizing processes. Such flaws were identified by Anderson in 1972 [18] and are still common. The Common Vulnerabilities and Exposures [19] website lists thousands of unique entries. A few of the major categories of flaws derived from Linde [20] and Anderson [18] are provided in Table 1.

The most insidious form of unspecified functionality is subversion [21], where a member of the system's development team intentionally adds clandestine functionality that permits the adversary to bypass system security mechanisms. The term *subversion* is generally applied to the operating system or kernel, whereas other forms of malicious

**TABLE 1 Examples of Errors Resulting in Security Flaws**

| General Error Category | Example |
|---|---|
| System design errors | Absence of least privilege |
| | Inappropriate mechanism for shared objects |
| | Poor choice of data types |
| Design errors | Error recovery results in exploitable side effects |
| | System modifications that deviate original intent of security mechanisms |
| Implementation errors | Buffers sizes are not checked, resulting in "buffer overflow" |
| | Failure to initialize variables |
| | Absent parameters are erroneously assumed |
| User interface errors | Gratuitous active execution |
| | Passwords too short |
| | Default access control lists are too permissive |
| Configuration errors | Insecure defaults render the system vulnerable |
| | Critical resources remain unprotected because of bad configuration choices |

software, for example, Trojan Horses, function in the context of applications. Karger and Schell [22] suggested a subversion in which a compiler could insert an artifice into an operating system. This concern regarding untrustworthy tools was popularized by Thompson [23].

A subversion mechanism executing within the operating system has full system privileges and is unconstrained by policy enforcement mechanisms. If it contains triggers for activation and deactivation, the adversary will have control over its execution.

In many cases, malicious code may be introduced into systems in the form of downloadable executables or scripts, updates, and patches. Code of unknown provenance should be given an integrity label such as *POND-SCUM* and be confined using mandatory integrity controls thus preventing the infliction of pervasive damage.

### 4.3 Assurance

As is the case with security, assurance is a term that is often misused. For example, some state that "software assurance" will improve the "security" of systems. Both these terms are meaningless without context. In the case of software assurance, some might say that a system possesses this quality if it functions as specified and if various tests indicate that the software behaves as expected over a set of inputs, but this definition assumes no malicious intent in the construction of the system. If, on the other hand, one assumes a malicious adversary, then assurance means correct policy enforcement in the face of sophisticated attacks.

The critical nature of the information processed within multilevel secure systems requires assurance through a carefully chosen combination of environmental and technical measures.

Given a particular security policy, an organization may seek more or less assurance that the policy is correctly enforced. For example, greater assurance might be required to show that only authorized individuals have access to trade secrets, whereas less assurance might be required for the protection of the agenda for the next staff meeting. Barriers to achieving high assurance multilevel secure systems include product development pressures that can lead to shortcuts and specious claims. For example, a vendor may claim to have a "secret" technique that makes a system secure, but close inspection by knowledgeable reviewers usually reveals serious flaws [17, 22]. (Such "secret" techniques often involve a combination of cryptography and handwaving.) It is generally accepted that an objective third party must provide an independent assessment of system assurance. The current framework for third party evaluation of system assurance is that of the Common Criteria [24], which provides for high-level requirements for various classes of security products. Through analysis and testing, product team evaluators establish that the product meets both functional and assurance security requirements. A second round of testing and analysis by independent evaluators validates the team's results.

### 4.4 Secure MLS System Development

Over time, a set of design principles that can guide the development of highly secure systems has emerged [14]. These principles take traditional constructive methods into account, as well as recent advances in hardware and networking.

A secure system should exhibit all of the characteristics of a classic *reference monitor* [17]: resistance to tamper, continuous policy enforcement, and an understandable implementation.

Dependencies are of great importance in designing a secure system. If the system is organized as a set of hierarchical layers, then it must be organized so that each layer of the system depends only upon layers that are of equal or higher assurance and that enforce equivalent or stronger policies. The number and extent of the layers depend upon whether the mandatory policy is void or richly populated, but it is important that mandatory policy enforcement mechanisms do not depend upon discretionary, viz., modifiable, policy components.

Once the system architecture has been delineated and policy has been allocated to its various layers, it is possible to focus on the construction of each layer. Here, the techniques used to develop a high assurance, low-level layer are sketched.

To start, a formal security policy model is developed. The model provides a proof that if the system starts in a secure state, then all operations will maintain that secure state [8, 9]. The formal model serves two important purposes: first, it demonstrates that the intended policy is logically self-consistent and not flawed, and second, it provides a mathematical description of the system to which the implementation can be mapped. The objective of this mapping is to demonstrate that everything in the implementation is both necessary and sufficient for the enforcement of the policy and that no unspecified functionality is present.

Because the objective in constructing the lowest layers of the system is to develop a coherent mechanism for the enforcement of the system's MLS policy, a combination of hardware and software is used to create the exported abstract machine. Rigorous security engineering techniques employing the concepts of layering, modularity, and data hiding ensure that the system has a coherent loop-free design and provides understandable abstractions. Within the system itself, the principle of least privilege can be applied as part of the engineering process. Ultimately, both the formal and informal efforts provide a mapping of the implementation to the formal security policy model as well as evidence that the system is correct and complete.

Although testing cannot prove that a system is secure, it can lessen the likelihood of obvious flaws. Traditional testing demonstrates that each function and module performs as specified. At the system level, this is supplemented by penetration testing. Here, the tester behaves as an adversary and attempts to abuse the system interfaces in an unexpected manner. A useful approach to penetration testing is the *flaw hypothesis methodology* [20].

System administrators and users must be provided with documentation and training. If a system with useful security mechanisms is configured and used improperly, a false sense of security may result that may have consequences far worse than if management believed security was inadequate.

Thorough documentation of the development process is needed so that the system can be assessed with respect to its security requirements by third party evaluators. To date, no viable alternative to either the reference monitor concept or the need for third party evaluation has been proposed. Future research may result in more streamlined approaches to secure system construction and assessment.

### 4.5 Covert Channels

A multilevel secure system is designed to export resources, including subjects and objects, at its interface and to actively mediate information flows between its exported subjects. Rules enforced by the MLS system will ensure that unauthorized flows do not occur as a result of interactions among exported resources; however, design measures must ensure

unintended information flows do not occur via covert channels [25] among elements internal to the policy enforcement mechanism.

Covert channels result from the manipulation of system interfaces in ways that cause unintended information flow and result from incomplete resource virtualization by the underlying protection mechanism. This means that some abstract data type presented at the system interface involves operating system constructs that can be manipulated to allow signaling to take place in violation of the system security policy.

An effective technique for covert channel analysis is the shared-resource matrix method [26]. Using this technique, the effects of each system call on operating system-level data structures are analyzed and their visibility, perhaps through exceptions or timing delays, to other processes is identified. When the effects could result in unintended transmission of information, either a system flaw or a covert channel is present.

Covert channels may take one of two forms: *storage channels* and *timing channels* (e.g. [27]). In the case of the former, a resource such as secondary memory is incompletely virtualized so that effects and exceptions viewed by the receiver can be manipulated by the sender. This causality permits the sender to signal a sequence of effects and exceptions, which may be interpreted as a series of 1s and 0s by the receiver, thus creating a binary channel. The bandwidth of the channel will depend upon the speed with which the sender can manipulate the observables for the sender. Complete elimination of covert storage channels is possible for classic monolithic single-processor systems. Multicore processors present new challenges to covert channel mitigation. Covert timing channels result from the ability of the sender to modulate the temporal activities of the system as seen by the sender. Because time is a shared resource that cannot be completely virtualized by the underlying security mechanism, requirements may only call for a reduction of the channel bandwidth below a certain threshold. This can prove challenging, as increases in processor speed can dramatically increase the bandwidth of a covert timing channel, and timing channel reduction may result in imprecise knowledge of system time, significant loss in overall performance, or both [28]. Careful configuration and scheduling can mitigate timing channels; their complete elimination has yet to be demonstrated in useful systems. If covert channel analysis is an objective, then the design and implementation framework and development methodology for the target system must ensure that adequate information for this analysis is available.

Another form of information leakage is via *side channels*. In this case, information leakage is not internal, but is possible through monitoring of external observables (e.g. [29]). Side channels are possible in any system intended to protect some secret, such as encryption key, from external observation.

### 4.6 Object Reuse Considerations

Objects, the information containers in systems, are constructed using system resources, usually primary and secondary memory, but devices must also be considered. When objects are deleted, the memory from which they were constructed is returned to a pool. To prevent inadvertent access to information previously stored in deleted objects, an object reuse mechanism is needed that will remove information from resources before their reuse. The system implementation determines whether the information is purged immediately after object deletion or before its allocation to a new object.

### 4.7 Target Environment

The requirements levied upon a multilevel system usually depend upon the conditions within which it is intended to operate. As a result, there are several *operational modes*.

*System high* operation requires that all users be cleared to the highest sensitivity level and all information is stored at the system high sensitivity level. Any labels are only advisory and a review is required to downgrade information for use in a less sensitive system. Physical controls commensurate with the highest sensitivity of information within the system are used to isolate the system and grant users physical access to it.

In a *compartmented mode* system, all information is treated to be at the highest sensitivity level. Users must be vetted to not disclose information on the system. Formal compartments subdivide the information and users are granted formal access to those compartments on a need-to-know basis. Information to be moved out of the system to lower sensitivity levels must be submitted to a review and downgrading process. Physical controls commensurate with the highest sensitivity of information within the system are used to both isolate the system and to control physical access to it.

A *multilevel mode* system permits information at more than one sensitivity level to be processed within the system for which users do not have authorizations to access all information on the system.

Multilevel mode does not imply that all sensitivity levels must be processed by the system, nor does it imply support for a full range of user authorizations. The range of information sensitivity levels and the range of user clearances will be dictated by the assurance of correct policy enforcement that the system provides. For example, in 1985, even with the highest assurance systems of the time, the risk was considered too high to permit the minimum clearance of users to be UNCLASSIFIED and the maximum sensitivity of data on a system to be TOP SECRET with multiple compartments [30].

### 4.8 Cascade Problem

Organizations may wish to link several MLS systems into a network. When doing so, it is necessary to consider the assurance characteristics of the interconnected components.

Consider two systems that have been certified to have sufficient assurance to separate two sensitivity levels. System A can process TOP-SECRET and SECRET information, and System B can process SECRET and CONFIDENTIAL information. As stand-alone systems, we are satisfied that although some information flow might occur, they will not be particularly damaging due to the small range in sensitivity levels being managed by the system. Now suppose that the systems are networked together so that the SECRET domain of System A is connected to the SECRET domain of System B, as shown in Figure 5. In this configuration, information might inadvertently flow from TOP SECRET to CONFIDENTIAL. This could pose an intolerable risk. The interconnection introduces an information flow cascade [31]. Because of the complexity of finding and correcting cascades, networks should be carefully designed to avoid the cascade problem from the outset.

## 5 PLATFORMS AND ARCHITECTURES FOR MULTILEVEL SECURITY

All multilevel secure systems must provide separation of the information equivalence classes derived from policy, enforcement of rules for interaction between the equivalence

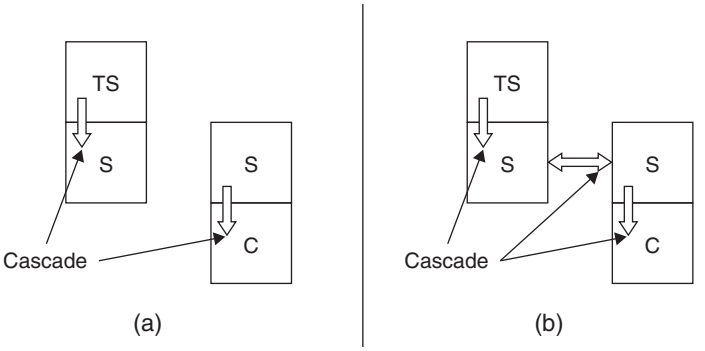

**FIGURE 5** Systems in (a) have sufficient assurance to address information flow between two equivalence classes. By interconnecting the same systems, as shown in (b), the assurance is insufficient with respect to flows between three equivalence classes, and an unacceptable cascade results.

classes, a mechanism to map the equivalence classes to human readable labels, and assurance that the system is complete and correct. Because enforcement of supporting policies, for example, identification and authentication and audit, would complicate the minimal kernel, an MLS system is usually organized as a *trusted computing base* (TCB) of which the kernel is a part. Figure 6 is a simplistic illustration of a kernel within a TCB.

Current approaches to multilevel secure platforms include classic security kernels [32] and separation kernels [33]. In the former, an internal policy module mediates access based upon the rules established for the equivalence classes it maintains. Information exported to networks will have either implicit labels, in the case of single-level networks, or explicit labels associated with each packet, in the case of multilevel networks. In these kernels, each process will be assigned either a single level or will be trusted over some range of labels. When combined with the use of ring-based privilege domains [11], traditional security kernels provide considerable granularity for information flow control.

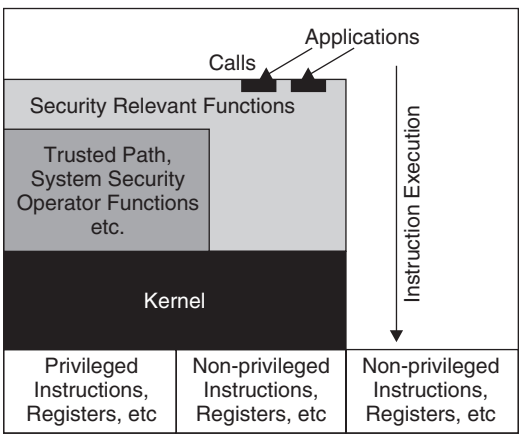

**FIGURE 6** A trusted computing base encompasses all security-relevant functionality and may contain a kernel.

Traditional security kernels dynamically allocate resources as different sensitivity levels are required.

A separation kernel creates partitions to which it exports resources based upon assignments loaded into the kernel in the form of a configuration table. Once the configuration is loaded, the sensitivity levels to be managed are fixed until a new configuration is applied, which in conservative cases requires a system restart [34]. Each partition represents an equivalence class, and an interpartition flow policy determines how subjects within a partition can cause flows to other partitions. These kernels are sometimes called *partitioning kernels* or *multiple independent levels of security* (MILS) architecture kernels, for example [35]. For these kernels, enforcement of the interpartition flow policy is allocated to a partition that has read and write access to all other partitions and contains a trusted subject to mediate and effect the interpartition flows.

Least privilege separation kernels [36] provide higher granularity with regard to flows than is present in MILS separation kernels. By combining a more granular configuration table with the use of hardware-supported rings and the ability to create many subjects per equivalence class, a least privilege separation kernel does not need a special partition for interpartition communication, but can create trusted partitions for other functions as needed.

The distinct advantages and disadvantages of each type of kernel should be considered when selecting a kernel to meet specific requirements [37].

Requirements exist for architectures that support heterogeneously trusted users, for example, [38]. Blacker was an early example of a multilevel secure network [39]. In essence, it was an MLS virtual private network (VPN) and was designed to provide both the platform assurance and cryptographic mechanisms required for highly distributed host-to-host communication. Various other solutions have been adopted as well. In system high and compartmented environments, workstations of low or medium assurance provide multilevel functionality, but do little to address the subversion threat. The cost is a specialized workstation for each user. Certain high assurance MLS systems can be used in distributed environments and a major vendor once developed a high assurance MLS virtual machine monitor (VMM), although the product was never released. Recent progress in VMMs has led to a resurgence of interest in their use for MLS.

Architectures that combine the use of popular commodity office productivity applications with components for high assurance of policy enforcement are possible [40]. This approach results in a network architecture that depends upon the use of high assurance multilevel components for servers as well as high assurance elements to support a distributed trusted path and for label enforcement at single-level network connections. An alternative approach uses many microarchitectural elements [41].

### 5.1 Use of Applications in MLS Systems

A challenge facing the developers of MLS systems has been the design of applications able to take advantage of the system's underlying multilevel technology. To avoid requiring every application to be a trusted subject, applications must be organized to execute as multilevel-aware untrusted single-level subjects that can easily read and write to objects as allowed by policy.

Early work in this area involved the design of a multilevel file system intended to provide applications with a complete set of file system features while constrained by

an underlying security kernel [42]. Subsequent work [43] has demonstrated that a wide variety of applications can be made multilevel aware.

User acceptability is often a problem for operational MLS systems. The rules to constrain Trojan Horses and other malicious software do not exist in the world of people and paper. A person cleared for TOP SECRET can hand write an UNCLASSIFIED memo without clearing the desk of all classified information. Typical users do not understand why the rules for automated MLS security policies exist and merely conclude that those developing MLS do not trust them. Others seek alternative solutions with relaxed rules or "vendor magic", which can endanger highly sensitive information.

## 6 CONCLUSION

Multilevel secure systems are required when heterogeneously trusted users must access information resources. They can be used to protect information from unauthorized disclosure and unauthorized modification of information. Although the challenges associated with the design and development of highly trustworthy multilevel secure systems have been understood since the late 1960s, their implementation and use have remained elusive. Consequently, many organizations adopt architectures comprising multiple single-level networks for which timely access to information at different sensitivity levels is often difficult or impossible. Challenges to the use of MLS systems include their proportionately higher cost relative to commodity products, user acceptability of the policy enforcement rules, and modern platform architectures that introduce opportunity for the existence and exploitation of high-bandwidth covert channels.

# CYBER SECURITY STANDARDS

KAREN SCARFONE, DAN BENIGNI, AND TIM GRANCE
*National Institute of Standards and Technology, Gaithersburg, Maryland*

## 1 INTRODUCTION

The International Organization for Standardization (ISO) defines a standard as "a document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines, or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context" [1]. Numerous standards have been developed for cyber security to help organizations better manage security risk, implement security controls that meet legal and regulatory requirements, and achieve performance and cost benefits. This article provides an overview of cyber security standards in general and highlights some of the major ongoing international, regional, national, industry, and government standards efforts. It also discusses the advantages of having standards and explains how organizations can participate in standards research and development.

## 2 CYBER SECURITY STANDARDS OVERVIEW

Cyber security standards are proliferating. Governments and businesses increasingly mandate their implementation. More manufacturers and vendors are building and selling standards-compliant products and services. In addition, a growing number of organizations are becoming involved in standards development. Cyber security standards are being embraced because they are useful. They provide tangible benefits that justify the time and financial resources required to produce and apply them.

Security technology has not kept pace with the rapid development of IT, leaving systems, data, and users vulnerable to both conventional and innovative security threats. Politically motivated adversaries, financially motivated criminals, mischievous attackers, and malicious or careless authorized users are among the threats to systems and technology that have the potential to jeopardize cyber security, US economic security, consumer identities and privacy, and US public health and safety. While it is impossible to eliminate all threats, improvements in cyber security can help manage security risks by making it harder for attacks to succeed and by reducing the effect of attacks that do occur.

Cyber security standards enhance security and contribute to risk management in several important ways. Standards help establish common security requirements and the capabilities needed for secure solutions. For example, Federal Information Processing Standards (FIPS) 140-2, *Security Requirements for Cryptographic Modules*, establishes standard requirements for all cryptographic-based security systems used by federal organizations to protect sensitive or valuable data [2]. Conformance testing can then be

performed against the standard to provide assurance to users that cryptographic modules are built to requirements.

Security standards facilitate sharing of knowledge and best practices by helping to ensure common understanding of concepts, terms, and definitions, which prevents errors. For example, the Information and Communications Technology (ICT) Security Standards Roadmap [3] includes references to several security glossaries, including the ISO/IEC JTC1/SC27 IT Security Terminology publication [4]. Other helpful resources include the Internet Security Glossary from the Internet Engineering Task Force (IETF), Request for Comments (RFC) 4949 [5] and a compendium of the International Telecommunications Union Telecommunication Standardization Sector (ITU-T) approved security definitions [6]. Using common definitions for security terminology saves time in the development of new standards and supports the interoperability of standards.

Cyber security standards also provide other benefits. Because standards generally incorporate best practices and conformance requirements, their use typically results in improvements in quality. Standards reduce the number of technical variations and allow consumers easy access to interchangeable technology. Standards compliance programs offer a way to measure products and services against objective criteria and provide a basis for comparing products, such as confirming that they offer certain sets of security features. Consumers often benefit from cost savings that result from the development, manufacture, sales, and delivery of standards-based, interoperable products and services. Another benefit of cyber security standards is that the standards development process, with its typical practices of involving a wide range of subject-matter experts, prototyping, and incorporating conformity assessment criteria and methodologies, helps ensure that standards are implementable and reflect recommended practices. Products or services that have been demonstrated to conform to IT security standards can then be expected to offer more assurance than nonstandard products.

When security standards are not available for a technology, several problems often occur. Organizations that adopt the technology may not be aware of its inherent security weaknesses and the implications of implementing the technology for the organization's security posture. Organizations also may not have reliable information on how to take advantage of the technology's security capabilities or on what additional security controls may be needed to compensate for weaknesses in those capabilities. This tends to lead to insecure implementations and insufficient security maintenance, making systems more likely to be exploited and the organization more vulnerable to harm.

### 2.1 Cyber Security Standards Characteristics

Standards can be defined as widely used rules or specifications for activities or their results. Nevertheless, there are often significant differences in how individual standards are developed and applied. These differences can help determine how quickly and easily a new standard is embraced and thereby influence the continued use or demise of alternatives. As a result, standards are often described by the specific characteristics of their development and intended application, including the development process used to produce the standard, the way in which the standard is regulated, the applicability of the standard to different audiences, the availability of the standard to the public, and the measurability of the standard.

Standards come into being in different ways. *Proprietary* or *company standards* are developed by companies with little or no participation by external parties. *De facto*

*standards* are created through the informal adoption of prevailing practices or norms. The majority are *voluntary standards* developed through some form of voluntary consensus process, in which stakeholders participate and agree. Some voluntary standards development efforts are open to all interested parties, while others are restricted to specific groups or individuals, such as members of a particular alliance or consortium.

Standards differ in the ways that they are regulated. Compliance with standards may be optional, or a governing or regulatory organization may make compliance a requirement. *Voluntary standards* are generally called *voluntary*, not only because they are created through volunteers' efforts but also because they are intended for optional use, although a regulating agency could adopt or mandate their use. *Mandatory standards* are standards whose use is prescribed by a regulatory agency or implementing organization. Mandatory standards typically implement laws and regulations.

The audience to whom a standard applies depends upon the entity that develops or adopts it. An *international standard* is one that is adopted by an international standards development organization (SDO) and made available to the public, such as ISO International Standards. A *regional standard* is a standard adopted by several nations in a particular geographic region, for example, European Committee for Standardization (CEN) standards. A *national standard* is a standard developed for use in a particular country either by a government entity or a national SDO. A national standard can also be an international standard that is adopted for use by an individual country. Examples include FIPS and American National Standards Institute (ANSI) standards in the United States and British Standards Institution (BSI) Standards in the United Kingdom. An *industry standard* is one that has been adopted by a particular industry for common use, for example, Security Industry Association (SIA) standards. Finally, a *company standard*, also known as a *proprietary standard*, is a standard developed and owned by a commercial entity that specifies practices or conventions unique to that entity.

Standards may or may not be freely accessible by everyone. By definition, *open standards* are publicly available, but their developer may charge for copies. Examples of open standards that are available to the public for a fee are ISO standards and standards developed by ANSI-accredited organizations. A vendor who develops and owns a *proprietary standard* may choose to make it available to promote interoperability and broaden the market, or choose not to share it.

A growing number of standards require a demonstration of conformance. A *performance standard* states requirements in terms of required results with criteria for verifying conformance, but without stating the methods for achieving required results. Examples of performance standards are the Federal Information Security Management Act (FISMA) and the Health Insurance Portability and Accountability Act (HIPAA). A *prescriptive standard* specifies design requirements, how a requirement is to be achieved, or how an item is to be constructed, but without criteria for measuring the conformity of the results with specified requirements. An example of a prescriptive standard is ISO/IEC 7810 on identification card physical construction. The development and use of performance standards are encouraged since they are less likely than prescriptive specifications to stand in the way of innovation. Still, prescriptive standards are sometimes more appropriate, particularly for describing test methods or procedures or for defining standards to achieve interoperability.

### 2.2 Cyber Security Standards Interaction

A standard is rarely applied in isolation. When technologies, processes, and management practices are combined to solve a business problem, multiple standards normally come into play. When components are integrated, each may entail one or more technical or management standards. For example, a given business solution is likely to involve a variety of IT security configuration standards, such as networking, communications, and security management standards. Each standard imposes requirements that may or may not conflict with the requirements of other standards.

Standards can interact in several ways. Some standards are *complementary*, which means that one standard supports or reinforces the requirements of another. For example, ISO frequently publishes multipart standards that can be considered complementary, where each part is a separately developed volume covering a different aspect of a central issue. Some standards may *conflict* with each other, which means that there are inconsistencies or contradictions between standards, resulting in issues such as technological incompatibility or legal noncompliance. Other standards are *discrete*, which means that they have no direct effect on one another. There are also *standards gaps*, where there is no formal standard developed for a particular area of security, although a guideline may exist. Standards gaps typically occur when a technology is evolving so rapidly that standards development cannot keep pace. In other cases, a gap exists because consensus has not been reached on either the technology or the standard.

### 2.3 Standards and Guidelines

Standards can be contrasted with another category of documents, generally referred to as *guidelines*. Both standards and guidelines provide guidance aimed at enhancing cyber security, but guidelines usually lack the level of consensus and formality associated with standards. Some standards, such as ANSI Standards and FIPS Publications, are easily recognized because they include the term *standard* in their titles. Others are harder to recognize. For example, standards issued by the International Telecommunications Union (ITU), an international standards developer, are designated as *Recommendations*. A standard issued by the IETF starts out as an *RFC* and retains that designation even after being adopted as a standard. In other cases, documents that are not standards in the strict sense of the word may be treated as such by an organization if it suits the organization's needs. For example, many US and international organizations and businesses have adopted National Institute of Standards and Technology (NIST) Special Publications as standards, even though those documents are published as guidelines for use by US Federal agencies.

Some organizations develop both standards and guidelines. For example, in addition to international standards, ISO/IEC issues several types of guidelines, including technical specifications, publicly available specifications (PAS), and technical reports, according to the ISO/IEC Directives, Part 1, Section 3 [7]. A technical specification may be published when the immediate release of an international standard is not feasible, such as when the subject in question is still under development. A PAS may be an intermediate specification published prior to the development of a full international standard, or in International Electrotechnical Commission (IEC) it may be a "dual logo" publication published in collaboration with an external organization. A PAS does not fulfill the requirements for

a standard. A technical report is an informative document generally intended to educate the reader, not to specify an international standard.

## 3 CYBER SECURITY STANDARDS DEVELOPERS

International, regional, national, industry, and government groups are involved in the development of cyber security standards. An *SDO* is an organization whose primary mission is the development of voluntary consensus standards on an international, regional, or on a national basis. Most SDOs cover a wide variety of technical areas, not just cyber security. *Consortia*, *industry alliances*, and *associations* are all groups of organizations or individuals with similar interests that promote standards development. A consortium is typically formed for a limited time to achieve a specific goal, such as the development of standards. *Industry alliances* and *associations* tend to be more loosely formed to foster common interests. Consortia and industry alliances comprise companies, and associations are made up of individuals. Finally, the US *government* and other national governments develop standards specifically intended for government audiences. Examples of organizations in each of these categories are provided below, along with brief discussions of some of the organizations' cyber security standards work.

### 3.1 International Standards Development Organizations

The Institute of Electrical and Electronics Engineers Standards Association (IEEE-SA) develops standards in many areas, including information technology, telecommunications, and power generation. An example of IEEE-SA's security work is its 802 Local Area Network (LAN)/Metropolitan Area Network (MAN) Standards Committee. Various working groups within the committee develop widely used standards for many types of networking technologies, such as Ethernet, wireless LANs, Bluetooth, and Worldwide Interoperability for Microwave Access (WiMAX). These standards include the security features built into the wireless networking protocols.

The IETF is concerned with the evolution of the Internet architecture and the operation of the Internet. The IETF has dozens of working groups that each focus on a different element of the Internet, including several groups working on Internet security. Topics addressed by these working groups include Domain Name System (DNS) security, authentication protocols, routing protocol security, Internet Protocol (IP) version 6, public key infrastructure, e-mail security, event logging, and network traffic encryption.

ISO, whose membership consists of the national standards institutes of more than 150 countries, addresses all standards except those for electrical and electronic engineering, which are the responsibility of the IEC. ISO and IEC formed the Joint Technical Committee 1 (JTC1) for IT standards development, including standards for the security of systems and information. JTC1 has a number of subcommittees (SC) and working groups that address specific technologies. For example, the SC17 group addresses identification cards and personal identification, the SC27 group focuses on IT security techniques, the SC31 group works on automatic identification and data capture (AIDC) techniques, and the SC37 group develops biometric standards.

The ITU-T produces standards, called *Recommendations*, for telecommunication networks. ITU-T's standards are developed by study groups (SG) such as SG17, which covers security, languages, and telecommunications software. SG17 led the development

of the ICT Security Standards Roadmap, which provides information on previous and current security standards work from several major standards developers, including ISO, IEC, IETF, Organization for the Advancement of Structured Information Standards (OASIS), Institute of Electrical and Electronics Engineers (IEEE), and telecommunications-specific organizations. It also lists current security standards gaps and provides pointers to security glossaries. SG17 developed the ICT Security Standards Roadmap in collaboration with the European Network and Information Security Agency (ENISA) and the Network and Information Security Steering Group (NISSG).

### 3.2 Regional Standards Development Organizations

The European Telecommunications Standards Institute (ETSI) produces telecommunications standards within Europe. ETSI's cyber security standards activities include work on electronic signatures, smart cards, lawful interception, and 3GPP.

The CEN, whose members are the national standards organizations of 30 European countries, develops cyber security standards on its own and in conjunction with other international, national, and government standards developers.

### 3.3 National Standards Development Organizations

In the narrowest sense of the term, ANSI is not an SDO, since it does not develop standards; rather, it administers and coordinates the activities of the US private sector voluntary standardization system. ANSI sponsors cyber security-related working groups, such as a Homeland Security Standards Panel and a Healthcare Information Technology Standards Panel.

The InterNational Committee for Information Technology Standards (INCITS) is an ANSI-accredited organization, which develops US standards for information and communications technologies. INCITS comprise technical committees (TCs) that create standards for different technology areas. Examples of cyber security-focused TCs are B10 (identification cards and related devices), CS1 (cyber security), M1 (biometrics), and T6 (radio frequency identification (RFID) technology).

### 3.4 Consortia, Industry Alliances, and Associations

The Association for Automatic Identification and Mobility (AIM) is a trade association for entities that are interested in AIDC technologies. AIM performs the development of cyber security standards in areas such as barcodes, card technologies, electronic article surveillance, RFID, real-time locating systems (RTLS), and other AIDC-related technologies.

The British Security Industry Association (BSIA) is the professional trade association for the security industry in the United Kingdom. The BSIA develops codes of practice and technical documents and submits some of them for consideration as British Standards. Security areas addressed by the BSIA include access control, information destruction, physical security equipment, and security systems.

The Information Systems Audit and Control Association (ISACA) is an organization for information assurance, governance, security, and audit professionals. It is best known for its information system auditing and control standards and related initiatives. For example, ISACA has developed Control Objectives for Information and related Technology (COBIT), which is a control framework that encompasses several aspects

of IT governance, including risk assessment. COBIT is based on various international standards and can be used to identify appropriate standards references during audits.

The Instrumentation, Systems, and Automation Society (ISA) is a professional association that develops standards for automation technologies. For example, its SP99 working group develops security standards for manufacturing and control systems, such as supervisory control and data acquisition (SCADA) systems and distributed control systems (DCS). Some of ISA's reports on this topic have become ANSI standards.

The OASIS develops standards for security and e-business, and is well known for its web services standards work. OASIS has several working groups focused on security topics such as biometrics, digital signature services, enterprise key management infrastructures, public key infrastructure adoption, and web services security.

The SIA is an ANSI-accredited SDO that develops systems integration and equipment performance standards. Several SIA working groups develop physical security standards on topics such as biometrics, mobile security devices, credential readers, security communications, and security control panels.

### 3.5 US Government Standards Developers

NIST develops security standards for US Federal information systems. NIST's FIPS have been made mandatory for federal use. Examples of FIPS include FIPS 200, which specifies minimum security requirements for federal information systems; FIPS 199, which provides standards for security categorization of federal systems; and FIPS 197, which defines the Advanced Encryption Standard (AES). NIST also hosts the National Center for Standards and Certification Information (NCSCI), which provides information on US standards and technical regulations, as well as other national, regional, and international standards.

The Office of Management and Budget (OMB) assists the President of the United States in the development of budget, management, and regulatory policies. OMB's products include OMB Circulars and OMB Memoranda, which are instructions or information issued to federal agencies. Some of these documents mandate the use of particular security standards or require federal agencies to meet other security requirements. For example, OMB Circular A-130 pertains to the management of federal information resources, and OMB Memorandum M-07-16 mandates security controls to protect the confidentiality of personally identifiable information.

## 4 GETTING INVOLVED IN STANDARDS DEVELOPMENT

In addition to those mentioned above, there are many other cyber security standards developers already working on creating new standards. The ICT Security Standards Roadmap provides information on a number of ongoing standards activities. Organizations interested in cyber security standards development can join existing standards efforts so that they can ensure that standards are developed in a way that is favorable to, or at least compatible with, their critical interests.

In addition to influencing the direction that a standard takes, actively participating in the standards development process offers other advantages. An organization gains a better understanding of the standards under development, their underlying designs,

the trade-offs and compromises made during their development, and the operating conditions and environments they are intended to serve. Organizations make contacts and build relationships with technical experts involved in the development effort, as well as improving their own technical knowledge. Participation in standards development also benefits the security community by sharing the effort across many organizations.

Most organizations do not participate in standards development activities. They may feel that it is not important, that it is impossible to influence the outcome, or that involvement is too expensive. Nevertheless, participation can be critical to realizing the benefits of standards. Also, organizations that choose not to get involved can find themselves faced with new standards with which they are not prepared to comply.

There are a number of ways to participate in the standards development process, each with its own level of resource commitment. Organizations can choose how fully to participate, depending upon the importance of the standard to the organization and the resources they have available to commit to the effort. *Trackers* follow the development of a standard at a high level, for example, by reading summaries and implementation timelines on the developer's public website. Tracking the progress of a new standard gives organizations the ability to anticipate its effects, even if they choose not to become more actively involved in its development. *Public reviewers* review drafts of the standard and submit comments, which can influence the content and impact of a standard under development. For particularly important standards, organizations should consider becoming *members* of the entity developing the standards. The role of *driver* may be appropriate when the organization's stake in a new standard is critical. It may be that producing the standard is part of the organization's charter or mission; driving the development of a standard may require significant resources.

In addition to contributing to the development of new standards, organizations should also consider participating in the maintenance of existing standards. Most standards undergo periodic review and revision. SDOs typically have established formal maintenance programs to help ensure that their standards do not become dated due to technological evolution, changes to related standards, or other causes.

# CYBER SECURITY METRICS AND MEASURES

PAUL E. BLACK, KAREN SCARFONE, AND MURUGIAH SOUPPAYA
*National Institute of Standards and Technology, Gaithersburg, Maryland*

## 1 INTRODUCTION

Cyber security metrics and measures can help organizations (i) verify that their security controls are in compliance with a policy, process, or procedure; (ii) identify their security strengths and weaknesses; and (iii) identify security trends, both within and outside the organization's control. Studying trends allows an organization to monitor its security performance over time and to identify changes that necessitate adjustments in the organization's security posture. At a higher level, these benefits can be combined to help an organization achieve its mission by (i) evaluating its compliance with legislation and regulations, (ii) improving the performance of its implemented security controls, and (iii) answering high-level business questions regarding security, which facilitate strategic decision making by the organization's highest levels of management. This article defines some terms, and then discusses the current state of security metrics, focusing on the measurement of operational security using existing data collected at the information system level. This article explains the importance of selecting measures that support particular metrics and then examines several problems with current practices related to the accuracy, selection, and use of measures and metrics. The article also presents an overview of a security metrics research effort, to illustrate the current state of metrics research, and suggests additional research topics.

## 2 CONTRASTING METRICS AND MEASURES

The term *metric* is often used to refer to the measurement of performance, but it is clearer to define metrics and measures separately. A *measure* is a concrete, objective attribute, such as the percentage of systems within an organization that are fully patched, the length of time between the release of a patch and its installation on a system, or the level of access to a system that a vulnerability in the system could provide. A *metric* is an abstract, somewhat subjective attribute, such as how well an organization's systems are secured against external threats or how effective the organization's incident response team is. An analyst can approximate the value of a metric by collecting and analyzing groups of measures, as is explained later.

Historically, many metrics efforts have focused on collecting individual measures, and given little or no thought as to how those measures could be combined into metrics. Ideally, organizations should first select their metrics, and then determine what measures they can perform that support those metrics. An organization should also have multiple

levels of metrics, each geared toward a particular type of audience. For example, technical security staff might be interested in lower-level metrics related to the effectiveness of particular types of security controls, such as malicious code detection capabilities. Security management might be interested in higher-level metrics regarding the organization's security posture, such as the overall effectiveness of the organization's incident prevention and handling capabilities. Lower-level metrics facilitate making more tactical decisions, whereas higher-level metrics are well suited for making more strategic decisions. The lower-level metrics are often used as input to the higher-level metrics.

Organizations can use measures and metrics to set goals, also known as *benchmarks*, and determine success or failure against the benchmarks. For example, suppose that an organization determines that 68% of its systems are in compliance with a particular policy. The organization could set a benchmark of 80%, implement changes in its practices to increase compliance, and then measure compliance again in six months to see if the benchmark has been achieved. Benchmarks are organization specific and are typically based on baselines from an operational environment.

## 3 SELECTING MEASURES TO SUPPORT METRICS

Once an organization has identified its metrics, it then needs to determine what measures can feasibly be collected to support those metrics. Organizations should favor measures that can be collected via automated means because they are more likely to be accurate than manual collection (e.g. self-evaluation surveys) and can also be collected as often as needed. Organizations should also seek opportunities to use existing data sources and automated collection mechanisms because of the cost of implementing and maintaining new systems and software simply for data collection purposes.

As measures are collected, organizations need a way to analyze them and generate reports for the metrics they support. Organizations can analyze the measures and metrics in many ways, such as grouping them by geographic location, logical division within the organization, system type, system criticality, and so on. Some organizations use products that roll up measures into metrics and present the metrics in a security dashboard format, with the measures underlying each metric available through drill-down. This allows a dashboard user to see the values of the presented metrics and changes in those metrics over time, as well as to examine the metrics and measures comprising those metrics.

## 4 PROBLEMS WITH THE ACCURACY OF MEASURES

The accuracy of a metric is by definition dependent on the accuracy of the measures that comprise the metric. Organizations currently face several problems related to the accuracy of measures. One problem is that measures are often defined imprecisely. Consider the percentage of systems that are fully patched: does this only include operating system patches or does it also include service and application patches? Does it only mean that the patches have been installed or that subsequent actions necessary to activate the patch (such as rebooting the system or changing configuration settings) have also

been performed? Another issue with measure definition is the terminology itself, such as measuring the number of port scans performed. What is the minimum number of ports that must be scanned in a port scan? If an attacker scans ports on 100 hosts, is it one port scan or 100 port scans? If the attacker performed the same scan but only scanned one host each day, is it one port scan or 100 port scans?

Measuring port scans is also a good example of a related common problem—inconsistent measurement methods. Port scans are often identified by intrusion detection systems (IDSs), but each IDS uses its own proprietary algorithms for identifying port scans, so activity identified as a port scan by one IDS may not be identified as such by another. This causes inconsistency in measurement if the organization uses multiple IDSs or if a single product is in use but its sensors have different port scan settings (e.g. the minimum number of ports in a scan or the maximum length of time to track a scan). Another example is system patch status—one operating system might report only on operating system patches, while another operating system might also include some application patches. In such a case, an organization could use multiple measures instead of one, with each measure corresponding to a different measurement method, and then combine the measures into a metric that approximates the collective values of the measures.

Many instances of problems with imprecise measure definitions have been mentioned in the security community, but to date no concerted effort has been made to exhaustively gather information on these problems, document it, and make it available to the security community. It would be much more helpful to identify the factors that organizations should consider when defining their measures than to attempt to provide a single definition for each measure. The best definition for an organization is driven by what the organization is trying to accomplish. For example, in the patching example mentioned above, an organization might be trying to gain insights on general patch distribution and installation practices to verify that all applications deemed critical by the organization have been patched or to verify that the organization's patch management software is functioning properly (e.g. patches are installed and operate properly based on a predefined schedule).

Another common problem with the accuracy of measures is the use of qualitative measures. As mentioned earlier, data collection methods such as self-evaluation surveys often produce inaccurate or skewed results, depending on the types of questions asked. For example, if users or administrators are asked if their systems comply with the organization's policies, they are very likely to say that they do. It would be more accurate to instead use quantitative measures that assess the systems' compliance. Qualitative measures that do not have well-defined scales or units of measure can be particularly problematic in terms of accuracy. For instance, asking a user to rate the reliability of their computer on a scale of 1–5 where 1 is simply defined as "poor" and 5 as "excellent" is subjective and imprecise. A qualitative measure may be useful if each rating is defined clearly without overlap between the ratings, so that different people, when given the same information, would be likely to assign the same rating. An objective scale might be 5—no crashes or hangs in six months, 4—one crash or hang, 3—two or three instances, 2—four to six instances, and 1—more than six instances. The rating may still be somewhat subjective because it is dependent on the user's recall or because "crash" and "hang" are not defined. Nonetheless, this qualitative measure is more precise than "poor" to "excellent".

Some measures are also considered qualitative because they provide absolute counts without a context, norm, or goal. For example, a measure that indicates that 100 attacks were attempted has no context. What is the period of time? Is 100 a lot or a little? A measure that indicates that 100 attacks were attempted out of 1,000,000 incoming Web server connections adds context.

Context is very important to measures and metrics. Most measures individually have little meaning. Even the example above—the number of attempted attacks per million incoming Web server connections—does not have much meaning by itself. Is the rate of attempted attacks rising, falling, or staying steady? Have any changes been made to the organization's security controls that would change how effectively they can detect attacks or has there truly been a change in the number of attacks? Do changes in the rate of attempted attacks correspond to observations about attack trends reported by other organizations? A single measure may need to be analyzed in context with several other measures, as well as separate events such as security control changes and external trends, to determine its true significance. It would be helpful to organizations to have additional information compiled on the relationships between measures and between measures and separate events, particularly if it includes empirical information based on analyses of real-world operational environments.

Also, because cyber technology is so dynamic, the meaning of measures and metrics changes over time. For example, a measure may have shown an increase in attacks succeeding last year, and the organization determined through other measures and knowledge of external events that this was primarily due to an increase in phishing attacks. This year antiphishing technologies are deployed, but the success rate for attacks continues to increase. Is this due to improved attack techniques, improperly configured antiphishing technologies, inadequately trained users, or other factors? Next year, there may be additional factors that influence the significance of the measure, as well as different relative importances for the existing factors.

## 5 PROBLEMS WITH THE SELECTION OF MEASURES

Most organizations have many existing sources of security measures, automatically generated by enterprise security controls such as antivirus and antispyware software, intrusion detection systems, firewalls, patch management systems, and vulnerability scanners. There may be accuracy issues with some of these measures, but this can still leave an organization with many existing measures from which to choose. Organizations could also create additional measures such as utilities to extract information from security logs, but there may be considerable cost in creating and deploying software and, in some cases, entire systems to collect such measures.

Some organizations collect many measures under the assumption that it is better to have more information than less information, or because it is easier to collect a lot of measures than it is to create a set of metrics and then determine which measures support those metrics. Collecting measures without evaluating their usefulness and having a plan for how to use them has several disadvantages. Firstly, it can waste considerable time and resources to collect, analyze, and report measures: only the measures that support the organization-selected metrics are generally needed. Secondly, if the measures are not selected and organized so that the dependencies between the measures

are clear and accurately represented in the corresponding metrics, analysis of the measures and related metrics is likely to generate misleading results. Thirdly, it often causes people involved in the measure collection process to feel that the effort is a waste of time, because it is unclear what value there is in collecting so many measures. Another reason is that if people are allowed to choose which measures they will collect and share with others, they are more likely to collect measures that demonstrate positive results (e.g. 100% of desktop computers have antivirus software installed) than measures that demonstrate negative results (e.g. 15% of antivirus software installations are up to date).

Currently, there are many suggestions in the security community for what measures organizations should collect. However, little work has been done to determine the value of these measures in real-world operational environments, including which measures are most supportive of particular metrics. For example, suppose that an organization wants a metric for how effectively its security controls detect and stop attacks. Dozens, if not hundreds, of measures that could support this metric have been suggested by the security community, but little research has been done as to which of those measures are most closely correlated with the metric. If the characteristics of real-world operations were studied and analyzed, it may become apparent which measures are most indicative of the overall security posture and which measures are of little or no value. It might also be possible to approximate a metric by using just a few carefully selected measures.

## 6 PROBLEMS WITH THE USE OF MEASURES

In addition to issues with measure accuracy and selection, many organizations also face challenges involving the use of measures. Some of these challenges, such as ensuring that the selected measures support the determination of the chosen metrics, have been discussed earlier. Another common challenge is determining how to combine the values of the measures into a metric. The measures may use different units of measurement, have different scales, and have varying precision; these issues can be addressed through careful creation of equations to combine the values. Also, some of the measures may be more important than others in the scope of the metric; however, it is often difficult to quantify what weight each measure should be given. Empirical research in this area could provide organizations with a factual basis for weighting measures instead of either guessing or weighting each measure equally.

Organizations need to recognize that over time, they will need to alter their measures and metrics. Although high-level metrics may stay the same, low-level metrics need to change over time as the security posture of the organization changes. For example, an organization with relatively immature security practices may need to initially focus on measures and metrics involving its most basic security controls, such as what percentage of computers are protected by antivirus software. As the organization's security controls mature, these metrics may become less useful, and the organization may want to answer new questions, such as how effective its security controls are at stopping malware. This may require the development of new metrics and corresponding measures, and the collection of the old metrics and measures can be stopped if the organization no longer finds them to be of value.

## 7 COMMON VULNERABILITY SCORING SYSTEM (CVSS)

To better illustrate the current state of research on security metrics, we will examine an ongoing research effort for metrics that indicate the significance of vulnerabilities in systems. The Common Vulnerability Scoring System (CVSS) is a standard for assessing the severity of flaws in operating system and application software [1]. CVSS is composed of three sets of measures: base measures that are constant over time, temporal measures that change over time but are the same for all environments, and environmental measures that may be different for each environment. There is a different equation for each set of measures, and the result of each equation is a score—a base, temporal, or environmental score—that is in essence a metric. The measures are for particular characteristics of each vulnerability, such as whether it can be exploited remotely (over a network) and to what degree the confidentiality, integrity, and availability of a target could be impacted. The score metric is intended to give a general indication of the relative severity of the vulnerability.

The initial version of the CVSS measures, equations, and metrics were released in 2005. On the basis of feedback from their real-world use, particularly examination of empirical measure and metric data by security experts, deficiencies in the CVSS standard were identified. The measures, equations, and metrics, as well as the corresponding documentation, have all been revised to make the measures more consistent and to improve the accuracy of the metric scores. Version 2 of the CVSS standard was released in mid-2007.

CVSS is most commonly used by organizations to prioritize their vulnerability mitigation activities, such as applying patches to systems. However, researchers are investigating other uses for CVSS. For example, work has been done at the National Institute of Standards and Technology (NIST) on using CVSS to determine metrics for security-related software configuration settings [2]. Researchers at Veracode are looking at using CVSS to rate software weaknesses [3]. There is also interest in bringing CVSS scores down from the enterprise level to the individual system level so that CVSS could be used to help assess the overall vulnerability of individual systems. To accomplish this, considerable research and empirical validation are needed for applying CVSS to software configuration settings and weaknesses, as well as a new way of measuring the strength of security controls on individual systems.

## 8 RESEARCH DIRECTIONS

Literature contains hundreds of measures. Research is needed to validate connections between measures and security, determine correlations, and model effects. Although there is some readily accessible data, for example, National Vulnerability Database [4] and A Chronology of Data Breaches [5], such research and analysis require more and higher-quality data. State laws requiring companies to notify consumers of data breaches have the benefit of supplying data. Additional information can come from developing or articulating motivations for organizations to share information, as is the practice for business case studies or the airline industry.

Beyond measures, a secure nation needs research to understand which metrics lead to higher security, the measures supporting those metrics, and analytical methods to aggregate measures.

# TRUSTED PLATFORMS: THE ROOT OF SECURITY

ROGER L. KAY
*Endpoint Technologies Associates, Inc., Wayland, Massachusetts*

## 1 INTRODUCTION

The ancient adage admonishes that a chain is only as strong as its weakest link, but this maxim might as well have been coined for computer security. A chain of trust is only as trustworthy as its most vulnerable node or layer. The computing industry has long understood this principle and has even generated adequate technological solutions. Two challenges remain unmet, however: standardization and adoption. Toward the end of the Millennium, IBM and its partners in the development of trusted architectures realized that no solution would work unless it was adopted universally. The industry embraced the principle of standardized security, even before 9/11, but all the more ardently since. Hardware manufacturers and software platform developers agreed that hardware-based security was necessary as the root of trust, and the industry embodied the basic standard in hardware circuitry, essentially a silicon chip. This circuitry ships with an ever growing proportion of personal computers, smart phones, and particularly embedded devices, but has not been put into use widely, particularly in its broader manifestation among devices across a network. Although the circuitry is in the computer, it remains inactive for the most part. Usage, such as it is, is mainly restricted to user-to-platform authentication and password management. Thus, the pace of implementation of secure base computing in the decade succeeding 9/11 has slowed to a crawl, as users await software that makes better use of the secure hardware, and remaining standardization issues get sorted out. There are some exceptions, islands of adoption, and areas of usefulness, but much of the work lies ahead.

## 2 THE STATE OF TRUSTED COMPUTING

It did not take the computing industry long to realize what an optimal security architecture looked like. Work done on encryption had shown that key pairs based on large prime numbers, generated through Public Key Infrastructure (PKI) technology [1], were the mathematically simplest and best way to create robust keys that could be used to encode and decode data securely as well as to identify a user publicly and authenticate a user privately. PKI creates key pairs, sometimes several sets. Each pair has a private and public key. Each is mathematically related to the other, but neither can be derived from the other. True to its name, the public key, everyone knows. If you send me something encoded in my public key, no one can intercept it or make sense of it, but I can open

it with my private key. If I send you something encoded with my private key and you can decrypt it with my public key, knowing it is me because no one else has my private key.

Important to this architecture's viability is the fact that sender and receiver need never share a secret. And the same relationship between sender and receiver holds between any two nodes in the infrastructure (e.g. hardware and firmware, operating system and application within a system, or any two adjacent communications points within the network). As long as each element or layer can be publicly identified and privately authenticated, the chain of trust can be extended through it.

Keys are large and difficult to crack. Theoretically, a key domain can be expanded to the point of precluding a crack, but this degree of security is not desirable for practical reasons. Arguably, "commercial-grade" security, whose primary job is to rapidly encrypt and decrypt transactional data in high volumes, is sufficient and the type of security appropriate for military-grade protection is unnecessary. It is typical of the commercial world that none of the transactions is of earth-shattering importance. However, all these transactions taken together represent a profile of the business in question and therefore need to be kept from prying eyes.

In fact, the PKI algorithm is asymmetrical; that is, it is a "one-way" formula. The metaphor is breaking a champagne glass. It is easy to turn a glass into shards by throwing it into a fireplace, but extremely difficult to reassemble a glass from shards in a fireplace. This characteristic helps make PKI hard to break, but it is also a reason that PKI is slow [2]. For this reason, a different algorithm, Advanced Encryption Standard (AES), a method that has the virtue of being symmetrical but the weakness of requiring a shared secret, is used for bulk encryption. Called *Triple AES*, the data is wrapped three times in AES encryption, a method deemed sufficient to stave off most intruders. The shared secret, which is a relative handful of code, is encoded with the heavier weight, more robust PKI algorithm, and thus the data is safe, whether in flight (i.e. traveling over data communication lines) or at rest (i.e. sitting on a hard drive).

In the late 1990s, when the original architecture for trusted computing was being forged, IBM, the senior partner on the development team, realized that the elegance of PKI could only be realized if everyone agreed to adhere to the same standard. After all, if the public is to know that *I am me*, it must be all the public and not just some of it. And if I want to send something to you that only you can see, I can do so only if I have access to your public key and you and only you have your private key within a system that recognizes both as being part of the same pair. None of this can work if separate domains exist. Potentially, one needs to interact with someone else.

Seeing developments swinging in this direction, IBM realized that it could not propagate the system on its own. Rivals would perceive the move as an attempt to control the industry at a choke point. So, the company changed course and decided to contribute its intellectual property to a neutral industry body and work with other vendors to bring everyone over to the new standard. That group evolved into the Trusted Computing Group (TCG), which is now comprised of most of the key players in the information technology industry.

The membership of the TCG, 140 companies drawn from all geographies, has spent the past decade refining and promoting standardized security for a number of platforms and circumstances. The TCG board includes AMD, Fujitsu Limited, Hewlett-Packard, IBM, Infineon, Intel, Lenovo, Microsoft, Seagate, Sun Microsystems, and Wave Systems [3].

### 2.1 Why Hardware Security?

A primary reason that the TCG decided to back hardware-based security is its clear superiority over software-based solutions. Of course, every solution has software, but the critical issue is how keys are created and handled. Because a software-only solution requires that a key, the algorithm that uses the key, and the data to be encrypted all reside in main memory at the same time in order to function, the key is vulnerable.

This fact was proven in January 2000, when researchers at nCipher in Cambridge, England, came up with an algorithm that can search main memory, looking for a high degree of entropy [4]. A good private key is going to be exceedingly entropic; that is the random numbers in the key will be well dispersed in numeric space. Other elements in memory—such as the clear text to be encrypted and the encryption program itself—will not be. Since all three—the program, the data, and the key—have to be in main memory at the same time for software encryption to take place, the nCipher algorithm could allow an intruder to scan the contents of main memory and find the user's private key. The nCipher program has been able to find a 1,024-bit private key, the best in commercial use at the time [5].

Another weakness of software solutions is that they cannot prevent "hammering," the practice of trying one possible key after another in rapid fire, because they are unable to keep a counter. A hacker can always freeze the state of the machine and continue to bombard it with attempts. Hardware security cannot be bypassed in this way and thus can institute a progressive lock-out program if too many password attempts are made. This type of program increases the delay between log-in offers after a set number of failed attempts. But, as a reason to avoid software-only security solutions, the hammering flaw pales beside the problem of leaving highly entropic private keys around in main memory.

### 2.2 Essentials of Trusted Computing

Thus, the industry agreed to pursue an architecture based on a hardware implementation of established security principles. The actual hardware involved circuitry insulated from the main computing mechanism. This circuitry, named the Trusted Platform Module (TPM), contained read-only memory, preloaded with the basic security program and a small amount of memory for storing keys generated by the program [6]. The circuitry, in its discrete implementation (a separate chip as opposed to a section of a larger chip), was connected to the processor via a secure bus, and in the off chance that this bus was attacked, the mechanism was designed to flag that it was in an insecure state. A bus attack became less of an issue with integrated implementations, as when the TPM circuitry is added as a module to core logic, the I/O chip, or even the processor itself.

A generic view of TPM architecture shows how it sits on a bus connected to core logic (Fig. 1). The trusted platform provides three basic elements: protected capabilities, integrity measurement, and integrity reporting. Protected capabilities are a set of commands that can access shielded locations (e.g. in memory, in the registry), where data operations can take place safely. The TPM uses shielded locations to protect and report integrity measurements. In addition, the TPM generates and stores cryptographic keys used to authenticate reported measurements.

Among other functions, the TPM can attest to the reliability of a platform, providing proof of a set of the platform's integrity measurements through digital signing. Also, the

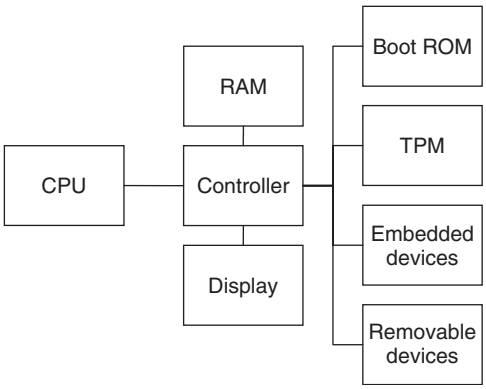

**FIGURE 1** Reference PC platform containing a TPM.

TPM can be used to authenticate a platform, a user, or both. Since the TPM is capable of generating an unlimited number of keys, it can be used to authenticate an unlimited number of identities, but in practice the number of identities is relatively few.

Integrity measurement assesses known platform metrics against the system state, stores this information, and reports it. This function is separated from judging the output, which is reserved for a policy entity. All the integrity measurement has to do is report accurately on the state of the computing platform. To do this, three functions—measurement, storage, and reporting—must be the basis for the roots of trust.

Outside the protected area, other building blocks based on the roots of trust do not have to be shielded. These building blocks include elements that may reside in main memory, core logic, the boot ROM, the processor, and I/O devices (Fig. 2). A combination of the roots of trust and the trusted building blocks constitutes a trusted boundary, within which measurement, storage, and reporting activity can take place. The basic operation consists of measuring an element in its known state, storing that information, and reporting this value when the element is encountered again in an unknown state. If the newly measured value agrees with the stored value, then the element is considered to be in a trusted state.

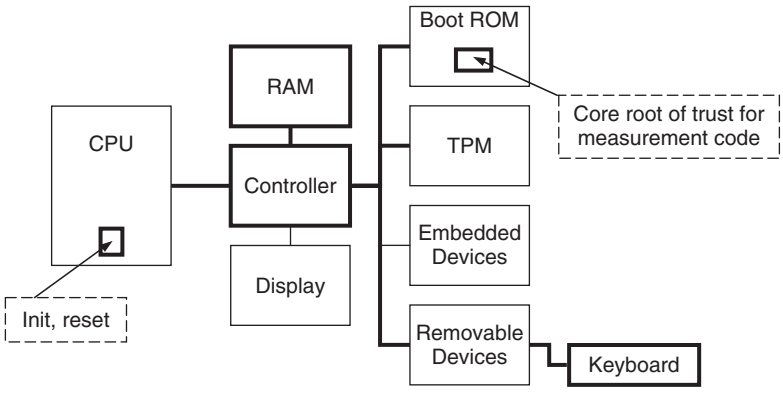

**FIGURE 2** Bold indicates part of the trusted building blocks of a trusted platform.

This basic function can be expanded through a property called *transitivity*. Essentially, the trusted boundary can be expanded if the already-trusted elements are used to attest to the trustworthiness of a secondary set of elements, assuming that the initial state of these secondary elements can be determined to be trustworthy. These secondary elements themselves can then be used to attest to the trustworthiness of a tertiary set, and so on, and the trusted boundary can be expanded theoretically infinitely in a chain of trust, so long as the roots of trust retain their integrity.

An example of transitivity demonstrates how the trusted boundary can be extended through various levels of the computing stack, right up to the application level (Fig. 3).

The TPM is capable of storing mathematically derived representations (hashes) of integrity measurements, which can be compared from time to time or on an event basis with system elements being measured.

A protocol has been established for reporting integrity to a challenger. This protocol involves an exchange of messages between the challenger and the platform, during which an agent on the platform receives the challenge, collects signed information from the TPM, and returns them to the challenger. The protocol is independent of transport and delivery mechanisms and is typical of remote procedure calls, messaging, and communications commonly in use [6].

From this infrastructure, a whole set of credentials can be developed, which allow platforms to gain access to services by disclosing only the minimum amount of identity information. Thus, if a service requires only that a platform be compliant, then it is not necessary to expose to the service the exact identity of the platform, only that it can be reliably said that it meets the compliance requirements. Hence, for example, a mapping service may only need to know that a platform is virus free in order to distribute geographic information to it, not that the platform belongs to a particular entity or individual.

As a communications' endpoint, the TPM is minimally comprised of asymmetric keys, key storage, and processing that protects protocol data items. With these capabilities, the TPM can perform traditional binding (encrypting a message with a public key), signing (using a separate key to compute a hash of the signed message and encrypt it), sealing

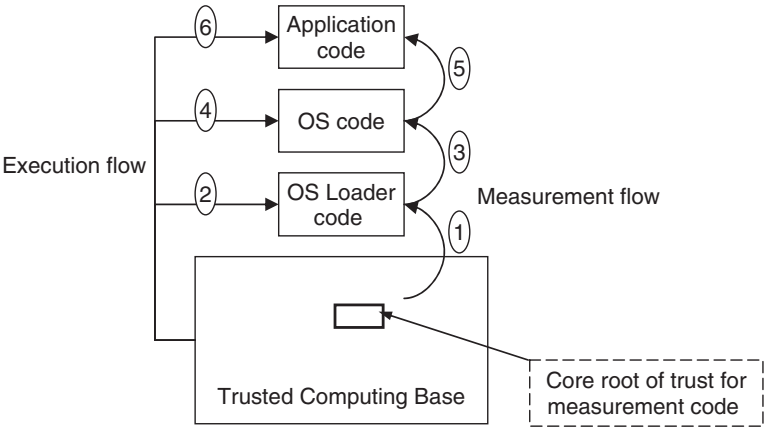

**FIGURE 3** Transitive trust applied to system boot from a static root of trust.

(binding a message further with platform metrics), and signed-sealing (a higher level of verified signing that takes into account the platform's configuration).

### 2.3 Extension to Storage

Although TPMs, despite widespread attachment, have not been put to much use, the architecture has been extended to storage devices successfully. Probably one of the most useful applications for TPM architecture to date has been its implementation in full- and partial drive encryption. Since the chain of trust can be extended to progressively larger areas, widening the trusted boundary, the hard drive is a natural candidate for inclusion inside the boundary.

Hard drives contain, in static form, all the most valuable information on a computer. Particularly given that an increasing proportion of personal computers are now mobile, the hard drive is constantly exposed to potential threats. The portable computer can be outright stolen, the drive can be read through the standard user interface, or its contents can be extracted by various means. It is highly important to encrypt the drive contents in such a manner that the information is readable only by authorized individuals and processes, but it is also critical that this encryption is easy enough to perform and fast enough so that the user is not tempted to eschew it. Drive encryption can be enforced by policy, but it still needs to be sufficiently usable so that ordinary operations can be conducted in a straightforward way. In schema available commercially today, encrypted data is written to the hard drive when the user execute a simple "save," and it is decrypted when the user performs a simple "open." The overhead of the encryption process is low enough so that, with modern high-speed processors, the user barely notices.

### 2.4 Biometric Devices as Physical Interface

One of the key issues with deployment, as opposed to implementation, is that the TPM circuitry is difficult to use. The software available thus far has not been user friendly, and many information technology (IT) managers have, after experimentation, declined to deploy the TPM widely in their organizations, despite its benefits, because of user resistance. This circumstance has left many organizations needlessly vulnerable.

One fairly straightforward way to bring the value of the TPM to the surface of the computer interface is through biometric devices, specifically fingerprint readers. A reader connected to the TPM allows a user to get immediate physical access to the encryption capabilities.

Fingerprint reader suppliers, notably UPEK and AuthenTec, offer software suits that allow a user to tie his or her unique identity to a particular platform without having to remember passwords or carry a secure token. In some circumstances, dual-factor authentication—such as fingerprint and password—may be desirable, but in many cases a fingerprint alone is sufficient.

Although the readers can operate without reference to the TPM, all available models allow for TPM interaction, which is useful since other utilities (e.g. full-drive encryption) may be tied to the TPM. The reader, which resides on the surface of an open laptop near the keyboard, on the keyboard peripheral of a desktop, or in an external device attached via USB connection, is the visible face of encryption, the simple, comprehensible interface through which secure procedures take place.

### 2.5 Usage Model

After failing to reach initial lofty goals of getting the whole world to interact across trusted platforms via standard hardware security, the industry turned to more modest objectives. The goal became to make the single-node experience workable. The areas of focus became user authentication to the platform, most often actuated by fingerprint sensor, file and folder encryption, and password management. File and folder encryption has evolved into full-drive encryption (FDE), which is one of the fastest growing areas of TPM adoption. Because of the hardware implementation, when file and folder encryption is working, the user perceives little latency. Nonetheless, TPM calculations do put a tax on system performance, which will disappear over time as hardware technology improves.

Password management has become the most popular consumer usage. The number of passwords users are called upon to manage has grown along with the Internet, and most people have far more than they can remember, particularly when strong password rules are enforced. It can be a great relief for a user to simply enter the user name and password once, and assign them to a fingerprint-actuated, encrypted password bank. And some utilities can generate strong user-password combinations automatically. Thereafter, the account owner can invoke the site with nothing more than a swipe of the finger. As trusted networking increases, the value of this capability will rise, aided by multifactor authentication backup.

## 3 INTERNATIONAL SCOPE

Over time, the TPM standard has been incorporated into basic technology. Microsoft uses the TPM to drive BitLocker, the FDE solution that the company incorporated into Vista, its mainstream operating system. The company continues to extend BitLocker technology to encompass server and mobile form factors. In the second half of 2008, Intel began including TPM support in high-end dual and quad desktops and advanced chipsets. Seagate offers a TPM-based FDE solution for its drives. Among PC hardware OEMs, TPM penetration has been heavier in commercial client lines and less so in consumer, but ecommerce opens a horizon of potential TPM usage among consumers over time. Virtually all embedded applications on kiosks, ATM machines, and factory automation systems now ship with TPM. In addition, the International Organization for Standardization (ISO) has recently approved the TPM specification. Finally, the governments of most countries in Western and Eastern Europe, including the EU as an entity, in Asia, and in North America have backed TPM architecture.

Support for TPM has been widespread geographically. Manufacturers of modules exist on most major continents, and many hardware OEMs ship systems with TPMs. China, Germany, Israel, Japan, Korea, Switzerland, and the United States all host factories that produce chips incorporating TPMs in various ways. TPM circuitry has been produced widely as a dedicated module and has also been realized as an integrated part of other subsystems, such as the processor, I/O chip, or core logic.

### 3.1 Integration

The inexorable economics of trusted computing rests on the simple idea that the wider the standard the better. It is not so much what the standard is exactly as the fact that

it is a standard at all. That is what makes the long-term adoption of this schema for secure storage and transmission of data more likely. As the volume rises, so the likelihood of incorporation in basic silicon, the way Intel has done. Thus, the modules are "free" in the sense that they come with, are there anyway, no extra charge, whether or not they are activated. A sufficiently large transistor budget, thanks to improved silicon processes, has made it simple to add the circuitry to core logic. Over time, this integration will likely lead some of the specialty subsystem vendors to leave the TPM market, but good arguments remain for others to continue to supply discrete modules. Funding in building the trusted stack will thus largely come from vendors in the field, with broad agreement about the architecture by participants and regulatory authorities.

### 3.2 Trusted Software

Software is readily available from many hardware OEMs and some software-only companies. Net-net, the interface, could stand an upgrade. Some of the lack of utilization by patrons of systems shipped with TPMs is due to poor usability. Nonetheless, hardware vendors such as Dell, Hewlett-Packard, and IBM, and software vendor Wave Systems all provide suites for individual and networked platform environments.

### 3.3 Networking Trusted Platforms

Another important and related TCG standard is Trusted Network Connect (TNC), which defines a protocol for any network element to conduct a dialog with any other over a trusted Internet Protocol (IP) network. This technology is in the infancy of its adoption, but long term it provides a powerful basis for ecommerce.

Essentially, a user is authenticated to a platform and a network, and the combination of the user and platform information becomes the basis for a grant of rights and privileges within a trusted network (Fig. 4). Authentication is performed via biometric, often fingerprint, and system information is read. The hash of this calculation becomes the stored value, which has to match on future entries. If it does not, the requestor can be denied entry. The technology is fine-tuned enough so that the concept of quarantine can be introduced. A system can be deemed friendly, but damaged; that is, it might be recognizable, but, for example, its virus signature file is out of date. This system can be granted provisional entry to a quarantined site, where it can be remediated, the virus definition file topped off, or whatever else needs to be done to prepare it for a retry. If it passes after remediation, it is granted its full rights and privileges, even if it is a mobile system connecting over wireless (Fig. 5).

For purchasing purposes, the Department of Defense (DoD), Office of the CIO, is on a several year program, moving toward requiring three infrastructure elements on all clients: a smart card, a fingerprint reader, and TNC connect activated through a TPM. This development is significant because DoD requirements are typically pushed out to contractors and vendors, expanding penetration.

In addition, the National Security Agency (NSA) has approved the TPM for its multiyear "high-assurance program" (HAP), a framework for next generation computing platforms. The effort has involved representatives from industry, academia, and other institutions, who are assembling a series of recommendations. HAP members are working

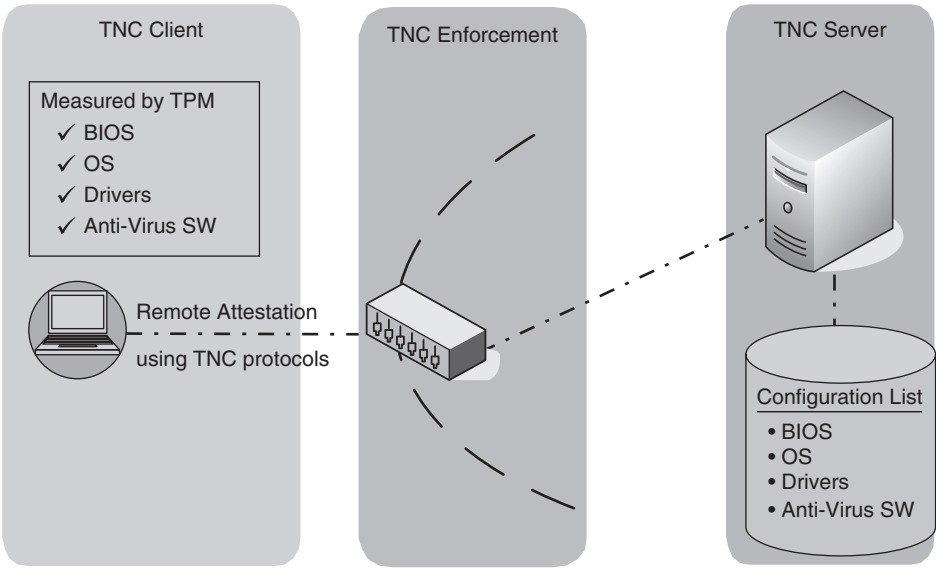

**FIGURE 4** Trusted hardware via the TPM and remote attestation via TNC verify critical client software.

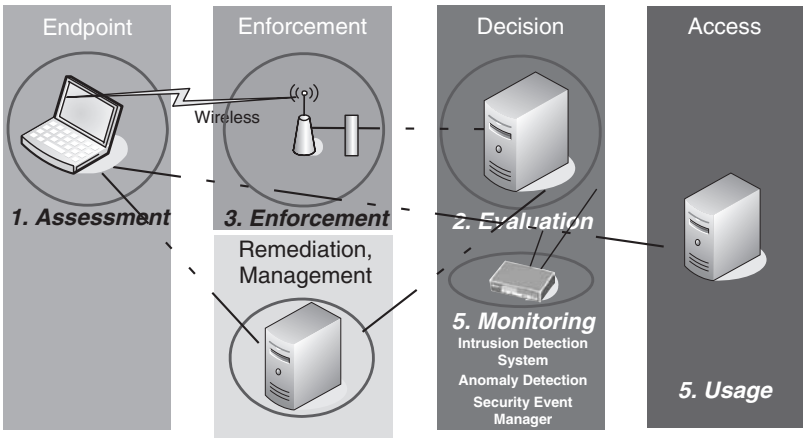

**FIGURE 5** Nodes with various roles challenge the endpoint. Its credentials are evaluated, policies are enforced, remediation occurs as necessary, and ongoing monitoring ensures that the endpoint's credentials remain valid.

with vendors to generate products and create initial applications for three levels of security clearance. With virtualization, these HAP platforms will allow three virtual machines, of varying levels of security, to reside together in a single physical computer. Each virtual machine will use its own TNC credentials to gain access to different networks, depending on its rights and privileges [7].

## 4 EXPANDING THE RING OF TRUST

The trusted computing base, grown as the rings of trusted computing expand, can be extended to vast networks, once the infrastructure is established, providing an umbrella under which eCommerce can be conducted safely. Any extension of trusted architecture benefits the whole. Any node can trust any other node. Friends and enemies are distinguishable. They can be sorted or not, depending on the need.

Thus, promoting the standard is advisable for the U.S. government, specifically with reference to homeland security and counterterrorism departments. Standards can be enforced within specific agencies as the need suggests itself. With an increasingly mobile workforce, trusted architecture can speed and secure remote access by laptops, which often seek a network connection from an unknown address.

While it is true that enemies can also conduct secure conversations and pass around secure communications among themselves, this behavior itself is indicative, and those who are interested can monitor those particular behavior patterns quite closely. Metadata, you could call them, information about the information. That notwithstanding, the value of the open use of common secure architecture outweighs the cost of allowing potentially unfriendly parties to use the same technology.

## 5 REMAINING CHALLENGES

Of course, every system is fallible, but it is useful to think of some helpful secrets sufficiently costly to crack so as to discourage all but the most determined adversary. It is not that back doors are built into these implementations of secure base computing. It is that by their nature, all secrets are subject to discovery. While the potential domain of keys in random space may be large enough to dissuade casual search, that space may be subject to preprocessing designed to intelligently limit it to a smaller portion for brute force hammering. Such techniques, when well funded, can yield results.

Thus, cracking a code could be a $64 problem or a $1 million problem. When the cracks start hitting $10 million, commercial entities back off. Only governments and very focused, well funded players remain in the game. And the stakes are generally small on any given device. Even given that valuable trade secrets reside on hard disks and credit card numbers are bought and sold on the open market, the average hard drive will yield information likely priced in the few hundreds of dollars, if that.

So, with the template for the infrastructure mostly in place, it is reasonable to ask why trusted base computing has not been more widely adopted by the public; that is, utilized, put into service, by IT departments and end users. Some industry watchers put the blame on lack of basic demand, saying the standard is being pushed by the industry and has no core constituency in IT departments and among users [8]. The real answer is probably somewhat less crisp. In fact, software needs to be made easier and public awareness increased. The whole trusted experience needs to be made smoother, and people find it difficult to imagine a capability they knew nothing about previously. The government could take a leading role here, creating a unifying voice. The cost is converging on negligible, and it will soon be included anyway.

Some of the attitude toward authentication and security is in flux in post-9/11 American culture. Before the attack, Americans ranked privacy at the very top of rights they valued,

whereas afterward their right to be proven who they are gained in stature. People want to be known as themselves. If they have to sacrifice a degree of privacy to achieve a clear identity, the cost seems relatively small compared to the value gained. For example, if swiping a finger on a reader gave a traveler rapid access to the flight areas of an airport, speeding the process through security, many users would agree to register a fingerprint.

The government should look at funding the promotion of trusted standards in wide usage. The flourishing of secure eCommerce alone promotes the interests of the United States, which is then the host to a leading-edge technical and social development. Over time, this ideal eCommerce infrastructure can be promoted to international audiences.

# HIGH ASSURANCE: PROVABLY SECURE SYSTEMS AND ARCHITECTURES

RANCE J. DELONG
*Santa Clara University, Santa Clara, California and LynuxWorks, San Jose, California*

## 1 INTRODUCTION

The need for high assurance provably secure systems and architectures is ever increasing due to the severity of the consequences of failure in critical cyber-physical systems and to the motivation of our adversaries to exploit those systems.

## 2 SCIENTIFIC OVERVIEW

### 2.1 Concepts of High Assurance Secure Systems

A *system* is an assembly of hardware and software that exhibits specific functional and nonfunctional properties. A *secure system* is one that, in addition to fulfilling its primary functional purpose, behaves in accordance with a security policy. The primary function delimits useful behaviors that give the system its reason for existence. Secure behaviors may be achieved by mechanisms that implement security functionality, such as authentication and access control, or by architectural structures that, without adding functionality, constrain the behaviors of a system to those that satisfy the desired security policy. To be considered secure, a system must be robust enough to resist attempts to violate the policy. Robustness may be achieved by requiring specific attributes of the design, implementation, or configuration, in concert with functionality that governs the behavior of the system at runtime to avoid actions that violate the security policy.

Unlike functionality, which often may be added or removed without affecting other features, security is a total system property, determining the legality of actions or states within the context of the system as a whole. The security properties of individual components of a system do not necessarily enable us to infer the security of the system as a whole.

Furthermore, security dictates that the system's behaviors comprise specified requirements *and nothing else*. This is a characteristic security shares with safety. Traditional approaches to safety strive to make a system robust in the face of probabilistic failures, while those for security strive to assure that a system is robust in the face of deliberate actions of intelligent and malicious agents. These considerations are not independent. In contrast with improbable random failures, a malicious agent can cause an otherwise improbable condition to occur with certainty. However, the similarities between safety

and security are too great to ignore, particularly considering that many safety-critical systems are subject not only to naturally occurring adverse phenomena but also to threats posed by deliberate human actions. Though typically pursued using distinct disciplines, it is advantageous to unify security and safety objectives and to pursue them together using common methods and tools.

### 2.2 Assurance as a Security Metric

It is said that in order to manage or control something it is necessary to measure it. Appropriately, to determine whether or not security has been achieved, to compare the security merits of alternatives, and, indeed, to manage the very pursuit of security a measure of security is needed. While security functionality is measured much as any other functionality, the system property of security requires a measure that reflects the *trustworthiness* of the system. That role has been filled by *assurance*: the basis for confidence that a system does what it is supposed to do, and does not do what it is not supposed to do. Reliance on assurance as a measure of security is based on the presumption that one could not produce assurance for the security of a system if it were not in fact secure.

Assurance is characterized as high, medium, low, or none, depending upon the extent of the evidence supporting the finding. *Assurance activities* are processes followed and analyses performed in the development or assessment of a secure system. Diverse assurance activities apply to each phase and aspect of development, for example requirements management, implementation standards, inspections, walkthroughs, formal verification, and testing. Traditional assurance activities are the result of experience, supposition, and anecdote, some having a dubious connection to the quality of security. As the needed level of assurance increases, the rigor of assurance activities increases, and the basis for confidence should be made explicit. Future research should strive to replace assurance activities that are costly and of dubious value with those having perspicuous connections to the practical security of a system.

### 2.3 Assessing Security: Evaluation, Certification, and Accreditation

The assessment of security amounts to judging the appropriateness of security functions and the evidence supporting confidence in claimed security properties. Products with a security component are individually subject to security *evaluation* according to the Common Criteria [1] or, for cryptographic components, *certification* according to FIPS PUB 140-2 [2]. Entire systems used in Department of Defense (DoD), intelligence, or other national security applications must undergo security *certification and accreditation* (C&A), a process through which the risks associated with operating a system in a particular environment are assessed, managed, and determined to be acceptable by a designated authority.

Security assessments, whether of products or systems, would not be useful if they did not have objective validity. Consequently, they are performed by independent experts according to established standards and repeatable assessment methodologies.

As a practical matter, production and assessment of assurance evidence are distinct activities. Developers of a system are uniquely positioned to produce the evidence, particularly for high assurance systems, since the evidence should be produced *during development*. According to the Common Criteria, evaluation confirms "that the

information provided [by the developer] meets all requirements for content and presentation of evidence." Evaluators are trained and approved to perform evaluations by a governing body, in the United States by the Common Criteria Evaluation and Validation Scheme (CCEVS).

C&A practices differ among the DoD, the intelligence community, and other government agencies, and often within those communities, making the C&A process a labyrinth. Efforts are underway to unify these practices through the Director of National Intelligence (DNI) CIO C&A revitalization effort [3].

### 2.4 Techniques and Tools for High Assurance

Specialized techniques and tools, and intricate and expensive processes are employed to develop systems with assurance. The highest form of assurance is widely recognized to be that which results from the use of *formal methods*, viz. analyses that establish a direct logical connection between security claims and objective supporting evidence. Formal verification requires a proof that a system possesses a certain property, or is free from a certain kind of flaw.

There are interactive and automated verification methods, each with its strengths and limitations. Other, less rigorous analyses may help to find certain kinds of bugs, but cannot guarantee the absence of bugs. A particular analysis method may be oriented toward a particular kind of property. Suppose we are interested in the property "free of buffer overflows." To perform the analysis one could determine the program features that characterize buffer overflow vulnerabilities, and then search for occurrences within a program of patterns that match those features. A failure to find matching occurrences supports the claim that the program is "free of buffer overflows." If the analysis is *sound*, then when it identifies a buffer overflow, we know it really is a buffer overflow. If the method is *complete*, then we know it will not fail to find a buffer overflow. Only the simplest of such analyses may be both sound and complete. Many analyses are either unsound, incomplete (or both), resulting in imprecision that manifests as false positives (indicating occurrences that are not real problems) and false negatives (failing to find real problems).

Verification requires the construction of a formal model of the system, a formal specification of the properties of interest and of a formal proof showing that the system model exhibits the specified property. The formal model is typically not the actual code but an abstraction of it. The executable code for the system should be developed to correspond closely to the formal model so that there is assurance that the proven properties are preserved in the implementation. Methods that can examine the code itself permit direct verification of the code. Often, the size and detail of the implementation make a direct proof of the code infeasible, and correspondence between the formal model and the code must be established by manual inspection or other informal processes. The Common Criteria, even at the highest assurance level, do not require a formal proof of correspondence between the code and the model. Special implementation languages and techniques, as well as advances in formal verification tools, are making feasible the formalization of the code to model correspondence.

Of central importance to verification is the property or properties to be verified. If the property is simple, the specification of the property may be a "one liner." If total functional correctness is desired, then the specification of the property may be of comparable size to the code. Fortunately, the properties of interest for security may often be

represented in a small number of lines of formal specifications, and only a portion of a system is security enforcing. In fact, it is known that many useful security policies can be reduced to assertions over the state of a system that can be checked by an execution monitor [4].

Formal method techniques and their supporting tools fall roughly into these categories: interactive and automated theorem proving, model checking, abstract interpretation, and other static and dynamic analyses. Interactive theorem proving is labor intensive, and, while it has experienced advancements over the decades, the changes brought about by new technologies, such as decision procedures, SAT solving (boolean satisfiability) [5], SMT solving (satisfiability modulo theories) [6], and model checking [7], have created a disruptive effect on the field, automating more of the verification activity. Model checkers, though subject to the state explosion problem, have increased in performance and can now handle much larger state spaces; and strategies such as abstraction and bounded model checking can cope with infinite state problems. SMT solvers and constraint solvers provide effective automation to a broader range of satisfiability problems.

Each technology has its strengths and weaknesses, and in yearly competitions developers pit their tools against each other. Future research may produce disruptive advancements from the fine-grained application of multiple methods interoperating in novel, mutually supportive combinations [8, p. 5].

### 2.5 Secure Architectures

Many of the principles that apply to systems apply also to architectures, if we regard an architecture as a class of systems that share the same early, or high level, design decisions. Abstractly, an architecture identifies a set of components, their interfaces, and their interactions. An architecture is an underspecified system, in that the details of the components are not specified. Normally, all details of a system design and implementation are considered in the performance of a complete security assessment. We are interested in how an architecture, as an underspecified system, can be said to be secure.

To say that an architecture is secure, one of two conditions must be met. Either the security properties of the architecture are independent of the details of the underspecified portions, or the security of the architecture can be proven by making assumptions concerning particular properties of the underspecified portions. Then, the security of a system based on the architecture is contingent upon proofs that the components corresponding to the underspecified portions possess the assumed properties.

## 3 RESEARCH INITIATIVES WORLDWIDE

Many countries have research programs in high assurance security. Following are a few of these initiatives in the United States and worldwide.

### 3.1 In the United States

Many high assurance security initiatives in the United States, as elsewhere, originate with defense acquisitions, but there are several noteworthy initiatives intended to substantially improve the practice of system security across a broad range of application areas.

Since November 2006, a series of workshops sponsored by NSF, DHS, IARPA, NSA, ONR, and OSD have considered the broad problems of security facing the nation, and approaches that might yield revolutionary improvements. Ranging in size up to 80 invitees, the workshops included many of the leading security experts in the nation. This ongoing activity is intended to produce a research agenda that is highly relevant to current and projected problems, and a "grand challenge" project to showcase the research results. The first meeting, the NSF Safe Computing Workshop, held in November 2006 resulted in an affirmation that the computer security ills facing the nation are real but curable with an appropriate application of resources. Subsequent meetings have elaborated prospective research thrusts. At the NCDI Workshop on Game-Changing Solutions for Cyber Security, in November 2007, 72 technology proposals in 18 topic areas were presented by the attendees.

The DoD sponsors research efforts through DARPA, NSA, NRL, AFRL, and ARL (the Navy, Air Force, and Army Research Labs, respectively) intended to advance high assurance security for application to DoD programs. These efforts include the MILS (Multiple Independent Levels of Security) initiative, the HAP (High Assurance Platform) program, the high robustness VMM (virtual machine monitor), and the Trusted Computing Exemplar (TCX).

The MILS initiative, promoted by AFRL and pursued by a coalition of vendors, integrators, and research labs, seeks to develop a marketplace for high assurance COTS components [9–11]. High assurance MILS systems, providing robust enforcement of application-level and system-level security policies, may be constructed from components in a layered compositional approach. MILS applications are being researched at the University of Idaho under sponsorship from NSA, and MILS theoretical foundations are being researched at SRI International under sponsorship from AFRL and Raytheon. Applied research and MILS product development are being performed by a number of product vendors, including Galois [12], Green Hills [13], LynuxWorks [14], Objective Interface Systems (OIS) [15], real-time innovations (RTI) [16], and Wind River [17].

The HAP Program [18], sponsored by NSA, seeks to develop a well-defined platform architecture that can be built from COTS hardware components, and securely provide access to COTS applications by running COTS operating systems within virtual machines. Specifications have been written for HAP security functions and subsystems, and prototypes have been developed. A series of HAP releases, with increasing levels of assurance and capability, are currently being developed. HAP, a successor to the NSA's NetTop project, is currently being performed by General Dynamics, IBM, and other vendors.

The High Robustness VMM project, being pursued at NRL, seeks to develop a robust VMM by analyzing the open source Xen hypervisor [19] to identify a provably secure subset that can then be enhanced with security features to meet military requirements. "The NRL project has two goals: (i) demonstrate the usefulness of VMMs for realistic security applications and (ii) using Xen, demonstrate how the US Navy, the DoD, and other enterprises with high robustness security requirements can take advantage of open source technology [20, p. 1]."

Since most existing instances of high assurance systems are proprietary and not available for study by students and other developers, the methods remain esoteric and the industry's ability to build such systems falls far short of the demand. The TCX Project, being performed at the Naval Postgraduate School, intends to "provide an openly distributed worked example of how high assurance [sic] trusted computing components can

be built [21, p. 109].” The reference implementation will be taken through high assurance evaluation.

Vendors such as Intel, AMD, IBM [22], and VMware [23] have research programs that include advanced virtualization support and secure hypervisors, while Secure64 [24] is delivering a hardened DNS server based on a small, robust operating system and communication stack.

Finally, Microsoft, though at one time widely maligned for the frequent crashes of the Windows operating system, has taken a prominent role in the assurance research community, with theoretical contributions and a variety of sophisticated tools developed at Microsoft Research [25] that are deployed in the company’s day-to-day software development practice.

In networking, two projects are concerned with the next-generation global communication infrastructure: Global Environment for Network Innovations (GENI) [26], sponsored by NSF, and Stanford University Clean Slate [27], sponsored by NSF and industry. Clean Slate intends to explore designs for the Internet in 15 years. Unlike the original Internet design, these research projects consider security to be an integral element of proposed designs.

### 3.2 Around the World

There are a number of national high assurance system initiatives, such as Germany’s Verisoft and Australia’s L4.verified projects. Similar initiatives are being pursued in Great Britain, France, Italy, and Japan.

The Verisoft project [28] is a long-term project funded by the German Federal Ministry of Education and Research (BMBF). “The main goal of the project is the pervasive formal verification of computer systems. The correct functionality of systems, as they are used, for example, in automotive engineering, in security technology, and in the sector of medical technology, is to be mathematically proved.” [28] The project has produced a verified processor and is working on the software stack.

L4.verified is a collaborative effort of the Australian Government Department of Defense DSTO (Defense Science and Technology Organisation), NICTA (National ICT Australia Limited), and the University of New South Wales. “The L4.verified project is developing a mathematical proof that the seL4 microkernel does exactly what it is intended to do.” [29] The seL4 kernel [30] is a secure version of the internationally known L4 microkernel [31].

Another noteworthy, truly international effort is the Verified Software Initiative (VSI), a series of international conferences and research efforts dedicated to “making verified software a reality within the next 15–20 years.” [32–35] The VSI was inspired by Sir Tony Hoare’s exhortation [36] to take up the goal of developing a verifying compiler as a scientific grand challenge for computing.

## 4 CRITICAL NEED ANALYSIS

Provably secure systems and architectures support critical needs of homeland security and counterterrorism. Their deployment in critical infrastructures can help to avoid mass disruption and crippling economic consequences; and, in military command and control systems to prevent the disabling, degrading, or usurping of military information and

weapon systems. Secrets obtained by hostile nation states or terrorists from the compromise of government or industrial computer systems could be used to harm the country diplomatically, economically or militarily. Subversion during development is a threat as well.

### 4.1 Critical Domestic Infrastructures

Security assessments have demonstrated vulnerabilities in the information systems that control and supervise the resources and processes of the nation's critical infrastructures, such as power, gas and water utilities, transportation systems, financial systems, SCADA (Supervisory Control and Data Acquisition) systems, and Internet-based supply chain support for commerce. Successful hacker or cyber terrorist attacks against these and other systems could wreak economic havoc and jeopardize lives. These infrastructure systems should be hardened, as should be tactical military systems, since in the post-9/11 world they must be viewed as prime targets of cyber-warfare and cyber-terrorism.

### 4.2 Counterterrorism—Critical Intelligence Sharing

A key finding of the 9/11 commission was that government agencies, such as law enforcement and intelligence agencies, did not effectively share information that might have thwarted the terror plot. While directives have subsequently been issued to rectify some of these inadequacies, effective technical measures are still needed to fully enable controlled information sharing. To share information, systems must be connected; to increase connectivity is to increase risk as systems are exposed to users having a range of authorizations. A system must be able to effectively control information whenever any of its users are unauthorized to access all of the information managed by the system. Such a user must be presumed to pose a threat of compromise, and the mechanisms that protect against unauthorized access must be strong enough to withstand a determined and skillful attack.

### 4.3 Contributions from High Assurance Secure Systems

Critical systems must be exceptionally dependable and robust against attack. The Department of Homeland Security's project, "Build Security In" [37], provides "resources that software developers, architects, and security practitioners can use to build security into software in every phase of its development." Initially, this project is focused on the low-hanging fruit of COTS software and commercial low to medium assurance practices, but it calls for collaboration from the community to broaden and deepen the resources presented. The aforementioned MILS and HAP initiatives are stimulating the emergence of affordable technologies that are robust by design and provably secure.

Network-based communications and transactions are even more pervasive and sophisticated. New protocols for such interactions are being designed and deployed regularly. They employ cryptographic operations that must be used appropriately, and the supporting cryptographic mechanisms must be securely embedded into the systems implementing the protocols. Experience has proven that even simple protocols can be wickedly difficult to design without introducing subtle vulnerabilities. Such protocols, and their supporting mechanisms, should be formally analyzed and verified.

## 5 RESEARCH DIRECTIONS

### 5.1 Foundations for Composable High Assurance Systems and Architectures

Previous studies and reports, such as [38] on composable high assurance secure systems, should be pursued to further the field's rigorous theoretical foundations and practical applications. The report urges "establishment and use of soundly based, highly disciplined, and principle-driven architectures, as well as development practices that systematically encompass trustworthiness and assurance as integral parts of what must become coherent development processes and sound subsequent operational practices. Only then can we have any realistic assurances that our computer-communication infrastructures—and indeed our critical national infrastructures—will be able to behave as needed, in times of crisis as well as in normal operation [38, p. ix.]."

### 5.2 Science of Certification

Corresponding to the need to build high assurance systems, there is the need for their effective and timely certification. The classical methods of certification used in security and safety are being taxed by the escalating demands. High assurance certifications of software systems can cost much more than developing the software. Complex and dynamic systems and systems-of-systems simply cannot continue to be certified in the labor-intensive and time-consuming ways of the past, which require scrutiny of the details of every component of the system as well as the structure and function of the system as a whole. A science and logic of certification would enable component-wise, incremental, and just-in-time certification [39]. The needs of both system construction and certification can be met by principled construction methods that produce, as a natural byproduct, the evidence needed for certification and a science of certification would provide the quantitative methods to combine the evidence and reach a certification judgment.

### 5.3 Formal Verification of Critical Properties of Systems

High assurance and provable security depend upon formal methods to model systems and to model and verify the properties that they are intended to exhibit. Such methods have often been very expensive to apply and have come to be considered limited in applicability to relatively simple systems. It should be noted that techniques to overcome such limitations were published in the 1970s! [40]. Technical advancements over the past decade have set the stage for disruptive innovation in formal verification [8]. Interactive theorem proving, the well-established but labor-intensive staple of formal methods, is now accompanied by powerful and highly automated methods, such as SMT, model checking, abstract interpretation, and counterexample-guided abstraction refinement [8]. Needed now are frameworks in which to combine the powerful new methods and tools in more automated ways to attack the old problems more comprehensively, and new, larger problems. The effective combination of methods through communication and interaction frameworks could dramatically advance further research and the power that could be delivered to practitioners.

### 5.4 Verified Software Initiative/Verified Software Repository

The aforementioned Verified Software Initiative has adopted a goal to establish a world-wide Verified Software Repository (VSR) [41].

### 5.5 Integrated Development Environments for High Assurance Systems

Developer tools have been combined through graphical user interface (GUI) to provide developers with unprecedented productivity for conventional software. Such integrated development environments (IDEs) must be extended with tools for high assurance development.

### 5.6 Design Patterns for Provably Secure Systems and Architectures

The monumental effort that goes into proving a system or architecture should be leveraged through reuse of secure design patterns and architectures [42–44].

### 5.7 Test Beds for Development, Integration, and Study of New Approaches

The research community should go beyond publications to share ideas and build on past results. Test beds for providing the integration of experimental systems would enable researchers to build on others' results in a concrete way. This capability would accelerate advancement and lead to innovative new ways of combining current technologies.

### 5.8 Open Source Examples of High Assurance Development

The demand for high assurance security has far outstripped the capacity of the industry to provide provably secure systems and architectures. Most software engineering curricula and development programs for practicing professionals do not teach the principles and methods of high assurance development. Those who are given the task of developing such systems have no obtainable examples upon which to pattern their work, because the few existing examples are proprietary. The aforementioned TCX project is the first of many needed examples. Future research projects should endeavor to go beyond simple examples in areas such as the design and implementation of protocols and cryptographic algorithms.

### 5.9 Next-Generation Processors and Networking Infrastructures

Contemporary processors and networking infrastructures evolved in an environment in which security was not a primary concern. Performance, features, and ease of implementation were the driving factors. Without assurable security as an imperative, these technologies have evolved to a state far from optimal, and in some respects outright inadequate, for the achievement of high assurance and provable security. The dilemma we now face is the enormous investment in the current infrastructure and the procrustean bed of backward compatibility. Research such as GENI and Clean Slate hold promise for networking.

Future processor design must better support high assurance security. The large vendors have had little incentive to undergo high assurance evaluation of their processor designs. The lack of independently evaluated proofs of hardware has left software system verification with an incomplete basis for confidence. The Verisoft project developed a new processor so that every detail of the hardware would be known and could be verified. Since the x86 architecture may reasonably be expected to continue to be dominant, the verification of such processors would be welcomed by the high assurance security community. A preliminary study done by the University of Texas at Austin and Centaur

Technology, a supplier of x86-compatible microprocessors, demonstrates the feasibility of a fully verified commercial microprocessor design [45]. It would be a great benefit to those attempting to develop high assurance and provably secure systems if other hardware vendors were to undertake similar efforts.

## 6 CONCLUSION

We have seen that critical systems are growing in complexity and facing escalating security challenges. The need for high assurance provably secure systems and architectures is ever increasing. We have surveyed concepts in assurance and techniques for achieving it. We presented examples of what has been achieved in the past, what is being pursued currently, and what are the challenges that research must still meet. The cited examples of ongoing research and development efforts represent only a snapshot in time. The field of provably secure systems is evolving rapidly in terms of both challenges and technologies.

# SECURITY OF DISTRIBUTED, UBIQUITOUS, AND EMBEDDED COMPUTING PLATFORMS

ANTHONY D. WOOD AND JOHN A. STANKOVIC
*University of Virginia, Charlottesville, Virginia*

## 1 INTRODUCTION

Computer systems and networks are becoming more capable—and more vulnerable—as they are embedded more deeply into our environment. In this article, we describe security challenges faced by ubiquitous distributed systems: ad hoc networks of handheld computers, sensor networks for directly interacting with the world, and radio frequency identification (RFID) tags that instantiate real-world objects with elements in our virtual computer systems. We review promising research approaches, and identify important future directions in these application areas.

## 2 SCIENTIFIC OVERVIEW

The confluence of wireless networking, increasing transistor densities (Moore's Law), and miniaturization of manufacturing processes has accelerated the deployment of computer networks. Computing devices are now lightweight, portable, unobtrusive, powerful, and more well connected than ever. Adding environmental and biological sensors tightens the connection with the real world, so that computing is not just embedded in non computing devices (like the proverbial Internet toaster), but is embedded in our living spaces.

We focus on three developing technology areas, represented in Figures 1 and 2: ad hoc networks, wireless sensor networks (WSNs), and RFID tags. Their applications range widely and are expanding, including military battlefield awareness, airport surveillance, emergency medical care, disaster response, critical infrastructure monitoring, container tracking, facilities access control, firearm and vehicle immobilizers, currency and travel document fraud detection, and border enforcement.

Security requirements are unique for each application, but overall they are becoming increasingly significant due to several factors. The systems being monitored, controlled, or protected are often critical for economic or safety reasons. Technological societies are becoming more dependent on their proper operation and real-time response. The networks are pervasive in many environments, where they are easily accessible and, therefore, exposed to greater threats. For example, wireless accessibility, while a great convenience, also makes it easier for attackers to find and interact with devices. Finally, the deepening of familiarity with and acceptance of computing devices extends to the unscrupulous, as well. The constant attacks that occur daily on the Internet, from ego-boosting web defacements to vengeful distributed denial of service botnets, may eventually be the norm on any accessible network.

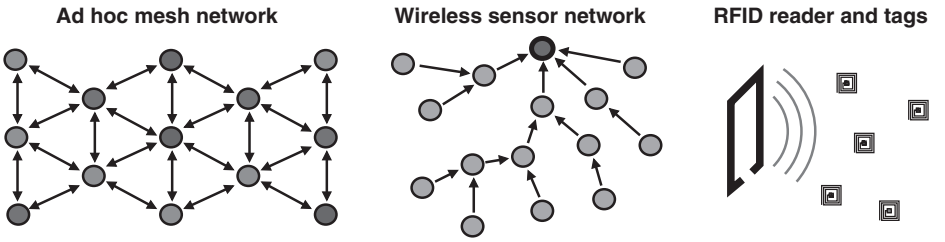

**FIGURE 1** Example network connectivity for an ad hoc network, sensor network, and RFID reader and tags.

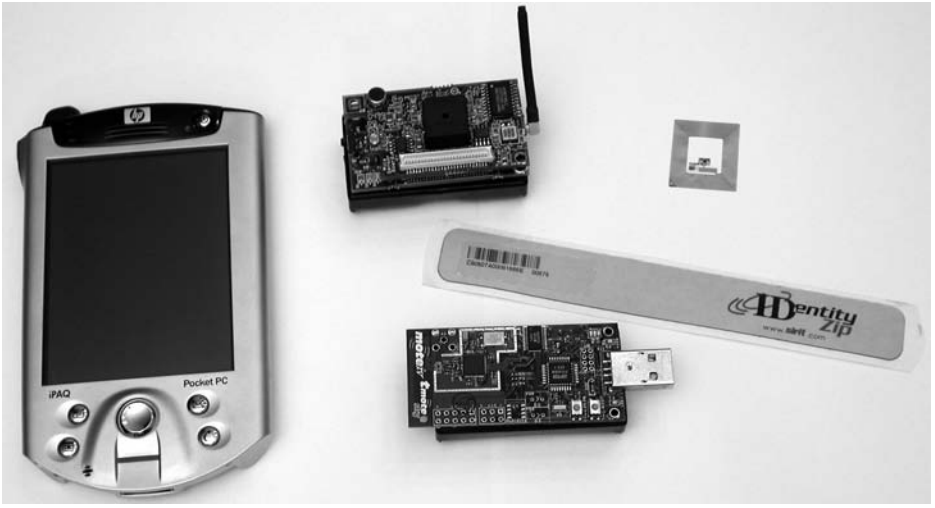

**FIGURE 2** Examples of embedded devices: PDA, sensors, and RFID tags.

### 2.1 Security Properties

Security properties can be distilled to a core set, many of which may be important for a given application. Many others are defined in the literature [1], and here we describe those discussed in this article, giving brief examples of their use.

- *Confidentiality.* Secrecy of communication between parties. Exposure of communications in wireless networks makes eavesdropping a constant threat.
- *Integrity.* Assurance that data has not been modified by an unauthorized party. This applies to messages in transit, records stored in databases, and even data possessed by attackers (such as on stolen smart cards).
- *Authenticity.* Assurance that a message originated from a known other party. Among others, command and control systems require high confidence that actions with large or dangerous effects have been issued by appropriate means. Message authentication codes (MACs) are often appended to protocol messages to provide this property.
- *Identification.* Determination of a contextually unique label for a party. It enables authentication of a party and authorization of actions it may take. Also, a persistent ID allows goods to be tracked through supply chains, from manufacturers to shelves.
- *Authorization.* Determination of privileges from a party's identity. System designs may change the authorized set of actions a party may take based on environmental contexts, for example, granting additional access during medical emergencies.
- *Access control.* Limitations on exposure or modification of protected resources to authorized parties. An RFID token that serves as a "key" for an automobile is a form of access control.
- *Availability.* A service or system performs its function in a timely manner for legitimate users. Denial of service attacks may crash a system completely, or may only slow it down enough to cause significantly disrupted service.
- *Auditability.* Logging of security-relevant actions or events for later analysis. Many attacks cannot be reliably detected in real time, but can be analyzed after the fact to help with future defenses.
- *Tamper resistance.* Ability of a device's packaging and design to withstand physical modification or interrogation. Smart cards, though in public possession, often contain secret keys, which must remain secret to prevent changing credit balances.
- *Nonrepudiation.* Inability of a user or device to deny participation in a protocol or performance of an operation after the fact. This is often related to auditability.

### 2.2 Constraints on the Design Space

Constraints on design are imposed by considerations such as available power, cost to manufacture and maintain, form factor and size, tamper resistance, development effort, the ability to dynamically reprogram, and intended architectures for deployment. Devices in ubiquitous embedded networks form a spectrum of capabilities, from PDAs to passive RFID tags, and are connected together in varying ways.

Ad hoc networks [2] connect (frequently) mobile devices together in a relatively flat mesh and usually depend on peer routing for connectivity (Fig. 1). Hardware typically consists of cell phones, mobile handheld computers (PDAs), and laptop computers, with

relatively powerful processors such as the Intel PXA255 running at 400 MHz. They may use networks with high bandwidth, for example Institute of Electrical and Electronics Engineers (IEEE) 802.11b/g, to deliver multimedia. Storage on internal and removable flash drives with capacity up to 2 GB is common.

WSNs [3] may also use node-to-node ad hoc connectivity, perhaps organized hierarchically with one or more nodes to act as sinks for generated data. Devices are primarily constrained by size, cost, and power. For example, the Crossbow Mica2 family of motes uses the 8-bit Atmel ATMEGA128 processor operating at 8 MHz, with 4 KB RAM and 128 KB flash. Simple Frequency Shift Keying (FSK) modulation at 900 MHz, IEEE 802.15.4, or Bluetooth radio communication is common.

RFID tags [4] are even more limited. Most are completely passive, using the energy of a reader's transmission to briefly power the tag's processing circuit. The tag communicates by modulating the reader's transmission. Tags may be smaller than 1–2 mm (without the antenna), and operate in the high-frequency (HF) band (13.56 MHz) for intermediate range.

Security comes at the cost of memory, computation, and messaging [5, 6]. Ad hoc network devices may be able to afford expensive asymmetric cryptography, storing 1024-bit keys for their neighbors, and participating in multi-round key establishment protocols. Sensor network devices cannot afford this computation and storage expense, unless very efficient elliptic-curve cryptographic (ECC) methods are used only infrequently. Instead, most researchers focus on lighter-weight symmetric cryptography and hashing in this context. Many RFID tags provide no security at all. Those that do may use only hashing or very efficient symmetric methods.

Hence, there are considerable differences in the security approaches that are practical and possible in distributed, embedded, and ubiquitous networks. Next, we describe the state of important research areas in security for these types of systems.

### 2.3 Solution Approaches

Distributed devices typically use layering to modularize hardware and software. Figure 3 shows generic software stacks for ad hoc and wireless sensor devices, and how services may be classified by layer. Because of their limited capabilities, RFID tags may be considered to have only a couple of layers. For this discussion, we abstract away many details unique to each network type.

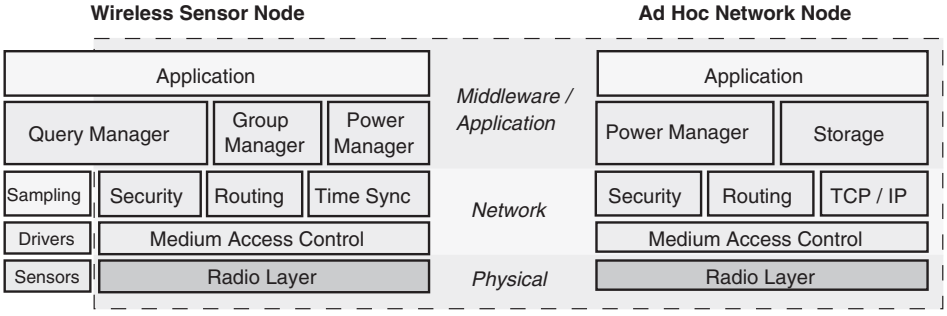

**FIGURE 3** Typical software stacks for wireless sensor network and ad hoc network devices. A dashed box surrounds the communication layers, which contain various services often found in the networks.

Strong security mechanisms at higher layers may be completely subverted by design or coding flaws at lower layers. Nowhere isthis more evident than at the physical layer. Therefore, we describe attacks and defenses proposed in the state of the art by focusing on solutions to securing services at the critical physical, network, and middleware/application layers of the stack, starting at the bottom. We discuss ad hoc, sensor, and RFID networks together in each layer.

### 2.4 Physical Layer

The ubiquity of network devices means that they are easily inspected and probed by attackers. There is by definition no physical access control to sensors that are deployed throughout a public building, in parks, forests, or other open spaces. RFID tags attached to books, clothes, or supplies are necessarily as accessible as the asset they help to track.

The simplest attack is to destroy or disable the devices entirely, creating a denial of service. This is as low-tech as briefly putting a banknote or passport in a microwave oven. However, a destruction attack can often be mitigated using fault-tolerant protocols. For example, a mesh network can continue to operate despite some fraction of the devices being destroyed—remaining connected nodes take over routing. Or, if a passport's RFID tag is destroyed, backup procedures such as optical scanning of barcodes may be used instead.

Probing of the physical device to deconstruct its internals is more powerful and damaging. By reading the contents of memory cells, the secret keys are recovered and then programmed into another device, which can fully masquerade as the original—yet is under attacker control. Messages originated by the clone are fully authentic, and the device can actively participate in formerly inaccessible transactions, as between a smart card and a payment terminal [7].

In addition to invasive techniques that usually require partial depackaging of a device, various physical properties of the circuits can be inspected without leaving a trace. Data-dependent computation affects the power consumption and timing of circuits, which can be analyzed statistically over many trials to determine bit patterns of a key [8]. Faults may be injected using heat or radiation, while the observed behavior is compared with correct behavior. Electromagnetic emissions may be inspected similarly to power consumption.

Proposed solutions include tamper-resistant packaging [7], better attack detection, fault recovery mechanisms, and reducing trust in external components [9]. For example, if a device can detect that it is being tampered with, it may erase its memory to prevent disclosure of sensitive data. Circuits may be shielded by distributing logical components across the die, bus traffic may be encrypted, and data values and timing can be randomized or "blinded" to thwart side-channel attacks.

Devices' use of wireless communication leaves them vulnerable to denial of service by radio jamming, which can be perpetrated at large distances and unobtrusively. Xu et al. propose channel hopping and "retreats" [10] to physically move away from the jammer. This is most appropriate for ad hoc networks, as it may be too energy consuming for sensor devices. Law et al. propose data blurting and changing transmission schedules as countermeasures [11]. Another approach, when the jamming cannot be avoided, is for nodes to determine the extent of the jammed area in a wide-scale network by collaboratively mapping and avoiding the region [12].

### 2.5 Networking Layers

We group the networking layers of the stack together to examine the security needs and vulnerabilities created when connecting multiple devices in networks. Services provided include channel arbitration, link establishment, one-hop data transmission, routing, and end-to-end data transport.

A primary concern is keeping data private, given the innate vulnerability to eavesdropping of wireless networks. Ad hoc networks often use protocols developed for the Internet, such as IPSec [13] and SSL/TLS [14]. Both these protocols allow the use of suites of cryptographic mechanisms to provide authenticity, integrity, and confidentiality of messages. IPSec is commonly used to establish a secure virtual private network (VPN) connection between peers. Secure Sockets Layer/Transport Layer Security (SSL/TLS) operates end-to-end, above an existing Transaction Control Protocol (TCP) connection, and further allows the client and server to negotiate a common set of capabilities. Though asymmetric methods may be used to establish keys and authenticate certificates, symmetric cryptographic protocols are used for data transfer.

In WSNs and RFID devices, symmetric mechanisms are encapsulated in lightweight protocols to provide data security. SPINS [15] provides two-party confidentiality and authenticity with the SNEP protocol. TinySec [16] similarly provides these properties using Skipjack or RC5 ciphers, in a fully implemented and compact form with low overheads.

Because of energy constraints, sensor devices cannot use asymmetric cryptographic operations often. TinyPK [17] is an implementation of the relatively less demanding signature verification and key agreement for sensor devices. Though processing times for a single message may be over a minute (depending on the key length), they argue that it is acceptable for rare events, like code updating. Recent elliptic-curve implementations [18] improve efficiency, making slightly more frequent use of public-key infrastructures possible. For RFID tags with modest resources, researchers have proposed simple authentication and encryption to prevent "skimming," or physical proximity-based interrogation of tags [4].

In addition to neighbor-to-neighbor communication, many networks require secure broadcast and multicast communication. Often a control station must broadcast parameter changes to an entire network, and authentication of these messages is imperative. Both Timed Efficient Stream Loss-tolerant Authentication (TESLA) [19] (for ad hoc networks) and uTESLA [15] (for sensor networks) provide broadcast authentication. A base station commits to a chain of one-way hashes, and then uses each in reverse sequence as a key to authenticate a message. After the message has been distributed, the next key in the chain is released. Network nodes validate that $K_i = H(K_{i-1})$ and deliver the message. If all keys in the chain are exhausted, the base station must again securely distribute the commitment (last value) for a new chain to every network node.

LKHW [20] merges logical key hierarchy (LKH) with directed diffusion to provide secure multicast for groups in sensor networks. Directed diffusion is a routing protocol in which sinks diffuse interests for events, and sources send messages along "interest gradients" that find all sinks. LKHW allows group membership to change and provides backward and forward secrecy.

Any protocol that uses cryptographic protection for confidentiality, integrity, or authentication relies on the presence of shared keys. Many approaches for creating and distributing these keys have been proposed. For public-key algorithms, a traditional centralized key distribution architecture may be used, such as Kerberos [21]. Centralized

key distribution centers can become performance bottlenecks and attractive targets for attacks, however. By using threshold cryptography, the certification function is distributed among multiple authorities, such that at least $k$ out of $n$ are required to grant certificates [22]. This is more resistant to compromise than a centralized approach, but has higher overhead.

Ad hoc network devices often must collaborate together in groups, using secure multicast communication. In the group key management protocol (GKMP) [23], a centralized controller for each group generates and distributes pairwise keys to the other members. The secure spread service [24] provides multiparty key creation using Group Diffie–Hellman, in which each member contributes to the key.

Any scheme that requires cryptography also requires keys. Much research on key distribution in WSNs has focused on distributing secrets prior to deployment [25–28]. Nodes are preloaded with multiple keys from a large key space. After deployment, nodes discover neighbors with whom they share keys, and use these paths to indirectly establish keys with other neighbors. Adding the requirement for nodes to share $q$ common keys improves the protocols' resistance to compromise. Other protocols, such as Localized Encryption and Authentication Protocol (LEAP) [29], use a globally shared key to create pairwise-shared keys with neighbors during a short initialization period. The network is assumed to be free from compromises during this time, and the global key is erased thereafter.

RFID tags interact only with readers and certain special purpose tags, so the security concerns mostly center on identification and authentication. To prevent cloning attacks, a tag may implement lightweight symmetric cryptography or hashing and be programmed with a unique key. A challenge-response protocol prevents replay attacks, and provides simple identification or authentication. With the most constraints on size and cost, RFID tags are often vulnerable to physical attacks such as those described in the previous section.

Tags that respond to any reader or that respond using the same ID or key pose privacy risks. Weis et al. propose using key-search techniques to conceal a tag's identity from any except legitimate readers [30]. The reader receives $H(k_i, N)$ from a tag, for key $k_i$ and nonce $N$, and searches through all keys known to the reader for a match, identifying tag $i$. This is expensive for large numbers of tags, however. Others propose tree-based and synchronization-based schemes to limit the searching necessary, for example, by computing outputs based on an increasing counter.

Ad hoc and sensor networks use devices connected together wirelessly for multihop routing. The use of redundant, dynamic routing paths provides protection against link failures, but it increases the risk of relying on a compromised or adversarial node.

Approaches to securing ad hoc routing have focused on retrofitting existing protocols, or creating new ones to provide desirable properties. Secure Ad hoc On-Demand Distance Vector (SAODV) [31] provides authentication, nonrepudiation, and integrity by means of a protocol extension to Ad hoc On-Demand Distance Vector (AODV) that relies on digital signatures and hashing.

Secure Efficient Ad hoc Distance-vector (SEAD) [32] also addresses security in distance-vector routing protocols, which are suitable for networks with limited mobility. It uses hash chains to secure routing updates, an approach that is more computationally efficient than SAODV and which provides some defense against denial of service attacks.

Protocols such as SEAD and SAODV rely on periodic routing updates, which have high overhead or poor performance when node mobility is high. In these networks, on-demand protocols like Ariadne [33] may be more suitable. Ariadne provides secure

on-demand routing based on the Dynamic Source Routing (DSR) protocol, and requires one of the following: network-wide pairwise-shared keys, neighborhood pairwise-shared keys and broadcast authentication (such as TESLA), or digital signatures.

WSNs require very efficient routing mechanisms, since radio transmission consumes so much of their energy budget. Their unique characteristics also pose special difficulties for secure routing [34]. Addressing the many attacks given the constraints of low-end sensor devices is problematic.

Aggregation of information to a centralized base station is a common communication pattern in WSNs. The authors of SPINS [15] suggest using underlying secure unicast and broadcast links (SNEP and uTESLA, respectively) to form routing trees from nodes back to base stations. LKHW targets communication within groups of collaborating devices (as described above), and secures directed diffusion for routing.

Secure Implicit Geographic Forwarding (SIGF) [35] is a family of routing protocols for WSNs, which allows very lightweight operation when no attacks are present, and stronger defenses—at the cost of overhead—when more attacks are detected. It is a form of on-demand routing based on geographic forwarding, where the message destination is specified as a location toward which each hop makes progress. The set of candidates considered at each hop may be increased, and their selection is randomized to prevent persistent selection of neighboring compromised nodes.

INtrusion-tolerant routing protocol for wireless SEnsor NetworkS (INSENS) [36] is an intrusion tolerant protocol for WSNs that need little or no sensor-to-sensor communication, but which have well-defended base stations. Network topology is collected from sensor devices by the base station. Routes are centrally computed and securely distributed to sensors using one-way hash chain sequence numbers, similar to uTESLA.

### 2.6 Middleware and Applications

Above the networking layers, which are concerned with relatively low-level details of interconnection, middleware and application-layer software provide rich and varied services. Networks connected to the physical world must provide mechanisms for extracting important data to authorized parties for analysis and manipulation. Several protocols have been proposed for querying, aggregating, and validating sensor data collected by WSNs.

Secure information aggregation (SIA) [37] uses special nodes in the network to aggregate sensor data. As data are collected and aggregated, results are reported to the base station along with a commitment to the data. Commitments are formed using a binary Merkle hash tree, which reduces the size of the verification information. The base station may then request particular sensor values from the aggregator in an interactive proof, until results are verified with a desired probability.

For large-scale networks where events of interest are witnessed by multiple sensors, Ye at al. propose statistical en-route filtering (SEF) of injected false data [38]. Nodes compute message authentication codes that are aggregated and sent with the reported data. Intermediate nodes check the MACs probabilistically, dropping incorrect messages. A Bloom filter is used to decrease the cost of aggregating multiple MACs.

Reprogramming widely distributed systems is expensive if it requires manual retrieval and manipulation of unattended devices. Over the network reprogramming alleviates this practical difficulty, but presents significant security concerns. All other hardware and software defenses may be subverted by a flaw that allows an attacker to replace nodes' programs with custom code.

Deng et al. [39] propose related schemes for securely distributing code in WSNs. The first uses a chain of hashes, where each message contains segment $i$ of code and a hash of segment $i + 1$. Upon receipt of a message, the previous code segment can be immediately and efficiently verified. To bootstrap the chain, an ECC signature of the first hash value is computed using the base station's private key. This method is suitable when there is little message loss and packets are received mostly in order. The second scheme uses a hash tree to distribute all the hashes in advance, so that out-of-order packets can be quickly checked. Resistance to denial of service is improved since packets need not be stored if they are corrupt.

SCUBA [40] is a protocol for detecting and recovering compromised nodes in sensor networks. Base stations verify code images on nodes using an indisputable code execution (ICE) facility, which ensures that unmodified self-checksumming code runs on the target in the expected time. The ICE code computes checksums over the ROM, ICE function, and main executable. Incorrect checksums or executions that take too long indicate that malicious code is interfering with proper operation of the device. The result of the full Secure Code Update By Attestation (SCUBA) protocol is a repaired or blacklisted node.

Many applications may be built upon the foundations provided by the protocols we have reviewed: physical and radio-layer protections, secure node-to-node communication, multihop routing, data aggregation, and code updating. System designers must determine the attack model most appropriate for their application domain and deployment environment, carefully choosing protocols that defend against possible attacks and that do not create additional points of vulnerability.

## 3 GLOBAL RESEARCH AND FUNDING

National Science Foundation (NSF)'s Embedded and Hybrid Systems (EHS) Program [41] supports research in many aspects of embedded systems technology. A pervasive theme of the EHS program is the high-confidence integration of real-time and other service guarantees with the coordination requirements of next-generation complex, secure, networked, embedded systems.

NSF's Cyber Trust (CT) Program [42] envisions computer networks that are more reliable, accountable, and resistant to attacks, and a workforce that is well trained and educated to operate them. Research proposals that will target security for applications, security for computer systems, security for networks, and new security foundations are solicited. The entire system life cycle may be considered, and multidisciplinary projects with behavioral and social science participation are encouraged.

The European ARTIST2 Consortium [43] supports the Network of Excellence on Embedded Systems Design, which intends to strengthen European research in this area. The testing and verification cluster targets verification of security properties in designs.

## 4 CRITICAL NEEDS ANALYSIS

Embedded systems have already become ubiquitous, but their composition into large-scale systems for monitoring and controlling the physical world is nascent. Advancements

in this field will enable many advanced applications, such as secure communication for emergency personnel, disaster-site coordination, border patrol, container tracking and inspection, biological and radiological sensing, traffic control, and civil infrastructure monitoring. Realization of these critical applications will be subject to research progress on many technical fronts, including security and privacy.

## 5 RESEARCH DIRECTIONS

Physical-layer security is often a weak spot in embedded devices even when higher layers are provably sound. Tamper-resistant packaging and designs for smart card, RFID, and sensor devices will be necessary for ubiquitous deployments and deserve more research.

Wireless devices expose the system to monitoring by and remote interaction with attackers. More research in resistance to denial of service attacks by jamming, flooding, and invoking expensive computations is needed to enable continued operation of critical components even while attacks are ongoing.

Connecting virtual and physical worlds raises many privacy concerns. Controversies over RFID-enabled passports and banknotes, urban camera networks, tracking of consumer-products post sale, and disclosure of aggregated data by companies and government agencies all portend a complex future of interdependent technical, legal, and political effects on personal privacy. More fundamental research is needed in ways to preserve privacy despite the collection of unprecedented amounts of data in the public and private sectors.

Data collected by WSNs will be useful for many purposes, but may inadvertently disclose sensitive information—even if the data payloads in network are encrypted. Traffic analysis or simple radio-activity detection may reveal to an attacker whether a home is occupied, the nationality of a traveler in a crowd, or the location of important control devices. Comprehensive research that crosses traditional functional layers and includes noncryptographic approaches to information hiding is needed.

# SECURITY OF WEB APPLICATION AND SERVICES AND SERVICE-ORIENTED ARCHITECTURES

MARC GOODNER
*Microsoft, Redmond, Washington*

## 1 INTRODUCTION

Service Oriented Architecture, or SOA, has had many characteristics ascribed to it. It has been hailed as a way for organizations to integrate heterogeneous systems, provide for increased reuse of software assets, provide multichannel access to common components, and as the way to build distributed systems, all while reducing complexity and increasing interoperability. SOA can mean all of these things depending upon how its principles are applied in a given project. Seen as a natural outgrowth of previous software design paradigms, the key distinguishing characteristic it has is facilitating interoperability between distributed software components. As an architectural style for designing software SOA does not mandate one implementation choice over another. While there are many realizations of these principles, Web services is the most pervasive implementation choice for SOA. This is because Web services are platform-agnostic protocols; thus they greatly facilitate interoperability between different implementations. This is critically important in enabling software systems that need to connect new and existing applications in and across environments as heterogeneous as a typical corporation, government agency, or even a home. The security requirements for these applications will vary greatly depending on the type of information they use, the policies of the application users, and the threats to the messages being exchanged. The techniques available to mitigate threats to the security of an SOA-based software application will be the same regardless of whether the threats are from non-state actors, corporate espionage agents or common criminals. From the perspective of homeland security, many of the sources of each of these threats are increasingly blurred due to an emerging common underground economy for those perpetrating the attacks. In that respect it is an imperative that security be a foremost concern in all distributed software implementations. This article will describe the security challenges in SOA, relate them to Web service protocols that address these challenges, and introduce some areas for further consideration.

## 2 SOA SECURITY CHALLENGES

In order to properly discuss the security challenges of SOA let us look a little closer at what SOA is. Newcomer and Lomow provide a succinct description: “A service-oriented architecture is a style of design that guides all aspects of creating and using business services throughout their life cycle (from conception to retirement). An SOA is also

a way to define and provision an IT infrastructure to allow different applications to exchange data and participate in business processes, regardless of the operating systems or programming languages underlying those applications." [1] The following properties of SOA can be derived from the above description:

- *Explicit boundaries.* When exposing functionality as a service it is important that the choice of what to expose is carefully considered. Only what is needed to exchange information should be exposed. What is critical here is that while services are explicitly exposed, nothing should ever be exposed as a service by default;
- *Service autonomy.* The application that supports a service should be independent of the service definition itself. This allows for revisions of the application while keeping the interface used by client applications stable. Services may also need to change their location over time;
- *Contracts.* There needs to be machine-processable formats to produce the necessary message structures for the service. Classes should never be shared to enable invocation of services;
- *Compatibility based on policies.* There also needs to be machine-processable policies in place at a service so that client applications can determine if they are compatible;
- *Interoperability.* Services need to be exposed in a way that facilitates use by the broadest base of applications.

What you can see in SOA are services exposed in a highly interoperable and machine-processable fashion. As SOA has gained the most traction within larger enterprises, it is important to step back and recognize that the environments in which these services are commonly deployed are often secured via tight perimeter controls. To properly secure these services a more granular approach is needed. Remember that a key promise of SOA is re-use. Services may not only find re-use within more areas of the organization that created them, but potentially externally as well as they begin to offer value to an organization's partners. The remainder of this section will focus on specific security concerns and concepts that need to be considered in the design of an SOA-based system. The next section will map these security concerns and concepts to specific Web services protocols.

It is important to state that this section is not intended as a substitute for proper risk analysis of your software design. The concerns and concepts below should be used in a formal risk assessment, not as a checklist. The following advice is based on applied experience in this area: "Before you take any technical steps to implement a specific security structure, you should capture the security requirements for all relevant pieces of software during a risk analysis. Based on this analysis, you build the software architecture to incorporate the defined security requirements" [2].

Choosing explicitly what to expose as a service is an important decision. If something does not need to be exposed as a service, it should not be. Services that are exposed should present the minimum amount of surface area for a malicious client to probe. At the point that a choice to expose a service is made, the decisions about how to protect the service endpoint and the messages it exchanges should also be made. The value of the information contained within the messages exchanged will guide some of the choices during a full risk assessment of what mechanisms to employ. From the client's

perspective, the analysis of the value of the information being exchanged is just as important. Clients should not interact with services that do not meet their own security requirements.

SOA-based systems are vulnerable to threats targeted at the messages they exchange over networks. These threats revolve around classic man-in-the-middle scenarios where messages are intercepted for inspection or alteration. In particular, substitution of messages in whole or in part must be guarded against. For instance, an attacker should not be able to change the message content while leaving security credentials intact; such a condition must be detectable. Similarly messages should not be allowed to be replayed, as that can be used to introduce application errors or cause other problems.

There are many other security challenges that need to be considered in designing an SOA-based system. We will attempt to answer many of these in the remaining space but this list should not be considered exhaustive.

- *Access.* How is access to a service granted?
- *Confidentiality.* How can the contents of a message be kept secret?
- *Integrity.* How can a message be protected from alteration en route to a recipient?
- *Non-repudiation.* How can it be proven that a message was received?
- *Trust.* How can parties in a given interaction rely upon the security credentials of each other?
- *Sessions.* How can a set of messages be exchanged securely?
- *Description.* How can the security requirements of a service be expressed?
- *Federation.* How can resources in one security domain be provided to clients whose identities are managed in another?
- *Identity.* How are the participants in an exchange known?
- *Privacy.* How is inadvertent information disclosure prevented?

There are other questions that cannot be answered within the scope of this paper as the answers are specific to the technologies used in an implementation, or to local requirements.

- *Performance.* Is there a resource penalty for securing services?
- *Audit.* How can messages be traced in a distributed environment?
- *Regulatory compliance.* Are there mandated security requirements from government agencies?

An SOA-based infrastructure may have many different types of client applications present, from large back-end systems and middleware to rich desktop applications and lightweight web clients. This article has not discussed the security issues involved in developing the client applications themselves.

## 3 SECURE WEB SERVICES FOR SOA

The use of Web services is one of the most common implementation strategies for SOA. Web services are widely supported and provide a high degree of interoperability. What

helps to make Web services interoperable is that they are based on XML [3] and a set of standards and specifications that have been developed by a diverse group of software vendors and users, and validated through implementation.

When a service is exposed as a Web service, it is typically exposed with a contract consisting of Web Services Description Language (WSDL) [4] and XML Schema [5]. The WSDL describes the message exchange patterns supported by the service. The XML Schema describes the message formats themselves, especially the application payload. Additional semantics around usage of the service, characteristics such as security and reliability, are expressed via WS-Policy [6]. This allows a client to determine if it is compatible with a given service or not by comparing the service's capabilities to its own. A Web service must have a service location, or address, where it can be accessed. The address is expressed in terms of WS-Addressing [7]. The messages themselves are based on SOAP (Simple Object Access Protocol) [8]. SOAP messages are broken into two basic wrapper elements, the header and the body, both of which are contained in a common "envelope" element. The SOAP header contains infrastructure information; the SOAP body contains the application message payload.

Before going on, it is worth noting that most other strategies for implementing SOA are specific to a particular vendor's software platform. As such, they each must have their own unique strategies for meeting the security challenges with the SOA outlined above. This situation is similar in a standards-based environment of Web services as well which has been described by Thomas Erl: "However, the SOAP messaging communications framework upon which contemporary SOA is built, emphasizes particular aspects of security that need to be accommodated by a security framework designed specifically for Web services." [9] Here, we look at the specifics without needing to consider a specific vendor's platform as we have publicly available specifications and standards to refer to.

Broadly speaking, there are two primary ways to secure Web services: transport, or message-based security.

### 3.1 Transport-Based Security

The most common way to secure Web service messages at the transport layer is SSL (secure sockets layer) or TLS (transport layer security) [10]. It can provide for both confidentiality and integrity, and it has an in-built mechanism for exchanging credentials. It is also widely supported and well-understood. Its use can even be described using WS-SecurityPolicy [11].

SSL/TLS protects communications from one point to the next point. This is satisfactory protection in many cases but it is also a limitation that must be considered when choosing to use it. At any time that communications need to be routed through an intermediary, the SSL/TLS session ends and the message will be in the clear. The lack of the client's visibility to this occurring makes SSL/TLS unacceptable in many cases.

While many think of Web services as being used exclusively over HTTP, they are not bound to that choice alone; they may be used over TCP (Transmission Control Protocol), SMTP (Simple Mail Transfer Protocol), UDP (User Datagram Protocol) etc. SSL/TLS can limit these choices of your underlying transport layer as some, like UDP, cannot support it at all, while others are not broadly supported. SSL/TLS is also limiting in the types of security credentials that can be used in establishing the secure channel. Both of these factors will be overly constraining in many instances.

SSL/TLS is suitable for short-lived sessions, but it does not provide the same capability for long-running protected sessions that something like WS-SecureConversation [12] does. While SSL/TLS does provide the capability for resumption, where the same SSL/TLS session is re-established after it is interrupted, it is not commonly implemented or used. In practice SSL/TLS is best used for short exchanges where communications are not expected to be interrupted or where it is acceptable for them to be resumed over a new protected channel. Note that in many instances it is not acceptable to resume communications from an invalidated secure channel, over a new one.

SSL/TLS should not be ruled out as a way to protect Web services but it is important to keep its constraints in mind. It is often best used in conjunction with the message-based security mechanisms described below.

### 3.2 Message-Based Security

Web Services Security (WSS) [13] enables the exchange of trusted messages. It defines an information structure for use in the SOAP header that provides the capability for expressing security information about a message. It leverages the capabilities of the SOAP header to facilitate securing parts of messages to specific roles in a message exchange, thus enabling end-to-end message security even in the presence of intermediaries.

A key part of WSS is its support for attaching and referencing security tokens. WSS was designed to be as flexible as possible in its support for different token types. It defines a Username Token and extensible binary and XML token types. These extensible types have been further refined by WSS token profiles that include X.509, SAML, Kerberos and others.

WSS builds on the work of XML-Signature [14] to address threats related to message alteration and to facilitate nonrepudiation. WSS uses signatures as a means to verify a message's integrity, that it was not altered in transit, and as a way to validate the claims of security tokens associated with the message. WSS also allows for the inclusion of multiple signatures and signature formats. This is important in distributed applications where different parts of a message may need to be signed by different parties involved in the processing of the information.

Message confidentiality is provided in WSS by leveraging XML Encryption [15]. There are facilities provided for protecting individual SOAP header or body elements or sub-elements.

WSS also introduces a security time-stamp element for use in protecting against message replay threats.

In order to ensure broad interoperability of WSS, the WS-I Basic Security Profile (BSP) [16] was created. The BSP constrains many of the options present within WSS, its security token profiles, as well as the carrying-forward requirements that are important for interoperability.

While WSS describes how to use different security token types, it does not describe how to get them. WS-Trust [17] describes a Web service-based interaction for the request and issuance of security tokens from a Security Token Service (STS). This takes the form of a Request Security Token (RST) request and a corresponding Request Security Token Response (RSTR). The tokens requested and issued are also capable of being scoped to a specific purpose. It is recommended that this scope be as constrained as possible to prevent possible abuse of issued tokens.

There is also the capability in WS-Trust for more complex negotiations for the establishment of the requested security tokens. This is accomplished by adding Signature Challenge and Response legs in between the initial RST and eventual RSTR. In addition to these capabilities, WS-Trust also provides capabilities for the validation, renewal, and cancellation of security tokens that have been issued.

In order to address the need to authenticate a series of messages, WS-SecureConversation [12] was defined. WS-SecureConversation builds upon WS-Trust to define a protocol that allows for the establishment of a security session including the establishment of efficient keys and key material. It defines the Security Context Token (SCT) to be used over the lifetime of messages that are part of an exchange. The SCT is referenced like any other token using the capabilities of WSS. It is important to note that an SCT need not contain any identity-related information. An SCT is often used just for a single exchange and may be discarded when it is completed.

The security requirements of a Web service are expressed using policy assertions that are defined by WS-SecurityPolicy (SP) [11]. There are assertions that allow the expression of a service's requirements of features provided by WSS, WS-Trust, and WS-SecureConversation. These assertions provide the necessary information for a client to determine its compatibility with a service and configure itself to produce messages that meet the service's security requirements. The assertions provide a great deal of flexibility for expressing the necessary token types, cryptographic algorithms, and transport requirements of the service.

## 4 WEB SERVICE SECURITY DIRECTIONS

### 4.1 Federation

Looking to more advanced security requirements, one that stands out is the need to enable different security realms to work together, where a realm is seen as a single unit of administration or trust. This is known as federation, where resources managed in one realm are made available to security principals whose identity is managed in another. The WS-Federation [18] specification addresses this topic by building upon WS-Trust.

WS-Federation provides capabilities for the sharing of identity, authentication, authorization, and privacy data when appropriate. It allows for the remote access of services without requiring the service provider to maintain local user identities. It provides optional pseudonym services that allow for the protection of identity information by providing alternative representations of it. A common claims dialect is also defined that allows for the expression of basic claims in WS-Trust messages. WS-Policy assertions are defined to allow a service to advertise its support for the features defined by WS-Federation.

WS-Federation defines bindings of WS-Trust for use with web-browser clients. This enables the use of web browsers in interactions in which they cannot directly make Web service requests on their own.

### 4.2 Identity

Another evolving area in WSS is identity. The internet has no identity layer. This is becoming increasingly problematic as mechanisms for managing who is connecting to

what on the internet are increasingly under attack, especially the most common form of user name and password. Kim Cameron's Laws of Identity [19] were arrived at through a dialog of many experts in digital identity and serve as the principles for establishing an Identity Metasystem for the internet to address this problem. The core idea is to put the user back at the center of managing their identity on-line. The realization of these concepts has been through the use of Web service protocols discussed above, especially WS-Trust.

The Identity Metasystem has three essential roles. Note, however, that participants may fulfill more than one of the following roles:

- *Identity providers.* the issuers of digital identities. Examples of potential identity providers are credit card issuers, banks or government agencies;
- *Relying parties.* parties that require a digital identity for use. On-line merchants are a fine example of a relying party that would require a digital identity issued by a credit card company;
- *Subjects.* the individual or other entity that claims are made about, for example, an end user or company.

The Identity Metasystem is an open and nonproprietary concept. The concepts that it consists of, described above, are realized using web service protocols that are not restricted to a specific platform. Specifically an identity provider is an STS as described in WS-Trust. Relying parties describe their own requirements using WS-SecurityPolicy and make them available through WS-MetadataExchange [20].

Users are always aware of interactions that are made on their behalf between parties, in the Identity Metasystem. This awareness is made possible through a consistent experience provided by an identity selector. The identity selector presents a user with the credentials that satisfy the requirements of the relying party. The relying party is clearly revealed as are the identity providers to the user. The user has visibility to whom is making the request (the relying party) for their digital identity. The user also has visibility to who issued the digital identity (the identity provider) they are going to release to the requestor. This identity selector is invoked by an application typically, but not necessarily, a web browser, and performs the necessary negotiations between identity providers and relying parties. The user has complete visibility to the claims being requested and released as part of this interaction.

The ideas of the Identity Metasystem have been reflected in implementations of both commercial and open-source software such as Microsoft's CardSpace, Mozilla Firefox, and Higgins which has backing from IBM and Novell.

## 5 SUMMARY

SOA will remain a popular approach to building distributed software applications for many years. Web services are, and will remain, a common SOA implementation strategy on many platforms. The above article has described many of the common threats present to SOA applications and how those threats are addressed via Web service security protocols. The threats to SOA applications are the same irrespective of the attacker; for example, a criminal, espionage agent, or common vandal. While transport security will remain an important option for securing Web service messages, message-based

security provides more flexibility, capability and generally better protection when properly deployed. This is an evolving area, particularly in the areas of federated trust and identity. The reader is encouraged to follow the references from this article to stay up-to-date.

# CYBER SECURITY TECHNOLOGY USABILITY AND MANAGEMENT

DIANA K. SMETTERS
*PARC, Palo Alto, California*

## 1 INTRODUCTION

Why does usability matter? Particularly when placed in the context of security, it sounds nice but is not *necessary*—after all, who would place their systems or data in jeopardy just for a little convenience? In practice, the answer to this question is anyone for whom maintaining system security is not the primary job, or in other words, almost everyone. People use computers to accomplish particular tasks, and anything ancillary to those tasks, and particularly anything that gets in the way of their accomplishment will be worked around, disabled, or avoided [1]. The net result of an unusable security measure is likely to be a system less secure than the one that started out as more insecure in the beginning. Luckily, recent work at the intersection of computer security and human—computer interaction (HCI) has begun to demonstrate that the "human element" is a critical component of security, and that it is possible, with care, to build systems that are both usable and secure.

## 2 USABILITY AND SECURITY: CURRENT RESEARCH

In their seminal 1974 paper, Salzer and Schroeder listed eight principles for the design of secure systems. The last was "psychological acceptability"—usability, which they saw as critical if mechanisms designed according to the other seven principles were to be applied correctly [2]. After 25 years of relative quiet, there has been an explosion of interest in how to make secure systems "psychologically acceptable", and how to make "acceptable", or *usable* systems secure.

We can divide the body of research in this new field, often referred to as *HCISEC* (referring to the interface between the fields of *human—computer interaction* and security), into three loose classes. The first takes existing secure systems, identifies their usability flaws, and then (sometimes) attempts to improve them through interface redesign. The second tries to design new systems from the ground up to be both usable and secure, often arriving at significantly different solutions than traditional, solely security-focused designs. The last attempts to develop design principles, or guidelines, to aid practitioners in better designing future systems. An overview of research in each class is given below.

Throughout, it is useful to consider the identity of the "user" in *usable*—while most usability work focuses on end users, usability for systems administrators and developers is also important to the building of effective systems. It is also useful to keep in mind

the difference between "security technologies"—technologies designed to accomplish an explicitly security-focused task, such as login interfaces or policy management systems, which permit a certain level of "security focus" in their design and interfaces, and systems that have security requirements, but whose primary goal is something other than security, for example, file sharing systems and e-mail systems [3].

## 2.1 Improving Existing Security Technologies

***2.1.1 Failures of Existing Systems.*** Perhaps the largest body of research in security usability looks at systems that are not studies of real users and the ways in which they find existing systems impenetrable or use them incorrectly. The first of these, due to Whitten and Tygar [4], asked users in a laboratory setting to encrypt their e-mail using relatively popular commercial e-mail encryption software (PGP 5.0), and demonstrated that the majority were simply unable to do so.

Even more disturbing is that users not only find managing security difficult, but they are also often unable to determine when they have accomplished security-critical tasks and when they have not. Good and Krekelberg looked at use of a popular peer-to-peer file sharing program, and discovered that the majority of users were unable to determine what files they were sharing with others, sometimes sharing the entire contents of their hard drives when they thought they had exposed nothing [5]. Notable industry studies have shown that although 92% of users think they have up-to-date antivirus software, only 51% actually do; even though 73% of users think they have a firewall, only 64% have turned it on; and that only a small fraction of users who think they have antispam and antiphishing software actually do have [6].

In case we forget that usability problems plague not only end users but also trained system administrators, a large-scale automated survey of secure web servers shows that as of January 1, 2008, 68% of web server SSL/TLS certificates were invalid [7].

***2.1.2 Passwords.*** Passwords are the most common form of security technology experienced by users, and perhaps the most overused—many users manage 15 or more [8–10]. Studies confirm that users do not know to pick good passwords, and are asked to remember far too many of them and change them too often, resulting in poor password choice, or passwords that are written down [9, 11].[1] Situations that require individuals to act on each others' behalf result in passwords that are shared [9, 12]. Users frequently reuse passwords across sites [10], reducing cognitive load but allowing an attacker to capture a password in one place and successfully use it in others.

A number of attempts have been made to help users choose better passwords and remember them more effectively [11, 13]. Better password choice algorithms suggest that users derive passwords from memorable phrases rather than words, resulting in passwords that appear as difficult to crack as random passwords but are more memorable [14]. An increasing number of graphical password systems ask users to draw, remember, or select regions of images rather than entering text-based passwords [15, 16]. Unfortunately, the very features that make things memorable to humans—their patterns and predictability—also make them vulnerable to attack. Humans can indeed remember

[1]Merely writing down a password is not always a security risk. Using a complex on-line banking password that you must write on a note attached to your monitor is much better protection against hackers on the internet than using a shorter password you can remember. However, it is not very good protection against your cleaning people.

phrase-derived passwords better than random passwords, but they also tend to pick the *same* phrases as easily memorable, making it possible to build a phrase-based dictionary that is highly effective at breaking such passwords [17]. Similarly, the properties of an image or image component that makes it likely a person will remember it or choose it as part of a graphical password are also predictable, resulting in the ability to construct "graphical dictionaries" effective in attacking such passwords [18, 19].

An alternate approach to this problem can be seen in the design of tools that help users remember their existing passwords, such as password toolbars. The best of these help the user create stronger passwords, while reducing the user burden. They do this by taking one (user-remembered) "master" password and generating from it individual, random passwords for each site the user visits. This limits the risk to the user if any single password is compromised [20, 21]. Such systems also attempt to protect the user from phishing attacks (see below) by detecting when the user attempts to enter such a protected password into a site that does not match the one it was created for, either warning the user [20, 21], or actually generating an incorrect password as a result [22]. These are difficult to implement in a fashion that can be used effectively and correctly, however [23], leaving the ultimate effectiveness and practicality of such approaches open to future research.

## 3 SYSTEMS MANAGEMENT

Systems management contains the largest fraction of "security-focused" tasks, and so is perhaps the area where usability of security comes first to mind. The "users" involved in systems management, however, range tremendously. There are typical end users struggling to update and secure their home PCs, who are asked to take on increasingly sophisticated management tasks [24]. There are systems administrators who, as "trained professionals", are often considered not to require special attention to usability, but who frequently have no special expertise in security. And there are specialized security administrators, often dealing with vast amounts of time sensitive information, usually with text-based tools [25].

Several recent ethnographic studies have documented the tools and practices of systems [26, 27] and security administrators [25]. These studies have documented that administrators are often skeptical of graphical management tools, particularly that they will scale effectively, and prefer to build tools themselves or adopt tools built by others within their professional communities. At the same time, these studies have examples where more effective tools would help administrators in visualizing information to more effectively monitor and understand situations, or to configure systems in ways that minimize error or increase speed or effectiveness. It is also the case that "user-friendly" tools designed to help end users with management tasks are sometimes adopted by professional administrators when they see that they can indeed simplify their work (e.g. [28], discussed below, where a secure wireless local area network (WLAN) configuration tool designed for end users was adopted for enterprise use at the request of administrators, and which has been used by those administrators in deployment for over 4 years at this writing).

Well-designed information visualization tools can aid in almost any complex task, including systems administration. An early example of a visualization tool designed specifically to illustrate the frequency of network attacks is the compellingly named

*Spinning Cube of Potential Doom* [29].[2] Though not designed for use in real-time administration of networks, one could easily imagine that a successor to this tool could be a powerful aid in understanding current network state. Recent work has begun to leverage visualization tools to assist even untrained end users in understanding and managing their computers. *Sesame* [30] is a visualization system that allows end users to graphically "drill down" and examine the state of their computer, its processes, and network connections, and to manage basic aspects of their systems. Using Sesame, users were more effective at simple security tasks than users using traditional tools (e.g. firewalls).

A number of studies have looked at whether better interfaces or tools can improve administrator effectiveness on standard security tasks.[3] Perhaps the largest group of these have looked at access control or the configuration of permissions to determine who can use files or other resources. The results are very encouraging, suggesting that effective attention to usability in system design can really improve performance on security tasks.

One of the earliest efforts to identify a link between usability and security is that of Zurko et al. [31, 32], who demonstrated that appropriate attention to usable interface design could improve the effectiveness of a role-based access control system. More recent work [33, 34] has demonstrated that improved graphical interfaces to traditional access control lists can improve users' ability to rapidly and correctly specify access policies. Going further, the SPARCLE system [35] allows minimally trained administrators to specify privacy policies in natural language; perhaps signaling the ultimate direction such management systems must go in to reach the ever-larger classes of individuals that must use them. Finally, Cao and Iverson [36] attempted to build the first systems—"intentional access management"—capable of taking a simple specification of what policy the user intends to apply, and automatically navigating the often complex and conflicting maze of effector mechanisms that can "make it so", avoiding common user error in the process.

## 4 WEB SECURITY AND PHISHING

Perhaps the most significant battleground wherein the end user is on the front lines, directly determining the success or failure of an attack, is the war against phishing. *Phishing* is the attempt to get users to hand over personal information or credentials to an attacker via subterfuge.[4] A user receives an e-mail message containing a request for information (e.g. "Update your account information to make sure your access is not disabled!"), and usually a clickable link to an attacker's website where that information can be entered. The e-mail, link, and website are carefully crafted by the attacker to resemble communications from a trusted provider with whom the user already has a relationship (e.g. their bank or an Internet provider such as PayPal or Amazon). Successful attacks enable the attacker to drain the user's bank or PayPal account, or to engage in further forms of identity theft [37].

The fundamental problem underlying the success of phishing attacks is the lack of effective *mutual authentication* in web-based interactions. Logins and passwords are designed to protect websites from unauthorized use. Unfortunately, the mechanisms

[2] So compelling is the name that I challenge any reader of this manuscript *not* to go and look at the corresponding website.

[3] By effectiveness here, we mean the administrator's ability to accomplish their stated goal rapidly and without error.

[4] Phishing is perhaps the most technical form of traditional social engineering attacks.

designed to protect users from being tricked into communicating with sites other than the ones they intend are much less effective. In the former case, a web server can automatically verify user credentials, in the latter a human user must look at a set of security indicators—for example, the use of TLS/SSL, the URL they are connecting to, and the content of the page—and determine whether they are connected to the correct server. Though some effort has been made to design features into modern web browsers to aid users in making this determination, most users do not look at them, instead primarily make trust decisions based on insecure aspects of the web content [38, 39] or use ineffective decision strategies [40].

Approaches to prevent or defend against phishing attacks largely take three forms. The first class of approaches attempts to educate the user: teaching them basic security information and heuristics to help them authenticate the websites they communicate with [41]. Some of these efforts are effective, increasing users' ability to distinguish good from malicious sites [41], and can even be enjoyable—embedding the learning experience in a game [42]. However, other attempts to educate the user about security indicators have resulted in subjects misidentifying malicious sites as good with improved confidence after training [39].

The second class of antiphishing efforts attempts to detect "bad" sites and warn users about them. All major web browsers incorporate increasingly sophisticated tools to do this, using a combination of website analysis and blacklisting. Add-on "antiphishing toolbars" abound. Unfortunately, users tend to ignore such warnings [43]. Even the best of current detection technology is highly inaccurate [44], making it currently unacceptable to simply prevent users from visiting identified supposedly malicious websites. Research continues on improving malicious website detection, from better approaches to content analysis [45], to combined analysis of phishing e-mails and the websites they point to [46], to attempts at large-scale surveys of every malicious site on the Internet [47].

The third class of antiphishing efforts focuses on improving users' abilities to authenticate the websites they interact with—to detect correct sites, rather than to be warned about impersonators. Dynamic security skins [48] allow the user to associate each website with a personal image, stored by that web server, and carefully integrate into the user interface (UI) presented to them in a manner that resists spoofing. Unless the server is able to present the correct image, the user is supposed to reject it as being a malicious impersonator. Limited features of this approach have been integrated into commercial banking sites in a system called *SiteKey* [49]. Though a promising approach, studies have determined that users do not notice the absence of their security image or other security indicators [50]. Password protection toolbars, mentioned above, can help prevent users from giving away their passwords. Some toolbars ensure that the user has a unique password for each site, and resist attempts by users to enter a protected password into the wrong site [20, 21]. Others operate by keying each password to the url of the site being visited, so that the password presented to a phishing site will not be the password required for the corresponding legitimate site [22]. However, they are often difficult to use correctly, and users may achieve a lower level of effective protection than they think they have [23].

### 4.1 Designing New Technologies with Usability in Mind

One of the most common complaints of security experts is that systems designers often attempt to "add security on at the end", after a system has already been built. This

is highly ineffective. Usability experts similarly run into efforts to "add-on usability", for example, to bring in an interface designer late in the development of a system in the hopes that better-designed dialog boxes will make up for a fundamentally flawed system interaction design. To design systems that are both usable and secure, perhaps the only truly effective approach is designing for both usability and security from the start [51]. Also the key is to take both seriously—for example, discounting neither security to get greater functionality in an end user focused application nor usability to get greater security. As we have seen, this often ends with users avoiding or abusing the provided security mechanisms, resulting in a system that is less secure than one that had not tried so hard for security to start with. Most interestingly, attempts to "design *usable* security in" from the start often result in systems that use existing technologies in creative and effective ways, as well as designing new technologies potentially useful for future systems. We sample a few such systems here.

The cryptographic literature abounds with techniques for securing network connections; however, difficulties in managing and distributing keys limit their use. *Public key infrastructures* (PKIs), an approach to binding public keys to user identities via signatures by trusted authorities on digital certificates, have been proposed as the universal solution to this problem, but they require that users obtain keys and certificates, and that there be a mechanism for distributing trust in the certificates of the very authorities used to bootstrap the system. Although used extensively to verify web transactions through the use of the SSL (TLS) protocol, digital certificates are in general only used to authenticate servers. Distributing client certificates to authenticate users is considered too difficult, so they are generally authenticated using only passwords.

The largest difficulties in deploying PKIs come firstly from attempting to manage PKIs "in the large" as they were originally designed—to identify people as part of a large-scale, even global, naming infrastructure; and secondly from forcing users to explicitly play their part in the PKI enrollment process—namely generating public/private key pairs and having them certified. By rethinking these assumptions, and considering PKI, or infrastructure "in the small", one can create flexible, small-scale public key infrastructures designed to meet particular goals [52]. If these PKIs, or "instant" PKIs, are tailored to a particular application context, the process of enrollment can then be made transparent to end users, by embedding it in that application's context. This approach tends to use such certificates as simple group membership credentials—group members have a certificate, others do not—rather than the more traditional identity credentials that at least X.509 digital certificates were designed to be.

Balfanz et al. [28] used this idea of an "instant" PKI to address the problem of allowing end users to easily set up highly secure WLANs in a system called *Network in a Box* (NiaB). The NiaB access point configured itself into all the components necessary to secure a WLAN using digital certificates and strong authentication. Users wishing to join a given NiaB-controlled WLAN simply "point out" the access point controlling the network using the infrared port of their laptop or PDA, as if they were using a remote control. Using this infrared connection as a form of *gesture-based authentication* [53], the prospective client and NiaB access point (AP) exchange public key information over this out of band channel, allowing them to authenticate each other and set up a secure connection over the WLAN. Over this wireless connection, the client is automatically given a digital certificate and configured to use this wireless network in the future. The resulting system is both intuitive and secure; providing a simple trust model wherein only people with physical access to the NiaB AP (able to communicate with it via infrared) are

able to join the WLAN. The user-friendly approach of using an automated out of band channel to bootstrap authentication between devices [53, 54] has been extensively used in recent years (e.g. [47, 55]). Similar approaches for automatic provisioning of certificates have also been used, for example, to provide client credentials for authenticating to secure websites [48, 49, 56, 57].

Another intuitive approach to delivering and establishing trust in public keys is termed *key continuity management* (KCM) [50, 58]. This simple model, originally adopted by the program *ssh*, simply promiscuously accepts the first key proffered for any identity for which it does not currently know one (offering the user the chance to verify that key first, though they rarely do), and sounding a warning if that key then changes. This approach significantly lowers the barriers to entry for using public key cryptography, in return for slightly reduced initial security. Garfinkel and Miller applied this model to the problem of key management for e-mail encryption, embedding it into a popular e-mail client program [51, 59]. Their results suggest that KCM offers promise for easing practical deployment of e-mail encryption.

Finally, one of the most promising approaches to easing the interface between security and the user is through the use of portable personal devices, such as cell phones, which can carry credentials and perform cryptographic protocols on behalf of end users. Such devices have been used as intermediaries to protect users from giving credentials away in response to phishing attacks [52, 60] or as intuitive tools for authenticating users [28, 61] or creating [53, 62] or effecting [54, 63] access control policy.

### 4.2 Design Guidelines for Building Better Systems

Finally, there has been extensive work developing design guidelines that aim to help systems designers come up with systems that are both usable and secure. Perhaps the most influential, clearly stated, and comprehensive of these is due to Yee [64, 65]. Yee's guidelines blend long-agreed security design goals, such as *the principle of least authority* (or *privilege*)—which says that systems should operate with only the ability to access those resources necessary to do their job, with the best interests of end users. The results are principles such as *the path of least resistance* [64], which say that the easiest way to perform a task ought to also be the one that requires the least granting of authority. These guidelines argue for a distinctly user-focused view of security, arguing that systems should respond to the user's expressed intent to grant or remove authority, where intent should be expressed in terms of the task at hand—terms that are relevant, and understandable to the user. Other guidelines emphasize both that the input from the user is privileged, and must be protected so that user intent can be correctly captured; and that clear and understandable feedback of state to the user is critical for allowing the user to achieve both their task and security goals. These guidelines can be further refined and specialized to address particular user aims; for example, Chiasson et al. present a set of usable security design guidelines tailored toward the needs of systems administrators [66].

## 5 OPEN CHALLENGES AND TAKE-AWAYS

The field of usable security is still very young, and it is marked more by the number of open questions than of accepted answers. The good news is that users generally want to "do the right thing" with regard to security—if only they can figure out what that is,

and it does not keep them from getting their primary tasks done [9]. The goal of usable system design is to help them do just that.

One of the most open areas of research mentioned above is that of developing usable tools for secure, and *correct*, systems management. Because the users in this case are often administrators, not end users,[5] the requirement for improved usability is often underestimated (even by the users themselves [26, 66]). Because the tasks and tools involved are *security focused*—designed to solve a task wherein security management is often an explicit goal—it is perhaps easier to achieve effective security while keeping the user's primary task foremost [3].

The failure of existing tools and approaches for usable systems management can most clearly be seen in the prevalence of configuration errors in deployed systems—for example, the fact that 68% of deployed web server security certificates are currently invalid [7]. Such misconfigurations are surprisingly common, and reflected to the user in potentially confusing ways (Figs. 1 and 2).

While it is well known that configuration errors may result in insecure systems, there is a more subtle effect of such mistakes—every misconfiguration, on any system, decreases the ability of all other existing systems to recruit end users in defending their own security. Consider the *error attack*. If a malicious server is attempting to impersonate a critical system to a user (e.g. to capture passwords or other credentials), the attacker can explain the absence of any security indicator the user has been trained to rely upon simply by suggesting that "there is a problem with the system" [50].

As long as attacks and system configuration errors generate warnings that are indistinguishable to the end user, the end user must make a determination—"does this warning signal an actual attack or merely a misconfiguration?" Evidence suggests that overwhelmingly they assume the latter [67]—that the warning simply reflects a *false alarm*, and that they should proceed with what is for them, their much more urgent primary task. Given the relative frequency of genuine attacks and simple configuration errors, *this is the rational decision for them to make*. And it will continue to be, until configuration errors are vanishingly less common than genuine attacks. There are two ways to achieve this state: the first is to wait until the attack frequency rises to the point that systems are completely unusable (and hope that configuration errors do not rise in parallel). The better option is to reduce the incidence of configuration errors to the point where warnings

**FIGURE 1** This figure shows an error message generated by the Mozilla Firefox web browser when attempting to visit the default secure (SSL-protected) management page offered by a common consumer-grade wireless access point. The access point has been provisioned by the vendor with an invalid certificate. The antiphishing protections built into Mozilla Firefox make it impossible to actually visit this site and administer the device.

[5]Though as computers get more critically involved in every aspect of day-to-day life, "average" users are more and more often systems administrators as well [24].

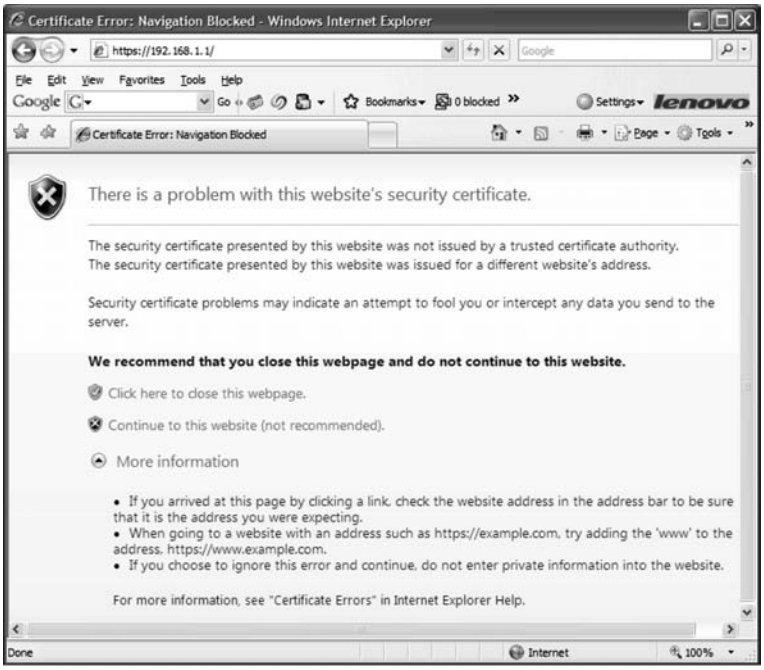

**FIGURE 2** This figure shows the error message generated by Internet Explorer 7 when attempting to visit the same SSL-protected configuration page as displayed in Figure 1. Using IE, one can override the security warnings and determine that the device contains a self-signed certificate with the serial number 0; this might be a certificate generated automatically by the device (and all devices incorrectly select 0 as a serial number, rather than say choosing a random value) or all devices might even be configured with the same certificate and private key. Note that the errors presented by Firefox and IE cite completely different problems with the certificate.

of attack are, with overwhelming likelihood, just that. To reduce configuration errors to that degree, we must either reduce the amount of configuration that must be performed or ensure that more of it is done correctly—this requires better systems management and configuration tools. Though those tools may not be "security tools" per se, they clearly play a security-critical function.

## 6 CONCLUSIONS

This article has presented a review of the current state of research in usable security. This is an extremely active, fast-moving field, as evidenced that most of the cited work was performed within the last 5 years. In any such rapidly moving area, new results are always appearing; the further reading list (below) contains pointers to places to find them. Equally important to the work reviewed here is the large body of work omitted for reasons of space—for example, this review does not consider work on usable *privacy*, itself an active area of research.

Perhaps the most important lessons to be learned from this body of work are that usability is indeed key to effective security and that it is possible to design systems that are simultaneously usable and secure—as long as you think it is important enough to do so.

# CYBER SECURITY EDUCATION, TRAINING, AND AWARENESS

RICHARD KISSEL AND MARK WILSON
*National Institute of Standards and Technology, Gaithersburg, Maryland*

## 1 INTRODUCTION

The cyber security education, training, and awareness (ETA) program is a critical component of the cyber security program. It is *the* vehicle for disseminating security information that the workforce, including managers, need to do their jobs. In terms of the total security solution the importance of the workforce in achieving cyber security goals and the importance of learning as a countermeasure, cannot be overstated. Establishing and maintaining a robust and relevant ETA program as part of the overall cyber security program is the primary conduit for providing the workforce with the information and tools needed to protect an organization's vital information resources. These programs will ensure that personnel at all levels of the organization understand their cyber security responsibilities to properly use and protect the information and resources entrusted to them. Organizations that continually train their workforce in organizational cyber security policy and role-based cyber security responsibilities will have a higher rate of success in protecting information. As cited in audit reports, periodicals, and conference presentations, people are arguably the weakest element in the cyber security formula that is used to secure systems and networks. The *people factor*, not technology, is a critical factor that is often overlooked in the cyber security equation. Robust and enterprise-wide ETA programs are needed to address this growing concern.

## 2 EDUCATION, TRAINING, AND AWARENESS POLICY

All users have cyber security responsibilities. Although there is no mandate for formal education (provided by colleges or universities) and certification of information security professionals, they are mentioned in this section since some organizations include them as part of a comprehensive training solution for employees.

## 3 COMPONENTS: EDUCATION, TRAINING, AWARENESS, AND CERTIFICATION

An organization's cyber security program policy should contain a clear and distinct section devoted to organization-wide requirements for the ETA program. Although cyber security ETA is generally referred to as *"a"* program, many organizations consider ETA to be three distinct functions, each with separate purposes, goals, and approaches. Proper

implementation of these components (with consideration of options such as professional certification) promotes professional development, which leads to a high-performance workforce.

Requirements for the cyber security ETA program should be documented in the enterprise-level policy and should include:

- definition of cyber security roles and responsibilities;
- development of program strategy and a program plan;
- implementation of the program plan; and
- maintenance of the cyber security ETA program.

### 3.1 Education

Education integrates all of the cyber security skills and competencies of the various functional specialties into a common body of knowledge and adds a multidisciplinary study of concepts, issues, and principles (technological and social). Cyber security education strives to produce cyber security specialists and professionals who are capable of vision and proactive response. A significant and increasing number of colleges and universities provide academic programs to support the cyber security needs of the public and private sectors. Many of these schools partner with the public sector to accomplish research and development tasks to improve cyber security. The National Security Agency (NSA) and the Department of Homeland Security (DHS) have built and are maintaining a robust program called the *Centers of Academic Excellence* in Information Assurance Education. The program seeks to produce a growing number of professionals with information assurance expertise in various disciplines.

### 3.2 Training

Cyber security training strives to produce the relevant and required security knowledge and skills within the workforce. Training supports competency development and helps personnel understand and learn how to perform their cyber security role. The most important difference between training and awareness is that training seeks to teach skills that allow a person to perform a specific function, while awareness seeks to focus an individual's attention on an issue or a set of issues.

Role-based training provides cyber security modules and/or courses that are tailored to the specific needs of each group of people who have been identified as having significant responsibilities for information security in their organization. The National Institute of Standards and Technology (NIST) Special Publication (SP) 800-16 provides guidance for establishing role- and performance-based cyber security training programs. Other models that can be used for developing role-based cyber security training are the Committee on National Security Systems (CNSS) Training Standards, the Office of Personnel Management (OPM) "IT Roadmap", and the DHS Essential Body of Knowledge (EBK).

Critical elements to address or consider when developing training material are:

- *Needs assessment.* A needs assessment will identify what additional cyber security training is needed or required, beyond what the organization is currently doing. Sometimes, the needs assessment takes the form of an auditor's report. The needs

assessment may identify additional people in particular roles who need training, or it may identify that people who have trained need additional training. A needs assessment will help an organization determine if a complete training course is necessary or if a module that focuses on particular topics will be sufficient.

- *Setting the bar.* "Setting the bar" means that a decision must be made as to the complexity of the material that will be developed. The complexity must be commensurate with the role and the needs of the person or people who will undergo the learning effort. Material should be developed based on two important criteria: (i) the target attendee's position within the organization, and (ii) knowledge of the cyber security skills required for that position. The complexity of the material must be determined before development begins. Setting the bar is an important aspect of the "scoping guidance" to be developed and utilized throughout the analysis, design, development, implementation, and evaluation ("Analysis, Design, Development, Implementation,and Evaluation (ADDIE)") process.
- *The ADDIE instructional design model.* The ADDIE model is a systematic instructional design model consisting of five phases: *a*nalysis, *d*esign, *d*evelopment, *i*mplementation, and *e*valuation. Each phase consists of outcomes that feed into the next phase in the model. For example, input to the Analysis Phase is the output of the needs assessment identifying the existing training gaps within the organization. As each role is analyzed, attention should be paid to the competencies or knowledge, skills, and abilities (KSAs) needed for each role as well as the particular topics, tasks, and/or elements that support the competencies or KSAs. Each competency or KSA used within each role may become a module that is suitable for use within other role-based training that may be required. For example, many cyber security roles require some level of knowledge of laws and organizational policy. A single development effort with multiple modules that can be added and removed based on the particular audience, could save significant development time.
- *Role-based training versus topic-based training.* Role-based cyber security training allows the recipient of the training to learn what he or she needs to know and be able to do, based on their current job. This is perhaps the most important distinction between role-based and topic-based training. While topic-based training is easier to develop because, for the most part, it can be developed once and for diverse audiences, it approaches being a one-size-fits-all solution. Unfortunately, an easy solution like this, to a complex issue like cyber security training, can in itself be a vulnerability as dangerous as a poorly configured operating system or firewall. Topic-based training is best employed within a role-based training framework, when a particular topic (e.g. incident response and reporting, configuration management, contingency planning) needs to be taught as a stand-alone module (or part of a training course) to people in a particular role, or to a group of people in different roles who need to know a similar amount of information about that topic.
- *Sources of cyber security training.* The first step in determining sources of training material to build a course or module is to decide if the material will be developed in-house or contracted out. If the organization has in-house expertise and can afford to allocate the necessary resources to develop training material for courses

and/or modules, there are several federal government-focused training documents or programs that can be used. These include:

- *NIST SP 800-16.* This document contains a robust role-based training methodology. The general-to-specific aspects of the methodology include a list of roles, role-specific matrices that contain responsibilities and training areas, and specific sets of cells for each role matrix that, in turn, contain cyber security topics and elements to be used to build training material for each cell.
- *CNSS training standards.* These standards are also role-based and contain sets of tasks, capabilities, and KSAs needed for those serving in each role.
- *OPM IT roadmap.* This OPM project is a web-based application based on the federal government's GS-2210 Information Technology (IT) Specialist Job Series. One of the IT Specialist subseries, the Information Security "parenthetical", has related levels of learning, competencies, expected behaviors, and recommended training courses.
- *DHS EBK.* This document is based on a number of existing federal guidelines and standards. It contains a methodology that includes roles, competency areas, responsibilities, terms, and concepts.

### 3.3 Awareness

Cyber security awareness is a blended solution of activities that promote security, establish accountability, and inform the workforce of security news. Awareness seeks to focus an individual's attention on an issue or a set of issues. Awareness is a program that continually pushes the cyber security message to users in a variety of formats.

An awareness program includes a variety of tools, communication, outreach, and metrics development.

- *Tools.* Awareness tools are used to promote cyber security and inform users of threats and vulnerabilities that impact their organization and "personal" work environment by explaining the "what" but not the "how" of security, and communicating what-is- and what-is-not-allowed. Awareness is used to explain the rules of behavior for using an organization's information and information systems and establishes a level of expectation on the acceptable use of the same. Awareness not only communicates cyber security policies and procedures that need to be followed, but also provides the foundation for any sanctions and disciplinary actions imposed for noncompliance. Types of tools include:
  - events, such as a cyber security awareness day;
  - promotional materials;
  - briefings (program- or system-specific or issue-specific); and
  - rules of behavior.
- *Communication.* A large part of an awareness effort is communication with users, managers, executives, system owners, and others. A communications plan is needed to identify stakeholders, types of information that is to be disseminated, channels for disseminating information, and the frequency of information exchanges. The plan

also identifies whether the communications are one-way or two-way. Activities that support communication include:
  - assessment (as is/to be models);
  - strategic plan; and
  - program implementation.
- *Outreach.* Outreach is critical for leveraging best practices within any organization. It has two elements for intra- and inter-organization awareness. The intraorganization element promotes internal awareness of cyber security. A Web portal that provides a one-stop shop for cyber security information can be an effective outreach tool. Policy, frequently asked questions (FAQs), cyber security e-newsletters, links to resources, and other useful information are easily accessible to all employees. This tool promotes a consistent and standard message. The interorganization element promotes sharing among organizations and is used to leverage training and awareness resources.

### 3.4 Certification

In response to the growing demand for cyber security personnel within organizations, in both the public and private sectors, there has been a movement toward increased professional standards for cyber security personnel. This "professionalization" integrates education, training, and experience with an assessment mechanism to validate knowledge and skills, resulting in the certification of a predefined level of competence.

## 4 DESIGNING, DEVELOPING, AND IMPLEMENTING AN EDUCATION, TRAINING, AND AWARENESS PROGRAM

The development of a cyber security ETA program involves three major steps:

1. *Designing* the program (including the development of the cyber security ETA program plan);
2. *Developing* the ETA material; and
3. *Implementing* the program.

Even a small amount of cyber security ETA can go a long way toward improving the cyber security posture of, and vigilance within, an organization.

### 4.1 Designing an ETA Program

ETA programs must be designed with the mission of the organization in mind. The ETA program must support the business needs of the organization and be relevant to the organization's culture and information technology architecture. The most successful programs are those that users feel are relevant to the subject matter and issues presented.

Designing an ETA program answers the question "What is our plan for developing and implementing ETA opportunities that are compliant with existing policies?" In the design step of the program, the organization's ETA needs are identified, an effective organization-wide plan is developed, organizational buy-in is sought and secured, and priorities are established.

### 4.2 Developing an ETA Program

Once the ETA program has been designed, supporting material can be developed. Material should be developed with the following in mind:

"What behavior do we want to reinforce?" (awareness);

"What skill or skills do we want the audience to learn and apply?" (training and education).

In both cases, the focus should be on specific material that the participants should integrate into their jobs. Attendees will pay attention and incorporate what they see or hear in a session if they feel that the material was developed specifically for them. Any presentation that feels so impersonal and general that it could be given to any audience, will be filed away as just another of the annual "We're here because we have to be here" sessions. An ETA program can be effective, however, if the material is interesting, current, and relevant.

The awareness audience must include all users in an organization. Users may include employees, contractors, other organization personnel, visitors, guests, and other collaborators or associates requiring access. The message to be spread through an awareness program, or campaign, should make all individuals aware of their commonly-shared cyber security responsibilities.

On the other hand, the message in a training class is directed at a specific audience. The message in training material should include everything related to cyber security that attendees need to know in order to perform their jobs. Training material is usually far more in-depth than material used in an awareness session or campaign.

An education course goes beyond the immediately practical skills taught in training sessions by presenting the underlying and related concepts, issues, and principles of particular aspects of the profession. This allows the student to understand the subject in far greater depth than is usually provided in training.

### 4.3 Implementing an ETA Program

A cyber security ETA program should be implemented only after a needs assessment has been conducted, a strategy has been developed, an ETA program plan for implementing that strategy has been completed, and ETA material has been developed.

The program's implementation must be fully explained to the organization to achieve support for its implementation and commitment of necessary resources. This explanation includes expectations of organization management and staff support, as well as expected results of the program and benefits to the organization. Funding issues must also be addressed. For example, organization managers must know if the cost to implement the ETA program will be totally funded by the Chief Information Officer (CIO) or the cyber security program budget, or if their budgets will be impacted to cover their share of the expense of implementing the program. It is essential that everyone involved in the implementation of the program understand their roles and responsibilities. In addition, schedules and completion requirements must be communicated.

Once the plan for implementing the ETA program has been explained to (and accepted by) organization management, the implementation can begin. Since there are several ways to present and disseminate ETA material throughout an organization, organizations should tailor their implementation to the size, organization, and complexity of their enterprise.

### 4.4 Postimplementation

An organization's cyber security ETA program can quickly become obsolete if sufficient attention is not paid to technological advancements, IT infrastructural changes, organizational changes, and shifts in organizational mission and priorities. CIOs and senior organization cyber security officers need to be cognizant of this potential problem and incorporate mechanisms into their strategy to ensure that the program continues to be relevant and compliant with overall objectives. Continuous improvement should always be the theme for cyber security ETA initiatives, as this is one area where *you can never do enough*. Efforts supporting this postimplementation feedback loop should be developed with respect to the cyber security organization's overall ongoing performance measures program.

### 4.5 Monitoring Compliance

Once the program has been implemented, processes should be put in place to monitor compliance and effectiveness. An automated tracking system can be designed to capture key information on program activity (e.g. courses, dates, audience, costs, sources etc.). The tracking system should capture this data at an organization level, so it can be used to provide enterprise-wide analysis and reporting regarding ETA initiatives. Tracking compliance involves assessing the status of the program as indicated by the database information, and mapping it to standards established by the organization. Reports can be generated and used to identify gaps or problems. Corrective action and necessary follow-up can then be taken. This follow-up may take the form of formal reminders to management; additional ETA offerings; and/or the establishment of a corrective plan with scheduled completion dates. A tracking system is likely to be more economically feasible in a government agency or a large company than in a small business. A small business may not be able to justify the costs of such a system, and in a small business it should be easier to track those employees needing and attending cyber security training.

### 4.6 Evaluation and Feedback

Formal evaluation and feedback mechanisms are critical components of any cyber security ETA program. Continuous improvement cannot occur without a good sense of how the existing program is working. In addition, the feedback mechanism must be designed to address objectives initially established for the program. Once the baseline requirements have been solidified, a feedback strategy can be designed and implemented. Various evaluation and feedback mechanisms that can be used to update the ETA program plan include surveys, evaluation forms, independent observation, status reports, interviews, focus groups, technology shifts, and/or benchmarking.

A feedback strategy should incorporate elements that address quality, scope, deployment method (e.g. Web-based, on-site, off-site), level of difficulty, ease of use, duration of session, relevancy, currency, and suggestions for modification.

Metrics are essential to feedback and evaluation. They can be used to:

- measure the effectiveness of the cyber security ETA program;
- provide information for many of the data requests that an organization may be required to provide with regard to compliance; and,

- provide an important gauge for demonstrating progress and identifying areas for improvement.

### 4.7 Managing Change

It is necessary to ensure that the program, as structured, continues to evolve as new technology and associated cyber security issues emerge. Training needs will shift as new skills and capabilities become necessary to respond to new architectural and technology changes. A change in the organizational mission and/or objectives can also influence ideas on how best to design training solutions and content. Emerging issues, such as homeland defense, will also impact the nature and extent of cyber security ETA activities that are necessary to keep users informed and/or trained about the latest threats, vulnerabilities, and countermeasures. New laws and court decisions may also impact organization policy that, in turn, may affect the development and/or implementation of ETA material. Finally, as cyber security policies evolve, ETA material should reflect these changes.

### 4.8 Program Success Indicators

CIOs, program officials, and organization cyber security officers should be primary advocates for ETA. Securing an organization's information and infrastructure is a team effort, requiring the dedication of capable individuals to carry out their assigned cyber security roles within the organization. Listed below are some key indicators to gauge the support for, and acceptance of, the program:

- key stakeholder demonstrates commitment and support;
- sufficient funding is budgeted and available to implement the agreed-upon ETA strategy;
- appropriate organizational placement of senior officials with key cyber security responsibilities;
- infrastructure to support broad distribution (e.g. Web, e-mail, learning management systems) and posting of cyber security ETA materials is funded and implemented;
- executive/senior-level officials deliver messages to staff regarding cyber security (e.g. staff meetings, broadcasts to all users by organization head), champion the program, and demonstrate support for training by committing financial resources to the program;
- metrics indicate improved cyber security performance by the workforce (e.g. to explain a decline in cyber security incidents or violations, indicate that the gap between existing ETA coverage and identified needs is shrinking, the percentage of users being exposed to awareness material is increasing, the percentage of users with significant cyber security responsibilities being appropriately trained is increasing);
- executives and managers do not use their status in the organization to avoid cyber security controls that are consistently adhered to by the rank and file;
- level of attendance at cyber security forums/briefings/training is consistently high.
- recognition of cyber security contributions (e.g. awards, contests) is a standard practice within an organization; and
- individuals playing key roles in managing/coordinating the cyber security program demonstrate commitment to the program and motivation to promote the program.

# INDUSTRIAL PROCESS CONTROL SYSTEM SECURITY

IVAN SUSANTO, RICH JACKSON JR., AND DONALD L. PAUL
*Chevron Corporation, San Ramon, California*

## 1 INTRODUCTION

Process control systems or industrial automation and control systems (IACS) used in the O&G Industry are vulnerable to new threats with potentially serious consequences. Vulnerabilities come from many sources, including, but not limited to increasing access to IACS, increased digital intensity in the form of digital oil fields, smart sensors generating ever increasing amounts of data, real-time optimization, reservoir modeling, and global value chains that are highly leveraged on information and connectivity. In order to address these vulnerabilities, a public–private partnership called *Project LOGIIC* was formed to create and execute projects that address critical O&G cyber security Research and Development (R&D) needs, and produce solutions upon their completion, which can be deployed in the industry. ISA Security Compliance Institute (ISCI) also combines the talents of industry leaders from a number of major control system users and manufacturers to create a collaborative industry certification-based program.

## 2 BACKGROUND

Process control systems or IACS are used by O&G companies at their offshore platforms, pipelines, refineries, plants, and other industrial assets. IACS are collections of personnel, hardware, and software that can affect or influence the safe, secure, and reliable operation of an industrial process. The systems include, but are not limited to [1]:

1. Industrial control systems including distributed control systems (DCSs), programmable logic controllers (PLCs), remote terminal units (RTUs), intelligent electronic devices, supervisory control and data acquisition (SCADA), networked electronic sensing and control, and monitoring and diagnostic systems. (In this context, process control systems include basic process control systems and safety-instrumented system [SIS] functions, whether they are physically separate or integrated.)
2. Associated information systems such as advanced or multivariable control, on-line optimizers, dedicated equipment monitors, graphical interfaces, process historians, manufacturing execution systems, and plant information management systems.
3. Associated internal, human, network, or machine interfaces used to provide control, safety, and manufacturing operations functionality to continuous, batch, discrete, and other processes.

There is an increased reliance on IACS for safe, secure, and reliable operations of facilities. Historically, it was thought that IACS were secure because they relied on proprietary networks and hardware and were considered immune to network attacks that plague corporate information systems. This is no longer true.

While no solution can offer a complete solution, defense-in-depth methods can help detect and delay or even prevent breaches. Without the right information at the right time, there cannot be an appropriate response to threats.

### 2.1 The Problem

IACS used in the O&G industry are potentially vulnerable to new threats. Standardization and integration with corporate business systems have increased the potential exposure to these systems. IACS data were traditionally used in a contained environment only by those in that environment. Now, government agencies, business partners, suppliers, and others want access to the IACS data, causing more time to be spent on filling requests and less attention to monitoring for potential breaches.

Most importantly, this integration requires network connections that provide access and raise risks and threats.

### 2.2 New Threats

Most people will click on interesting links, especially when they are sent by someone known to them. Employees and vendors often use thumb drives, CDs, or DVDs to support IACS, and these portable media are readily inserted into an IACS environment without scanning for viruses first. It takes real effort to stop and think about risk; whether it is real or a cleverly disguised threat.

Removable drives and e-mail links are just two ways that these threats can be introduced. Threats to energy industry systems have expanded beyond the typical physical attacks of the past. When these physical attacks are combined with cyber attacks on the control systems, the results could be much more damaging. The changing nature of control systems means that attackers ranging from hackers through organized cyber criminals and sophisticated insiders can have physical effects through cyber means.

The new networked control systems and commercial off the shelf (COTS) technology are vulnerable to attacks that are not specifically aimed at them. For example, the Port

of Houston had to shut down operation of its control system in September, 2001. This system controlled ship movement, docking, mooring, loading, and unloading. They were affected by a "denial of service" attack, which was not aimed at them but which affected them just the same. The attack was the result of a "botnet" or robot network of computers, typical to those used by organized crime.

There are other known security incidents happening in the industries as well, such as the Maroochy Shire Sewage Spill, an IP Address change shut down chemical plant, and a slammer-infected laptop shutting down a DCS.

These are the factors that contribute to risk in the IACS environment [2]:

- Adoption of open standardized technologies susceptible to known vulnerabilities;
- Connectivity of Control Systems with other networks, including the Corporate network;
- Insecure remote connections;
- Widespread availability of technical information about control systems.

On the basis of a recent industry trend, both security risks from insiders and outsiders still continue to be of most concern, with hackers gaining a greater understanding of IACS.

### 2.3 The Solution

LOGIIC-1 Team [3] within a critical infrastructure environment, addressing security risk is a shared problem that can only be addressed and solved collaboratively. In the LOGIIC partnership, the following were the goals:

- Demonstrating a forward-looking opportunity to reduce vulnerabilities of O&G process control environments.
- Creating a working model to leverage the collective resources of the O&G industry, government agencies, and national laboratories for future cyber security projects.
- Leveraging existing SCADA cyber security knowledge and tools from the O&G industry, government, and vendors to
  - align with existing and future activities being performed in the SCADA industry, National Laboratory Testbeds, and O&G industry;
  - assist the National Laboratory Testbeds with the research and development of new solutions focused on the O&G industry, which will address existing security weaknesses (evolutionary) and breakthrough security solutions (revolutionary).

ISA Certification is one resource that promises to provide asset owners [4] a well-designed and managed product security certification process, leading to improved process reliability and safety. Certification responds to a common need for a shared security vision to be executed by suppliers, asset owners, and consultants. It also will promote better field-tested standards that are clearly followed by industry.

## 3 SCIENTIFIC STUDY

In the LOGIIC-1 Project (Event Correlation), a defense-in-depth solution can collect all raw events (data) from IACS to business/corporate network, correlate it and analyze

abnormal events to provide information to decision makers enabling them to validate threats and take appropriate action.

Monitoring is the key to building better defenses, especially for new unknown threats and vulnerabilities, but implementing even a simple perimeter intrusion detection system (IDS) can produce such volumes of data that it can become overwhelming. Too much data from an IDS would then become a hindrance rather than a help.

And as illustrated in Figure 1, for systems without layered security architecture, it only takes a single vulnerability for an attacker to bring a system down. Even for systems with layered, defense-in-depth approaches to security, an attacker can still cause damage. We need to know how many "open doors" we have left for attackers.

One answer to the problem is to have a central correlation engine that is fed with inputs from IACS to the business/corporate network.

### 3.1 Correlation Benefits

While there are many sources of security data available, the amount of data is substantial and often in incompatible formats. Both of these factors hinder transforming the raw data into useful information [5]. A best-in-class correlation system can help by gathering data from all sources and analyzing it for trends.

Some benefits of implementing such a correlation system are

- Event and log aggregation;
- Normalizing of events into a standard format;
- Categorizing and prioritizing events;

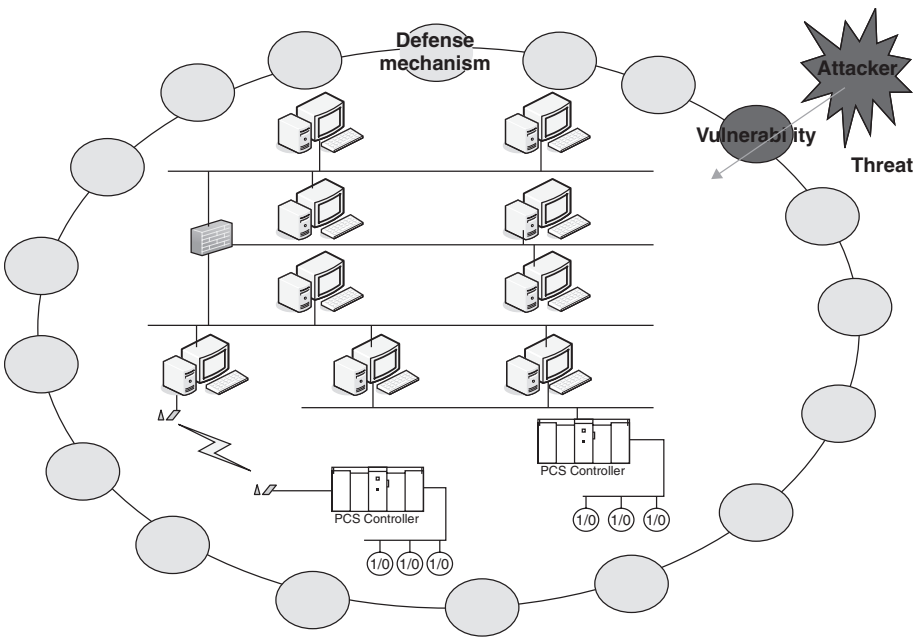

**FIGURE 1** Threats and vulnerabilities.

- Filtering extraneous events;
- Grouping similar events;
- Discovering relationships between events;
- Health monitoring from many small data points;
- Building big picture of the IACS health.

Awareness of a problem is the first step to implementing preventive or corrective measures.

### 3.2 Detection

There are four types of security events that should be detected.

In Figure 2, we let the depicted barrier abstractly to represent the perimeter defense. The four categories of events that we want to detect apply to the physical world as well as to computer systems and networks.

The probing/provocation category represents the case when attackers attempt to penetrate the defense but are unsuccessful. Examples in the cyber realm include port scanning and repeated authentication or authorization failures, such as password-guessing or file system browsing. Even though the perimeter defense works as intended, we still want to detect this kind of event because we are under attack and the attackers could eventually succeed.

Circumvention occurs when attackers find a way to reach their goal without confronting the perimeter defense. As an example, a corporation could have a strictly configured firewall protecting its corporate network from the Internet, but a badly configured wireless access point on the corporate network can allow an attacker parked on the street outside to get to the network without even going through a firewall.

Penetration occurs when vulnerability in the perimeter defense allows attackers to get through. An example of penetration is when an attacker with knowledge of software bugs can compromise the system using access that allows through well-configured firewall.

Finally, Insiders are attackers already inside the perimeter. For example, a firewall between the corporate network and the Internet does nothing to stop a disgruntled employee from stealing data from an internal database and hand-carrying it out of the building on a CD-ROM or other portable storage device. It should be noted that an

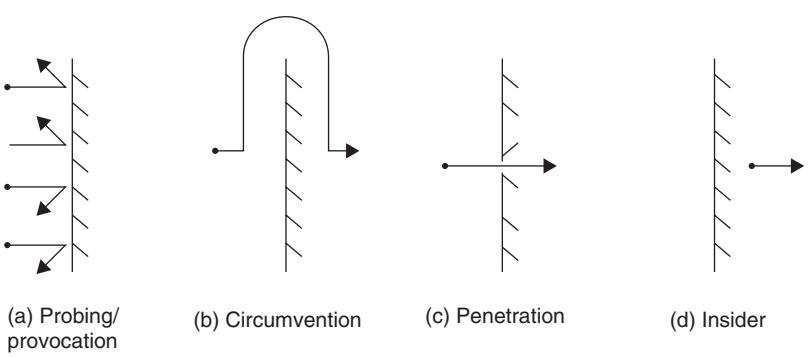

**FIGURE 2** IDS event triggered responses [6, p. 7].

attacker who has used circumvention or penetration to get inside the perimeter could also be considered an insider, from a detection perspective.

## 3.3 Technical Challenges

***3.3.1 Typical IACS Environment.*** A test bed model (Fig. 3) in LOGIIC-1 project was developed using generic DCS and SCADA system with field devices to describe typical IACS environment. Some trade-offs and assumptions were taken into account in this testing model.

***3.3.2 IACS Abnormal Events.*** There is a technical challenge in understanding the abnormal events that can be caused by an adversary in a PCSs [3]. IACS are vulnerable to the same kind of attacks experienced in a standard IT environment, but have the added vulnerability of attacks that are unique to IACS.

***3.3.3 Detecting IACS Abnormal Events.*** Another challenge is in understanding how to detect the abnormal events that can be caused by an adversary in a PCSs [3]. Standard information technology defenses can detect and defend against the same types of attacks in PCSs.

## 3.4 Implementing Defense and Detection in-Depth

The next technical challenge is to identify the layers that need to be instrumented to achieve a defensive in-depth detection [3]. The following layers were identified:

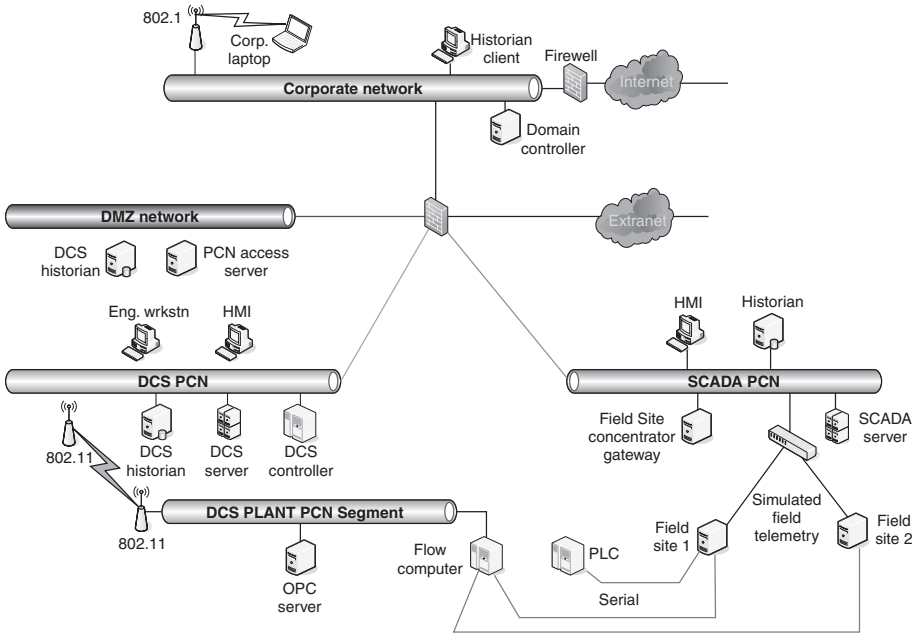

**FIGURE 3** LOGIIC-1 Baseline O&G lab environment (courtesy of DHS LOGIIC brochure).

- Network Boundary
- Host Network Connection
- Host Operating System
- Process Control Application.

The final challenge is to show that IT network devices (e.g. IDSs) can be used with IACS, as well as with their field devices such as flow computers or PLCs. Security alerts from the devices must be able to be correlated to provide the proper intrusion detection in a realistic control system environment.

### 3.5 Test Bed Operating Model

The LOGIIC-1 test bed included four individual networks: a Corporate Network, a DMZ Network, a DCS Network, and a SCADA Network. The test environment includes both a SCADA application typically used to manage pipelines as well as a DCS application used to run refineries. These applications reside on process control networks (PCNs) with other IACS-specific equipment.

The standard IT defenses selected as event sources include the following:

- Network segment firewalls (in reporting, not blocking modes);
- Host firewalls (again, in reporting, not blocking modes);
- Network IDSs;
- Network devices (wired and wireless routers).

Three sources specific to control systems are

- PCS-protocol aware IDSs on the PCNs;
- Alarms from the DCS and SCADA;
- Alarms from flow computers.

A suite of sensors was selected to implement this defense-in-depth strategy. These sensors are triggered by abnormal activity and produce security events that are collected and correlated by an Enterprise Security Management (ESM) application. It is critical to relate security events in the IT network with IACS events to provide situational awareness. This allows IACS operators to identify threats that would previously go unnoticed. These threats can now be mitigated before potentially serious process disruptions occur.

Three sets of correlation rules were developed to enable this awareness:

1. Rules that identify steps of the critical attack scenarios (e.g. moving from network segment to another).
2. Rules that implement common IACS policies. IACS is quite static compared to business/corporate networks, so violation alerts can include rogue systems, IACS configuration changes, and port scans.
3. Rules that apply a data dictionary for IACS-specific security events. This dictionary would map proprietary logged IACS events to standardized security events.

## 4 SUMMARY

In the LOGIIC-1 Project, the team was able to implement ESM application (correlation engine) in generic O&G DCS & SCADA systems within a laboratory environment and integrated them with a simulated business network [5]. As a result, the project

- Successfully developed, implemented, and tested four attack scenarios, which model new threats to IACS brought by standardization and interconnectivity;
- Implemented a PCS security data dictionary;
- Identified, correlated, and alerted the compromises to environment at and across all levels;
- Provided enhanced situational awareness;
- Built an in-depth solution for industry deployment.

IT-type sensors were placed to detect events on the IACS generated information, which was combined with events extracted from the control system applications. Attack pictures were created using events from both sources.

The IT types of sensors provided events generated by their standard IT signature set, as well as events generated by a Modbus signature set to detect PCS-specific attacks. The control system applications were also able to provide unique control system alarm events for correlation.

On the basis of the results, it was predicted that there would be a reduction in workload for a security analyst looking for attacks, since filtering reduced the number of events an analyst would need to examine. One of the attack scenarios used created over 7,000,000 low-level events from the system sensors, which were reduced to about 1000 correlated events and then further prioritized to only 130 high-priority alerts.

The LOGIIC-1 results have now been implemented by several companies in their real-world environment, proving that this LOGIIC collaboration/partnership works very effectively.

## 5 NEXT STEPS

The LOGIIC model was developed to have broad applicability within the O&G industry as well as other IACS-dependent industries and government, and the synergy from such a private–public partnership results in higher quality results, reduced R&D, and lower costs. Addressing IACS cyber security risks within any critical infrastructure environment is a shared problem and needs to be addressed through a collaborative effort. The LOGIIC model has proven to be a vehicle that provide the necessary collaborative results.

In addition to the LOGIIC model, industries can improve PCSs security by supporting other industry collaboration such as the following:

- ISA-99 Committee that establishes standards, recommended practices, technical reports, and related information that will define procedures for implementing electronically secure manufacturing and control systems and security practices and assessing electronic security performance. The Committee's focus is to improve

the confidentiality, integrity, and availability of components or systems used for manufacturing or control, and to provide criteria for procuring and implementing secure control systems. Compliance with the Committee's guidance will improve manufacturing and control system electronic security, and will help identify vulnerabilities and address them, thereby reducing the risk of compromising confidential information or causing manufacturing control systems degradation or failure [7].

- ISCI, which is an industry consortium that facilitates an efficient forum of asset owners and suppliers for proposing, reviewing, and approving security conformance requirements for products in the automation controls industry. The resulting requirements form the basis for the *ISASecure*™ compliance designation, enabling suppliers to develop secure automation control products based on industry consensus security standards (security compliance "out of the box"). The *ISASecure*™ designation creates instant recognition of automation control products and systems that comply with *ISASecure*™ technical specifications. As a result, asset owners are able to efficiently procure and deploy *ISASecure*™ products with well-known security characteristics that are in conformance with industry consensus security standards such as ISA99. [8]
- Other security collaboration/partnerships such as API and NPRA.

## 6 CONCLUSION

The Event Correlation research conducted by the LOGIIC program addresses the need for coordination at many levels if our nation's critical PCSs are going to be secure. At the technology level, security data from many disparate sources must be collected and analyzed as an integrated resource. Otherwise, a potential avalanche of events can result in valuable security information being overlooked or misinterpreted, increasing the probability of a successful attack.

At the same time, coordination at the organizational and national level is also critical. Without it, each company would be forced to proceed on its own, achieving far less in the end. Instead, the synergy generated by the private–public partnership in LOGIIC resulted in a security project with higher quality results, reduced research time, and lower costs. We believe it stands as a model for industry and government cooperation in critical infrastructure security going forward.

## ACKNOWLEDGMENTS

We would like to thank:

- Chevron Corporation, for supporting cyber security activities such as LOGIIC, ISCI, and ISA-99 in the O&G industry, and also for assistance in publishing this article.
- The members of LOGIIC-1(Correlation Project) for their participation in the project and their significant contributions to the solution (http://www.cyber.st.dhs.gov/logiic.html).

- Ulf Lindqvist, Dale Peterson, Thomas Culling, Eric J. Byres, and Linda Shaltz for their special contributions to the completion of this paper.
- The Department of Homeland Security for providing valuable information via the LOGIIC website http://www.cyber.st.dhs.gov/docs/LOGIICbrochure.pdf.

## 1 HISTORY OF COOPERATION

The US government and financial institutions have a long history of cooperation. The government recognized financial institutions as an integral part of the nation's critical

infrastructure. As such, financial institutions are highly regulated and constantly supervised by regulatory agencies to ensure that they are able to withstand the various and increasing threats they face.

Examples of cooperation between the public and private sector in the late 1990s include preparations for the Century Date Change or "Y2K", *Preliminary Research and Development Roadmap for Protecting and Assuring Critical National Infrastructures* (July 1998) by the President's Commission on Critical Infrastructure Protection (PCCIP) and the Critical Infrastructure Assurance Office (CIAO),[1] and Presidential Decision Directive (PDD) 63 on Critical Infrastructure Protection (CIP, May 1998). PDD 63 established the first governmental approach to protecting the nation's critical infrastructures, assigning responsibility for protecting infrastructures in different economic segments to different governmental agencies, provided each responsible agency would appoint a private sector "Sector Coordinator" to work with the agency to pursue infrastructure protection in the sector, and encouraging the sharing of infrastructure protection information between government and private industry through the formation of information sharing and analysis centers (ISACs). It also supported research and development, outreach, and vulnerability assessment. PDD 63 described "A National Goal" as follows:

> "No later than the year 2000, the United States shall have achieved an initial operating capability and no later than five years from today [i.e. by May 22, 2003] *the United States shall have achieved and shall maintain the ability to protect the nation's critical infrastructures form intentional acts that would significantly diminish the abilities of*
>
> - the Federal Government to perform essential national security missions and to ensure the general public health and safety;
> - state and local governments to maintain order and to deliver minimal essential public services;
> - *the private sector to ensure the orderly functioning of the economy and the delivery of essential* telecommunications, energy, *financial* and transportation *services*." [emphasis added]

Under PDD 63, the Department of the Treasury ("Treasury") was assigned the responsibility for the banking and finance sector, and appointed Steve Katz, then Chief Information Security Officer for Citibank, as the first private sector "Sector Coordinator".

In the following years, the US Congress focused on cyber security issues as it related to privacy protection. Two significant laws governing privacy and security protections were enacted in the 1990s, the Health Insurance Portability and Accountability Act of (1996) also known as (HIPPA) and the Financial Services Modernization Act of 1999,[2] also known as the Gramm–Leach–Bliley Act (GLBA) (1999).

HIPAA[3] was enacted to restrict control of and access to patients' information and GLBA includes a provision requiring financial institutions to safeguard personal information. In 2001, regulators finalized regulations requiring financial institutions

[1]The *Preliminary Research and Development Roadmap for Protecting and Assuring Critical National Infrastructures* is available at http://cipp.gmu.edu/archive/190_PCCIPCIAORandDRoadmap_0798.pdf Other pertinent documents can be found in the CIP Digital Archive in the George Mason University School of Law Critical Infrastructure Protection Program website at http://cipp.gmu.edu/clib/CIPDigitalArchive.php.

[2]Public Law No. 106–102.

[3]Public Law 104–191, 42 U.S.C. 1301 et seq.

to establish appropriate safeguards for the use, disclosure, privacy, and security of personal information, including Social Security Numbers (SSNs). The regulators applied strong enforcement tools to ensure that financial institutions complied with these security requirements. In addition, the Federal Financial Institutions Examination Council (FFIEC),[4] issued several Information Technology booklets on topics including information security, business continuity planning (BCP), and outsourcing.[5]

In January 2000, the Clinton Administration released *Defending America's Cyberspace: National Plan for Information Systems Protection, Version 1.0: An Invitation to a Dialogue*. This report urged the creation of public private partnerships to address cyber security issues

Shortly after the 9/11 attacks of September 11, 2001, the government and financial services industry responded. Executive Order (EO) 13228[6] *Establishing the Office of Homeland Security (HLS) and the Homeland Security Council* created the present structure for the protection of the homeland and EO 13231[7] *Critical Infrastructure Protection in the Information Age*, outlined, *inter alia*, the public partnerships context for the protection of the critical infrastructure. Private sector advisory councils were formed, including the Homeland Security Advisory Council(HSAC) (EO 13228) and the National Infrastructure Advisory Council (NIAC) (EO 13231). The Office of HLS, first headed by former Pennsylvania Governor Thomas Ridge, was formed. In addition, the President's Critical Infrastructure Protection Board (PCIPB), based on the Clinton administration's *Defending America's Cyberspace* plan, was established. The PCIPB coordinated an effort to draft a national infrastructure protection strategy that included contributions from both public and private participants. All participants were asked to comment on how this effort should evolve. In particular, the goal was to avoid legislation and regulation by means of proactive collaborative measures. Each of the critical sectors was directed to publish its own strategy.[8]

Several financial services industry organizations supported these efforts, including the Securities Industry Association (formerly SIA, now Securities Industry and Financial Markets Association [SIFMA]), BITS (the Financial Services Roundtable's technology and operations division), and the Financial Services Information Sharing and Analysis Center (FS-ISAC). This support was intended to foster closer working relationships between government and the finance sector.

The US financial regulators and the US Treasury Department were also looking at these issues. Following a series of organizational meetings in 2001, the US Treasury and financial regulators developed a process to coordinate the activities of federal and state financial services regulators by establishing the Financial and Banking Information Infrastructure Committee (FBIIC).[9]

The FBIIC, originally a standing committee of the PCIPB, but currently chartered under the President's Working Group on Financial Markets, is charged with improving coordination and communication among financial regulators, enhancing the resiliency of

[4]An interagency body with representation from the Board of Governors of the Federal Reserve System, Federal Deposit Insurance Corporation (FDIC), the National Credit Union Administration (NCUA), Office of the Comptroller of the Currency (OCC), and Office of Thrift Supervision (OTS).

[9]Membership information can be found at www.fbiic.gov.

the financial sector, and promoting the public–private partnership. Treasury's Assistant Secretary for Financial Institutions chairs the committee.

In fulfilling its mission, the FBIIC set out to:

- identify critical infrastructure assets, their locations, potential vulnerabilities, and prioritize their importance to the financial system of the US;
- establish secure communications capability among the financial regulators and protocols for communicating during an emergency; and
- ensure sufficient staff at each member agency with appropriate security clearances to handle classified information and to coordinate in the event of an emergency.

Working with appropriate members of financial institution regulatory agencies, the FBIIC has accomplished the following:

- provided key federal and state financial regulators with secure telecommunications equipment for use in a crisis, and we adding a capacity for encrypted e-mail;
- written emergency communications procedures allowing communication between financial regulators and Federal, state, and local stakeholders;
- worked to systematically identify critical financial infrastructures, assess vulnerabilities within the critical financial infrastructure, address vulnerabilities, and evaluate progress; and
- identified the infrastructure that is critical to the retail payments system, the insurance industry, and the housing finance industry.

On May 10, 2002, key leaders from the financial services industry, with the encouragement of the Treasury, established the Financial Services Sector Coordinating Council (FSSCC).[10] Rhonda MacLean, then Chief Information Security Officer at Bank of America Corporation, was appointed the second Sector Coordinator for Financial Services by Treasury, and served as the founding Chairman of the FSSCC. The banking and finance sector published its first version of the sector's critical infrastructure protection plan in May 2002. The "National Strategy for Critical Infrastructure Protection" was jointly drafted by several associations including BITS, SIA, FS-ISAC, AbA, and in consultation with the financial regulators.[11]

Members of the FSSCC and FBIIC meet three times a year for discussions and briefings.

On September 18, 2002, the Bush administration released a draft of *The National Strategy to Secure Cyberspace*. The *National Strategy* outlined the "preferred" means of interaction between the public and private sectors. After incorporating comments, the Bush administration released the final *National Strategy to Secure Cyberspace* in February 2003.[12] On March 1, 2003, the Department of Homeland Security (DHS) was formally established and many of the responsibilities of the PCIPB were transferred to DHS.

[10]Details about the FSSCC and its activities can be found at the FSSCC website at www.fsscc.org.

[11]A 2004 update of this strategy and other publications about the FSSCC's activities can be found at the FSSCC website.

[12]*The National Strategy to Secure Cyberspace*, The White House, February 2003, is available at www.whitehouse.gov/pcipb/cyberspace_strategy.pdf. This document implements a component of *The National Strategy for Homeland Security* and is complemented by *The National Strategy for the Physical Protection of Critical Infrastructures and Key Assets*, which are available at www.whitehouse.gov/pcipb/physical_strategy.pdf.

In September 2002, several regulatory agencies released a draft paper outlining more stringent BCP requirements for certain types of large financial institutions. The *Draft Interagency White Paper on Sound Practices to Strengthen the Resilience of the US Financial System* was released for public comment by the Federal Reserve Board (FRB), Office of the Comptroller of the Currency (OCC), Securities and Exchange Commission(SEC), and the New York State Banking Department. Several financial institutions and associations submitted detailed comment letters on the proposal and objected to several onerous proposed requirements. In April 2003, three of the original agencies (the FRB, OCC, and SEC) released the final *Sound Practices White Paper* after considering 90 comment letters from industry participants.[13] The revised final paper did not insist on a minimum distance between primary and backup sites (e.g., 300 mile mission distance between primary and backup sites). However, it does require that institutions have staff, located outside their primary sites, which can conduct business if those at the primary site cannot get to the backup facilities. This became a good precedent for how meaningful, respectful discussion can lead to a proposal that meets requirements but is not overly burdensome on industry members.

In 2003, the President released the *National Strategy to Secure Cyberspace* and *National Strategy for Physical Protection of Critical Infrastructures and Key Assets*. These documents called for Treasury, as the lead agency for the banking and finance sector, to develop a research and development agenda for the sector. Treasury, working with the FBIIC and the FSSCC, published an agenda for the sector entitled "Closing the Gap". The driving force behind the document was a desire to identify key areas where additional research dollars could be spent to make the sector more secure. This document was socialized among Federal departments and agencies, academics, and financial services participants.

On March 7 and 8, 2005, Treasury, in conjunction with the National Science Foundation (NSF), hosted a workshop entitled "Resilient Financial Information Systems". Participants from academia and the public and private sectors worked to discuss and identify research priorities to advance the resilience of the financial sector and protect the nation's critical financial infrastructure. As the issue of research and development (R&D) for the financial services sector matured, the FSSCC developed a working group to focus specifically on the issue for R&D and to coordinate its activities with respect to critical infrastructure and key resources (CI/KR) R&D. At Treasury's request, the FSSCC joined DHS in a May 2005 workshop focused on R&D priorities.

DHS published an updated version of the National Infrastructure Protection Plan (NIPP) in 2005. The role of the sector-specific agencies in coordinating the activities of the sector was again reaffirmed in the document. As DHS was finalizing the NIPP R&D plans and programs, the FSSCC formed an R&D Committee to focus on those plans and programs that would provide the most significant benefits with respect to the specific CI/KR requirements of the financial services industry. In May 2006, this committee issued a list of priority research projects. The FSSCC Research and Development Committee Research Challenges and the FSSCC Research and Development Research Agenda were issued to assist researchers in focussing research on top concerns.[14] In February 2008, the FSSCC R&D Committee began to "beta test" the Subject Matter Advisory Response Team (SMART) program. The SMART program assists research

[13]The Interagency Paper is available at www.sec.gov/news/studies/34-47638.htm.
[14]Both of these documents are available at www.fsscc.org.

and development organizations working on Critical Infrastructure Protection Projects by providing subject matter expertise for financial institutions necessary to facilitate their R&D endeavors.

## 2 ORGANIZATIONAL ROLES

### 2.1 FSSCC

The Financial Services Sector Coordinating Council (FSSCC) for critical infrastructure protection and homeland security (CIP/HLS) is a group of more than 30 private sector firms and financial trade associations that works to help reinforce the financial services sector's resilience against terrorist attacks and other threats to the nation's financial infrastructure. Formed in 2002, FSSCC works with Treasury, which has direct responsibility for infrastructure protection and HLS efforts for the financial services sector.

The mission of the FSSCC is to foster and facilitate the coordination of financial services sector-wide voluntary activities and initiatives designed to improve CIP/HLS. Its objectives are to:

- provide broad industry representation for CIP/HLS and related matters for the financial services sector and for voluntary sector-wide partnership efforts;
- foster and promote coordination and cooperation among participating sector constituencies on CIP/HLS related activities and initiatives;
- identify voluntary efforts where improvements in coordination can foster sector preparedness for CIP/HLS;
- establish and promote broad sector activities and initiatives that improve CIP/HLS;
- identify barriers and recommend initiatives to improve sector-wide voluntary CIP/HLS information and knowledge sharing and the timely dissemination processes for critical information sharing among all sector constituencies; and
- improve sector awareness of CIP/HLS issues, available information, sector activities/initiatives, and opportunities for improved coordination.

As described above, the FSSCC is the private side of the public–private partnership which supports the National Infrastructure Protection Plan (NIPP). The other organizations listed in this section are all members of the FSSCC. Each organization has strengths in different areas, allowing the FSSCC to coordinate efforts of various members in support of overall infrastructure protection goals. Since the FSSCC was established, it has been chaired by distinguished and prominent members of the financial community Rhonda MacLean of Bank of America from 2002–2004, Donald Donahue of The Depository Trust and Clearing Corporation from 2004 through 2006 and George S. Hender of The Options Clearing Corporation from 2006 to 2008, and Shawn Johnson of State Street Global Advisors in 2008.

### 2.2 FSSCC Member Organizations

All FSSCC member organizations have contributed to industry goals for CIP. The organizations described below have provided the most direct focus on collaboration with respect to cyber security issues in the Banking and Finance Sector.

***2.2.1 BITS.*** In 1996, members of Bankers Roundtable (now The Financial Services Roundtable) created BITS in order to respond to significant technological changes facing the banking industry. BITS initially focused on changes in electronic commerce and the payments system, but evolved over time to focus on new threats that emerged in the areas of Internet security, fraud reduction, and CIP. Before 9/11, BITS helped to create the FS-ISAC. After 9/11, BITS helped to create the FSSCC and ChicagoFIRST.[15]

In 2001, BITS established the BITS Crisis Management Coordination Working Group (CMC-WG). This working group implemented The BITS and Financial Services Roundtable Crisis Communicator, a high-speed communications programs, that allowed the organization to connect all the key players—member CEOs and government and other business leaders—who might need to convene and determine how to address a crisis. The *BITS and Financial Services Roundtable (FSR) Crisis Management Process: Members' Manual of Procedures* was developed to provide BITS' members with the ability to communicate and coordinate with each other, government agencies, and other sectors in order to implement the emergency response and recovery process for the financial services sector.

One of the greatest lessons learned from 9/11 was the extent of the financial services sector's interdependencies and reliance on other critical sectors, specifically telecommunications and power. With the help of the Board of Governors of the Federal Reserve System, notably Steve Malphrus, BITS convened a conference in New York City in July 2002. The conference focused on ways to get tangible progress from other critical infrastructure sectors toward the goal of cooperation between government and the private sector.

One tool that resulted from the BITS Telecommunications Working Group efforts is the *BITS Guide to Business—Critical Telecommunications Services*. Completed in 2004[16], the Guide is based on extensive work by BITS members, participation by major telecommunications companies, and involvement by the National Communications System (NCS) and the President's National Security Telecommunications Advisory Council (NSTAC). The Guide is a comprehensive tool used by BITS' member institutions to better understand the risks of telecommunications interdependencies and achieve greater resiliency.

***2.2.2 ChicagoFIRST.*** Another clear lesson from 9/11 was the stunning impact an event could have on critical financial services operations that are heavily located in one regional area. Louis Rosenthal, ABN AMRO, and Ro Kumar, The Options Clearing Corporation, saw the potential risks in the Chicago area and energized their peers and a set of partners. BITS facilitated the process of forming the regional coalition. In 2003–04 the US Treasury Department founded an evaluation and guide for establishing regional coalition through the Boston Consulting Group and BITS. ChicagoFIRST, the result of these efforts, is a free-standing nonprofit organization that provides robust coordination services to maintain the resilience of the critical financial services that reside in the area. It continues to serve as a model for others, including FloridaFIRST and other regional coalitions.[17]

[15]ChicagoFIRST is a nonprofit association dedicated to addressing HLS and emergency management issues affecting financial institutions and requiring a coordinated response.

[16]The BITS Telecommunications Working Group, led by John DiNuzzo (formerly of FleetBoston/Bank of America Corporation) was a subgroup of the BITS CMC-WG.

[17]Improving Business Continuity in the Financial Services Sector: A Model for Starting Regional Coalitions (US Treasury: November, 2004). http://www.treas.gov/press/releases/reports/chicagofirst_handbook.pdf

***2.2.3 Financial Services Information Sharing and Analysis Center (FS-ISAC).*** The FS-ISAC was conceived at a meeting of Financial Industry leaders with the Treasury at the White House Conference Center in March 1999. An Information Sharing Working Group was established. The financial services industry members participating in the original Information Sharing Working Group appointed a Board of Managers, who formed FS-ISAC limited liability corporation (LLC). It was officially launched by US Treasury Secretary Lawrence A. Summers at a ceremony in the Treasury building on October 1, 1999, as a means of meeting the finance sector's information-sharing obligation under PDD 63 on CIP.

On December 9, 2003, the Treasury announced that it would purchase $2 million in services from the FS-ISAC. Treasury's contract with the FS-ISAC resulted in a new, next-generation FS-ISAC that is intended to benefit the Treasury, other financial regulators, and the private sector. In the press release, the Treasury indicated the purposes for the funding were as follows[18]

- Transform the FS-ISAC from a technology platform that serves approximately 80 financial institutions to one that serves the entire 30,000 institution financial sector, including banks, credit unions, securities firms, insurance companies, commodity futures merchants, exchanges, and others.
- Provide a secure, confidential forum for financial institutions to share information among each other as they respond in real time to particular threats.
- Add information about physical threats to the cyber threat information that the FS-ISAC currently disseminates.
- Include an advance notification service that will notify member financial institutions of threats. The primary means of notification will be by Internet. If, however, Internet traffic is disrupted, the notification will be by other means, including telephone calls and faxes.
- Include over 16 quantitative measures of the FS-ISAC's effectiveness that will enable the leadership of the FS-ISAC and Treasury to assess both the FS-ISAC's performance and the aggregate state of information sharing within the industry in response to particular threats.

The FS-ISAC was able to arrange with a managed security service provider to fund the initial development and implementation of the FS-ISAC systems and networks in return for the right to reuse the technology developed. The FS-ISAC thus succeeded in meeting its original goal of becoming a viable means for the banking and finance sector to share information about security threats, vulnerabilities, incidents, and remedies. E-mail alerts and notifications sent by the FS-ISAC give financial firms advanced notice of threats, vulnerabilities, and events so that they can proactively protect themselves. The FS-ISAC also hosts an information-sharing website, conference calls, and conferences that allow its members more interactive sharing opportunities.

In 2006, the FS-ISAC established a Survey Review Committee to provide oversight of the process of member-submitted surveys of the FS-ISAC membership. The FS-ISAC survey process allows for one live poll at a time to ensure maximum participation. The primary contact at each member organization is asked to complete each survey or route it to the appropriate area within their company to have it answered by the

[18]http://www.ustreas.gov/press/releases/reports/factsheet_js1048.pdf.

most qualified individual. Surveys conducted in 2007 included *Employee Access to HR Information*, *Data Transfer Methods*, and *Information Security Program Organization*. Once the survey is completed, a Poll Results Report is created that includes a brief summary and the final poll results. Using the survey tool link provided, members can also conduct their own detailed analysis of survey results to meet their unique needs.

Through the personal involvement of members of the FS-ISAC's Board of Managers and the FS-ISAC membership at large, the reach of the FS-ISAC members[19] quickly spread well beyond the original mandate. Early on, board members were involved in efforts such as

- participating, through the FSSCC, in drafting the finance sector's segment of Version 2.0 of the NIPP;
- assisting in, and being supportive of, the establishment of the BITS laboratory for testing and certifying security software relevant to financial services institutions;
- working with Treasury to develop an outreach and education program to increase awareness of sector security threats, vulnerabilities, and best practices, and to indicate how the FS-ISAC might assist them in these areas;
- briefing Federal agencies as to the workings of the FS-ISAC; and
- testifying before congressional committees and otherwise representing the views of the banking and finance sector on cyber security and CIP.

The FS-ISAC has been a model for a number of other ISACs in critical US sectors, such as transportation, energy and information technology, as well as ISACs in foreign countries (e.g. Canada) and in individual corporate organizations (e.g. the Worldwide ISAC). Its October 2007 biannual conference was recently coordinated in conjunction with the CIP Congress, carrying the theme "When Failure is Not an Option" and was accordingly attended by members of other ISACs.

***2.2.4 FSTC.*** The Financial Services Technology Consortium (FSTC) was established in 1993 at the dawn of the commercialization of the Internet. FSTC is a nonprofit organization with members from the financial services industry (financial services providers and vendors), government agencies, and academia, who collaborate on projects to explore and solve strategic business–technology issues through concept validation, prototype and piloting, and development of standards. Its mission is to harness technology advances and innovative thinking to help solve the problems of the financial services industry.

Early projects dealt with paper check imaging, the convergence of the payments products, and securing electronic banking, commerce, and payments over the Internet. These projects helped spur the growth of electronic commerce and paved the way for Check 21 and the electronification of the paper check through the development of important new standards and industry utilities and collaborations.

After September 11, FSTC's focus expanded to include addressing business continuity issues in addition to security, fraud management, and payments, leading to a partnership with Carnegie Mellon that developed a Resiliency Framework. FSTC also initiated a focus on enterprise architecture aimed at helping financial services firms to streamline and consolidate their siloed systems and processes, enabling the reduction of redundant

[19]The Board of Managers and members of the FS-ISAC are not restricted from other industry activities beyond the work of the FS-ISAC.

processes and systems, to provide a more efficient and flexible organization, able to more rapidly and easily accommodate new products, services, and processes needed to meet new business opportunities and threats.

FSTC thrives when the knowledge of members comes together through the formation of initiatives and projects that will better the industry as a whole. FSTC projects are its core activity and one of the key benefits of FSTC membership.

***2.2.5 SIFMA.*** SIFMA provides a forum for securities firms, exchanges, industry utilities, and regulators to share knowledge, plans, and information. It is responsible for developing and promoting industry-specific practice guidelines, for providing liaison between the securities industry and regulators and legislators, and for coordinating industry-wide initiatives. SIFMA has standing committees to coordinate industry-wide initiatives for various types of securities industry trading and operations activities.

The SIFMA BCP Committee was established as the SIA BCP in November 2001 to address and coordinate business continuity issues for the securities industry. In conjunction with the BCP Committee mission, SIFMA (and its predecessors, the SIA and the Bond Markets Association) has led an extensive on-going industry-wide business continuity testing initiative since 2002. The effort allows the industry as a whole to verify and demonstrate the resilience of the securities markets and to provide individual firms with opportunities to test their procedures with other industry participants in a way they could not do on their own. Industry tests include tabletop exercises, connectivity tests, communications tests, participation in national disaster recovery tests, and pandemic flu exercises. SIFMA in conjunction with the BCP Committee operates the Securities Industry Emergency Command Center that functions as the industry's central point of emergency communications and coordination during significant emergencies.

Initial testing efforts in 2002, 2003, and 2004 involved basic connectivity tests between individual firms and exchanges. Much more robust business continuity tests were conducted in 2005 and 2006. Over 250 firms, exchanges and industry utilities participated in these tests, which involved transmission of dummy transactions from firms' and exchanges' backup sites using backup communications links. The industry demonstrated a 95% pass rate on these tests. SIFMA also coordinates securities industry participation in the national TopOff emergency exercises and focuses heavily on planning for a potential flu pandemic and on conducting pandemic planning exercises.

SIFMA's Information Security Subcommittee, which was established in 2003, addresses and coordinates information security issues from an industry perspective and facilitates information sharing among SIFMA member firms. The Subcommittee provides comments to regulatory authorities on proposed information security rules and regulations and develops industry initiatives. The Subcommittee has focused on a variety of issues including developing guidance on the design and testing of Sarbanes Oxley controls, working with legislators on proposed Security Breach Legislation, tracking and assessing Microsoft security releases, and establishing guidance on effective means of dealing with phishing attempts.

In 2007, SIFMA formed the Information Risk Advisory Council to provide advice to SIFMA's Technology, Information Security, BCP, and Privacy Committees. The Council identifies issues of significant importance to securities firms and works with SIFMA Committee to integrate these into the committees' annual goals.

## 3 SAMPLE SIGNIFICANT EVENTS

Although cyber security-related events are a daily occurrence in the financial industry, some events are more significant than the others with respect to collaborative information sharing. The events listed below were significant in that the collaboration that occurred during the event served to strengthen the bonds of communication between public and private sector CIP organizations.

### 3.1 Russian Hacker Case

In June 1994, a Russian crime ring managed to get inside the Citibank computer system and transfer $140,000 from the Philippine National Bank to a bank in Finland. The bank in the Philippines called to complain that the transaction had not been authorized. Citibank realized something was amiss and set up a special team to start looking into transactions of similar circumstance. However, it was not given that the unauthorized transfer was the first discovery of a chain of illegal activity. By the middle of July, the team identified a similar transfer had taken place and yet a third by the end of the month. By this time, Citibank had called in the Federal Bureau of Investigation (FBI) and the investigation was in full swing. Transactions were being illegally transferred from cities as far away as Djakarta and Buenos Aires to banks in San Francisco and Israel. In total, fraudulent transactions amounted to more than $3 million; though in the end, the gang of thieves managed to abscond with only $400,000.

The system breached was called the Citibank Cash Management system. This system allowed corporate customers to transfer money automatically from their accounts to whoever they are paying. And it handled approximately 100,000 transactions a day, totaling $500 billion. The Citibank system relied on static passwords, which they intend for users to memorize. The passwords remain the same each time a user enters the system, and although they are encrypted, the crime ring was somehow able to get a password and identification numbers of some of these corporate customers. The investigation team realized that the passwords traversed through many network links that were not necessarily fully owned and operated by the bank, but many were leased from telecommunication companies in various countries which provided the bank with network links between its offices. The question the investigators faced was did the perpetrator have an insider in Citibank or was he able to get them using conventional "network-sniffing" software.

On August 5, a fraudster transferred $218,000 from a Citibank account in Djakarta and another $304,000 from a bank in Argentina to Bank of America accounts in San Francisco that had been set up by a Russian couple. They would go to the bank after the money was transferred and attempt to withdraw it. At that point, investigators identified the perpetrators. They were kept under observation by both the public and private sector through October, transferring money from and to more accounts.

The idea of computer control of funds was new to the media at that time. It was a new idea to reporters that a person could be sitting at a computer in Russia in the middle of the night keying in passwords and watching money move across a screen. The Internet was still young at the time and largely unused commercially. The transfers were done through a proprietary network managed by Citibank. But, like the Internet, these proprietary networks cross over other proprietary networks and it is at these points that

passwords become most vulnerable. Yet cooperation between the bank investigators, telecommunications administrators, and law enforcement led eventually to Vladimir Levin, a young Russian hacker. He was trapped through a traced telecommunications line performing a fraudulent transaction and was imprisoned. In the course of the investigation, several people were arrested (including half a dozen Russian citizens, for which this story is known as the "Russian Hacker Case"). Immediately after, Citibank ended the use of static passwords over its Funds Transfer networks and started issuing One Time Password tokens to customers using those networks (these tokens were a form of two factor authentication from a small company named RSA from its founders, Rivest, Shamir, and Adelman, then infrequently encountered).

### 3.2 Slammer Worm

On January 23, 2003, a structured query language (SQL) injection dubbed the "slammer worm" started to infect rapidly through computer systems throughout the world. Although a patch was released for the vulnerability, many organizations had not installed it. As a result, the worm spread very quickly, infecting, by one account, 75,000 victims within 10 min after its release.

Although financial institutions were not greatly affected by the worm, Treasury, in coordination with the FBIIC and FSSCC, convened a meeting on February 25, 2003, to discuss issues related to the worm. In addition to members of the FBIIC and FSSCC, several private sector groups attended, including Microsoft and electronic data system (EDS). At the meeting, communications protocols were developed to aid in the sharing of information in the event of another incident. The protocols were exercised during several other virus/worm attacks, including SoBig.F and BugBear.b.

### 3.3 2003 Power Outage

At approximately 4:11 pm Eastern Daylight Time (EDT) on August 14, 2003, a power outage affected a large portion of the Northeastern United States, roughly from Detroit to New York City. Although there was minimal disruption to delivery of financial services in the affected area, the incident did expose a greater need to continue to examine the backup systems institutions. For example, the American Stock Exchange had relied upon steam power to cool their trading floor. Upon reaching out to the SEC and the Treasury, a backup steam generator was located and the exchange was able to open and close on Friday, August 15, 2003.[20] Many lessons learned from that set of events. One lesson led to the *BITS Guide to Business—Critical Power*, developed in cooperation with the Critical Power Coalition and Power Management Concepts, and published in 2006. It provides financial institutions with industry business practices for understanding, evaluating, and managing the associated risks, when the predicted reliability and availability of the electrical system are disrupted—and it outlines ways by which financial institutions can enhance reliability and ensure uninterrupted backup power.

The following table, Table 1 describes a series of publications and events related to information sharing and coordination within the finance and banking sectors.

[20]The report, *Impact of the Recent Power Blackout and Hurricane Isabel on the Financial Services Sector*, can be found at http://www.treas.gov/offices/domestic-finance/financial-institution/cip.

### 3.4 Pandemic Planning

In September and October 2007, SIFMA, in partnership with the FSSCC, the FBIIC, and the Treasury, conducted a multiweek pandemic flu exercise for the full financial services sector. This was the largest most ambitious financial services exercise to date that addressed business process recovery as a sector in communication with its sector-specific agency. The exercise offered a realistic simulation of the spread of a pandemic wave in the United States. It was designed to identify how a pandemic could affect the financial markets and to provide participants with an opportunity to examine their pandemic business recovery plans under a demanding scenario. Over 2700 financial services organizations participated.

### 3.5 Operation Firewall

On October 28, 2004, the US Department of Justice, in coordination with the United States Secret Service (USSS), executed over 28 search and arrest warrants in connect

with Operation Firewall,[21] an undercover investigation designed to stop the flow of stolen credit card numbers and other personal information. This operation lured criminals into a false sense of security by creating a fake website for buying and selling purloined credit card information. The main target was a group that called itself Shadowcrew, whose sole purpose was to defraud the financial services sector.

The operation, which lasted over an 18 month period, ended with the seizure of over 100 computers and the arrest of 28 individuals—21 in the United States and seven in Europe and Russia. Through the cooperation of several major financial services sector entities, the underground "carding" scene was dealt a major blow from which it is still attempting to recover.

## 4 FUTURE CHALLENGES

The examples above demonstrate high levels of collaboration among dedicated individuals representatives financial institutions, associations, and government agencies. For this collaboration to continue, it will require proactive engagement, open communications, and trust. The industry needs to cooperatively work with the respective agencies to develop rules and regulations that best meet the requirements of government while maintaining a strong finance sector and not overburdening financial institutions.

Since 9/11, government has proven its willingness to reach out and ensure the consensus of the financial community in its efforts to strengthen the infrastructure. It has also demonstrated increased trust on the part of the private side of the financial sector of government's intent and a willingness to work with the various agencies, and to persuade others that cooperation is ultimately the best approach where each side can achieve its goals.

# SYSTEM AND SECTOR INTERDEPENDENCIES

# SYSTEM AND SECTOR INTERDEPENDENCIES: AN OVERVIEW

JAMES P. PEERENBOOM AND RONALD E. FISHER
*Argonne National Laboratory, Argonne, Illinois*

## 1 INTRODUCTION

The importance of infrastructure interdependencies was first highlighted at the national level in 1997 when the President's Commission on Critical Infrastructure Protection (CIP) released its landmark report, *Critical Foundations: Protecting America's Infrastructures* [1]. The report pointed out that the security, economic prosperity, and social well-being of the nation depend on the reliable functioning of our increasingly complex and interdependent infrastructures.

In defining its case for action, the Commission noted that interdependency between and among our infrastructures increases the possibility that a rather minor and routine disturbance could cascade into regional or national problems. The Commission further concluded that technical complexity could also permit interdependencies and associated vulnerabilities to go unrecognized until a major failure occurs. The blackout on August 14, 2003, in which large portions of the Midwest and Northeast United States and Ontario, Canada, experienced an electric power outage, dramatically illustrated the enormously complex technical challenge that we face in preventing cascading impacts [2].

In the nearly 10 years since the release of the *Critical Foundations* report, much has been written about identifying, understanding, and analyzing infrastructure interdependencies, and significant progress has been made [3]. This progress has been the result of a number of interrelated factors, including the following:

- the emergence of a risk-based national strategy for all-hazards infrastructure protection that explicitly addresses dependencies and interdependencies;
- focused national Research and Development (R&D) efforts that address both physical and cyber infrastructures and their interdependencies in a more integrated manner;
- new analytical techniques that capture complex system response and human behavior;
- a growing awareness of interdependencies issues and increased interest by local and regional stakeholder groups who have held interdependencies-related exercises,

captured lessons learned from natural and man-made infrastructure disruptions, and been proactive in addressing interdependencies-related needs; and
- a new generation of professionals who have the requisite educational backgrounds and skill sets to address infrastructure and interdependencies.

These factors are briefly discussed in the following sections of this article and in more detail in the subsequent articles of this handbook.

## 2 CONCEPTS AND TERMINOLOGY

The release, over the past several years, of national strategy and policy documents, such as *Homeland Security Presidential Directive 7: Critical Infrastructure Identification, Prioritization, and Protection* (HSPD-7), *The National Strategy for the Physical Protection of Critical Infrastructures and Key Assets*, *The National Strategy to Secure Cyberspace*, and the *National Infrastructure Protection Plan* (NIPP), have reshaped the definition of critical infrastructure and key resources (CIKR) in the United States [4–7]. These documents define 18 CIKR as follows: agriculture and food, water, health care and public health, emergency services, defense industrial base, energy, information technology, banking and finance, telecommunications, dams, transportation systems, chemical, postal and shipping, national monuments and icons, government facilities, commercial facilities, and commercial nuclear reactors critical manufacturing was added in 2008 as the 18th sector. Although other countries may aggregate differently (e.g. Canada identifies 10 critical infrastructures), significant similarities can be found in terms of capturing the assets, systems, and networks that, if lost or degraded to varying degrees, would have a debilitating impact on national security, public health and safety, the economy, and other dimensions of concern.

A variety of concepts and definitions can be used to describe interdependencies among the CIKR sectors [8, 9]. The NIPP defines interdependency as the "multi- or bi-directional reliance of an asset, system, network, or collection thereof, within or across sectors, on input, interaction, or other requirement from other sources in order to function properly" [7]. Infrastructure interdependencies are characterized in terms of four general categories:

- physical (e.g. the material output of one infrastructure is used by another);
- cyber (e.g. infrastructures utilize electronic information and control systems);
- geographic (e.g. infrastructures are co-located in a common corridor); and
- logical (e.g. infrastructures are linked through financial markets).

The proliferation of information technology, along with the widespread use of automated monitoring and control systems and increased reliance on the open marketplace for purchasing and selling infrastructure commodities and services (e.g. electric power), has intensified the prevalence and importance of cyber and logical interdependencies.

Physical, cyber, geographic, and logical infrastructure interdependencies transcend individual infrastructure sectors (by definition) and generally transcend individual public and private-sector companies. Further, they vary significantly in scale and complexity, ranging from local linkages (e.g. municipal water-supply systems and local emergency services), to regional linkages (e.g. electric power coordinating councils), to national

linkages (e.g. interstate natural gas and transportation systems), to international linkages (e.g. telecommunications and banking and finance systems). These scale and complexity differences create a variety of spatial, temporal, and system representation issues that are difficult to identify and analyze.

To facilitate analysis, infrastructure interdependencies must be viewed from a "system of systems," or holistic, perspective. Failures affecting interdependent infrastructures can be described in terms of three general categories:

- *Cascading failure.* A disruption in one infrastructure causes a disruption in a second infrastructure (e.g. the August 2003 blackout led to communications and water-supply outages, air traffic disruptions, chemical plant shutdowns, and other interdependency-related impacts).
- *Escalating failure.* A disruption in one infrastructure exacerbates an independent disruption of a second infrastructure (e.g. the time for recovery or restoration of an infrastructure increases because another infrastructure is not available).
- *Common cause failure.* A disruption of two or more infrastructures at the same time results from a common cause (e.g. Hurricane Katrina simultaneously impacted electric power, natural gas, petroleum, water supply, emergency services, telecommunications, and other infrastructures).

As an illustration of cascading and escalating failures, consider the disruption of a microwave communications network that is used for the supervisory control and data acquisition (SCADA) system in an electric power network. The lack of monitoring and control capabilities by the SCADA system could cause generating units to be taken off-line, which, in turn, could cause a loss of power at a distribution substation. This loss could lead to blackouts for the area served by the substation.

The electricity outages could affect multiple dependent infrastructures (depending on the availability of backup systems), such as transportation and water systems, commercial office buildings, schools, chemical facilities, banking and financial institutions, and many others. These disruptions could lead to delays in repair and restoration activities (i.e. an escalating failure) because of logistics, communications, business services, and other interdependency-related problems.

This simplified example reinforces the notion that understanding and analyzing cascading and escalating failures require a systems perspective and a broad set of interdisciplinary skills.

The state of operation of an infrastructure—which can range from normal operation to various levels of stress, disruption, or repair and restoration—must also be considered in examining interdependencies. Further, it is necessary to understand backup systems, other mitigation mechanisms that reduce interdependency-related problems, and the change in interdependencies as they relate to outage duration and frequency. Such considerations add complexity to the process of quantifying infrastructure interdependencies.

### 2.1 Lessons Learned

Analytical studies and real-world events have highlighted the importance of the characteristics and complexities described above. A number of lessons have been learned that have broad implications for interdependencies planning and analysis:

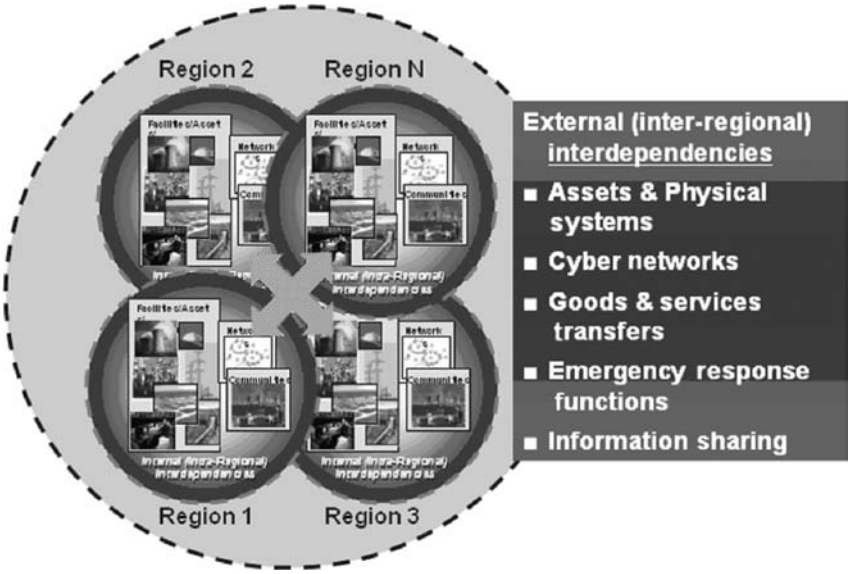

**FIGURE 1** Intra- and interregional interdependencies.

- *Interdependencies have no borders.* Infrastructure systems and supply chains transcend geographic and geopolitical boundaries, allowing disruptions to cascade in ways that are not well documented or well understood.
- *Interdependencies can be considered at multiple levels.* Different perspectives can be applied in analyzing interdependencies, ranging from an asset- or facility-level perspective to a network-, community-, region-, systems-, or CIKR sector-level perspective.
- *Intra- and interregional interdependencies are fundamental to ensuring regional resilience.* Analysts must examine interdependencies that are internal to a region (intraregional interdependencies), as well as the interconnections with other regions (interregional interdependencies), which could include backbone infrastructure systems and networks, transfers of goods and services, and shared emergency response capabilities (Fig. 1).
- *Interdependencies can influence all components of risk.* Interdependencies can act as a "risk multiplier" in that they can influence all components of risk. For example, interdependencies can (i) amplify the consequences of a disruption because of cascading and escalating impacts, (ii) expand the set of vulnerabilities because CIKR can be affected indirectly, and (iii) in the case of terrorism, change the threat (intent) through innovative targeting to specifically exploit interdependencies.
- *Interdependencies change during events.* Pre-event interdependencies, which are a function of system operations and topologies, change during an event (trans-event) depending on the specific assets affected, the use of backup systems, and the implementation of contingency plans. Post-event interdependencies may be different from pre-event interdependencies depending on how infrastructure systems are reconstituted, how supply chains are reconfigured, and how operational procedures and contingency plans are modified.

Given these considerations, key questions—from an owner/operator viewpoint—that facilitate discovery of interdependencies information and help determine the importance of interdependencies impacts include the following:

- Do you know what CIKR you depend on and who are your suppliers?
  - direct reliance on infrastructures;
  - indirect reliance through supply chains; and
  - reliance on vendors (goods and services).
- Do you know what cascading impacts might result from disruptions?
- Do you know what backup systems are in place and how long they are likely to last?
- Do you know where to get information about infrastructure restoration priorities and time lines?

### 2.2 Research and Development Needs

Consistent with the new national strategy described in the NIPP, *The National Plan for Research and Development in Support of Critical Infrastructure Protection* (NCIP R&D Plan)—prepared by the Office of Science and Technology Policy and the Department of Homeland Security (DHS) Directorate for Science and Technology—recognizes that physical and cyber infrastructures must be addressed in an integrated manner because these two areas are interdependent in all sectors, and each can disrupt or disable the other [10]. The NCIP R&D Plan represents an important shift in philosophy in that past R&D roadmaps for CIP tended to separate physical and cyber considerations.

As described more fully in later articles of this handbook, the NCIP R&D Plan notes that "critical infrastructure systems are complex, interconnected physical and cyber networks that include nodes and links with multiple components. Analysis and decision support methods help decision makers make informed choices involving these complex systems using structured, analytic approaches that incorporate controlling factors and detailed knowledge relevant to the critical infrastructure systems and their interconnectivity and reliance on one another."

Among the many R&D needs described in the Plan, decision and analysis R&D work is needed to achieve the following:

- Develop risk-informed prioritization and investment strategies to fund research, to address the most serious issues first, and to achieve the best return from the limited funding resources available.
- Develop precision vulnerability analysis tools to quantitatively predict the performance of critical infrastructure network elements if attacked, and advance these engineering tools to include new materials, innovative network design concepts, and emerging computational methods.
- Develop high-fidelity modeling and simulation capabilities to quantitatively represent the sectors and their interconnectivity and to identify realistic, science-based consequences if attacked.
- Develop integrated, multi-infrastructure advanced action and response plans for a range of threat/hazard scenarios, and "war-game" these actions and plans to anticipate problems and prepare in advance the most effective combinations and sequences of protection measures before an event occurs.

The emphasis on developing modeling and simulation capabilities and making risk-informed decisions underscores the need to (i) devise new approaches for addressing CIKR as a "system of systems" and (ii) explicitly include interdependencies considerations. Difficult issues related to spatial and temporal modeling resolution, propagation pathways for cascading disruptions, system complexity and nonlinear behavior, uncertainty, and human factors remain largely unanswered (although, as described below, progress is being made).

## 3 MODELING OF INFRASTRUCTURE INTERDEPENDENCIES

The "science" of interdependencies is still relatively new, although new modeling and simulation tools are beginning to address selected dimensions of interdependency (Fig. 2). A variety of models and computer simulations have been developed to analyze the operational aspects of individual infrastructures (e.g. load flow and stability programs for electric power networks, connectivity and hydraulic analyses for pipeline systems, traffic management models for transportation networks). In addition, simulation frameworks that allow the coupling of multiple, interdependent infrastructures are beginning to emerge.

For example, the DHS National Infrastructure Simulation and Analysis Center (NISAC)—built around a core partnership of Los Alamos National Laboratory and Sandia National Laboratories and chartered to develop advanced modeling, simulation, and analysis capabilities for the nation's CIKR—has developed tools to address physical and cyber dependencies and interdependencies in an all-hazards context [7]. Actor-based

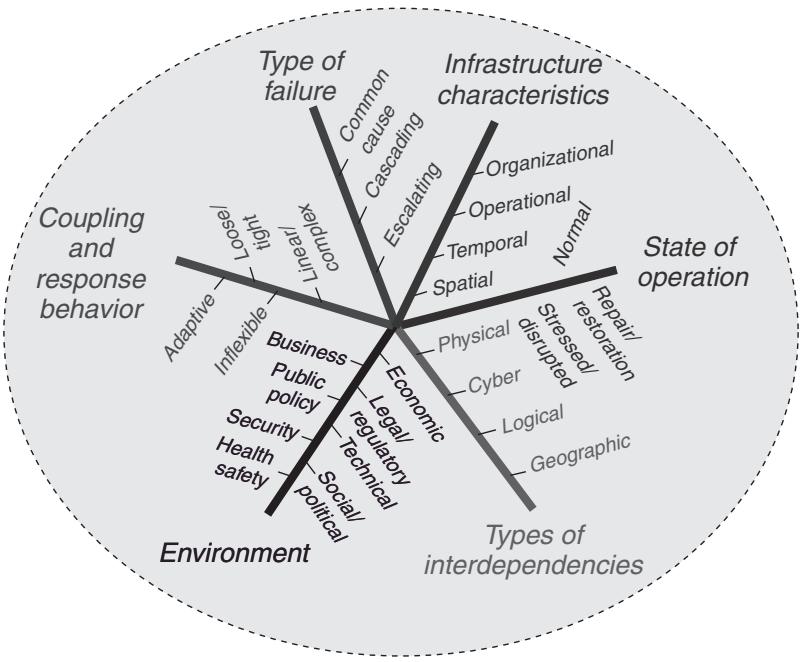

**FIGURE 2** Dimensions of interdependencies [3].

infrastructure modeling, simulation, and analysis tools, such as the Interdependent Energy Infrastructure Simulation System (IEISS), have been developed to assist individuals in analyzing and understanding interdependent energy infrastructures [11]. Dynamic systems and agent-based models also are being developed to capture economic interactions between the decision makers in infrastructure networks [12].

NISAC also has developed tools such as N-ABLE, a large-scale microeconomic simulation tool that captures the complex supply chain and market dynamics of businesses in the US economy, and the Fast Analysis Infrastructure Tool, which provides information on infrastructure assets, including their interrelationships with other infrastructure assets. Other interdependencies-related tools include the Urban Infrastructure Suite, a set of seven interoperable modules that employ advanced modeling and simulation methodologies to represent urban infrastructures and their interdependencies, as well as populations [13].

In a joint effort, Argonne, Los Alamos, and Sandia national laboratories, under the sponsorship of the DHS Science and Technology Directorate, are developing a risk-informed decision support system (DSS)—the Critical Infrastructure Protection/Decision Support System (CIP/DSS)—that provides insights for making CIP decisions by considering all CIKR sectors and their primary interdependencies [14]. CIP/DSS will assist decision makers in making informed choices by functionally representing the CIKR sectors and their interdependencies; computing human health and safety, economic, public confidence, national security, and environmental impacts; and synthesizing a methodology that is technically sound, defensible, and extendable.

CIP/DSS will address questions such as the following:

- What are the consequences of attacks on infrastructure in terms of national security, economic impact, public health, and conduct of government, including the consequences that propagate to other infrastructures?
- Are there choke points in our nation's infrastructures (i.e. areas where one or two attacks could have the largest impact)? What and where are the choke points?
- What are the highest-risk areas when consequence, vulnerability, and threat information are incorporated into an overall risk assessment?
- What investment strategies can the United States make that will have the most impact in reducing overall risk?

CIP/DSS has been applied to problems involving an agricultural pathogen that affected the food chain and involved regional transportation quarantines, as well as a telecommunications disruption that degraded the operation of other infrastructure sectors. Using CIP/DSS, analysts computed decision metrics and utility values for several investment alternatives that would mitigate the impact of the incidents.

Argonne National Laboratory has developed a series of modeling and simulation tools to address various facets of infrastructure assurance and interdependencies. These tools include the Electricity Market Complex Adaptive Systems (EMCAS) model, which is designed to provide new insights into today's dynamic electricity markets [15–17]. EMCAS uses agent-based modeling techniques that represent multiple and diverse market participants or "agents," each with its own unique set of business and bidding strategies, risk preferences, objectives, and decision rules. The success of an agent is a function not only of its own decisions and actions, but also of the decisions and actions of other market participants. Because minimal amounts of local information are shared among

participants, agent decisions in EMCAS are made without either perfect knowledge or certainty.

The model's complex adaptive systems (CAS) approach empowers market agents to learn from past experience and change and adapt their behavior when future opportunities arise. With EMCAS, analysts can capture and investigate the complex interactions between the physical infrastructures (i.e. generation, transmission, and distribution) and the economic behaviors of market participants, which are a trademark of the newly emerging markets. The model does this by representing the transmission grid in detail and simulating the market operation on a chronological, hourly basis. This feature is particularly important when trying to assess the issue of market power.

Other CAS models, such as SMART II+ and SymSuite, have been developed to analyze large-scale, interconnected infrastructures with complex physical architectures [18, 19]. These models emphasize the specific evolution of integrated infrastructures and their participants' behavior, not just simple trends or end states. Argonne is also developing a next-generation drag-and-drop simulation-building platform that offers a unique, comprehensive, and unified modeling environment with capabilities for developing and integrating dynamic physical systems models, agent-based simulations, real-time data flows, advanced visualization, and postprocessing tools.

Another tool, called Restore, was developed at Argonne to address the postdisruption elements of interdependencies. Through Monte Carlo simulation, Restore estimates the time and/or cost to restore a given infrastructure component, a specific infrastructure system, or an interdependent set of infrastructures to an operational state [20]. The tool allows users to create a representative model of recovery and restoration activities. Graphical and tabular results allow analysts to better quantify the impact of infrastructure disruptions. Restore also provides a framework for incorporating uncertainty into the analysis of critical infrastructures.

Considerable research and model development are also underway at academic institutions and research centers throughout the world. For example, a Critical Infrastructure Simulation by Interdependent Agents (CISIA) simulator was developed at the Universita Roma Tre using CAS techniques to analyze the short-term effects of infrastructure failures in terms of fault propagation and performance degradation [21]. An interoperability input–output Model was developed at the University of Virginia Center for Risk Management of Engineering Systems to analyze the impacts of an attack on an infrastructure and the cascading effects (in economic and inoperability terms) on all other interconnected and interdependent infrastructures [22]. Although it is not possible to cite all relevant researches, an inventory and analysis of protection policies in 20 countries and 6 international organizations was published in 2006 by the Center for Security Studies in Zurich, Switzerland [23].

## 4 EDUCATION AND SKILL REQUIREMENTS

Multiple viewpoints and a broad set of interdisciplinary skills are required to understand, analyze, and sustain the robustness and resilience of our interdependent infrastructures [9]. For example, engineers (e.g. chemical, civil, electrical, industrial, mechanical, nuclear, structural, and systems) are needed to understand the technological underpinnings of

the infrastructures, as well as the complex physical architectures and dynamic feedback mechanisms that govern their operation and response (e.g. response to stresses and natural and man-made disruptions). Supply-chain analysts are needed to unravel and analyze, from an interdependencies perspective, the local, regional, national, and international flows of goods and services that support the functioning of our infrastructures.

Computer scientists, information technology specialists, and network and telecommunications experts are needed to understand the electronic and informational (cyber) linkages among the infrastructures. Information security and information assurance professionals are needed to ensure cyber security.

Economists are needed to understand the myriad marketplace and financial considerations that shape the business environment for public and private-sector infrastructure owners and operators. Expertise in estimating the direct and indirect economic consequences of infrastructure disruptions and building the necessary business cases for action is critical.

Social scientists are needed to understand the behaviors of infrastructure service providers, brokers, consumers, and other organizational entities that compete in the new economy. Health physicists and safety professionals are needed to quantify the public health and safety consequences of various disruption events that involve a wide range of threats (e.g. chemical, biological, radiological, nuclear, and explosive sources).

Lawyers, regulatory analysts, and public policy experts are needed to understand the legal, regulatory, and policy environment within which the infrastructures operate. Security and risk management experts are needed to perform vulnerability assessments (physical and cyber) and develop strategies to protect against, mitigate the effects of, respond to, and recover from infrastructure disruptions.

Software engineers, along with appropriate infrastructure domain and interdependencies experts, are needed to develop modeling and simulation tools to assess the technical, economic, psychological, and national security implications of technology and policy decisions designed to ensure the reliability and security of the nation's interdependent infrastructures. Insights from such tools will inform policy and decision-making processes.

Most important, risk and decision analysts are needed to help government officials at all levels, as well as private-sector infrastructure owners and operators, make cost-effective operation, protection, and risk management decisions. Such skills are also required to make defensible public policy, R&D, and resource-allocation decisions—and to effectively communicate those decisions.

## 5 PATH FORWARD

Important progress is being made in developing analytical approaches and modeling and simulation tools to address various facets of interdependencies. However, much remains to be accomplished, particularly because of the complexity and pervasive nature of interdependencies, and because they influence—in complex and uncertain ways—each component of the risk equation (threat, vulnerability, and consequence). A wide range of interdisciplinary skills are clearly required for comprehensive interdependencies analysis. This creates an additional challenge in terms of training across the diverse range of skill sets (e.g. software engineers, economists, and social scientists) and developing integrated

analyses and assessments. Exercises, such as the Blue Cascades exercises undertaken in the Pacific Northwest, provide a forum for discussing such issues and uncovering critical concerns at both the local and regional levels [24]. Information captured in responding to accidents and natural disasters, such as the August 2003 blackout and the recent hurricanes along the Gulf Coast, also provide valuable insights.

The following actions provide a foundation and path forward for understanding and analyzing interdependencies:

- Identify internal and external infrastructure assets, systems, and networks that, if lost or degraded, could adversely affect the facility, sector, or region of interest.
- Study natural disasters and incidents to gain insight into interdependencies problems and solutions.
- Develop contingency plans to deal with cascading outages.
- Identify how backup systems and other mitigation mechanisms can reduce interdependencies problems (and implement these mechanisms, as appropriate).
- Address interdependencies-related security through contractual arrangements with suppliers and distributors.
- Develop effective and secure procedures to share sensitive information, as appropriate, and tools to analyze interdependencies-related impacts.
- Collaborate, cooperate, and participate with supply/security partners; avoid failure of imagination in terms of "what if" events that could lead to infrastructure disruptions and associated interdependencies-related impacts.

# SYSTEM AND SECTOR INTERDEPENDENCIES: AN OVERVIEW OF RESEARCH AND DEVELOPMENT

PAUL D. DOMICH
*CIP Consulting, Inc., Boulder, Colorado*

## 1 INTRODUCTION

This article will address the National Critical Infrastructure Protection Research and Development (NCIP R&D) Plan, the National Infrastructure Protection Plan (NIPP) and sector-specific agencies' (SSAs) R&D efforts.

## 2 HIGH-LEVEL R&D PRIORITIES FOR CRITICAL INFRASTRUCTURE/KEY RESOURCE

As recognized in the *National Strategy for Homeland Security*, "The Nation's advantage in science and technology is a key to securing the homeland." Research and development in modeling complex systems, data analysis, information sharing, threat identification and the detection of attacks, and the development of effective countermeasures will help prevent or limit the damage from disasters both man-made and naturally occurring. A systematic national effort has been created to leverage science and technology capabilities in support of national homeland security goals that involve private sector companies, universities, research institutes, and government laboratories involved in research and development on a very broad range of issues.

## 3 MOTIVATION FOR A NATIONAL R&D PLAN

Achieving this potential to field important new capabilities and focus new efforts in support of homeland security is a major undertaking. The Department of Homeland Security (DHS) and other federal agencies have been given responsibility to work with private and public entities to ensure that our homeland security research and development efforts are of sufficient size and sophistication to counter the threats posed by natural disasters and terrorism. The goal of this national R&D effort is to develop the desired new capabilities through "an unprecedented level of cooperation throughout all levels of government, with private industry and institutions, and with the American people to protect our critical infrastructures (CIs) and key assets from terrorist attack."[1]

[1]Homeland Security Presidential Directive 7/HSPD-7.

## 4 NATIONAL STRATEGIES, PRESIDENTIAL DIRECTIVES, AND AUTHORIZING LEGISLATION

The roles and responsibilities related to critical infrastructure/key resource (CIKR) research and development follow from a series of authorities, including the Homeland Security Act of 2002, CIKR protection-related legislation, Presidential Executive Orders, Homeland Security Presidential Directives, and National Strategies. These current authorities and directives have built upon those previously issued including Presidential Decision Directive 63—Protecting America's Critical Infrastructures (PDD-63) released in May of 1998 and spanning the broad homeland security landscape. The most significant authorities related to CIKR research and development are the Homeland Security Act of 2002 and Homeland Security Presidential Directive/HSPD-7.

*Critical infrastructures as defined include food and water systems, agriculture, health systems and emergency services, information technology, telecommunications, banking and finance, energy (electrical, nuclear, gas and oil, and dams), transportation (air, highways, rail, ports, and waterways), the chemical and defense industries, postal and shipping entities, and national monuments and icons. Key resources refer to publicly or privately controlled resources essential to the minimal operations of the economy or government.*

The Homeland Security Act of 2002 provides the basis for the roles and responsibilities of the US Department of Homeland Security (DHS) in the protection of the nation's CIKR. This act defined the DHS mission as that of "reducing the nation's vulnerability to terrorist attacks," major disasters, and other emergencies, and charged the department with the responsibility of evaluating vulnerabilities and ensuring that steps are implemented to protect the high-risk elements of America's CIKR. The Homeland Security Act created the DHS Science and Technology Directorate and assigned it the responsibility to perform research and development in these areas in support of the broad DHS mission. Title II, Section 201 of the Act also assigned primary responsibility to the DHS to develop a comprehensive national plan for securing CIKR and for recommending "measures necessary to protect the key resources and CI of the United States in coordination with other agencies of the Federal Government and in cooperation with state and local government agencies and authorities, the private sector, and other entities."

Similarly, Homeland Security Presidential Directive/HSPD-7 established the official US policy for "enhancing protection of the Nation's CIKR" and mandated a national plan. This directive sets forth additional roles and responsibilities for DHS, sector-specific agencies (SSAs), other federal departments and agencies, state, local, and tribal governments, the private sector, and other security partners to fulfill HSPD requirements and calls for the collaborative development of the NIPP. HSPD-7 designates Federal Government SSAs for each of the CIKR sectors and requires development of an annual plan for each sector. HSPD-7 also directed the Secretary of DHS in coordination with the Director of the Office of Science and Technology Policy to prepare on an annual basis, a federal research and development plan in support of critical infrastructure identification, prioritization, and protection. This plan is the National Plan for Research and Development in support of National Critical Infrastructure Protection (NCIP R&D) and was first released in 2005 (www.dhs.gov).

## 5 NATIONAL INFRASTRUCTURE PROTECTION PLAN

The NIPP is a multiyear plan describing mechanisms for sustaining the nation's steady-state protective posture. The NIPP and its component sector-specific plans (SSPs) (see below) include a process for annual review, periodic interim updates as required, and regularly scheduled partial reviews and reissuance every 3 years, or more frequently, if directed by the Secretary of the DHS.

In accordance with HSPD-7, the NIPP defines the framework for security partners to identify, prioritize, and protect the nation's CIKR from terrorist attacks emphasizing protection against catastrophic health effects and mass casualties. The NIPP coordinates the activities for both public and private security partners in carrying out CIKR protection activities while respecting and integrating the authorities, jurisdictions, and prerogatives of each. While DHS has overall responsibility for developing the NIPP, the SSAs and their public and private sector counterparts are active partners in its development.

The goal of the NIPP, to achieve a safer, more secure, and more resilient America, consists of the following principal objectives:

- understanding and sharing information about terrorist threats and other hazards;
- building security partnerships to share information and implement CIKR protection programs;
- implementing a long-term risk management program that includes:
  - hardening and ensuring the resiliency of CIKR against known threats and hazards, as well as other potential contingencies;
  - processes to interdict human threats to prevent potential attacks;
  - planning for rapid response to CIKR disruptions to limit the impacts on public health and safety, the economy, and government functions;
  - planning for rapid CIKR restoration and recovery for those events that are not preventable; and
- maximizing efficient use of resources for CIKR protection.

The NIPP comprehensive risk management framework clearly defines CIP roles and responsibilities for the DHS; federal SSAs; and other federal, state, local, territorial, tribal, and private sector security partners.

The NIPP risk management framework is applied on an asset, system, network, or function basis, depending on the fundamental characteristics of the individual CIKR sectors. As illustrated in Figure 1, the framework relies on a continuous improvement cycle

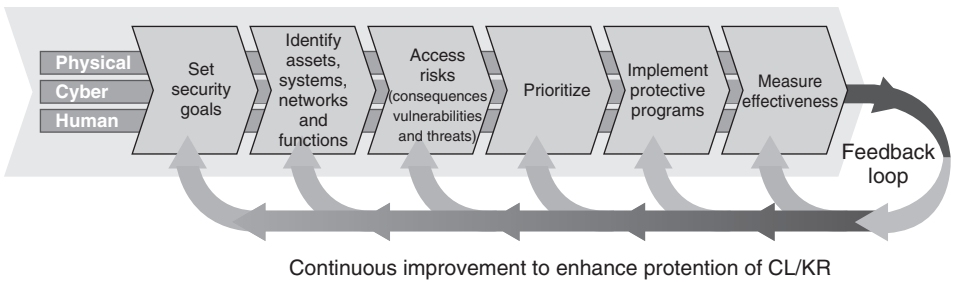

**FIGURE 1** NIPP risk management framework.

| Sector-Specific Agency | Critical Infrastructure/Key Resources Sector |
|---|---|
| Department of Agriculture<br>Department of Health and Human Services | Agriculture and food |

so as to address the ever-changing homeland security landscape. The NIPP also provides the coordinated approach needed to establish national CIKR priorities, goals, and requirements for infrastructure protection, including related short-term R&D requirements. The NIPP was first released in June 2006 (www.dhs.gov).

## 6 SECTOR-SPECIFIC PLANS

Annual SSPs are required from each of the federal SSAs (See Fig. 2). These plans provide a common vehicle across all CIKR sectors to communicate CIKR protection performance and progress to security partners and other government entities and focuses on: priorities and annual goals for CIKR protection and associated gaps; sector-specific requirements for CIKR protection activities and programs based on risk and need; and projected CIKR-related resource requirements for the sector. Emphasis is placed on anticipated gaps or shortfalls in funding for sector-level CIKR protection and/or for protection efforts related to national-level CIKR that exists within the sector. The SSP plans address R&D requirements and activities relevant to the sector and include a description of future capabilities and R&D needed for that sector. These R&D sections align with the high

level federal CIKR R&D priorities but may also contain desired capabilities unique to the sector requirements and, therefore, not included in the broader and prioritized NIPP and NCIP R&D strategies and plans.

*The sector coordinating councils (SCCs) are self-organized and self-governed forums comprised of private sector owners and operators with specific membership varying from sector to sector, reflecting the demographics of each sector. The SCCs serve as principal sector policy coordination and planning entities for CIKR issues.*

*The government coordinating councils (GCCs) are the government counterpart for each SCC established to facilitate interagency and cross-jurisdictional coordination. The GCC is comprised of representatives across various levels of government (federal, state, local, or tribal) as appropriate to the individual sector.*

SSPs are developed by a designated lead federal agency in close collaboration with the corresponding SCCs, GCCs, and their state, local, territorial, and tribal homeland security partners. These plans address the unique characteristics and risk for each sector while coordinating their activities with other sector and national priorities. The SSPs for each sector must be completed and submitted to DHS within 180 days of issuance of the NIPP.

The SSPs serve to clearly define sector security partners and their authorities, regulatory bases, and roles and responsibilities. The plans address sector interdependencies and identify existing procedures for sector interaction, information sharing, coordination, and partnership as is appropriate. The SSAs and the various security partners identify and agree upon the goals and objectives for the sector as well as the desired protective posture for that sector. Consistent with the NIPP, the SSPs independently define the methodology used for assessing the risks and vulnerabilities of the sector and the mitigation strategy used.

Specifically, the SSPs identify priority CIKR and functions within the sector, including cyber considerations; assess sector risks including potential consequences, vulnerabilities, and threats; assess and prioritize assets, systems, networks, and functions of national-level significance within the sector; and develop risk-mitigation programs based on detailed knowledge of sector operations and risk landscape. The plans also develop the protocols to transition between steady-state CIKR protection and incident response in an all-hazards environment and define the performance metrics to measure the effectiveness of the approaches employed. The SSP concurrence process includes a formal review process for GCC member departments and agencies, as well as demonstrated or documented collaboration and coordination within the SCC, which may include letters of endorsement or statements of concurrence.

## 7 NATIONAL PLAN FOR RESEARCH AND DEVELOPMENT IN SUPPORT OF CRITICAL INFRASTRUCTURE PROTECTION

The research and development plan for protecting CIKR mandated by HSPD-7 is the NCIP R&D. This plan focuses on (i) creating a baseline that identifies major research

and technology development efforts within federal agencies and (ii) articulating a vision that takes into account future needs and identifies threat-based research gaps. The NCIP R&D Plan is developed through an intensive, collaborative, interagency effort and is coordinated with the R&D requirements coming from the NIPP and the associated SSPs. This public document highlights the longer-term targeted investments needed to help secure and protect the nation's key infrastructures and resources from acts of terrorism, natural disasters, or other emergencies. The plan is organized around nine major focus areas or themes that impact all CIs, identifies three high level goals for protecting CIKR, and prioritizes key R&D areas needed for CIKR protection. Additional details on the NCIP R&D plan are described below.

## 8 RELATIONSHIP BETWEEN THE THREE CIKR PLANS FROM AN R&D PERSPECTIVE

The NIPP Plan and SSPs together provide key elements to the operationally focused CIKR protection strategy applicable within and across all sectors. The SSPs also address the unique needs, vulnerabilities, and methodologies associated with each sector while the NIPP provides the high level strategies and overall coordination of these activities. The SSP and NIPP plans encourage alignment with other homeland security plans and strategies at the state, local, territorial, and tribal levels, providing for coordinated CIKR protection responsibilities appropriate within each of the respective jurisdictions. The strategy outlined in the NIPP processes is also intended to provide the coordination, cooperation, and collaboration among private sector security partners within and across sectors to synchronize efforts and avoid duplicative security requirements.

From an R&D perspective, each of the three national plans has wholly, or as a key component, the requirement to identify and prioritize new capabilities and future CIKR R&D needs. Proper coordination and alignment of these three plans are essential to making intelligent and effective investments in those R&D areas deemed most critical in the presence of limited R&D resources (both monetary and human).

The proper coordination of these R&D activities takes into account the effective planning horizon for each plan, the stakeholder focus, and national R&D priorities established for protecting CIKR. With respect to R&D requirements, the NCIP R&D Plan represents the longer-term comprehensive strategy for research and development across all sectors, focusing on new and ongoing federal R&D. In contrast, the annual NIPP and SSP reports include R&D requirements over a 1- and 3-year planning horizon respectively and address the most pressing capabilities needed immediately.

Stakeholder input is central to an effective short- and long-term R&D strategy. Similar to the NIPP, the NCIP R&D Plan provides for the coordination, cooperation, and collaboration among other federal agencies, and private sector security partners within and across sectors to synchronize related R&D efforts and avoid duplicative programs. Asset owners and operators across all sectors, public and private sector commercial service providers and product developers, professional and trade associations, and the broad national research and development community including academia, federal agencies and National Laboratories, and private sector groups, all provide valuable input to the R&D agenda for CIKR. The NCIP R&D working with these stakeholder groups develops the long-term R&D strategy for CIKR.

## 9 CYCLICAL DEVELOPMENT

The NCIP R&D plan includes a survey of current top-priority CIKR research and development underway at federal agencies and National Laboratories. This baseline represents current R&D in support of homeland security as well as other traditional agency mission areas impacting CIKR. The future capabilities identified in each of these three plans assume a cyclical development cycle where current technology is successively evolved building upon existing applications and capabilities. This development approach provides security providers with interim technologies while maintaining focus on longer-term national CIKR priority R&D goals and objectives.

## 10 MOTIVATION FOR CROSS-CUTTING R&D THEMES FOR ALL SECTORS AND INFRASTRUCTURES

Previous efforts to develop the R&D requirements for infrastructure protection were typically assembled along individual sector categories. In particular, directed planning activities to be organized along sector lines. Following the extensive work to implement PDD 63, it was apparent that this sector orientation challenged our ability to cost-effectively and efficiently address key factors related to the R&D. Relevant factors identified in the 2005 National Plan for Research and Development in Support of Critical Infrastructure Protection include the following:

- Many different sectors contain infrastructure systems that are vulnerable to the same threats.
- Combined planning of related sectors more directly addresses the inherent and broadly applicable interconnections and interdependencies among infrastructure sectors.
- Past efforts had a tendency to separately consider cyber and physical, which are interdependent in all sectors.
- The efforts to reduce vulnerability were separate from the efforts to design new infrastructure for higher performance and quality. Efforts to reduce vulnerability are more effective if they are incorporated into new designs.
- The challenge of evaluating cross-cutting new threats against opportunities coming from new technological advances has not been adequately addressed. Cross-cutting observations of threats and opportunities could potentially be incorporated by designers into future specialized systems.

The NIPP together with the accompanying SSPs provide detailed sector plans essential for operational-level focus and for strategic and resource prioritization. However for R&D planning purposes, important cross-sector synergies can be realized and funding better leveraged by grouping the sector R&D requirements across common themes. Due to the functional and operational requirements, the sector focus though is retained in the NIPP together with the SSPs for obvious reasons.

## 11 NINE COMMON THEMES

The NCIP R&D Plan is structured around nine themes in the fields of science, engineering, and technology that support all CI sectors, encompass both cyber and physical

concerns, and are strongly integrated into an overall security strategy. The basis for selection of these nine themes was their repeated occurrence in the expressed concerns of infrastructure owners and operators, industry representatives, academia and government officials. The nine themes identified in the NCIP R&D plan are as follows:

1. Detection and sensor systems;
2. Protection and prevention;
3. Entry and access portals;
4. Insider threats;
5. Analysis and decision support systems;
6. Response, recovery, and reconstitution;
7. New and emerging threats and vulnerabilities;
8. Advanced infrastructure architectures and systems design; and
9. Human and social issues.

Through a broad interagency collaborative effort, federal agency experts and others have confirmed the completeness of nine themes and identified three broad long-term strategic goals for CIKR. The three overarching CIKR strategic goals identified are as follows:

- Goal 1: A national common operating picture for CI
- Goal 2: A next-generation computing and communications network with security "designed-in" and inherent in all elements and
- Goal 3: A resilient, self-diagnosing, and self-healing physical and cyber infrastructure system.

The nines themes of the NCIP R&D Plan map directly onto each of the three long-term strategic goals and contain both long-term and short-term priority research and development areas. Figure 3 below which appears in the 2005 National Plan for Research and Development in Support of Critical Infrastructure Protection, illustrates a mapping of a single theme area priority onto a strategic goal.

These high level goals and their associated high priority R&D areas were vetted with stakeholder groups from the private sector, academia, and the National Laboratories, and serve to drive future R&D efforts and ensure that new and effective technologies will be available for the future security of the Nation's CIKR.

## 12 NCIP R&D PLAN THEME AREA: ANALYSIS AND DECISION SUPPORT SYSTEMS

This section describes the analysis and decision support system theme of the NCIP R&D Plan. This development is representative of the conclusions identified and serves to illustrate the range of R&D activities inherent in each theme area. Two examples are provided: The critical infrastructure protection decision support system and the interdependency models used to analyze the collapse of the World Trade Center (WTC) towers resulting from a terrorist attack.

Examination of trade-offs between the benefits of risk reduction and the costs of protective action require analysis and decision support systems that incorporate threat

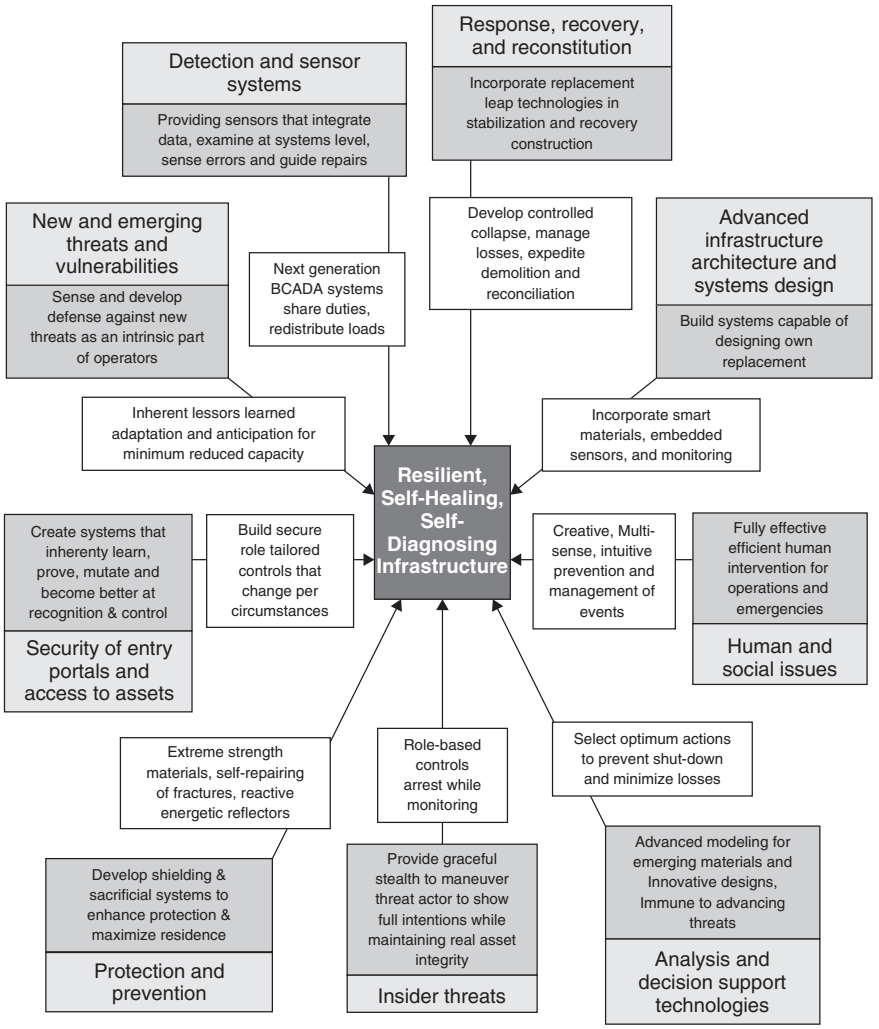

**FIGURE 3** Relationship of NCIP R&D goals and themes.

information, vulnerability assessments, and disruption consequences in quantitative analyses through advanced modeling and simulation. Broadly interpreted, the analysis and decision support technologies area addresses future R&D needs in

- risk analysis and decision theory for evaluating strategies and prioritizing CIP investments;
- threat evaluation;
- vulnerability and performance evaluation and design of upgrades;
- forensic analysis and reconstruction;
- consequence analysis and modeling of interconnected CI sectors, and;
- integrated systems modeling.

Of the existing systems and technologies available presently, many are focused on military applications and are classified or otherwise restricted and have not been examined within the broad, integrated context necessary for homeland security in a domestic setting. As such, future work is needed to transform Department of Defense-focused technologies to homeland security applications were possible and to develop new technologies where gaps in current capabilities exist.

Many of these topic areas are ripe for future research and development opportunities. Future R&D in analysis and decision support should be cognizant of, and attempt to address the major challenges in this field of study are as follows:

- the increasing size and complexity of the models under examination;
- the vast size and complexity of the sectors being modeled;
- the need to tightly couple or integrate multiple models across disciplines and across sectors;
- the absence of standardized analysis metrics and measures across sectors; and
- the need for more agile, robust, and high confidence systems.

Future advances in the analysis and decision support approaches will change how analyses are performed and informed decisions are made. Together with improvements in graphical and computational capabilities and improved communication capability, accurate and timely decision information will transform how the nation responds to man-made and natural disasters. Central to all three of the strategic goals for CIKR is the development of effective and validated analysis and decision support systems.

## 13 OVERVIEW OF CONSEQUENCE ANALYSIS AND MODELING OF INTERCONNECTED CRITICAL INFRASTRUCTURE SECTORS

Of particular interest for this section is decision support through consequence analysis and the analytical modeling of interconnected and interdependent CIs. These consequence and impact analyses are central to quantifying the severity of disasters and are used in decision support systems by decision makers both for planning purposes and for *real-time* protection, response, and recovery activities. Decision- makers must have the capability to understand the causes of disruptions to infrastructures (e.g. cascading failures), the consequences of decisions, and the trade-offs between alternative actions in the decision-making process.

Through HSPD-7, 13 CI sectors have been identified: Agriculture and Food, Public Health/Health Care, Drinking Water and Wastewater Treatment Systems, Energy, Banking and Finance, National Monuments and Icons, Defense Industrial Base, Information Technology, Telecommunications, Chemical, Transportation Systems, Emergency Services, and Postal and Shipping. Analytical models of these CIs must possess sufficient accuracy to accurately represent their normal behavior and the effects of disruptions due to a range of threats. The inherent interconnectivity and interdependencies of these systems make this modeling effort a long-term monumental challenge.

## 14 OVERVIEW OF MODELS

There has been considerable effort put forth in providing analytical models for select infrastructure sectors. For energy and the telecommunications sectors, for example,

detailed models have been previously developed by Department of Energy (DOE), National Communications System, and private sector organizations from these sectors. As mentioned previously, the DOE National Laboratories and the DHS National Infrastructure Simulation and Analysis Center (NISAC) have developed and/or extended the number of infrastructure models to include interdependencies and to enhance model fidelity and breadth of application. Models for agriculture, food, banking and finance, government facilities, are either less mature or not well understood or characterized. For specific biological events, such as pandemic/avian flu, the US Department of Health and Human Services and DHS have developed detailed models to analyze the spread and impact of a major biological disease outbreak.

## 15 INFRASTRUCTURE SYSTEM AND SECTOR INTERDEPENDENCY R&D PRIORITIES

Current infrastructure system and sector interdependency development at three DOE National Laboratories are focusing on new tools for interdependency modeling and simulation of the CI sectors. These models use a system dynamics approach to analyze changes in supplies and demands within and between infrastructures. These models study disasters ranging from major hurricane impacts to biological/agriculture disease outbreaks to failures in key components of the telecommunication system. These studies use existing knowledge and understanding of the systems and sectors under examination and verify model behaviors-—where possible—using past disaster events to confirm that the predicted interdependencies and computational results were realistic.

Other efforts such as those of NISAC seek to develop higher fidelity models with comparable vulnerability and consequence analyses for select CI sectors. These focused sector models provide detailed understanding of the progression and impact of disruptions to the associated infrastructures though they embody more limited interdependencies with other infrastructures. Important advances in vulnerability assessments will include new integrated physics-based models for analyzing highly complex and integrated systems such as those that were developed for the fire dynamics and structural failure analyses of the WTC towers. Advances are still needed in the development of practical tools for quantifying the full spectrum of the consequence metrics identified in HSPD-7 in order to inform investment decisions for all-hazards risk management and emergency preparedness.

These types of models must be developed to address the needs for CIP with data and results that are compatible and interoperable with other sector models. These systems must be flexible and responsive to evolving requirements and conditions imposed by decision makers and changes in the physical and cyber environments. Data for these systems must remain current and contain sufficient granularity to provide adequate specification to the models to be useful in detailed analyses. And there is a need for improved modeling and simulation methods that will make it easier to predict the behavior of complex generic computer networks under various scenarios, and to perform ”what-if” analyses. This latter development will be analogous to a virtual experiment performed on a computer network under a range of different conditions. Integration of such cyber network models into larger infrastructure models will contribute to the understanding that is gained from interdependency modeling for the CI sectors.

Example 1: The Critical Infrastructure Protection-Decision Support System (CIP-DSS)

The Critical Infrastructure Protection-Decision Support System (CIP-DSS), developed by the DOE National Laboratories at Sandia, Los Alamos, and Argonne through funding from the DHS, is a risk-informed decision analysis tool using a suite of mathematical models for assessing the consequences of CI disruption at both the metropolitan and national levels. This modeling effort is the first of its kind to incorporate infrastructure interdependencies along with workforce or population, and geographical influences, in a unified decision support system.

The CIP-DSS modeling system comprises a wide range of mathematical models, tools, and associated data. Included are system dynamics models that: represent each of the 17 relevant sectors/assets; include geographical influences that interact with each sector component in the model; represent the primary interdependencies among infrastructures and primary processes, activities and interactions of each infrastructure; provide for important feedback mechanisms and all critical inputs and outputs across infrastructures; and have the capability to handle major substitution effects. The data for the models comes from a range of sources and include, for example, industry production reports, published literature, and data from the Census Bureau and Bureau of Labor Statistics.

This system is used to simulate the steady-state conditions simultaneously across all infrastructures and the effects of disruptions to steady state, caused by specific threat scenarios in a Monte Carlo simulation setting. The outputs to the consequence modeling are used in a decision-support methodology to analyze and evaluate alternative strategies and their related impacts.

Examples of questions that this decision support system is designed to answer include the following:[2]

- What are the consequences of attacks on infrastructure in terms of national security, economic impact, public health, and conduct of government, including the consequences that propagate to other infrastructures?
- Are there choke points in our nation's infrastructures (i.e. areas where one or two attacks could have the largest impact)? What and where are the choke points?
- Incorporating consequence, vulnerability, and threat information into an overall risk assessment, what are the highest risk areas?
- What investment strategies can the United States make such that it will have the most impact in reducing overall risk?

To develop the CIP-DSS decision support methodology, the system developers conducted a series of formal and informal interviews of CIKR decision makers and stakeholders in order to identify requirements for the decision support system, define the decision environment, and quantify the prioritization of consequences. The taxonomy of decision metrics derived from this research involves six categories: (i) sector-specific, (ii) human health and safety, (iii) economic, (iv) environmental, (v) sociopolitical, and (vi) national security. The risk-related preferences for the decision

[2]CIP-DSS Documentation.

makers were encoded to arrive at multi-attribute utility functions consistent with the output of the consequence models and applicable to the scenarios under consideration. These multi-attribute utility functions describe the preferences of the decision maker as a function of the frequency of the disaster and its consequences relative to the decision metrics previously defined.

Currently, the CIP-DSS system is fully operational. The model has been used to produce detailed analyses of both simulated and real-life disasters providing analysis and insights to decision makers and strategic planners. The initial model representations provide broad infrastructure coverage and are iteratively being refined and enhanced. Significant efforts are underway to analyze specific threat scenarios as defined by stakeholders and program sponsors. The system requires continuous testing and refinement as a result of insights developed in the threat scenario build-out.

The CIP-DSS system has provided a valuable understanding of the infrastructures and their dynamics, developed insight into infrastructures viewed as dynamic systems, and provided analyses that can identify high leverage points and suggest mitigation strategies. This simulation and assessment capability allows decision makers to understand the CI of the United States including its components, their coupling, and their vulnerabilities. This capability can be used in a crisis response mode as well as in an analysis and assessment mode to provide decision makers with a better basis to make prudent, strategic investments, and policy resolutions needed to improve the security of our infrastructure.

Example 2: Integrated high-fidelity models—NIST Analysis of the WTC tower Collapse

The second example area of the analysis and decision support system is the National Institute of Standards and Technology (NIST) Analysis of the WTC tower collapse. A complex and broad suite of software models were used in the analysis that led to a series of recommendations for changes in design and material requirements for tall buildings. These tools together with detailed laboratory forensic analysis provided an extensive and comprehensive list of recommended changes to building codes and standards.

Following the terrorist attacks on September 11, 2001, NIST was authorized by the US Congress to conduct a multiyear building and fire safety investigation into the collapse of the WTC Towers (WTC 1 and 2) and WTC 7. The analysis studied the factors contributing to the probable cause of post-impact collapse and required a thorough examination of the planes' impact, fire dynamics and structural failures, the effectiveness of resistance design and retrofit of the structures, and the effectiveness of the fire resistive coatings on structural steel. The subsequent analysis resulted in the most detailed study of a complex system/structure ever performed and was successful in integrating the dynamical effects within multiple software-based mathematical models. Model outputs were combined to provide a thorough understanding of the effects of the explosion and resulting fire, and the effects of superheated steel on the structural integrity of a steel structure.

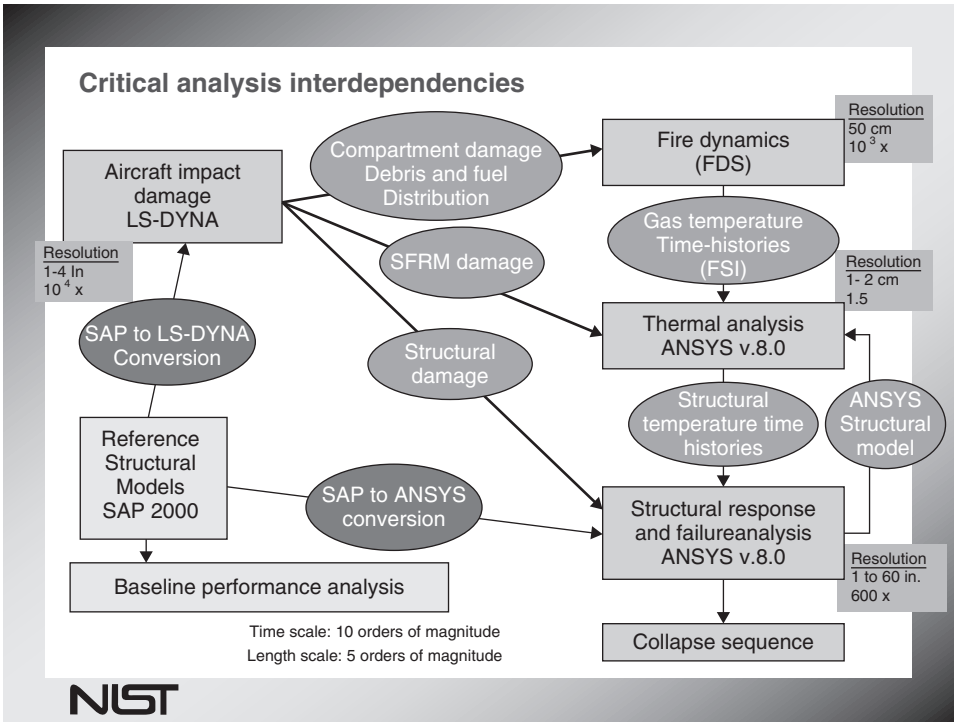

**FIGURE 4** Model interdependencies from the NIST WTC collapse investigation.

The analysis of probable collapse sequences for the WTC required analyzing a variety of factors. This included the effects of the aircraft impact on the structures, the spread of jet-fuel and the resulting fire on multiple floors, the thermal weakening of structural components, and the progression of local structural failures that initiated the catastrophic collapse of the WTC Towers 1 and 2. The mathematical analysis was supported by laboratory-based experiments, visual and physical evidence acquired from multiple sources. The following Figure (Fig. 4) depicts the models and their interdependencies that were used in the NIST analysis.[3]

[3]Taken from the US Federal Building and Fire Safety Investigation of the World Trade Center Disaster to the 4th Annual Congress on Infrastructure Security for the Built Environment, October 19, 2005, Dr. James E. Hill, Director, Building and Fire Research Laboratory, NIST.

Also modeled in this investigation was the occupant evacuation of the towers, the condition of stairwells and the flow of evacuees from the buildings. The results of the modeling effort combined with a thorough laboratory analysis provided the key insights needed to accurately describe the factors that led to the collapse of the WTC towers in New York City on September 11, 2001. The key findings from the entire WTC study, as a result of the 3-year effort, can be found at http://wtc.nist.gov/.

### 16 FUTURE DIRECTIONS FOR SECTOR AND SYSTEM INTERDEPENDENCY R&D, PARTNERSHIP FOR CRITICAL INFRASTRUCTURE SECURITY

The previous examples illustrate just two areas where analysis and decision support techniques have been advanced significantly. These are exemplary of the R&D required to address the complex systems and infrastructures currently present. Many new areas of research exist in analyzing the complex interdependencies of CIKR as well as development of accurate high-fidelity analysis models for specific infrastructures.

## 1 INTRODUCTION

Following is a brief history that led to the creation of the President's Commission on Critical Infrastructure Protection (PCCIP), selected details of the Commission's inner-workings, an overview of the Presidential Decision Directive (PDD) promulgated as a result of the PCCIP report, and six research and development (R&D) areas targeted for further exploration.

It is important to fully understand the concepts of infrastructure *dependency* and *interdependency*. Figure 1 depicts illustrative infrastructure dependencies for electric power, while Figure 2 depicts examples of interdependent infrastructures. In Figure 1 examples of dependencies of other infrastructures are shown for the electric power infrastructure operation. A problem with any function can adversely affect the operation of the infrastructure. In Figure 2 the interaction of two or more functions is shown. The definition of

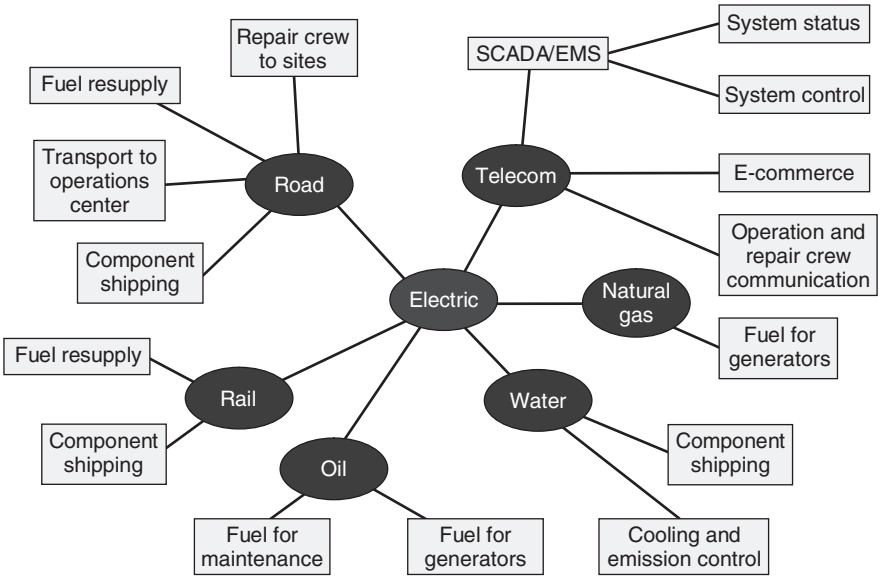

**FIGURE 1** Illustrative infrastructure dependencies for electric power.

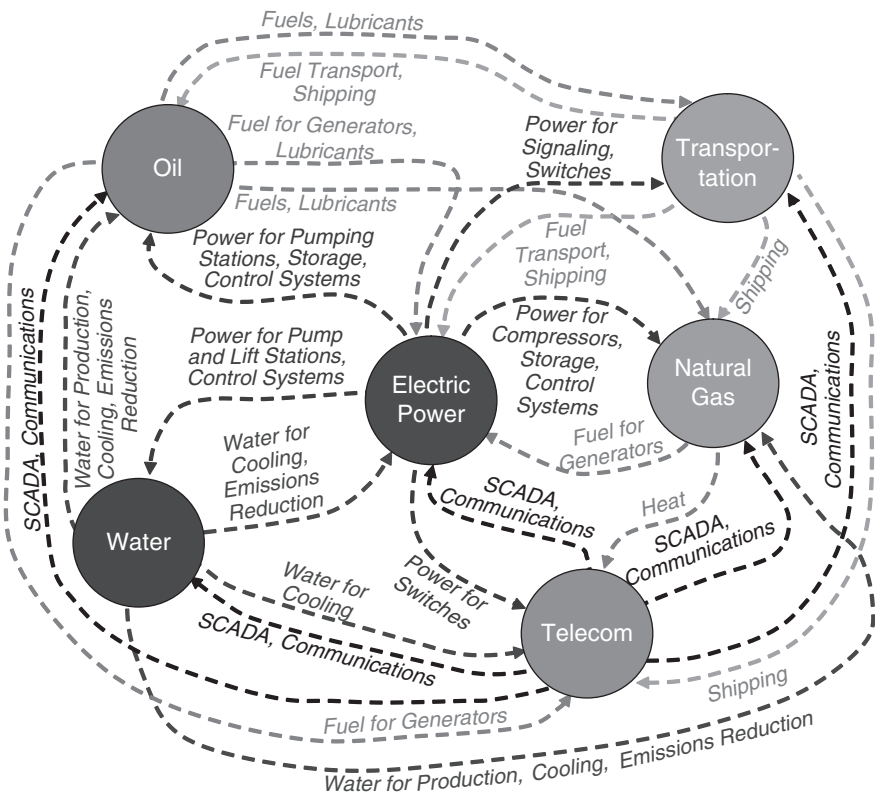

**FIGURE 2** Examples of interdependent infrastructures.

*interdependency* can be found in the Glossary of Key Terms in the National Infrastructure Protection Plan—"The multi- or bi-directional reliance of an asset, system, network, or collection thereof, within or across sectors, on input, interaction, or other requirement from other sources in order to function properly." The key to *interdependency* is that two or more assets depend on one another.

Even though research on interdependencies in the United States began many years ago with efforts in the Department of Defense (DoD), the broader federal government effort began with the PCCIP in 1996–1997.

## 2 PROLOGUE—PRECURSOR EVENTS TO THE PCCIP

Early critical infrastructure efforts began with military strategic targeting, as databases of key potential targets were assembled. Initiatives to identify the most critical targets drew on strategic insights from system experts who identified such targets as vital bridges and other transportation hubs, critical industrial capabilities, and similar strategic sites. In the 1980s, such approaches were further advanced by bringing in civilian engineers with greater insights as to how particular infrastructures functioned and how they might depend on external needs such as power or water. With the dynamic growth of computer processing capability and the creation of infrastructure databases, coupled with knowledge of how particular systems functioned, engineers began to model the performance of particular infrastructures. Though initially challenging, modeling became a vital tool for improving a particular infrastructure's reliability, robustness, and recoverability in an emergency. As the models matured, they became more valuable for assessing system performance and predicting how systems would respond during particular events or in case of casualties. However, these models usually focused only on a specific system or infrastructure segment; they did not incorporate other infrastructure sectors. Thus, computer models of infrastructures had not yet begun to consider and model interdependencies.

Consideration of interdependencies began in the late 1980s, whereby models of one particular infrastructure, such as electric power, could be considered alongside another infrastructure sector, such as telecommunications, thus beginning to explore where one infrastructure depended on signals, communications, or other processes within a separate infrastructure. This interdependency raised the possibility that an infrastructure could be attacked through its dependent elements; that is, something could be attacked without ever touching the obvious components within that infrastructure. However, while models of individual sectors were becoming increasingly mature, models of other sectors were often not compatible (i.e., in format, protocols, or input/outputs), and the merging of models to achieve interdependency modeling became a real challenge. With a significant increase of available open-source information on infrastructures in the 1990s, the ability to consider and assess infrastructure performance and interdependency improved. Thus, in the military targeting world, critical infrastructure targeting was continuing to advance. Targeting techniques were exploiting technology to render a particular infrastructure more vulnerable. In some ways, therefore, the more dependent a particular nation or system was on technology potentially increased the vulnerability of its critical infrastructures. Within DoD, these concepts advanced significantly, within an organization that evolved to become the Joint Warfare Analysis Center in Dahlgren, Virginia, and within the Joint Program Office for Special Technology Countermeasures, also in Dahlgren.

In 1992–1993, the maturation of critical node targeting led to discussions (within DoD's Office of the Under Secretary for Policy) concerning the need to explore the potential vulnerability of our nation to similar targeting approaches. As indicated above, interdependencies rendered particular infrastructures potentially more vulnerable. This possibility was countered in part by another factor: the increasing complexity of our infrastructures—how they interconnected, what software systems operated them, and what security tools were in place to enhance both physical and cyber security. This complexity could make it more difficult to attack a particular infrastructure. Even though increased complexity of our infrastructures may reduce some vulnerabilities, new ones could also be introduced that need to be examined and understood. Some infrastructure sectors began to consider interdependency issues long before others. Among the earliest infrastructure sectors to begin building reliability and security into their systems were the telecommunications and the banking and finance sectors. The early efforts to assure telecommunications functionality and survivability were born following the Cuban Missile Crisis (1962) with the establishment of the National Communications System, which focused on building national security and emergency preparedness features into the nation's communications infrastructure. Similarly, though for different reasons, banking and finance led most infrastructure sectors in building security into their facilities by asking such questions and answers as "Why do people rob banks?" "Because that is where the money is." The industry's concern over security was similarly advanced as they developed information technology processes that linked banking systems.

Other policy efforts across government to consider potential vulnerabilities in our nation came to light—efforts often unknown to other branches of government. For example, a senate-directed study of infrastructure vulnerability was undertaken in the 1989–1990 time frame. Led by a Secret Service agent, this study produced a sensitive report that was delivered to both Senate leadership and the National Security Council (NSC). Similarly, the Center for Strategic and International Studies conducted a review of infrastructure vulnerability. All these efforts came to a similar conclusion: the potential vulnerability of critical infrastructure was an issue that warranted a more detailed study and possible actions to bolster our national security. Following the first World Trade Center bombing in 1993, New York City government established a committee on counterterrorism, with several subgroups that focused on infrastructure and emergency response issues. As a result, New York City bolstered its emergency operations center and developed very comprehensive planning on emergency response.

As concerns for infrastructure vulnerability gained momentum within the national security policy community, a series of briefings were held in 1994–1995 to highlight potential critical infrastructure vulnerabilities and to assess terrorist threats that could potentially exploit such vulnerabilities. In late 1995, the Department of Justice and the DoD cosigned a document directing the establishment of a working group to explore critical infrastructure vulnerabilities in this light. The group, called the *Critical Infrastructure Working Group* (CIWG), was under the leadership and guidance of Ms Jamie Gorelick, Deputy Attorney General at that time. The CIWG consisted of eight members, including five subject-matter experts from the Defense, Justice, and Intelligence communities. Curiously, because many interagency legal issues began to surface in these discussions, the CIWG included three representatives from the offices of various general counsels. The tasking for the CIWG was to explore the concept of domestic vulnerability and, from that, recommend a possible course of action for the nation's security. Following delivery of the CIWG report to the White House in January 1996, the CIWG was

reconvened to prepare a draft Executive Order, which established the PCCIP to explore critical infrastructure.

## 3 PCCIP REPORT OVERVIEW

### 3.1 Executive Order 13010, Critical Infrastructure Protection: Scope and Key Sections

On July 15, 1996, President Clinton signed Executive Order 13010, titled *Critical Infrastructure Protection*, which focused on protecting those national infrastructures vital to the defense and economic security of the United States. The Order named eight specific infrastructures as critical to the United States and identified both physical and cyber threats to these infrastructures. The infrastructures were telecommunications, electric power systems, gas and oil storage and transportation, banking and finance, transportation, water supply systems, emergency services (including medical, police, fire, and rescue), and continuity of government. The Order also noted that many infrastructure enterprises are owned and/or operated by the private sector. Thus, a partnership between the government and the private sector was considered essential.

The Order established a Presidential Commission to, among other things, assess the nature and scope of threats and the vulnerabilities of these critical infrastructures and recommend a comprehensive national policy and implementation strategy for assuring their continued operation.

The Commission was to consist of a full-time chair, appointed by the president, and up to 20 full-time commissioners, no more than 2 of whom were to be nominated by each of 10 named departments and agencies. The departments and agencies directed to nominate commissioners were Treasury, Justice, Defense, Commerce, Transportation, Energy, Central Intelligence Agency, Federal Emergency Management Agency, Federal Bureau of Investigation (FBI), and National Security Agency. The Commission had authorized staff and contracting authority. Anticipating the sensitive nature of the information to be dealt with, each commissioner and many of the staff held high-level security clearances.

Nothing in the Order explicitly cited the importance of interdependencies among the infrastructures, but interactions among the infrastructures was an implicit priority in the interdisciplinary structure of the Commission and the Order's mandate to assess the scope and nature of the wide-ranging vulnerabilities of and threats to critical infrastructures.

### 3.2 Commission Structure

One of the first tasks in the operation of the Commission was the development of a work plan. To help simplify the effort and rationalize work assignments, the Commission adopted a structure focused on five infrastructure sectors that incorporated the eight critical infrastructures named in the Executive Order and allowed for some necessary amplification. The five sectors were as follows:

1. *Information and communications.* Recognized the intimate and necessary connection between telecommunications and the entire range of information technology. The original scope was expanded to include the threats to and vulnerabilities of the full range of information systems, including, but not limited to, the telecommunications links. The sector included the Public Telecommunications Network, the

Internet, and millions of computers and related equipment in homes, businesses, academe, and other organizations across the nation.

2. *Energy.* Included both the entire electric power infrastructure and portions of the oil and gas infrastructure. Both the Department of Energy (DOE) and Department of Transportation (DOT) have statutory authority pertaining to aspects of the oil and gas infrastructure. The DOE has responsibilities in the production and storage elements, while the DOT has responsibilities in the pipeline and transportation elements.
3. *Physical distribution.* Included air, water, surface (including rail, road, and pipeline), and subsurface transportation subsectors—systems that facilitate the movement of people and goods. It also included navigation systems such as global positioning systems.
4. *Banking and finance.* Included all infrastructure elements relating to financial transactions, including various financial institutions, financial markets, and the companies that service and work with them.
5. *Vital human services.* Included water supply, emergency services, and government services at all levels (such as Social Security, weather forecasting, and aid to dependent children). The original mandate to include continuity of government was changed, with the approval of the White House, to focus on services provided by the government since issues of continuity of government were being addressed in other forums. The Commission explored the possibility of expanding the scope of this sector to include agriculture and public health but because of the limited time and resources available, decided that such expansion should be considered in the next phase of the government effort following the work of this Commission.

### 3.3 Commission Process

After establishing the sectors and assigning lead and supporting commissioners and staff, the Commission, through the five sector teams, turned to developing a detailed characterization of each sector. This exercise served as a basis for understanding the nature of the vulnerabilities of the infrastructure, the threats it might face, and the potential consequences that might be expected from a successful attack. The work plan then called for the Commission to develop a national policy and a strategy for implementation. At every stage of the effort, the Commission took extraordinary measures to ensure that it acquired a solid base of information and that it vetted the work and thinking with a wide range of experts and stakeholders.

Each sector arranged briefings (in many cases for the entire Commission) on the structure of the sector; its operations, dependencies on other sectors, particular weaknesses, and critical vulnerabilities; and potential consequences of failure, not only for customers but also for the broader community. Among the experts from whom briefings were requested were owners/operators of infrastructure organizations, trade associations, professional societies, community leaders, government officials, and subject-matter experts. Some briefings were classified, and nearly all were treated as highly sensitive even if not officially classified under national security procedures.

Each sector group developed a thorough characterization of its respective infrastructure. In some cases, contractors were hired to develop the product—under the guidance of and with assistance from the commissioners. In other cases, the sector staff did the

bulk of the work with assistance from contractors. In at least one sector, a series of meetings across the nation in cooperation with the American Public Works Association elicited the views and concerns about infrastructure protection from local private and government groups.

The Commission conducted several open "town meetings" at locations across the country (e.g., Boston and Houston), both to raise the level of awareness among the general public about critical infrastructure protection and to elicit information and perspectives concerning the issues.

The Commission's final report, *Critical Foundations: Protecting America's Infrastructures*, was released publicly in October 1997. Much of the documentation developed by the Commission, however, has not been released to the public and is exempt from such release under statutes and executive orders.

## 3.4 Selected Case Studies of Infrastructures

***3.4.1 Water Infrastructure.*** The water infrastructure was part of the vital human services sector, a varied collection of critical infrastructures that did not fit into the other four sectors. The Commissioner from the Department of Commerce was chosen to lead this sector, and several other commissioners were appointed to the team. In contradistinction from some other sectors, this team decided against contracting with an outside firm to help characterize the infrastructure and probe its vulnerabilities. Rather, this team hired a few staff to be responsible for the effort and several outside consultants to address specific problems.

The team conducted a characterization of the water infrastructure through a series of discussions with the US Environmental Protection Agency, the US Geological Survey, the US Army Corps of Engineers, the Department of Health and Human Services, the American Water Works Association, and a number of individual water utilities across the country. In addition, facts and data provided by the organizations and utilities interviewed were analyzed and included in the characterization. These results were documented in the sector report, which, to date, has not been publicly released because of their sensitivity.

The major security concerns that emerged were the potential for

- large-scale impacts on public health through purposeful contamination of the water supply with toxins and/or pathogens and
- disruption of the water supply through destruction of assets such as pumps, pipes, valves, control systems (including supervisory control and data acquisition [SCADA]), and treatment facilities that would not only cause some challenges to public health but would also cause serious economic damage through the disruption of activities that depend on water supply.

Both contamination and physical destruction of system assets are physical threats. The primary cyber threat relevant directly to water supply is through the SCADA system. While in principle, it is possible for a cyber attack to have serious consequences, even more dramatic and extensive impacts would be achievable more easily through the use of physical attacks, such as explosives and contaminants. The primary advantages of a cyber attack on water supply would be that, in many cases, an adversary could gain sufficient access, while maintaining a physical distance far from the target, and would have a better chance at disguising or hiding his or her identity.

At the time, opinion within the water sector concerning the importance of a threat of water contamination was divided, and no definitive studies had been conducted. The Commission team tasked one of the national laboratories to undertake a definitive study aimed at determining whether there were any chemical or biological agents, reasonably available to terrorists, in quantities that could be carried by one or two people that could cause thousands of deaths when introduced into a municipal water supply system. The study, which was not exhaustive, identified several such agents. This alerted the Commission to the extraordinary importance of preventing, detecting, and mitigating such potential contamination.

The team also addressed several interdependencies of water supply systems. For example, water utilities use large quantities of chemical disinfectants such as chlorine or chloramine to kill a number of biological contaminants. Utilities generally have limited storage capacity for these materials and depend on timely delivery through either rail or truck transport. In addition, many water utilities run their SCADA systems over the public switched network, and disruption in those communication elements could wreak havoc on the operation of dependent utilities. Finally, with regard to dependencies of water on other infrastructures, most utilities require externally provided electric power to operate pumps and automatic controls, including valves and monitoring equipment.

Other sectors, of course, depend on water. For example, illnesses and death caused by contaminated water would affect the workforce and strain resources needed for dealing with other emergencies. Few hospitals have alternate supplies of clean water, so a disruption could seriously affect their ability to care for patients. Many industries require clean water for their manufacturing processes. Most municipalities access water for fighting fires from the water supply utility. Therefore, a disruption in the supply of clean water could also affect fire fighting. In some cases, disruption in the flow of source waters could impair hydro-generation of electricity.

The Commission found no indications of interdependencies leading from an attack on water supply to cascading (singularity) failures in other infrastructures in the near term. If longer term outages were encountered, the potential for such cascading failures seemed intuitively to be increased.

***3.4.2 Energy Infrastructure.*** The Commission established an Energy team to lead the effort for the electric and oil and gas sectors. A DOE commissioner led a team consisting of several commissioners with supplemental help from DOE national laboratory experts in the electric power and the oil and natural gas infrastructures, as well as cyber security. The team generated two detailed reports that characterized the sectors, current trends, impacts from significant outages, threats and vulnerabilities, issues, risk management, interdependencies, protective measures, Commission outreach, and strategies and recommendations. Significant physical security information was drawn from previous reports because of terrorist concerns in the late 1980s [1, 2]. Organizations providing a wealth of reference material included DOE, Energy Information Administration, North American Electric Reliability Council (NERC), and Federal Energy Regulatory Commission.

In addition, the Energy team conducted an extensive outreach program to many sector organizations (NERC, Edison Electric Institute, National Petroleum Council, American Petroleum Institute), and leading companies within the sectors. This effort collected the ideas and concerns of the owners/operators and invited review and comment of their thoughts on the subject.

Several vulnerability concerns emerged as listed below:

- more reliance on computer networks and telecommunication systems not designed for secure operations;
- control systems (including SCADA) using commercial off-the-shelf hardware and software;
- proliferation of modems;
- sabotage of critical parts and difficulty of replacement;
- insufficient effort to correct previously identified physical security vulnerabilities; and
- availability of vulnerability information.

As stated in the Commission's report, interdependencies were a key concern of the energy sector. "The security, economic prosperity, and social well being of the US depend on a complex system of interdependent infrastructures. The life blood of these interdependent infrastructures is energy ... [3]." The power outages of July and August 1996 in the western United States clearly demonstrated the extensive impact to all of the other critical infrastructures. Telecommunications, water supply systems, transportation, emergency services, government services, and banking were all significantly affected by the blackouts, which covered most of that region.

### 3.5 The Nature of Interdependencies

The Commission dealt with interdependencies as an integral part of the work of each infrastructure group. The final report did not deal with the subject separately but did recognize the overarching importance in connection with several strategic objectives and policy initiatives.

There are two main sources of interdependency: geographic proximity (in which an attack on one element causes damage to proximate elements of other infrastructures) and functional interdependency (in which other infrastructure elements depend on the functioning of the attacked element in order to perform adequately). One of the most serious concerns due to the interdependencies among infrastructures is that the effects of an attack on one might, under certain conditions, cause cascading failures among other infrastructures, which in turn might amplify the effect on the originally attacked infrastructure and cause disproportionately high levels of damage on a wide geographic and functional scale. It is unlikely that an adversary would unknowingly choose such a critical target; however, the potential consequences call for special protective efforts for those specific assets.

It became clear to the Commission that the degree of interdependency throughout the critical infrastructures was much higher than was first apparent on the surface. Energy and communications/information clearly underlie virtually everything else. But, in fact, significant outages in any of the critical infrastructures could be expected to seriously affect at least several other infrastructures. While the initial effects of a particular attack would be localized to the target assets, the degree of interconnectedness would, in many cases, lead well beyond the initial locale. The specific consequences of an event would be a function of the detailed nature of the interdependencies on an enterprise level.

In addition to noting the extensive nature of interdependencies among the critical infrastructures, and therefore the need for wide-ranging partnership between government

and many elements of the private sector, the Commission considered a number of specific examples of interdependencies. For example, the loss of electric power would prevent the pumps at gasoline stations from operating, which would prevent vehicles from delivering products and services, which would cripple other infrastructure services and hamper repairs to the electric power infrastructure, thus compounding the cycle of consequences.

During its limited life, the Commission was not able to delve more deeply into the nature and characterization of failure modes through interdependencies. It was clear that the real failure events unfolded through the effects on specific interdependent individual enterprises. That realization, however, would not lead to a generalized approach to understanding the phenomenon. On the other hand, integrating or averaging over entire sectors could provide a more workable approach because data would be more readily available, but would lose the reality of what actually causes the interlinked failures, and thus would likely lead to incorrect conclusions. Moreover, an averaged approach would not illuminate specific needs for protective measures. This clearly was an area in need of more research.

### 3.6 Partnership between Government and Industry

The Commission noted as a fundamental requirement that a wide-ranging partnership among governmental organizations and industrial entities was key to the success in protecting the nation's critical infrastructures for the following reasons:

- the infrastructure enterprises were largely owned and/or operated by the private sector;
- the owners/operators were in a better position to assess their vulnerabilities and design protective measures;
- the large-scale consequences of an event affect the broad community, beyond the specific business responsibilities of the infrastructure enterprise;
- the government has regulatory and law enforcement responsibilities and authority and can also provide a mechanism for spreading the risk/costs; and
- the government can bring unique resources, such as intelligence and analysis capabilities, as well as diplomacy, to bear.

The Commission identified seven specific areas of responsibility for the owners/operators of critical infrastructure (paraphrased here):

1. provide and manage the assets needed to ensure the delivery of infrastructure services efficiently and effectively;
2. meet customer expectations for quality and reliability;
3. manage risks effectively:
   (a) identify threats and vulnerabilities,
   (b) mitigate risks cost-effectively,
   (c) maintain emergency response and management capability;
4. give special consideration to vulnerabilities in information systems;
5. cooperate with others in the sector to identify the best reliability and security practices;

6. report criminal activities to law enforcement and cooperate with investigations;and
7. build working relationships with intelligence and law enforcement.

State and local governments play several roles: regulation, law enforcement, administration of justice, response to incidents, and ownership/operation of certain infrastructures.

The federal government has overarching responsibilities for national security, public health and safety, and the general welfare of the nation. Thus, unique resources are available, such as collection and analysis of intelligence, training and equipment for first responders, and relations with other countries and international organizations.

The Commission recommended the establishment of national structures to facilitate the partnership and to address matters of policy formulation, planning for critical infrastructure protection, and the design and implementation of specific programs. The pros and cons were weighed for establishing a new department to protect the nation's critical infrastructures, but it was decided that the political costs and barriers would render such a recommendation impossible to implement. Instead, the Commission recommended a small office in the White House (called the Critical Infrastructure Assurance Office [CIAO]) located in the Department of Commerce. In the aftermath of the terrorist attacks of September 11, 2001, the government did establish the Department of Homeland Security (DHS) with responsibilities that encompass most of the elements of critical infrastructure protection. These functions have been transferred to the DHS.

Each of the infrastructure sectors was to have a lead government agency that would be responsible for identifying and working with sector coordinators from within the infrastructure community and for ensuring that the sector was tied in to the entire government activity in critical infrastructure protection.

The indispensable step to establishing the partnership is ***information sharing***. Chapter 5 of the PCCIP report, *Establishing the Partnership*, discusses the reluctance of private sector entities to share sensitive information with the government because of their concern about the government's inability to protect the information. To address this concern, the Commission recommended that the government establish appropriate measures to protect private sector information. Also, the private sector noted that the limited information available from the government (e.g., specific threat information). However, on the other hand, elements of the government were frustrated by the perceived lack of information flow from the private sector.

Among the innovative mechanisms recommended by the Commission was the establishment of Information Sharing and Analysis Centers (ISACs) in each sector. Their primary functions were

- to provide a forum for the infrastructure enterprises to share information and experiences concerning threats to and vulnerabilities of their sector as well as various problems encountered and possible solutions and
- to provide a mechanism for the federal government to disseminate information and advice throughout the sector.

Another innovative suggestion was that communication and cooperation among the ISA Cs could be very helpful in identifying and dealing with sector interdependencies. ISACs have now been established in most of the critical infrastructure sectors with varying results. It is a valuable mechanism that is still evolving in its implementation. However, the private sector business model has only worked for a few of

them. All of the new sectors and some of the PDD 63 sectors no longer have ISACs. Most of them did have the capacity to do real analysis but acted as "pass-throughs" for information. Now each sector coordinating council (which replaced the PDD 63 sector coordinator) has the option to identify an ISAC to be their sector information sharing mechanism.

### 3.7 Risks in the Information Age

The Commission anticipated that the threat of cyber attacks would grow rapidly to become a dominant concern for infrastructure assurance. The increasing reliance of all the nation's sectors on the information and communications infrastructure suggested that one of the major risks would soon be that of a cyber attack. Such an attack would cause extraordinary damage and loss of capability through large-scale interdependencies with devastating effects on the United States.

While the direction of the threat trend was correctly predicted, it has not yet reached the magnitude or urgency foreseen. The major threats to critical infrastructure remain physical—mostly kinetic—attacks. As an instrument of terror, an explosion is far more impressive than a cyber attack. When the attackers turn toward creating economic impacts instead of terrorizing populations, the role of cyber threats will undoubtedly increase.

## 4 PRESIDENTIAL DECISION DIRECTIVE 63 OVERVIEW

PDD 63 institutionalized many of the recommendations from the PCCIP report [3]. Initially, PDD 63 noted a "growing potential vulnerability" and stated that "[m]any of the nation's critical infrastructures have historically been physically and logically separate systems that had little *interdependence*. As a result of advances in information technology and the necessity of improved efficiency, however, these infrastructures have become increasingly automated and *interlinked*" [4].

PDD 63 set a national goal that "any interruptions or manipulations of these critical infrastructures must be brief, infrequent, manageable, geographically isolated and minimally detrimental to the welfare of the United States" [5].

The President directed elements of the federal government to implement activities and encouraged the private sector to take steps to improve the protection of the US critical infrastructures as reported on by the PCCIP. The following three sections summarize his direction.

### 4.1 Federal Government

PDD 63 established an organizational structure within the Executive Branch of the federal government to implement the Directive. Lead agencies were designated for each critical infrastructure with an appointed sector liaison official, as well as lead agencies and officials for special functions (national defense, foreign affairs, intelligence, and law enforcement). Also established was the position of national coordinator to chair an interagency group (Critical Infrastructure Coordination Group) to coordinate the overall implementation activities. The national coordinator would be supported by the National Plan coordination staff (Table 1).

To strengthen the protection of critical infrastructures within the jurisdiction of the federal government, each department/agency was directed to appoint a senior-level official

**TABLE 1 Presidential Directive Directive 63 Federal Government Organization, Annex A**

**National Coordinator**—Chair of Critical Infrastructure Coordination Group and supported by National Plan Coordination staff

| **Lead Agency** | **Sector Liaison** |
|---|---|
| Commerce | Information and communications |
| Energy | Electric power |
| | Oil and gas production and storage |
| Environmental Protection Agency | Water supply |
| Federal Emergency Management Administration | Emergency fire services<br>Continuity of government services |
| Health and Human Services | Public health services, including prevention, surveillance, laboratory services, and personal health services |
| Justice/FBI | Emergency law enforcement services |
| Transportation | Aviation, Highways, Mass transit, Pipelines, Rail, Waterborne commerce |
| Treasury | Banking and finance |
| **Lead Agency** | **Special Functions** |
| Central Intelligence Agency | Foreign intelligence |
| Defense | National defense |
| Justice/FBI | Law enforcement and internal security |
| State | Foreign affairs |
| Office of Science and Technology Policy | R&D coordination |

to be the Critical Infrastructure Assurance Officer. The existing Chief Information Officer would be responsible for information assurance, while the Critical Infrastructure Assurance Officer would be responsible for protecting all other aspects of the department's/agency's critical infrastructure. To facilitate gathering of threat information and rapid distribution of such information, "the President immediately authorizes the FBI to expand its current organization to a full scale National Infrastructure Protection Center (NIPC) [6]."

### 4.2 Private Sector

For the private sector, a National Infrastructure Assurance Council was to be established. It consisted of "a panel of major infrastructure providers and state and local government officials" appointed by the President to provide him advice. Periodic meetings were "to be held to enhance the partnership of the public and private sectors" [7]. Subsequently, the Council was established as the National Infrastructure Advisory Council by Executive Order 13231, and amended by EO 13286 and EO 13385.

A private-sector coordinator to represent each sector was to be identified as the counterpart to the federal government's sector liaison official.

Owners/operators were "strongly encouraged" to create ISACs. "Such a center could serve as the mechanism for gathering, analyzing, appropriately sanitizing and disseminating private sector information to both industry and the NIPC" [8].

### 4.3 Research and Development

The Directive established a formal R&D program with guidelines and specific tasking.

- *Section V, Guidelines.* "The Federal Government shall, through its research, development and procurement, encourage the introduction of increasingly capable methods of infrastructure protection."
- *Section VIII, Tasks.* The President requested the Principal's Committee to submit to him a National Infrastructure Assurance Plan with milestones. R&D was one of the subordinate and related tasks:
  - "*Research and Development*: Federally sponsored research and development in support of infrastructure protection shall be coordinated, be subject to multi-year planning, take into account private sector research, and be adequately funded to minimize our vulnerabilities on a rapid but achievable timetable."
- *Annex A, Structure and Organization.* "In addition, OSTP (*Office of Science and Technology Policy*) shall be responsible for coordinating research and development agendas and programs for the government through the National Science and Technology Council."

### 4.4 Problems and Major Shortfalls of PDD 63

***4.4.1 Lack of Partnership.*** There was significant resistance to the new concept of Critical Infrastructure Protection, both in the private sector and in many elements of the government. Also, many government departments and agencies were not familiar with the concept of a partnership with the private sector. Building the "partnership" would be a long-term process that would need to be developed over time (years), starting with personal relationships established on trust, followed by awareness and education efforts, and the active participation of partners with leadership skills with the ability to focus on outcomes of mutual benefit.

The Directive was promulgated with minimal collaboration between the government and private sector. PDD 63 was written within the federal government. A senior official in the NSC led the effort to draft the document, relying on their support organization and an interagency group of senior representatives selected from the agencies involved.

There was a need to stimulate dialogue across and within particular infrastructure sectors to drive and accelerate more collaboration on critical infrastructure thinking within infrastructure sector leadership. Part of the challenge is that many sectors had not previously engaged in critical infrastructure dialogues among themselves to consider opinions and develop conclusions toward their approach to critical infrastructure. While PDD 63 encouraged such efforts, little was done to bring together the leadership to stimulate such efforts. Fortunately, both the CIAO and the Partnership for Critical Infrastructure Security (PCIS) caused much of the internal sector dialogues to begin, though these successes took several years to begin consolidating effectively.

Similarly, once a dialogue began within a particular sector, it took further effort (and time) to generate trusted dialogue between that sector and government. In some cases, this dialogue moved ahead very effectively while in some sectors, it still struggles a decade after the PCCIP. Further, many superb efforts are driven primarily by several very effective individuals leading their particular sector, though broad acceptance and understanding of CIP issues remain a challenge—thus, if that person ceased driving

leadership, many initiatives could potentially fade or be weakened. The need for sector CIP dialogues was vitally important at three levels: (i) within and across the sector; (ii) between the sector and other sectors, many of which had interdependent elements; and (iii) between the sector and government. While PDD 63 was ineffective in successfully achieving these ends, the CIAO and PCIS made significant strides prior to the establishment of DHS.

***4.4.2 Lack of Resources for Implementation.*** To initiate a new program, the departments and agencies realized that the resources had to be taken out of existing funds. No new funds were available! Although the agencies submitted budget requests through their normal channels, and they were accepted by the Office of Management and Budget to some extent, the White House did not develop or present a unified set of supporting arguments to the congressional oversight committees involved. Because of the need to make Congress aware of the critical infrastructure issues and concerns, there was no clear idea of the need or magnitude of the undertaking. Thus, the implementation of PDD 63 began with a long-term effort of awareness and education. A key lesson learned in the government sphere is that central coordination of a distributed program is an essential element in its success.

***4.4.3 Lack of Emphasis on Interdependencies.*** Even though interdependencies were stressed throughout the PCCIP report, PDD 63 gave it minimal emphasis. The most significant reference came at the end of Section IV: "During the preparation of the sectoral plans, the National Coordinator (see section VI), in conjunction with the Lead Agency Sector Liaison Officials and a representative from the National Economic Council, shall ensure their overall coordination and the integration of the various sectoral plans, with a particular focus on interdependencies" [9]. No single agency or department was given a lead role for interdependencies.

Interdependency was one example of a crosscutting issue that could have been addressed by the Critical Infrastructure Coordination Group. However, the "unfunded mandate" problem made performance of the sector lead agency responsibilities too spotty and inconsistent to allow the different agencies to work on common issues.

## 5 CASE AND STRATEGY FOR ACTION IN TERMS OF INFRASTRUCTURE INTERDEPENDENCIES

The tremendous explosion of technologies, including computers, processing, and communications processes, led to a complex mosaic of technology in every infrastructure sector. The reliance on other infrastructures continued to grow, led in large part by a markedly increased reliance on communications and control systems, providing signals and feedback mechanisms by which infrastructures are monitored and operated to include an expanded range of remote operations. Although experts in each of these processes are fluent as to how their particular systems interact dynamically to control and operate segments of the infrastructure, their insights are often limited to the narrow scope of their particular system or functional role. With the expanded complexity of technology, individual infrastructure sectors have advanced modeling and simulation processes that can mimic and, in some cases, function predictively in the operational control of an infrastructure sector, especially in localized or regional operations. However, it becomes far

more difficult for managers and decision makers to fully understand the broad range of detailed interactions and nuances by which their entire infrastructure functions technologically and operationally, especially during crises or emergency scenarios where dynamic changes occur more rapidly within the sector. This challenge becomes even greater when the scope of interdependencies upon other infrastructure sectors is considered.

Each infrastructure sector's consideration of critical infrastructure issues has advanced at its own pace; some sectors are further along the path of understanding and are taking appropriate actions to better assure resilience, recoverability, and robustness. This disparity becomes more obvious as we consider infrastructure outage events that occur periodically during any given year. In some cases, a sector's response is impressively swift, mitigating the damaging effects of an outage and accelerating a return-to-normal operation. In other cases, a flawed response leads to open criticism, causing either governmental or privately led efforts to force improvements in emergency response-and-recovery processes and driving greater investments toward greater assurance of acceptable sector performance. The point is that different sectors, and sometimes varying management elements within the same sector, often are at different levels of technological and operational maturity in the understanding and response within their sector. This is further exacerbated when the issue of infrastructure interdependency is considered.

Even sectors with mature processes for operations and recovery often have given limited consideration to developing predictive means for assessing their systematic reactions to emergency events occurring in other sectors on which they rely. In their defense, given (i) the difference in modeling and simulation maturity within each sector; (ii) the reliance on different and often incompatible technologies; and (iii) the variety of signal and protocol formats, the interoperability of modeling processes between infrastructure sectors is both complex and very limited. Furthermore, the best way to coordinate the operations among multiple infrastructures is often through leveraging preexisting relationships among the leaders, managers, and operators of those separate infrastructures.

The more interdependent our infrastructures become—and their interdependence continues to grow year after year—the more urgent it becomes for our nation and its critical infrastructure owners/operators to more thoroughly consider critical infrastructure interdependencies. Operational processes, service-level agreements, emergency response systems, and organizational interactions and procedures must better address interdependencies to assure critical infrastructure protection. To do so will require many types of investments to help assure critical infrastructure performance for the future.

## 6 SUMMARY OF COMMISSION'S CONCLUSIONS ON RESEARCH AND DEVELOPMENT NEEDS

Consistent with the scope of its charter and in recognition of the importance of interdependencies, the Commission addressed R&D needs not only for the eight specific infrastructures identified in Executive Order 13010, but also explicitly for the crosscutting interdependency issues that affect more than one infrastructure. The goal was to provide a road map for the development of technologies that will counter threats (physical, cyber, and other threats that arise from the complexity of automated systems and from increasing interdependencies among infrastructures) and reduce the vulnerabilities in those areas with the potential for causing "significant" national security, economic, and/or social impacts.

Basic research requiring long-term government investment was emphasized. However, it was recognized that this research must be accompanied by the development of technology within the private sector. As broadly defined by the Commission, technology includes processes, systems, models and simulations, and hardware and software. Strong involvement from infrastructure owners/operators was deemed essential to ensure the development of useful and usable products.

The Commission concluded that federal R&D efforts were inadequate for the size of the R&D challenge presented by emerging cyber threats. They further noted that real-time detection, identification, and response tools were urgently needed and that R&D for infrastructure protection requires partnership among government, industry, and academia to ensure a successful and focused research and technology development effort.

The Commission proposed a substantial increase in federal investment in infrastructure assurance research, targeting R&D and focusing on six R&D areas:

1. *Information assurance.* Assurance of vital information is increasingly a key component for the functioning of our interdependent infrastructures. The urgent need to develop new, affordable means of protection is apparent, given the increasing rate of incidents, the expanding list of known vulnerabilities, and the inadequate set of solutions available.
2. *Intrusion monitoring and detection.* Reliable automated monitoring and detection systems, timely and effective information collection technologies, and efficient data reduction and analysis tools are needed to identify and characterize structured attacks against infrastructure.
3. *Vulnerability assessment and systems analysis.* Advanced methods and tools for vulnerability assessment and systems analysis are needed to identify critical nodes within infrastructures, examine interdependencies, and help understand the behavior of these complex systems. Modeling and simulation tools and test beds for studying infrastructure-related problems are essential for understanding the interdependent infrastructures.
4. *Risk management decision support.* Decision support system methodologies and tools are needed to help government and private-sector decision makers effectively prioritize the use of finite resources to reduce risk.
5. *Protection and mitigation.* Real-time system control, infrastructure hardening, and containment and isolation technologies are needed to protect infrastructure systems against the entire threat spectrum.
6. *Incident response and recovery.* A wide range of new technologies and tools is needed for effective planning, response, and recovery from physical and cyber incidents that affect critical infrastructures.

The fundamental R&D issue for critical infrastructure protection was framed by the Commission in terms of three interrelated questions:

- What R&D is needed to achieve the nation's infrastructure assurance objectives?
- What level of corresponding investment is required?
- Who should make this investment?

These questions remain relevant and must be answered within a partnership between government and the private sector. The Commission noted that both entities must recognize that (i) infrastructure assurance risks cut across the public and private sectors; (ii) the private sector holds much of the relevant technical and empirical data on infrastructure operations, vulnerabilities, and interdependencies; and (iii) the private sector develops technology only when it identifies a market for it. The Commission concluded that successful implementation of technologies developed from government-funded research efforts requires close cooperation from private-sector owners and operators of our nation's infrastructures.

## 7 CLOSING STATEMENT

The PCCIP set the stage and Presidential Decision Directive 63 initiated the path forward. As stated in the *Onward* section of the PCCIP report—the Commission's effort was "the prologue to a new era of infrastructure assurance (p. 101)."

# INPUT–OUTPUT MODELING FOR INTERDEPENDENT INFRASTRUCTURE SECTORS

JOOST R. SANTOS AND YACOV Y. HAIMES
*Center for Risk Management of Engineering Systems, University of Virginia, Charlottesville, Virginia*

## 1 BACKGROUND: LEONTIEF INPUT–OUTPUT MODEL

No literature survey on interdependency analysis is complete without mentioning the input–output (I–O) model, for which Wassily Leontief received the 1973 Nobel Prize in Economics. This model is useful for studying the effects of consumption shocks on interdependent sectors of the economy [1, 2]. Miller and Blair [3] provide a comprehensive introduction of the model and its applications. Leontief's I–O model describes the equilibrium behavior of both regional and national economies [4, 5] and presents a framework capable of describing the interactive nature of economic systems. Extensions and current frontiers of I–O analysis can be found in Lahr and Dietzenbacher [6] and Dietzenbacher and Lahr [7]. It is worth noting that the traditional use of input–output analysis for estimating the effects of economic shifts (e.g. changes in consumption) has been extended to other applications, such as disaster risk management, environmental impact analysis, and energy consumption, among others. Various studies for estimating losses pursuant to disasters have employed traditional I–O analysis and extended approaches such as computable general equilibrium (CGE) models. Rose and Liao [8] conducted a case study of water-supply disruption scenarios in Portland using CGE to account for resilience factors (e.g. substitution and conservation) that business sectors typically consider in order to minimize potential losses. (Note that Rose [9] states that CGE is an extension rather than a replacement of the traditional I–O model). Cho et al. [10] identified the I–O model as a useful tool for estimating the economic costs associated with major earthquakes in urban areas. Lenzen et al. [11] implemented a multiregion environmental input–output analysis to determine $CO_2$ multipliers based on international trade data for commodities that emit greenhouse gas by-products. Alcántara and Padilla [12] developed an I–O-based methodology that considers energy demand elasticities for determining the key sectors that are involved in the final consumption of energy.

The formulation of the basic Leontief I–O model is shown in Eq. (1). The notation $x_i$ refers to the total production output of industry $i$. The Leontief technical coefficient $a_{ij}$ indicates the ratio of the input of industry $i$ to industry $j$, with respect to the total production requirements of industry $j$. Thus, given $n$ industries, $a_{ij}$ can tell the distribution of inputs contributed by various industries $i = 1, 2, \ldots, n$ to the total inputs required by industry $j$. Finally, the notation $c_i$ refers to the final demand for the $i^{th}$ industry—the portion of industry $i$'s total output for final consumption by end users (i.e. the excess of all intermediate consumptions by various industries $j = 1, 2, \ldots, n$).

$$\mathbf{x} = \mathbf{A}\mathbf{x} + \mathbf{c} \Leftrightarrow \left\{ x_i = \sum_j a_{ij} x_j + c_i \right\} \forall\, i \tag{1}$$

## 2 INOPERABILITY INPUT–OUTPUT MODEL (IIM)

Today, the infrastructure sectors in the United States (and the entire global economy) are highly interdependent—making them more vulnerable to natural- and human-caused disruptive events. Such events upset the "business-as-usual" production levels of the affected systems and lead to a variety of economic losses, such as demand/supply reductions. Interdependency analysis applies to ripple effects triggered by various sources of disruption, including terrorism, natural calamities, and accidents, among others.

On the basis of Leontief's work, Haimes and Jiang [13] developed the inoperability input–output model (IIM) for interconnected systems. One of the metrics offered by the IIM is *inoperability*, which is defined as the inability of a system to perform its intended functions. In the IIM, inoperability can denote the level of the system's dysfunction, expressed as a percentage of the system's intended production level. Inoperability can be caused by internal failures or external perturbations, which adversely affect the delivery of a system's intended output. The IIM was later expanded by Santos and Haimes [14] to quantify the economic losses triggered by terrorism and other disruptive events to economic systems (or industry sectors). The analysis of economic impacts associated with such events is made possible through the economic I–O data published by the Bureau of Economic Analysis (BEA) [15, 16].

The formulation of the IIM is as follows:

$$\mathbf{q} = \mathbf{A}^*\mathbf{q} + \mathbf{c}^* \tag{2}$$

The details of model derivation and an extensive discussion of model components are found in Santos and Haimes [14]. In a nutshell, the terms in the IIM formulation in Eq. (2) are defined as follows:

- $\mathbf{q}$ is the inoperability vector expressed in terms of normalized economic loss. The elements of $\mathbf{q}$ represent the ratio of unrealized production (i.e. "business-as-usual" production minus degraded production) with respect to the "business-as-usual" production level of the industry sectors.
- $\mathbf{A}^*$ is the interdependency matrix, which indicates the degree of coupling of the industry sectors. The elements in a particular row of this matrix can tell how much additional inoperability is contributed by a column industry to the row industry.
- $\mathbf{c}^*$ is a demand-side perturbation vector expressed in terms of normalized degraded final demand (i.e. "business-as-usual" final demand minus actual final demand, divided by the "business-as-usual" production level).

Previous IIM-based works on infrastructure interdependencies and risks of terrorism include Haimes [17], Jiang and Haimes [18], Crowther and Haimes [19], Haimes et al. [20, 21], Lian and Haimes [22], and Santos [23]. Other quantitative research on modeling terrorism risks has emerged in recent years because of sustained threats to homeland security. Apostolakis and Lemon [24] proposed the use of graph theory for modeling infrastructure interconnectedness and employed multiattribute utility theory for setting priorities to vulnerabilities. Paté-Cornell and Guikema [25] employed probabilistic risk analysis (PRA), decision analysis, and game theory for prioritizing vulnerabilities and their associated countermeasures. Bier and Abhichandani [26] proposed a game theory approach to model the way defenders and offenders determine optimal strategies for achieving their respective objectives of protecting or destroying a system.

## 3 APPLICATIONS OF THE IIM

This section discusses representative applications of the IIM that resulted from three government-commissioned projects: (i) high-altitude electromagnetic pulse (HEMP) impact on interconnected sectors; (ii) economic impact of homeland security advisory system (HSAS) threat levels; and (iii) Virginia Department of Transportation (VDOT) interdependencies.

### 3.1 High-Altitude Electromagnetic Pulse (HEMP) Impact on Interconnected Sectors

HEMP is defined as intense electromagnetic blasts induced by high-elevation nuclear explosions, which can potentially cause damage to electronic and electrical systems. National- and regional-level case studies have been conducted in this study to analyze the impacts of HEMP on the electric power, electromagnetic pulse (EMP) vulnerable equipment, workforce, and health services sectors. The EMP Commission's guidance has been solicited to generate the perturbation scenarios employed in the case studies. Systemic parametric and sensitivity analyses of HEMP attack scenarios are achieved via consideration of various sources of uncertainties relating to (a) geographic scope and detail (e.g. national versus regional); (b) intensity of perturbation to an initial set of affected sectors (e.g. electric power, EMP-vulnerable equipment, and workforce); and (c) temporal characteristics surrounding sector recoveries (e.g. 60-day versus 1-year recovery rates). Trade-off analyses have been performed to analyze the effectiveness of resource allocation strategies associated with restoring diversely affected sectors. Recommendations from this study include developing cost-benefit-risk-balanced policies and solutions for managing disruptions and expediting recovery time from potential terrorist attacks [see [16] for details]. For a 60-day exponential electric power outage in the Greater Northeastern Region (GNR), as shown in Figure 1, the resulting direct and indirect sector impacts were ranked and classified according to two types of metrics: economic loss and inoperability. Approximately $14 billion in losses are incurred for this scenario, of which about 80% is realized within the first 20 days.

### 3.2 Economic Impact of Homeland Security Advisory System (HSAS) Threat Levels

The IIM was used to estimate the economic impact of heightened HSAS threat levels and the corresponding courses of actions relating to the period of implementation and the regional scope of the alert. A system for generating the direct-sector impacts associated with various HSAS courses of actions was developed, along with a process for visualizing the results. Parametric analyses were conducted to address critical factors, such as impacted sectors, nature of impact (productivity loss versus demand reduction), and duration of effects. Input–output datasets for the Greater New York Metropolitan Region and the Newark Statistical Area (a subset consisting of six counties contiguous to Newark) were obtained from the BEA. These datasets enabled us to estimate the magnitude of economic impacts associated with the specified HSAS scenarios. National IIM analysis was also implemented to estimate the psychological response of the general public to HSAS alert modifications. In particular, we studied the sensitivity of recreation and other discretionary sectors to demand reductions potentially caused by increasing alert levels. The results show that economic repercussions of a red alert are large and are highly sensitive to the definition of nonessential businesses (i.e. discretionary vs. fundamental

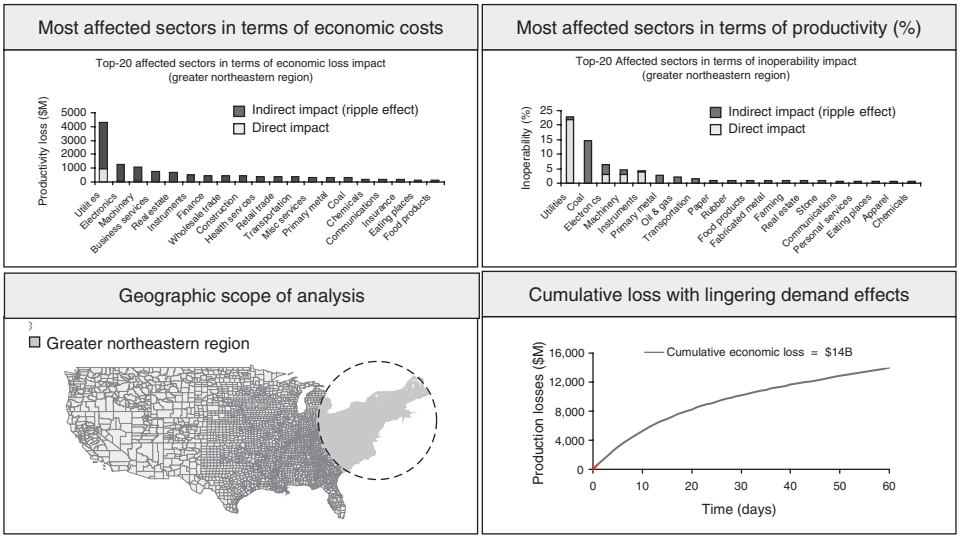

**FIGURE 1** Sample IIM results for a regional HEMP attack scenario.

sectors). On the basis of the assumption that approximately 10% of the businesses are nonessential, red alerts would likely result in $210 billion losses for the nation, $50 billion for the Greater New York Metropolitan Region, and $6.3 billion for the Newark Statistical Area. These losses are based on a one-week red alert followed by one year of consumption losses due to lingering public fear. Lingering demand effects have substantial economic impacts and should not be ignored—IIM results indicate that these losses are approximately 3 times the losses incurred during the first week of a red alert. Also, losses incurred in smaller regions are proportionately higher compared to overall domestic production. This observation may be attributable to the greater effort required to manage security and/or more focused public reaction when the red alert is local.

### 3.3 Virginia Department of Transportation (VDOT) Interdependencies

The transportation network, being a lifeline infrastructure, is designed to support other infrastructures and systems. This symbiotic relationship creates vulnerabilities that affect not only the highway system but also all other systems dependent on transportation modes and facilities. The IIM was used for modeling and analysis of transportation interdependencies, which requires investigation of various transportation elements, such as road network structure, flow, and capacity, as well as the type of economic activities they support [27]. Mobility is an important aspect of recovery and can be assured through availability of transportation modes and facilities. Furthermore, workforce mobility is an important consideration during recovery to ensure uninterrupted availability of essential services other than transportation (health care, food supply, electric power, communication, etc.). The focus of the case study is to understand how a terrorist attack (or other disruption) on a highway system element (bridge, overpass, tunnel, road, etc.) propagates to other physical and economic sectors within Virginia and its contiguous region, so that management policies can be implemented to reduce the consequences of the event. These sectors include utilities, commerce, communication, and providers of basic necessities (food, water, and health care), among others.

## 1 INTRODUCTION

The Dams Sector comprises dams, navigation locks, levees, flood damage reduction systems, hurricane protection systems, mine tailings impoundments, and other similar water retention and/or control facilities. There are over 82,000 dams in the United States;

approximately 65% are privately owned and more than 85% are regulated by State Dam Safety Offices. The Dams Sector is a vital part of the nation's infrastructure, and continually provides a wide range of economic, environmental, and social benefits, including hydroelectric power, river navigation, water supply, flood control, and recreation. The potential impacts associated with damage or destruction of dams could include significant loss of life, massive property damage, and severe long-term consequences. Many of these infrastructures were built before man-made threats were recognized as a possibility and their implications were fully understood. While many differences exist between the needs of individual dam owners and operators, the Dams Sector shares a collective goal of incorporating appropriate and practical protective measures to improve awareness, prevention, protection, response, and recovery. Meaningful assessment of risks and systematic prioritization of risk mitigation measures are critical elements to accomplish this goal.

## 2 RISK METHODOLOGY COMPARISON STUDY

In 2006, the US Army Corps of Engineers (USACE) initiated a risk methodology comparison study for civil infrastructure projects. The initial phase of this study (see Figure 1) focused on a review of the state-of-practice of critical infrastructure security risk assessments, which could be applied to Corps civil works infrastructure projects. This study [1] identified a significant opportunity for collaboration with other Dams Sector partners, based on a clearer, more comprehensive understanding of requirements for a consistently applied, sector-wide risk assessment approach. The development of a framework that enables a sector-wide risk assessment is the primary goal of the Dams Sector-Specific Agency (SSA) within the Office of Infrastructure Protection in the US Department of Homeland Security (DHS). As a continuation to the comparison study effort, and through the auspices of an interagency agreement between USACE and DHS, the study was further expanded to establish the comparative advantages and limitations of a number of risk assessment methodologies. In this second phase, a technical review led by an external panel of experts was conducted to assess the technical approach and implementation of the selected methodologies.

As a final phase, a select set of owners and operators conducted an analysis of requirements that provided a more detailed understanding of how well each methodology compared to the needs of organizations responsible for assessing security risks. Each of these phases is covered in additional detail below.

### 2.1 Phase 1—Site Assessments

This phase primarily involved a literature review of risk analysis methodologies currently in use for security assessments of critical infrastructure, to assist in the identification of existing state-of-practice approaches with most applicability to dams. The term *state-of-practice* was used to denote those approaches currently in use that can provide useful input to decisions on managing risks associated with various threat scenarios. From this research, a preliminary screening of existing assessment methodologies was conducted and five methodologies were identified for application at two typical USACE projects; a navigation lock and dam, and a combined flood control, hydropower, and

navigation lock project. The five methodologies were: Dam Assessment Matrix for Security and Vulnerability Risk (DAMSVR), developed by the Federal Energy Regulatory Commission; Risk Assessment Methodology for Dams (RAM-D), developed by Sandia National Laboratories; Critical Asset and Portfolio Risk Analysis (CAPRA), developed by the University of Maryland; Reclamation's Risk Quantification Methodology (RRQUM) and Matrix Security Risk Analysis (MSRA), both developed by the US Bureau of Reclamation, and Joint Antiterrorism (JAT) Risk Assessment Methodology, developed by the US Department of Defense (DoD). It must be pointed out that some of these methodologies and approaches have continued evolving over time, and therefore their current versions may show differences with respect to those used in the initial phase of this effort.

Technical teams with representatives from each of the risk assessment methodologies under consideration conducted site assessment visits at select dam sites during the November 2006 time frame. Each team conducted an independent evaluation of the sites, and collected the information required for the application of the corresponding assessment methodology. In advance of the site assessments, each methodology team was provided with the same read-ahead package, consisting of site information and descriptions of the functions and components of the project, including pictures, drawings, and other relevant information. For the purpose of this effort, a definition of threat scenarios was also provided. After the site assessment, each team provided a technical report summarizing the analysis resulting from the application of the risk assessment methodology to each site.

### 2.2 Phase II—Panel Reviews

Phase II was initiated during 2007 by an external panel of experts who reviewed the risk assessment reports and evaluated the application of the corresponding methodologies to the two sites selected for the study. The objective was to establish comparative advantages and limitations of the technical approaches, as well as to identify any challenges encountered during the implementation process.

The panel developed a systematic approach that included a comprehensive set of criteria to evaluate the results arising from Phase I of the study. The criteria established by the panel took into consideration the requirements from the National Infrastructure Protection Plan (NIPP) developed in 2006 [2] and updated in 2009. The NIPP provides a coordinated approach for the protection of critical infrastructure and key resources (CIKR). Other provisions in the NIPP include a risk management framework for systematically combining consequence, vulnerability, and threat information. The 2006 NIPP included specifications for baseline criteria that risk assessment methodologies should meet in order to enable comparative analyses between multiple sectors. The purpose of these baseline criteria was to assist in the use of assessments previously performed by owners and operators. These baseline criteria aimed to ensure that a given methodology is credible and comparable with other methods. The challenge of comparing results from multiple risk methodologies is significant since there is wide variation among methodologies on aspects such as assumptions, comprehensiveness, objectivity, inclusion of threat and consequence considerations, physical and cyber dependencies, and other characteristics.

In addition to the 2006 NIPP baseline criteria, the expert panel considered some additional basic elements that are relevant to the types of infrastructures included within the Dams Sector. These sector-specific considerations were used to augment the 2006 NIPP baseline criteria. Table 1 shows the entire set of criteria used to facilitate the comparative evaluation by the panel.

**TABLE 1 Evaluation Criteria**

**NIPP-related criteria**

1. Is the methodology based on documented risk analysis and security vulnerability analysis?
2. Does it specifically address consequences? Vulnerability? Threat?
3. Does the methodology provide reasonably complete results via a quantitative, systematic and rigorous process that
   (a) provides numerical values for estimated consequences, vulnerability and threat whenever possible, or uses scales when numerical values are not practical?
   (b) specifically addresses both public health and safety and direct economic consequences?
   (c) considers existing protective measures and their effects on vulnerabilities as a baseline?
   (d) examines physical, cyber, and human vulnerabilities?
   (e) applies the worst-reasonable-case standard when assessing consequences and choosing threat scenarios?
   (f) uses threat-based vulnerability assessments?
4. Is the methodology thorough and does it use the recognized methods of the professional disciplines relevant to the analysis?
5. Does it adequately address the relevant concerns of government, the CIKR workforce, and the public?
6. Does the methodology provide clear and sufficient documentation of the analysis process and the products that result from its use?
7. Is the methodology easily understandable to others as to assumptions used, key definitions, units of measurement, and implementation?
8. Does the methodology provide results that are reproducible or verifiable by equivalently experienced or knowledgeable personnel?
9. Is the methodology free from significant errors or omissions so that the results are suitable for decision-making?

**Dams Sector-specific criteria**

1. Is the methodology able to conduct comparisons between assets and comparisons with other sectors?
2. Is the process Six Sigma friendly to allow for trend analysis involving similar structures or regional groupings of structures?
3. Can the methodology be used to identify security and protection measures that will result in quantifiable risk reduction?
4. Will implementation of the methodology result in distinguishing characteristics that can be used for meaningful prioritization and are important for decision-making?
5. Is the theoretical/analytical/mathematical formulation logically sound, consistently carried over across the whole methodology and reasonable/practical in terms of data/input requirements?
6. Does the method clearly identify and consider direct and indirect consequences associated with damage/failure of the facility and/or disruption of its functions? Does it consider potential effects on downstream population (population at risk, number of fatalities, and number of injuries)? Does it consider economic impacts (facility replacement and repair cost, direct property damage, business interruption costs and loss of benefits, emergency response impacts, search and rescue costs, short- and/or long-term environmental remediation and restoration costs, indirect effects on other infrastructure)?

(*continued overleaf*)

**TABLE 1 (*Continued*)**

7. Does the method identify a process for aggregating losses across various consequence types to allow an assessment of the cumulative loss of an attack?
8. Does the method clearly identify and quantify interdependency impacts?
9. Does the method effectively address economic impacts on regional interdependencies as many of these dams affect numerous entities upstream, downstream, and across state lines?
10. Does the threat assessment portion of the methodology have an "intelligence quality" process for identifying, quantifying, and qualifying intelligence and information from both public and private sectors, leading to a formal threat estimate that identifies the most credible threats to a facility, activity, organization, or region?
11. Does the method identify a process for allocating the threat for the entire Dams Sector down to the threat for a specific dam?
12. Does the methodology consider the structural condition and maintenance state of the facility or asset when evaluating the vulnerabilities?
13. Does the methodology consider the response effectiveness (time for arrival of first responders) when evaluating the vulnerabilities, or their effects on their resulting risk?
14. Is the methodology sensitive enough to capture the influence of alternative security/protection/response measures on the vulnerabilities and/or the resulting risk?

In August 2007, the expert panel convened to complete the review of the application of the five methodologies. The panel, facilitated by the Oak Ridge Institute for Science and Education, met for 3 days to share findings arising from their evaluation and to identify desirable features or limitations in current approaches. Results from the discussions were documented; some of the key highlights are as follows:

- The baseline criteria for risk assessment methodologies can identify desirable overall characteristics, but are inadequate to ensure that the results of methodologies will be compatible or their resulting data consistent. For the Dams Sector to produce comparable risk estimates, the basic criteria must be augmented with additional sector-specific technical considerations.
- In some cases, the expert panel evaluation criteria required "yes" or "no" answers, yet many panelists felt that the most accurate answer lay in between. This led to disagreements among panelists, which were not capable of being resolved within the limitations of the evaluation criteria. Where possible, ordinal scales (e.g. "low, moderately low, moderate, moderately high, and high") should be developed that would permit panelists to estimate the "degree" to which a methodology met a required criterion. Alternatively, questions which permitted panelists to provide somewhat open-ended descriptions that described and defended the panelist's assessment were deemed desirable in some cases.
- The evaluation lacked benchmarks or defined standards for best practices against which methods could be compared; thus, evaluators tended to evaluate each method against their own undefined "best practice" standards.
- Experts agreed on the need to develop rational methods for transforming threat information and intelligence into comparative estimates (e.g. rank order or probabilities) for different attack scenarios (i.e. threat vector and target combinations) within the sector.

- To obtain credible vulnerability results, expressed as a probability of attacker success given an attack, it is necessary to develop rational models that appropriately account for all layers of protection (including passive and active detection, assessment, and interdiction features).
- It is necessary to establish a method for aggregating consequences across various consequence categories (human impacts, economic impacts, etc.), including cascading impacts and indirect effects arising from long-term project disruptions.
- The methodology has to include a clear communication strategy for documenting attack-target predictions in a way that accounts for model limitations and data uncertainty.
- Development of a sector-wide risk assessment approach will require a set of tools that can integrate information available from asset-specific assessments conducted at the facility level.

### 2.3 Phase III—Independent Analysis

The third phase of the study was initiated in June 2008. Additional analysis of the requirements defined by the Dams Sector was conducted to develop a more detailed understanding of the results of the prior phases of the study. The primary objective of this phase was to further analyze the outcomes from Phase II, which included making a more detailed evaluation of the advantages and limitations of the representative methodologies considered. The desired end-state of the final phase of the study was to provide additional recommendation on the desired attributes that an effective risk assessment methodology should have, and to take additional steps toward achieving risk analysis interoperability across the Dams Sector.

SRA International was funded to facilitate this phase of the study and develop an objective framework of common requirements and features for security risk analysis methodologies. Noting that much of the Phase II panel analysis generated agreement on "yes" and "no" answers while demonstrating significant differences in the open-ended comments, it was perceived that a more discriminating scale such as an ordinal scale could generate greater clarity. The result of this enabling step was the development of a methodology evaluation tool that could facilitate comparison of risk assessment methodologies on a more detailed and objective basis. This process identified a set of measurable requirements and preferences commonly associated with security risk analysis methodologies.

This phase of the study relied on additional data elicited from a number of security risk experts affiliated with organizations with large portfolios of high-consequence dams. The interviews were conducted in September 2008. Each interview lasted between 1 and 2 h, and they were conducted via teleconference.

First, the facilitators intentionally focused questions toward sector-wide needs and requirements, given likely resources and time constraints. Recognizing that most of the participants could identify many improvements to current security risk analysis that may be beyond current budget and resources, participants were directed to consider the best methodology achievable in the near term. The acronym BMAN ("best methodology available now") was coined by the SRA team to identify this target methodology. The features of this benchmark methodology were explicitly defined based on the set of measurable requirements and preferences incorporated in the methodology evaluation tool.

Second, participants were also asked to give a narrative response for a set of open-ended questions. The open-ended responses were particularly important because they allowed participants to reflect upon overarching risk methodology issues in a narrative format. It also permitted interviewees to express a more detailed and contextual perspective about methodology features for the Dams Sector. A systematic process was followed to capture these methodological requirements and preferences.

In Phase II, in the absence of a thorough understanding of requirements and preferences, expert reviewers had little choice but to evaluate methods against a notional "ideal methodology," without consideration of capabilities or resources needed to develop such an elusive perfect solution. The incorporation of a practical benchmark allows the objective comparison of methodologies through a set of technical requirements, while incorporating additional elements such as measures of their fitness with respect to practical capabilities and available resources. The study succeeded in identifying a wealth of critical issues and observations for further research. The final consolidation into a comprehensive requirements document however, would require additional development and approval across formal Dams Sector collaboration channels (Sector Coordinating Council and Government Coordinating Council). Once completed, the Dams Sector could be in a better position to evaluate, develop, or modify methodologies to bring them in line with sector-accepted requirements and preferences.

## 3 FINDINGS AND OBSERVATIONS

Methodologies currently in use across the Dams Sector are hindered by the lack of common terminology and standards for security risk analysis. Compounding the issues are data quality and availability limitations that present further technical and logistical obstacles—often resulting in the creation of unique and incompatible solutions. As a result, these methodologies—while useful in their own right at the organization level—cannot meet the evolving requirements and expectations at the national and sector levels.

If the achievement of sector-wide interoperability of risk assessment methods and compatibility of risk assessment results is to be achieved, significant work is still necessary to synchronize the requirements of stakeholders at several multiple levels, as indicated in Figure 2. For example, asset-level risk assessment methodologies must meet the needs of owners and operators who must use them to secure their assets and develop facility-specific security programs. Sector-wide risk assessments must be able to compare, consolidate, and prioritize basic results and information from facility-specific analyses. Finally, sector-specific assessments must also provide data that is deemed acceptably comparable with assessment results from the other 18 CIKR sectors, to facilitate national-level analysis.

Numerous observations were captured during the interview process leading to the definition of benchmark methodological requirements and preferences. These are addressed below.

- Interview participants envisioned a benchmark methodology that was consistent, functional, and user-friendly. Participants unanimously stated that the consistency of a methodology would bolster the overall capability of the Dams Sector to aggregate risk values and prioritize assets and programs.

**FIGURE 1** Project elements.

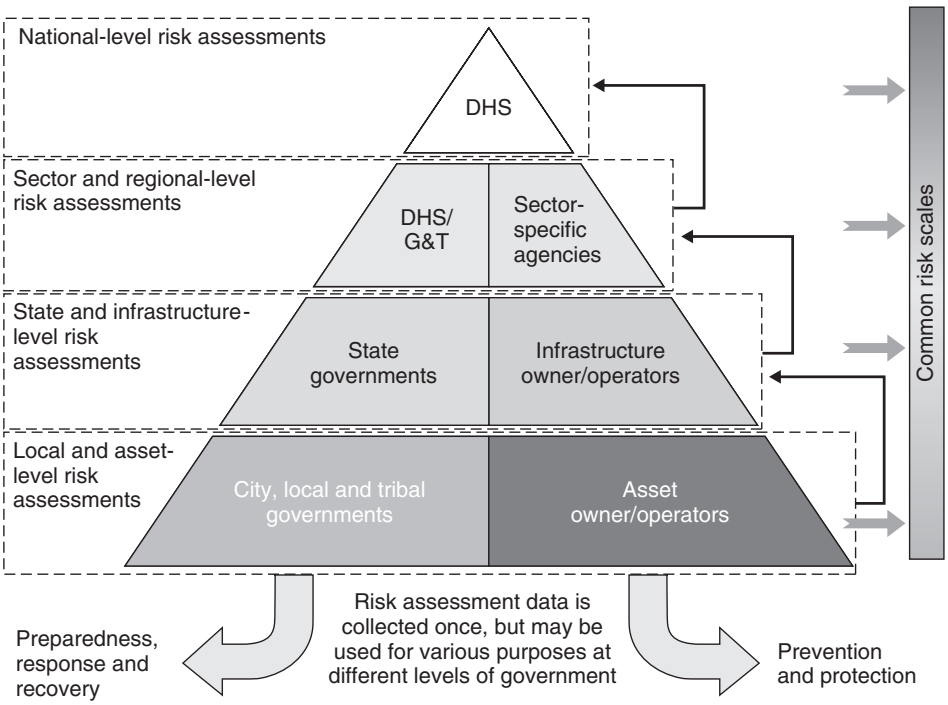

**FIGURE 2** Assessing risk at multiple levels.

- A probabilistic approach using the standard risk equation risk = f(threat, vulnerability, consequence) was considered the best practical option in the near term.
- Participants envisioned that the BMAN should principally address international terrorism, domestic terrorism, and insider threats. While this may appear somewhat limited in scope when compared to efforts to achieve an "all-hazards" methodology, it was noted that the Dams Sector has multiple programs that separately address security and safety concerns. Focusing one methodology on man-made hazards, while other programs addressed natural hazards and industrial accidents was not only stated as acceptable, but preferable. Therefore, the BMAN was envisioned as a stand-alone terrorist risk assessment methodology that did not weigh terrorism risk, natural disasters, and industrial/safety risks against one another.
- Interviewees expressed a clear preference that the BMAN should be able to assist in improving resiliency, recovery, response, and protection, even though most current methodologies focus primarily on protection alone.

- Participants agreed that it is the shared responsibility of asset owners and operators and sector-wide decision-makers to determine how best to address sector-level risks, and indicated that BMAN should measure risk at the asset level and support prioritization needs at the sector level.
- Participants envisioned a BMAN that addresses a broad array of consequences and their impacts, including loss of life, economic costs, mission disruption, interdependencies and dependencies, national security, symbolic impacts, and environmental impacts.
- Some of the participants agreed that the threat portion of the ideal methodology should be scenario-based, as is a requirement in the NIPP. Intention, capability, target attractiveness, and history of adversary were all considered critical analysis factors. Participants also articulated that the threat portion of the BMAN should be amenable to customization, particularly at the asset level, where it should facilitate development of detailed scenarios that could capture unique site characteristics.
- Participants were nearly unanimous in expecting that the BMAN should strive for a high standard of completeness and documentation. Full documentation for BMAN was defined by the participants as including detailed coverage of scope, formulas, limitations, assumptions, scales, and instructions for use.
- Interviewees identified a number of additional features necessary for the BMAN that would make it as much a risk management tool as a risk assessment tool. For example, participants preferred a methodology that included techniques for prescreening assets and enabled cost–benefit analyses.

The interview process also discovered a series of issues affecting most if not all, of the five methodologies in the initial phase of the study. It was noted that methodology developers often took divergent approaches to overcome these obstacles, influenced in large part by the needs of their original organization and their own approach to risk management. The specifics of these issues and their implications for the Dams Sector are discussed below:

### 3.1 Lexicon Problem

The ability to compare risk between assets, or to even identify which asset is at greatest risk, is undermined by the inability to compare risk results derived from one risk assessment methodology against those derived in another. At their highest level, almost all security risk assessments address consequence, vulnerability, and threat components of the problem, but more often than not they define and measure these variables in very different ways. There is little agreement on what factors are examined and how they are measured. While each methodology measures vulnerabilities, a risk analyst could not examine the results from each of these assessments side-by-side. This inconsistency is caused by design features in the methodologies themselves, as shown in Table 2, derived from information found in various parts of Ref. 1.

For example, all of the methodologies address consequences in some way (Table 2); however, by definition, consequence categories differ in significant ways. Given the same unwanted event, a methodology measuring the economic costs resulting from cascading failures associated with infrastructure dependencies and interdependencies will present a different consequence rating than the methodology that measures only direct consequences.

**TABLE 2 Risk Variables**

| | Risk Methodology No. 1 | Risk Methodology No. 2 | Risk Methodology No. 3 | Risk Methodology No. 4 | Risk Methodology No. 5 |
|---|---|---|---|---|---|
| **Consequence** | Casualties | Loss of life | Fatalities | Loss of life | Loss of life |
| | Economic impacts | Loss of dam function | Serious injuries | Economic impacts | |
| | Mission disruption | Secondary losses | Property damage | Mission disruption | |
| | Recuperation | Recovery | Equipment | | |
| | | Disruption to essential facilities | Direct economic | | |
| | | | Indirect economic | | |
| **Vulnerability** | Intrusion paths | Dam type | Adversary tactics | Security effectiveness | Likelihood of success |
| | Delivery vehicles | Feature or component vulnerabilities | Weapons | | Dam type |
| | Attack profiles | Redundancy | Delivery method | | Likelihood of failure (lack of inherent strength) |
| | Security effectiveness | Strength | Perimeter | | |
| | | Probability of loss | Facility exterior | | |
| | | | Facility interior | | |

| | | | | | |
|---|---|---|---|---|---|
| **Threat** | Profile attractiveness | Dam type | Location | Existence | Base threat (attack frequency) |
| | Scenario attractiveness | Security system effectiveness | Publicity | Capability | Criticality |
| | Relative asset attractiveness | | Asset location | Terrorist history and intentions | Suspicious activities |
| | Annual rate of attack | | Asset availability | Targeting | Security system effectiveness |
| | | | Existence | | |
| | | | Security measures | | |
| | | | Perception of success | | |
| | | | Threat level | | |
| | | | History of capability | | |
| | | | Terrorist operating environment | | |
| | | | Terrorist activities in country | | |

### 3.2 How You Measure Matters

The scales and estimation that a methodology uses to estimate risk and its components greatly influence the risk assessment process as well as the final prioritization and decision-making. Measurement methods determine how data, such as expert elicitation, modeling, or owner and operator judgments, is synthesized and aggregated into quantitative values. Four of the five methodologies use some form of ordinal scales or bins, but the criteria defining the bins are incommensurate; therefore, the various scales used by these methodologies are incompatible. Instead of using ordinal scales, the fifth methodology uses ratio scales and probabilities, which yield well-known risk metrics (e.g. *expected* loss measured in dollar amounts for a given time frame) that are mathematically defensible when the risk parameters are multiplied to yield the final result.

### 3.3 Assessing Threat is a Continuing Challenge for Quantitative Analysis

Calculating the threat posed by adversaries is one of the most pressing challenges in the broad risk-management community. This challenge is particularly acute at the facility-level analysis because local threat information is difficult to obtain, while sector-level threat data is often missing, inconsistent, or difficult to quantify. The majority of adversary threat data currently comes from intelligence reporting, which can be incomplete, conflicting, and sometimes "unfinished." Analytical products are also not written with the premise that the data will be quantified, which makes threat data difficult to incorporate into risk assessments. The weakest piece of every methodology reviewed was threat assessment. Each dealt with this problem differently, and in most cases the alternative solutions provided further undermined the credibility and compatibility of the assessments. Adopting or facilitating the development of standardized threat scenarios and corresponding quantitative threat estimates is crucial to being able to compare risk assessments at the sector and national levels.

### 3.4 The Complexity versus Practicality Problem

Many facilities in the Dams Sector do not require a complex model for assessing risk. It was considered more important to strive for a practical methodology rather than provide something that may tend to overcomplicate the process. Furthermore, employing complex methodologies often necessitates organizations looking outside of their current personnel to find the mix of skill sets necessary to conduct the most advanced assessments. As the methodology becomes more complex and rigorous, more time is not only required to perform the assessment, but also for training participants and decision-makers to understand the methodology itself. Given the number of dams within the sector, the availability of resources to produce a sector-wide assessment becomes an increasingly important constraint.

## 4 PROPOSED REQUIREMENTS FOR A SECTOR-WIDE RISK ASSESSMENT METHODOLOGY

A comprehensive, sector-wide risk assessment and management program is achievable and within the Dams Sector's reach. While each of the models reviewed has merit within a narrow field of use, none has the desirable properties of (i) satisfying the need for a

practical approach suitable for comprehensive sector-wide use, and (ii) yielding risks results that can be objectively compared to risk results across the sector as well as results from other infrastructure sectors. The model that is both ideal and achievable will allow risk analysts at the sector level to be able to leverage the data already collected by owners and operators through facility-specific assessments, with the goal of conducting a sector-wide prioritization—without having to collect or develop significant amounts of new data. This sector-wide risk assessment framework will strive for the lowest achievable complexity and logistical burden, while taking maximum advantage of existing assessments. The model that results needs to be not only simple, transparent, and easy to use, but also mathematically defensible and ratio-scalable to provide for more rigorous analyses, if needed. This joint effort between the USACE and Dams SSA has identified and consolidated a substantial set of requirements that will be critical in achieving this practical goal.

To be useful to stakeholders, a transparent and rigorous methodology would be able to evaluate risk numerically and to do this simply, so that risks ascribed to elements across critical infrastructure could be easily compared to each other. To accomplish this in a mathematically defensible way, the methodology would assign real, ratio-scalable numbers to each of the three parameters commonly accepted to compose risk: threat, vulnerability, and consequences. The simplest and most widely accepted approach for calculating risk is to multiply these three together, arriving at a value interpreted as *total risk*.

To explain the concept clearly, a system of calculations is said to be "ratio scalable" if, within the system, a number $x$ has a defined value that is half of $2x$, one-third of $3x$, and so on. As examples, a probability of 0.6 is twice the probability of 0.3; \$20 has a value of twice \$10. Such scales, probabilities, and dollars are ratio scalable. This is as opposed to ordinal scales, in which the numbers ascribed to a system do not necessarily have any well-defined ratio (such as scales that indicate relative qualities of 1 = "good" to 5 = "bad").

Threat may be considered as the *likelihood (or probability) of attack* and vulnerability as the *probability of success given an attack*. These probabilities should be treated as obeying the established laws of probability. Each will have a value between 0 and 1; when the two probabilities are multiplied together, the result will also be between 0 and 1. This product is most easily interpreted as the *probability of a successful attack* against that asset in a given time frame. When this probability is multiplied by the estimated consequences of a successful attack, the result may be logically interpreted as the *expected value of the loss in a given time frame*—or simply risk. If consequences are measured in dollars (this unit is obviously applicable to direct and indirect economic losses, and—using existing US government determinations—human casualties may be represented by an economic loss), the total risk is then estimated as the *expected loss* in dollars to an asset from a defined terrorist (or other) event.

An ideal methodology would need to include a rigorous and repeatable procedure for estimating the probability of success given an attack, assuming that an attack was attempted in the first place. More precisely, the "probability of success given an attack" is defined as the probability of success for a particular and well-defined scenario, that is, for a given attack type on a given type of asset.

A straight-forward way of determining this quantity would be to elicit from a panel of security experts the probability of success for the terrorist attack, based on the attack scenario, the generic characteristics of the asset, and the type of security measures in

place. This probability would not be calculated each time for each asset, but, once determined and systematically validated, would be made readily accessible in a lookup table or matrix that lists probabilities of success versus generic security configurations for a general type of asset. There would be a separate table for each attack type.

In the Dams Sector, much effort has already been devoted to calculating and then further refining estimates of consequences for total or partial failure of a dam or its appurtenant structures. There is a significant body of knowledge that has been developed by the dam safety community, and that could be applied to the consequence estimation problem associated with security scenarios. Therefore, the evaluation of security risks could take advantage of consequence estimates developed by different owners and operators. However, there are still significant methodological differences between the different approaches currently available, and this hinders the direct comparison of the corresponding results. Eventually, Dams Sector owners and operators should agree on recommended methodologies for dam failure consequence calculations.

Armed with a defined probability of success given an attack, and the consequences of a successful attack, these two parameters may be multiplied together to yield a *conditional risk*, that is, an expected loss given an attack attempt. A sector-wide conditional risk could offer an extremely useful insight on the attack types that could affect large segments of the sector or its subsectors, or the types of assets that could be associated with the highest risk for specific attack vectors.

Finally, the next logical step beyond the determination of conditional risk would be the estimation of *total risk*. This requires the actual determination of the *probability of attack* as the additional parameter needed to complete the risk picture. How might an ideal methodology assign a probability, over a given time period, for an attack on a given type of asset? This number would have to be derived from intelligence information, as provided through a formalized process by the corresponding analysts. The probability could be derived by first assigning a value to the probability of a significant attack on the US critical infrastructure, then multiplying this by the likelihood that, given an attack, it would be aimed at the sector being considered (i.e. Dams Sector). Finally, one would have to assign a probability that the attack on this sector would be conducted against a specific type of dam or a particular dam. Extensions of the technique would include various probabilities estimated for different types of significant attack scenarios.

The intelligence community is not usually forthcoming in producing numerical assessments of this sort. However, methods of expert elicitation have been used to dissect intelligence analysts' opinions and assessments of likelihoods, even to the point of assigning relative likelihoods to different events. Expert elicitation, using intelligence experts, is analogous to the expert elicitation described earlier for estimating the probability of success given an attack (which is accomplished using security experts rather than intelligence experts). Estimating the probability of attack, loosely termed the *threat probability*, may be done by asking the experts to engage in a series of direct pair-wise comparisons of different potential threats, given intelligence information on adversary intents and capabilities. This method can produce at least defensible probabilities of attack that can feed the risk evaluation methodology described above. As in the case of calculating a probability of success given an attack, the output from this stage of analysis would be a lookup table of probabilities of occurrence for each significant attack type on a given facility type.

Using the requirements and procedures sketched out above, different analysts would be able to apply a common methodology to facilities within a given sector and arrive

at similar, if not identical, answers that would be fully consistent. This would enable a systematic and reliable process that would directly support an effective sector-wide risk assessment framework.

## 1 CRITICAL INFRASTRUCTURES: THE EUROPEAN POLICY CONTEXT

Today's infrastructures and their associated systems such as energy, pipelines, water, telecommunication, banking, Internet etc. are delivering services for addressing an adequate quality of life. They have greatly developed and advanced during the last century, growing from facilities with limited reach to continent-wide infrastructures. Most importantly, these systems were neither designed as integrated systems nor as systems-of-systems (SoS), but gradually evolved over time. Due to their relevance to the daily functioning of society, the impairment or failure of these infrastructures can have severe consequences, beyond simple business impact. As failures of critical infrastructures can affect the welfare of society at large and the stability of economic

and political systems, they are an expression of protecting our national security, that is, our homeland security [1].

Most infrastructures originate from local networks. Over time, municipal networks evolved. Interconnection of city networks and network expansion to rural areas were forged through intervention of the provincial authorities. Provincial networks thus emerged in the first half of the twentieth century. The national grid was not fully established until the second half of the century. Over time, the density of end user connections increased. Transport functions in the infrastructure were intensified (augmenting throughput and economy of scale), to serve a steadily increasing number of users and a steadily increasing demand per user. In the case of electric power, to improve the security of service, the national grid was interconnected across regions and national borders, most notably in Europe. At the moment, most national grids in Europe are interconnected and are operated as a single SoS. In the course of about one century the system's dimensions have grown by several orders of magnitude. Currently we are managing and crucially depend upon transcontinental networks for electricity transmission, oil, and gas pipelines, vastly distributed information and telecommunication infrastructures. It is fair to say that the distinguishing attribute of our society is this capacity to develop, operate, and control the risks of extensive infrastructures composed of many interconnected systems, each one run by different (mainly private) companies.

This evolution was not exempt of cross-links between politics, business, technologies and a variety of risks including financial, environmental, and political. The incorporation of new technologies, most notably the information and communications ones, enabled the expansion and networking of infrastructural systems and the improvement of their efficiency. While these infrastructures were becoming critical to society at large, policy-makers and business decision-makers realized that the assessment and management of risks was not just one more business function.

One point that still requires full recognition is the implication of the term "critical". In modern infrastructures it conveys the need to cope with new types of emerging risks. These risks are cross-organizational and international by nature: the interconnection of systems knows no borders but the risk management solutions proposed are basically a new edition of old models. This is still the case with solutions commonly offered by business continuity, civil defence, or emergency management institutions.

Some infrastructures such as energy, water supply, and telecommunications are so vital and ubiquitous that their incapacity or destruction would not only affect the security and social welfare of any nation, but would also cascade across borders. Critical infrastructures are exposed to multiple threats – such as terrorist attacks, natural disasters, or institutional changes, – and in addition their failure might induce risks to other interconnected systems. Consequently, there is an urgent need to address such problems with appropriate risk assessment and governance instruments, supported by timely policy analysis at an international level.

The main factors that have transformed the nature of infrastructures, that is, how these systems are designed, developed, deployed, and operated, are listed below:

- the liberalization of markets, mainly affecting the electric power and telecommunications fields which caused the previous monopolies to cede their position, unbundle their integrated business models, and compete with other players;

- the networking among infrastructures, that require each other for completing their functioning, generating an intertwined mesh of interdependent systems;
- the increase of cross-border interconnections, justified by the need to share capacity in case of major malfunctions, and also the mechanism for the integration of markets;
- the technological change brought about by the evolution of information and communication technologies (ICT) and their pervasive use for improving the functionality and control of technical systems, the interaction with the industrial and business sides of companies, and the relations among the actors in the supply chains;
- the advent of new systemic risks generated by complexity and nonlinear behavior of newly established SoS.

*The liberalization of markets* has diluted responsibilities with respect to potential shortcomings. Each operator of an infrastructural system licitly looks after its own business interests. The countermeasures implemented for countering the risks respond to their own judgment of costs and benefits, in the context of the rules and constraints defined by the authorities. Typically, infrastructural services are recognized as basic public services and for that reason they are subject to governmental regulation. Nevertheless, risks are still managed piecewise, without an overall consideration of the compound effectiveness of single risk management approaches.

*The interdependencies among infrastructures* makes it possible for system failures to originate from external systems. The normal way of dealing with risks is to consider systems with clearly defined interactions with their environment. But the complexity of interdependent infrastructures precludes the comprehensive knowledge of potential threats without a deeper understanding of the connected systems. The most that can be expected is the definition of service levels among the individual operators of the systems.

*The increase of cross-border interconnections* has made each nation's infrastructure dependent on the proper functioning of the ones in other countries. Some of these interconnections are part of long and complex international infrastructural corridors (e.g. energy, transport, telecommunications, etc.), that need to be consider in their entirety. Most of them will lose much of their functionality and usefulness if disconnected. In addition, this interaction means that each interconnected system is at the same time, a provider of services and a potential source of risk problems. These interconnections are not only structural and operational as they are further enmeshed in the links between markets, with operators making transactions in several of them.

The great *changes in ICT* have extended the channels connecting the systems, with most of them using open public networks. This fact augments the possibility of suffering malicious attacks. Open networks, now reachable worldwide and accessible by many users, involve many disciplines in the problem: legal and market issues, technologies, international relations, homeland, and national security.

*Systemic risks* are inevitable when implementing and operating these vast infrastructures. They originate not only from the composition of many technical installations, each one operated independently and following mainly its own autonomous rules, but also from the overlaying of several strata (technical, market, regulatory), each one split across several jurisdictional spaces.

There is no simple answer to the question of how to deal with these critical systems. The first consequence of this situation is the conjunction of subjects previously treated in a separate manner: industrial policies for the regulation and development of services and the companies offering them, civil defense and emergency management for dealing

with the negative consequences of potential accidents, law enforcement for coping with organized crime, national defense for responding to external threats and so on. In light of the nature and challenges posed by *critical infrastructures*, a convergence of these topics is required.

However, one question remains open: how should decisions about the risks in critical infrastructures be made? This goes beyond the realm of governments, as infrastructures are operated (almost exclusively) by private companies. But the accumulation of the risk management decisions by single companies will only rarely provide a proper answer to global risk situations. If the international dimension is added, the need for an apposite answer is indisputable. There is a new trend worldwide in addressing risks of complex systems, and this leads to the concept of *risk governance*.

## 2 EUROPEAN VIEW OF FUTURE CRITICAL INFRASTRUCTURE DEVELOPMENTS

At of the beginning of 2007, some policy developments in the European Union regarding Critical Infrastructure Protection (CIP) were vigorously initiated. Due to their intrinsic nature, many infrastructures show a cross-border character. Therefore, during 2005–2006 the concept of European Critical Infrastructure (ECI) has been elaborated, which materializes from an adopted directive [2] on the identification and designation of European critical infrastructures and the assessment of the need to improve their protection. It is worth noting that, although recognizing the nation-state's precedence when dealing with this subject and the privileged link between infrastructure operators and national governments, it has been accepted that certain transnational coordination is required for coping with the ECI risk. The European Union has established a European Programme for Critical Infrastructure Protection (EPCIP), under which several sector-specific programs are being implemented (e.g. information, transport, energy, etc). In addition, the CIP (Critical Infrastructure Protection) subject is also considered a priority within the European Commission's R&D 7th Framework Programme, 2007–2013.

CIP has duly been treated as a national issue within the European Union. Nevertheless, several factors have made it evident that there is a need for joint action:

- several infrastructures are composed of networks that cross borders;
- the potential widespread effects of some situations deriving from different threats (e.g. natural causes and malicious attacks);
- the potential benefits from joint investments in the development of solutions.

The European Council requested the Commission in June 2004, to prepare a comprehensive strategy aiming at the protection of critical infrastructures [3]. The Commission reacted with a communication entitled "Critical Infrastructure Protection in the Fight against Terrorism" [4] presented on October 20, 2004. There, the Commission discussed concrete proposals for improving the state of European prevention, preparedness, and response to potential terrorist attacks involving critical infrastructures [3–9].

This initial focus on terrorist attacks was then widened to all kinds of potentially malicious attacks, and ultimately to a so-called *all hazards approach*. The reason for this was the understanding that the management of risks to infrastructures should, in the end, be calibrated according to all sources of danger.

It is clear that in most, if not all sectors, there are consolidated legal frameworks for countering safety risk (caused for instance, by natural hazards, technical failures or human errors). The security dimension somewhat overlaps with these safety situations when considering the possible consequences of some events. However there are obvious dissimilarities in their causes, and therefore in the required countermeasures. The difficult task in an all-hazards approach is to provide a comprehensive stance on risk, without unnecessarily disturbing other existing industrial requirements and obligations.

In December 2004 the European Council approved the Commission's proposal for setting up a *European Programme for Critical Infrastructure Protection* (EPCIP) and a *Critical Infrastructure Warning Information Network* (CIWIN) [3]. In 2005, the Commission, led by EC Directorate General Justice, Freedom and Security (DG JLS), worked on the elaboration of EPCIP, organized two European seminars on critical infrastructure protection and a number of informal meetings together with experts from all EU member states. As a result of this process, the Commission adopted the Green Paper on a European Programme for Critical Infrastructure Protection [6] in November 2005.

This Green Paper not only put forward the definition of the principles that should guide European actions in the field, concrete proposals for the EPCIP framework, and the links between national and European critical infrastructures to the countries and society at large, but also anticipated the arrangement of funding sources for activities related to EPCIP which could include relevant studies and the development of specific methodologies.

The Green Paper was then complemented by a detailed impact assessment. A policy package on EPCIP composed of a communication and a directive was adopted by the Commission in December 2006 [8]. The communication contains nonbinding measures designed to facilitate the implementation of EPCIP, and includes an EPCIP Action Plan. It discusses the general policy framework of EPCIP (including CIWIN, the work-streams to develop the programme, sectoral interdependencies, annual work planning, and the residual work on National Critical Infrastructure), and the directive defines the approach for the designation of critical infrastructure of a European dimension (that is, ECI).

In parallel to this development, other Directorate Generals of the Commission began working on policies for the protection of the infrastructures under their remit. While EPCIP is intended to provide an overall framework for action, the specific discussions on policy measures and on how to coordinate the protection are done on a sector-by-sector basis.

DG Energy and Transport (TREN) worked with national authorities and regulators, infrastructure operators and experts, in the definition of an approach for the infrastructures in its field of reference. This resulted in the adoption of the "Communication on Protecting Europe's Critical Energy and Transport Infrastructure" in February 2007 [9]. This is the first sector-level initiative in the framework of the EPCIP programme.

The main content of the communication—which due to the sensitivity of some of the subjects discussed has been defined as restricted, meaning that it is not available to the general public—is composed of criteria for the identification of ECI in each energy and transport sector. The communication does not contain any proposals for legislative measures, but legislation remains one of the options for subsequent work.

In 2006, the EC Directorate General Information Society and Media (DG INFSO), presented a proposal of a structured process of consultation and dialogue on network and information security to be established with relevant stakeholders, including public administrations, the private sector, and individual users. The Commission adopted the

communication "Dialogue, partnership and empowerment" in 31 May 2006, creating a strategy for a Secure Information Society [7].

This strategy is partially dedicated to aspects of the Critical Information Infrastructure (CII), and recognizes that both the public and the private sector have pivotal roles to play. It aims to provide a basis for responding to the major challenge faced by Europe in that field, namely:

- *raising awareness* on the security risks;
- establishing *a culture of security* in which security is seen as a business value and an opportunity rather than as a liability and an additional cost;
- fostering an appropriate framework of conditions for *interoperable*, *open*, *and diverse solutions* provided by a competitive, innovative European industry.

The strategy recognizes that there is an increased *connectivity between information and communication networks with other critical infrastructures* (like transport and energy). The proposal is to develop a sector-specific policy for the information and communications sector for examining via a multi-stakeholder dialogue and the relevant economic, business, and societal drivers with a view to enhancing the security and resilience of the information infrastructure.

Any review of the regulatory framework for electronic communications will have to consider elements to improve network and information security. These should include both technical and organizational measures by service providers, provisions dealing with the notification of security breaches, and specific remedies and penalties regarding breaches of obligations. But although legal norms might help in fostering the creation of markets for security products and services, it is obvious that those products and services will be born out of the interaction between the operators of critical infrastructures and the suppliers of technology.

On the other hand, national governments need to put into practice best practices and be secure from the information and network point of view. A key point here is the communication and sharing of information threats, risks, and alerts but the global dimension of network and information security cannot be ignored. Europe needs to take into account the international level when coordinating and promoting cooperation on network and information security (e.g. implementing the agenda adopted at the *World Summit on the Information Society*, WSIS in November 2005).

Finally, in December 2008, an agreement on the definition of ECI was reached. It has been defined as such critical infrastructure as located in member states of the European Union, the disruption or destruction of which would have a significant impact on at least two member states [2]. The identification of the ECI is the responsibility of each country, although the European Commission on a collaborative basis "draw the attention of the relevant Member States to the existence of potential critical infrastructures which may be deemed to satisfy the requirements for designation as an ECI" [2].

The EU Directive on Critical Infrastructures defined a first period of two years in which the EU countries are obliged to identify and designate critical infrastructures in the following sectors: energy (oil, gas, and electric power), and transport (including road transport, rail transport, air transport, inland waterways transport, ocean and short-sea shipping, and ports). The oil sector includes oil production, refining, treatment, storage, and transmission by pipelines. Similarly, the gas sector includes gas production, refining, treatment, storage, and transmission by pipelines, as well as liquefied natural gas (LNG)

terminals. The electricity sector includes infrastructures and facilities for generation and transmission.

The identification of ECI will be based on an assessment of the significance of the impact of their potential loss, evaluated according to the so-called "cross-cutting" criteria. This includes effects resulting from cross-sector dependencies on other types of infrastructure, and comprises of the following: (i) potential casualties; (ii) economic effects (significance of economic loss and/or degradation of products or services, including potential environmental effects); and (iii) public effects (impact on public confidence, physical suffering, and disruption of daily life including the loss of essential services).

In the field of CII, a new European policy initiative was presented [10] in early 2009. This initiative complements EPCIP since it deals with the ICT aspects. The initiative proposes actions that supplement other existing measures (e.g. judicial cooperation for dealing with cyber crime and terrorism targeting CIIs).

This policy is based on the recognition that, with due respect for national autonomy, there is an urgent need to integrate the collaboration of all interested stakeholders as CII is essentially international in nature. Five streams of action have been identified.

- *Preparedness and prevention.* This requires the collaboration of Computer Emergency Response Teams. It is proposed that a European Public-Private Partnership for Resilience and a European Forum of Member States be created, to share information and good policy, operational practices.
- *Detection and response.* It is recognized that the need for early warning mechanisms can result in the establishment of a European Information Sharing and Alert System. This should provide services to citizens and Small and Medium Enterprises (SMEs), taking advantage of national and private sector information systems.
- *Mitigation and recovery.* The setting up of national contingency plans will be encouraged along with the organization of regular exercises for large-scale networks security incident response and disaster recovery. This is seen as the basis for the need for pan-European coordination.
- *International and EU-wide cooperation.* This is required for agreeing on EU priorities for long-term goals (e.g. regarding the resilience and stability of the Internet), establishing common guidelines where needed, and promoting principles and guidelines at the global level.
- *Criteria for the ICT sector.* In the context of EPCIP, these criteria will support the EU countries in the identification and designation of ECI regarding the ICT sector.

## 3 EUROPEAN CRITICAL INFRASTRUCTURES: CHALLENGES AND PRINCIPLES

The European Programme on CIP aims to identify and characterize ECI and also to define a common framework for managing and governing risks. For this reason, a key element is the ability to determine which systems could be of relevance to more than one country, and then to establish how it would be possible to deal with those events in terms of prevention and reaction to hazards. This relationship between national and European approaches has to be flexible enough to take into account their complementarity. The respect for national jurisdiction has to be accompanied by the examination of potentially

harmonized approaches and similar levels of protection for infrastructures crossing borders or having a potential impact on other countries. In addition, any legal framework for enhancing security should be compatible with competition rules and internal market. This indicates the many prerequisites that should be considered by Europe while setting up EPCIP viz. national and local jurisdictions, sectoral industrial policies, fair competition, law enforcement requirements concerning malicious acts, civil protection and emergency management, and last but not the least, national security.

To meet all these objectives, the EPCIP proposal identified both binding and nonbinding measures to be adopted by the Member States. The nonbinding measures are indicative of good practices that are advisable: (i) participation in CIP expert groups at EU level, (ii) use of a CIP information-sharing process, (iii) identification and analysis of interdependencies, (iv) elaboration of national CIP programmes, and (v) identification of national critical infrastructure.

The EPCIP binding measures aim at fostering a harmonious collaboration among the different countries and infrastructure actors. The proposed ones are (i) nomination of CIP contact points, (ii) identification and designation of ECI, (iii) conducting threat and risk assessments for ECI, and (iv) elaboration of Operator Security Plans and the designation of Security Liaison Officers.

In addition, the proposal of the directive presents several principles that summarized the approach that the Commission proposes for the implementation of EPCIP. They are as follows:

- *Subsidiarity.* Efforts in the CIP field should focus on ECI, and not on the ones falling under national or regional jurisdiction.
- *Complementarity.* Efforts should not be duplicated, and should be developed where they have proven to be effective, complementing and building on existing sectoral measures.
- *Confidentiality.* CIP data is sensitive and should be classified in an appropriate way, with access granted only on a need-to-know basis
- *Stakeholder cooperation.* All relevant stakeholders should be involved: owners or operators of critical infrastructures, public authorities, and other relevant bodies.
- *Proportionality.* Only relevant measures should be proposed for satisfying specific needs, proportionate to the level of risk and type of threat involved.
- *Sector-by-sector approach.* A list of CIP will be agreed upon, and then concrete actions will be developed.

## 4 CRITICAL ELECTRICITY INFRASTRUCTURE: THE EVOLUTION OF THE RISK

Europe witnessed in the last few years a number of significant power contingencies. Some of them revealed the potentiality for a vast impact on the welfare of society, and triggered off pressing questions on the nature and reliability of electric power systems. Society has incorporated electricity as an intrinsic component, indispensable for achieving the expected level of quality of life. Therefore, any impingement on the continuity and properties of the electricity service would be able to distress society as a whole, affecting individuals, social and economic activities, other infrastructures, and essential government

functions [11]. It would be possible to hypothesize that in extreme situations this could even upset national security.

The blackouts and near-misses that happened in the last few years illustrate several notable lessons that have to be carefully taken into consideration:

- *There are hints of some inadequacy*. Heavy workloads and limited reserve generation capacities make systems vulnerable to widespread disruptions. Protection systems have been found to play a key role in the majority of catastrophic failures. Power systems have not been designed to cope with the concurrent outage of two or more critical components.
- *Incidents were aggravated by other factors*. These include the lack of timely comprehension by control-room operators of potentially far-reaching failures and short-term emergency requirements.
- *The recent liberalization of the European electricity market*. This has led to increased cross-border trade for which power systems were not originally designed.
- *European TSOs*. Transmission System Operators, which only recently have developed a more system-of-systems-wide monitoring capability, have no or limited influence on international power trading and the resulting power flows, and therefore confront more and more *unanticipated congestions* on the tie-lines.

During the last decade, Europe has developed a comprehensive energy supply policy unbundling the previous monopolies and opening the generation and distribution markets [12]. This policy has deeply changed the business and regulatory landscape of the electric power infrastructure. From the consumer point of view, the effects have been positive: there are more potential suppliers, and prices follow market rules.

The immediate economic effects of the new policy have not been accompanied by changes in the underpinning physical systems whose evolution demand at least medium-term investments and planning. For the time being, the power infrastructure has shown an appropriate reliability level, but new threats can be foreseen in the horizon. Some of these threats are internal to the infrastructure mainly due to the increasing complexity of many technical and market elements; some of them are external, for instance, the menace of terrorism.

Therefore the security of the evolving European electric power infrastructure deserves a cautious and thorough consideration. A comparative analysis of policy and regulation in Western Europe has been provided earlier in Midttun [13]. Electricity is a *common good*, central to the security and welfare of almost half a billion people, and the stability and future economic development of more than 30 countries. For this reason, although local contingencies can be tolerated up to a given degree, if the power system appears unreliable at the continental level, this will become a matter of major concern. Europe cannot afford systematic failures of its power infrastructure that could eventually lead to the weakening of the citizens' trust on societal institutions.

The various national European electricity systems, after the transformation experienced in the last few years, now form part of a unique and integrated *European Critical Electricity System-of-Systems* (ECESoS). This situation results from an evolution spanning decades and is determined by two main driving forces, namely, market liberalization at the continental scale, and the high degree of interconnection among regional systems [14]. This has been made possible by the pervasive incorporation of ICT.

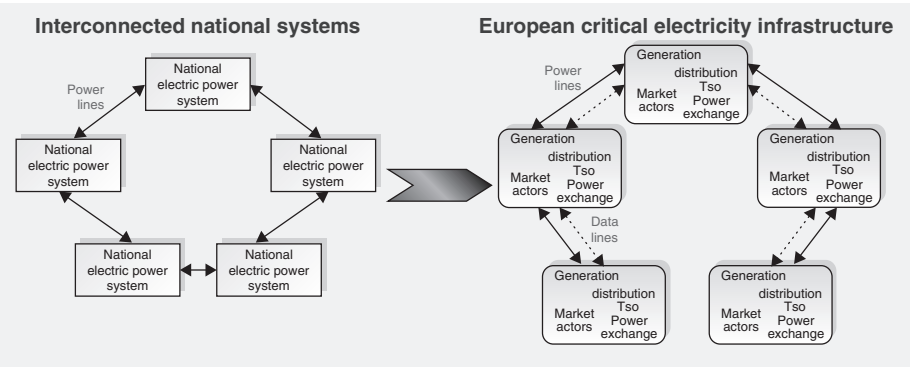

**FIGURE 1** The ECESoS concept.

This complex system is a socio-technical artifact, and tends to function as a single entity, although it includes several jurisdictions, operators, and markets. It is derived from the interconnection of national and regional systems, but at the same time it behaves as a single, *compound SoS*. It is decentralized; still, disturbances can propagate through all of it and risks have to be coped with in a coordinated way. The passage from a set of electricity systems to the ECESoS is not just a question of more elements or actors, it represents a qualitative leap. ECESoS, an infrastructural SoS, is intrinsically different from a set of weakly connected power systems where energy flows among different systems are marginal.

The materialization of ECESoS presents clear advantages, but also brings about vulnerabilities which may threaten its serviceability. The fact that these shortcomings exceed the providence of individual parties means that there is a need for new, effective instruments for managing risks.

Figure 1 outlines this evolution of national electricity power systems (EPS) being embedded into ECESoS. This paper outlines the implications of this development, and studies the positive and negative effects of the extensive interconnectedness and digitalization (i.e. the ubiquitous application of ICT).

## 5 TRENDS AND DRIVING FORCES

The *liberalization* of the European electricity sector has replaced centralized control by regional monopolies with a complex, decentralized market structure, in which many different agents control each part of a technically highly integrated ECESoS infrastructure. The distribution of the many functions in the electricity supply industry among numerous different actors and their coordination through national market mechanisms and grid codes has greatly increased the management complexity of the sector.

This *de facto* decentralized control can work appropriately in the long term only if all the different agents in the system experience the correct incentives and comply with compatible rules throughout the European infrastructure. Technical reliability, which used to be the goal for gauging the performance of electric power systems, is not enough for the ECESoS reality. Many other factors including environmental compatibility, market practicality, and national security have to be included in the decision-making process.

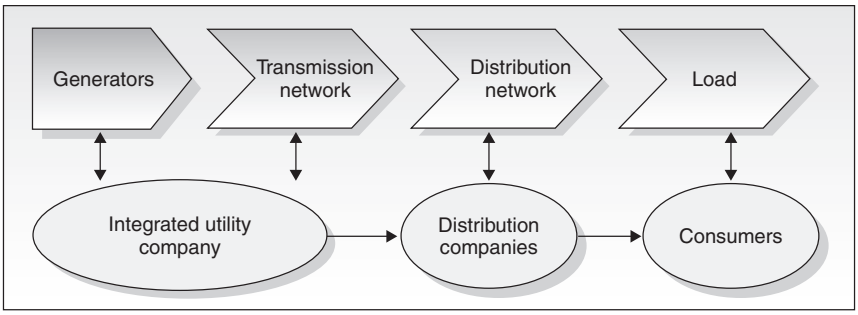

**FIGURE 2** The organizational structure of the electricity system before liberalization.

These factors can be structured in five ranked layers (where the upper one comprises the lower ones): security, sustainability, economic efficiency, reliability, and technical performance. *Security* can be used as the overarching concept that includes all the other objectives.

With respect to this notion of security, all stakeholders need to have a common understanding of the overall system goals and be willing to work toward them, both during normal operation and in case of contingencies. If not, the pursuit of their own private ends although legitimate, may be in conflict with public objectives such as availability and affordability. Whereas the regional monopolies of the past required only a relatively simple regulation of their performance and tariffs, the complex decentralized system that is the result of liberalization requires careful crafting of its institutional structure to ensure that the multiple, and sometimes conflicting, public goals are met (Fig. 2).

Figures 2 and 3 illustrate the organizational changes that liberalization has brought about. Figure 2 shows, schematically, the structure of a regional monopoly: nearly all functions are performed by the same agent, the electricity utility company. Often, distribution and end user supply were managed by separate companies but these were again regional monopolies. Figure 3 shows a simple model of a liberalized electricity system. The figure shows the different groups of actors who together control the physical system. In Europe, many of these electricity systems are interconnected with each other. The operation is coordinated in several regional blocks (e.g. UCTE or the Union for the Coordination of Transmission of Electricity, Nordel, UK), whose composition leads to ECESoS.

A second trend, which already existed prior to liberalization but was further stimulated by it, is the *internationalization* (i.e. interconnection among national grids) of the electricity system. The operation of the vast European power network is complicated by the many different jurisdictions that exist. At a technical level, the TSOs cooperate with each other. At the economic level, large differences continue to exist between the markets in different countries. In order to create an internationally level playing field, the economic conditions such as *transmission tariffs* and *network access rules* in different countries should be put into synergy. In practice, however, different countries liberalize with different speeds and implement different models, not always considering the global consequences of local measures. In addition, the changes in environmental standards, taxes, and subsidies should also be considered.

The complexity that results from the combination of the liberalization and the internationalization of the ECESoS poses a threat to the reliability of electricity services.

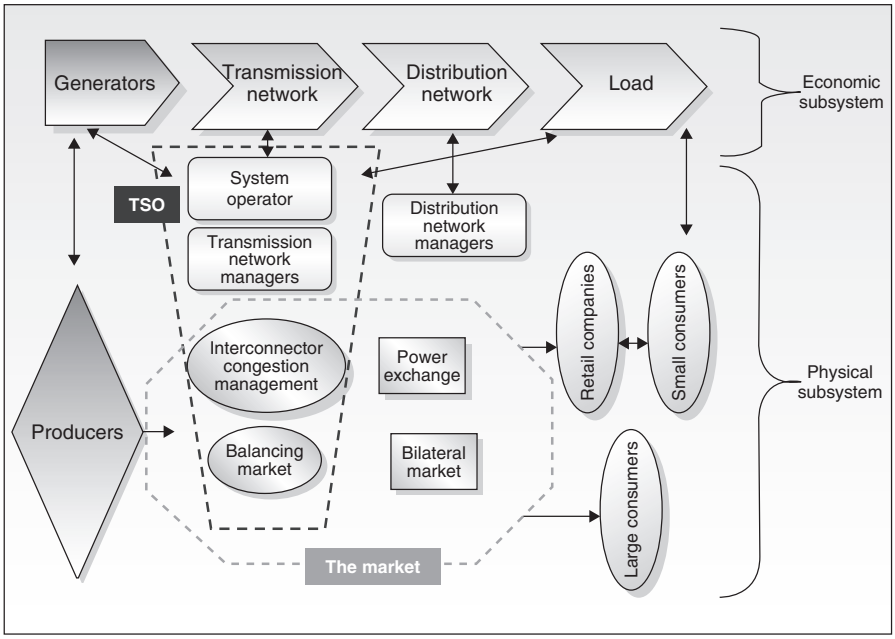

**FIGURE 3** The organizational structure of a liberalized electricity system (decentralized model).

A clear case is given by the difficulties faced in the coordination of the responses to contingencies spread over a wide area. The multitude of industrial actors and the many countries involved also complicate the achievement of a balanced development of the system in the long-term, which in turn may give rise to more contingencies.

The liberalization and the internationalization of the power systems and the facilitation of international trading, has also resulted in the adjustment of the association and cooperation among the operators of the power infrastructure. Partly as recognition of the continental reach of the power infrastructure, and partly due to the European policy initiatives toward the integration of cross-border collaboration, on 19 December 2008, 42 European TSOs from 34 European countries created a new association: the European Network of Transmission System Operators for Electricity (ENTSO-E). The declared objective is to contribute to the reliable and efficient management of pan-European and regional markets.

A third trend, which we will call *evolutionary unsuitability*, is caused by the fact that electricity transmission networks are increasingly being used in ways for which they were not initially designed. Electricity systems are not just operated under high stress conditions, but also beyond the limits of their original design. The increasing development of wind power is already leading to stability problems in certain areas. The changes in the electric output of wind parks led to fast and significant changes in the way the electricity network is used but the network was not designed for such rapid operational changes. Distributed generation, which means the generation of electricity (and often also heat) in small units close to consumers, may also change the way the networks are used. Whereas large scale wind energy mainly impacts the transmission networks, distributed generation would change the nature of distribution networks. This trend is unavoidable in an ECESoS scenario. It is impossible to foresee the many uses that the infrastructure

will be subjected to. This will require a new approach to the engineering, deployment, and operation of the infrastructure including several non-engineering aspects. It is a "Science and Art" issue that requires continuous collective learning in the production and management of complex systems.

A fourth significant trend is the wide-scale application of ICT in electricity systems from the level of individual switches up to the operational control of entire electricity networks, and from customer databases to automated spot markets. While the use of ICT provides many opportunities, the large increase in connected devices and information flows also increases the vulnerability of the ECESoS to both, failures of the information infrastructure and deliberate harm through the use of it. Therefore there is a double effect: on the one hand there is an increase in the functional capabilities due to the availability of information; but on the other there is a greater exposure of the system to cyber threats. All stakeholders have access, in one way or another, to the information components of the infrastructure therefore it is more difficult to prevent access to illegitimate intruders (Table 1).

This amalgamation of electric power systems and ICT produces a new construct, "Electricity plus Information" (or ***E+I***). The ECESoS is connatural to this E+I paradigm; it is immersed into a reality where all electricity functions (i.e. production, trading, transmission, distribution, billing, customer interaction, etc.) are dependent on information. Electricity (the physical dimension of the infrastructural services) coexists with data (the digital dimension of the same infrastructural services). The first dimension is composed of tangible assets: generators, transmission lines, transformers, control and protection equipment, etc that are the traditional objects for the valuation of the power business. The second dimension corresponds to intangibles: knowledge, transaction relationships, customer information, contracts, consumption profiles, security culture, etc. Currently, the perceived value of intangibles is overtaking that of tangibles. This happens in a continuous process that transforms the electric power infrastructure, driving the formation and establishment of the E+I paradigm (Fig. 4).

E+I is an ongoing process, with the power industry continuously incorporating ICT for the sake of improving the operations, functions, and protection of the power systems, as well as integrating engineering and business functions for linking with other technical and market operators. We can talk of the digitization of the power infrastructure. And looking into the future, we can only predict a more intense use of ICT, driven by the shift toward smart grids, distributed generation, diversity of energy sources, and further integration of the infrastructure with neighboring regions (e.g. North Africa, Russia, and Middle East).

When assessing security, this E+I reality cannot be ignored. This affects which vulnerabilities and threats have to be taken into consideration, which measures can be taken for solving the problems, and also how the governance of risk can be implemented. The wealth of information and the easy access to data sources, have to be factored in when designing the risk governance process [4].

## 6 THREATS AND VULNERABILITIES

The transformation of the electric power infrastructure driven by those trends indubitably bears favorable effects (e.g. diminishing prices for consumers, more competitive markets inducing innovative behaviors, alternative sources of electric power supply), but it might

**TABLE 1 Sequence of Events: Italian Blackout**

Importance of Risk Awareness and Crisis Management: the Italian Blackout (A Short Description)
Sequence of Events (September 28, 2003)

- 3:00 Italy imports 6.9 GW, 25% of the country's total load, 300 MW more than scheduled
- 3:01 Trip of the 380-kV line Mettlen–Lavorgo caused by tree flash-over (no adequate tree cutting); overload of the adjacent 380-kV line Sils-Soazza
- 3:11 ETRANS (CH) informs GRTN (I): Request by phone to reduce the import by 300 MW (not enough), GRTN responded within 10 min
- 3:25 Trip of the Sils–Soazza line due to tree flash-over (at 110% of its nominal capacity) Italian grid loses its synchronism with the UCTE grid; almost simultaneous tripping of all the remaining connecting lines
- 3:27 Breakdown of the Italian system, which was not able to operate separately
- 21:40 Restoration of the Italian system complete

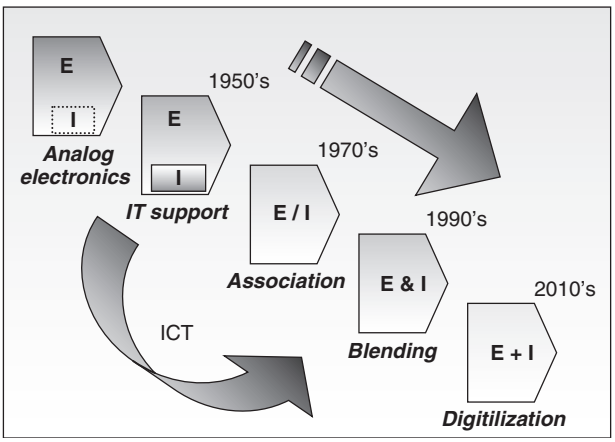

**FIGURE 4** The evolution of the E + I paradigm.

also generate negative conditions for the overall security of the infrastructure. These situations that are prone to risks are related to many facets of the infrastructure such as the organization of the power market, the regulation of the interconnections to the power grid, its topology, and the technological solutions applied. In addition, it is necessary to consider the perception and reaction of society to those risks.

The liberalization of power markets has fragmented investment decisions upon many industrial players (mainly on the generation side). The relatively long time required for developing new installations causes uncertainties about whether the combination of individual decisions will guarantee the security and adequacy of the infrastructure.

This situation can be complicated by the dependence of investments on environmental considerations, fuel prices, and fuel availability. A key fact is that the growth of transmission capacity, and in some places of generation, falls very far behind the growth in consumption. The main constraint on the creation of new power lines and generation plants is the difficulty in obtaining the necessary permits, mainly related to environmental considerations while the fuel aspects are obviously determined by geopolitical circumstances. Markets entail the danger that all new power plants will make use of the same cheapest (available) fuel and the transition to liberalized markets has brought additional uncertainties provoked by changes in the regulatory frameworks.

The central question is whether competitive markets, even in a stable phase after liberalization, provide adequate and timely investment incentives. The new regulation of power systems in Europe has a strong focus on costs. Nevertheless, it is not clear if the reduction of costs can be balanced with the need to maintain security and expand the power grid in a timely and economically efficient manner.

A key point is that different European countries have liberalized with different speeds and implemented different market models. This creates a significant risk of market distortions, which is further aggravated by the complexity of the institutional design.

Electricity generation has observed the development of power based on renewables. These are placed where the resources are available, not where the consumption exists. As a result, power transmission networks and international interconnectors are used in ways for which they were not designed, and their control and protection systems are put under stress.

These changes in power markets and in power generation and transmission are accompanied by a pervasive use of ICT. This has had a beneficial effect on the operation of power systems, and the integration of the industrial and business information systems within and between companies. But it has opened up opportunities for new types of system failures, both of accidental and malicious origins.

First of all, information security was never a point for industrial systems, and therefore there is a lack of proper security-related standards and specific security technologies. Only in the very last years, with the awareness that interconnected information systems were open to electronic attacks, standardization bodies (e.g. IEC, IEEE, NERC) have begun to work on appropriate security norms. However, technologies change rapidly and the application of standards necessitates time. This opens a window of opportunity for this kind of newly emerging risks.

The power grid is exposed to accidental failures and natural hazards similar to the ones endured in the past. The question is whether the new structure with multiple operators is as *resilient* as the more centralized one in the past. The complexity of the European power network topology creates the possibility of failures that escalate from local problems to broad disturbances, and that propagate throughout the system potentially leading to cascading blackouts across international borders. This requires well-orchestrated protection, and the coordination of restoring services in case of widespread contingencies. As a matter of fact, many of the existing control and protection strategies and contingency defence plans are outdated because they were developed at a time when international flows were smaller, generation was dispatched by the system operator, and the use of ICT was much more limited.

Much attention is currently given to the risk of terrorist attacks. The likelihood is difficult to estimate, but it would require a sophisticated, well-coordinated attack to bring a large part of the European power system down. Failure of individual power plants or

power lines is a contingency that the system is designed to withstand, but a complete assessment, considering the interdependencies with other infrastructures, has not been performed yet.

## 7 NEEDS: RISK GOVERNANCE, SCIENCE AND TECHNOLOGY

The European electric power industry has been evolving rapidly in the last decade. The Electricity Directive 96/92/EC adopted in 1996 set common rules for the EU internal electricity market. It established the basis for the opening of the national markets, for the unbundling of the vertically integrated electricity companies, and in general for the organization of the generation, transmission, and distribution business.

As a means for establishing communication between the stakeholders, electric power systems, and the policy decision-makers, a forum was organized to discuss the regulatory process and the formation of the European internal electricity market. It was set up and organized by the European Commission. The first meeting was held in 1988, and it is commonly known as the Florence Forum. Its objective is to provide a neutral and informal framework for discussions concerning the implementation of the Electricity Directives.

The normative context was complete in 2003 with the new Electricity Directive n. 54 [15], complemented by the Regulation 1228 on cross-border trade [16]. This directive aims at establishing (at the latest by July 2007), an open European market for electricity where consumers will be free to shop around across borders. At the same time, a set of regulators have been instituted in all countries for ensuring the correct operation of the market and the regularity of the public services of the electricity supply.

The fundamental issue of this policy initiative has been the institution of the European internal market for electricity, and it is possible to say that up to now it has been successful and beneficial for the European citizen. Nevertheless, risk and security (in the broad sense employed in this White Book) have not been considered main concerns. Security of supply is mentioned as one of the public service attributes to be guaranteed [17]. Specifically it is said that the goal is to achieve a "competitive, secure, and environmentally sustainable market in electricity" (Article 3) [17]. Some issues mentioned in the directive are market mechanisms for ensuring sufficient electricity generation, long-term planning, the need to monitor the balance between supply and demand, and topics left to the responsibility of each country. But no provision has been made for coping with the systemic risks that affect the European infrastructure as a whole.

Therefore it is possible to discern a mismatch between the policy goal of developing a secure market, and the lack of dedicated mechanisms for dealing with risks that might rise beyond the control of the single power company and the single country. Would current instruments be effective for dealing with systemic risks affecting the infrastructure? The only group that brings together all stakeholders (industry, regulators, policy decision-makers, consumers) is the Florence Forum. Could it be used to take care of the infrastructure risks? The answer is negative, considering its current structure and working style. It is not a decision-oriented organization, and it is oriented toward informal debates.

However, on the other hand, traditional methods of risk management (applied for instance by electric power companies) do not suffice for coping with the new challenges faced by the electricity infrastructure in its entirety. This paper analyzes these changes and proposes a new way for society to handle them: *risk governance*. On a parallel line

of work, in relation to CII (), one can consult "Policymaking for Critical Infrastructure. A Case Study on Strategic Interventions in Public Safety Telecommunications", by Gow [18].

While the regional monopolies of the past were well-equipped to handle most challenges to the system, individually or in cooperation with each other, the scale and geographical scope of the potential security risks requires decision-making at many different levels: by international bodies such as the EU and associations of TSOs, at the national level by governments and regulators, at the company level by generation companies, network companies, system operators etc., and finally, perhaps also by the end users themselves. As both the causes of the risks and the possible strategies for handling them often involve many different parties, this paper proposes an approach of risk governance to arrive at joint solutions amongst all the involved stakeholders in addition to the management of risks by individual parties.

The need for a new approach is partly due to the nature of the new risks, which range from terrorism and cyber attacks to international cascading blackouts, and partly due to the transformation of the national electricity systems into a continental infrastructure. In addition, the changing nature of the European electricity markets creates new vulnerabilities that need to be addressed. Liberalization has distributed control over the system among many more parties than used to be the case before, whereas the response to a contingency requires fast, coordinated actions. The increasing internationalization of the sector poses an additional challenge to contingency management across borders. In the near future, the European electricity infrastructure will be interconnected with North Africa, the Middle East, the whole Balkans, and substantial parts of Eastern Europe and Central Asia (from Lisbon to Vladivostok, and from the Arctic Circle to the Maghreb). Not the least, the ubiquitous application of ICT in every part of the sector creates many new opportunities but also incorporates new vulnerabilities.

Past methods of managing risk in the electricity industry are no longer adequate in the realities of the current ECESoS scenario. This is partly due to the emergence of new risks and also due to the restructuring of the electricity industry. In the past, utility companies with a regional monopoly could be held responsible for virtually every aspect of the delivery of electricity. Electric utilities managed technical risks as well as environmental and health risks, and it was common practice to apply cost-benefit analysis in order to fulfill primarily the shareholders concerns. This can have trans-European impacts.

The consequence of the current decentralized nature of liberalized electricity systems, is that individual actors cannot be held responsible for the way the system as a whole functions. This means that, more than in the past, issues such as reliability and resilience need to be addressed at the level of the whole system. This requires a new approach, which is *risk governance*, in addition to the risk management actions which were, and still need to be performed by the individual power companies. Risk governance admits the existence of multiple stakeholders, with their individual interests and viewpoints, in parallel with overall objectives (related to society as a whole). The decision-making process in general, and specifically that which is related to risks, has to take into consideration all these aspects. The diversity of objectives and actors has to be structured as a multi-criteria problem.

In a liberalized system, all these parties need to work together with each other, as well as with parties who do not directly influence the physical system such as traders, brokers, power exchanges, and retail companies. Through the risk governance process, the different affected actors (should) cooperate to handle risks that exceed the boundaries of

their own risk management processes. Risks that are (or should be) the subject of the risk governance processes are either risks that involve multiple actors or risks that originate outside the control of the involved actors.

Which issues should be dealt with through the risk governance process and which ones through the risk management process? If the solution is within the risk management loop, there is no need for governance of the issue. However, if the solution is beyond the powers of the actor who is affected, there is a need for risk governance.

## 8 CONCLUDING REMARKS: INTERDISCIPLINARY AND INTERNATIONAL DIMENSIONS

In the following we would like to summarize the main inferences drawn from the preceding discussions:

- European society is witnessing the advent of ECESoS, a new kind of human construct of great technical and organizational complexity, which—for technical and political reasons—is managed on a piecemeal basis by tens of entities. It is subject to risks that are critical for society. Those risks are of a very varied nature, and have to be counteracted with a proper approach which will inevitably be based on parallel assessments and decisions by many actors.
- The ECESoS is evolving into an "Electricity plus Information" (E+I) infrastructure. The operation of the power systems, the functioning of the markets, the links between industry, regulators, and users all are information-based. The efficiency of the system, the management of the security, the adequacy, and the market all are E+I matters. So, the electric service is now an E+I compound product.
- The new risk landscape faced by ECESoS can be deconstructed into three layers:
  - *Technical layer.* Risks are caused by technical deficiencies (including failure of components, human errors, and engineering flaws). Solutions are mainly technical in nature (e.g. strict application of information and communication security measures, proper training of operators, review of protection mechanisms). Some problems can be addressed by single actors, or by the joint effort of a limited group of them.
  - *System layer.* Risks are caused by the interaction of several technical, organizational and market factors, with effects that are not always predictable (e.g. the discrepancy between electricity flows demanded by the market, and the available capacity of transmission lines). Solutions have to unavoidably combine different aspects (e.g. technical, financial) and actors, at times crossing national boundaries.
  - *Societal layer.* Risks have a society-wide resonance, potentially affecting the proper performance of a whole community, its security and survivability. Due to the interconnectedness of ECESoS, these situations are transboundary by nature. Solutions have to address the infrastructure as a whole. This complexity calls for a European approach to risk governance.
- Most importantly, the central focus of the debate should consider the assessment and management processes related to the risk affecting the ECESoS as a whole:
  - ECESoS's emerging risks that are of relevance across Europe, have to be governed by means of a decision-making process tailored to its specific needs and

requirements. Key features to be considered are the multiplicity of stakeholders, the emergent security attributes of the infrastructure, and the dynamic nature of the system.

- In order to be successful, the *risk governance* of ECESoS needs to take into account all risk factors and all threats that cannot be dealt with adequately by individual actors' risk management processes. Risk governance should treat them in a comprehensive and systematic way: for example, bearing in mind power system dynamics, market incentives, ICT, and potential malicious attacks.
- Risk governance implies the *involvement of all stakeholders*, and clear rules for the deliberation and development of decisions. In Europe, due to the international nature of the problem, this situation will require the participation of national authorities, all businesses associated with the electric power infrastructure, international organizations, the European Union, and not least the end users.
- Risk governance is a new discipline, and more research is urgently needed to develop it. However, this should not discourage the application of current solutions to pressing problems such as those presented by ECESoS, because other alternatives are clearly less adequate.
- Risk governance needs to be *supported by proper tools*. The deployment of a risk governance process for the electric power infrastructure will require the utilization of advanced instruments (most likely based on digital platforms). These instruments should provide capabilities such as risk-related modeling, simulation, assessment, strategic gaming, metrics and visualization.

Implementing such a risk governance process for the ECESoS will require appropriate institutional settings. If nobody will be in charge of the problem, this can lead to two possible alternatives:

(a) the modification of the mission statements of current organizations of the power sector in Europe;
(b) the institution of a new organization with the specific purpose of governing the risks of ECESoS.

In the first case, the many political and industrial actors concerned with the problem will have to reflect upon the convenience of modifying the status of entities created for other purposes. In the case of similar initiatives in the USA, the certification of the North American Electric Reliability Corporation as the "Electric Reliability Organisation" with the power of U.S. Energy Policty Act [19] followed the long-term involvement of that organization with the security and adequacy of the power infrastructure. Europe does not have such an existing entity. Without trying to mimic that approach, there are some lessons worth considering: the potential effectiveness of self-regulation with a direct involvement of the operators of the power system, and the convenience in developing standards and guidance for security and reliability as a means for disseminating awareness and good practices, and promoting a common reference baseline.

The second line, that is creating a new entity for the governance of risks in the ECESoS, will require new legislative instruments. We can foresee that this road will not be straightforward–and we recognize that it is not considered a priority under the current political conditions. The focus of the attention is justifiably set on issues such

as emissions, renewable sources, and the consolidation of ownership, unbundling of the power infrastructure and the electric power markets. After the Third Energy Package issued in September 2007, no new initiatives are expected in the next few years unless a major event, as a significant blackout, proves the insufficiency of the current approaches.

With risk governance of the power infrastructure in Europe remaining an open issue, many questions still await satisfactory answers:

- Will the sum of the individual risk management measures by each operator of the ECESoS suffice to assure the reliability and security of the whole infrastructure?
- Is there a need for common standards? And in that case, is there a need for monitoring and enforcing compliance? Compliance can be guaranteed by a set of different mechanisms: peer pressure, penalties, economic incentives, etc. The verification of capabilities can be linked to certification, auditing, and other qualification procedures. Who will decide this?
- While facing systemic risks, which are the appropriate joint capabilities and how can they be developed?

A typical attribute of risk is that it is made fully apparent only with the occurrence of detrimental events which could even degenerate into disasters with catastrophic consequences. Then not only is it too late for any risk management action, but infrastructure and society might suffer serious negative consequences for years. In this respect, Europe still needs to develop a comprehensive strategy.

# VULNERABILITY ASSESSMENT METHODOLOGIES FOR INTERDEPENDENT SYSTEMS

WADE R. TOWNSEND

*U.S. Department of Homeland Security, Washington, D.C.*

## 1 INTRODUCTION

The importance of infrastructure interdependencies was first highlighted at the national level by the President's Commission on Critical Infrastructure Protection (PCCIP) [1, 2].

The energy sector (both industry and government) was proactive in recognizing the need to include interdependencies into vulnerability assessments and infrastructure analyses. The National Petroleum Council report, *Securing Oil and Natural Gas Infrastructures in The New Economy*, identified the need to include interdependencies considerations in all aspects [3]. The new business model (e.g. globalization, increasing reliance on other infrastructures) is complex and requires a broad perspective to include interdependencies analyses. The level of dependency among all critical infrastructures continues to rise due to increasing reliance on one another (e.g. information technology, telecommunications, and electric power).

An example of increasing dependencies and interdependencies is the Northeast Blackout in 2003. Even though this event began in the electric sector, other infrastructures were quickly impacted. Cleveland, OH, and Detroit, MI, lost pressure in their water systems and had to issue boil water advisories. Both cities rely on electric power to operate their pumps and had inadequate backup power available to continue pump operations, and thus, could not maintain pressure in their water systems. The 2003 power outage also affected the telecommunications network. Although the telephone systems remained operational in most areas, the increased demand caused some switches to reach their capacity, resulting in some blocked calls. Cell phone users also experienced service disruptions because cellular towers generally have only battery banks with limited battery backup. Many other infrastructures, such as wastewater treatment, transportation systems, gasoline distribution including pumps, and heating, ventilation, and air-conditioning (HVAC), and fire suppression systems were also impacted.

Widespread infrastructure disruptions stress the need to look at entire systems and not just individual facilities when conducting vulnerability assessments. Many infrastructures are designed with operational redundancies so the overall system can withstand the loss of any one asset, but when multiple assets are taken offline, an entire infrastructure service can be disrupted. Hurricanes Katrina and Rita crippled several infrastructures with cascading effects to other regions throughout the country. Natural gas prices throughout the nation were impacted by these hurricanes. Even telecommunications networks hundreds of miles away from the impact areas were affected by the storms.

In 1988, in response to the PCCIP findings along with the increasing concerns about vulnerabilities from interdependencies, Department of Energy (DOE), coordinating with industry, developed the Vulnerability and Risk Analysis Program (VRAP). VRAP included the development and implementation of a vulnerability assessment methodology for the energy sector that included interdependencies. Interdependencies considerations are crucial to risk analysis in providing a holistic perspective. Teams of national laboratory experts, led by Argonne National Laboratory and working in partnership with the energy industry, successfully applied the methodology to help organizations in the energy sector to identify and understand the threats and vulnerabilities (physical, cyber, and interdependencies) of their infrastructures. Approximately 75 vulnerability assessments were conducted by DOE from 1997 to 2002. Lessons learned from these assessments, as well as best practice approaches to mitigate vulnerabilities, were documented. Several reports were developed and shared with industry to promote risk analysis. These documents include the following.

- *Vulnerability Assessment and Survey Program: Overview of Assessment Methodology* [4],

- *Energy Infrastructure Risk Management Checklists for Small and Medium Sized Energy Facilities* [5],
- *Vulnerability Assessment Methodology: Electric Power Infrastructure* [6],
- *Energy Infrastructure Vulnerability Survey Checklists Template* [7], and
- *Vulnerability and Risk Analysis Program: Lessons Learned and Best Practices* [8].

Some of the lessons learned from these initial vulnerability assessments in regards to interdependencies are provided below.

- Interdependencies among infrastructures must be thoroughly investigated because they can create subtle interactions and feedback mechanisms that often lead to unintended behaviors and consequences. Problems in one infrastructure can cascade to other infrastructures.
- Interdependencies increase the complexity of infrastructures and introduce additional vulnerabilities.
- Interdependencies among infrastructures vary significantly in scale and complexity, and they also typically involve many system components. The process of identifying and analyzing these linkages requires a detailed understanding of how the components of each infrastructure and their associated functions or activities depend on, or are supported by, each of the other infrastructures.
- Contingency and response plans need to be evaluated from an infrastructure interdependencies perspective, and coordination with other infrastructure providers needs to be enhanced.

In March 2003, with the stand up of Department of Homeland Security (DHS), the DOE VRAP was absorbed by DHS/IP, and the core vulnerability assessment methodology (including interdependencies) became the foundation for DHS/IP risk analysis. DHS/IP conducted a survey of existing vulnerability assessment methodologies to identify element areas including interdependencies. This report, *Survey of Vulnerability Assessment Methodologies*, noted that the interdependencies element area was not considered in most existing government and industrial methodologies [9].

The DHS/IP Site Assistance Visit Program and Buffer Zone Protection Program's methodologies leveraged the DOE efforts and included the interdependencies element [10, 11]. Other DHS program methodologies (e.g. Risk Analysis and Management for Critical Asset Protection and Comprehensive Reviews) incorporated and refined the interdependencies element area. For example, Comprehensive Reviews include dependencies between critical facilities within a community with first responders and emergency management entities. GIS technologies bolster the DHS program methodologies and assist assessment teams in identifying infrastructure dependencies and interdependencies (e.g. single point failures and common corridors) [12].

## 2 PETROLEUM REFINERY INTERDEPENDENCIES

In early 2003, a joint industry/government working group was formed to develop a vulnerability assessment methodology for the oil infrastructure that focused on petroleum refineries and included physical and cyber security along with interdependencies. At the time, several oil industry firms were using the Center for Chemical Process Safety

(CCPS), *Guidelines for Analyzing and Managing the Security Vulnerabilities of Fixed Chemical Sites* [13]. Although no universal methodology was adopted, the CCPS was the most common since petroleum refineries share similarities with chemical facilities. Also, many oil companies own both energy and chemical facility assets. The CCPS methodology provided a sound foundation for physical security. The DOE/DHS interdependencies element area was leveraged and integrated into the CCPS methodology, resulting in a customized methodology for the oil infrastructure that was adopted by the American Petroleum Institute (API) and the National Petrochemical & Refiners Association (NPRA) [14].

The petroleum refinery methodology includes vulnerabilities from interdependencies including information technology, making the methodology more inclusive and comprehensive. While traditional assessments focused on on-site physical security (e.g. gates, guards, and guns), the API/NPRA methodology considers a facility's supporting infrastructure, supply chain, cyber infrastructure, operations security, as well as physical security. Thus, in order to examine vulnerabilities at a petroleum refinery, it is crucial to understand the inputs and outputs along with the various functions that take place. Figure 1 illustrates the systems' representation concept for interdependency analysis. It is important to map inputs and outputs (e.g. robustness and redundancy considerations) against key asset functions (e.g. criticality to operations). Within the assessment process, if an input is not critical to operations, then it is a lower priority.

Interdependency analysis also includes both upstream and downstream considerations. Figure 2 illustrates the petroleum fuel cycle. Petroleum refineries are a midstream function, or, part of the processing stage. For the entire petroleum infrastructure to operate, all stages of the fuel cycle, from production to distribution, must be functional. A disruption in any stage of the fuel cycle has the ability to ripple throughout the petroleum infrastructure and potentially cascade to other critical infrastructures. Petroleum refineries require oil production and gathering for sufficient crude oil (petroleum refinery inputs). Refineries typically maintain a limited supply of crude oil on-site, which can be quickly depleted

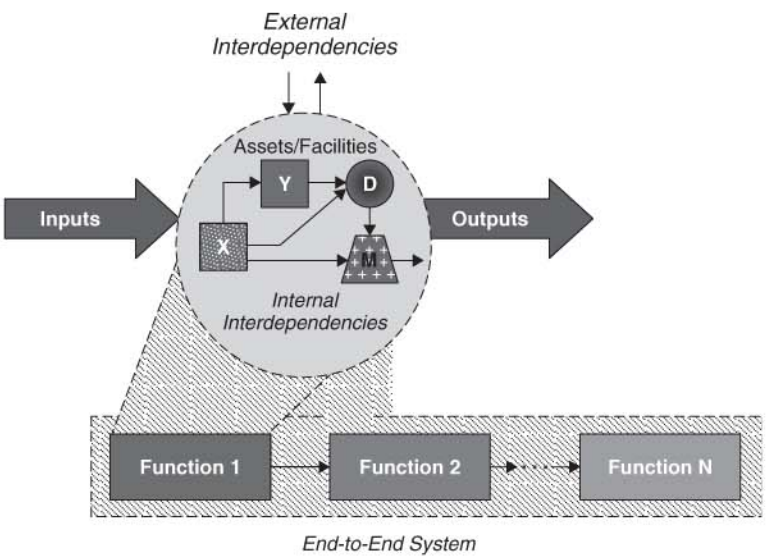

**FIGURE 1** Systems representation for interdependencies analysis.

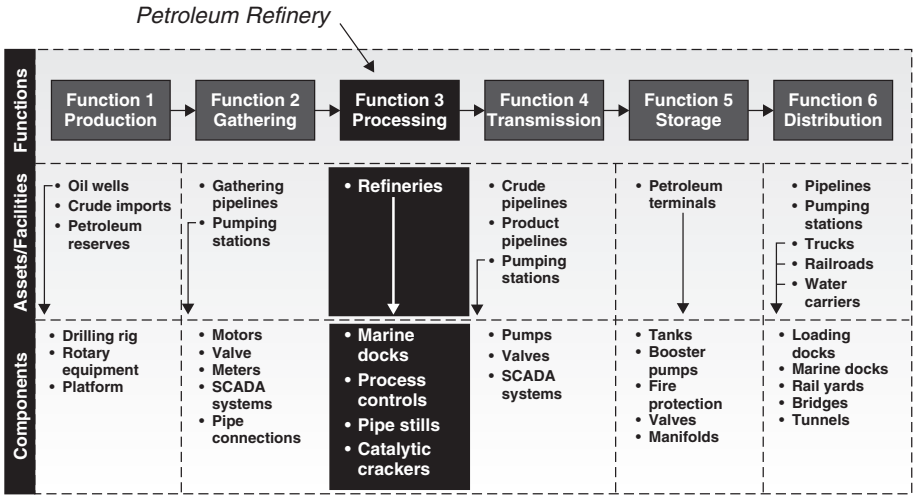

**FIGURE 2** Petroleum fuel cycle.

and result in a shutdown of the refining process if oil production and processing stages do not replenish the on-site supplies. The downstream petroleum refinery impacts are similar. If the transmission, storage, and distribution stages are nonfunctional, petroleum refineries may shut down.

Figures 1 and 2 illustrate the broader perspective that is taken through interdependencies analysis. Figure 3 provides a high-level view of petroleum refinery interdependencies to include suppliers and distributors. Petroleum refinery interdependencies include crude oil that can be deliverable by tanker, pipeline, barge, or rail; process chemicals (e.g. hydrogen, alkylation acids, and nitrogen); and other infrastructures (e.g. electric power, natural gas, water, telecommunications, and so on). All of these inputs are required to produce refined petroleum products (e.g. gasoline, heating oil, diesel, and so on) and

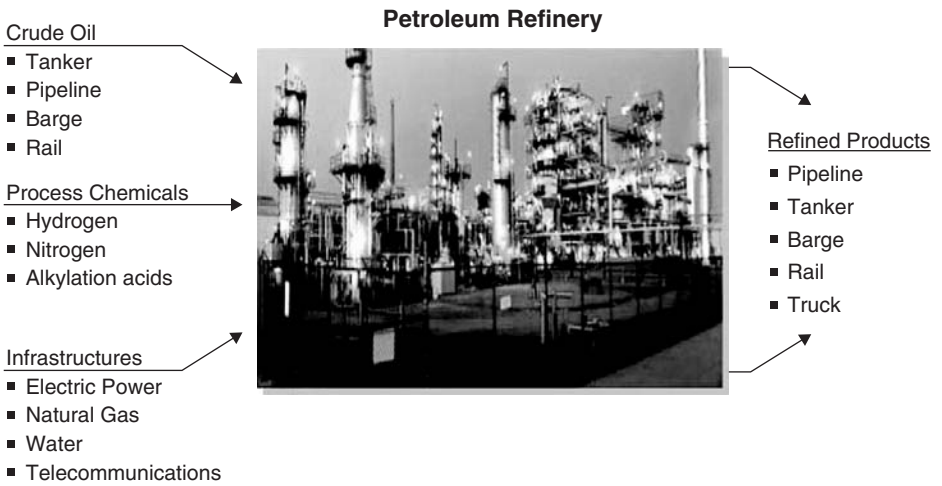

**FIGURE 3** Petroleum refinery macro illustration of interdependencies.

the resulting complex dependencies and interdependencies. Since petroleum refineries require many inputs and outputs and rely on multiple infrastructures, they provide an excellent representation of interdependency analysis.

Figures 4 and 5 further break down the petroleum refinery interdependencies model. Figure 4 identifies internal interdependencies (inside the petroleum refinery) and Figure 5

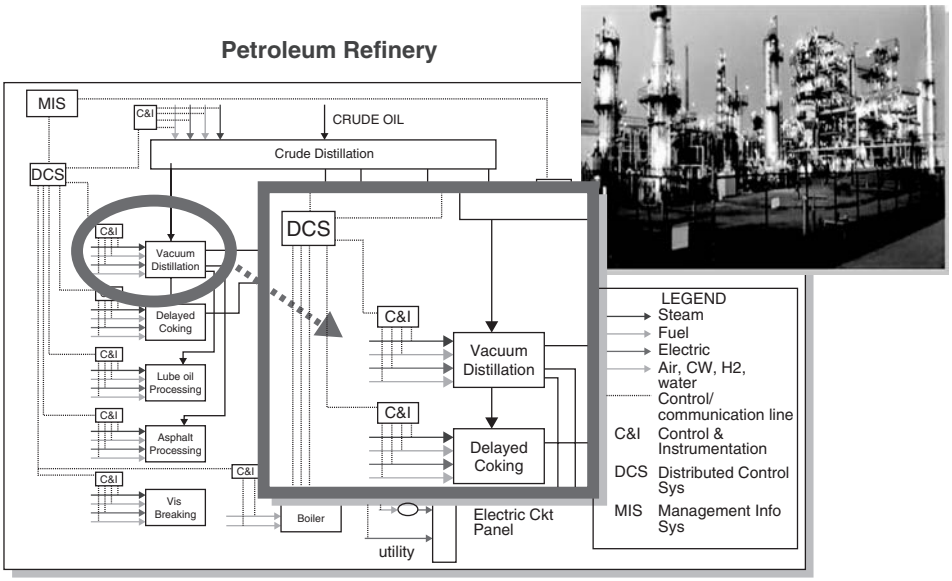

**FIGURE 4** Example of petroleum refinery internal interdependency.

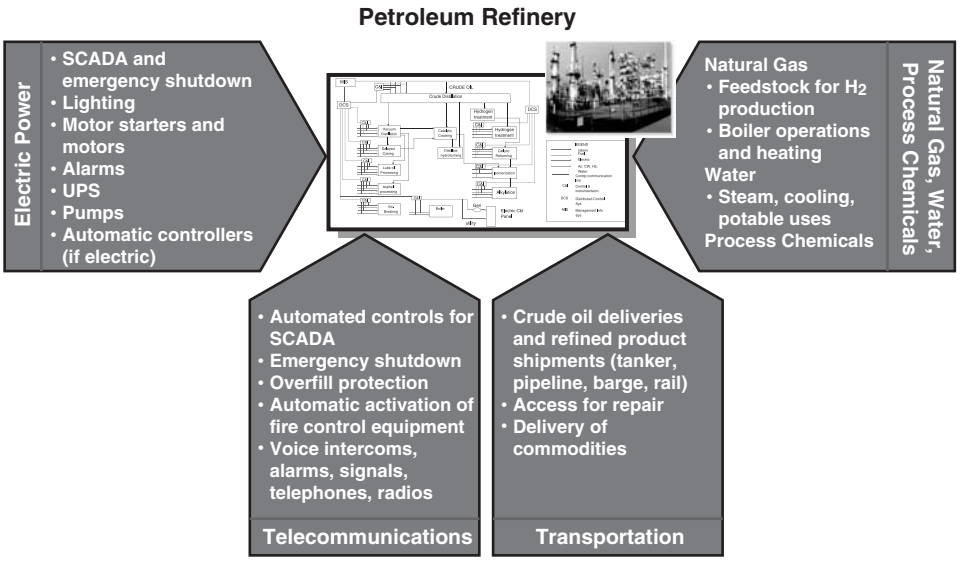

**FIGURE 5** Example of petroleum refinery external interdependency.

**TABLE 1 Interdependencies Survey Questions**

| **Checklist Considerations: Interdependencies Survey** |
|---|
| *(a) Infrastructure Oversight* |
| Does the facility have a department responsible for overseeing all or most the infrastructures? |
| *(b) Infrastructure Procedures* |
| In general, are operating procedures in place for the systems that make up the internal infrastructures and for the physical connections and contracts with the external infrastructures that support them? Describe the extent of these procedures, their format, their availability to relevant staff, and the extent to which they are regularly followed. |
| Are contingency procedures in place for the systems that make up the internal infrastructures and for the physical connections and contracts with the external infrastructures that support them? Describe the extent of these procedures, their format, and their availability to relevant staff (Note: contingencies refer to situations brought about by a failure or disruption within an infrastructure or the infrastructures that support it.). |
| If they exist, have the contingency procedures been tested and are they exercised regularly either as a part of normal operations as through specially designed drills? Describe the drills and their results. |
| *(c) Electric Power Supply and Distribution* |
| Primary source of electric power |
| If the primary source of electric power is a commercial source, are there multiple independent feeds? If so, describe the feeds and their locations. Also specify who controls the termination points of any multiple feeds. |
| If the primary source of electric power is a system operated by the facility or asset, what type of system is it? |
| Electric distribution system |
| Are the components of the electric system that are located outside of buildings (such as generators, fuel storage facilities, transformers, and transfer switches) protected from vandalism or accidental damage by fences or barriers? If so, describe the type of protection and level of security it provides. |
| Are the various sources of electric power and the components of the internal electric distribution systems such that they may be isolated for maintenance or replacement without affecting the critical functions of the asset/facility? If not, describe the limitations. |
| Have any single points of failure been identified for the electrical power supply and distribution system? If so, list them and describe. |
| Backup electric power systems |
| Are there additional emergency sources of electric supply beyond the primary system (such as multiple independent commercial feeds, backup generators, and uninterruptible power supply [UPSs])? If there are, describe them and who controls them. |
| Commercial electric power sources |
| How many substations feed the area of the asset/facility and the asset/facility itself? That is, is the area supplied by multiple substations? If more than one, which ones have sufficient individual capacities to supply the critical needs of the asset/facility? |

(*continued overleaf*)

**TABLE 1 (*Continued*)**

| **Checklist Considerations: Interdependencies Survey** |
|---|
| Commercial electric power pathways |
| Are the power lines into the area of the asset/facility and into the asset/facility itself above ground (on utility poles), buried, or a combination of both? If both, indicate locations of portions above ground. |
| *(d) Petroleum Fuels and Bulk Chemicals Supply and Storage* |
| Uses of petroleum fuels and bulk chemicals |
| Are petroleum fuels or bulk chemicals used in normal operations at the asset/facility? If yes, specify the types and uses. |
| Reception facilities |
| How are the various petroleum fuels and bulk chemicals normally delivered to the asset/facility? Indicate the delivery mode and normal frequency of shipments for each fuel type. |
| Supply contracts |
| Are contracts in place for the supply of petroleum fuels and bulk chemicals? Specify the name of the contractors, the types of contracts, the modes of transport (pipeline, rail car, tank truck, etc.), and the frequency of normal shipments. |
| *(e) Natural Gas Supply* |
| Sources of natural gas |
| How many city gate stations supply the natural gas distribution system in the area of the asset/facility and the asset/facility itself?<br>How may distinct independent transmission pipelines supply the city gate stations? Indicate if an individual gate station is supplied by more than one transmission pipeline and which stations are supplied by independent transmission pipelines. |
| Natural gas contracts |
| Does the asset/facility have a firm delivery contract, an interruptible contract, or a mixed contract with the natural gas distribution company or the transmission companies? Specify the companies involved and specify whether there is a direct physical link (pipeline) to each company. |
| *(f) Telecommunications* |
| Internal telephone system |
| What types of telephone systems are used within the asset/facility? Are there multiple independent telephone systems? Specify the types of systems, their uses, and specify whether they are copper-wire or fiber-optic based.<br>If there are multiple (from independent systems) or redundant (from built-in backups) switches and cables, are they physically separated and isolated to avoid common causes of failure?<br>Are the telephone switches located in limited-access or secured areas away from potential damage due to weather or water leaks? Specify types of protection provided. |

**TABLE 1 (*Continued*)**

| **Checklist Considerations: Interdependencies Survey** |
|---|
| Data transfer |
| If there is a separate system for large volume and high-speed data transfer, are there redundant switches and cables. If yes, describe the situation. |
| If there are redundant switches and cables, are they physically separated and isolated to avoid common causes of failure? |
| Are the data transfer switches located in limited-access or secured areas away from potential damage due to weather or water leaks? Specify the types of protection provided. |
| Cellular/wireless/satellite systems |
| Are cellular/wireless/satellite telephones and pagers in widespread use within the asset/facility? If yes, briefly describe their uses. |
| Intranet and e-mail system |
| Is the asset's/facility's Intranet and e-mail system dependent on the asset's/facility's computers and servers or telephone system? If yes, describe the dependence. |
| Are there any critical operational items that require use of the e-mail system or internet? |
| Redundant access to intranet and e-mail system |
| Does the asset/facility have a backup or redundant Intranet and e-mail system? If yes, describe the system and the amount of backup it provides. Does an outside contractor maintain the backup? If so, what type of security oversight measures does the contractor have in place? |
| On-site fixed components of microwave/radio system |
| Are there multiple or redundant radio communications systems in place within the asset/facility? If yes, specify the types of systems and their uses. |
| Mobile and remote components of microwave/radio system |
| Are there mobile components to the radio communications system (such as on vehicles or vessels)? If yes, describe the mobile components. |
| Are the mobile components of the radio communications system protected from vandalism or accidental damage by locked boxes or lockable vehicle cabs? Specify the types of protection and level of security they provide. |
| Commercial telecommunications' carriers |
| Are there multiple telecommunications carriers used by the asset/facility (possibly commercial, contracted, or organization-owned)? List them, specify the service they provide or the type of information carried (such as analog telephone voice and FAX, digital telephone voice, Internet connections, and dedicated data transfer), and the type of media used (copper cable, fiber-optic cable, microwave, and satellite) |
| Pathways of commercial telecommunications' cables |
| Are the telecommunications' cables into the area of the asset/facility and into the asset/facility itself above ground (on utility poles), buried, or a combination of both? If both, indicate locations of portions above ground. |

(*continued overleaf*)

**TABLE 1 (*Continued*)**

| **Checklist Considerations: Interdependencies Survey** |
|---|
| Are the paths of the telecommunications cables located in areas susceptible to natural or accidental damage (such as overhead cables near highways; cables across bridges, dams, or landslide areas)? If yes, indicate the locations and types of potential disruptions. |
| Backup communications systems |
| Are there redundant or backup telephone systems in place if the primary system is disrupted? Specify the extent to which the secondary systems can support the critical functions and activities at the asset/facility. |
| *(g) Transportation* |
| Road and rail access |
| Are there multiple roadways or rail routes into the area of the asset/facility? Describe the route or routes and indicate any load or throughput limitations with respect to the needs of the asset/facility. |
| Airports and air routes |
| Are there multiple airports in the area of the site of sufficient size and with sufficient service to support the critical functions and activities at the asset/facility? Enumerate the airports and indicate any limitations.<br>Are there any regular air routes that pass over or near the asset/facility that could present a danger to the asset/facility if there were some sort of an air disaster? Record any concerns. |
| Waterway access |
| Are there multiple water routes to the ports, harbors, or landings used by the asset/facility from the open ocean or major waterway? Describe the route or routes and indicate any load, draft, beam, or throughput limitations with respect to the needs of the organization. |
| Pipeline Access |
| What materials, feedstocks, or products (such as crude oil, intermediate petroleum products, refined petroleum products, or liquefied petroleum gas) are supplied to or shipped from the asset/facility by way of pipeline transportation?<br>Are there multiple pipelines and pipeline routes into the area of the asset/facility from major interstate transportation pipelines? If yes, indicate which pipelines or combinations of pipelines have sufficient capacity to serve the asset/facility.<br>Are the paths of the pipelines colocated with the rights-of-way of other infrastructures? If yes, indicate how often and where they follow the same rights-of-way and the infrastructures that are colocated.<br>Are the paths of the pipelines located in areas susceptible to natural or accidental damage (such as across bridges or dams, in earthquake or landslide areas)? If yes, indicate the locations and types of potential disruptions. If disruptions due to scheduled maintenance or system modifications occur, how is this communicated to your organization? |
| *(h) Water and Wastewater* |
| Primary domestic/industrial water system |
| Does the asset/facility have a domestic/industrial water system? If yes, specify the uses of the water. |

**TABLE 1 (*Continued*)**

| **Checklist Considerations: Interdependencies Survey** |
|---|
| Does the water supply for the domestic/industrial water system come from an external source (such as community, city, or regional water mains) or from an internal system (such as wells, river, or reservoir)? If internal, describe the system. |
| Backup domestic/industrial water system |
| Is there an independent backup water source to the primary domestic supply system? If yes, specify the type of backup system (such as wells, river, reservoir, and tank truck), describe the specific source of the water, indicate the adequacy of the backup supply's capacity, and indicate if it is gravity feed or requires active pumps (generally electric). |
| Primary industrial wastewater system |
| Does the asset/facility have an on-site industrial wastewater system? If yes, specify the types of wastewater that are processed and the processes used. |
| Backup wastewater system |
| Is there an independent backup system that can be used to handle the industrial wastewater? If yes, specify the type of backup system (such as a redundant system, holding ponds, and temporary discharge of unprocessed wastewater), describe the specific process, indicate the adequacy of the backup's capacity and any limitations on how long it can operate, and indicate if it is gravity feed or requires active lift pumps (generally electric). |
| Commercial/public water/wastewater supply reliability |
| Historically, has the city water/wastewater supply in the area been reliable and adequate? Quantify the reliability and specify any shortfall in the supply pressure or flow rate. |
| Typically, when disruptions in the city water/wastewater supply occur, are they of significant duration (as opposed to just a few hours)? Quantify in terms of potential effects on the critical functions and activities at the asset/facility. |
| *(i) Emergency Services (Police, Fire, And Emergency Medical)* |
| Local police, county/state police, and federal bureau of investigation (FBI) |
| How are these agencies involved in protecting the asset/facility? |
| What are typical response times and response capabilities? |
| Fire department and emergency medical services |
| How are these agencies involved in protecting or treating the asset/facility? |
| Do they provide inspection and/or certification services? |
| What are typical response times and response capabilities? |
| *(j) Computers and Servers (Mainframes, Firewalls, and Router Equipment)* |
| Electric power sources |
| Are there provisions within the asset's/facility's primary electric power supply and distribution system to supply power for the computers and servers? If yes, indicate under what conditions and for how long. |
| Do the computers and servers have their own backup electric power supply (such as local UPSs or generators)? If yes, specify the types of backup and how long they can operate. |

(*continued overleaf*)

**TABLE 1 (*Continued*)**

| **Checklist Considerations: Interdependencies Survey** |
|---|
| Environmental control |
| Does the asset's/facility's central HVAC system provide environment control to the computer and server areas or do the computer and server areas have their own independent environmental control system? If they have their own system, specify the type. |
| Protection |
| Is there special physical security provided for the computer and server areas? If yes, specify the type of security and the level of protection provided. |
| *(k) HVAC System (Air Handlers, Heating Plants, Cooling Towers, and Chillers)* |
| Primary HVAC system |
| Can critical functions and activities dependent on environmental conditions continue without the HVAC system? If yes, specify which functions and for how long they can continue under various external weather conditions. |
| Backup HVAC systems |
| Is there a separate backup or contingency plan for the HVAC system? If yes, describe the system and the energy and water supply systems it requires. |
| *(l) Fire Suppression and Fire Fighting System* |
| Alarms |
| Does the entire asset/facility (or at least most of it) have a fire and/or smoke detection and alarm system? If yes, specify the type of system, how it is monitored, and the response procedure. |
| Fire suppression |
| Does the entire asset/facility (or at least most of it) have a fire suppression system such as an overhead sprinkler system? If yes, specify the medium (usually water) and whether it is of the flooded-pipe or prearmed type.<br>Does the water supply for the fire suppression system come from city water mains or an on-site system, such as wells, rivers, or reservoir? |
| Other systems |
| Is there special fire suppression equipment, such as Halon, Inergen, inert gases, or carbon dioxide in certain areas such as computer or telecommunications areas? If yes, indicate the types and adequacies of these special systems. |
| *(m) SCADA System* |
| Type of system |
| Does the asset/facility make use of a substantial SCADA system (i.e. one that covers a large area or a large number of components and functions)? If yes, indicate what functions are monitored and/or controlled, the type of system, and the extent of the system. |

**TABLE 1 (*Continued*)**

| **Checklist Considerations: Interdependencies Survey** |
|---|
| Control centers |
| Where is the primary control center for the SCADA system located?<br>Is there a backup control center? If yes, where is it located? Is it sufficiently remote from the primary control center to avoid common causes of failure, such as fires, explosions, or other large threats? |
| *(n) Physical Security System* |
| Electric power sources |
| Are the asset's/facility's monitoring and alarm systems normally dependent on the asset's/facility's primary electric power supply and distribution system (i.e. is the asset's/facility's primary electric power supply and distribution system the primary electric power source?)?<br>If there a backup system that can support all the functions of the monitoring and alarm systems in terms of capacity? Specify for how long it can operate. |
| Communications pathways |
| Are the asset's/facility's monitoring and alarm systems normally dependent upon the asset's/facility's telephone system? |
| Computer support |
| Are the asset's/facility's monitoring and alarm systems normally dependent upon the facility's main computers and servers? |
| *(o) Financial System (Including Monetary Transactions)* |
| Electric power sources |
| Are the asset's/facility's financial systems and functions normally dependent on the asset's/facility's primary electric power supply and distribution system (i.e. is the facility's electric power supply and distribution system the primary electric power source?)? |
| Communications pathways |
| Are the asset's/facility's financial systems and functions normally dependent upon the asset's/facility's telephone system? |
| Computer support |
| Are the asset's/facility's financial systems and functions normally dependent upon the facility's main computers and servers? |

identifies external interdependencies (outside the petroleum refinery). Internal interdependencies include on-site energy generation, process control and monitoring, and steam. External interdependencies include commercial electricity, water sources, and feedstock. The primary focus is on critical interdependencies where loss would severely degrade or shut down operations and where no redundancy or limited redundancy exists.

By answering specific questions, assessment teams are able to determine which internal and external infrastructures are critical to operations and the redundancies of these systems. The question areas include infrastructure oversight, infrastructure procedures, and infrastructure considerations. It is important to note that although many questions are the same across all sectors, sector specific questions also have been developed. For example, the *Security Vulnerability Analysis Methodology for the Petroleum Industry* [14] provides detailed questions associated with each of these categories. A subset of infrastructure dependency questions is provided in Table 1.

## 3 NEXT STEPS

The interdependency element area is evolving and should continue to develop. DOE and DHS programs have provided a foundation for this work, and several current programs within the government and industry continue to leverage this effort. For example, the State of Ohio has adopted the interdependency questions into its statewide vulnerability assessment model in identifying state vulnerabilities and mitigation strategies. The State of Ohio had an existing vulnerability assessment template; however, the template was based on physical security. The state recognized the need for an interdependencies perspective to broaden its perspective and to help prioritize mitigation options. Thus, the state integrated a subset of the interdependency questions presented into its template.

Another example is the Pacific Northwest Economic Region (PNWER) that has conducted interdependencies seminars to bring regional stakeholders together. PNWER has developed an Infrastructure Interdependencies Identification and Assessment Tool to identify detailed interdependencies-related information relevant to operations and business continuity, and to determine appropriate ways to share data among stakeholder organizations. The questions implemented in the tool were based on the interdependency questions mentioned. The tool is helping PNWER to better understand, at a regional level, their supply chains and infrastructure dependencies and interdependencies. Taking a regional perspective allows for a more holistic approach to interdependencies and provides insights into bottlenecks within the region.

DHS continues to leverage the interdependencies work into various ongoing programs. DHS has evolved from conducting vulnerability assessments to conducting risk assessments. However, interdependencies have become increasingly important since risk comprises threats, vulnerabilities, and consequences. Each of these risk elements requires an interdependencies perspective to properly identify and quantify risk. The various assessment methodologies at DHS/IP (e.g. Site Assistance Visits, Buffer Zone Protection Plans, Comprehensive Reviews, Maritime Security Risk Assessment Model, and Risk Analysis and Management for Critical Asset Protection) continue to evolve interdependencies aspects in different ways.

# ROBUSTNESS, RESILIENCE, AND SECURITY OF NATIONAL CRITICAL INFRASTRUCTURE SYSTEMS

S. MASSOUD AMIN[I]

*University of Minnesota, Minneapolis, Minnesota*

## 1 NATIONAL CRITICAL INFRASTRUCTURE SYSTEMS: UNDERPINNING OUR ECONOMY, GLOBAL COMPETITIVENESS, SECURITY, AND QUALITY OF LIFE

Virtually every crucial economic and social function depends on the secure, reliable operation of energy, telecommunications, transportation, financial, and other infrastructures.

[I]Honeywell/H.W. Sweatt Chair in Technological Leadership, Director of the Technological Leadership Institute, Professor of Electrical & Computer Engineering, and University Distinguished Teaching Professor. Contact information: amin@umn.edu, or http://umn.edu/amin.

Indeed, they have provided much of the good life that the more developed countries enjoy. However, with increased benefit has come increased risk. As these infrastructures have grown more complex to handle a variety of demands, they have become more interdependent.

The Internet, computer networks, and our digital economy have increased the demand for reliable and disturbance-free electricity; banking and finance depends on the robustness of electric power, cable, and wireless telecommunications. Transportation systems, including military and commercial aircraft and land and sea vessels, depend on communication and energy networks. Links between the power grid and telecommunications and between electrical power and oil, water, and gas pipelines continue to be a lynchpin of energy supply networks. This strong interdependence means that an action in one part of one infrastructure network can rapidly create global effects by cascading throughout the same network and even infiltrating other networks.

A growing portion of the world's business and industry, art and science, entertainment and even crime are conducted through the World Wide Web and the Internet. But the use of these electronic information systems depends, as do the more mundane activities of daily life, on many other complex infrastructures, such as cable and wireless telecommunications, banking and finance, land, water, and air transportation, gas, water, and oil pipelines, and the electric power grid. All of these are, themselves, complex networks, geographically dispersed, nonlinear, and interacting both among themselves and with their human owners, operators, and users. Energy, telecommunications, transportation, and financial infrastructures are becoming increasingly interconnected, thus, posing new challenges for their secure and reliable operation.

*What is "Infrastructure"?* Infrastructure is the linked sociotechnological system of facilities and activities that provides the range of essential services generally necessary to support our economy and quality of life.

*What is a sociotechnological system?* Sociotechnological systems include the physical infrastructure, the people, and organizations who build, run, and use it, as well as the economic and legal conditions for operations.

There is reasonable concern that both national and international energy and information infrastructures have reached a level of complexity, and interconnection which makes them particularly vulnerable to cascading outages, initiated by material failure, natural calamities, intentional attack, or human error. The potential ramifications of network failures have never been greater, as the transportation, telecommunications, oil and gas, banking and finance, and other infrastructures depend on the continental power grid to energize and control their operations. Although there are some similarities, the electric power grid is quite different from gas, oil, or water networks-phase shifters rather than valves are used, and there is no way to store significant amounts of electricity. To provide the desired flow on one line often results in "loop flows" on several other lines.

Our studies in the areas of stability, robustness, resilience, and security span from marco systems (including interdependent national infrastructure and enterprises), to micro (individuals/people) within these large-scale uncertain systems, which are modeled as complex adaptive systems.

As a "micro" example, living beings must constantly adapt to changing environmental conditions and turbulence. Some seem inherently more capable of this resilient adaptation than others. As with leadership in general, there are some innate attributes that predispose

some to be more resilient than others. And as cumulative life stress increases pushing one to his/her "maximum emotional capacity" we need to learn to diffuse some of this emotion or it will push us beyond our upper control limit (i.e. exceed our maximum emotional bandwidth). The key is to learn to manage our "signal to noise ratio" in such a way that we never lose sight of our own unique inner signal. Similarly, understanding how to transform our complex infrastructure systems to be much more sensitive, discerning yet resilient, robust, and adaptive will represent a breakthrough in systems engineering.

As the world becomes increasingly VUCA (volatile, uncertain, complex, and adaptive), resulting in a wide spectrum of opportunities and challenges of complex systems abound, and concerns about the instability of these systems and their potential for large and possible catastrophic regime shifts are a dominant social concern, with "systemic risk" as a generic problem.

These concerns are at the leading edge of many environmental and engineering sciences: for example, in atmospheric science in studies of climate change; for financial risk management in the couplings and resultant systemic risks; for fisheries managers concerned with the sudden collapse of certain economically important fish stocks; for communication networks concerned with system reliability and security in the face of evolving cyber risks; in electrical and power engineering concerned with preventing disruptions to the North American power grid.

The commonality of the problem of stability and resilience to shocks in complex systems that these examples point to raises the possibility that approaches to risk management in natural and physical systems with pertinence to nearly all aspects of our lives. Some of the methods for managing risk in engineering systems, such as "multi-objective trade-off analysis" in which Pareto-optimal actions are derived by considering the subjective probabilities and payoffs associated with different shocks and their primary, secondary, and tertiary propagation pathways and consequences.

Modeling interdependent complex systems and lifeline infrastructures (e.g. the electric power, together with telecommunications, oil/gas pipelines, and energy markets) in a control theory context is especially pertinent since the current movement toward deregulation and competition will ultimately be limited only by the physics of electricity and the topology of the grid. In addition, mathematical models of complex networks are typically vague (or may not even exist); existing and classical methods of solution are either unavailable, or are not sufficiently powerful. For the most part, no present methodologies are suitable for understanding their behavior. In what follows, as examples, we briefly summarize four interdependent infrastructures, and the associated countermeasures for increased robustness, resilience, and security.

### 1.1 Example: Transportation

The backbone of the US transportation system and economy—the road infrastructure system—has continually evolved since the 1930s, but the cost to build and maintain it is rising. The US Department of Transportation estimates that the annual cost of congestion in lost productivity alone is more than $100 billion. In addition, more than 40,000 persons are killed and another five million injured each year in traffic accidents. This infrastructure, faced with the increased density in today's urban population centers, is becoming increasingly congested. Human population centers have grown dramatically in the past century, creating a "trilemma" of sustainability issues: population, poverty, and pollution. The United States along with many other nations is seeking a solution to

this worsening traffic congestion problem. Such solutions have to be viewed in terms of the economic, social, and political environments, along with the technological capability of the nation. Furthermore, the costs associated with generating and maintaining the road infrastructure are becoming increasingly higher, and the impact of inefficiencies can be measured in quantifiable terms of loss of labor-hours in the work place, loss of fuel, as well as intangibly in terms of pollution, and the general increased stress level of the work force who uses these transportation channels.

Where feasible, increasing the number of lanes or building new roads can expand present capacity, but the demand in some areas (both from population growth and travel demand) cannot be met by adding roads. A less expensive and disruptive solution is to intelligently manage the existing road infrastructure. The idea is to create and deploy technologies to improve the safety, capacity, and operational efficiency of the surface transportation system, while simultaneously reducing the burden on the environment and on our energy sources. With these objectives in mind, Congress launched the US Intelligent Transportation Systems (ITS) program in 1991. One of the program's goals is to develop Advanced Traffic Management Systems (ATMS). ATMS will rely on the consolidation of information, automotive, and highway technology. A wide range of small, complementary systems—from electronic route guidance to preemptive signal control—will essentially automate highways. Sensors and communication devices will be along the roads, as well as in the vehicle. Thus, the road will "know" its operational status, which it will then communicate to the vehicle. The vehicle operator can then make informed decisions about which routes to take to optimize individual trips and daily travel plans. Entities such as traveler information services and fleet management can use the data to plan, implement, and manage their daily operations.

Both public and private outfits can also use the road to plan, implement, and manage their daily operations, including traveler information, traffic management, public and rural transportation management, priority vehicle management, and freight and fleet management. Thus, although they pose great analytical challenges, the ATMS thrust offers significant payoff because of its broad geographical coverage and direct impact on regional economies. As complex as it is[2], the road system is only one segment of

[2]A few statistics on how we get around in America:

- Length of public roads: 46,036 miles of interstate highways (1%); over 112,450 miles of national highway System (3%); and 3.76 million miles of other (96%)
- Personal travel by mode:
  - 208 million vehicles: private vehicles 85.9%, public transport 2.8%, other means 11.3%
  - About 130 million cars, 69 million light trucks, 7 million commercial trucks, and 700,000 buses (e.g. California has 15.5 million motor vehicles, Florida has 7.3 million, ... )
  - About 1.2 million rail cars, 68 ferries, 6,000 aircraft
- Half of the total petroleum consumption in the United States is for highway vehicles and another 18% for other transportation:
  - Fuel consumption: 148 billion gallons of gasoline, 28 billion gallons of diesel, and about 4 billion gallons other
- Fatalities: 22,416 in cars (50.4%), 9,901 truck occupants (22.2%), 2,160 on motorcycles (4.9%), 1,088 on aircraft (3.1%), and 624 on trains (1.4%)
- Fatal accident types amenable to technological prevention: off-road (36%), angle collision (18%), head-on collision (17%), rear-end collision (5%), sideswipe (2%).

the transportation network. As in the other infrastructures, there are diverse sources of complexity and interdependence. Emerging issues include the following:

- Impact of Information Technology: IT and transportation systems' interrelations. Transportation is increasing links with sensors, telecommunications, and even satellites.
- Electrification of multimodal transportation systems: for example, rail networks are becoming increasingly dependent on electricity (electric and magnetic levitation trains).
- Fertile area at the intersection of CE/CS/EnvE/EE/ME/OR/Math/Control/Economics.
- Traffic modeling, prediction, and management: from operational issues to expansion planning.
- Multiresolutional simulations; real-time optimization, epsilon-optimality, and provable performance bounds.

In the area of multimodal transportation and distribution networks (air, land, and sea), emerging issues include electrification of transportation; links with sensors, telecommunications and satellites; traffic modeling, prediction, and management; multiresolutional simulations; real-time optimization with provable performance bounds with risk management; and how to develop tools in the intersection of mathematics, risk management, operations research, control theory, system science, computer science, artificial intelligence (AI), economics, and even biology to tackle these problems. Several researchers have referred to this as "*intelligent or adaptive control*"; the challenge is how to develop systems that can sense, identify, and build realistic models, and can also adapt, control, and achieve their goals.

These are challenges not only in transportation systems, but are the characteristics of any industry made up of many, geographically dispersed components that can exhibit rapid global change as a result of local actions. Prime examples are the highly interconnected and interactive industries, which make up a national or international "infrastructure," including telecommunications, transportation, gas, water and oil pipelines, the electric power grid, and even the collection of satellites in the earth orbit.

### 1.2 Example: Telecommunications

The globalization of our economy is built on telecommunication networks, including fixed networks (public switched telephone and data networks), wireless (cellular, PCS, wireless ATM), and computers (Internet and millions of computers in public and private use). These networks are growing rapidly and require secure, reliable, and high quality power supplies. This telecommunication infrastructure, like the power grid, is becoming overburdened. The satellite network, just one segment of the infrastructure, is a good example. The satellite network has three main layers:

- low earth orbit (LEO), 200–2,000 km ("little LEOs" at 750–1500 km), operating at VHF, UHF below 500 MHz; low complexity;
- medium earth orbit (MEO), 2000–20,000 km (big LEOs/MEOs at 750–11,000 km) operating at L and S microwave (1.6 and 2.5 GHz) with high to very high complexity; and

- geosynchronous orbit (GEO), at 36,000 km, operating at K microwave (19 and 29 GHz), with variable low to high complexity.

Some of the most familiar services are detailed Earth imaging, remote monitoring of dispersed locations, and highly accurate location and tracking using the continuous signals of the global positioning system (GPS). Satellite-based business and personal voice and data services are now available throughout much of the world.

The Internet is rapidly expanding the range of applications for satellite-based data communications; two of the most popular applications are accessing the Internet itself and connecting remote sites to corporate networks. Some satellite systems, including those of satellite TV providers, let users browse Web pages and download data—at 400 kbps—through a 21-in. (53 cm) roof-mounted dish receiver connected to a personal computer with an interface card. This capability could become a valuable tool for expanding an enterprise network to remote offices around the world.

Some utilities are diversifying their businesses by investing in telecommunications and creating innovative communications networks that cope with industry trends toward distributed resources, two-way customer communications, and business expansion, as well as addressing the measurement of complex and data-intensive energy systems via wide-area monitoring and control. Challenges include how to handle network disruptions and delays and manage orbits from the satellite. A big source of complexity is the interdependence of the telecommunication networks and the power grid.

The telecommunications network and the electric power grid are becoming increasingly interdependent. Issues range from the highest command and control level to the individual power stations and substations at the middle level, and then to the devices and power equipment at the lowest level.

### 1.3 Example: Financial Systems[3]

The stability of the financial system and the potential for systemic events to alter the functioning of that system have long been important topics for central banks and the related research community. Developments such as increasing industry consolidation, global networking, terrorist threats, and an increasing dependence on computer technologies underscore the importance of this area of research. Recent events, however, including the terrorist attacks of September 11th and the demise of long-term capital management, suggest that existing models of systemic shocks in the financial system may no longer adequately capture the possible channels of propagation and feedback arising from major disturbances. Nor do existing models fully account for the increasing complexity of the financial system's structure, the complete range of financial and information flows, or the endogenous behavior of different agents in the system. Fresh thinking on systemic risk is, therefore, required.

In order to promote a better understanding of systemic risk, the National Academy of Sciences and the Federal Reserve Bank of New York convened a conference in New York

[3]This section on financial systems is based on my presentation and related discussions at the "New Directions for Understanding Systemic Risk: A report on a Conference Cosponsored by the Federal Reserve Bank of New York and the National Academy of Sciences"; for the NAS book and complete FRBNY report please see: Economic Policy Review, Federal reserve Bank of New York, Vol. 13, Number 2, Nov. 2007, and New Directions for Understanding Systemic Risk, 108 pp, Nat'l Acad. Press, Washington DC, 2007. Input and material from NAS/BMSA and FRBNY is gratefully acknowledged.

in May of 2006 drawing together a broadly interdisciplinary group of scientists, engineers, and financial practitioners, ranging from electrical engineers and academic economists to risk analysts and asset managers from major investment banks. The primary purpose of the conference was to promote a cross-disciplinary dialogue in order to examine what possible leverage on the topic of systemic risk could be gained from areas of science not directly related to finance or economics. Accordingly, conference participants from the natural and mathematical sciences and from engineering disciplines drew heavily upon research on complex adaptive systems in order to build a framework both to give some substance and definition to the notion of systemic risk and to point to the possible linkages between this research and research on the financial system. Similarly, research economists presented papers that showed how some of these linkages could be leveraged, for example, in studies of international trade and, crucially for the Federal Reserve policy, in the management of the payments system. Participants from the financial industry also highlighted how thinking on systemic risk and actual systemic events affect trading activities in order to provide a context for the discussion.

For more information, please see the above-referenced report as well as the prevalence of systemic risk in very diverse areas ranging from biological and natural ecologies to financial, built and engineered complex systems in which prediction and management of systemic failures are critical.

In an engineered system, like the electric power grid or a telecommunication network, there is indeed the opportunity for control systems, and these can be quite advanced. Creating such a control capability for the electric grid required a mixture of tools from dynamical systems, statistical physics, information and communication science, along with research to reduce the computational complexity of the algorithms so they can scale up with the large size of the system being controlled. Our earlier work has led to working methods that have been applied to a variety of situations, including the electricity infrastructure coupled with telecommunications and the energy markets, cell phone networks on the Internet, and some biological systems. This is a multiscale challenge: detection of troublesome signals must be done within milliseconds, with some compensatory actions taken automatically, while some load balancing and frequency control on the grid is controlled on a timescale of seconds. At the same time, control functions such as load forecasting and management and generation scheduling take place on a timescale of hours or days. Developing a picture at the atomic level of what is going on in a system and then building up to the macroscale is a challenge that requires multiresolutional modeling in both space and time.

Just to give an idea of the complexity of modeling and controlling the electrical grid, in North America, there are more than 15,000 generators, and over 216,000 miles of high voltage lines. The overall grid is divided in several very large interconnected regions, and modeling one of them (which is necessary for understanding the systemic risks) might entail a simulation with 50,000 lines and 3000 generators. The system is typically designed to withstand the loss of any single element. To determine whether the grid can attain that design goal, we need to simulate the loss of each of 53,000 elements and calculate the effects on each of 50,000 lines, leading to over 2.6 billion cases. The analysis of these systemic risks is very challenging, but it can really make a difference in how to operate the system.

As an additional illustration of the level of detail that can successfully be modeled, we developed an example of a complex model to predict load and demand for DeKalb,

Illinois, which is a sizeable market with a mixture of commercial and residential customers. Deregulation of the electric system has reduced the correlation between power flow and demand, thus introducing uncertainty into the system, and so there has been a good deal of research to understand this phenomenon and develop the means to monitor and control it. The models and algorithms are now good enough to simulate the demand by customer type (residential, small commercial, and large commercial) on an hour-by-hour basis and attain 99.6–99.7% accuracy over the entire year. One value of these predictions is that they enable the power company to proactively dispatch small generators to meet anticipated high demands.

From a broader perspective, any critical national infrastructure typically has many layers and decision-making units and is vulnerable to various types of disturbances. Effective, intelligent, distributed control is required that would enable parts of the constituent networks to remain operational and even automatically reconfigure in the event of local failures or threats of failure. In any situation subject to rapid changes, completely centralized control requires multiple, high data-rate, two-way communication links, a powerful central computing facility, and an elaborate operations control center. But all of these are liable to disruption at the very time when they are most needed (i.e. when the system is stressed by natural disasters, purposeful attack, or unusually high demand).

When failures occur at various locations in such a network, the whole system breaks into isolated "islands," each of which must then fend for itself. With the intelligence distributed, and the components acting as independent agents, those in each island have the ability to reorganize themselves and make efficient use of whatever local resources remain to them in ways consonant with the established global goals to minimize adverse impact on the overall network. Local controllers will guide the isolated areas to operate independently while preparing them to rejoin the network, without creating unacceptable local conditions either during or after the transition. A network of local controllers can act as a parallel, distributed computer, communicating via microwaves, optical cables, or the power lines themselves, and intelligently limiting their messages to only that information necessary to achieve global optimization and facilitate recovery after failure.

If organized in coordination with the internal structure existing in a complex infrastructure and with the physics specific to the components they control, these agents promise to provide effective local oversight and control without need of excessive communications, supervision, or initial programming. Indeed, they can be used even if human understanding of the complex system in question is incomplete. These agents exist in every local subsystem—from "horseshoe nail" up to "kingdom"—and perform preprogrammed self-healing actions that require an immediate response. Such simple agents already are embedded in many systems today, such as circuit breakers and fuses as well as diagnostic routines. The observation is that we can definitely account for loose nails and to save the kingdom.

Another key insight came out of analysis of forest fires, which researchers in one of the six funded consortia found to have similar "failure-cascade" behavior to electric power grids. In a forest fire the spread of a spark into a conflagration depends on how close together the trees are. If there is just one tree in a barren field and it is hit by lightning, it burns but no large blaze results. But if there are many trees and they are close enough together—which is the usual case with trees because Nature is prolific and efficient in using resources—the single lightning strike can result in a forest fire that burns until it reaches a natural barrier such as a rocky ridge, river, or road. If the barrier is narrow enough that a burning tree can fall across it or it includes a burnable flaw such

as a wooden bridge, the fire jumps the barrier and burns on. It is the role of first-response wild-land firefighters such as smokejumpers to contain a small fire before it spreads by reinforcing an existing barrier or scraping out a defensible fire line barrier around the original blaze.

Similar results hold for failures in electric power grids. For power grids, the "one-tree" situation is a case in which every single electric socket had a dedicated wire connecting it to a dedicated generator. A lightning strike on any wire would take out that one circuit and no more. But like trees in Nature, electrical systems are designed for efficient use of resources, which means numerous sockets served by a single circuit and multiple circuits for each generator. A failure anywhere on the system causes additional failures until a barrier—such as a surge protector or circuit breaker—is reached. If the barrier does not function properly or is insufficiently large, the failure bypasses it and continues cascading across the system.

These findings suggest approaches by which the natural barriers in power grids may be made more robust by simple design changes in the configuration of the system, and eventually how small failures might be contained by active smokejumper-like controllers before they grow into large problems. Other research into fundamental theory of complex interactive systems is exploring means of quickly identifying weak links and failures within a system.

Work during the past 11 years in this area has developed, among other things, a new vision for the integrated sensing, communications, and control-issues surrounding the power grid. Some of the pertinent issues are why/how to develop protection and control devices for centralized versus decentralized control, as well as issues involving adaptive operation and robustness to various destabilizers. However, instead of performing *in vivo* societal tests which can be disruptive, we have performed extensive "wind-tunnel" simulation testing (*in silico*) of devices and policies in the context of the whole system along with prediction of unintended consequences of designs and policies to provide a greater understanding of how policies, economic designs, and technologies might fit into the continental grid, as well as guidance for their effective deployment and operation.

This is not meant to imply that ecology and engineering have overcome all the challenges associated with representing and analyzing complex adaptive systems. Sensing the state of such systems is one ongoing challenge, as is the question of what to measure. Validation of models and verification of software remains a major challenge. There are major computational problems, including how to break models into tractable components. Self-similar systems can be reduced, but not complex systems like the electrical grid. One can use approximations to decouple complex systems, but it is difficult to analyze the errors thus introduced. One can find parts of an engineered system—and presumably in other systems—that are weakly coupled in terms of the dynamics transferred through the system and then approximate those portions with stand-alone models. This can help us reduce the complexity by dividing and conquering.

It is important to emphasize the difficulty of identifying meaningful signals from complex systems. For example, when monitoring a large fraction of the US electrical grid, how can we discern whether a perturbation in the system (be it financial, physical, communication, or cyber or a combination of them), is a natural fluctuation or the signature of a catastrophic failure. Does it reflect a naturally caused phenomenon, perhaps triggered by heat, high humidity, or a high demand in one portion of the grid, or is it actually an attack on the system or the precursor to major disturbance? How close is it to a regime shift or system flip? That can only be addressed with detection systems that can pull up

all the data, do data mining, pattern recognition, and then statistical analysis to derive the probability that we were sensing a catastrophic failure or a precursor of one.

This system monitoring problem is exacerbated if sharing of information is limited, as is the case in the banking sector. For example, I am often asked how one would monitor and control the reliability of the electrical grid under the assumption that companies did not cooperate with each other but, instead, competed and did not share the information. Such a situation would lead to a new control mechanism, and the logical question is whether this would stabilize or destabilize the system. For an Electric Power Research Institute (EPRI) project from the late 1990s, Simulator for Electric Power Industry Agents (SEPIA), we began exploring this case. The analysis was done for four large regions of the United States, and explored whether one could increase efficiency without diminishing reliability. This concept would need to be scaled up in order to reach a definitive conclusion.[4]

There is also a work on highly optimized tolerance that Professors John Doyle and Jean Carlson have been developing in California, in which they basically use a genetic algorithm, a neural network approach to evolve the properties of systems. They consider a variety of systems with particular structures and feedback properties, expose them to perturbations, observe their recovery, and just as one would train a chess playing program, these systems are modified until they become more tolerant to the disturbances to which they are exposed. So that is a way how even when one can not solve mathematics, but one can improve the structure of systems. The difficulty with these approaches, as Doyle and Carlson point out, is that systems become robust yet fragile in their terminology, meaning, systems that are engineered or have evolved to be tolerant to a particular set of disturbances often do so at the expense of their response to other classes of disturbances, something that we have to be careful about in the design of systems.[5]

Complex systems abound, and many different disciplines are concerned with understanding catastrophic change in such systems. We focus on three principal areas: risk assessment, modeling and prediction, and mitigation.

## 1.4 Example: North American Power Grid

***1.4.1 Electrification of transportation and enabling a smart self-healing grid.*** Our economy places increased demand for reliable, and disturbance-free electricity. The electric power grid is quite different from other infrastructure systems, such as gas, oil or water networks. A distinguishing characteristic of electricity, for example, is that there is no way to store significant amounts of energy; thus the system is fundamentally operating in real time. For this and related reasons, energy infrastructure systems have a unique combination of characteristics that makes control and reliable operation challenging like:

- Attacks and disturbances can lead to widespread failure almost instantaneously.
- Billions of distributed heterogeneous infrastructure components are tightly interconnected.

[4]See Amin, Massoud, Restructuring the Electric Enterprise: Simulating the Evolution of the Electric Power Industry with Adaptive Agents, Chapter 3 in *Market Based Pricing of Electricity*, A. Faruqui and M. Crew, eds., Kluwer Academic Publishers, Dec. 2002.

[5]See, for example, T. Zhou, J. M. Carlson and J. Doyle, Mutation, specialization, and hypersensitivity in highly optimized tolerance, *Proceedings of the National Academy of Sciences* 99:2049–2054. 2002. and J. M. Carlson and J. Doyle, Complexity and robustness, *Proceedings of the National Academy of Sciences* 99 suppl. 1:2538–2545. 2002.

- A variety of participants—owners, operators, sellers, buyers, customers, data and information providers, data and information users—interact at many points.
- The number of possible interactions increases dramatically as participants are added. No single centralized entity can evaluate, monitor, and manage them in real time.
- The relationships and interdependencies are too complex for conventional mathematical theories and control methods.

These characteristics create unique challenges in modeling, prediction, simulation, cause and effect relationships, analysis, optimization, and control, which have important implications for the use of IT for electric power. This article addresses these challenges by first presenting the technologies involved in the electricity infrastructure and then considers management and policy challenges to the effective performance both in the short and long term.

The North American power network may realistically be considered to be the largest and most complex machine in the world—its transmission lines connect all the electric generation and distribution on the continent. In that respect, it exemplifies many of the complexities of electric power infrastructure and how IT can address them. This network represents an enormous investment, including over 15,000 generators in 10,000 power plants, and hundreds of thousands of miles of transmission lines and distribution networks, whose estimated worth is over US$800 billion. In 2000, transmission and distribution was valued at US$358 billion (EIA 2003; EPRI 1999–2003).

At its most fundamental level, the network's transmission lines form a vertically integrated hierarchical network consisting of the generation layer (noted above) and three other network levels. The first is the *transmission* network, which is meshed networks combining extrahigh voltage (above 300 kV) and high voltage (100–300 kV), connected to large generation units and very large customers and, via tie-lines, to neighboring transmission networks and to the subtransmission level. The second level is *subtransmission*, which consists of a radial or weakly coupled network including some high voltage (100–300 kV) but typically 5–15 kV, connected to large customers and medium size generators. Finally, the third network level is *distribution*, which is typically a tree network including low voltage (110–115 or 220–240 V) and medium voltage (1–100 kV) connected to small generators, medium size customers, and local low voltage networks for small customers.

In its adaptation to disturbances, a power system can be characterized as having multiple states, or "modes," during which specific operational and control actions and reactions take place: normal, disturbance, and restorative. In the normal mode, the priority is on economic dispatch, load frequency control, maintenance, and forecasting. In the disturbance mode, attention shifts to faults, instability, and load shedding. And in the restorative mode, priorities include rescheduling, resynchronization, and load restoration. Some authors include an Alert Mode before a disturbance actually affects the system. Others add a System Failure Mode before restoration is attempted.

Beyond the risk management note above, the electric power grid's emerging issues include (i) integration and management of renewable resources and "microgrids"; (ii) use and management of the integrated infrastructure integrated with an overlaid sensor networks, secure communications and intelligent software agents (including dollars/economic factors and watts); (iii) active-control high voltage devices; (iv) developing new business strategies for a deregulated energy market; and (v) ensuring

system stability, reliability, robustness, and efficiency in a competitive marketplace and carbon-constrained world.

In addition, the electricity grid faces (at least) three looming challenges: its organization, its technical ability to meet 25-year and 50-year electricity needs, and its ability to increase its efficiency without diminishing its reliability and security.

***1.4.2 Smart self-healing grid.*** The term smart grid refers to the use of computer, communication, sensing and control technology which operates in parallel with an electric power grid for the purpose of enhancing the reliability of electric power delivery, minimizing the cost of electric energy to consumers, and facilitating the interconnection of new generating sources to the grid.

The concept for smart grid research and development was originally conceived by this author when I was at the EPRI during 1998–2003. The genesis of the smart grid was in the EPRI/DOD Complex Interactive Networks/Systems Initiative (CIN/SI) that I created and led during 1998–2001.

Beginning in 1998, the original concept and tools developed within CIN/SI were referred to as *The Self-Healing Grid*. This name has undergone several changes and finally emerged as "The Smart grid."

More recently, after joining the University of Minnesota in 2003, my research team and I have been engaged in research and also in telling our colleagues about this concept through publications, lectures, and seminars to diverse stakeholders, which include a wide spectrum from local to international utilities, companies, state and federal organizations, universities and think tanks, to congressional staffers, R&D caucus and committees who have invited our assessments and presentations.

The smart grid is a term also built into the Energy Independence and Security Act (EISA) of 2007, and more recently the American Recovery and Reinvestment Act of 2009 (the stimulus bill). The US Congress allocated $11 billion to research and demonstration projects in the smart grid area. This technology is currently an active topic on TV news and is discussed widely in the media.

Title XIII of EISA 2007 mandates a "Smart Grid" that modernizes and improves the information infrastructure. The Smart Grid represents the information and control functionality that will monitor, control, manage, coordinate, integrate, facilitate, and enable achievement of many of the benefits of innovations envisioned in national energy policy. Examples of Smart Grid functionality include the following:

- Connecting end user loads to grid information and control to facilitate energy efficiency improvements.
- Integrating alternative energy sources and providing the means for mitigating their intermittency.
- Providing the necessary information and control to integrate pluggable hybrids into the grid.
- Allowing problems to be detected and addressed before they become grid disturbances.

Information on these is widely available through EPRI assessments and reports, the US Department of Energy (The Smart Grid—An Introduction, 2008), and the IEEE National Energy Policy Recommendations related to the Smart Grid is a great resource.

In summary, an electric power system has two infrastructures:

- an electric infrastructure—that carries the electric energy in the power system, and,
- an information infrastructure that monitors, controls, and performs other functions related to the electric infrastructure.

The existing electric power grid is not dumb. It has long been designed to continue operating even in the face of problems. Equipment breaks, thunderstorms happen, curious animals get into substations, and drivers crash cars into distribution poles. The power grid is designed and operated so that any single situation does not interrupt the flow of power (the so-called "$n - 1$ criterion"). That requires intelligence, which comes from electromechanical automation, intelligent electronic devices (IEDs), control centers, computers, and communications systems. Such functions have been part of the electric grid for many years. However, because of a combination of cost and operational continuity issues, many of these systems lag, sometimes by decades, advances and capabilities in computer and communications technology.

The institutional and economic framework envisioned for the twenty-first century power system ultimately depends upon building new types and levels of functionality into today's power system. These needed capabilities will be "enabled" by several breakthrough innovations, including, but not limited to the following:

- *Digitally controlling the power delivery network* by replacing today's electromechanical switching with real-time and power-electronic controls. This will become the foundation of a new "smart, self-healing power delivery system" that will enable innovative productivity advances throughout the economy. Digital control, coupled with communications and computational ability is the essential step needed to most cost-effectively address the combined reliability, capacity, security, and market-service vulnerabilities of today's power delivery system.
- *Integrating communications* to create a dynamic, interactive power system for real-time information and power exchange. This capability is needed to enable retail energy markets; power interactive, microprocessor-based service networks; and fundamentally raise the value proposition for electricity. Through advanced information technology coupled with sensors, the system would be "self-healing" in the sense that it is constantly self-monitoring and self-correcting to keep high quality, reliable power flowing. It can sense disturbances and instantaneously counteract them, or reconfigure the flow of power to cordon off any damage before it can propagate.
- *Automating the distribution* system to meet evolving consumer needs. The value of a fully automated distribution system integrated with communication—derives from four basic functionality advantages:
  1. Reduced number and duration of consumer interruptions, fault anticipation, and rapid restoration.
  2. Increased ability to deliver varying levels of reliable, digital-grade power.
  3. Increased functional value for all consumers in terms of metering, billing, energy management, demand control, and security monitoring, among others.
  4. Access to selective consumer services including energy-smart appliances, electricity-market participation, security monitoring, and distributed generation.

  The value of these advantages to consumers, suppliers, and society alike more than justify the needed public/private investment commitment. This transformation

will enable additional innovations in electricity service that are bounded only by our imagination.

- *Transforming the meter* into an EnergyPort (EnergyPort is a service mark of EPRI). EnergyPort is a consumer gateway that allows price signals, decisions, communications, and network intelligence to flow back and forth through the two-way energy/information portal. This will be the linchpin technology that leads to a fully functioning marketplace with consumers responding (through microprocessor agents) to service offerings and price signals. This offers a tool for moving beyond the commodity paradigm of twentieth century electricity service, and quite possibly ushering in a set of new energy/information services as diverse as those in today's telecommunications.
- *Integrating distributed energy resources including intermittent and renewable generation and storage systems*. The smart power delivery system would also be able to seamlessly integrate an array of locally installed, distributed power generation as power system assets. Distributed power sources could be deployed on both the supply and consumer side of the energy/information portal as essential assets dispatching reliability, capacity, and efficiency.
- *Accelerating end-use efficiency*. The growing trend toward digital control can enable sustained improvements in efficiency and productivity for nearly all industrial and commercial operations. Similarly, the growth in end-use energy consuming devices and appliances, networked with system controls, will afford continuous improvements in productivity and efficiency.

Other benefits of the Smart Grid go beyond energy efficiency:

- The Smart Grid will facilitate use of alternative generation that supports energy independence. This is a matter of national security.
- Both cyber-security protection and defense against EMP: Components of the Smart Grid will need to be hardened by design.
- There are likely to be numerous benefits of the Smart Grid that defy quantification. Examples include the flexibility to accommodate new requirements, the ability to accommodate innovative grid technology, and the ability to support innovative regulatory concepts, all without major replacement of existing equipment.
- The flexibility may help avoid future rate increases as new technology or requirements arise, but the exact benefit might not be quantifiable.

Revolutionary developments in both information technology and material science and engineering promise significant improvement in the security, reliability, efficiency, and cost-effectiveness of all critical infrastructures. Steps taken now can ensure that critical infrastructures continue to support population growth and economic growth without environmental harm.

## 2 DIGITAL NETWORK CONTROL: OPERATIONAL SYSTEMS

IT has and will play a critical role in ensuring the reliable transmission and distribution of electricity. Electricity's share of total energy in the world is expected to continue

to grow, as more efficient and intelligent processes are introduced, such as controllers based on power electronics combined with wide-area sensing and management systems for improved performance. In the next two decades, it is envisioned that the electric power grid will move from an electro-mechanically controlled system to one that is electronically controlled.

In this sense, the electrical infrastructure is becoming increasingly intertwined with the IT infrastructure that supports it. Current and future power systems applications for telecommunications include the following:

- surveying overhead transmission circuits and rights-of-way;
- transmitting supervisory control and data acquisition (SCADA) system data (usually via telephone circuits);
- measuring overhead conductor sag;
- measuring phasors (using a precise timing signal derived from the GPS to time-lag measurements of AC signals);
- fitting sine waves to AC signals, and determining magnitude and phase of v(t), i(t) in remote locations;
- enhancing situational awareness by generating real-time pictures of system states and real-time power flow as well as real-time estimation of the systems' state and topology;
- using data from LEO satellites for faster-response control (more than 100 times less delay than High Earth Orbit (HEO) satellites) and connecting to existing parallel data stream facilities (effectively a high speed global RS-232 channel).

The technologies support the operational control of electrical networks, ranging from energy management systems (EMS) to remote field devices. Critical systems include those described below.

*EMS.* The objective of the EMS is to manage production, purchase, transmission, distribution, and sale of electrical energy in the power system at a minimal cost with respect to safety and reliability. Management of the real-time operation of an electric power system is a complex task requiring interaction of human operators, computer systems, communications networks, and real-time data-gathering devices in power plants and substations. An EMS consists of computers, display devices, software, communication channels and remote terminal units that are connected to Remote Terminal Units (RTUs), control actuators, and transducers in power plants and substations. The main tasks it performs is dependent upon generator control and scheduling, network analysis and operator training. Control of generation requires that the EMS maintain system frequency and tie line flows while economically dispatching each generating unit. Management of the transmission network requires that the EMS monitor up to thousands of telemetered values, estimate the electrical state of the network, and inform the operator of the best strategy to handle potential outages that could result in an overload or voltage limits violation. EMSs can have real-time two-way communication links between substations, power plants, independent system operators, and other utility EMSs.

*SCADA system.* A SCADA system supports the operator control of remote (or local) equipment, such as opening or closing a breaker. A SCADA system provides three

critical functions in the operation of an electric power system: data acquisition, supervisory control, and alarm display and control. It consists of one or more computers with appropriate applications software connected by a communications system to a number of RTUs placed at various locations to collect data, perform intelligent control of electrical system devices and report results back to an EMS. SCADAs can also be used for similar applications in natural gas pipeline transmission and distribution applications. A SCADA can have real-time communication links with one or more EMSs and hundreds of substations.

*RTU.* RTUs are special purpose microprocessor-based computers that contain analog to digital converters (ADCs) and digital to analog converters (DACs), digital inputs for status and digital output for control. There are transmission substation RTUs and distribution automation (DA) RTUs. Transmission substation RTUs are deployed at substation and generation facilities where a large number of status and control points are required. DA RTUs are used to control air switches and various compensation capacitor banks (that support voltage) on utility poles, control pad-mounted switches, monitor and automate feeders, monitor and control underground networks, and for various uses in smaller distribution substations. RTUs can be configured and interrogated using telecommunication technologies. They can have hundreds of real-time communication links with other substations, EMS, and power plants.

*Programmable logic controller(PLC).* PLCs have been used extensively in manufacturing and process industries for many years and are now being used to implement relay and control systems in substations. PLCs have extended input/output (I/O) systems similar to transmission substation RTUs. The control outputs can be controlled by software residing in the PLC and via remote commands from a SCADA system. The PLC user can make changes in the software without making any major hardware or software changes. In some applications, PLCs with RTU reporting capability may have advantages over conventional RTUs. PLCs are also used in many power plant and refinery applications. They were originally designed for use in discrete applications like coal handling. They are now being used in continuous control applications such as feedwater control. PLCs can have many real-time communication links inside and outside substations or plants.

*Protective relays.* Protective relays are designed to respond to system faults such as short circuits. When faults occur, the relays must signal the appropriate circuit breakers to trip and isolate the faulted equipment. Distribution system relaying must coordinate with fuses and reclosures for faults while ignoring cold-load pickup, capacitor bank switching, and transformer energization. Transmission line relaying must locate and isolate a fault with sufficient speed to preserve stability, reduce fault damage, and minimize the impact on the power system. Certain types of "smart" protective relays can be configured and interrogated using telecommunication technologies.

*Automated metering.* Automated metering is designed to upload residential and/or commercial gas and/or electric meter data. This data can then be automatically downloaded to a PC or other device and transmitted to a central collection point. With this technology, real-time communication links exist outside the utility infrastructure.

*Plant distributed control systems ( DCSs).* Plant DCSs are plantwide control systems that can be used for control and/or data acquisition. The I/O count can be as high as 20,000 data points or higher. Often, the DCS is used as the plant data highway for communication to/from intelligent field devices, other control systems such as PLCs, RTUs, and even the corporate data network for enterprise resource planning (ERP) applications. The DCS traditionally has used a proprietary operating system. Newer versions are moving toward open systems such as Windows NT and Sun Solaris. DCS technology has been developed with operating efficiency and user configurability as drivers, rather than system security. Additionally, technologies have been developed that allow remote access, usually via PC, to view and potentially reconfigure the operating parameters.

*Field devices.* Examples of field devices are process instrumentation such as pressure and temperature sensor and chemical analyzers. Other standard types of field devices include electric actuators. Intelligent field devices include electronics to enable field configuration, upload of calibration data, and so on. These devices can be configured off-line. They also can have real-time communication links between plant control systems, maintenance management systems, stand-alone PCs, and other devices inside and outside the facility.

## 3 DIGITAL INTERDEPENDENCIES AND SECURITY RISKS

Recognizing the increased interdependence between IT and electricity infrastructures, along with technical and business opportunities, electric power utilities typically own and operate at least parts of their own telecommunications systems which often consist of backbone fiber optic or microwave connecting major substations, with spurs to smaller sites. The energy industry has historically operated closed, tightly controlled networks. Deregulation and the resulting commercial influences have placed new information sharing demands on the energy industry. Traditional external entities like suppliers, consumers, regulators, and even competitors now must have access to segments of the network. The definition of the network must be expanded to include the external wide-area network connections for these external entities. This greatly increases the security risk to other functional segments of the internal network that must be protected from external connections. This is true whether a private network or the Internet is used to support the external wide-area network.

The external entities already have connections to the Internet and as such the Internet can provide the backbone for the External Wide-Area Network. Duplicating this backbone to create a private network requires not only large up front start up costs, but also ongoing maintenance costs and potentially higher individual transaction costs than using the Internet.

Information systems and on-line data processing tools include: the Open-Access Same-time Information System (OASIS), which is now in operation over the Internet; and Transfer Capability Evaluation (TRACE) software, which determines the total transfer capability for each transmission path posted on the OASIS network, while taking into account thermal, voltage, and interface limits.

Increased use of electronic automation raises issues regarding adequacy of operational security: (i) reduced personnel at remote sites makes them more vulnerable to hostile threats; (ii) interconnection of automation and control systems with public data networks

makes them accessible to individuals and organizations, from any worldwide location using an inexpensive computer and a modem; (iii) use of networked electronic systems for metering, scheduling, trading or e-commerce imposes numerous financial risks.

Utility telecommunications often include several media and diversified communications networks which in part provide redundancy; these range from dedicated fiber-optic cables, digital and analog microwave, and VSAT satellite to power line carrier technology as well as the use of multiple address radio, spread spectrum radio, trunked mobile radio, and cellular digital packet data. Security of the cyber and communication networks now used by businesses is fundamental to the reliable operation of the grid; as power systems start to rely more heavily on computerized communications and control, system security has become increasingly dependent on protecting the integrity of the associated information systems. Part of the problem is that existing control systems, which were originally designed for use with proprietary, stand-alone communications networks, were later connected to the Internet (because of its productivity advantages and lower costs), but without adding the technology needed to make them secure. Communication of critical business information and controlled sharing of that information are essential parts of all business operations and processes.

If the deregulation of the energy industry resumes, information security will become more important. Energy-related industries will have to balance what appear to be mutually exclusive goals of operating system flexibility with the need for security. Key electric energy operational systems depend on real-time communication links both internal and external to the enterprise. The functional diversity of these organizations has resulted in a need for these key systems to be designed with a focus on open systems that are user configurable to enable integration with other systems both internal and external to the enterprise. In many cases, these systems can be reconfigured for security using telecommunication technologies and in nearly all cases the systems dynamically exchange data in real time. Power plant DCS systems produce information necessary for dispatch and control. This requires real-time information flow between the power plant and the utility's control center, system dispatch center, regulatory authorities, and so on. A power plant operating as part of a large wholesale power network may have links to an independent system operator, a power pool, and so on. As the generation business moves more and more into market-driven competitive operation, both data integrity and confidentiality will become major concerns for the operating organizations.

Any telecommunication link which is even partially outside the control of the organization owning and operating power plants, SCADA systems or EMSs represents a potentially insecure pathway into business operations and to the grid itself. The interdependency analysis done by most companies during Y2K preparations have both identified these links and the systems' vulnerability to their failures. Thus, they provide an excellent reference point for a cyber-vulnerability analysis.

In particular, monitoring and control of the overall grid system is a major challenge. Existing communication and information system architectures lack coordination among various operational components, which usually is the cause for the unchecked development of problems and delayed system restoration. Like any complex dynamic infrastructure system, the electricity grid has many layers and is vulnerable to many different types of disturbances. While strong centralized control is essential to reliable operations, this requires multiple, high data-rate, two-way communication links, a powerful central computing facility, and an elaborate operations control center, all of which are especially vulnerable when they are needed most—during serious system stresses or

power disruptions. For deeper protection, intelligent distributed control is also required; this would enable parts of the network to remain operational and even automatically reconfigure in the event of local failures or threats of failures.

Distributed control capability is becoming available in next-generation integrated sensors that are equipped with two-way communication capability and support "intelligent agent" functions—not just sensing, but data assessment, adaptive learning, decision-making, and actuation. The development of IEDs that combine sensors, telecommunication units, computers, and actuators will allow highly automated adjustments to be made at many points on the system and protect substantially against cascading failures. The use of distributed intelligent agents also opens the door to the development of a self-healing power grid that responds adaptively to counteract disturbances at the site of their occurrence.

Intelligent sensors will be capable of gathering a wide range of operating data, including time-stamped measurements of voltage, current, frequency, phase angle, and harmonics. This information, that provides input for distributed control, can also be integrated into a real-time system-wide database and coupled with analysis tools that perform dynamic monitoring, state estimation, disturbance analysis, and contingency assessment for the grid as a whole. Unfortunately, simulation-based techniques and mathematical models are presently unable to accurately portray the behavior of interactive networks, whose dynamics can be highly nonlinear. Fine-tuning existing models with real-world input from distributed sensors may offer improvements, but substantial progress will require the formulation of new models.

SCADA and EMS system operations are critically dependent on the telecommunication links that gather data from geographically dispersed sources and transmit operational and control instructions to geographically dispersed facilities. In the North American grid, these telecommunications links run the gamut from hardwired private networks to multinetwork systems using a combination of private and public networks for both data acquisition and control. Not all of the networks are hardwired. Microwave and satellite communications links are common alternatives in areas where topography and/or distance makes wireless more cost effective. At first glance it would seem that a private, hardwired network that is totally within the control of the owner organization is a secure system. However, even hardwired private networks will be linked to networks outside the control of the company. Typical outside data sources are bulk power customers, major retail customers, bulk power providers, power pools, independent system operating entities, and so on. These connections can offer a multitude of paths into the SCADA and EMS systems. Without proper security design and management, each link is a potential security risk.

Challenges include how to handle network disruptions and delays and manage orbits from the satellite. A major source of complexity is the interdependence of the telecommunication networks and the power grid. Issues range from the highest command and control level to the individual power stations and substations at the middle level, and then to the devices and power equipment at the lowest level.

As the readers of this Handbook know, technology is a two-edged sword. In the case of electricity, the aforementioned discussion reveals one edge (i.e. the risk) to be the extent to which IT introduces a new set of security concerns. The other edge (i.e. the promise) remains because of the substantial increases in capacity and efficiency that are made possible through continuing IT advancements. The following is a sample of the emerging technologies that promise continuing gains in the electricity sector:

- Flexible Alternating Current Transmission System (FACTS) devices, which are high voltage thyristor-based electronic controllers that increase the power capacity of transmission lines and have already been deployed in several high value applications (At peak demand, up to 50% more power can be controlled through existing lines.);
- Unified Power Flow Controller (UPFC), a third-generation FACTS device that uses solid-state electronics to direct power flow from one line to another to reduce overloads and improve reliability;
- Fault Current Limiters (FCLs), which absorb the shock of short circuits for a few cycles to provide adequate time for a breaker to trip (Preliminary results of post–August 14th outage show that FCLs could have served as "shock absorbers" to limit the size of blackouts.);
- Innovations in materials science and processing, including high temperature superconducting (HTS) cables, oxide-power-in-tube technology for HTS wire, and advanced silicon devices and wide-bandgap semiconductors for power electronics;
- Information systems and on-line data processing tools such as the OASIS and TRACE software, which determine total transfer capability for each transmission path posted on the OASIS network, while taking into account thermal, voltage, and interface limits;
- Wide-Area Measurement Systems (WAMS), which integrate advanced sensors with satellite communication and time stamping using GPSs to detect and report angle swings and other transmission system changes;
- Enhanced IT systems for Wide-Area Measurement/Management Systems (WAMS), OASIS, SCADA systems, and EMS;
- Advanced software systems for dynamic security assessment of large/wide-area networks augmented with market/risk assessment; and
- IEDs with security provisions built in by combining sensors, computers, telecommunication units, and actuators; related "intelligent agent" functions such as assessment, decision, and learning.

However, even if most of the above technologies are developed and deployed, there is still a major management challenge in making such a complex network perform reliably with security. These issues are taken up next.

## 4 MANAGEMENT

*Human performance.* Infrastructures are systems with "humans in the loop". This is indeed the case for electricity networks. Several key human resources issues arise in bringing IT to improve the performance of electric power. The first is operator experience. The second is retaining professionals in the field of electric power engineering. The third is how users and consumers can interface with IT-enabled electric power systems.

*Operator training.* Several root causes of the August 14th outage point to lack of operators' situational awareness and coordination. IT has a key role to play in the optimization of operator interfaces and other human factor issues. Basically, the problem is finding the most effective way for machines and humans to work together, and the data glut and maintaining operator attention is largely at the center

of the problem. Good operator interfaces provide adequate visualization of the state of the system, and they should be designed so that the user can remain tuned in to many different factors while giving active attention to only a few.

Much of the answer is simply a matter of how information is packaged for viewing. IT innovations are expected to have applications in personnel training and optimization of human performance, for example, through the use of virtual reality for training, for maintenance or rapid repair work, especially, those involving hazardous situations. Voice recognition is another technology expected to come into broad use over the next decade; replacement of keyboarding with voice-based input capability could greatly streamline and simplify human interaction with computers and other electronic control equipment.

Since humans interact with these infrastructures as managers, operators, and users, human performance plays an important role in their efficiency and security. In many complex networks, human participants themselves are both the most susceptible to failure and the most adaptable in the management of recovery. Modeling and simulating these networks, especially, their economic and financial aspects, will require modeling the bounded rationality of actual human thinking, unlike that of a hypothetical "expert" human as in most applications of AI. Even more directly, most of these networks require some human intervention for their routine control and especially, when they are exhibiting anomalous behavior that may suggest actual or incipient failure.

*Retaining a trained workforce.* A growing concern related to the human network is the erosion of technical knowledge within the power industry. To a large extent this is a matter of the retirement of seasoned power engineers, exacerbated by recent downsizing and reductions of in-house workforce. These key employees take their knowledge with them when they go. It will take a long time to recruit replacements. A second related issue is that new engineers are not entering the field rapidly enough to replace retirees. The average power engineer's age has increased significantly over the last two decades. A serious shortage of power engineers is developing, and is expected to continue for several decades.

*Users.* Operators and maintenance personnel are obviously "inside" these networks and can have direct, real-time effects on them. But users of a telecommunication, transportation, electric power or pipeline system also affect the behavior of those systems, often without conscious intent. The amounts, and often nature, of demands put on the network can be the immediate cause of conflict, diminished performance, and even collapse. Reflected harmonics from one user's machinery degrade power quality for all. Long transmissions from a few users create Internet congestion. Simultaneous, lawn watering drops everyone's water pressure. No one is "outside" the infrastructure.

Given that there is some automatic way to detect actual or immanent local failures, the obvious next step is to warn the operators. Unfortunately, the operators are usually busy with other tasks, sometimes even responding to previous warnings. In the worst case, detected failure sets off a multitude of almost simultaneous alarms as it begins to cascade through the system, and, before the operators can determine the real source of the problem, the whole network has shut itself down automatically.

Unfortunately, humans have cognitive limitations that can cause them to make serious mistakes when they are interrupted. In recent years, a number of systems have

been designed that allow users to delegate tasks to intelligent software assistants ("softbots") that operate in the background, handling routine tasks and informing the operators in accordance with some protocol that establishes the level of their delegated authority to act independently. In this arrangement, the operator becomes a supervisor, who must either cede almost all authority to subordinates or be subject to interruption by them. At present, we have very limited understanding of how to design user interfaces to accommodate interruption.

*Information security.* The electric power industry traditionally has been a vertically integrated industry that in some cases operated in pseudo-monopolistic fashion. However, the industry is currently undergoing restructuring, which frequently results in a break-up of the vertical structure. Additionally, there has been a significant move on the part of the control system suppliers to electric and petrochemical industries toward open, user-configurable systems utilizing real-time communications. With a vertical structure, local and wide-area networks were sufficient to maintain a reasonably secure data network. However, deregulation and new networking technologies are making secure communications more important, and more difficult to develop and maintain.

Information security is concerned with the relationships between people and information. In these relationships, people are owners, custodians, creators, readers, modifiers, certifiers, or even subjects of the information. It follows then that the information itself is the object of various actions by people—creation, destruction, reading, modification, and certification. Information security is concerned with first defining appropriate relationships between people as actors and information resources as objects; these relationships are usually defined as a set of rules defining permitted actions. Not all threats come from outside the organization nor are all threats malicious.

Information security is also concerned with controlling the relationships between people and information so that information is managed according to well-defined rules. Some human agent or institutional agency of authority is usually charged with creating, communicating, applying, monitoring, and enforcing these information security rules. Examples of contemporary information security rules are: rules for handling government classified documents; rules for ensuring client-attorney privilege or privacy of shared information; rules followed by corporate accountants and checked by financial auditors; and rules for ensuring accuracy and completeness of patients' health records. Generally, these rules define information security controls based on properties of special classes of information; these properties fall into three broad categories: confidentiality of sensitive information; integrity and authenticity of critical information; and availability of necessary information. These principles need to be applied to the management of electricity systems, including the operators and managers of these systems.

*Complex system failure.* Beyond the human dimension, there is a strategic need to understand the societal consequences of infrastructure failure risks along with benefits of various tiers of increased reliability. From an infrastructure interdependency perspective, power, telecommunications, banking and finance, transportation and distribution, infrastructures are becoming more and more congested, and are increasingly vulnerable to failures cascading through and between them. A key concern is the avoidance of widespread network failure because of cascading and

interactive effects. Moreover, interdependence is only one of the several characteristics that challenge the control and reliable operation of these networks. Other factors that place increased stress on the power grid include dependencies on adjacent power grids (increasing because of deregulation), telecommunications, markets, and computer networks. Furthermore, reliable electric service is critically dependent on the whole grid's ability to respond to changed conditions instantaneously.

Prior to the tragic events of September 11th, the US President's Commission on Critical Infrastructure Protection in 1997 highlighted growing concern (CIAO 1997). It noted the damaging and dangerous ways cascading failures could unpredictably affect the economy, security, and health of citizens. Secure and reliable operation of these systems is fundamental to our economy, security and quality of life, as noted by the President's Commission on Critical Infrastructure Protection Report published in October 1997 and the subsequent Presidential Directive 63 on Critical Infrastructure protection, issued on May 22, 1998.

Secure and reliable operation of critical infrastructures poses significant theoretical and practical challenges in analysis, modeling, simulation, prediction, control, and optimization. To address these challenges, a research initiative—the EPRI/DOD CIN/SI—was undertaken during 1998–2001 to enable critical infrastructures to adapt to a broad array of potential disturbances, including terrorist attacks, natural disasters, and equipment failures.

The CIN/SI overcame the long-standing problems of complexity, analysis, and management for large interconnected systems—and systems of systems—by opening up new concepts and techniques for the strategic management of this infrastructure system. Dynamical systems, statistical physics, information and communication science, and computational complexity were extended to provide practical tools to measure and model the power grid, cell phone networks, Internet, and other complex systems. For the first time, global dynamics for such systems can be understood fundamentally.

## 5 NEXT STEPS

Funding and sustaining innovations, such as the smart self-healing grid, remain a challenge as utilities must meet many competing demands on precious resources while trying to be responsive to their stakeholders, who tend to limit R&D investments to immediate applications and short-term return on investment. In addition, utilities have little incentive to invest in the longer term. For regulated investor-owned utilities there is added pressure caused by Wall Street to increase dividends.

Several reports and studies have estimated that for existing technologies to evolve and for the innovative technologies to be realized, a sustained annual research and development investment of $10 billion is required. However, the current level of R&D funding in the electric industry is at an all-time low. The investment rates for the electricity sector are the lowest rates of any major industrial sector with the exception of the pulp and paper industry. The electricity sector invests at most only a few tenths of a percent of sales in research—this in contrast to fields such as electronics and pharmaceuticals in which R&D investment rates have been running between 8% and 12% of net sales—and all of these industry sectors fundamentally depend on reliable electricity.

A balanced, cost-effective approach to investments and use of technology can make a sizable difference in mitigating the risk.

## ACKNOWLEDGMENTS

I developed most of the context and many of the findings presented here while I was at the EPRI in Palo Alto (during 1998–2003), and for the Galvin Electricity Initiative (during 2005–2006). I gratefully acknowledge the feedback from Mr John Voeller (the editor of this series). The support and feedback from numerous colleagues at EPRI, universities, industry, national laboratories, and government agencies with funding from EPRI, NSF, and the ORNL is gratefully acknowledged.

## 1 INTRODUCTION

Security is of vital interest to all participants in the control system sphere of interest. This includes governmental agencies, vendors, users, and consultants, as well as industry advisory groups. The article explores some of the efforts being used by these participants to identify and mitigate security exposures using risk management methodologies, technology tools, and standards.

## 2 STANDARDS, GUIDELINES, AND BEST PRACTICES

Standardization has a major impact on each of us, yet most of us do not understand what it means or how it affects our lives. Standardization is the process of establishing a technical benchmark that may be defined by written documents that lay out the criteria for the standardized measure. This technical benchmark document may take one of several forms, depending on its level of acceptance, and can be described as a set of criteria some of which may be mandatory, voluntary guidelines, and/or best practices.

## 3 STANDARDS

Standards are an important part of the total effort to achieve control system cyber security. As rules or requirements that define accepted operational criteria, they provide a measure of consistency and a means for quantifying quality and reliability. Standards provide a performance framework for hardware and software vendors who build the components for a control system. Standards provide a similar service for the personnel who operate and maintain the control system, once it becomes operational. Standards are most effective when the engineers and operators using the standards understand the capabilities and limitations of each standard and its history.

A standard, as defined by the National Standards Policy Advisory Committee is:

> "A prescribed set of rules, conditions, or requirements concerning definitions of terms; classification of components; specification of materials, performance, or operations; delineation of procedures; or measurement of quantity and quality in describing materials, products, systems, services, or practices" [1].

Standards are sets of rules or requirements, which define the accepted criteria for a component, procedure, system, and so on. Standards are developed by a consensus of the judgment of volunteers, which pool their knowledge base and experience.

### 3.1 Guidelines

Guidelines are tools that attempt to streamline a process or procedure. They may consist of rules or suggestions that, when applied, may simplify the process or procedure, and provide a level of quality and consistency. Guidelines may be issued by any organization to make the processes more uniform and expectantly, of high quality. By definition, guidelines are not mandatory but attempt to provide a set of knowledge that can be applied [2, 3].

## 4 BEST PRACTICE

*Best practices*, sometimes referred to as *recommended practices*, are a management tool that asserts that there is a technique, method, process, and so on, which is more effective at delivering a particular result than any other. As with standards and guidelines, best practices may consist of a set of good and practical industry practices or suggestions, which, when followed, will produce superior performance. As with guidelines, best practices are not mandatory, unless they become a standard and are imposed by a particular organization as a requirement [4, 5].

### 4.1 Cyber and Control Systems Security Standards in Common Use

The use of cyber security standards (including standards, guidelines, and best practices) can greatly assist in the protection of critical infrastructure by providing requirements, guidelines, and requisite imperatives in the implementation and maintenance of computer-controlled systems. Standards are most effective when the decision-makers, engineers, and operators using the standards understand what each addresses and does not address.

There is a link between cyber vulnerabilities and the standards that are intended to provide mitigation opportunities. For example, standards for equipment design and operation offer direction for vendors to use in bringing usable and compatible products to market, while providing companies the specifications required to select and implement the appropriate equipment and procedures. Most of all, these standards ensure that equipment is operated and maintained efficiently [6].

Standards' organizations are, for the most part, public organizations that have little or no enforcement ability. They rely on educating the users as to the importance of security, and of the potential benefits that standards can add to their operations. Where cyber security standards are implemented, they provide reliable direction toward achieving an acceptable level of cyber security by providing a framework

on which to construct a viable and rational security policy. They also provide an important frame of reference when performing risk analysis of an operating control system.

The cyber security standards issued by these organizations are frequently referred to as either *sector-specific* or *cross-sector* in their focus. Sector-specific standards include standards and associated documents, which address cyber security considerations that are specific to operators within the issuing industry.

Cross-sector standards are developed and issued by organizations whose focus extends across several discrete and dissimilar operating arenas, whose only common interest may be the prevention and mitigation of cyber attack upon their facilities. These standards address security issues that are of universal concern to infrastructure operators, without regard to the particular industry that may be implementing the standard.

Certain of these standards, such as those issued by the Federal Energy Regulatory Commission (FERC) and the Health Insurance Portability and Accountability Act (HIPAA), come from the Federal government and have the driving force of public law. Most others are issued by private and/or public industry organizations, and are dependent upon voluntary compliance.

## 5 MEASURE AND ASSESS SECURITY POSTURE

### 5.1 Risk Assessment Factors

Managing the security risks associated with the industry's growing reliance on control system and information technology (IT) is a continuing challenge. In particular, many private organizations have struggled to find efficient ways to ensure that they fully understand the cyber security risks affecting their operations, and can implement appropriate controls to mitigate these risks. A principal challenge that many companies face is identifying and ranking the cyber and control systems' security risks to their operations, which is the first step in developing and managing an effective security program. Taking this step helps ensure that organizations identify the most significant risks, and determines what actions are appropriate to mitigate them [7].

The General Accounting Office, in its white paper titled, "Information Security Risk Assessment: Practices of Leading Organizations" [8], has identified a set of common critical success factors that are important to the efficient and effective implementation of the organizations' information security risk assessment programs. These factors help ensure that the organizations benefit fully from the expertise and experience of their senior managers and staff, that risk assessments are conducted efficiently, and that the assessment results lead to appropriate remedial actions. The critical risk assessment success factors include the following:

1. Obtain senior management commitment, support, approval, and involvement to ensure that the resources are available to implement the program, and that assessment findings result in implementation of appropriate changes to policies and controls.
2. Designate individuals or groups as focal points to oversee and guide the overall risk assessment processes.

3. Define documented procedures for conducting risk assessments, and develop tools to facilitate and standardize the process.
4. Involve business and technical experts including a variety of individuals from the business unit having expertise in business operations, business processes, security, information resource management, IT, and system operations.
5. Hold business units responsible for initiating and conducting risk assessments, as well as evaluating and implementing the resulting recommendations.
6. Limit the scope of individual assessments by conducting a series of narrower assessments on various individual segments of the business and operations.
7. Document and maintain results so that managers could be held accountable for the decisions made, and a permanent record is established that can be used by auditors for compliance to the security policy [8].

### 5.2 Risk Measurement

The challenge in measuring risk is determining what to measure and how it should be measured. To measure the security posture of a control system, the organization needs to follow a set of rules that focuses the company security goals by applying the risk assessment factors described earlier. When assessing vulnerability, it is worthwhile to be aware of certain qualitative terms. Exposure is about possibility. Risk is about probability. And impact is about consequence. The following equation is sometimes used to express these mathematically: [9]

$$\text{Expected loss} \times \text{threat} \times \text{vulnerability} = \text{exposure} = \text{risk}$$

Exposure measurements can be used as a relative comparison within an environment or across companies. If one can assume that risk is constant for like-sized companies (even if we do not know the number itself), this exposure measure can act as a "risk proxy" to measure the relative difference in risk levels.

The Department of Homeland Security (DHS) under the FY2007 Homeland Security Grant Guidance describes the DHS approach to risk assessment as follows: risk will be evaluated at the federal level using a risk analysis model developed by DHS in conjunction with other federal entities. Risk is defined as the product of three principal variables:

- Threat (T)—the likelihood of an attack occurring.
- Vulnerability and consequence (V&C)—the relative exposure and expected impact of an attack [10].

$$\text{Risk } (R) = T \times V \times C$$

### 5.3 Security Metrics

Metrics and measurement are two vastly different concepts. Measurements are generated by counting, and provide specific views of discrete factors. Metrics, on the other hand, are generated through analysis. They are derived from measurements, to which contextual

information has been added for comparison, to a predetermined baseline, or comparing two or more measurements taken over time [11]. The measure of security policies, processes and products is the much-sought-after solution to this conundrum. Security managers in industry look for a magic formula that calculates risk and effectiveness in reducing risk, but the reality is that security metrics are not that simple. Measuring security is about using common sense. An organization needs to determine what to measure, and to organize the variables in a way that makes them manageable and meaningful. It needs to build repeatable formulas that show the snapshot status of security and how it changes over time.

Truly useful metrics indicate the degree to which goals are being met, and then drive actions taken to improve organizational processes. When applied to control system security performance, the metric is the expression of the state and/or quality of a critical aspect of the control system infrastructure. It is the basis for directing investments to areas of high risk, as well as a forum for communication to stakeholders both inside and outside the organization. Applying regular, repeatable metrics to a security performance initiative can benefit organizations in a number of ways. They:

1. provide a measurement of the effectiveness of controls;
2. identify and target areas for improvement;
3. communicate the effectiveness of risk management programs;
4. drive proper actions in focused areas and extend accountability;
5. provide hard evidence of compliance for internal and external use; and,
6. provide actionable views across the enterprise, lines of business, or specific areas of IT and control systems infrastructures [11].

## 6 CYBER SECURITY THREATS AND VULNERABILITIES

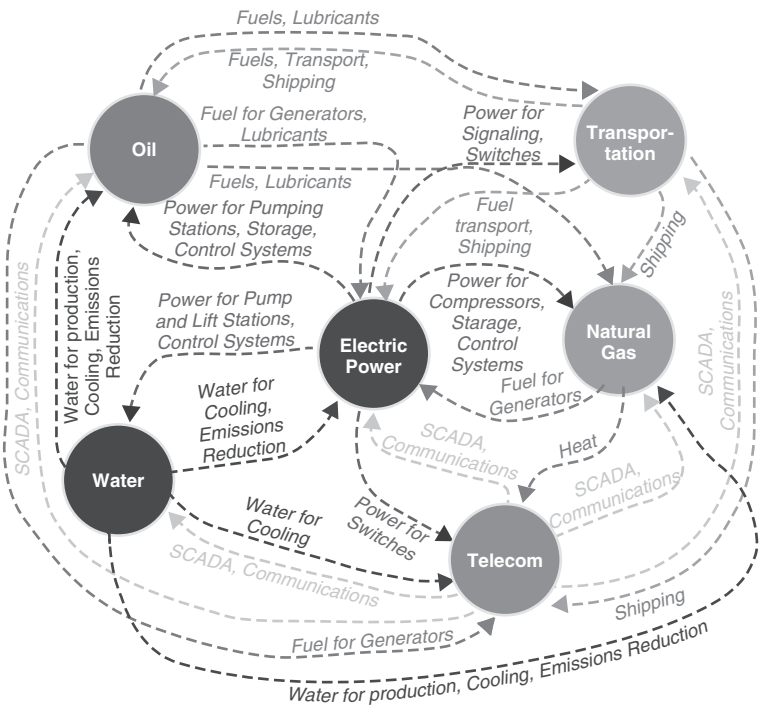
Many companies today have and are conducting security vulnerability analyses to evaluate the risks of physical attacks on their facilities, and many of these facilities have been hardened since 9/11. However, the importance of cyber security for manufacturing and control systems has only recently been recognized, and therefore has not yet been fully addressed by most industrial companies. Appropriate security measures must be taken to avoid events, which could have cascading impacts on other critical infrastructures (Figure 1) [12].

Lesser cyber attacks have and are occurring everyday. Actions are needed now to deal with this threat. Companies must conduct cyber security vulnerability analyses to identify threats to their control and support systems, to determine if vulnerabilities are present, and to evaluate existing countermeasures to determine if they need to be strengthened or new ones implemented. Control systems, and their support systems, are subject to threats from adversaries who may wish to disable or manipulate them by cyber or physical means, or who may want to obtain, corrupt, damage, destroy, or prohibit access to valuable information. The organization should evaluate the risk of these threats in order to decide what protective measures should be taken to protect systems from disruption. The vulnerabilities typically observed in the course of conducting vulnerability assessments are grouped in the following five categories: data, security administration, architecture, network, and platforms. Any given control system will usually exhibit a subset of these vulnerabilities, but may also have some unique additional problems [13]. The

Federal government has played an irreplaceable role in providing support for fundamental, long-term IT research and development (R&D), generating technologies that gave rise to the multibillion-dollar IT industry. The President's Information Technology Advisory Committee (PITAC) review of current federally supported R&D in cyber security finds an imbalance, however, in the current cyber security R&D portfolio. Most support is for short-term, defense-oriented research; there is relatively little support for fundamental research to address the larger security vulnerabilities of the civilian IT infrastructure, which supports defense systems as well.

In the report to the President in 2005, PITAC urged changes in the Federal government's cyber security R&D portfolio to increase federal support for fundamental research in civilian cyber security, intensify federal efforts to promote recruitment and retention of cyber security researchers and students at research universities, provide increased support for the rapid transfer of federally developed cutting-edge cyber security technologies to the private sector, and strengthen the coordination of the Interagency Working Group on Critical Information Infrastructure Protection and integrate it under the Networking and Information Technology Research and Development Program [14]. The Homeland Security Department has teamed with 13 organizations on a 12-month project to secure the process control systems of the nation's oil and gas industries against cyber security threats.

A cyber attack on the control and data systems that operate electric power plants, oil refineries, and gas pipelines, which are pieces of the nation's 18 critical infrastructure



Peerenboom, Fisher, and Whitfield, 2001

**FIGURE 1** Illustrative infrastructure interdependencies.

sectors, could potentially bring the country to a halt. The problem is compounded because private companies control more than 85% of the country's critical infrastructure, leaving the government few avenues to ensure that IT and control systems are secure. The potential costs of an infrastructure attack are significant. The Northeast Blackout on August 14, 2003, left 50 million customers and parts of eight states and Canada without power. According to a report by an electricity consumers research council, the outage cost an estimated $7–10 billion in financial losses; shut down parts of a 2 million barrel-per-day pipeline; and airports in 13 cities, To combat the cyber threats, the government, industry, research labs, security vendors, and process control technology vendors embarked on the project, "Linking the Oil and Gas Industry to Improve Cyber security", to come up with technology that could reduce vulnerabilities in infrastructure and could fix system vulnerabilities. The potential solution to such cyber threats is a strong cyber security posture by the entities that may be vulnerable to such attacks. A major challenge to preserve system protection is that system architectures change, technology changes, and threats change, all of which means that defenses must change.

## 7 CASCADING FAILURE

A cascading failure occurs when a disruption in one infrastructure causes a disruption in a second infrastructure (e.g. the August, 2003, blackout led to communications and water-supply outages, air traffic disruptions, chemical plant shutdowns, and other interdependency-related impacts) [12]. The complexity of multiple infrastructure linkages and the implications of multiple contingency events that may affect the infrastructures are apparent even in the highly simplified representation shown in Figure 1. The security, economic prosperity, and social well being of the nation depend on the reliable functioning of our increasingly complex and interdependent infrastructures. These include energy systems (electric power, oil, and natural gas), telecommunications, water-supply systems, transportation (road, rail, air, and water), banking and finance, and emergency and government services. In the new economy, these interconnected infrastructures have become increasingly fragile and subject to disruptions that can have broad regional, national, and global consequences. A disruption in an infrastructure would be magnified by the codependencies in supervisory control and data acquisition (SCADA) systems. An example might be a power loss that affects telecommunication systems upon which banking transactions rely. Vulnerability to these cascading effects was seen during Hurricanes Katrina and Rita in 2005, where a major American city came to a virtual standstill. As we are now seeing, it will take years to rebuild. Failure nodes are repeatedly created at the intersections of our tightly coupled, highly sophisticated transportation, electric power, and telecommunications systems. These failure potentials are compounded by the infrastructures' reliance on information and control systems' hardware and software. Understanding, analyzing, and sustaining the robustness and resilience of these infrastructures require multiple viewpoints and a broad set of interdisciplinary skills. For example, engineers (civil, electrical, industrial, mechanical, systems, etc.) are needed to understand the technological underpinnings of the infrastructures, as well as the complex physical architectures and dynamic feedback mechanisms that govern their operation and response (e.g. response to stresses and disruptions). Computer scientists, IT specialists, and network/telecommunication experts are needed to understand the electronic and informational (cyber) linkages among the

infrastructures. IT security, information assurance professionals, and control engineers are needed to ensure information and control system security [15].

## 8 LEGACY SYSTEMS

The term *legacy control system* is used variously to refer to old mainframe, dumb-terminal applications from the 1970s and 1980s; client/server systems of the 1990s; and even to first generation web-based business applications developed in the late 1990s [16]. In this section we will refer to legacy systems in the context of the first two examples. Legacy control systems were originally designed to be free standing networks without Internet access. These control systems monitored and controlled critical infrastructure processes. They were operated in an isolated or stand-alone environment where computer systems and devices communicated with each other exclusively, and typically did not communicate or share information with systems not directly connected to the control system network. These control systems typically comprised proprietary hardware, software, and protocols designed specifically for control system operations. Knowledge of these proprietary applications and protocols was limited to a small population. Proprietary control system protocols and data were not readily available to the general population and significant effort and resources would have been required to acquire the proprietary information, understand the control system, discover vulnerabilities in the control system, develop the tools to exploit the identified vulnerabilities, and gain sufficient access to the control system so that vulnerabilities could be exploited to carry out unauthorized or malicious activities. For the reasons presented, in particular because access to control systems was greatly limited, critical infrastructure control system security efforts were primarily focused on protecting control systems from physical attacks. More recently, with the vast IT expansion and the drive toward having information readily available from any location, many previously stand-alone control systems are being transitioned to the "always connected" world, where real-time control system information can be readily and easily accessed remotely by vendors, engineers, maintenance personnel, business managers, and others via corporate networks, the Internet, telephone lines, and various wireless devices.

Legacy systems that have been retrofitted to incorporate Internet accessibility may be especially vulnerable to attack due to the ad hoc manner of their integration with the network. This imperfect fit between the different software applications could generate more vulnerable code aspects than would be found in a single piece of software. It may be possible, for example, through a poorly defined variable, to force a software program to behave in a way not expected by the author. When two programs are brought together, the potential program weaknesses are multiplied. Thus, legacy systems with network access added may be more prone to security flaws and weaknesses than systems that use a single piece of software for both functions [17]. To reduce operational costs and improve performance, control system vendors and critical infrastructure owners and operators have been transitioning from proprietary systems to less expensive standardized technologies, operating systems, and protocols currently prevalent on the Internet. These widely accepted technologies, protocols, and operating systems, such as Ethernet, Internet Protocol, Microsoft Windows, and web technologies, have a large number of known cyber vulnerabilities, and new vulnerabilities are reported on a daily basis. Exploitation tools, malware, and how-to papers are often readily available shortly after the announcement of a new vulnerability. Significant information on control systems is

now publicly available, including design and maintenance documents, technical standards for the component interconnections, and standards for communicating between devices. In addition, control system security concerns are elevated because control systems are typically not up-to-date with the latest security patches, fixes, and best practices due to concerns with taking real-time systems off-line and concerns over making system modifications, which might affect the time sensitive operations of the control system or potentially affect existing agreements with control system vendors or others [18]. Legacy system operators must be aware of the vulnerabilities inherent with upgrading to meet today's networking capabilities, and implement appropriate protection options. Some examples of "best practice" options (that are applicable to all systems, from legacy to state-of-the-art) include: disabling unused ports; encryption; dual authentication; and working with both private sector and government agencies to identify and put into use more robust security measures.

## 9 INTRUSION DETECTION AND RESPONSE TECHNOLOGY

The increasing speed of attacks against IT and control systems highlights a requirement for comparably timely responses. Threats such as malware and scripted exploits often allow a time frame of only a few minutes or even seconds to respond, which effectively eliminates the feasibility of manual intervention and highlights a requirement for automated approaches to provide a solution. However, it can be seen that existing security technologies are often insufficient. For example, although intrusion detection systems (IDS) can be used to identify potential incidents, they have a tendency to produce high volumes of false alarms and consequently cannot be trusted to issue automated responses for fear of disrupting legitimate activity. Intrusion detection has been at the center of intense research in the last decade, owing to the rapid increase of sophisticated attacks on computer systems. Typically, intrusion detection refers to a variety of techniques for detecting attacks in the form of malicious and unauthorized activity. In the event that intrusive behavior is detected, it is desirable to take evasive and/or corrective actions to thwart attacks and ensure safety of the computing environment. Such countermeasures are referred to as *intrusion response*. Although the intrusion response component is often integrated with the IDS, it receives considerably less attention than IDS research, owing to the inherent complexity in developing and deploying responses in an automated fashion. Development of an effective response mechanism for potential intrusions is inherently complex due to the requirement to analyze a number of "unknown" factors in various dimensions: intrusion cause/effect, identification of optimal response, state of the system, maintainability, and so on. As such, it is necessary to have a complete understanding of the problems that need to be addressed for developing a smart and effective response system.

Considerable research has focused on intrusion response specification that addresses the countermeasure steps to sophisticated attacks on the control and computer support systems. For example, the following specifications are being considered as requirements in the development of an ideal intrusion response system:

1. *Automatic.* The volume and the intensity of intrusions today require rapid and automated response. The system must be reliable to run without human intervention. Human supervision often brings a significant delay into intrusion handling; the response system alone should have means to contain incurred damage and

prevent harmful activity. Although complete automation may not be achievable in practice due to presence of novel intractable intrusions, significant reduction of human effort and expert knowledge is desirable.

2. *Proactive.* Modern software systems are built on multiple heterogeneously developed components that have complex interactions with each other. Because of these interactions, intrusions are likely to spread rapidly, causing more damage. A proactive approach to response is the most practical in intrusion containment.
3. *Adaptable.* The presence of multiple components that constitute a software system also results in a dynamic environment owing to the complex interactions between components. As such, intrusive behavior can affect systems in a way that is unpredictable. The intrusion response system should be equipped with means to recognize and react to changes in the dynamic environment.
4. *Cost-sensitive.* Response to intrusions in dynamic and complex systems requires a careful consideration of the trade-offs among cost and benefits factors. A simple basic response action, triggered every time certain symptoms are observed, might be a wasteful effort and may cause more damage [19].

## 10 RESEARCH DIRECTION

Because of the constantly changing threats to control systems, as well as the vulnerabilities of these systems to cyber attack, multiple approaches to security should be undertaken. For one, continued research is needed to develop security policies, guidelines, and standards for control system security. This could include things such as authentication methods and the use of networks. The results of this research should then be incorporated into standards, in order that all stakeholders may benefit from the research. Continued development of strong standards is a key in securing control systems from cyber intrusions.

Another approach to be considered is the use of vulnerability assessments. An organization must be able to conduct a comprehensive vulnerability assessment if it intends to successfully measure the security posture of its control systems. A key step in this process is to learn and apply the seven critical risk assessment success factors listed earlier in the article. These factors are important to the efficient and effective implementation of the organizations' information security risk assessment programs. The Federal government must continue to be in the forefront of programs providing support for fundamental research in civilian cyber security.

Organizations should implement effective security management programs that include consideration of control system security. To measure security posture of the control systems, the organization needs to employ a set of rules, or metrics that quantify its achievement in terms of the company security goals. Vulnerability should be determined in terms of exposure to attack, probability of attack, and consequences of an attack. The goal should always be to identify vulnerabilities and then to implement mitigation strategies. Possible strategies include developing or improving the organization security policy. Adherence to one or more recognized security standard should always be part of organization policy.

Cascading failures can have broad regional, national, and global consequences. Control systems need to be carefully designed to reduce the interdependence of multiple infrastructures, and to mitigate the effects when a failure occurs.

Legacy control systems no longer profit from "security through obscurity" [20]. In fact, those that have been retrofitted to incorporate Internet accessibility may be especially vulnerable to attack, due to imperfect matchups between software applications. Legacy system operators must be aware of the vulnerabilities inherent with upgrading to meet today's networking capabilities, and implement all appropriate protection options.

In order to cope with the speed and frequency of today's cyber attacks, effective intrusion detection and response systems must react in similar rapid fashion. Current research and development efforts focused on new technology and tools to counter such attacks indicate a need for automated, proactive responses, which are adaptable to changing situations and technology, and are cost-effective.

# IMPLICATIONS OF REGULATION ON THE PROTECTION OF CRITICAL INFRASTRUCTURES

REBECCA HAFFENDEN

*Los Alamos National Laboratory, Los Alamos, New Mexico*

## 1 INTRODUCTION

In analyzing the security of a nation's infrastructure facilities, the impact of the regulatory environment on an infrastructure or a facility must also be considered. Laws and regulations that control both the day-to-day operations and emergency response activities for any facility can originate from a variety of sources. Such regulations are promulgated on the basis of very specific legislation enacted in response to public needs, political forces, or particular events. These regulations, although well written and well thought out for their particular purpose, can have unintended impacts on the security of infrastructure facilities and on the interaction between infrastructures (i.e., interdependencies). Consequently, there should be a mandatory review process for proposed legislation and the corresponding regulations to determine if the legislation or regulation could impact security or emergency response requirements and policies at both the federal and state levels, if the regulation could unintentionally result in increasing the vulnerability of the affected facilities/industries or even if other interdependent facilities/industries will be impacted.

## 2 THE REGULATORY PROCESS

In the United States, the general regulatory process starts with the enactment of legislation granting authority to one or more federal agencies to create, implement, and enforce a regulatory program based on the intent and scope of the legislation (the legislative mandate). The federal agency then drafts its proposed regulations pursuant to that authority.

Under the Administrative Procedures Act, the agency must publish the proposed regulation in the Federal Register to allow the public to comment. The federal agency then reviews the proposed regulation in light of the comments received and issues a final rule. The final rule is also published in the Federal Register and after the indicated effective date, it can be implemented and enforced.

In general, regulations are limited to the intent and scope established in the enabling legislation and to the express statutory authority granted to a federal agency.[1] This legislative mandate or statutory authority generally addresses either the specific industry or a specific topic within the jurisdiction of the implementing regulatory agency. For example, the Nuclear Regulatory Commission (NRC) issues regulations pertinent to a specific type of facility, namely, nuclear power plants; it does not issue regulations on the operation of airports. The Environmental Protection Agency (EPA) issues regulations on activities that impact the environment; even though the regulatory program may impact a number of different types of infrastructures or industries, they address only the environmental impact, not the stock issuance requirements of those industries. Therefore, it is likely that proposed industry, facility, or activity specific regulations may only be reviewed for their impact on the industry/topical activities they specifically address and not on their unintentional impact on the security of the affected facilities/industries, the emergency planning that may involve the affected facilities/industries, or the impact on other critical interdependent infrastructures.

A classic example of this conflict is found in the regulatory implementation of Section 112(r) of the Clean Air Act (CAA) [2]. The accidental and sudden release of methyl isocyanate in an industrial accident at the Union Carbide plant in December 1984 in Bhopal, India spurred the study of the risk of accidental chemical releases in the United States. In 1990, Congress enacted Section 112(r) of the CAA to address the threat of catastrophic releases of chemicals that might cause immediate deaths or injuries in surrounding communities. Pursuant to this legislation, EPA promulgated regulations for the prevention and mitigation of accidental releases of extremely hazardous substances. Covered facilities are required to submit to EPA a risk management plan (RMP) describing the source's risk management program. Covered facilities are required to conduct potential off-site consequences analysis (OCA) of hypothetical worst case and alternative accidental release scenarios. Under the original rule, facilities were required to include a brief description of this analysis in the executive summary of their RMPs. The RMPs were required to be made available to the public and the executive summaries were to be posted to the EPA Internet site.

The Federal Bureau of Investigation and other representatives of the law enforcement and intelligence communities raised concerns that releasing the OCA portions of RMPs via Internet would enable individuals anywhere in the world anonymously to search electronically for industrial facilities in the United States to target for purposes of causing an intentional industrial chemical release. In response to those concerns, EPA posted RMPs on the Internet without the OCA results.

However, those OCA sections, and any EPA electronic database created from those sections, were still subject to public release in electronic format pursuant to the Freedom

[1]The interpretation put on the statute by the agency charged with administering it is entitled to deference, [1], but the courts are the final authorities on issues of statutory construction. They must reject administrative constructions of the statute, whether reached by adjudication or by rulemaking, that are inconsistent with the statutory mandate or that frustrate the policy that Congress sought to implement.

of Information Act (FOIA).[2] On August 5, 1999, the Chemical Safety Information, Site Security and Fuels Regulatory Relief Act (CSISSFRRA) was enacted[3] to provide at least a one-year exemption from FOIA for the OCA portions of RMPs and any EPA database created from those portions. As required by the CSISSFRRA, assessments were conducted of both the increased risk of terrorist and other criminal activity that would result from posting OCA information on the Internet and the chemical safety benefits of allowing public access to the information.

Based on the assessments, the EPA and the Department of Justice (DOJ) issued regulations governing access to, and dissemination of, restricted forms of information about the potential off-site consequences of accidental chemical releases from industrial facilities. That regulation, found at 40 Code of Federal Regulations (CFR) 1400, allows the public with access to paper copies of OCA information through at least 50 federal reading rooms distributed across the United States and its territories. It also provides Internet access to the OCA data elements that pose the least serious criminal risk. In addition, the rule authorizes any member of the public will be able to read at federal reading rooms, although not remove or mechanically reproduce, a paper copy of OCA information for up to ten facilities per calendar month located anywhere in the country, without geographical restriction. In addition, any person will be able to view OCA information for facilities located in the jurisdiction of the Local Environmental Protection Committee (LEPC) where the person lives or works and for any additional facilities with a vulnerable zone extending into that LEPC's jurisdiction. This rule was effective from August 4, 2000.

The regulations promulgated by the EPA under Section 112(r), were intended to carry out the legislative mandate to inform communities from the release of hazardous chemicals in their area; however, only after promulgation and implementation was the impact on chemical facility security recognized.

In addition, in the United States, some rule making is accomplished through regulatory negotiation (RegNeg) where the implementing agency works with industry partners, industry associations, or other related entities to formulate regulations in a cooperative atmosphere. These regulations are thus negotiated with a small, narrow group of like partners that may not consider the impact of their decisions on other infrastructures or activities.

Another form of rule making is that conducted pursuant to Office of Management and Budget (OMB) Circular A119 and the National Technology Transfer and Advancement Act [3]. OMB Circular A119 directs federal agencies to use voluntary consensus standards in lieu of government-unique standards except where inconsistent with law or otherwise impractical. Voluntary consensus standards bodies are usually made up of interested parties and have the following attributes: openness, balance of interest, due process, an appeals process, and consensus (or general agreement). Therefore, standards developed or adopted by voluntary consensus standards bodies again would be, if adopted by a federal agency, a regulation made up by a small, narrow group of like partners that may not consider the impacts of the regulation on other aspects of the affected infrastructure or other interdependent infrastructures.

[3]Public Law No. 106–40.

## 3 FEDERAL VERSUS STATE/LOCAL LAW

Many laws and regulations that impact critical infrastructure industries and facilities originate at the federal level. Some regulatory schemes specifically create a process for states to be authorized to implement and enforce the federal regulatory programs within their individual states, for example, the EPA hazardous waste regulations[4] or the Department of Transportation Office of Pipeline Safety pipeline inspection and safety regulations.[5] Under most of the state-delegated authority regulatory schemes, the state may adopt more stringent, but not less stringent, requirements than those in the federal regulations.

However, states may adopt state-specific requirements for critical infrastructure industries and facilities, such as state permitting or siting requirements for federally licensed energy facilities.[6,7] In general, under Article VI of the United States Constitution, the "Supremacy Clause", federal law is the law of the land "anything in the constitutions or laws of any State to the contrary notwithstanding." Therefore, states can legislate/regulate only those areas where federal law does not apply or those areas where the federal law specifically delegates authority to the states. Federal preemption of state law can be (i) expressed or directly stated in the federal legislation or regulation, (ii) implied, where it is inferred from the Congressional intent, as revealed by legislative history or statutory language, (iii) where the federal regulatory program is found to be pervasive and there is nothing left for the states to regulate, often called "occupation of the field", (iv) where the state law frustrates the perceived Congressional policy or program, and/or (v) where there is a direct conflict between the state and the federal regulatory programs. States can also adopt state-specific laws and regulations regarding areas where the federal government has not implemented a regulatory scheme, or where the safety and health of the state citizens is a major factor in regulation [5].

Although the terminology discussed above represents the regulatory process in the United States, most nations have a similar process. For instance, similar to the United States Congress, the Australian Commonwealth Parliament is able to make laws only in relation to a range of specific subjects listed in the Constitution, including defense, external affairs, trade, and immigration, and taxation. The Commonwealth has also legislated by agreement with the states, in areas with Australia-wide application, such as broadcasting, navigation, and food standards. Again, similar to the United States, the Australian Constitution does not limit the subjects on which the states may make laws; however, a state law is invalid to the extent it is inconsistent with a valid Commonwealth law on the same subject [6].

For the European Union (EU), legislation is proposed by the European Commission. Such proposed legislation, depending on the legal basis of the proposal, is either adopted or rejected by the European Council or by the Council and the European Parliament jointly. The legal basis of the proposed legislation also determines whether there should be consultation with other EU institutions or agencies. Once adopted, legislation is applicable

[4]40 Code of Federal Regulations (CFR) 260, et seq.

[5]49 CFR. Parts 190, 191, and 192.

[6]For example, Oregon Revised Statutes, Chapter 469: Energy Conservation Chapter 345-021-0000 et seq., Oregon Administrative Rules; In 2001, the Colorado Legislature approved House Bill 01-1195. The bill provided a legal means for public utilities to appeal local land use decisions on utility siting issues to the Public Utilities Commission.

[7]The regulation of health and safety matters is primarily and historically a matter of local concern [4].

to all EU members and each nation must adopt its own laws and regulations to implement the legislation.

In addition, and often forgotten, local agencies can have local ordinances (e.g. city or county zoning, building, and fire codes) that apply to critical infrastructure assets.[8] Local ordinances (i.e., county or municipal), can also impact infrastructure facilities. As with the federal—state regulatory scheme, local ordinances are either based on delegated powers from the state government or are limited to those areas where local jurisdiction is either statutorily established or historically left to local governments. Examples include property zoning regulations; fire, building, and electrical codes; noise limits; and highway requirements (e.g. traffic patterns, speed limits, and road weight restrictions).

This regulatory scheme results in multiple layers of regulation for each infrastructure and each facility/asset. Each layer (federal, state, or local) has a different jurisdiction and each agency within each layer has its own statutory mandate.

## 4 THE REGULATORY ENVIRONMENT FOR CRITICAL INFRASTRUCTURES

Regulations may provide for agency oversight (e.g. agency inspections, recordkeeping, and reporting requirements), may be economic based (e.g. rate setting or investment incentives) or may involve very specific, detailed prescriptive or performance-based requirements for operational activities or even physical configuration of a facility. Some regulations are specific to a particular industry (e.g. air emissions from publication rotogravure printing facilities[9]), whereas others affect a number of industries and asset types (e.g. Occupational Safety and Health Administration (OSHA) worker safety[10] or American with Disabilities Act (ADA) regulations [7]).

In general, most private industry owners resist any governmental regulation of their activities, including security and vulnerability reduction. There are arguments on both sides of the issue with some, including the Congressional Budget Office, stating businesses would be "inclined to spend less on security than might be appropriate for the nation as a whole if they faced losses from an attack that would be less than the overall losses for society;" [8] whereas others would argue companies are motivated to invest in security in order to protect their own continuity of operations, without which the company has no income/profit, which is in their best interest[11]. Many critical infrastructure facilities and activities were already heavily regulated before the events of September 11, 2001. However, at this time, only a few critical infrastructures have had in-depth governmental security regulations imposed upon them, generally in the transportation, maritime, and nuclear power industries.

However, all 17 critical infrastructures and key resources[12], both governmental and privately owned, are regulated by a variety of overarching health, safety, environmental,

employee, and privacy regulations (i.e., nonsecurity-related regulations) that impact their day-to-day operations as well as their response to emergency situations. Some infrastructures have deregulated such that economic regulatory control and oversight may have lessened, including telecommunications, electric power, natural gas, and oil production, however, these general overarching regulations would still apply to the activities and facilities of these "deregulated" industries. Table 1 shows the major regulatory agencies for each infrastructure, as well as a list of the general areas of jurisdiction.

The commercial sector, which is usually made up of privately owned industrial facilities, commercial buildings, shopping malls, arenas, or stadiums, has few industry-specific security regulations, though they will be subject to worker safety, general zoning, fire protection, and other building safety regulations.

In addition, many infrastructures also must meet independent industry association requirements. For instance, since rate deregulation, energy infrastructures must also meet the requirements of the Independent System Operator (ISO) for marketing energy in interstate and intrastate commerce. In addition, the North American Electric Reliability Council requires its members to meet its regulations for safety and security of the electric power transmission grid. The chemical and hazardous materials infrastructure has numerous independent industry associations that impose member requirements for safety and security, including the American Chemical Council's Responsible Care initiative. These industry self-regulations add another layer of requirements that could impact nonsecurity regulatory requirements and security policy requirements.

As discussed above, most federal, state, and local regulations are established on the basis of implementing each agency's specific statutory scope of authority. Therefore, a critical infrastructure facility may be regulated by various federal, state, and local agencies, each for a separate purpose. In addition, many infrastructures are systems, made up of many assets. For example, the electric power infrastructure has generation facilities (which can be nuclear, fossil fuel, or hydropowered), transmission and distribution facilities, substations, communication networks, marketing activities, personnel, equipment/trucks, and other transportation facilities (e.g. railroads for coal). Regulation by these various local, state, and federal agencies can be additive, duplicative or even conflicting. Figure 1 shows an example of the numerous regulatory interfaces for the electric power infrastructure.

## 5 THE INTERRELATIONSHIP BETWEEN SECURITY AND NONSECURITY-RELATED REGULATIONS

Nonsecurity-related regulations might have an unintentional positive or negative impact on the security of critical infrastructure facilities and assets. Conversely, new security-related regulations may unintentionally impact and even conflict with nonsecurity regulations, rights, or policies.

The security of critical infrastructures/key assets is dependent on many factors. Each type of critical asset has a need for a different type of security depending on the type of threat. Some critical assets are susceptible to physical attack; others to cyber infiltration.

Nonsecurity regulations may impact both the physical security/vulnerability of the regulated facility, the cyber security/vulnerability of information, the facility/industry operational security/vulnerability (e.g. availability of sensitive information about the regulated facility/industry), or the ability of the facility to recover from a catastrophic incident. On the other hand, security-related regulations may impact health and safety requirements,

**TABLE 1 Key Regulatory Authorities by Infrastructure**

| Infrastructure | Regulating Agencies | General Areas of Jurisdiction |

individual or corporate privacy, or interstate commerce. The following section discusses some examples of where regulations may impact the security/vulnerability of critical infrastructure facilities and assets.

### 5.1 Health and Safety Versus Security

An example of safety regulations assisting in protecting critical infrastructure/assets is found in Federal Energy Regulatory Commission (FERC) regulations applied to FERC-regulated dams. Pursuant to FERC regulations, an owner of a project may be required to install and properly maintain any signs, lights, sirens, barriers, or other safety devices necessary to adequately warn and/or protect the public in its use of project lands and waters. Under FERC Guidelines[13] for Public Safety at Hydropower Projects certain physical protections are suggested for dam owners, such as restraining devices, fences, or guards.

Restraining devices include boat restraining barriers, fences, guardrails, natural barriers, trashracks, debris deflector booms, and other similar devices. Under the Guidelines, boat- restraining barriers, as well as warning devices, should be provided at those projects, where boaters and canoeists are exposed to hazardous spillways, tailrace areas, or intake areas. However, boat restraining barriers are not required at those projects where bridges or other structures constitute an adequate physical barrier, or if it can be assured that hazardous flows and conditions do not occur at the projects during time of the year when boaters or canoeists use the reservoirs. Any type of barrier, such as trash booms, debris deflector booms, log booms, and specially designed barriers that have been placed

[13]For Example, City of Chicago Municipal Code, Section 13-196-084, which requires access to the interior of the building and to the second vertical exit from a stairwell.

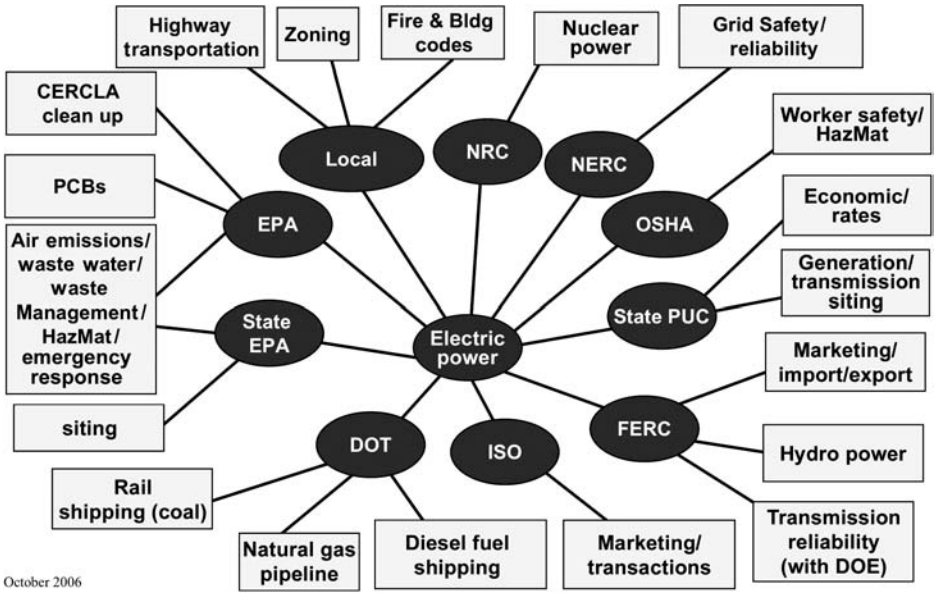

**FIGURE 1** Electric power infrastructure regulatory environment.

upstream of dams may be considered as satisfactory boat restraining barriers. In addition, no-boating zones are often established regardless of physical barriers. These requirements are implemented to protect the public from the hazardous areas and components of hydropower projects, though they also serve to restrict maritime avenues of approach to critical assets at the dam.

However, other nonsecurity-related regulations might adversely impact the security at critical infrastructure facilities/assets. Local health and safety codes frequently require emergency exit stairwell doors remain unlocked, if not all of the time, at least during a fire emergency (e.g. when the fire alarm is activated), allowing access to all floors of the building during evacuation.[14] This, however, also impacts the security of a facility in that, once someone has access to the bottom stairwell door, they have access to the entire facility. Therefore, building security must be adjusted to accommodate the factor that the stairwell doors may not be locked or must be equipped with an electronic mechanism that unlocks all stairwell doors only when the fire alarm is activated.

In another example, Title III of the ADA[10] prohibits discrimination on the basis of disability by public accommodations and requires places of public accommodation and commercial facilities to be designed, constructed, and altered in compliance with the accessibility standards established by this part. The DOJ has promulgated regulations to implement Title III.[15] These regulations require handicapped accessible parking spaces serving a particular building be located on the shortest accessible route of travel from adjacent parking to an accessible entrance and that accessible route cannot have curbs or stairs or other barriers.[16] In addition, passenger loading zones shall provide an access

[14]42 U.S.C. 12181.
[10]28 CFR Part 36.
[15]28 CFR Part 36, Appendix A, Section 4.3 and 4.6.
[16]49 CFR Part 171 and 172.

aisle at least 60 in. (1525 mm) wide and 20 ft (6100 mm) long adjacent and parallel to the vehicle pull-up space and if there are curbs between the access aisle and the vehicle pull-up space, then a curb ramp must be provided. Generally, at public entrances to facilities where there are large gatherings of people (e.g. stadiums, arenas, shopping malls, or convention centers), security policy would require barriers to protect populated main entrances from speeding vehicle-borne improvised explosive devices (VBIEDs). Similarly, security policy would limit parking near public buildings within designated blast effect distances. However, such requirements could impact the accessibility of the facility to those protected under the ADA.

### 5.2 Public Availability of Information Versus Security

Federal DOT regulations require placards to be placed on all shipments of hazardous materials, based on the type and quantity of material in the vehicle/container [9]. There are two placarding hazard classes. One requires placards be displayed to identify any quantity of material in the vehicle/container and the other to identify only when the quantity of material is over 1001 pounds. The first class includes high explosives, poison gas, dangerous when wet material, some organic peroxides, poison inhalation material and certain radioactive materials. The second includes explosives, flammable and non-flammable gases, flammable and combustible liquids, flammable solids, spontaneously combustible materials, oxidizers, some organic peroxides, poisons that do not pose an inhalation hazard, and corrosive materials.

The placards are diamond-shaped signs placed on both ends and both sides of trucks, railcars, and intermodal containers that carry hazardous materials. They are coded by color and contain symbols and numbers that designate the hazard class of the hazardous material that is contained in the vehicle/container. In addition, the placarding requirements are based on the United Nations' (UN) Model Regulation on the Transport of Dangerous Goods, which are widely adopted into national and international regulations.

In addition, these regulations may require other markings such as proper shipping names and material identification numbers, including for shipments of certain bulk commodities and for other shipments of materials that are poisonous by inhalation, marine pollutants, and elevated temperature materials. Under the North American Free Trade Agreement, the United States, Canada, and Mexico have harmonized the hazardous materials placarding requirements of the three countries and jointly published the Emergency Response Guidebook (ERG2004). The Emergency Response Guidebook (ERG2004) is available from the DOT website. It allows anyone to search for a chemical by the material identification number or shipping name with reference to a specific hazard guide. It provides fire or explosive and health hazards, public safety information (e.g. personal protective equipment and evacuation), as well as emergency response for fire, spill/leak, or first aid.

The DOT has recognized that placards, which are important for communicating the presence of hazardous materials, also might aid a terrorist in identifying hazardous materials in transportation. In this case, DOT has studied this interrelationship between the existing federal hazardous materials regulations and transportation security concerns [10]. At this time, DOT has concluded that placards are a critical source of hazard information to emergency response personnel, transport workers, and to regulatory enforcement personnel and play a critical role in the event of a hazardous materials incident. DOT

concluded that there are more appropriate means of enhancing security related to the transportation of hazardous materials rather than entirely replace the placard system.

Having discussed situations where nonsecurity-related regulations may impact security policies or requirements, the following section now discusses some examples where security regulations may unintentionally impact the nonsecurity-related regulations of and requirements at critical infrastructure facilities and assets.

### 5.3 Security Versus Personnel, Health, or Safety

A General Accounting Office (GAO) report found that security directives issued by the Department of Homeland Security Transportation Security Administration (TSA) conflicted with certain safety regulations.[17] After the bombing of passenger rail facilities in Spain, the TSA, on May 20, 2004, issued emergency security directives applicable to the passenger rail industry (effective May 23, 2004). The directives required rail operators to implement a number of security measures, such as conducting frequent inspections of stations, terminals, and other assets, or utilizing canine explosive detection teams, if available. According to TSA officials, because of the need to act quickly, the rule-making process for these security directives did not include a public comment period.

Examples of conflicting provisions include a requirement that the doors of the rail engineer's compartment be locked. However, according to the Federal Railroad Administration (FRA), the provision conflicts with an existing FRA safety regulation calling for these doors to remain unlocked for escape purposes.[18] What follows is as stated by the GAO Report:

> According to FRA, a locked door pursuant to the directive would not allow the locomotive engineer to quickly exit the cab when faced with an impending highway rail grade crossing collision or other accident. In some cases, the door providing access to the locomotive's cab also serves as one of only two primary paths for emergency exit by passengers and is marked as an emergency exit. According to FRA, if these doors are locked pursuant to the directives, they may not be usable in an emergency, and passenger evacuation time could be substantially increased.

Another example raised in the report is the requirement to remove trash receptacles at stations determined by a vulnerability assessment to be at significant risk and only to the extent practical, *except for clear plastic or bomb-resistant containers*. However, the American Public Transportation Association, Association of American Railroads, and some rail operators raised concerns about the feasibility of installing bomb-resistant trash cans in certain rail stations because they could direct the force of a bomb blast upward, possibly causing structural damage in underground or enclosed stations.

### 5.4 Security Versus Privacy

Closed-circuit television (CCTV) systems typically involve a camera or cameras linked to monitors and recording devices. A CCTV system allows the remote cameras to be viewed and operated from a centralized control room. CCTV systems have been installed

[17] 49 CFR 238.235.

[18] Alabama, Arkansas, California, Delaware, Georgia, Hawaii, Kansas, Maine, Michigan, Minnesota, New Hampshire, South Dakota, and Utah.

at many types of infrastructure facilities, including commercial establishments, schools, and places of employment. In addition, more Police departments in the United States now use CCTV to deter and detect crime. Since September 11, 2001, law enforcement has also begun to use CCTV to combat terrorism.

There are currently no specific federal regulations concerning the use of CCTV cameras in public places, such as public streets, parks, and subways, or semipublic, such as schools and workplaces. However, the laws of 13 states [11] expressly prohibit the unauthorized installation or use of cameras in private places without permission of the people photographed or observed.

A private place is defined by the courts as one where a person may reasonably expect to be safe from unauthorized surveillance. The Fourth Amendment protects people from unreasonable searches and seizures. According to the Supreme Court, if the person under surveillance has a reasonable expectation of privacy, the Fourth Amendment applies, and a warrant is generally required to conduct a lawful search. Conversely, if the person under surveillance does not have a reasonable expectation of privacy, the Fourth Amendment does not apply, and no warrant is required for police surveillance [12]. A recent GAO report found that civil liberties advocates have raised issues concerning CCTV's potential impact on individual privacy as well as the potential for inappropriate use of CCTV systems and the mishandling of CCTV images [13]. The Security Industry Association (SIA) and International Association of Chiefs of Police (IACP) and other organizations have developed guidelines for CCTV users that address some of the issues raised by civil liberties advocates through the use of management controls [14]. These include developing written operating protocols, establishing supervision and training requirements, providing for public notification, and requiring periodic audits. These legal issues will continue to be raised as more schools, workplaces, subways, shopping malls, and other areas install and use CCTV to monitor employees and visitors. Fear of criminal prosecution may deter some institutions from installing CCTV for security purposes.

## 6 INTERDEPENDENCY BETWEEN INFRASTRUCTURE REGULATORY SCHEMES

In addition, interdependency of infrastructures adds another layer of overlapping and possibly conflicting regulatory schemes. Interdependency refers to the failure in one asset or infrastructure which can cascade to cause disruption or failure in others, and the combined effect could prompt far-reaching consequences affecting government, the economy, public health and safety, national security, and public confidence [15]. This interdependency impact can affect the performance of other infrastructures under normal and stressed operations, due to disruptions (including coincident events), or during repair and restoration. Interdependencies also change as a function of outage duration, frequency, and other factors. Backup systems or other mitigation mechanisms can reduce interdependency problems. There are also linkages between critical infrastructures and community assets (for response and recovery) (Figure 2).

Interdependency can be

- physical (e.g. material output of one infrastructure used by another),
- cyber (e.g. electronic, informational linkages),
- geographic (e.g. common corridor), and
- logical (e.g. dependency through financial markets).

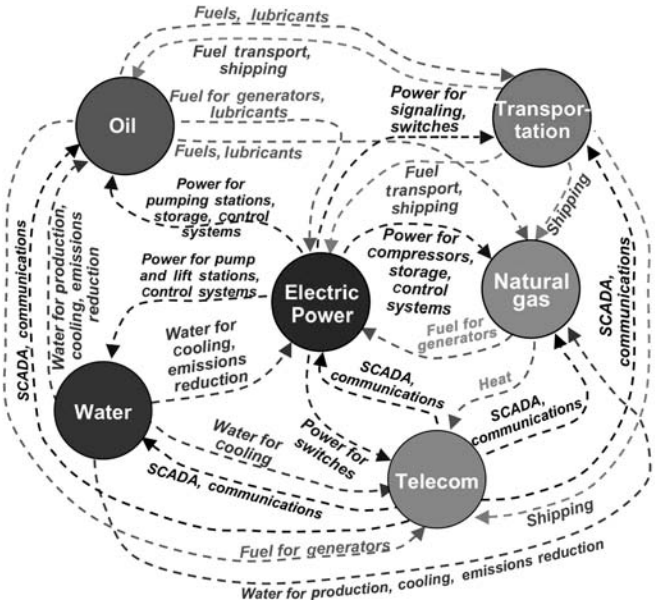

**FIGURE 2** Electric power infrastructure interdependencies.

Interdependency impacts can be caused by the following:

- *Common cause failure.* A disruption of two or more infrastructures at the same time because of a common cause.
- *Cascading failure.* A disruption in one infrastructure causes a disruption in a second infrastructure.
- *Escalating failure.* A disruption in one infrastructure exacerbates a disruption of a second infrastructure.

An example of the impact of regulations on geographic interdependency can be seen in the application of environmental and zoning regulations for siting infrastructure assets. As stated in the Congressional Research Service Report to Congress on Vulnerability of Concentrated Critical Infrastructure the Background and Policy Options are as follows:[19]

> When infrastructure is physically concentrated in a limited geographic area it may be particularly vulnerable to geographic hazards such as natural disasters, epidemics, and certain kinds of terrorist attacks. Whereas a typical geographic disruption is often expected to affect infrastructure in proportion to the size of an affected region, a disruption of concentrated infrastructure could have greatly disproportionate—and national—effects.

Geographic concentrations of national critical infrastructure have developed for multiple reasons—typically some combination of resource proximity, agglomeration economies, scale economies, capital efficiency and federal, state, and local regulations. For instance, state environmental and local zoning or health regulations can limit the siting of industries that use hazardous materials near sensitive areas (e.g. schools)

[19]For example, Massachusetts regulations on Wellhead Protection Zoning and Non-zoning Controls, found at 310 CMR 22.21 (2).

and environmental regulations regulate the operation of facilities handling hazardous materials in groundwater (wellhead) protection zones.[20,21]

Regulatory limitations on the siting of critical infrastructure tend to group infrastructure assets together along roadways and other established corridors or public utility rights-of-way or in specific zoning districts. For example, in many communities, zoning regulations/ordinances allow transmission lines utilizing multiple-legged structures, generating or treatment plants, substations, pumping, or regulator stations to be built only in certain zoning districts. In other cases, utility siting is encouraged only in existing corridors, which forces utilities to share existing corridors.[22] This clustering of infrastructure assets into close proximity can result in escalating failures of these geographically interdependent infrastructures.

An example of cascading failure is the disruption in rail service for coal deliveries to power plants. This would result in determining alternative transportation infrastructure options. However, local road restrictions on load weights could prevent the transportation of coal by truck, particularly given the amount of coal required to replace one coal unit train delivery.[23] Another such example, may be the need to haul heavy replacement transformers by truck rather than the usual specialized rail cars could require a permit or a waiver.

## 7 CONCLUSION

Since September 11, 2001 (9/11), there has been an impetus to evaluate the vulnerabilities of the nation's critical infrastructures and to implement programs to reduce or mitigate those vulnerabilities. Over the last five years, a flurry of legislation, regulatory rule making, policy directives, and federal agency guidance documents have created security-related requirements applicable to some critical infrastructure facilities. Therefore, at this time, vulnerability mitigation activities can take the form of strict governmental security regulation, governmental information-gathering-and-assistance programs aimed at the private sector, governmental policies, and programs for implementation at governmental facilities, industry association developed and implemented security programs (both voluntary and mandatory) for their members (e.g. North American Electric Reliability Council and American Chemical Council), and, finally, security planning, policies, and technology installations by private businesses using in-house personnel and outside security consultants. However, there are also many nonsecurity-related regulations that are promulgated every month that could also impact the security of critical infrastructure assets or impede mitigation or emergency response. These proposed regulations are not reviewed in light of the security laws, regulations, and policies being enacted at the federal level.

[20]For example, Wellesley, Massachusetts Zoning Bylaws Section XIVE, Water Supply Protection Districts.

[21]See, Aberdeen, Maryland Zoning Regulations, Appendix A—Table of Use Regulations or Alameda, California, Chapter XXX—Development Regulations, Article I—Zoning and District Regulations, Section 30-4—District Uses and Regulations. Both regulations limit the construction of transmission lines, generating plants, substations and other infrastructure facilities without approval in some districts.

[22]For example, City of Redmond, Washington, Comprehensive Plan, Utilities Chapter.

[23]The usual unit train has about 100 cars, each holding about 100 tons of coal. The maximum weight for interstate highway trucks is 80,000 pounds gross weight (tractor/tare weight/cargo weight) (29 CFR 658.17). It may be lower on non-interstate (state or country) roads. However, in general, for 40' equipment this would equal a cargo weight of 45,000 depending on tractor weight. Thus, it would take approximately 450 legal interstate truck shipments to make up for one unit train delivery.

Section 603(b) of the Regulatory Flexibility Act of 1980 (5 U.S.C. 601 et seq.) specifies that the contents of the Regulatory Flexibility Analysis (RFA) include the following five requirements:

- description of the reasons why action by the agency is being considered;
- statement of the objectives of, and legal basis for, the final rule;
- description of and, where feasible, an estimate of the number of small entities to which the final rule will apply;
- description of the projected reporting, recordkeeping and other (Page 39, 362) compliance requirements of the rule, including an estimate of the classes of small entities which will be subject to the requirement and the type of professional skills necessary for preparation of the report or record; and
- identification, to the extent practicable, of all relevant Federal rules that may duplicate, overlap, or conflict with the final rule.

Therefore, under the Regulatory Flexibility Act, all proposed federal regulations should be reviewed for conflict with or impact to the security of critical infrastructure facilities and assets. It should be recognized by those conducting the RFA that any regulation could impact not only the security, including physical, cyber, and sensitive information, of critical infrastructures and assets. In fact, it may have an impact on an infrastructure other than the one for which the proposed regulations was intended to regulate.

In addition, proposed state and local regulations, as well as federal policy and guidance documents from a wide variety of federal regulatory agencies, could also impact the security of critical infrastructure facilities and assets. However, there is no requirement for these to be analyzed against existing security regulations or existing knowledge of vulnerability reduction and mitigation programs.

This chapter only presents a few examples of regulations that could impact the security of critical infrastructure assets. A review of existing regulations could also be prudent to determine if there are regulations that could be unintentionally increasing critical infrastructure vulnerabilities or impeding mitigation or emergency planning.

In addition, nonsecurity-related regulations should be reviewed and their impact should be determined before developing infrastructure security/vulnerability assessment methodologies, recommending protective measures, and/or undertaking research and development activities.

# CHARACTERIZING INFRASTRUCTURE FAILURE INTERDEPENDENCIES TO INFORM SYSTEMIC RISK

TIMOTHY MCDANIELS AND STEPHANIE CHANG
*University of British Columbia, Vancouver, BC, Canada*
DOROTHY A. REED
*University of Washington, Seattle, Washington*

## 1 SCIENTIFIC OVERVIEW

Critical infrastructure systems, sometimes referred to as lifelines, provide vital services for societal functions. Until recently, planning and management for provision of these

services has focused on individual infrastructure systems. Yet, analysts, planners, and decision makers increasingly recognize that these systems are highly interconnected and mutually interdependent in a number of ways [1, 2]. For example, the US government established the National Infrastructure Simulation and Analysis Center to examine infrastructure interdependencies through modeling and simulation [3].

Infrastructure systems have become more congested and thus increasingly vulnerable to failures due to interactions within and between systems. The electrical power delivery system is a prime example. It has increased risk of large-scale failures, due to increasing demands on the system that have not been met by a corresponding increase in capacity [4]. Major power outages, affecting 1 million or more people, occur about every 4 months on an average in the United States [3]. This research examines infrastructure interdependencies by focusing on major outages in the electrical system and the effects these outages have on other infrastructures. Extreme events, as defined by the National Science Foundation, are typified by nonlinear responses, low probabilities, high consequences, and the potential for systems interaction that leads to catastrophic losses [5].

Models of outage impacts in which the power delivery system is treated as an individual civil infrastructure system are common. Recently, new conceptual models and simulation approaches have been developed as a means of representing complex, interconnected systems. Examples include the infrastructure risk analysis model [6], hierarchical holographic modeling [7], and agent-based simulation [8]. Additionally, models that integrate civil engineering, electrical engineering, and social science dimensions of infrastructure failures are becoming more common [4, 9, 10].

We employ an empirical approach to understand infrastructure interdependencies, which we refer to as *infrastructure failure interdependencies* (IFI). We define IFIs as failures in interdependent infrastructure systems, which are due to an initial infrastructure failure stemming from an extreme event. When major power outages affect other infrastructures, the interdependencies among the systems prolong and greatly exacerbate the consequences of the initial outage. Planning to address extreme events should take into account these interdependencies because they are the pathways through which indirect impacts of a major outage ripple through societal interactions and economic activity. As framed at present, ours is not a predictive model but rather an *ex post* risk analysis approach derived from observation of actual events. This model can be used to help clarify IFI patterns. Such information is important for setting priorities about potential ways to mitigate the likelihood and the consequences of these infrastructure interactions.

The next section outlines relevant concepts and presents a framework for characterizing the nature, extent, and severity of IFIs. This framework is applied in Section 3 to IFIs occurring in two extreme outage events, the August 2003 blackout and the 1998 ice storm, both of which affected northeastern North America. Section 4 discusses the implications of this analysis and a conclusion is reached in Section 5.

## 2 CONCEPTS AND FRAMEWORK

### 2.1 Partitioning Patterns and Consequences

Haimes and his colleagues have addressed fundamental aspects of the analysis of extreme events and interdependent systems. Their approach recognizes the pitfalls of simple

expected value calculations as a means of characterizing the implications of extreme events within an overall distribution for a given random variable [11]. Their work on the *conditional* expected value (e.g. conditional on exceeding some threshold value) (e.g. [12, 13]) helps focus the attention of decision makers and analysts on the tails of a probability distribution.

This work is similar in spirit to the approach of Haimes and his colleagues, by partitioning both patterns of occurrence and consequences, but with a different emphasis. Here we deal with a *vector* of events, which are all the potential IFIs (defined above) that could arise, given an extreme event occurrence within a given system of infrastructure systems. This approach partitions a vector defining all specific kinds of IFIs, by considering their patterns of occurrence, given that an extreme event to trigger IFIs has occurred. It also partitions consequences, by considering the consequences of a vector containing each specific kind of IFI, separate from the direct consequences of the initial extreme event. In this respect, the approach here also partitions the patterns and consequences in time. It is an approach that is effectively *ex post*, conditional on the occurrence of an extreme event.

### 2.2 A Matrix of Infrastructure Failure Relationships

Haimes and Jiang [14] developed a Leontief-based model of risk in interconnected infrastructure systems. Their risk measure is cast as the *risk of inoperability* of a given infrastructure system, which is the product of the probability and degree (percentage) of inoperability for that system. They provide a model definition, drawing on what is termed the $\boldsymbol{A}$ matrix in input–output analysis, cast in terms of inoperability or failure relationships among infrastructure systems, rather than economic interdependencies as the Leontief work. In this article, we proceed in the spirit of the Haimes and Jiang framework, with somewhat different terminology, notation, and emphasis.

We adopt the following definitions: $\mathbf{X}$ is defined as an overall system of interdependent, nonredundant infrastructure systems $X_i$, where $i = 1, 2, 3 \ldots, n$. $\mathbf{X}$ could be defined for spatial or physical units ranging from a building to a neighborhood, city, region, nation, or even a continent, depending on the scale of interest. Systems $X_i$ and $X_j$ within $\mathbf{X}$ have an interdependent relationship defined as $\mathrm{A}_{ij}$, which characterizes the extent to which a failure of operability in $X_i$ could lead to operability failures in $X_j$. An operability failure $C$ could render the system $X_i$ completely or partially inoperable, as in Haimes and Jiang [14]. An $\mathrm{IFI}_{ij}$ is a specific failure event $C\ (X_i)$ within a specific infrastructure system $X_i$, given a specific failure of a different infrastructure system $C(X_j)$ where both $X_i$ and $X_j$ are within $\mathbf{X}$. The matrix $\mathbf{C}$ contains all the specific IFI events $C(X_i)$ that could arise within a defined system of infrastructure systems $\mathbf{X}$, given that the initial extreme event triggers opportunities for the $\mathrm{IFI}_{ij}$ events in $\mathbf{C}$. The dimensions of $\mathbf{C}$ include the specific system that fails and the degree of impairment of the functions of the system.

### 2.3 Event Patterns as Ex Post Risk Analysis

Risk is sometimes defined as a triplet of conditions: what could go wrong, how likely it is to go wrong, and the consequences if it does go wrong [15, 16]. Here we add an additional initiating event $C(X_j)$, which has already gone wrong, as the conditional basis for examining this triplet approach to define risk of IFI. We use patterns of events to explore the nature of $C(X_j)|C(X_j)$. Characterizing probabilities in terms

of $P(C(X_i)|C(X_j))$ would require data from (i) databases to characterize the relative frequency of $P(C(X_i)|C(X_j)$; (ii) expert judgments informed by these databases; or (iii) simulation efforts again informed by such databases. Yet, to our knowledge, the efforts discussed here are among the first to empirically examine such interactions. Hence, we provide an early step toward characterizing such probabilities in future studies by exploring the patterns of these $\mathrm{IFI}_{ij}$ events in specific contexts and their broad social consequences. In effect, we use these patterns as a basis for characterizing event patterns to help inform planning. This approach characterizes IFIs in terms of an *ex post* version of systematic risk analysis.

### 2.4 A Framework for Characterizing IFIs

We discuss this framework in terms of infrastructure systems $X_i$ that could be affected due to interrelationships $\mathrm{A}_{ij}$, given that a large scale failure $C(X_e)$ in the electrical system $X_{(e)}$ has occurred. This electrical system failure could be the result of an extreme event involving equipment failure within the electrical system, as in the case of the August 2003 blackout that affected northeastern North America. It could also be the effect of an extreme event outside the electrical system such as the ice storm in Quebec in 1998. The framework will be applied to these outages in the next section.

The basis for this framework is the observation that an IFI arising from an outage leads to certain societal consequences. The framework is thus divided into three sections characterizing the outage itself, the IFIs resulting from the outage, and the consequences of those IFIs as shown in Table 1. The outage is characterized by date, a description of the event, whether the initiating event was internal or external (to the electrical system), the spatial extent and duration of the event, and the weather conditions and temperature at the time of the event. This information remains constant for any one event. For example, the Northeast blackout is characterized as beginning on August 14, 2003, initiated by an event internal to the power system. Because it affected both the United States and Canada, the spatial extent is considered to be international. The blackout lasted for days in some areas and the weather conditions were moderate, though the temperature was hot. In contrast, the 1998 ice storm occurred in winter with extreme weather conditions causing the blackout. The initiating event in this case is deemed to be external to the power system; in some locales, the system was out for weeks (Also, a storm is a "continuous" event that lasts a minimum of hours, possibly days, or weeks.).

The second part of our framework characterizes the infrastructure failure interactions. The values associated with this part of the framework, many of which are drawn from key concepts in the work of Peerenboom et al. [17], Nojima and Kameda [18], and Yao et al. [19], are shown in Table 2. The four interdependency characteristics—physical, cyber, geographic, and logical—are discussed by Peerenboom et al. [17]. Human actions play a particular role in interdependencies categorized as logical. The IFI types *cascading* and *escalating* also come from their work, as well as the characteristics' *complexity*, *operational state*, and *adaptive potential*. The research of Nojima and Kameda in lifeline interactions in the Kobe earthquake yields the IFI types, *compound damage propagation* and *restoration*. Yao et al. [19] use multiple earthquakes to develop their classification of lifeline interactions, containing all of the categories used by the other two groups, but with different names. In addition, they include a category called *substitute interaction* or *substitutive* in our framework.

Rinaldi et al. [9] distinguish between dependency and interdependency, where dependency is a unidirectional relationship and interdependency is a bidirectional relationship

**TABLE 1 Infrastructure Failure Interdependencies**

| Characteristic | Values | Explanation |
|---|---|---|
| Impacted system | Building support, business, education, emergency services, finance, food supply, government, healthcare, telecommunications, transportation, utilities | The infrastructure systems |
| Specific system | *Various* | A subdivision of the impacted system |
| Description | *Various* | A brief summary of the impact on the system |
| Types of interdependency | Physical | The system requires electricity to operate |
| | Geographic | The system is colocated with electrical infrastructure |
| | Cyber | The system is linked to the electrical system electronically or through information sharing |
| | Logical | The system depends on the electrical system in a way that is not physical, cyber, or geographic |
| Types of IFI | Cascading | The disruption of the power system directly causes the disruption in the impacted system |
| | Escalating | The disruption of the power system exacerbates an already-existing disruption in the impacted system, increasing the severity or outage time |
| | Restoration | The power outage hampers the restoration of the impacted system |
| | Compound damage propagation | The power system disruption leads to a disruption that then causes serious damage in the impacted system |
| | Substitutive | A system is disrupted due to demands placed on it to substitute for the power system |
| Order | Direct | The IFI is a direct result of the power outage |
| | Second order | The power outage is once removed as the cause of the system disruption |
| | Higher order | The power outage is twice or more removed as the cause of the system disruption |
| System failure leading to this effect | See impacted systems' list | Electrical in the case of direct order events; the system that caused the disruption in the impacted system for second- and higher order events |
| Complexity | Linear | Expected and familiar interactions, often intended by design |

**TABLE 1 (*Continued*)**

| Characteristic | Values | Explanation |
|---|---|---|
| | Complex | Unplanned or unexpected sequences of events |
| Feedback | Yes | The impacted system affects the power system |
| | No | The impacted system does not affect the power system |
| Operational state | At capacity | The impacted system was operating at 100% when the power outage occurred |
| | Near capacity | The impacted system was operating above 90% when the power outage occurred |
| | Below capacity | The impacted system was operating at 90% or below when the power outage occurred |
| Adaptive potential | High | The system has ways to respond quickly in a crisis |
| | Low | An inflexible system that cannot quickly respond |
| Restart time | Minutes, hours, days, weeks | The amount of time required for the impacted system to return to preoutage operating capacity once electric power has been restored |

between systems. We make no such distinction in our framework, except for the inclusion of a feedback characteristic that indicates whether a particular IFI has a return effect on the power system.

The division into direct, second, and higher order effects is important due to the complex interactions that can occur between systems. Often the direct impacts of a power outage can be anticipated, such as electrical machinery and appliances not working. Failure to understand the higher order impacts leaves decision makers unprepared to effectively deal with these disruptions [1]. The final five characteristics in the framework as shown in Table 1, explained in Table 2, relate to the consequences of the IFI. These characteristics are most important for designing mitigation strategies, as will be shown in the analysis and comparison in Section 3 of two major outage events.

## 3 APPLICATIONS OF THE IFI FRAMEWORK

### 3.1 Database and Applications

This section discusses two applications of the framework described above. The intent is to explore how the patterns of $C(X_i)$ arise in real events, within a defined $\mathbf{X}$ for each event, where the triggering event $C(X_e)$ is a major electrical outage $X_{(e)}$ stemming from either an extreme event within or external to the electrical system. In order to characterize IFIs from various power outages, we constructed a database employing the characteristics

**TABLE 2 Consequence Characteristics**

| Characteristic | Value | Explanation |
|---|---|---|
| Severity | Minor | Minor modifications in daily routine or plans that cause negligible hardship to the person or entity |
| | Moderate | A few modifications in daily routine or plans that cause some hardship to the person or entity |
| | Major | Significant modifications in daily routine or plans that cause considerable hardship to the person or entity |
| Type | Economic, health, safety, social, environmental | Primary category under which the consequence falls |
| Spatial extent | Local | One city or area affected |
| | Regional | More than one city or area within a province or state affected |
| | National | More than one state or province affected |
| | International | More than one country affected |
| Number of people | Few | In the spatial extent of the consequence, one neighborhood or isolated individuals were affected |
| | Many | In the spatial extent of the consequence, up to 50% of the population was affected |
| | Most | In the spatial extent of the consequence, at least 50% of the population was affected |
| Duration | Minutes, hours, days, weeks | The amount of time the consequence endures, which may be greater than the restart time |

and values in the conceptual framework. Each record in the database consists of an observed IFI, from a societal standpoint, reported in major media or in technical reports. The database contains hundreds of IFIs from a number of recent outages, including the August 2003 Northeast blackout and the 1998 Quebec ice storm. Searches were conducted on the Nexus–Lexus database and other search engines to identify information and published sources related to the events. The data sources include major newspapers, such as the *Montreal Gazette*, *Ottawa Citizen*, *New York Times*, and *Toronto Star* and technical reports regarding these events (e.g. [20]).

Figures 1 and 2 illustrate the kinds of interactions and consequences in the database. The first figure characterizes the consequences of the 2003 Northeast blackout while the second portrays consequences that occurred during the 1998 ice storm. These diagrams show that we divide impacts by the infrastructure affected (e.g. transportation) and the specific subsystems (e.g. mass transit). Each also includes a table with a coding system to generally indicate the severity and extent of impacts.

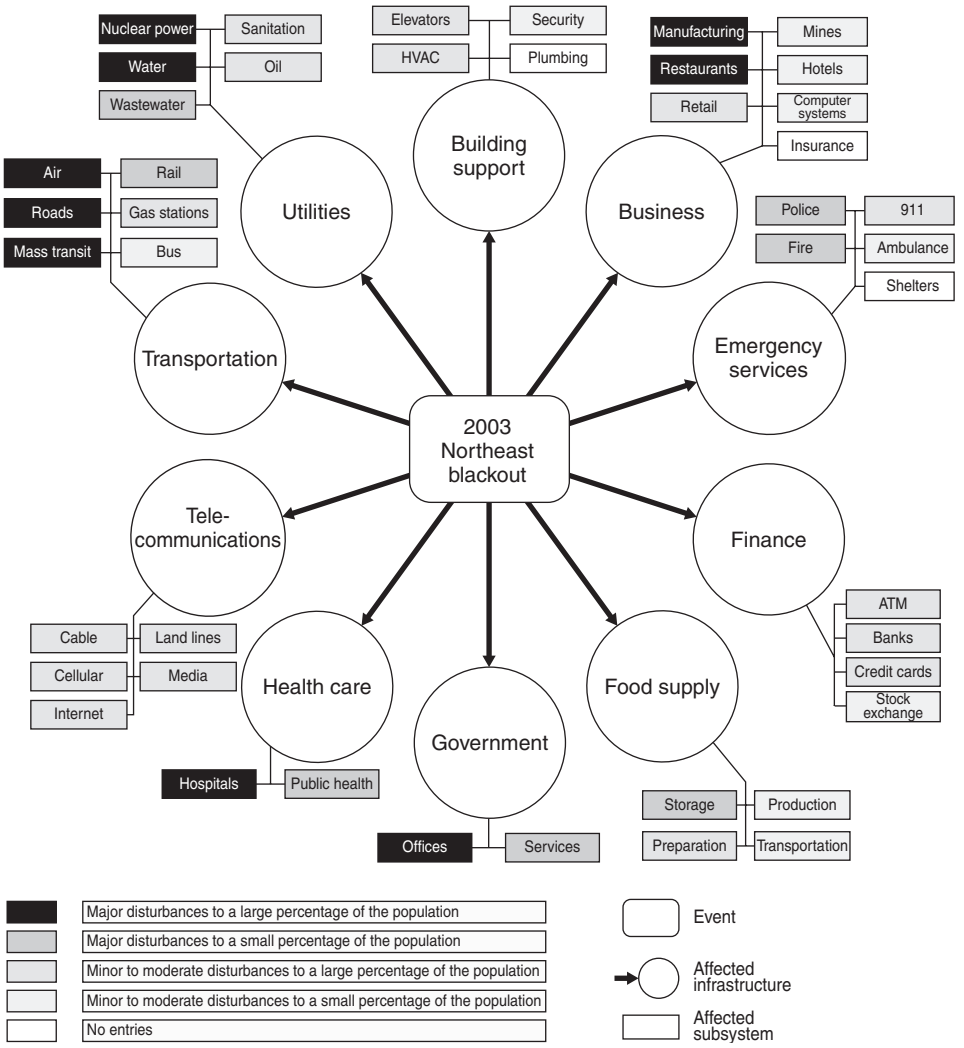

**FIGURE 1** Infrastructure failure interdependencies and their consequences for the 2003 Northeast blackout.

For analysis, we developed indices of consequences using the weights shown in Table 3. The weights were assigned in terms of subjective three-point scales (e.g. 1–3), and were treated as cardinal numbers to serve as a basis for differentiating the IFIs. The impact value (ranging from 1 to 9) is the product of the IFIs duration and severity weights. For example, a moderately severe IFI (weight = 2) that lasted for weeks (weight = 3) would have an impact value of 6. The midpoint for the scale is 5; hence values above that indicate more severe consequences with longer duration than those less than 5. The extent value (ranging from 1 to 9) is the product of the IFIs spatial extent and number of people affected. An IFI that affects only a few people (weight = 1) regionally (weight = 2) would have an extent value of 2. Values of extent greater than 5 indicate that large numbers of people were affected over an extensive geographic area. It is also

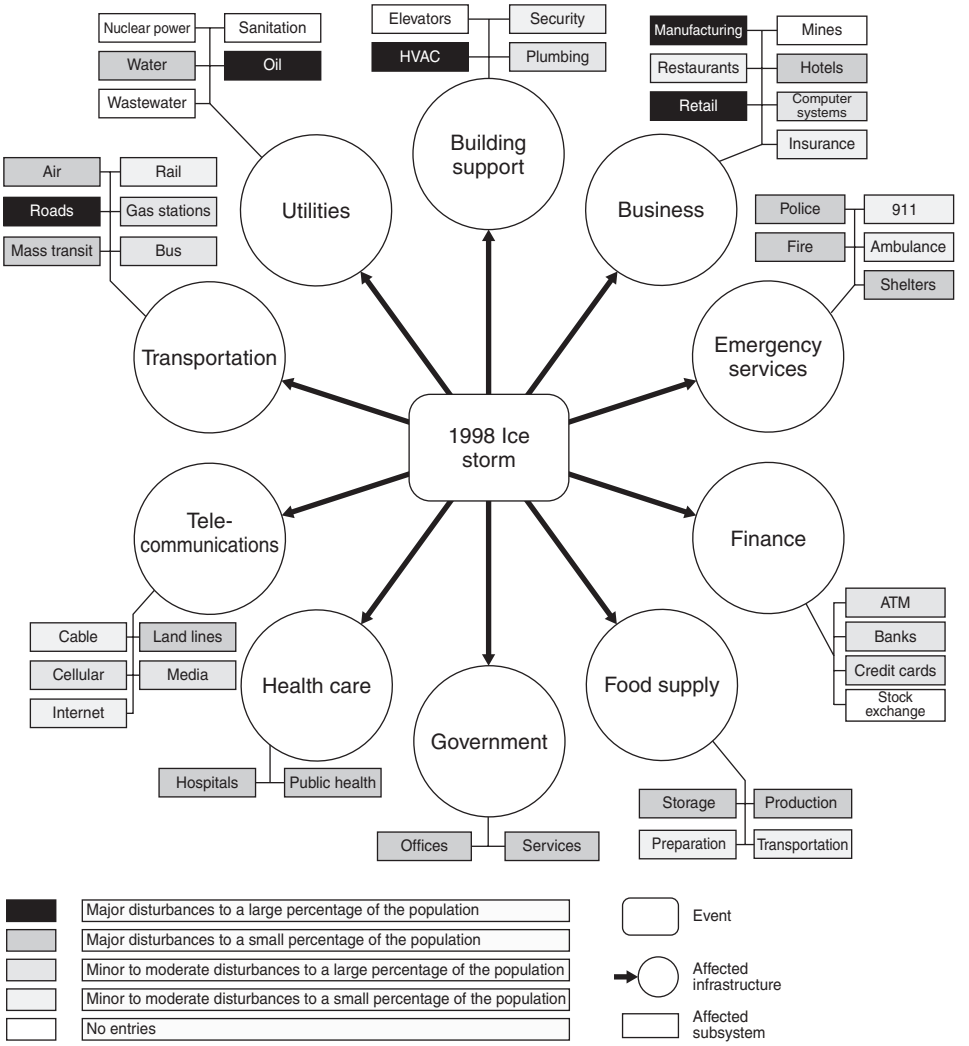

**FIGURE 2** Infrastructure failure interdependencies and their consequences for the 1998 ice storm blackout.

important to note that the impact and extent indices can only take on certain discrete values (i.e. 1, 2, 3, 4, 6 . . . , 9).

### 3.2 August 2003 Blackout

On August 14, 2003, the largest blackout in North American history occurred, with over 50 million people in Ontario, Canada, and parts of the Northeast and Midwest United States affected by the power outage. Our initial examination of this event has focused on the four major cities most affected by the blackout: New York City, Detroit, Cleveland, and Toronto. Figure 1 characterizes the 2003 Northeast blackout in terms of first and second order failure interdependencies and degree of disruption.

**TABLE 3 Weights for Consequence Indices**

| Weights | Duration | Severity | Spatial Extent | Number of People |
|---|---|---|---|---|
| **3** | Weeks | Major | International, national | Most |
| **2** | Days | Moderate | Regional | Many |
| **1** | Hours, minutes | Minor | Local | Few |

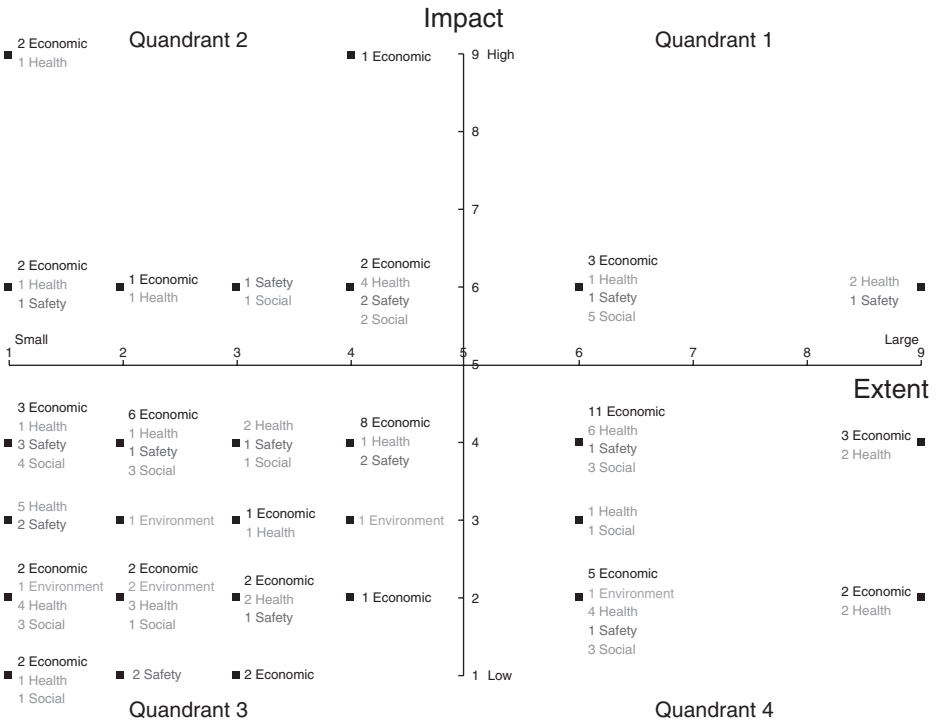

**FIGURE 3** Consequence indices for infrastructure failure interdependencies and their consequences for the 2003 Northeast blackout.

Figure 3 provides a compact summary of information in Figure 1, but disaggregated in terms of the nature of the consequences of the IFI. The colors indicate the types of consequences and the number indicates how many times that particular consequence was reported.

Figure 3 also separates the IFIs into four quadrants or categories. Axes separating the quadrants are located at the respective midpoint values of the potential range of impact and extent values (i.e. 5 on a scale of 1–9). Quadrant 1 represents major disturbances to a majority of the population, while Quadrant 2 includes major disturbances to a small percentage of the population. Quadrant 3 indicates minor inconveniences to a small percentage of the population. Quadrant 4 represents IFIs that caused minor inconveniences to a large percentage of the population. From a societal point of view, IFIs in Quadrant 1 are of greatest concern. This quadrant includes IFIs that have both high impact and broad extent of impact.

Out of the 162 IFIs in the database for the Northeast blackout, 13 are in Quadrant 1, which contain IFIs of large extent and high impact. In the far right of this quadrant are the three most serious IFIs. The two consequences to health are (i) water delivery systems malfunctioning or failing in some areas and (ii) the resulting boil water advisories that were issued. Compliance with the advisories was especially difficult for those who had electric stoves. Safety problems were created by numerous traffic signals being inoperable, resulting in traffic jams and collisions.

A joint US—Canadian task force traced the origin of the 2003 outage to northern Ohio, where a series of electrical, human, and computer incidents led to cascading failures in the North American electrical grid [21]. The next event analyzed was not caused by human and mechanical errors, but by a natural hazard.

### 3.3 Ice Storm

In January 1998, parts of Ontario, Quebec, and New Brunswick and the northeastern United States experienced one of the worst ice storms in recent history. The storm started on January 4 and continued for 6 days. In Canada, the weight of the ice caused 1000 transmission towers and 30,000 distribution poles to collapse [22], and at the peak of the outage, close to 1.4 million people in Quebec and 230,000 in Ontario were without power. Some people in rural areas went without power for more than 30 days. The ice storm consequences are summarized in Figure 4.

The ice storm database contains 102 IFIs, two of which are of large extent and high consequence in Quadrant 1. The two most serious IFIs in the ice storm were major employers shutting down for up to 2 weeks and communication problems for emergency services. In entering IFIs into the ice storm database, it was sometimes difficult to distinguish between problems caused by the storm itself and problems caused by the power outage. This is one of the differences between analyzing internally and externally initiated events. The next subsection has further comparison of the two events.

### 3.4 Comparative Analysis

In both these events, less than one percent of the total IFIs captured in the database are found in Quadrant 1; the majority of IFIs are contained in Quadrant 3. These are all minor disturbances that probably do not require mitigation attention but could become more serious in outages of longer duration. Reporting is also less likely to be complete with minor disturbances. In the financial system, for example, many bank branches were closed and bank machines did not work because of the outages. While this is an inconvenience if it lasts only for a short period of time, it could become a major disturbance in an outage of longer duration. Also, blood supplies dwindled in both events and could become a serious public health issue over a longer outage period.

Figure 5 shows the distribution of types of consequences for the two events. In the ice storm, there are more health consequences than any other type, while a higher percentage of consequences in the Northeast blackout are economic. The season and the longer duration of the ice storm outage are two possible explanations for this difference. IFIs associated with the ice storm outage had no environmental consequences, and the Northeast blackout very few, none of which are rated high on the impact index. The consequence characteristics, as explained in Table 3, are related to the direct, immediate effect the IFI has on people, instead of long-term effects that could result from environmental degradation.

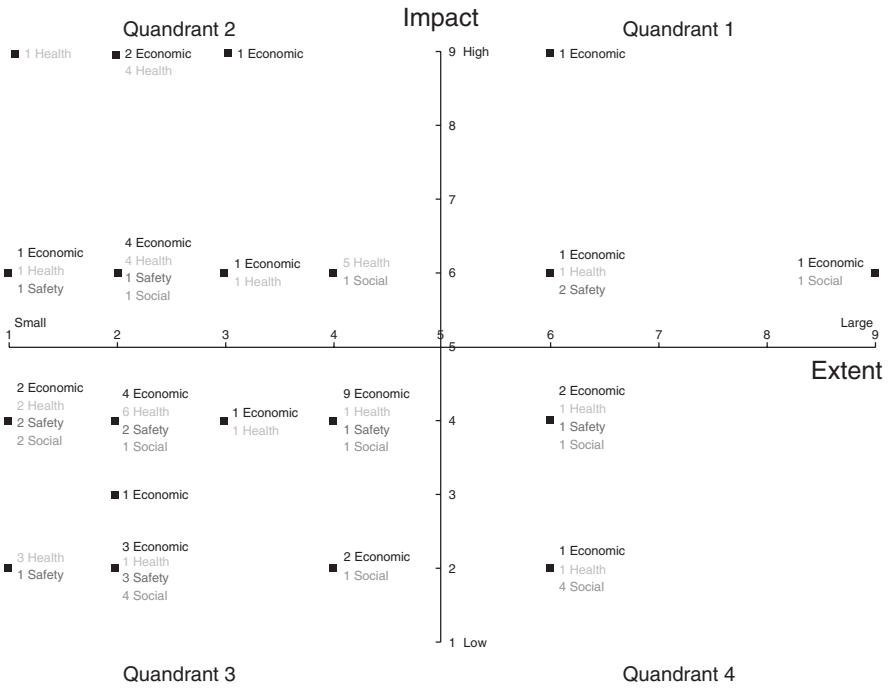

**FIGURE 4** Consequence indices for infrastructure failure interdependencies and their consequences for the 1998 ice storm.

Figure 6 compares the infrastructure systems disrupted by IFIs in Quadrants 1, 2, and 4 and shows notable differences between the two events. In the ice storm event, from the standpoint of societal impacts, emergency services and building support were the systems most affected by the blackout. Building support includes plumbing, heating, ventilation, and elevators, among other functions. The Northeast blackout had significantly more IFIs in the transportation system than did the ice storm event, which may be a result of the internal nature of the outage event. In an external event like the ice storm, weather causes initial problems in the transportation system that are only minimally exacerbated by the outage. Further analysis of these and other extreme events will help determine which systems are more likely to be affected by outages internal to the electrical system and those affected more by external events, such as storms and earthquakes.

## 4 DISCUSSION

We noted earlier that risk analysis often begins by asking what can go wrong, how it can go wrong, and what the consequences are. The analysis of the 2003 Northeast blackout and the 1998 ice storm is the first step in answering those questions, more specifically framed as follows.

What consequences matter most when examining the potential for failures in interconnected infrastructure systems? What consequences matter most for decisions about managing these failures?

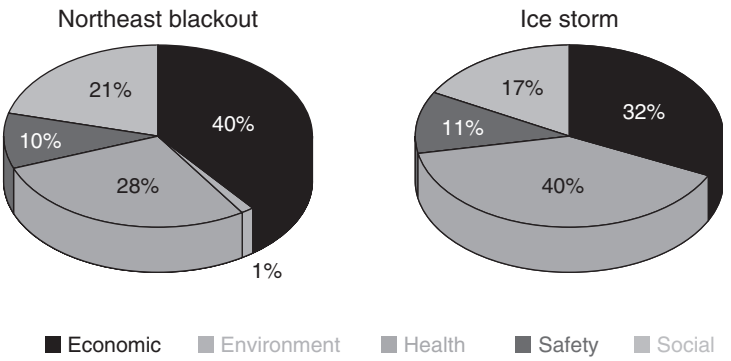

**FIGURE 5** Consequence indices for infrastructure failure interdependencies in Quadrants 1, 2, and 4 by type.

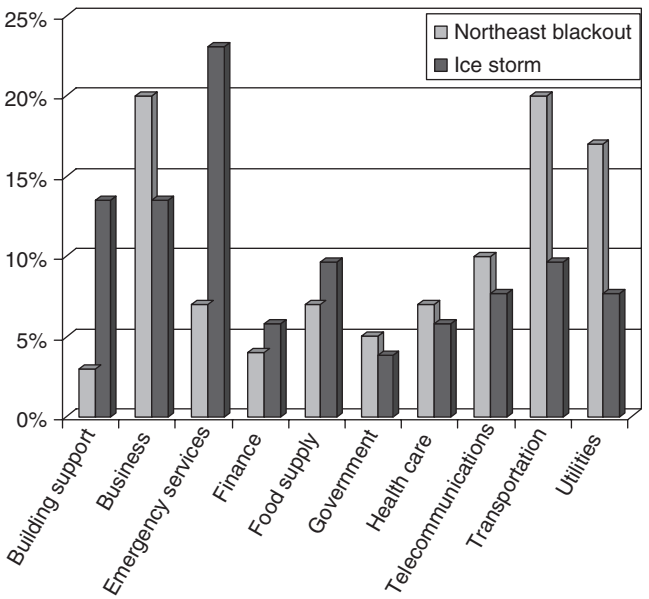

**FIGURE 6** Disruptions of infrastructure failure interdependencies in Quadrants 1, 2, and 4 by affected system.

How can one judge the severity of the consequences of IFIs?

What patterns of IFIs are the most significant sources of concern?

In order to answer Question 2, we developed the consequence indices, which took into account the severity, duration, spatial extent, and number of people affected by an IFI. These calculations were matched with the type of consequence and are shown in Figures 2 and 3 to answer Question 1. For Question 3, the comparative analysis of the two events in Section 3.3 is the initial step toward identifying patterns. Moreover, applications in two very different outage events—a summer short duration event originating in the electric power transmission system versus a winter long duration natural disaster

affecting primarily the power distribution system—provide many useful insights. While our particular focus here is on electric power failures, the framework could be generalized to any source of IFIs.

## 5 FUTURE RESEARCH

The analysis conducted thus far suggests several areas for further research. For example, duration of outage is a key difference that should be further explored. We have found that IFIs are expected to exhibit nonlinear and threshold effects in relation to power outage duration. Preliminary analysis also indicates that impacts on transportation tend to be severe and widespread across different types of outage events. The transportation system is therefore an important system to target for mitigation purposes. Further data collection and analysis across a broader range of disasters and disaster-affected communities will help develop more robust findings. Lastly, our analysis does not incorporate weights or value judgments across types of IFI impacts. Developing frameworks for addressing differences in types of consequences will be important in future research studies.

Some of the results produced by this study may also be of use to other similar research projects. For example, the empirical approach we adopted can be used to provide a complimentary approach (based on IFIs that have actually occurred) to probabilistic, system-based, and simulation models for power outages and their impacts. A robust empirical basis that incorporates experiences across a range of event and community types is also needed. Commonalties and differences in IFIs that occur across types of natural, technological, and willful disasters should also be explored. For example, identifying IFIs that occur in many types of events would be promising targets of mitigation from a multihazard perspective. Further, while this study focuses on IFIs deriving from electric power failure, the framework can be readily extended to assess other types of infrastructure interdependencies and for setting priorities about potential ways to mitigate the likelihood and the consequences of their interdependent failures.

# MANAGING CRITICAL INFRASTRUCTURE INTERDEPENDENCIES: THE ONTARIO APPROACH

BRUCE D. NELSON

*Emergency Management Ontario, Ministry of Community Safety and Correctional Services, Toronto, Ontario, Canada*

## 1 INTRODUCTION

In Canada, the federal government has developed a draft national strategy for critical infrastructure (CI) protection, which respects the jurisdictional prerogatives of the provincial and municipal levels of government and the propriety interests of the private sector. As such, the federal government uses a collaborative risk management–based strategy that aims to increase the resiliency of the national infrastructure through the development of trusted partnerships, the adoption of an all-hazards risk management approach, and the timely sharing of information. The national strategy recognizes the prerogative of provinces and territories to develop their own CI activities or programs and, as such, is highly supportive of these initiatives.

Within this national context, the province of Ontario developed the Ontario Critical Infrastructure Assurance Program (OCIAP). To properly understand OCIAP's approach, we must understand the environment in which it was developed; the context of CI in Ontario's emergency management program; the relationship of the three functions of public safety: preparedness and response, counterterrorism, and CI; and the development of the program itself.

This article then describes a program whose aim is to make Ontario's CI more disaster resilient and sustainable during threats from all hazards through the collaboration effort of government and the private sector in a sectorial approach.

## 2 CANADIAN ENVIRONMENT

In Canada, the responsibility for civil emergencies lies with the regions (provinces and territories) and the principal responsibility for war-related preparedness and emergency planning rests with the Federal Government [1–3]. This has been established by the division of powers, which articulated the Constitution Act of 1867 and Memorandums of Agreement between the Federal Government and the regions.

Public Safety Canada (PS Canada) supports OCIAP through their regional office. The collaboration between this group and the Emergency Management Ontario (EMO) Critical Infrastructure Assurance Program (CIAP) Staff has aided the development and success of the Ontario Program.

PS Canada also supports the Ontario CI program through cost sharing arrangements that sustain sector working group (SWG) meetings, awareness workshops, the annual conference, the production of CI materials and tools, and a modeling project.

## 3 THE PROVINCE OF ONTARIO AS A MAJOR REGION

The Province of Ontario has the largest and most concentrated population compared to other provinces and territories of Canada. One third of all Canadians live in Ontario, most of those within an hour's drive of the Canada–US border. Ontario is home to the nation's capital in the city of Ottawa and 40% of the federal government's infrastructure.

Toronto, the capital of Ontario, is the largest city in Canada and the center for many head offices of major corporations. Ontario is Canada's manufacturing leader producing 58% of all manufactured goods that are shipped out of the country.

The US is Ontario's biggest trading partner: more than 90% of exports are sent there. Every day, more than $700 million in goods crosses the Ontario–US border by highway. Ontario has 14 Canada–US border crossings, the most of Canada's provinces and territories. Approximately, 110 million tonnes of cargo move between Canada and the United States via waterways and coastal ports every year.

Ontario is the largest nuclear jurisdiction in North America and more than 50% of Canada's chemical industry is located in Ontario.

Within this context, the development of the Ontario program occurred as a result of significant infrastructure failures, which required two other public safety functions to be addressed: CI and counterterrorism. Following the Eastern Ontario Ice Storm of 1998, EMO laid the foundation for an increase in capacity and the need to address CI; the September 11, 2001 terrorist attacks broadened the view of threats facing Ontario's infrastructure. Although the CI program was developing, the SARS epidemic and the Blackout of 2003 demonstrated the vulnerabilities of networks and their interdependencies. These events caused political leaders to engage actively in the EMO-led reforms.

At the heart of these reforms was the movement toward the adoption of comprehensive emergency management programs based on a risk management approach, including activities in the five core components of emergency management: prevention, mitigation, preparedness, response, and recovery.

As part of the reforms, Ontario requires provincial ministries and communities to develop, implement, and maintain comprehensive emergency management programs (Figure 1).

The Emergency Management Act requires ministries and municipalities to conduct hazard identification and risk assessment, as prescribed by the Act and Regulation, and identify CI. The Act went on to change the Freedom of Information legislation at the provincial and municipal level allowing for protection of CI information—recognizing the need to demonstrate its commitment to creating a secure and trusted information-sharing network amongst governments and the private sector.

## 4 GETTING STARTED

In March 2002, a planning team, ably assisted by my federal counterpart from the PS Canada regional office in Toronto, was established to develop and implement a CIAP

for the province. The program was to be a province-wide program that will identify and assess Ontario's key facilities, systems, and networks, and their interdependencies, and develop a strategy to protect their vulnerabilities from physical and cyber threats. In developing the program, it became readily apparent that we would have to reconcile the public safety functions of counterterrorism, emergency management, and critical infrastructure assurance into a coherent approach. This conceptual understanding of the mutually supportive interrelationship of functions has proven to be a valuable intellectual tool, particularly when engaging in discussions with police and intelligence agencies.

In Figure 2, time flows from the top to the bottom. The event line represents the moment that the adverse event occurs, whether that is a natural hazard, a technological failure, or a human-caused event. The three "circles" represent the three core functions of public safety and security that directly relate to the successful implementation of the program. Counterterrorism is a police and intelligence function that responds to human-induced threats. Most counterterrorism functions occur before the anticipated event. And, although consequence-based emergency management planning occurs before the anticipated event, most emergency management activities are consequence based, and occur as a response after the event takes place.

CI assurance is a science-based risk management analysis of specifically identified infrastructure to assure its continued functioning. Like counterterrorism, it is a prevention or mitigation strategy intended to reduce the impact of adverse events. CI assurance differs from counterterrorism in that it focuses on the overall vulnerability of systems rather than specific, imminent threats. However, as the diagram shows, there is considerable overlap among the three functions, emergency management, counterterrorism, and critical infrastructure assurance. The star indicates the position where the circles overlap

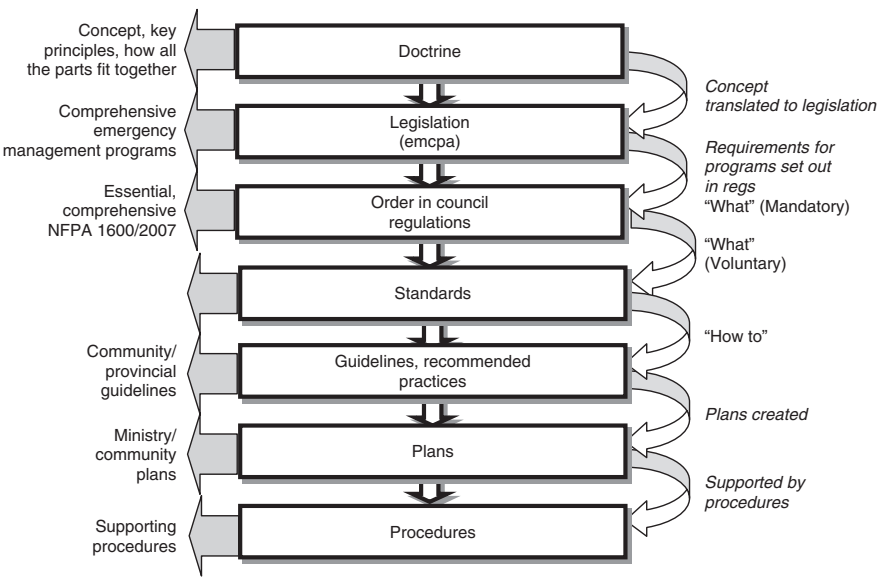

**FIGURE 1** Hierarchy of emergency management documents in Ontario.

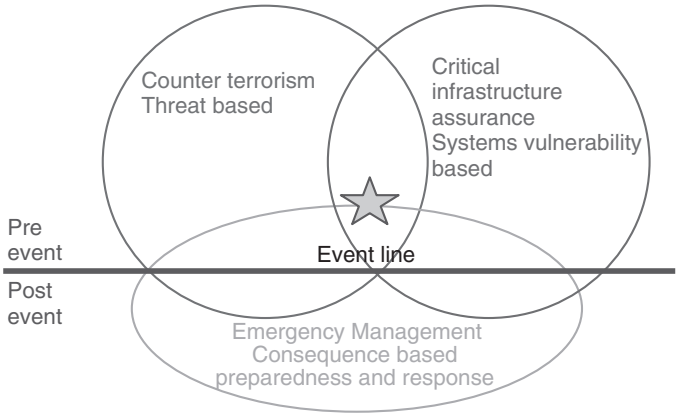

**FIGURE 2** The functional approach.

and it is at this position the decision makers, during an emergency, must bring the three circles together.

## 5 PROGRAM DEVELOPMENT—THE CONCEPT

The CIAP planning team started with a clean sheet and began researching CI programs nationally and internationally. The planners realized that it is more difficult and costly to protect against all hazards or threats than to take the business continuity process (BCP) approach and assure the continuance of key facilities. The program then became the CI assurance program addressing vulnerability and resilience. The program takes a strategic approach when it comes to sector working group (SWG) networks. The owner/operators retain the specific location of a networks' critical infrastructure; the program requires an understanding of the networks in general and their types of critical infrastructure in order to facilitate informed emergency management decisions, and enable senior leaders to set appropriate response priorities.

Determining that it takes a network to address a network, the program concept developed required a program that would bring the three levels of government together (federal, provincial, and municipal) with the private sector (owner/operators) to address critical infrastructure. The challenge is to remain within the requirements of legislation and, in particular, respecting the divisions of authority each government has and the regulatory requirements placed on the private sector. The program would bring regulators, inspectors, and owner/operators together as equals in a trusted information-sharing network.

The question of categorizing human resources and cyber as sectors remained an issue until they were determined to be enablers that play a key role in all sectors. The program stressed the need for key personnel and safeguards to the cyber component of systems and networks that permeate through all the sectors.

The CIAP concept was approved by management and moved to the implementation stage in the spring of 2003. The program continues to evolve as the sector work progresses.

## 6 THE CRITICAL INFRASTRUCTURE ASSURANCE PROGRAM

The following outlines the program as designed by the CIAP planning team.

### 6.1 Program Vision

*Ontario's critical infrastructure will become disaster resilient and sustainable during threats from all hazards through the collaborative effort of government and the private sector*.

### 6.2 Program Aim and Objectives

The aim of the OCIAP is to increase the resiliency of the province's critical infrastructure, so that it is more sustainable during an adverse event.

The central objectives of the OCIAP are to

- engage the owners and operators of critical infrastructure (public and private) in a comprehensive provincial approach;
- focus efforts to assure infrastructure assets of the greatest criticality and vulnerability;
- increase communication and collaboration within and between sectors to share information on critical infrastructure risks and interdependencies and to address threats and hazards; and
- collaborate with all levels of government and the private sector to develop and promote best practices to assure critical infrastructure.

### 6.3 Definitions

The following definitions were developed for the program:

> *CI defined as follows. interdependent, interactive, interconnected networks of institutions, services, systems, and processes that meet vital human needs, sustain the economy, protect public health, safety and security, and maintain continuity of and confidence in government*.

Since the Ontario program is an assurance program that assists practitioners in understanding the assurance concept, the following definition became important:

> *CI assurance defined as follows. the application of risk management and business continuity processes for the purpose of reducing the vulnerabilities of critical infrastructure by decreasing the frequency, duration, and scope of disruption and facilitating preparedness, response, and recovery*.

The program's key principles are risk management, business continuity, and collaboration. As part of comprehensive emergency management, the program is integral to the five components of emergency management: *prevention, mitigation, preparedness, response, and recovery*. However, the majority of work in critical infrastructure assurance occurs before an event, and the majority of the work addresses prevention and mitigation.

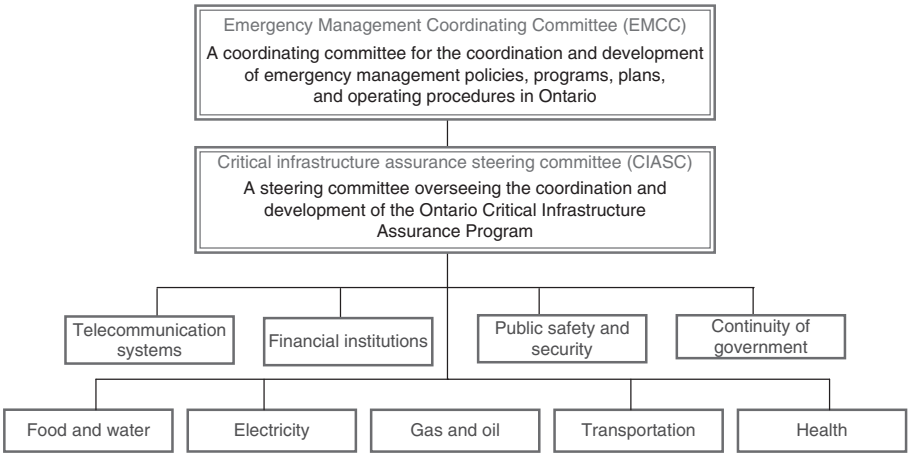

**FIGURE 3** Ontario's Critical Infrastructure Assurance Program Committee structure.

CI can be damaged, destroyed, or disrupted by natural hazards, negligence, accidents, criminal activity, and terrorist activity. Accordingly, the program assesses the potential likelihood and impact for both human-induced and natural hazards and relates this to the resiliency of the province's critical infrastructure.

### 6.4 Managing Interdependencies

Consistency of the CIAP with a comprehensive provincial emergency management program will be ensured through the following structure.

There will be an SWG for each of the identified critical infrastructure sectors. The program requires the SWG to meet four times a year at a minimum during the development stage. In practice, some sectors meet monthly to complete the required work. SWGs report to the Critical Infrastructure Assurance Steering Committee (CIASC), which oversees the coordination and development of the program.

The EMO Deputy Chief, Operations and Analysis, chairs the CIASC. The committee oversees the coordination and development of the program and addresses the issues concerning research and funding. It comprises EMO CI staff, SWG lead/coleads, representatives from PS Canada, and the provincial Ministry of the Attorney General to address freedom of information issues, Ministry of Infrastructure Renewal to address funding issues, and others as required. This committee meets four times a year.

The CIASC reports to the Emergency Management Coordinating Committee (EMCC), which is tasked with the coordination and development of emergency management programs, policies, plans, and procedures in Ontario. The Chair of the CIASC reports to the EMCC, (Figure 3).

## 7 SECTOR WORKING GROUPS

The SWGs are the key to the program and their composition reflects the federal, provincial, municipal, and private owner/operator stakeholders of their defined sector. The

**TABLE 1 The Sectors and their Respective Lead/Colead Ministries**

| | SWG Lead/Co-Lead Ministries |
|---|---|
| Food and Water Sector | Ministry of Agriculture and Food (food)<br>Ministry of the Environment (water) |
| Electricity Sector | Ministry of Energy |
| Transportation Sector | Ministry of Transportation |
| Gas and Oil Sector | Ministry of Energy |
| Financial Institutions Sector | Ministry of Finance |
| Telecommunication Systems Sector | Ministry of Economic Development and Trade Ministry of Government Services |
| Public Safety and Security Sector | Ministry of Community Safety and Correctional Services |
| Continuity of Government Sector | Ministry of Government Services |
| Health Sector | Ministry of Health and Long-term Care |

objectives for each SWG are to meet regularly to outline the industry within the sector, identify and assess they key elements of critical infrastructure within their particular sector having considered vulnerabilities, threats, and ensuing risks, identify assurance indicators, and facilitate mitigation to reduce the vulnerability or lessen the consequence created by a particular threat or hazard. All these will be documented in the model and assurance document for the sector. The assurance document is meant to provide senior management leaders comfort that the owners and operators are applying the appropriate due diligence to ensure that their systems are resilient to physical and cyber threats.

The success of the SWGs and ultimately the entire program will result in and depend upon the development of an open and trusting communication network of participants. CI information is protected under the *Emergency Management and Civil Protection Act* as indicated previously. It is important that information flow seamlessly among SWGs in order to address interdependencies; however, that information must be treated as confidential. To assist participants in the SWGs, the assurance document contains a section on communication protocol for SWG information sharing and communication protocols during an emergency.

The program identified nine broad CI sectors, and assigned a ministry lead, in some case coleads, to chair the sector and direct its activities. The determination of lead ministries was based upon the business lines and responsibilities (Table 1).

### 7.1 Establishing a Sector Working Group

Each sector lead and colead is responsible for forming the SWG, establishing their own individual protocols, and for keeping files and records related to the working group. SWG lead/coleads report to sit on the CIASC. The following steps have proved successful in forming the groups:

- The EMO Staff and PS Canada CI Coordinator (facilitating group) meet with the assigned lead representative and outline the concept of the program and their work. Program information and guide materials are provided.
- The facilitation group and the lead determine the ministries that should be involved and are invited to a CI information meeting with presentations by the facilitation group and the lead. The ministries participating then develop a relationship.

- The group now determines the federal representation based upon their normal business connections and existing federal responsibilities. The PS Canada CI Coordinator facilitates the inclusion of federal regional department representatives who would have a responsibility to the sector.
- The next step is to include the municipal representatives who have an interest in the sector.
- Finally, the private sector (owner/operators) is included. Because of the sheer number of potential representatives, the private sector is normally represented by regional associations.

## 7.2 SWG Deliverables

***7.2.1 Sector Model.*** The sector model is a generic systems map of the sector depicting its network, critical nodes, and dependencies/interdependencies. This model will provide decision makers with a better understanding of the sector and its interdependencies, as well as serve as a tool to work with scenarios during exercises and real-time emergencies. From this model, a risk matrix for the sector can be produced, which will show the vulnerable nodes in the sector; assurance solutions and best practices can then be developed to mitigate against those vulnerabilities. The model is then used in the interdependencies modeling software program under development at this time.

***7.2.2 Assurance Document.*** The assurance document outlines the sector industry, identifies CI, addresses vulnerabilities, identifies assurance indicators, and provides assurance solutions. The assurance document will give decision makers a good understanding of the sector, and its vulnerabilities and dependencies, and will ultimately aid in decision making during an emergency. EMO provides a template for the assurance document, which includes the following:

- vision and mandate
- resiliency statement
- background on the sector
- SWG participants list
- terms of reference
- communication protocol (SWG information sharing in committee and during an emergency)
- CI assurance indicators that support the resiliency statement
- sector risk management process
- assurance solutions/best practices (next steps).

## 7.3 Sector Working Group Interdependency Exercises

An important component to the program's development and the determining of sector dependencies/interdependencies and strength of relationships is the exercise component. The program conducts an annual fall conference, which includes an interdependency

exercise involving all sectors. The program also conducts smaller workshops where a number of sectors get together to address a particular vulnerability and determine best practices to increase the sectors' resiliencies. Scenarios at these exercises range from pandemic to fuel shortage.

### 7.4 Modeling Project

The program includes the Ontario Critical Infrastructure Modeling Project, which aims to produce a dynamic interdependencies model of Ontario's critical infrastructure. It is a 5-year joint pilot project with the federal government that ends in March 2010.

The primary software is RiskOutLook, a software developed in Canada for national level Y2K application and which is now being further developed to depict the cascading effects of interdependencies over time.

RiskOutLook creates a model of CI and its interdependencies, and using the assigned impact, vulnerability, and dependency ratings creates a risk matrix. The risk matrix identifies the CI with the highest impact, and the most vulnerable CI in the system; assurance solutions and best practices can then be developed to mitigate these vulnerabilities. The model will also allow for scenarios to be played out in order to study the impact of the disruption or destruction of a particular node of CI. Along with the assurance document, the model will provide a better understanding of Ontario's infrastructure and its interdependencies and will be used during emergencies and exercises to aid in decision making.

This project is dependent upon the mapping work done by the sectors. As each SWG provides input, a true determination of the software's capabilities can be documented.

## 8 CONCLUSION

The OCIAP is managing Ontario's complex interrelated infrastructure. The program's design allows it to start at a strategic level and become more granular as the program matures. With this approach, the program has had good support from the participants and they have not been overwhelmed by the complexity. The most important part of the program is the information-sharing network and from that network the SWG deliverables are attained. Senior managers have recognized work being done in the program and its importance as a prevention/mitigation program that provides input into the emergency management functions of preparedness, response, and recovery. Once implementation is completed, the program will be fully proactive identifying vulnerabilities and preventing/mitigating threats to raise the resiliency of Ontario's critical infrastructure.

# ANALYSIS OF CASCADING INFRASTRUCTURE FAILURES

IAN DOBSON
*University of Wisconsin-Madison, Madison, Wisconsin*

## 1 SCIENTIFIC OVERVIEW

Cascading failure is the primary mechanism by which an attack or accident of limited scale can yield a major and widespread failure of networked infrastructures. For example, disabling a limited number of components of an electric power grid can induce a cascade of failures leading to a widespread blackout, and this blackout can lead to further failures in other infrastructures, such as transportation, communication, and water supply. The characteristic feature of cascading failure is that a series of failures weakens the system and makes further failures increasingly more likely as the failures become widespread. Cascading failure is of interest to terrorists because a modest attack on a suitably chosen set of system components can propagate via cascading failure to become a widespread failure that is much more visible and destructive. Strategies of preventing and deterring an attack need to be augmented with strategies of limiting the propagation of infrastructure failures consequent to the attack.

We think of cascading failure as having some initial failures that are followed by the propagation of a series of further failures. The failures may propagate within a single infrastructure or between infrastructures [1, 2]. The initial failures can arise from different causes, such as terrorism, sabotage, errors, accidents, weather, or system overload but the subsequent propagation of the failures is a property of the design and operation of the infrastructure. It is desirable to design and operate infrastructures to be resistant to cascading failure so that, regardless of the cause of the initial failures, the risk of the initial failures cascading to a much more widespread infrastructure failure is managed and minimized. To realize this goal, we need to be able to quantify the extent to which failures propagate and relate this to the risks of infrastructure failure. This chapter gives an overview of a method that is emerging to quantify failure propagation and estimate the risk of infrastructure failure from simulations of cascading failure. The method is first being developed and tested for cascading blackouts of large-scale electric power networks.

Catastrophic cascading events in large networked infrastructures are a challenge to risk analysis, as the astronomical number and variety of ways in which failures interact in realistic large networks preclude any exhaustive analysis of the detail of long and intricate sequences of cascading failures. Indeed, many of the ways in which failures interact in actual incidents are of low probability or unanticipated [3]. The reason these interactions occur in practice is owing to the vast number of possible rare or unanticipated interactions and the fact that good engineering practice tends to eliminate the likely and anticipated interactions. It is possible, with effort, to do a detailed analysis of the sequence

of failures *after* the cascade has occurred [4]. Indeed this is one useful way to identify weak components or problematic interactions in the system that could be upgraded or mitigated. However, one sample from a vast number of possibilities gives no guidance to predicting the overall risk of the other possible cascades. To quantify the overall risk, it is necessary to take a top-down approach that neglects many of the details and to study the essential and hopefully universal features of cascading failure.

### 1.1 Review Of Cascading

We briefly review the literature related to quantifying cascading failure in large interconnected infrastructures (the established risk analysis that applies to a smaller number of components and interactions that can be analyzed in detail is not addressed). Cascading failure leading to widespread loss of infrastructure is well recognized and there has recently been much progress both in modeling the physical and operational details of the interactions and in recognizing and qualitatively describing cascading between infrastructures as surveyed in [1, 5, 6]. There are several approaches to developing more quantitative methods.

An analytically tractable probabilistic model of cascading failure in which overloaded components fail and successively load other components is described in [7]. A critical loading of the model produces a probability distribution of the total number of failures with a power law region consistent with the observed frequency of North American blackout sizes [8] and blackout simulations [9–12]. The model can be approximated by a probabilistic branching process model [13]. Branching processes have been routinely applied to cascading processes in many fields such as epidemics, cosmic rays, and population growth but have only recently been applied to the risk analysis of cascading failure [13–16]. North American data for the distribution of electric power transmission line outages are fit with several probabilistic models, including an exponentially accelerating cascading model in [17].

There are Markov models for abstract graphs representing interactions between idealized system components [18]. The percentages of inoperability of interdependent infrastructures are obtained as a linear function of the disturbance by solving a Leontief input–output model in [19, 20]. A network of influence factors between system components is considered in [21] and ratios of infrastructure impacts are obtained in [2].

There are many simulations of electric power systems using Monte Carlo and other methods that can be used to estimate the risk of blackouts such as in [9, 10, 12, 22–24]. Another useful approach to blackout risk is to identify and mitigate only the high risk or likely failures as for example in [25]. There are complex system approaches to blackout risk [10, , 26–28] that account for self-organizing dynamics such as network upgrades.

There is an extensive literature on cascading in graphs surveyed in [29, 30] that is partially motivated by idealized models of propagation of failures in infrastructure networks such as the Internet. The dynamics of cascading is related to statistical topological properties of the graphs. Work on phase transitions and network vulnerability that accounts for forms of network loading includes the references [31–33].

***1.1.1 Galton–Watson Branching Processes.*** In this section, an informal and introductory overview of Galton–Watson branching processes for their application to the risk of cascading failure is given; for a detailed and elegant formal treatment of these classical probabilistic models, see [34, 35]. Galton–Watson branching processes apply to discrete

numbers of failures of system components. For simplicity, we suppose that the failure of only one type of component is being tracked. The failures are produced in stages or generations starting from some initial failures, and if the number of failures in a stage becomes zero, then all subsequent stages have zero failures and the cascade of failures stops. Each failure in each stage (a "parent" failure) produces a probabilistic number of failures ("children" failures) in the next stage according to the *offspring distribution*. For example, the offspring distribution can be a Poisson distribution. The children failures then become parents to produce the next generation and so on. A key property making branching processes tractable is that the parents in each generation produce their respective children in a manner statistically independent of each other. The intent of the modeling is not that each parent failure in some sense "causes" its children failures; the branching process simply produces random numbers of failures in each generation that can match the outcome of cascading processes. To model the initial disturbance produced by terrorism or otherwise, we assume an initial distribution of failures for the first stage that is different from the offspring distribution assumed for the generation of all the following stages.

A key parameter of the branching process is $\lambda$, which is the mean of the offspring distribution or the average number of children failure per parent failure. If $\lambda < 1$, then the cascading process will die out to zero failures at some stage and usually corresponds to an infrastructure failure of small or modest size. If $\lambda > 1$, then the cascading process can possibly die out, but it can also propagate to a catastrophe with all components failed. Another parameter is $\theta$, the mean number of initial failures.

We consider cascading failure in infrastructures with a large but finite number of interconnected components. Therefore, if all components fail, the cascade stops and is said to saturate. More generally, there may be a tendency for the cascades to be inhibited when a certain number of components $S$ less than or equal to the total number of components is reached and this can also be roughly modeled as a saturation.

The branching process produces a random total number of failures $Y$ considering all the stages; that is, $Y$ is the total family size. If we measure the disturbance size by $Y$, then the main data produced by the branching process model is the probability distribution of $Y$. If the cost of the disturbance as a function of $Y$ is known, then the distribution of risk as a function of disturbance size can be obtained by multiplying the distribution of $Y$ by the cost. The distribution of risk as a function of disturbance size is basic to a quantitative approach to managing the risk [26].

### 1.2 Behavior of A Cascading Model

We illustrate the qualitative behavior of the saturating branching process model of cascading failure as the amount of propagation $\lambda$ and the average number of initial failures $\theta$ are varied. This behavior is similar to the behavior of other probabilistic cascading failure models [7].

Suppose that the failures propagate in a large number of components $S$ so that each failure has approximately a small uniform probability of independently causing failure in a large number of other components. Then the offspring and initial failure distributions can be approximated by Poisson distributions, and the distribution of the total number of failures $Y$ has an analytic formula given by a saturating form of the generalized Poisson distribution [13, 14]:

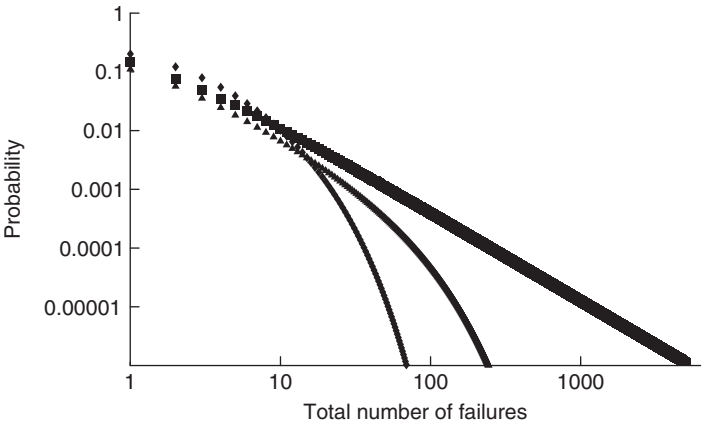

**FIGURE 1** Log–log plot of probability distribution of the total number of failures $Y$ in branching process model for three values of propagation $\lambda$. $\lambda = 0.6$ is indicated by the diamonds. $\lambda = 1.0$ (criticality) is indicated by the boxes. $\lambda = 1.2$ is indicated by the triangles (note the triangle in the upper right indicating a high probability of all components failing). The mean number of initial failures is $\theta = 1$ and there are $S = 5000$ components.

$$P[Y = r] = \begin{cases} \theta(r\lambda + \theta)^{r-1} \dfrac{e^{-r\lambda-\theta}}{r!(1 - e^{-\theta})}; & 1 \le r < S \\ 1 - \displaystyle\sum_{i=1}^{S-1} P[Y = i]; & r = S \end{cases} \tag{1}$$

First we assume a small initial attack with a mean number of initial failures $\theta = 1$. Then Figure 1 shows the probability distributions obtained for $S = 5000$ components and three values of propagation $\lambda$. For subcritical $\lambda = 0.6$ well below 1, the probability of a large number of failures less than 5000 is exponentially small. The probability of exactly 5000 failures (all components failed) is also very small. As $\lambda$ increases in the subcritical range $\lambda < 1$, the mechanism by which there develops a significant probability of large number of failures near 5000 is that the power law region of approximate slope $-1.5$ extends toward 5000 failures [36]. (A straight line of slope $-1.5$ on a log–log plot indicates the power relationship probability $\propto$ (number of failures)$^{-1.5}$.) For the near critical $\lambda = 1$, there is a power law region extending to 5000 failures. For supercritical $\lambda = 1.2$, there is an exponential tail. This again implies that the probability of large number of failures less than 5000 is exponentially small. However, there is a significant probability of exactly 5000 failures that increases with $\lambda$.

If we assume a fixed propagation $\lambda = 0.6$ and increase the mean number of failures in the initial attack to $\theta = 20$, then the distribution of the total number of failures changes as shown in Figure 2.

Consider in Figure 3 how the mean number of total failures $EY$ increases with increasing propagation $\lambda$. The mean number of total failures at first increases slowly and then increases much more rapidly at the critical point near $\lambda = 1$. It is called a critical point because the sharp change in gradient in Figure 3 and corresponding power law in the distribution of the number of failures in Figure 1 is analogous to a type 2 phase transition in statistical physics.

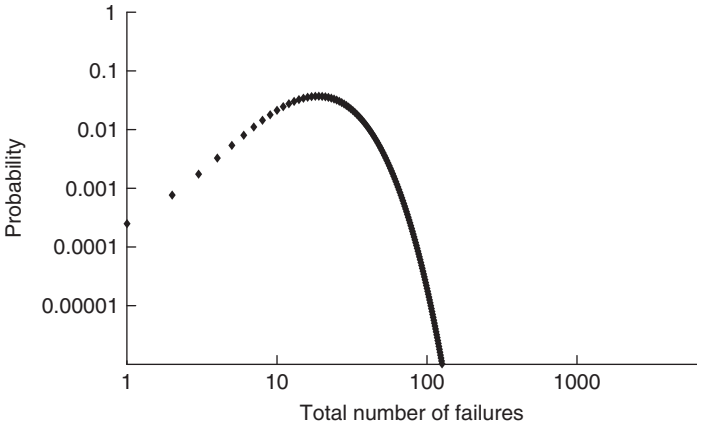

**FIGURE 2** Log–log plot of probability distribution of total number of failures $Y$ in branching process model for average number of initial failures $\theta = 10$ and propagation $\lambda = 0.6$. There are $S = 5000$ components.

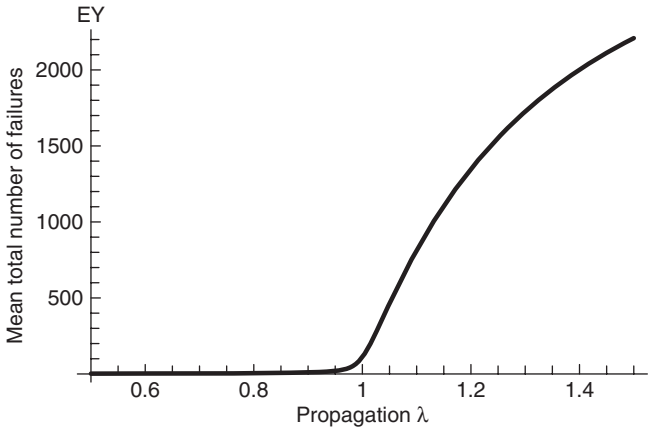

**FIGURE 3** Mean total number of failures $EY$ as a function of propagation $\lambda$.

### 1.3 Estimating Propagation from Simulations

There are many infrastructure simulations that can produce samples of cascading failures in stages. Without quantitative statistical analysis of these sample cascades, it is not clear how robust the infrastructure is to cascading failure. For example, if one of the sample cascades is a very large failure, does this indicate a vulnerable infrastructure, an unrepresentative rare event, or simply bad luck? We briefly indicate how propagation and the distribution of total failure size can be estimated from a relatively small sample of simulated cascades.

If we assume that the cascading in the infrastructure is approximated by a branching process model, we can estimate the parameters $\lambda$ and $\theta$ of the branching process model from the simulated cascades. In the branching process model, the propagation $\lambda$ is the mean of the offspring distribution or the average number of children failures per parent failure. In fact, $\lambda$ may be estimated from a sample of cascades by dividing the total

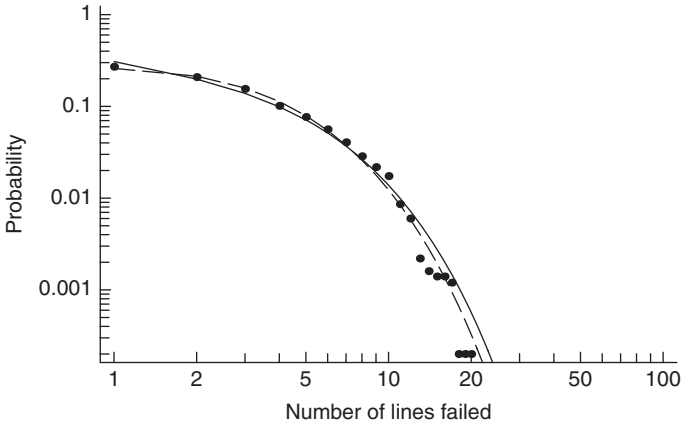

**FIGURE 4** Probability distributions of total number of electric power transmission lines failed obtained by different methods. The dashed line is obtained by estimating parameters ($\lambda = 0.4$ and $\theta = 1.5$) from simulation data and assuming a branching process model of the cascading. The dots are obtained empirically from the same simulation data. The simulation is the OPA model of cascading line outages in blackouts [9] and the test case is the IEEE 118 bus system with loading factor 1.0. Figure reprinted with permission from [15].

number of children failures in the sample cascades by the total number of parent failures. (Failures arising in stages after the first stage are children failures and failures arising in the stages before the last stage are parent failures. The last stage may be a stage with zero failures at which the cascade ends.) However, this standard computation [37, 38] may require adjustment to account for saturation effects [15]. The mean $\theta$ of the number of initial failures is estimated simply as the total number of initial failures divided by the number of sample cascades.

The propagation $\lambda$ and mean initial failures $\theta$ are useful metrics describing the cascading in the simulation data. Moreover, estimation of these parameters provides an estimate of the distribution of the total number of failures using equation (1). This provides a way to verify the assumption that a branching process approximates the simulation results. One can simply run the simulation exhaustively to obtain an empirical distribution of total number of failures. This empirical distribution can then be compared to the estimated distribution of the total number of failures. If the match is acceptable, then the estimation via the branching process can be used to approximate the estimated distribution of total number of failures. An example of the match obtained in a subcritical test case from [15] is shown in Figure 4.

Why use an approximate estimation of the distribution of the total number of failures by estimating $\lambda$ and $\theta$ when an empirical distribution can be produced simply by running the simulation exhaustively? The estimation of the distribution via estimating $\lambda$ and $\theta$ is much more efficient in that it requires many fewer simulated cascades. The distribution of total number of failures for a cascading process can have a heavy tail (power law region of exponent about $-1.5$). Estimating these heavy tails takes a large number of simulated cascades to obtain accurate statistics. On the other hand, the offspring distribution does not have a heavy tail and each stage of each cascade contributes data about the offspring distribution. Moreover, if the form of the offspring distribution is known (for example, a Poisson distribution), then estimating the mean of the distribution is quicker

than estimating the entire offspring distribution. Therefore, estimating the mean of the offspring distribution $\lambda$ and thereby computing the distribution of total number of failures is expected to require much fewer simulation runs [15].

### 1.4 More General Branching Processes

Tracking the numbers of one type of component that have failed in each stage of the cascade gives an integer number of failures in each stage. This is modeled by the Galton–Watson branching process explained above. However, it is also useful to track continuously variable quantities in each stage of the cascade, especially those quantities that determine the impact of the failures. For example, in a blackout one can track the electrical power that is disconnected. Cascades of continuously varying quantities are modeled by continuous state branching processes [39, 40]. These can be applied in a similar way to estimate branching process parameters and compute the probability distribution of the quantity determining the impact of the failures [16].

There are many generalizations of branching processes that could potentially model such factors as multiple types of component and variations in amount of propagation. The initial work is investigating and testing the simplest modeling assumptions. The limits of application of the method and the potential need for more sophisticated models are not yet clear.

## 2 CRITICAL NEEDS ANALYSIS

Cascading failure is fundamental to the rare but high-impact failures of substantial portions of infrastructures. Although there has been considerable progress in detailed modeling and qualitative descriptions of cascading failure in and between large networked infrastructures, there remains a need to understand and quantify the essential features of cascading processes and deduce the probability and risk of various sizes of failure events. To manage the risk of cascading failure, it is necessary not only to inhibit the initial attack or accident, but also to design and operate the system to limit the propagation of failures so that initial failures are less likely to propagate much further.

It would be valuable to be able to efficiently predict the distribution of cascade sizes from a modest number of simulated cascades and also to monitor real infrastructure failures to determine the extent to which failures propagate after an initial attack or accident. Note that although the initial failures may differ for an intentional attack and an accident, the extent to which the failures propagate after the initial failures should be similar. Thus, estimates of propagation of infrastructure failure arising from accidents should be effective in estimating how much the rarer terrorist attacks are magnified by cascading.

## 3 RESEARCH DIRECTIONS

Initial work on cascading in simulations of electric power system blackouts shows how overall cascading failure risk could be quantified. We have proposed the simplest branching process models of cascading failure and can fit parameters to quickly determine the

amount of propagation of failures and the distribution of total failure size. Initial testing is promising but much more testing and development is needed on more elaborate simulations of blackouts and on more general models of cascading infrastructure failure. Once efficient methods for predicting cascading failure risk from simulated cascades are established, the next step is to adapt these methods to monitor cascading failures in the actual infrastructures. The observed data would provide a benchmark for the necessarily simplified simulation models. The monitoring would in effect predict the frequency of catastrophic infrastructure failures much more quickly than the empirical approach of simply waiting for a very long time for enough rare catastrophic events to occur in order to get accurate statistics to quantify the risk.

# WATER INFRASTRUCTURE INTERDEPENDENCIES

NEIL S. GRIGG
*Colorado State University, Fort Collins, Colorado*

## 1 INTRODUCTION

Managers of water and electric systems are more concerned about security failures of the infrastructures they depend on than about failures in their own systems. Their concerns were reported in a workshop on water, electricity, and transportation managers, where they expressed confidence in their own security plans but sought guidance on managing interdependencies [1]. This article identifies the interdependencies among water and other infrastructure systems and explains how to reduce the corresponding risk and improve infrastructure security. Other articles in the volume explain the nature of water infrastructure and how to address direct security issues.

## 2 OVERVIEW OF WATER SYSTEM INTERDEPENDENCY

As other articles in this volume explain, water system managers face threats to their systems from natural causes such as earthquakes and from human-induced causes such as attacks on their supervisory control and data acquisition (SCADA) systems. To respond,

these managers must assess vulnerabilities and mitigate risk by multiple actions to strengthen emergency plans and response capabilities.

Water system managers also face vulnerabilities from interdependencies with elements of the water infrastructure that they may not control (such as their raw water supplies) and with other infrastructures (such as with electric power). These two sources of vulnerabilities represent different situations that require distinct types of responses. In addition, water system managers must take actions to reduce the risk that failures of their systems will harm those that depend on them.

Study of these interdependencies involves relationships between elements and levels of systems. Interdependency can be explained at a high level of systems aggregation, but security threats and responses require explanations at detailed levels to create a valid picture. The many types of interdependencies do not fit well into a classification system, and discussions about them can seem ad hoc and without unifying themes. To clarify these interdependencies, the article uses two models to explain the situations that water managers face.

The first model explains interdependencies among elements of the water infrastructure itself and those between the water infrastructure and other infrastructures. For the purposes of this article, these are named *intrasystem interdependencies* among water system elements and *intersystem interdependences* where water systems have relationships to other infrastructures.

The framework of the model is shown in Figure 1, which illustrates the two types of interdependencies. On the left side of the figure, water infrastructure is shown as having five parts or subsystems. These illustrate the supply chain of the water supply system and shows how irrigation is linked to the water supply system in parts of the nation.

On the right hand side of Figure 1 are shown five infrastructure sectors with close links to water. These are the sectors from among the critical infrastructures and key resources identified in the National Infrastructure Protection Plan that exhibit the greatest degrees of interdependence with water infrastructure [2].

The terms (intrasystem and intersystem) can be confusing, but the concept of interdependency is inherently complex and the concepts are explained in Figure 1.

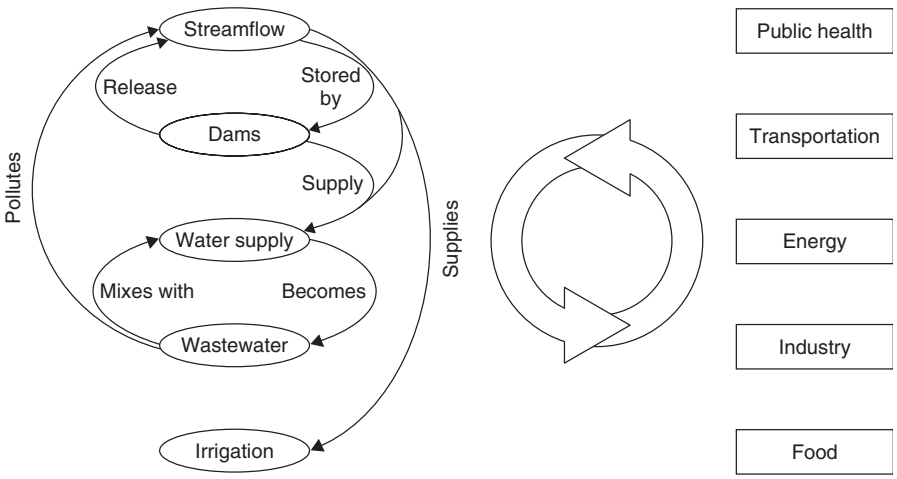

**FIGURE 1** Water infrastructure interdependency model.

The second model maps the supply chain of water production and the provision of direct and indirect water services to customers. This enables the explanation of interdependencies that arise from supply chain disruption and impacts on other sectors from failures in water services. This model will be illustrated later.

## 3 KNOWLEDGE BASE ABOUT INTERDEPENDENCIES IN THE WATER SECTOR

The knowledge base about interdependencies among water sector elements resides in the broad field of water resources management. In this field, the concept of integrated water resources management (IWRM) has been developed to explain the many interdependencies that arise in water systems management [3]. Managers of water systems are aware of these, and have formulated conceptual frameworks to explain them, but the institutional capacity to respond is lacking [4].

The knowledge base about technologies for integrated water resources management is rich, and includes advanced computer-based methods involving large databases and simulation models. For example, the State of Colorado is developing an extensive set of advanced decision support systems for management of its river basins [5]. The serious knowledge gap is in development of institutional responses to overcome barriers among water system managers and their governing boards [6].

International research about needed institutional responses focuses on shared governance, but achieving effective methods for it involves overcoming political challenges. Examples can be seen in the many water wars and transboundary conflicts that arise over sharing of water supplies. Given these institutional difficulties, water system managers are forced to develop security plans that do not depend on the success of their partners in managing shared waters.

Research about relationships between water and other infrastructures focuses on intergovernmental relations. Current trends toward privatization and downsizing of government work against the kind of cooperative planning and mutual aid arrangements needed to bolster intersystem security. The responsibilities of water system managers to address cross-system issues differ from those of their water system partners.

## 4 INTRASYSTEM INTERDEPENDENCIES

Although they are operated as distinct utility services, water and wastewater systems are inextricably linked to other elements of the overall water system. This overall water system includes a number of subsectors as follows [7]:

- municipal and industrial water supply and wastewater;
- irrigation and drainage for farming and landscaping;
- environmental water for natural systems or habitat;
- water-based recreation;
- dam and reservoir management;
- aquifer management for groundwater systems;
- hydropower generation;

- waterborne transportation and navigation;
- stormwater and flood control.

Management of water resources within the subsectors involves links among hydrologic subsystems, between water quantity and quality, and between the physical processes of water use. The left side of Figure 1 shows a simplified view of these.

Water and wastewater utilities are the organized units with the most influence on overall water management. In the United States, there are over 50,000 water supply systems and nearly as many wastewater systems. Although most of these are small, they are the management organizations with most authority and responsibility to manage water through its hydrologic cycle. The other group with great influence comprises the agencies that manage the nation's some 75,000 dams and reservoirs. These involve a much smaller number of management units, such as the Corps of Engineers, Bureau of Reclamation, and many hydroelectric producers, among others [8].

The interdependences among these elements of the overall water resources system occur because water flows under natural forces through its hydrologic cycle. This cycle takes water from the atmosphere, deposits precipitation that becomes runoff or ground water and flows to various receiving waters, from which it is evaporated. Sometimes the water is diverted from one basin to another using tunnels and other infrastructure. However the water flows, its continually flowing nature creates intrasystem interdependences.

Briefly, streamflow is stored in reservoirs by dams, which are in turn operated to control the release of flows downstream. Streamflow and dam releases provide raw water supplies to cities, industries, and irrigators. Water supply releases become wastewater that affects the quality of streamflow and mixes with water supply through discharge–diversion sequences. These elements may be operated by different management agencies and require numerous administrative arrangements and communication channels to identify vulnerabilities and manage risk. For example, a federal agency may operate a reservoir that provides water supply to a city. The city is thus dependent on the agency to deliver raw water reliably.

Many details must be supplied to describe these interactions fully. Although a valid watershed model can illustrate the important linkages among subsystems, it will not be able to replicate all processes at the micro level. For example, groundwater–surface water interactions are important but difficult to model accurately.

The interactions shown in Figure 1 illustrate important intrasystem interdependencies and vulnerabilities. For example, raw water must be available and transported to points of storage, treatment, and/or use. Wastewater systems also involve treatment plants and pipes, and have vulnerable components. However, their purposes differ from drinking water and the consequences of security breaches are different. Their security is addressed in a separate article in this volume. Irrigation systems can be disrupted but the direct consequences to water systems are normally not as critical as they are for drinking water.

Examples of important intrasystem interdependences among parts of the overall water system are shown in Table 1.

## 5 INTERDEPENDENCIES WITH OTHER INFRASTRUCTURES

Although, at a high level, water has clear interdependencies with other infrastructures, the nature of the relationships must be defined at the subsystem level. The discussion in

**TABLE 1 Examples of Intrasystem Interdependencies for Water Systems**

| Intrasystem Interdependency | Example |
|---|---|
| Disruption of transportation routes for raw water | An earthquake might block a tunnel and cut off raw water supplies |
| Drought to reduce raw water supplies | Water supply systems can extend for long distances, and drought in an upper basin can reduce supplies lower down |
| Flood to damage water handling facilities | River flooding may disrupt operation of raw or treated water facilities |
| Intentional or unintentional contamination of raw or treated water | Intentional contamination of treated water is an obvious threat. Contamination of raw water supplies is normally not a major threat because of its volume, but it is important to keep watersheds clean and contaminated reservoirs are difficult to clean |
| Dam safety | Security of dams is critical because their failure can affect water supplies, public safety, and the environment. Dams can be threatened by sudden events or lack of maintenance |
| Treated water systems | Treated water may be distributed to wholesale customers, thus disruptions can propagate through the systems. Security of treated water is addressed in a separate article in this volume |

this section is organized around the six critical infrastructure sectors shown on the right side of Figure 1.

The water service most closely aligned with public health is drinking water. Wastewater and irrigation water are also linked to health issues. Contaminated drinking water or failed water systems have many links to public health, which are explained in another article. The public health system also presents threats to water systems. For example, a source of pharmaceuticals in drinking water is the disposal of outdated medicines in hospitals and other health care facilities. Another example is that inadequate regulation of public activity in swimming and fishing areas can pollute water that the public is exposed to.

Food security is another health-related water issue because water is an ingredient in food, from the farm to the dining room table. Contaminated irrigation water can create hazards up the wholesale to retail chain and lead to outbreaks of waterborne disease. Failure of raw water systems can also lead to crop failures and economic hardship.

Water and industry exhibit interdependencies because industrial production requires large inputs of high quality water. This dependency can be quickly noted by examining categories of NAICS industries as published by the US Census Bureau. NAICS is the North American Industry Classification System, see Reference [9] for an explanation. In particular, the chemical industry exhibits interdependencies with water in several ways. It produces water treatment chemicals such as phosphates and chlorine gas. Shortages of these will impede water treatment and transportation of some of them can create hazardous conditions, as with transportation of chlorine gas to water treatment plants. Water

is also linked to critical industries. For example, during World War I, the Muscle Shoals dam facility on the Tennessee River produced nitrates for ammunition and explosives. The facility is now part of the Tennessee Valley Authority system.

As water must be transported to points of use, its infrastructure has a number of interdependences with transportation systems. For example, vulnerable bridges and tunnels may form part of water conveyance systems. If a dam fails, it will often fail downstream transportation arteries. If roadways and bridges are not protected against floods, they can be failed by water forces. Waterborne transportation has obvious links to water management. During drought, water utilities often call for reduced navigation flows for barges that may be used for transporting vital commodities.

Energy systems and water are linked because if raw or treated water is pumped, the systems are vulnerable to power outages. Also, control of many water systems has become automated and loss of energy can fail critical monitoring and control systems. Hydroelectricity is produced from flowing water. Cooling water is required for all electricity generation, and thermoelectric cooling is a large user of water for once-through cooling and cooling towers.

## 6 RESPONSES TO INTERDEPENDENCIES

Although water system interdependencies are inherently complex and difficult to manage, they can be explained with the metaphor of the business corporation's supply chain and customer relations. The supply chain models the water utility's ability to produce high quality finished water using inputs of raw water, electric power, chemicals, and other resources. The customer base comprises direct and indirect water users. Direct water users are people who drink water, swim in it, cook with it, or use it for other purposes. Indirect users are people who use any product that requires water as an input, such as food that is produced through irrigation.

This model can be illustrated with a simple diagram (Figure 2) that shows the producer of water services as receiving supply chain inputs from within the water industry (such as raw water) and from outside the industry (such as electric power or chemicals). The producer then provides water services to its customers, who will be impacted by any failures in water quantity or quality. These customers will then produce their products, which often depend on high quality and reliable water.

As shown in Figure 2, water service providers often lack control over all the resources they require. This is the same situation faced by any production unit that relies on others for its supply chain. The water utility normally cannot gain ownership and complete control over all of its supply chain, and coordination strategies are its main tool to strengthen security of supply chain interdependencies. These strategies will involve different measures and combinations of stakeholders for intrasystem water elements, such as between raw water and treated water, than they will for intersystem infrastructures, such as between water and its electric power inputs.

Coordination can be modeled by forms of business organization based on relationships between a business and its suppliers and production units. Three types of supply relationships help visualize interdependencies:

- A vertically integrated water utility with its supply chain within the span of control of one executive. An example could be a water supply utility serving 50,000 customers in a single city.

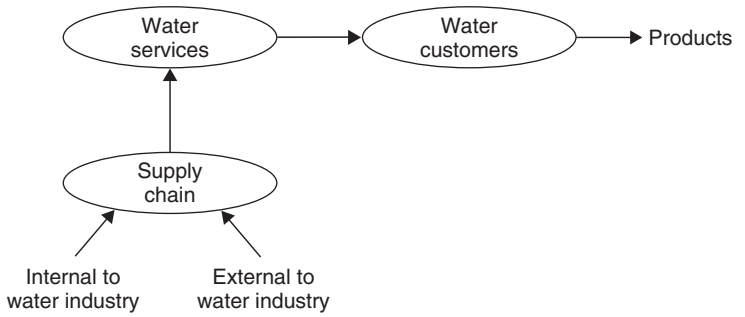

**FIGURE 2** Supply chain and outputs of water service providers.

- A horizontally integrated water utility with divisions under separate executives who treat each other as "customers." An example could be an integrated utility with its own raw water supplies, treatment and distribution systems, and wastewater services.
- A water utility that contracts with suppliers in independent organizations in similar and different industries. An example could be a water utility that performs business operations but does not own or control its own water or infrastructure.

Supply chain interdependencies must be managed through relationships between water system managers and their suppliers. For a smaller, vertically integrated utility, these relationships can probably be managed through day-to-day meetings and shared problem-solving. For larger, horizontally integrated utilities it is more difficult to achieve effective communication and it might be necessary to make more formal arrangements through contracts and working agreements that are audited through performance reports. When the water utility operates by contracting with independent organizations for its supply chain, formal contracts and agreements become essential.

Coordination does not have to occur in formal and informal venues inside of organizations. When water services are provided by different agencies, the participants may see each other in regional planning meetings, at professional associations, and at other occasions.

Coordination presents different challenges, as in the case of intersystem infrastructures where the managers may not know each other at all. For example, public health officials who receive reports of waterborne disease outbreaks are normally not in touch with water officials on a regular basis. By the same token, the chain-of-responsibility for food contamination from irrigation water is long and convoluted. Even the more direct link between electric power and water systems does not involve regular communications between managers. It is not reasonable to rely simply on more communication and coordination among managers of disparate infrastructures to improve security. Rather, managers of these infrastructures must take matters into their own hands to mitigate threats from failures in the infrastructures they depend on. They must assess the risk of failure of other systems and take measures to mitigate the risk or create redundancies.

Barriers to coordination occur among interdependent water systems from the same problems that occur within organizations, where coordination requires frequent communication, meetings, sharing of information, and other means to improve cooperative work. Coordination and communication are always more difficult between organizations than

within them, but both cases present barriers. Examples of barriers might include not being aware of interdependencies, being busy and overloaded with other work, not wanting to work together, and lack of incentives from governing boards.

## 7 CRITICAL NEEDS ANALYSIS

The model of water system risk used in the article shows vulnerabilities from interdependencies among elements of the water infrastructure and between water and other infrastructures. The interdependencies go two ways: those that affect the supply chain of water and those that exhibit impacts on others from water system failures.

One example of intrasystem interdependency is failure of raw water supplies, which prevents water treatment organizations from performing their missions. Another would be uncontrolled river flooding that disrupts operation of water infrastructures. An example of a supply chain failure from another category of infrastructure is loss of electric power to a water system.

Examples of impacts from failure of water services include public health incidents and contamination of food supplies from polluted water. Also, industrial and energy systems depend on reliable water supplies to function.

Planning for interdependencies requires the water system manager to recognize categories of relationships that include supply chain inputs from within and outside of the water industry. These supply chain interdependencies must be managed through coordination among water system managers and their suppliers. The coordination can range from informal arrangements to formal contracts and agreements.

In the case of intersystem infrastructures, managers may not be able to coordinate well because they are not in frequent contact and may not even be aware of each other's activities. In these cases, infrastructure managers must take matters into their own hands, and consider threats from failures in other infrastructures just the same as other uncontrolled threats.

Regardless of the type of interdependency, threats from failures within the water industry or outside of it can be included in a vulnerability analysis. To include them, the analyst must recognize the threats from interdependencies in the same way as a direct threat is recognized, whether from natural or human causes. Once the threats are recognized, they can be mitigated by direct actions or coordinated arrangements with partner organizations.

## 8 RESEARCH DIRECTIONS

Management of threats that arise to water systems from interdependencies among themselves and with other infrastructures requires responses in technological, management, and institutional arenas. The technological responses involve the same types of instrumentation, control devices, and other tools that are needed for ongoing security programs and have been described in Reference [10].

Required management responses range across governance, organizational planning, data management, coordination with partnership organizations, and reporting. Research into these topics is robust for business and government organizations but little research has been conducted specifically for water utilities and their interdependencies [11].

The most difficult arena for enhanced security is in institutional responses that include organizational structures, incentives, and relationships. For example, the United States has some 85,000 units of local government, many of which are involved in infrastructure services [12]. In addition to working effectively among themselves, they must work with many independent private water and energy companies. The regulatory structure that governs water and related infrastructures involves a patchwork of federal and state agencies and local governing boards. Research needed focuses on improving intergovernmental arrangements within the existing structure of the water industry as it relates to the management structure of other infrastructures.

# INFRASTRUCTURE DEPENDENCY INDICATORS

THERESA BROWN
*Sandia National Laboratories, Albuquerque, New Mexico*

## 1 INTRODUCTION

Interdependencies are created by multiple dependencies between two or more infrastructures. Hence, dependencies are the fundamental building block of interdependencies and models of these interconnected, interdependent systems. This article provides an overview of the state of the art in identifying infrastructure dependencies and analyzing their importance with respect to infrastructure protection measures.

## 2 SCIENTIFIC OVERVIEW

Infrastructures evolved with society and technology. Infrastructure dependency analysis for homeland security applications is a relatively new field of study encouraged in the United States by the National Research Council [1], endorsed and funded by the federal government [2]. Funding over the last 6–10 years, primarily by government agencies, produced new interdisciplinary programs and centers at universities (e.g. Department of Homeland Security Centers of Excellence at Michigan State University, University of Southern California, John Hopkins University, University of Minnesota, Texas A&M University, and the University of Maryland; the Critical Infrastructure Modeling and Assessment Program at the Virginia Tech Center for Energy and the Global Environment); new analysis centers at national laboratories (e.g. National Infrastructure Simulation and Analysis Center at Sandia and Los Alamos National Laboratories and Infrastructure Assurance Center at Argonne National Laboratory); and private research organizations. Each of these research and analysis centers is focused on improving our understanding of infrastructures, how they interact and influence one another, the overall well-being of the populations they serve, and the economies they support. Since this is a new area of study, there are relatively few publications devoted to the broad field of infrastructures. Two journals, *Journal of Infrastructure Systems* published by the American Society of Civil Engineers (since 1984) and *International Journal on Critical Infrastructures* published by Inderscience (since 2004), focus on new contributions to infrastructure design, protection, and management. The literature for this field is just developing.

Rinaldi et al. [3] provide a useful classification system for infrastructures, defined by four major categories of interdependencies: geographical, physical, logical, and cyber. Since interdependencies imply multiple, interrelated dependencies between two or more elements, dependencies are the more fundamental relationship. Dependencies can be classified using the same categories as interdependencies, or in this case, with cyber

dependencies as a subset of physical dependencies. The fundamental indicators of dependencies can also be classified as geographical, physical, and logical. In the following sections, examples of work in the area of infrastructure dependency identification and analysis are provided, along with areas for improvement.

## 3 GEOGRAPHICAL DEPENDENCY INDICATORS

The easiest dependencies to identify are geographical dependencies, when elements of multiple infrastructures are close enough to be damaged by the same event. The only complication in identifying these dependencies is in defining the events of concern, including the location or potential locations and obtaining locations for all of the nearby infrastructure elements to identify which are the ones within the potential damage zone. For many events, the infrastructure elements must be in very close proximity for geographical dependencies to exist. When infrastructures use a common right-of-way, such as a dam, bridge, tunnel or sewer pipeline, catastrophic accidents or failures at those locations can disrupt multiple infrastructures at the same time. The presence of multiple infrastructures in a single location (colocation) is the indicator of geographic dependency for isolated incidents (e.g. tanker truck accident and explosion that leads to the collapse of a bridge). As we understand the potential threats, the vulnerability of infrastructure elements to each of those threats, and the likelihood of the threat at any location, we can develop risk-based indicators of dependencies.

Large, destructive events such as hurricanes create geographical dependencies across multiple infrastructures, populations, industries, and commercial sectors due to damage and injuries caused by high winds and flooding. The map in Figure 1 depicts the relative risk (by county) posed by hurricane strikes. A risk indicator was calculated by multiplying a likelihood factor by a consequence factor. The likelihood factor is a combination of the probability of hurricane occurrence and probability of damage to infrastructure. An estimate of the probability of a hurricane impacting a county is based on the historic frequency of hurricanes. The probability of damage to infrastructures within each county was estimated using a wind damage contour for each historical hurricane path based upon its intensity. A consequence factor was developed as a function of the population living in each county.

$$\text{Risk indicator} = \text{population}[1000\text{s}] \times \text{hurricane frequency} \times \text{damaging-wind frequency}$$

The result is a geographical distribution of the risk of direct damage due to hurricanes.

Similar indicators exist for other natural threats, such as seismic activity, flooding, landslides, and wild fire. The US Geological Survey publishes seismic hazard maps that can be used in conjunction with fragility curves for specific engineered structures to estimate the risk of damage due to ground motion. The Federal Emergency Management Agency provides maps of flood, fire, geologic, and other hazards in the United States.

More refined indicators can be developed to represent the risk to specific infrastructures or assets, the duration of the expected disruption, or the total consequences. These refinements would be the first step toward developing indicators of the risk due to propagating effects created by physical and logical dependencies.

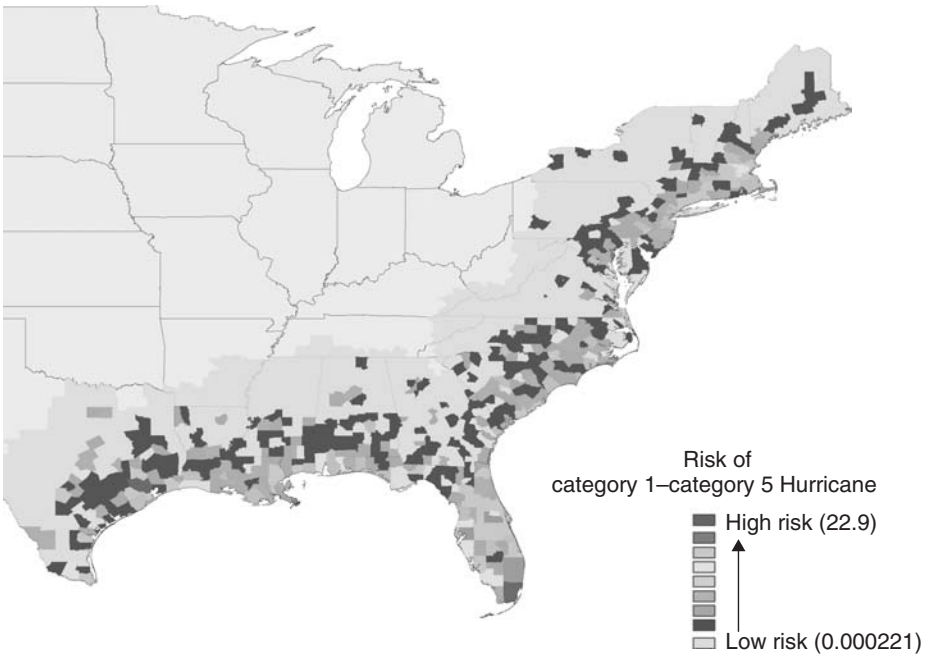

**FIGURE 1** Geographical dependency indicator: relative risk to infrastructure by county due to hurricane; on the basis of frequency of occurrence, category of hurricane and population density (risk indicator developed by the National Infrastructure Simulation and Analysis Center in 2006 for prioritizing off-season hurricane planning scenarios and analyses).

## 4 PHYSICAL DEPENDENCY INDICATORS

Physical dependencies are created when two or more systems are physically connected and one is dependent on the other to function. Interdependencies are created if there are mutual dependencies or if the state of their interaction influences the state of another infrastructure. Connectedness is the basic physical dependency indicator. If a compressor station for a natural gas pipeline is connected to the electric power distribution system, the compressor is likely electric powered. However, it does not indicate if electric power is the primary or only energy source for the compressor or how the loss of power at that compressor station influences the flow of gas in the pipeline. Connectedness only indicates the potential for dependency.

Even simple indicators like connectedness may be difficult to verify on a large scale, because many forms of connection cannot be easily observed (underground utilities), alternative sources may exist (e.g. backup electric power generation capabilities, fuels in onsite storage, and water storage system), and utility data are generally proprietary. In some cases surrogate information exists, such as economic supply and demand data, allowing inference of physical or logical connections. Developing more refined indicators of physical dependencies requires knowledge of the operational impacts of infrastructure input disruptions.

The most connected infrastructures, the ones that create the greatest number of dependencies, are energy (includes electric power, coal, natural gas, nuclear fuels, and petroleum, oils, and lubricants (POL)), communications (includes telecommunications,

information systems, and broadcast), transportation (includes water, rail, pipeline, road, and air transportation systems), and banking and finance (includes federal and commercial banking systems, insurance, commodity markets, and other financial institutions) [4–6]. The overall connectivity of the network is an indicator of system robustness. Abstract models of power networks with different topologies indicate that the greater the overall connectivity, the more robust the network [6]. This implies that while the connected systems are more dependent on each other, the dependency comes with a benefit if it leads to greater connectivity. The connectivity within each of these systems and with other infrastructures depends on which systems and locations are evaluated. The road system in the United States is one of the most highly connected networks, yet it has zones of low connectivity at the edges and in isolated portions of the network. In models of banking transactions, the topology and behaviors are required to estimate system robustness [7].

A general understanding of specific infrastructure processes allows us to develop dependency models and begin the process of refining dependency indicators to include the dynamics of the problem. Only a few of the physical dependencies for energy, telecommunications and transportation, and indicators of those dependencies are provided here.

### 4.1 Electric Power Dependencies

Electric power generation and system control are the processes creating dependencies for the electric power infrastructure. Hydroelectric generation is dependent on the sufficient supply of water and environmental conditions that allow the release of water. Other types of power generation are dependent on water for cooling, specific fuels (coal, natural gas, nuclear, and refined products e.g. diesel and jet fuel), regulatory limits on emissions, and the transportation of fuels from the production region to the generator facility. Indicators of dependencies between electric power generation in a particular location (or region) and fuel production in another location (or region) are developed based on the type of generator(s) and connectivity of the generator to the production region via feasible transportation system(s) for the fuel or fuels.

Transport feasibility requires an economically viable route and mode. In this case, connectivity occurs via the transportation network, making electric power generation dependent on transportation and fuel production. If the generator is connected to multiple fuel production locations (or regions) the dependency on a specific fuel source or specific transportation route is reduced. Figure 2 shows the natural gas pipelines (transportation) and electric power generation plants in the Midwest, focusing on Illinois. The region is able to import natural gas from Canada and the central and southeast regions of the United States. Even more crucial is the fact that natural gas generation is not the primary source of power in this area. Coal-fired generation and nuclear power plants provide most of the power in Illinois [8].

The dependency of a specific facility or region on a specific electric power generator is a little more difficult to quantify than a geographical dependency because of all the factors that influence the steady supply of electric power. First, it must be determined whether the generator has or could have a substantial impact on the electric power supply in the region of concern. In order to understand the influence of a single generator, knowledge about the state of the system is required. The best indicator is the ratio of the plant's generation capacity to the region's reserve margin (the expected amount of

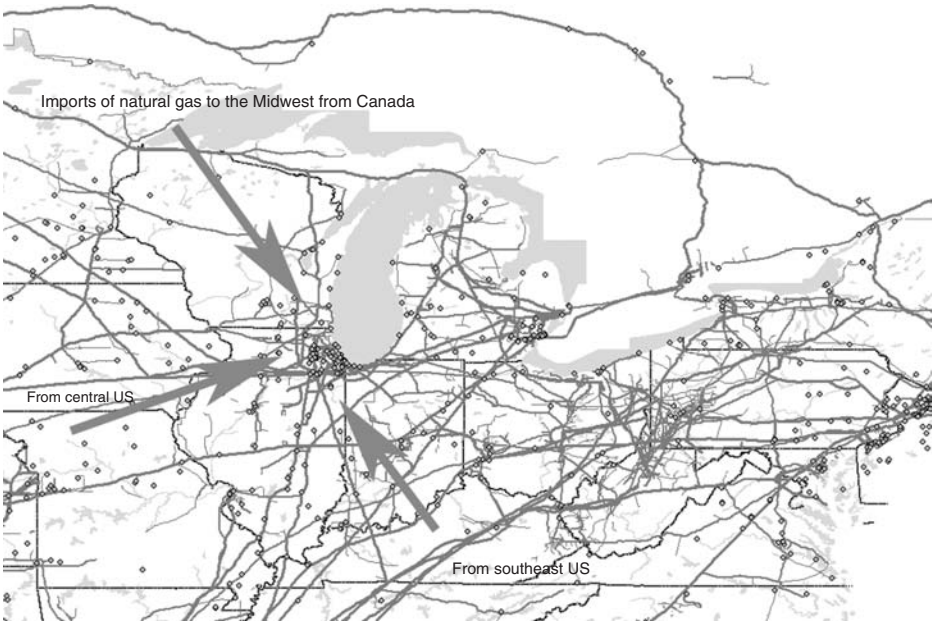

**FIGURE 2** Natural gas pipelines ($\geq$ 10 in. in diameter) and natural gas fired generation in the Midwest US illustrates connectivity to multiple supply regions (based on 2005 data from Plants (power plants) and Penwell (on-shore pipelines)).

available capacity that is greater than the expected peak demand). The reserve margin is an indicator of the state of the electric power system within a specific region, reflecting the likelihood that the region is self-sufficient, can export power to other regions, or will be dependent on power imports from other regions. The indicator for specific generators provides an estimate of how close the system would be moving from one state to another (e.g. self-sufficient to power importer) if that particular generator is taken off-line. Peak demand is used to provide a bounding case, since the regional demand for electric power varies diurnally and seasonally. The indicator has to be updated because peak demand and aggregate generation capacity change over time as changes in population, behaviors, and technology alter power demands and as generation capacity is built or taken off-line (for repairs or permanently retired).

Electric power transmission and distribution system operations are highly automated, human-in-the-loop, remote control systems. Control systems are dependent on reliable communications and data. The power outage in the northeastern United States in August 2003 was due in part to unreliable and missing information [9].

### 4.2 Communication Dependencies

Communication systems can change state very quickly due to a wide variety of reasons, tied to both logical and physical dependencies. Within the telecommunication system there are a large number of system operators that constantly monitor to anticipate conditions that may lead to sudden, prolonged high call volume that creates network congestion and call blocking. It is not clear whether the telecommunication operation indicators will

be of use for the power operation systems, because power operation systems utilize multiple communication systems that are not part of the public telecommunication network. The difference between data system dependencies and other physical dependencies is that data systems are vulnerable to more threats, such as denial of service attacks or malicious software programs (sent from remote sites, using information or wireless communication networks) or electromagnetic disturbances.

The best indicator of dependency on specific communication assets is geographical, local service areas called *local access and transport areas* (*LATAs*). Maps of publicly available LATAs are relatively well known. They correspond to the region of an area code, but some have multiple area codes.

The impact of telecommunication disruptions on the operation of other infrastructures requires more evaluation, but may depend on whether the systems have sufficient volume of critical inputs. Just-in-time management of inventories creates systems that are less robust to supply disruptions [6].

### 4.3 Transportation Dependencies

Transportation systems are dependent upon the physical transportation networks (pipelines, roads, rail, and waterways), fuels for the combustion engines that power the transport (natural gas or electric power for pipeline compressors; diesel for trucks, tankers, and barges; jet fuel for airplanes), specialized labor (commercial drivers, pilots, longshoremen, engineers, and airline pilots), and communication systems for logistics. Given the ubiquity and connectedness of most of the transportation networks anything more than delay in transportation is unlikely for any of the modes, with a few exceptions at the edges and in sparsely populated regions of the networks. Multiple transportation modes mean demand can shift to another mode. Whether that shift occurs, depends on the economics of the shift relative to the cost of the delay.

Fuel supplies are also difficult to disrupt on a large scale because there are significant amounts of fuel of all types distributed around the country in storage systems. Price may be the best indicator of fuel supply, or at least the perceived risks of short supply, and transportation costs. Local fuel shortages can occur when perceived shortages in supply or concern about the reliability of supply lead to hoarding (a logical dependency).

## 5 LOGICAL DEPENDENCY INDICATORS

Logical dependencies, when one infrastructure influences another without being physically connected, are due to human decisions and actions. The state of, or perceived risks in, one infrastructure could influence behaviors/operations in another infrastructure due to loss of confidence in supply; through competition for labor or market share; or due to shifts to alternate inputs as a result of price or regulatory changes.

Economic relationships represent logical dependencies. Input–output models based on sales and production data compiled by government agencies provide indicators of long-term equilibrium conditions between sectors of the economy. They are often used to evaluate the net economic impact of the decline or loss of output in one sector on the other sectors and country or region as a whole. They indicate logical dependencies for a specific period of time, but do not account for production limitations, the ability to offset disruptions through withdrawals from storage, or other adaptations. Without

physical connections, logical dependencies can change suddenly, creating uncertainty and significant instability in supply that ripples through the connected systems. Inventory or production oscillations can be caused by unexpected time delays in receiving shipments or orders [9].

Labor is a logical dependency for all infrastructures. Local labor shortages have occurred during renegotiation of union contracts due to labor walkouts and/or lockouts. Labor has been impacted on a broader scale by large military deployments (World War II and the call for women to enter the manufacturing workforce to offset labor shortages) and pandemics. Infrastructures have continued to function through all those situations because of adaptive behaviors.

Change in demand due to price (demand elasticity) is an indicator of the logical response that moderates the impacts' supply disruptions. Demand elasticity for infrastructure services may be a function of the capability to switch to an alternative supply, implementation of conservation measures, or delaying purchases or production.

Unless a situation has historical precedent, it is difficult to develop proven indicators for this class of dependency. If the event has historical precedent, the reactions may be vastly different, given the knowledge of the previous event or events. And, if the disruption had caused severe problems, effective protective measures may have been put in place. It is not clear that system dynamics models of logical dependencies are predictive but they provide a better indicator of possible outcomes because they are able to represent all types of dependencies in a single, functioning, representation of the complex system. Figure 3 shows the structure of the dependencies in a model developed to evaluate the

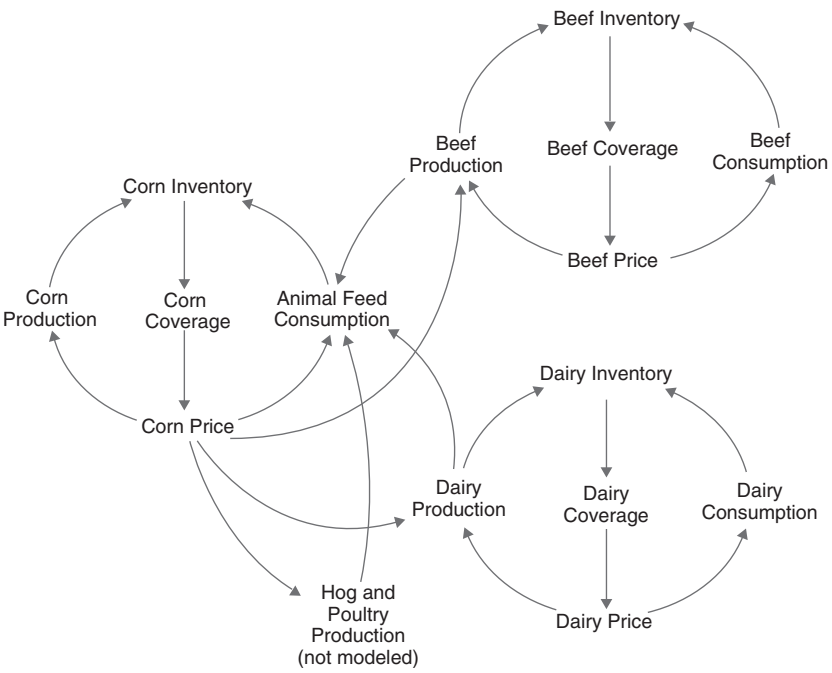

**FIGURE 3** Model structure of dynamic dependencies between livestock, corn, and dairy production showing the logical dependencies between production sectors, created through the price of feed, influencing the characteristics of each production cycle.

dynamic dependencies between beef, dairy, and corn production. The beef–dairy–corn dynamics model was developed as part of the National Infrastructure Interdependency Model in the Critical Infrastructure Protection Decision Support System (CIPDSS) by Sandia, Los Alamos, and Argonne National Laboratories for the Department of Homeland Security Office of Science and Technology, to evaluate the impacts of disease outbreak in the beef cattle industry. The interactions between the three sectors shown in Figure 3 illustrate some of the new, logical dependencies developing between agriculture and energy.

Recently, concern over crude oil prices and supply led to increased use of corn for ethanol production [10], which has increased the price of corn for animal feed. This is causing a switch to cheaper, soy-based feeds in livestock industry. Soy and corn are grown in the same fields (a geographical dependency); high prices for corn reduced the amount of soy grown (a logical dependency) [11]. Short supplies increase soy prices, putting increased pressure on the livestock industry. Beef prices increase. The result being, the prices of all commodities depending on fuels or transportation, physically and logically, increase. The only way to anticipate all these changes is to understand the dependencies and dynamics of this system. Simple indicators do not provide that kind of insight.

# OBJECT-ORIENTED APPROACHES FOR INTEGRATED ANALYSIS OF INTERDEPENDENT ENERGY NETWORKS

RODRIGO PALMA-BEHNKE AND LUIS S. VARGAS
*Department of Electrical Engineering, University of Chile, Santiago, Chile*

## 1 INTRODUCTION

In many fields, there is a growing interest for tools to study the interdependencies of different areas of activity or production. Driven forces in this process have been security, economy, and environmental problems, where the cross effects of policies are highly linked [1]. In the literature, an important part of the investigation is dedicated to the study of critical infrastructure in order to prevent possible catastrophes [2], whereas another line of research is given by environmentally sustainable development [3, 4]. The underlying objective of those works is to study the cross effects of policies in different fields in order to measure their effect on environmental conditions [5]. All these studies recognize the high complexity of the problem, which is characterized by multiple agents and decision makers, large-scale systems with numerous components, nonlinear coupled subsystems, spatially distributed, adaptive in time, and investment decisions of discrete nature. Another aspect of complexity is the need of know-how integration of different disciplines. The mathematical formulation of these problems usually leads to extremely complex systems. In addition, the trend of market liberalization toward decentralized decision process has increased even further the complexity of the problem [6, 7].

This article is organized in seven sections. Section 2 presents the general models used to represent the transportation and energy networks. Section 3 presents the classes and objects relationship. Section 4 describes the software developed according to the system models. In Section 5, the methodology to state the scenarios for the studies is presented. In Section 6, a case study considering the network in the Chilean territory is developed. Finally, in Section 7, the main conclusions of this section are summarized.

## 2 SCIENTIFIC OVERVIEW

In the literature, an important part of the investigation is dedicated to the study of critical infrastructure in order to prevent possible catastrophes [8]. This topic was particularly sensitive during 1999 due to the Y2k effect. Another line of research is given by environmentally sustainable development, where the cross effects of policies in different fields on the improvement of environmental conditions are studied [9]. It is recognized that the high complexity of the problem is characterized by

- large-scale systems with numerous components;
- hierarchical multiple noncommensurable, conflicting, and competing objectives;
- multiple agents and decision makers;
- multiple governmental agencies with different missions, resources, timetables, and agendas;
- multiple constituencies;
- multiple transcending aspects and functions;
- nonlinear coupled subsystems;
- spatially distributed, adaptive in time; and
- investment decisions of discrete nature.

Overall, analysis and design of complex, large-scale nonlinear dynamic interacting systems constitute an open theoretical challenge.

The object-oriented programming (OOP) offers a methodological alternative to deal with the problem of interactions among energy and transportation. Specifically, in this article the development of activity models for each sector and a method for studying their effects on the environment is proposed. This methodology should be capable of measuring the impact due to the future implementation of technological improvements and policies at a country-wide level.

## 3 SYSTEM MODELING

The modeling approach presented in this section is inspired by previous research work [6, 7, 10] based on two main criteria. The first criterion imposes that the main feature of the modeling technique is versatility, that is, it must be capable of being used for the electricity, fuel, and transportation sectors. In addition, a systematic approach to deal with the problem of interdependencies among those sectors is required. To achieve these tasks, the modeling must fulfill the following needs:

- consistent system and component modeling (scaling, databases, and granularity);
- well-defined system frontiers;
- adequate modeling of the interdependencies among different sectors;
- activity models and tools (i.e. agent-based and game theory) inside each sector;
- data mining and visualization.

In the field of software development, two advancements have gained wide spread importance and acceptance: the OOP [11, 12] and the graphical user interface (GUI) [13]. The OOP has recognized advantages that concern flexibility, expandability, maintainability, and data integrity. In this field, the unified/universal modeling language (UML) is a standardized visual specification language for object modeling. UML is a general-purpose modeling language that includes a graphical notation used to create an abstract model of a system, referred to as a *UML model* [10, 12]. This approach is the conceptual base for several popular OOP languages.

Likewise, the GUI improves the user interaction with the computer allowing a more comprehensive analysis tools manipulation and data interpretation. Accordingly, this work

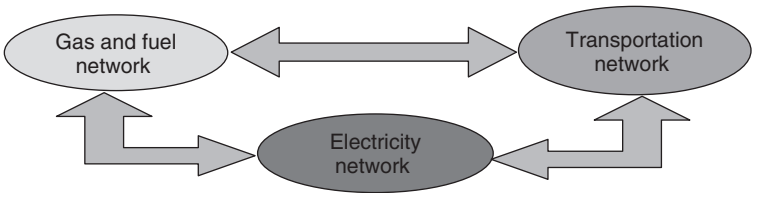

**FIGURE 1** Interdependencies among large-scale infrastructures.

applies an OOP methodology to the new energy market structure in order to create a simulation software package.

The second criterion states that, from a physical point of view, the interdependencies among large-scale infrastructures, such as electric power, transportation, and fuel sectors, often have a network structure (Fig. 1).

This structure reflects an explicit, physical set of network interconnected devices. Also, it can handle implicit interconnections created by communications, control, and functional dependence. Thus, according to the above criteria a model based on the object-oriented (OO) paradigm was chosen in this work. The large box in the center of Figure 2 represents the physical models (urban and interurban) where each network physically and functionally interacts. The regulatory, economic, and technological frameworks are also highlighted as relevant inputs to the two major models. The outputs of the modeling framework are the transport activity levels that are used to compute the fuel and energy consumptions and the environmental impact of the emissions resulting from future economic and technological developments.

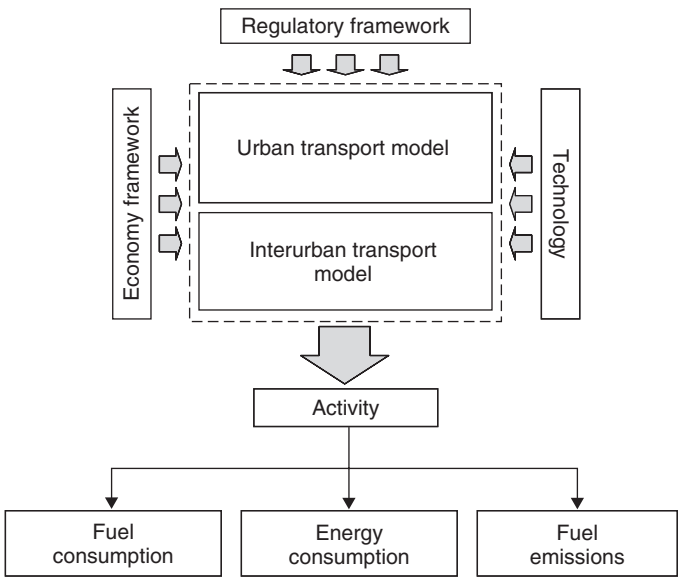

**FIGURE 2** System network model.

The individual characteristics of power, fuel, and transportation components are described by object attributes. On the other hand, the information exchange among objects is represented by messages following the OOP paradigm.

The object modeling technique has been used for developing the object models for each network.

They are shown in Figure 3.

In the OOP terminology, generalization of a data object along with its data variables and methods is a class of data objects. The data variables are referred to as *class attributes* and an instance of a class is called an *object*. The concept of inheritance makes it possible to define subclasses of a class, which share characteristics of the parent class and so on.

The proposed modeling breaks down a "system component" object into three subclasses: namely, "fuel component", "power component", and "transportation component". Each of these components makes a further use of inheritance to encompass all the components of its network. For example, the power system is represented by 1-pole and 2-pole elements.

In the list of attributes for each object, there are emission factors in order to estimate their environmental pollution features. The pollutants considered in this work are CO, HC, No*x*, particle material (MP)10, $SO_2$, $CH_4$, $N_2O$, $NH_3$, and $CO_2$.

## 4 CLASSES AND OBJECTS RELATIONSHIPS

In this section, a description of the classes together with the interdependencies among them is presented.

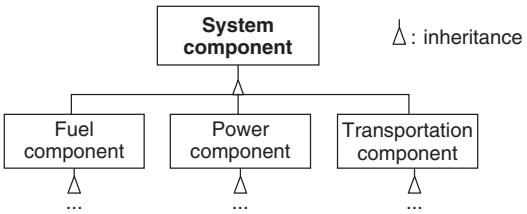

**FIGURE 3** Object model of the system.

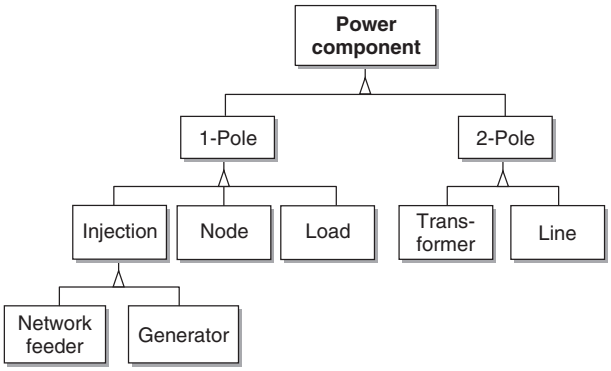

**FIGURE 4** Hierarchy chart of power system classes.

### 4.1 Power System Classes

Figure 4 shows the hierarchy chart of the power system classes, which corresponds to a simplified version of the hierarchy presented in Ref. [12]. Power component is the most general class and its attributes and methods are available for all subclasses [10–12]. Since simulation models are typically based on a node/branch-representation, these classes are explicitly included in the OO data model. The *1-pole* subclass encompasses all elements connected between a bus and the neutral (or ground). The subclass *2-pole* contains all branch facilities having impedance such as transmission lines and transformer subclasses. Note that a three winding transformer may be represented by the *2-pole* subclass by using a wye-star transformation. Some Flexible Alternate Current Transmission Systems (FACTS) devices like UPFC can also be modeled through this concept [14].

All the technical parameters of the power system devices are stored in attributes. These attributes include location, economical data, and the set of emission factors.

### 4.2 Hydro Database

Catchment models that are very important in hydrothermal power systems can be incorporated as an additional OO class hierarchy. The set of classes that compound the hydro database (HDB) is depicted in the hierarchy class of Figure 5. With it, it is possible to model the hydrographic basin or catchments involved in hydro generation in a simplified way. An inflow of water in a natural regime is characterized by the "natural inflow" class, so objects of this kind usually stand at the head of a basin. The "hydro unit" constitutes a decision or an action taken over the water flow, a decision that is specialized in child classes. From the connectivity point of view, the "natural inflow" objects have one output and the "hydro unit" has one input and two output attributes, while the connection between input–output pairs is performed by a "link" object. Following the hierarchy, the "hydro unit" is split into three classes to implement the hydrothermal coordination modeling. While a "series unit" allows full connectivity and could be associated to an network database (NDB's) "generator", an "isolated run of the river" can only receive water from a "natural inflow" and must be associated to a "generator". On the other hand, the "irrigation constraint" class represents extractions from a river course with irrigation purposes, so neither can be related to electrical generation nor can the extractions be the inflow of another object. A more specialized class is the "reservoir unit", which adds to

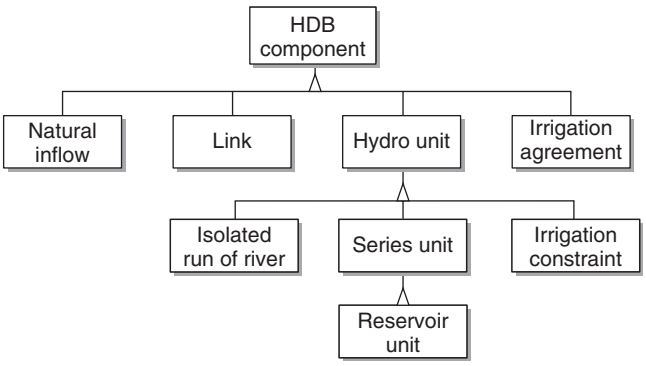

**FIGURE 5** Hierarchy chart of the hydro database (HDB).

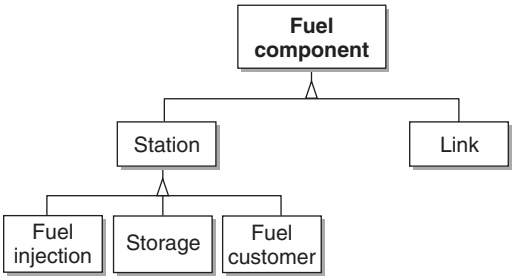

**FIGURE 6** Hierarchy chart of fuel network classes.

the "series unit" the capability to store water attributes. Finally, an abstract class "irrigation agreement" has been created to include a set of rules that comprise water use rights. An "irrigation agreement" object usually restricts the administration of reservoirs and drives the extractions of "irrigation constraint" based on information such as reservoir storage height, period of the year, and caudal measurements at predefined basin points.

### 4.3 Fuel Network Classes

The hierarchy chart of the fuel network classes is shown in Figure 6. Two abstract classes and four final subclasses represent the whole network. A fuel injection system, a storage system, and a customer system can be generalized in a *station* class with common attributes like position and capacity.

A *fuel injection* subclass manages simultaneously different fuel sources in the network. This model can handle 27 different fuel types such as crude oil, city gas, liquefied petroleum gas (LPG), natural gas (NG), gas oil, gasoline (81, 86, 91, 93 lead and unlead), different diesel types, and petcoke.

A *storage object* subclass manages just one of the fuel types. It keeps an initial, current, and final state of stored volume. A more realistic model of a storage can be built with several storage objects.

A *fuel customer* subclass is characterized by the type and amount of each fuel. It can manage simultaneously all possible fuel types coming from the fuel stations.

The *link* represents a union element between two *station* objects. The main attributes are the fuel type, the capacity, and length. Additional *links* are differentiated by the transportation mode of the fuel: pipeline, train, truck, and ship.

### 4.4 Transportation Network Classes

The hierarchy chart of the transportation network classes defines an *arc* and a *generic node* class. The generic node is further specialized into two classes called *node* and *centroid*, as shown in Figure 7.

For transportation networks, a first conceptual separation between urban and interurban networks must be made [15]. A strategic planning study with a national coverage must include an interurban traffic representation. Therefore, in the context of the proposed model, a *centroid* is associated with a conurbation or a vast urban area around and including a large city. The transportation activity of a *conurbation* is stored in attributes,

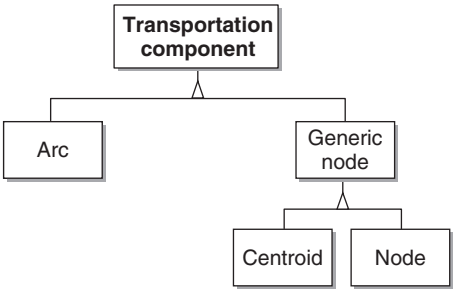

**FIGURE 7** Hierarchy chart of transportation network classes.

which register the number of attracted and generated travels, the rate of growth, and other relevant parameters.

The *node* component intends to represent only bifurcation and convergence points of transportation ways (with or without population). A *node* either generates or attracts travels. The transportation ways are modeled through a generic class called *Arc*, considering only one-way travels. *Arcs* define capacity, flow, length and speed for each of the following transportation modes: train, electric train, light vehicle, bus, heavy duty vehicle, ship, and plane.

### 4.5 Objects Relationship

One of the main objectives of the proposed modeling is to capture the interdependencies among different sectors. This is accomplished easily by using the classes of each OOP database (power, fuel, and transportation). In fact, a direct relationship between objects, from different databases, occurs through references to objects in the OOP. These references, as shown in Figure 8, are given as attributes, of the individual classes. Let us see some examples:

- A combined cycle generating plant is represented as a NG customer in the fuel network.
- Electricity consumption of arcs, centroids, injections, and links of the transportation network are represented by loads in the electric power network.
- Fuel consumption, resulting from the activity of centroids and arcs in transportation networks, is represented by customers in the fuel network.

In the case of HDB, hydro units processed water is electrically generated by generators and/or network feeders from NDB.

These references define information that is directly available to objects. Thus, the fuel customer "knows" the electrical behavior of a generator, the electrical load "*knows*" the energy consumption of an oil refinery, and so on.

## 5 INFORMATION PLATFORM

On the basis of the preceding models, the PIET (an acronym in Spanish for Transportation and Energy Information Platform) software was developed using Java technology

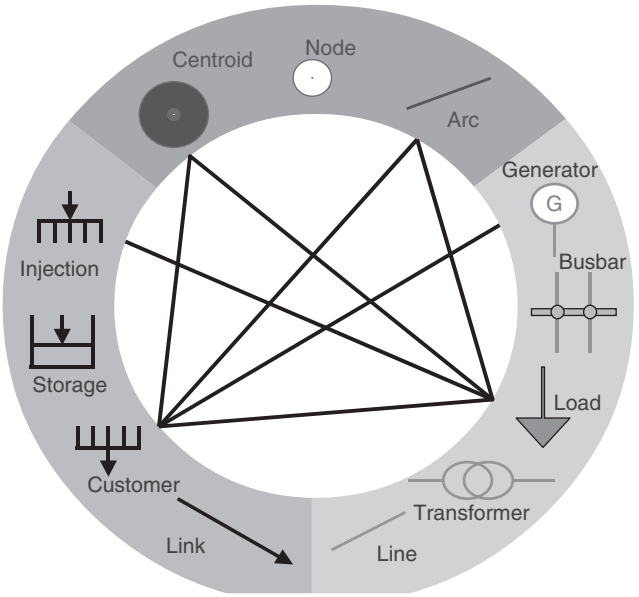

**FIGURE 8** Physical relationship between objects.

(Fig. 9) [10].[1] The OO database (server), which is required by the rest of the platform components, constitutes the core of the application. Source-file and specific power, fuel, and transportation editors allow user interaction with the system information and options.

The gray arrows represent the transmission of required services from clients to their respective servers and the black arrows represent data exchange flows. The design deals with critical aspects of the data management requirements for commercial software and energy companies by building a bridge to existing databases in different source/data file formats.

## 6 SCENARIO DESCRIPTION

The proposed model has the ability to generate, simulate, and analyze global potential scenarios. In this work, we define scenario as a "case study", expressed in words and numbers, about the way future events and the alternatives can develop. Although uncertainties dominate what really will happen, it is possible to write interesting and believable histories regarding the future.

The generation of a scenario usually involves the following steps:

- Defining the limit of space analysis (global, regional, etc.), thematic (sectors to cover, etc.), and temporal (time horizon).
- Describe the current economic, demographic, environmental, and institutional situation.
- Incorporating the driving and conditioning forces of the system and sectors.

[1]The final code (around 400 classes) runs efficiently on a Pentium IV computer with 512 MB RAM.

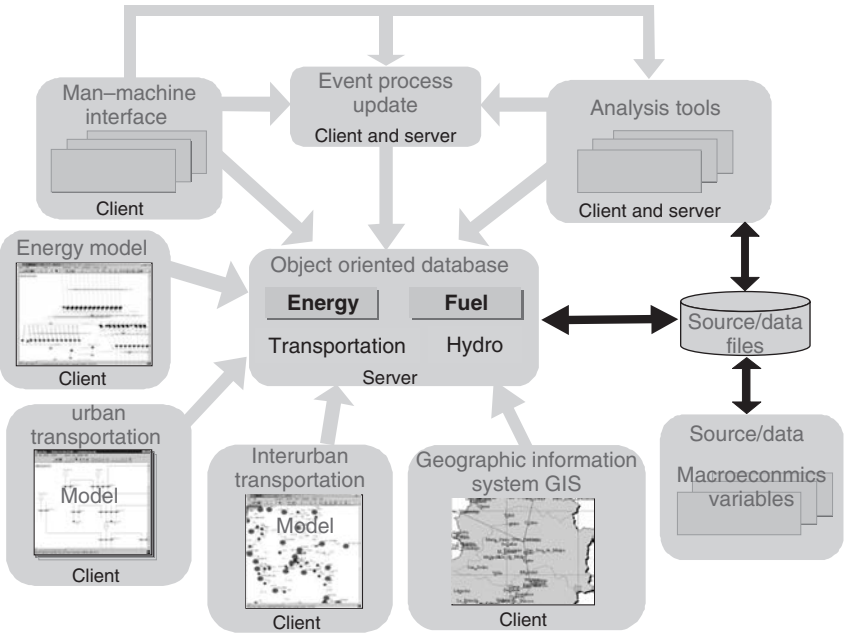

**FIGURE 9** PIET client-server architecture.

- Setting up a narrative that gives the context to the scenario. Often quantitative indicators are used to point out certain aspects.
- Drawing an image of the future. This involves specifying conditions and constraints for one or more points in the time horizon.

The outcome of this procedure is the definition of the following variables: demography, economy, social variables, culture, technology, environment, structures of administration (governance), and infrastructure. These variables work as the entry parameters defining a scenario in PIET. In practical terms, the OO design of PIET allows the following four ways to configure scenarios:

1. Through a direct linking with a *support model*. Support models, refers to those tools (computational programs, rules, databases, etc.) that allow the definition of a scenario. This can be a specific model usually used in the sector (i.e. transportation, energy, or environment) that can provide directly the information for the operation of the PIET.
2. A second alternative is through the use of *activity models* to obtain specific values for variables or entrance parameters to PIET. An example of an activity model is the calculation of fuel price profiles and deviations for a given scenario.
3. By using directly PIET dialogs and frames, that is, objects, system, and tools attributes.
4. Finally, structural changes in networks (for example, the expected generation expansion plan) can be incorporated in PIET by using the respective Editor. Typically it consists of drawing new objects in the networks.

Once the scenario has been incorporated into PIET, specific activity models for each network are run in order to obtain the quantification of interdependencies and the emissions of the scenario. The following studies can be carried out with PIET:

- fuel price variation effects;
- new technology impact;
- effects on energy sector produced by an efficient use of the transportation network;
- identification of network capacity constraints (critical expansion sectors);
- map with possible locations for power plants.

## 7 CASE STUDY EXAMPLE

For a validation of the proposed model, PIET was applied to Chile including the whole national territory. In this case, the hydro network was not considered.

### 7.1 Physical Chilean Networks

The Chilean mainland territory covers an area of 750,000 $km^2$ with a population of nearly 16 million. Chile has a market-oriented economy characterized by a high level of foreign trade. As a consequence, the electric, fuel, and transportation infrastructure come mainly from private investors. The electricity production was 39.577 billion kWh in 2000, which comprised fossil fuel (51.17%), hydro (46.36%), and others (2.47%). The transmission system, conformed by two main interconnected systems, includes voltage levels up to 500 kV.

NG is imported from neighbor countries using a pipeline system, while fuel and coal arrive in ships from different countries. In summary, the fuel network encompasses a pipeline system of crude oil (755 km), petroleum products (785 km), and NG (320 km).

In the transportation sector, all transport services are privately owned and/or operated with the exceptions of the interurban passenger trains and the urban railroad (Metro). Overall, the railroad system has 6702 km of railways, including 2831 km of broad gauge (1317 km electrified), 117 km narrow gauge (28 km electrified), and 3,754 km of meter gauge (37 km electrified). The highway system covers 79,800 km.

Because of data availability and geographical features of the country, the territory information is described at a province level by 51 zones. Nevertheless, major projects in any network, for example, a new mining site or a new combined cycle unit, are modeled explicitly in the networks (new objects).

In summary, as shown in Table 1, the modeling into PIET of the previous described networks (power system, transportation, and fuel network) can be translated in a collection of 1927 objects: 1127 objects are defined for representing the transportation sector, 492 for the electric sector, and 308 for the fuel network.

### 7.2 Network Dependencies

Network dependencies can be classified into two main categories: activity and physical dependencies.

On the one hand, the activity of each network—annual flow (vehicle·km/year) in transportation, annual energy (MWh/year) in electricity sector, and annual consumption

**TABLE 1 Objects in the Chilean Case**

| | |
|---|---|
| **Power system network** | |
| Number of nodes | 103 |
| Number of lines | 106 |
| Number of transformers | 39 |
| Number of generators | 42 |
| Number of loads | 202 |
| Total | 492 |
| **Transportation network** | |
| Number of centroids | 272 |
| Number of nodes | 183 |
| Number of arcs | 672 |
| Total | 1127 |
| **Fuel network** | |
| Number of fuel injections | 20 |
| Number of fuel storages Centers | 0 |
| Number of fuel links | 257 |
| Number of fuel customers centers | 31 |
| Total | 308 |

(barrel/year or ton/year) in fuel and NG—in the case of Chile can be related with a common set of economic indices. These indices are as follows: gross domestic product (GDP)/year for each province, international and domestic fuel prices, fuel taxes, population (inhabitants/province), and average income. These indices simultaneously shape the behavior of each network.

On the other hand, several physical interactions among the different networks are detected. A diagram with the main physical interdependencies among the networks in the Chilean territory is shown in Figure 10.

Figure 10 shows that in the whole Chilean territory, there are 133 links among electric, fuel, and transportation networks. As these links are geographically referenced, this information is useful for many purposes such as mapping of pollution in zones, energy consumption, available transfer capabilities of lines, pipelines, and so on.

The national power network is further divided into two main interconnected systems covering the north (Spanish the Northern Interconnected System (SING) with 800 km length) and the central part of the territory (Spanish the Central Interconnected System (SIC) with 2000 km length). As stated before, a major advantage of this representation is that it can be used for planning studies. For example, a new power plant may be drawn in the editor and the impact of this new project is seen inside the power grid and in the fuel network that will provide oil or NG for that plant. In addition, the pollution that this new project will produce will be displayed accordingly.

### 7.3 Specific Activity Models

On the basis of the studies carried out by the government and independent institutions, activity indices and physical dependencies are estimated for each year in the time horizon. A specific activity model is developed for each network.

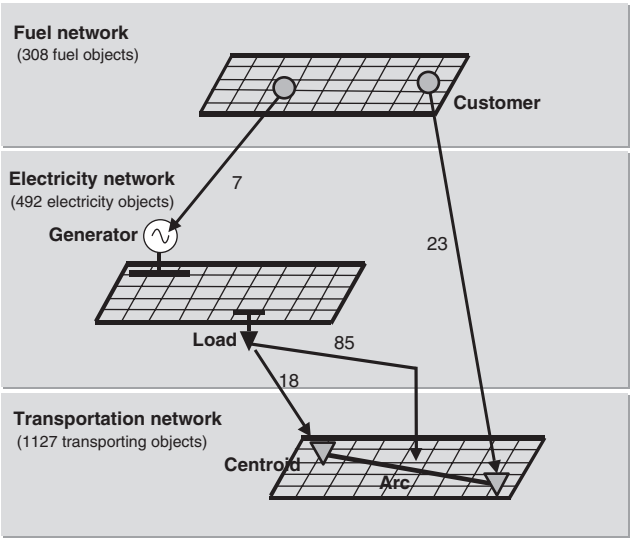

**FIGURE 10** Diagram with links among sectors.

***7.3.1 Power Systems.*** A multinodal, multireservoir dynamic stochastic model, with monthly stages and a time horizon of 10 years is used. Energy production and fuel consumption of each generating unit and their related emissions are obtained. The active power flow pattern for peak demand is computed [10].
