Table of Contents

Section 1.2 Change Control Management

Section 1.3 Data Classification

Section 1.4 Risk Management

Section 1.5 Policies, Standards, Procedures and Guidelines

Section 1.6 Security Awareness Training

Section 1.7 Security Management Planning

Section 1.8 Ethics

Section 2.1 Access Control Techniques

Section 2.2 Access Control Administration

Section 2.3 Identification and Authentication Techniques

Section 2.4 Access Control Methodologies and Implementation

Section 2.5 Methods of Attack

Section 2.6 Monitoring and Penetration Testing

3 CRYPTOGRAPHY 1019

Section 3.1 Use of Cryptography

Section 3.2 Cryptographic Concepts, Methodologies, and Practices

Section 3.3 Private Key Algorithms

Section 3.4 Public Key Infrastructure (PKI)

Section 3.5 System Architecture for Implementing Cryptographic Functions

Section 3.6 Methods of Attack

Section 4.1 Elements of Physical Security

Section 4.2 Technical Controls

Section 4.3 Environment and Life Safety

Section 5.1 Principles of Computer and Network Organizations, Architectures, and Designs

Section 5.2 Principles of Security Models, Architectures and Evaluation Criteria

Section 5.3 Common Flaws and Security Issues: System Architecture and Design

6 BUSINESS CONTINUITY PLANNING AND DISASTER RECOVERY PLANNING

Section 6.1 Business Continuity Planning

Section 6.2 Disaster Recovery Planning

Section 6.3 Elements of Business Continuity Planning

Section 7.1 Communications and Network Security

Section 7.2 Internet, Intranet, Extranet Security

Section 7.3 E-mail Security

Section 7.4 Secure Voice Communications

Section 7.5 Network Attacks and Countermeasures

8 APPLICATION SECURITY 2263

Section 8.1 Application Issues

Section 8.2 Databases and Data Warehousing

Section 8.3 Systems Development Controls

Section 8.4 Methods of Attack

Section 9.1 Concepts

Section 9.2 Resource Protection Requirements

Section 9.3 Auditing

Section 10.1 Information Law

Section 10.2 Investigations

Section 10.3 Major Categories of Computer Crime

Section 10.4 Incident Handling

Introduction

As this book goes to galley, a federal jury has found former Enron Corporation executives Kenneth L. Lay and Jeffrey K. Skilling guilty of conspiracy and fraud in connection with the 2001 collapse of the onetime energy trading giant.

However, long before the guilty verdicts against Lay and Skilling, the "Enron Effect" was already impacting the behavior of some corporations.

Houston oil service company Dresser-Rand Group Inc., responded to the public outrage that followed Enron Corp.'s 2001 collapse, referencing its more stringent ethics policy, announced its dogma of corporate good behavior on the company's Website. Engineering giant Fluor Corp.'s new code of conduct has a one word description under the Exceptions section: "None."

Moreover, new laws and regulations have forced companies to develop stronger ethics policies. More so than ever before, shareholders are holding publicly traded companies more accountable for their practices.

What does this have to do with Information Security? In a word, *everything*.

An organization's information security program is a direct result of its management ethics and values. Principles such as "we comply with applicable laws and regulations" and "we protect our customers' privacy" lead directly to the technical, physical, and administrative controls that should be implemented.

US federal and state legislators continue to make certain that information security is a board-level conversation vis-à-vis the enactment of regulations such as Sarbanes-Oxley, Gramm-Leach-Bliley, the Payment Card Industry Standard (PCI), the Health Insurance Portability and Accountability Act (HIPAA) and the Federal Information Security Management Act (FISMA).

Current EU privacy legislation and evolving US privacy laws, such as California's Senate Bill 1386, demonstrate the concerns that consumers continue to verbalize relative to the privacy of their personal information. These laws ensure that the topic of information security remains on the board of directors' agenda.

Is this good news for those that are tasked with securing information assets? Or are these new rules contending for valuable resources that would otherwise be deployed for other priorities?

At some point in time, security and compliance efforts should converge. One way or the other, private or public organizations must deal with protecting the sensitive information for which they are entrusted.

So where do we turn for practical, viable solutions? Clearly, there are more options available than at any other time: trade magazines, internet websites, technical compositions, practitioner classes, certificate courses, industry associations and this handbook. All sources are worth a look-see.

Many of these sources are worth placing in a spot that is easily accessible, at arm's reach, so they can be pulled off the shelf when a question must be answered or a solution sought.

I submit that this handbook is one of those references that should be "close at hand."

The handbook is a compilation of treatises which address risk assessments, metrics, security governance, emerging threats, standards, physical security and business continuity, and a plethora of technology issues including application controls, network security, virus controls and hacking.

As always, this volume balances contemporary articles with relevant articles from past editions. And as always, we offer this information to empower you, the reader, with valuable knowledge supplied by fellow practitioners and authorities in their fields.

Best of luck,
Hal Tipton and Micki Krause

Editors

Harold F. Tipton, CISSP, currently an independent consultant and past president of the International Information System Security Certification Consortium (ISC)^2, was Director of Computer Security for Rockwell International Corporation for 15 years. He initiated the Rockwell computer and data security program in 1977, and he continued to administer, develop, enhance, and expand the program to accommodate the control needs produced by technological advances until his retirement from Rockwell in 1994. He became a member of the Information Systems Security Association (ISSA) in 1982, and he served as president of the Los Angeles Chapter in 1984. From 1987 to 1989, he served as president of the national organization of ISSA. He was added to the ISSA Hall of Fame and the ISSA Honor Role in 2000. He received the Computer Security Institute "Lifetime Achievement Award" in 1994 and the (ISC)^2 "Hal Tipton Award" in 2001.

He was a member of the National Institute for Standards and Technology (NIST) Computer and Telecommunications Security Council and the National Research Council Secure Systems Study Committee (for the National Academy of Science). He has a B.S. in engineering from the U.S. Naval Academy, an M.P.A. from George Washington University, and a certificate in computer science from the University of California, Irvine. He has published several papers on information security issues in the *Information Security Management Handbook*, *Data Security Management*, *Information Systems Security*, and the National Academy of Sciences report *Computers at Risk*.

He has been a speaker at all of the major information security conferences, including the Computer Security Institute, ISSA Annual Working Conference, Computer Security Workshop, MIS Conferences, AIS Security for Space Operations, DOE Computer Security Conference, National Computer Security Conference, IIA Security Conference, EDPAA, UCCEL Security and Audit Users Conference, and Industrial Security Awareness Conference. He has conducted and participated in information security seminars for (ISC)^2, Frost and Sullivan, UCI, CSULB, System Exchange Seminars, and the Institute for International Research.

Micki Krause, CISSP, has held positions in the information security profession for the past 20 years. She currently serves as the Chief Information Security Officer at Pacific Life Insurance Company in Newport Beach, California, where she is accountable for directing its information protection and security program enterprise-wide. She has held several leadership roles in industry-influential groups, including the Information Systems Security Association (ISSA) and the International Information System Security Certification Consortium. She is a long-term advocate for professional security education and certification. In 2003, she received industry recognition as a recipient of the "Women of Vision" award given by *Information Security* magazine. In 2002, she was honored as the second recipient of the Harold F. Tipton Award in recognition of sustained career excellence and outstanding contributions to the profession. She is a reputed speaker, published author, and co-editor of the *Information Security Management Handbook* series.

Contributors

Thomas Akin, CISSP, has worked in information security for almost a decade. He is the founding director of the Southeast Cybercrime Institute where he also serves as chairman for the Institute's Board of Advisors. He is an active member of the Georgia Cybercrime Task Force where he heads up the task force's education committee. He also works with Atlanta's ISSA, InfraGard, and HTCIA professional organizations. He has published several articles on information security, and he is the author of *Hardening Cisco Routers.* He developed Kennesaw State University's highly successful UNIX and Cisco training programs and, in addition to his security certifications, is also certified in Solaris, Linux, and AIX; is a Cisco Certified Academic Instructor (CCAI); and is a Certified Network Expert (CNX).

Mandy Andress, CISSP, SSCP, CPA, CISA, is founder and president of ArcSec Technologies, a security consulting firm specializing in product/technology analysis. Before starting ArcSec Technologies, she worked for Exxon, USA, and several Big 5 accounting firms, including Deloitte & Touche and Ernst & Young. After leaving the Big 5, she became the director of security for Privada, Inc., a privacy start-up in San Jose. At Privada, she helped develop security policies, secure network design, develop Firewall/VPN solutions, increase physical security, secure product design, and periodic network vulnerability testing. She has written numerous security product and technology reviews for various computer trade publications. A member of the Network World Global Test Alliance, she is also a frequent presenter at conferences, including Networld + Interop, Black Hat, and TISC. She is the author of *Surviving Security, 2nd Edition* (Auerbach Publications, 2003).

Jim Appleyard is a senior security consultant with the IBM Security and Privacy Services consulting practice. With 33 years of technical and management experience in information technology, he specializes in enterprise-wide information security policies and security architecture design. He has specific expertise in developing information security policies, procedures, and standards; conducting business impact analysis; performing enterprise-wide security assessments; and designing data classification and security awareness programs.

Ioana V. Bazavan, CISSP, is a manager with Accenture's global security consulting practice. She has written security policies, standards, and processes for clients in a range of industries, including financial services, high-tech, resources, and government.

Chuck Bianco, FTTR, CISA, CISSP, is an IT examination manager for the Office of Thrift Supervision in Dallas, Texas. He has represented his agency on the IT subcommittee of the FFIEC. He has experienced more than 600 IT examinations, participated in six IT symposia, written OTS' original Disaster Recovery Bulletin, and led the Interagency Symposium, resulting in SP-5. He was awarded the FFIEC Outstanding Examiner Award for significant contributions, and he received two Department of the Treasury Awards for Outstanding Performance.

Christina M. Bird, PhD, CISSP, was responsible for technical review and implementation of Internet firewalls, virtual private networks, and authentication systems at Cerner Corporation in Kansas City, and, subsequently, for Secure Network Group in Lawrence, Kansas; she was the director of network intelligence at Counterpane Internet Security and a computer security officer for Stanford University. Her responsibilities have included assessment of threats to corporate assets and current security practices, technical evaluation of available products, planning for long-term growth of Internet and extranet infrastructure, and network configuration and management in accordance with security policy. She is the moderator of the Virtual Private Networks mailing list and the owner of *VPN Resources on the World Wide Web*, a vendor neutral source of information about VPN technology.

Steven F. Blanding, CIA, CISA, CSP, CFE, CQA, was, when his contributions were written, the regional director of technology for Arthur Andersen based in Houston, Texas. He has 25 years of experience in the areas of financial auditing, systems auditing, quality assurance, information security, and business resumption planning for large corporations in the consulting services, financial services, manufacturing, retail electronics, and defense contract industries.

David Bonewell, CISSP, CISSP/EP, is the president of Accomac Consulting LLC, Cincinnati, Ohio. He was a chief security architect with Teradata, Cincinnati, Ohio.

Dan M. Bowers, CISSP, is a consulting engineer, author, and inventor in the field of security engineering.

Gerald Bowman is currently the North American director of ACE and advanced technologies for SYSTIMAX® Solutions for the design of the professional community and advanced technology in the corporate enterprise. He joined the SYSTIMAX team from Superior Systems Technologies where he was COO. Prior to that appointment, he was vice president of engineering for Riser Management Systems, a telecommunications design, engineering, management, and consulting firm responsible for consulting engineering projects for 78 of the tallest buildings in the United States, including 12 Carrier Hotels, numerous data centers for ISPs, high-end telecom real estate, and other corporate enterprises.

Robert Braun, a partner in the Corporate Department of Jeffer, Mangles, Butler, & Marmaro LLP, specializes in corporate, finance, and securities law with an emphasis on technology-oriented firms. His practice includes the establishment and development of strategies to implement computer software, computer hardware, communications, and e-commerce solutions as well as public and private securities offerings; mergers and acquisitions; venture capital financing; and joint ventures. He counsels a variety of firms on software development and licensing; formation, maintenance, and linking of websites; electronic commerce transactions and related matters; and acquisitions, divestitures, and corporate and strategic functions. He is a member of the American, California, and Los Angeles County Bar Associations and is an active participant in a variety of business and technology committees and task forces.

Thomas J. Bray, CISSP, is a principal security consultant with SecureImpact. He has more than 13 years of information security experience in banking, information technology, and consulting. SecureImpact is a company dedicated to providing premier security consulting expertise and advice. SecureImpact has created its information and network service offerings to address the growing proliferation of security risks experienced by small to mid-sized companies.

Al Bredenberg is a writer, web developer, and Internet marketing consultant. He is author of *The Small Business Guide to Internet Marketing* and the editor of *The NET Results News Service*, both of which are electronic publications available over the Internet.

Anthony Bruno, CCIE #2738, CISSP, CIPTSS, CCDP, is a senior principal consultant for INS, an international professional services company, with over 16 years of experience in data networks and telecommunications. Prior to consulting, he was an Air Force captain in charge of the operation and maintenance of a large metropolitan area network. He is author of the *CCDA Exam Certification Guide, 2nd Edition* and the *CCIE Routing & Switching Certification Exam Guide.*

Alan Brusewitz, CISSP, CBCP, has more than 30 years of experience in computing in various capacities, including system development, EDP auditing, computer operations, and information security. He has continued his professional career leading consulting teams in cyber security services with an emphasis on e-commerce security. He also participates in business continuity planning projects, and he is charged with developing that practice with his current company for delivery to commercial organizations.

Graham Bucholz is a computer security research analyst for the United States government in Baltimore, Maryland.

Carl Burney, CISSP, is a senior Internet security analyst with IBM in Salt Lake City, Utah.

Ken Buszta, CISSP, is the chief information security officer for the City of Cincinnati, Ohio, and he has more than ten years of IT experience and six years of InfoSec experience. He served in the U.S. Navy's intelligence community before entering the consulting field in 1994.

Mark Carey is the CEO of DelCreo Inc., an enterprise risk management company. He directs DelCreo operations and consulting services, including enterprise-wide risk management, business continuity and disaster recovery planning, incident management, information security, and e-business risk management programs in the technology industry. Prior to starting DelCreo, he managed Ernst & Young's western U.S. region of the business risk solutions practice. He coordinated the relationship and managed delivery of all risk management related services, including program management, business continuity planning, enterprise risk assessments, information security, incident management, and privacy advisory services.

Glenn Cater, CISSP, has more than 11 combined years experience in information security, IT management, and application development. He currently holds the position of director of IT risk consulting at Aon Consulting, Inc. In this role, he supports Aon's electronic discovery services, high-tech investigations, and IT security consulting practices. He joined Aon from Lucent Technologies where he held the position of technical manager within the IT security organization. At Lucent, he supervised the Computer Security Incident Response Team, supporting the intrusion prevention and security event management systems. He also worked as managing principal of the reliability and security consulting practice at Lucent Worldwide Services, leading and supporting security consulting engagements for LWS clients. Before that, he worked as a senior network security manager at Lucent Technologies where he managed a development team and supported internal security solutions. Prior to joining Lucent, he began his career as a software engineer at British Aerospace working on military systems.

Tara Chand, Esq., CISSP, is the founder of Internet Promise Group LLC.

Samuel W. Chun, CISSP, is the director of information and risk assurance services with TechTeam Global Government Solutions Inc. He has over fifteen years of experience in technical architecture and network engineering with an emphasis on secure network environments. He is currently leading his company's technical compliance effort to the Sarbanes-Oxley Act of 2002.

Anton Chuvakin, PhD, GCIA, GCIH, GCFA, is a recognized security expert and book author. In his current role as a director of product management with LogLogic, he is involved with defining and executing on a product vision and strategy, driving the product roadmap, conducting research, and assisting key customers with its LogLogic implementations. He was previously a chief security strategist with netForensics, a security information management company. A frequent conference speaker, he is an author of *Security Warrior* and a contributor to *Know Your Enemy II*, *Information Security Management Handbook*, and the upcoming *Hacker's Challenge 3*. He also published numerous papers on a broad range of security subjects. In his spare time, he maintains his security portal http://www.info-secure.org, http://www.chuvakin.org, and several blogs.

Ian Clark is the security portfolio manager for Nokia's business infrastructure where he has been working on global security projects for the past five years. Prior to Nokia, he worked for EDS and spent 11 years in the British army specializing in secure communications. He is a member of the BCS.

Douglas G. Conorich is the global solutions manager for IBM Global Service's Managed Security Services with over 30 years of experience with computer security through his holding a variety of technical and management positions. He is responsible for developing new security offerings, ensuring that the current offerings are standardized globally, and overseeing the training of new members of the MSS team worldwide. He teaches people how to use the latest vulnerability testing tools to monitor Internet and intranet connections and how to develop vulnerably assessments by suggesting security-related improvements. He is also actively engaged in the research of bugs and vulnerabilities in computer operating systems and Internet protocols, and he is involved in the development of customized alerts, notifying clients of new potential risks to security. He has presented papers at over 400 conferences, published numerous computer security-related articles on information security in various magazines and periodicals, and held associate professor positions at several colleges and universities.

Michael J. Corby, CCP, CISSP, the senior director of Risk Management at Gartner Consulting, has over 35 years of experience in IT strategy, operations, development, and security. He has successfully managed large projects and developed flexible IT infrastructures and sound security organizations for hundreds of the world's most successful organizations. He is also the founder of (ISC) ^{2} Inc., the organization that established the CISSP credential. In 1992, he was named the first recipient of the Computer Security Institute's Lifetime Achievement Award. A frequent global speaker and author, he formerly held executive positions with several global consulting organizations, including Netigy Corporation and QinetiQ prior to joining Gartner Group Consulting through the acquisition of Meta Group, and he was formerly CIO for a division of Ashland Oil and for Bain & Company. A business owner for over 15 years (M Corby & Associates, Inc.) and a community supporter, he has established a reputation for creativity and excellence in technology and its application to business needs. He is based in the Lowell, Massachusetts office.

Mignona Cote, CISA, CISM, has over 15 years of management-level experience securing and improving technical operations for companies like PepsiCo, Nortel Networks, and Verizon. She recently joined a large financial institution to leverage her expertise in the security and auditing field into the financial control environment. Her experience spans across multiple technologies and disciplines, ranging from running incident response teams, vulnerability management initiatives to leading hardening programs to secure networks and large scale application environments. She maintains hands-on experience with the growing malware concerns while ensuring proactive and detective controls such as IPS/IDS solutions are protecting enterprises. She is a member of the North Dallas chapter of the Institute of Internal Auditors and a member of ISACA.

Kellina M. Craig-Henderson, PhD, is an associate professor of social psychology at Howard University in Washington, D.C. His work has been supported by grants from the National Science Foundation and the Center for Human Resource Management at the University of Illinois.

Chris R. Cunningham, CISSP, is an Internet security engineer at Wilmington Trust Corporation. His responsibilities include the security architecture and management of policies and technologies that contribute to the security of the Wilmington Trust Corporation and its affiliates in the United States and abroad. His experience is in both cyber and physical security for financial institutions.

Jeffrey Davis, CISSP, has been working in information security for over ten years. He is currently a senior manager at Lucent Technologies, and he is involved with intrusion detection, anti-virus, and threat assessment.

Matthew J. Decker, CISSP, CISA, CISM, CBCP, is a principal with Agile Risk Management, specializing in information security consulting and computer forensics services. During his career, he has been a senior manager with a Big 4 accounting firm, provided security consulting services for Lucent Technologies and International Network Services, devoted engineering and security consulting support to the United States Special Operations Command (USSOCOM) with Booz Allen Hamilton, and served nine years with the National Security Agency (NSA). He is a member of the ISSA, ISACA, and DRII, and he served as president to the Tampa Bay Chapter of ISSA from 1999 to 2003.

Gildas Deograt-Lumy, CISSP, is a CISSP CBK seminar instructor. He has been working in the IT field for more than eleven years with a focus over the past six years on information security. His experience includes development and implementation of physical access control, security policy, architecture, and awareness programs. Presently, he is an information system security officer for Total E&P Head Quarter, implementing policy, conducting audits, and responsible for various projects such as implementing network-based IDS/IPS across worldwide corporate networks and creating enclave systems to deal with high-grade attacks. Before working in France, he was the chief information security officer at TotalFinaElf E&P Indonesia, a board member of the Information System Security Association Indonesia, and a board member of Kampus Diakoneia Modern, a non-government organization in Indonesia that serves homeless people and street children.

John Dorf, ARM, is a senior manager in the Actuarial Services Group of Ernst & Young. Specializing in insurance underwriting and risk management consulting, he earned his 19 years of experience as a risk manager at several Fortune 500 financial service and manufacturing firms. Before joining Ernst & Young, he was a senior risk manager at General Electric Capital Corporation. He has also held risk management positions at Witco Corporation, National Westminster Bank, and the American Bureau of Shipping. Prior to becoming a risk manager, he spent seven years as an underwriting manager and senior marine insurance underwriter at AIG and Atlantic Mutual.

Ken Doughty, has over 25 years experience in IS auditing and business continuity both in the public and private sectors. He holds an Accounting Degree and a Graduate Diploma in Internal Auditing from the University of Technology, Sydney (UTS). In September 2000, he had his first book published, “Business Continuity: Protecting Your Organization’s Life” (Auerbach Publications, 2000). In 2002 he received the ISACA’s Best Speaker & Conference Contributor Award. A former TAB Limited (NSW) CIO and lecturer at UTS, Ken was one of the standout presenters at both the 2003 and 2004 itSMFA National Conferences.

Mark Edmead, CISSP, SSCP, TICSA, is president of MTE Software, Inc., and he has more than 25 years of experience in software development, product development, and network/information systems security. Fortune 500 companies have often turned to him to help them with projects related to Internet and computer security. He previously worked for KPMG Information Risk Management Group and IBM’s Privacy and Security Group where he performed network security assessments, security system reviews, development of security recommendations, and ethical hacking. Other projects include helping companies develop secure and reliable network system architecture for their Web-enabled businesses. He was managing editor of the *SANS Digest* and contributing editor to the *SANS Step-by-Step Windows NT Security Guide*. He is co-author of *Windows NT: Performance, Monitoring and Tuning*, and he developed the *SANS Business Continuity/Disaster Recovery Plan Step-by-Step Guide*.

Carl F. Endorf, CISSP, is a senior security analyst for one of the largest insurance and banking companies in the United States. He has practical experience in forensics, corporate investigations, and Internet security.

Jeffrey H. Fenton, CBCP, CISSP, is the corporate IT crisis assurance/mitigation manager and technical lead for IT risk management and a senior staff computer system security analyst in the corporate information security office at Lockheed Martin Corporation. He joined Lockheed Missiles and Space Company in Sunnyvale, California, as a system engineer in 1982, and he transferred into its telecommunications group in 1985. Fenton completed a succession of increasingly complex assignments, including project manager for the construction and activation of an earthquake resistant network center on the Sunnyvale campus in 1992 and group leader for network design and operations from 1993 through 1996.

Bryan D. Fish, CISSP, is a security consultant for Lucent Technologies in Dallas, Texas. He holds a BS in computer engineering and an MCS with a focus on internetworking and computer system security, both of which are from Texas A&M University. His professional interests include security programs and policies and applications of cryptography in network security.

Patricia A.P. Fisher, is president of Janus Associates, a company that specializes in computer security.

Todd Fitzgerald, CISSP, CISA, CISM, is the director of systems security and systems security officer for United Government Services LLC. He has over 25 years of broad-based information technology experience, holding senior IT management positions with Fortune 500 and Global Fortune 250 companies. He is a member of the Board of Directors and Security Taskforce co-chair for the HIPAA Collaborative of Wisconsin (HIPAA COW), a participant in the CMS/Gartner Security Best Practices Group, Blue Cross Blue Shield Association Information Security Advisory Group; he is a previous board member for several Information Systems Security Associations (ISSA), and he is a frequent speaker and writer on security issues. He largely focuses on issues related to security management, risk assessments, policy development, organizing security, security assessments, regulatory compliance (HIPAA, CAST, NIST, ISO 17799), security awareness, and developing security programs.

Stephen D. Fried, CISSP, is the vice president for information security and privacy at Metavante Corporation. He is a seasoned information security professional with over 20 years experience in information technology. For the past ten years, he has concentrated his efforts on providing effective information security management to large organizations. He has led the creation of security programs for two Fortune 500 companies, and he has extensive background in such diverse security issues as risk assessment and management, security policy development, security architecture, infrastructure and perimeter security design, outsource relationship security, offshore development, intellectual property protection, security technology development, business continuity, secure e-business design, and information technology auditing. A frequent speaker at conferences in the United States as well as international locations, he is active in many security industry organizations.

Robby Fussell, CISSP, NSA IAM, GSEC, is an information security/assurance manager for a government contracting company. He is currently performing academic research in the area of preventing cascading failures in scale-free networks using artificial intelligence techniques.

Karen Gibbs is a senior data warehouse architect with Teradata in Dayton, Ohio.

Bonnie A. Goins, MSIS, CISSP, NSA IAM, ISS, is a senior security strategist at Isthmus Group, Inc. where she is the co-practice leader for IGI's Security Practice. She has over 15 years experience in the areas of information security; secure network design and implementation; risk, business impact, and security assessment methods; project management; executive strategy and management consulting; and information technology. She has extensive working experience in regulated industries. She has functioned as a National Security Practice competency leader for multiple companies, and she has also established premier partnerships with Novell and Microsoft across the business continuity/disaster recovery and security disciplines. She is a co-author of the *Digital Crime Prevention Lab* and a contributing reviewer for SANS' *HIPAA Step-by-Step*.

Alex Golod, CISSP, is an infrastructure specialist for EDS in Troy, Michigan.

Ronald A. Gove, PhD, is Vice President, Science Applications International Corp., Columbia, MD.

Robert L. Gray, PhD, is currently chair of the Quantitative Methods and Computer Information Systems Department at Western New England College, and he has more than 20 years of academic and management experience in the IT field.

Geoffrey C. Grabow, CISSP, was Chief Technology Officer of beTRUSTED and Leader - PricewaterhouseCoopers Cryptographic Centre of Excellence.

Frandinata Halim, CISSP, MCSE**, is** a senior security consultant at ITPro Citra Indonesia PT. He has ample experience and qualifications in providing clients with managed security services, information system security consulting, secure network deployment, and other services. In addition, he is competent and knowledgeable in the use and hardening of the Windows environment, Cisco security devices, the number of IDSs, firewalls, and others, currently holding certifications from the (ISC)^2, Cisco Systems, and Microsoft.

Sasan Hamidi, PhD, is the chief security officer at Interval International, Inc.

Susan D. Hansche, CISSP-ISSEP, is a senior manager for information system security awareness and training at PEC Solutions based in Fairfax, Virginia. She has designed numerous training courses on information technology and information systems security for both private-sector and government clients. She is co-author of the *Official (ISC)^2 Guide to the CISSP Exam.*

William T. Harding, PhD, is the dean of the College of Business Administration and an associate professor at Texas A & M University, in Corpus Christi.

Chris Hare, CISSP, CISA, CISM, **is** employed with a large U.S. financial institution as the information systems auditor. He has taught information security at Algonquin College (Ottawa, Canada), and he sat on the advisory council for this program. He frequently speaks on Unix, specialized technology and applications, security, and audit at conferences.

Gilbert Held is an award-winning author and lecturer. He is the author of over 40 books and 450 technical articles. Some of his recent book titles include *Building a Wireless Office* and *The ABCs of IP Addressing*, published by Auerbach Publications.

Jonathan S. Held, graduated from the University of Pennsylvania with a B.A. in mathematics and proceeded to serve seven years in the U.S. Navy as a cryptologic officer. Awarded an M.S. in computer science from the Naval Postgraduate School, he is currently a software design engineer for Microsoft in Seattle, Washington. He has been involved in the design and testing of a variety of Microsoft product offerings, including Commerce Server 2002, BizTalk Accelerator for Suppliers, Solution for Internet Business, and BizTalk Accelerator for Financial Services. He co-authored the books *Data Encryption*

Techniques with Basic and C++ as well as *Securing E-Business Applications and Communications* (Auerbach Publications).

Foster J. Henderson, CISSP, MCSE, CRP, CNA, is an information assurance analyst for Analytic Services, Inc. (ANSER). He is currently a member of the Network Operations and Security Branch within the federal government, covering a wide range of IA matters.

Kevin Henry, CISA, CISSP, is the director of program development for (ISC)^2 Institute, and he is a regular speaker at conferences and training seminars worldwide with frequent requests to provide in-depth training, foundational and advanced information systems security and audit courses, and detailed presentations and workshops on key issues surrounding the latest issues in the information systems security field. He combines over twenty years experience in telecom and consulting engagements for major government and corporate clients with an interesting and comfortable learning style that enhances the understanding, relevance, and practical applications of the subject matter. He has also had several articles published in leading trade journals and in the *Handbook of Information Security Management.*

Paul A. Henry, CISSP, is the senior vice president of CyberGuard Corporation. He has more than 20 years experience with security and safety controls for high-risk environments such as nuclear power plants and industrial boiler sites. In addition, he has developed and managed security projects for major government and commercial organizations worldwide. He has written technical papers on port scanning basics, buffer over-runs, firewall architectures and burner management and process controls for nuclear power plants as well as white papers on covert channel attacks, distributed denial of service (DDoS) attacks, common mode noise and common mode rejection, PLC programming, and buffer over-runs. He also frequently serves as a featured and keynote speaker at network security seminars and conferences worldwide, presenting white papers on diverse topics, including DDoS attack risk mitigation, firewall architectures, intrusion methodology, enterprise security, and managed security services. In addition to his CISSP certification, he holds many other security certifications such as MCP + I, MCSE, CCSA, CCSE, CFSA, CFSO, CISM, and CISA.

Rebecca Herold, CISM, CISA, CISSP, FLMI, is an information privacy, security, and compliance consultant, author, and instructor. She has over 15 years of information privacy, security, and regulatory compliance experience, and she assists organizations of all sizes with their information privacy, security, and regulatory compliance programs. Prior to owning her own business, she was the vice president of privacy services and chief procurement officer at DelCreo for two years. She was also the senior systems security consultant at Principal Financial Group where she was instrumental in building an information security and privacy program that was awarded the 1998 CSI Information Security Program of the Year. She is the author of *The Privacy Papers* (Auerbach, 2001) and *Managing an Information Security and Privacy Training and Awareness Program* (Auerbach, 2005), and she is coauthor of *The Practical Guide to HIPAA Privacy and Security Compliance* (Auerbach, 2003) and *The Business Executive Practical Guides to Compliance and Security Risks* book series in 2004.

Debra S. Herrmann is the technical advisor for information security and software safety in the FAA Office of the Chief Scientist. In this capacity, she is leading four major collaborative research initiatives: security metrics, adaptive quarantine, FAA protection profile library, and integration of common criteria and security certification and accreditation (C&A) evaluations. Previously, she was the manager of security engineering for the $1.7B FAA Telecommunications Infrastructure (FTI) program, one of the first programs to apply the common criteria to a nation-wide safety-critical WAN. Prior to that position, she worked for a number of years in the defense/intelligence community. She has published several papers and three books, including *Using the Common Criteria for IT Security Evaluation (*Auerbach, 2003); *A Practical Guide to Security Engineering and Information*

*Assurance (*Auerbach, 2001); and *Software Safety and Reliability—Techniques, Approaches and Standards of Key Industrial Sectors* (IEEE Computer Society, 1999). She has also been active in the international standards community for many years, serving as the U.S. government representative to International Electrotechnical Commission (IEC) software safety engineering standards committees, chair of the Society of Aerospace Engineers (SAE) subcommittee that issued the JA 1003 software reliability engineering standard, and a member of the IEEE Software Engineering Standards balloting pool.

Steven Hofmeyr, PhD, is chief scientist and founder of Sana Security, Inc. Hofmeyr has authored and coauthored many articles published in conference proceedings and peer- reviewed journals on computer security, immunology, and adaptive computation. He has served on the program committee for the ACM's New Security Paradigms Workshop, and he is currently on the program committee for the Artificial Immune Systems workshop at the IEEE World Congress on Computational Intelligence.

Joseph T. Hootman is the president of Computer Security Systems, Inc., a computer and information security consulting and product sales firm based in Northern California.

Daniel D. Houser, CISSP, MBA, e-Biz+, is a senior security engineer with Nationwide Mutual Insurance Company.

Joost Houwen, CISSP, CISA, is the security manager for Network Computing Services at BCHydro. He has a diverse range of IT and information security experience.

Patrick D. Howard, CISSP **is** a senior information security consultant for the Titan Corporation, and he has over 31 years experience in security management and law enforcement. He has been performing security certification and accreditation tasks for over 14 years as both a security manager and a consultant from both government and commercial industry perspectives. He has experience with implementing security C&A with numerous federal departments and agencies, and he has been charged with developing C&A and risk management guidance for a wide variety of organizations. He has extensive practical experience in implementing programs and processes based on NIST guidance, OMB Circular A-130, Appendix III, and BS 7799/ISO 17799. He has direct working experience in security plan development for complex systems, sensitivity definition, use of minimum security baselines, risk analysis, vulnerability assessment, controls validation, risk mitigation, and documenting certification and accreditation decisions. He has also developed and presented training on all of these processes. He is the author of *Building and Implementing a Security Certification and Accreditation Program* (Auerbach Publications, 2005).

Charles R. Hudson, Jr., CISSP, CISM, is an information security manager and assistant vice president at Wilmington Trust Company. He is a regular speaker at national conferences, speaking at more than fifteen conferences in the past five years as a subject matter expert. He has been involved in writing magazine articles for *Computer World, Security Watch,* and *Information Security.*

Lee Imrey, CISSP, CISA, CPP, is an information security specialist with the U.S. Department of Justice where he writes policies to secure critical and classified information, and he works with various government organizations to implement practices and technological procedures consistent with those policies. Previously, he was a senior communications manager with (ISC)^2 and a lead instructor for the CISSP CBK Review Seminar. He has worked for telecommunications, retail, and consulting organizations, and he continues to contribute to the profession in several volunteer capacities, including as a member of the ASIS Information Technology Security Council and as chair of the ISSA Committee on Professional Ethics.

Carl B. Jackson, CISSP, CBCP, is the business continuity program director with Pacific Life Insurance. He has more than 25 years experience in the areas of continuity planning, information security, and information technology internal control and quality assurance reviews and audits. Prior to joining Pacific Life, he worked with several information security consulting companies and as a partner with Ernst & Young where he was the firm's BCP line leader. He has extensive consulting experience with numerous major organizations in multiple industries, including manufacturing, financial services, transportation, healthcare, technology, pharmaceutical, retail, aerospace, insurance, and professional sports management. He also has extensive industry business information security experience as an information security practitioner and manager in the field of information security and business continuity planning. He has written extensively, and he is a frequent public speaker on all aspects of information security and business continuity planning.

Georges J. Jahchan, CISA, CISM, BS7799 Lead Auditor, has been in various personal computer-related positions for over twenty five years, six of which were addressing gateway security and three as a security officer in a university. He currently works as a senior security consultant in Levant with Computer Associates.

Martin Johnson is senior manager of information systems assurance and advisory services with Ernst & Young LLP.

Andy Jones, PhD, MBE, is a research group leader, Security Research Centre, BT Group Chief Technology Office. An experienced military intelligence analyst and information technology security specialist, he moved into research in information warfare and information security after completing 25 years service with the British Army's Intelligence Corps. He has experience as a project manager within the U.K. Defense Evaluation and Research Agency (DERA) for security aspects of digitization of the battlefield initiative, and he has gained considerable expertise on the criminal and terrorist aspects of information security.

Ray Kaplan, CISSP, CISA, CISM, Qualified BS7799 Auditor Credentials, and CHSP (Certified HIPAA Security Professional), is an information security consultant with Ray Kaplan and Associates in Minneapolis, Minnesota. He has been a consultant and a frequent writer and speaker in information security for over two decades.

Kenneth J. Knapp, PhD, is an assistant professor of management at the U.S. Air Force Academy, Colorado. In 2005, he earned his doctorate in Management Information Systems at Auburn University, Alabama. He has over 15 years of information technology and security experience in the Air Force. His publications include *Communications of the Associatio*n for *Information Systems*, *Information Systems Management*, *Information Systems Security, and Information Management & Computer Security.*

Walter S. Kobus, Jr., CISSP, is the vice president of security consulting services with Total Enterprise Security Solutions LLC. He has over 35 years experience in information systems with 15 years experience in security, and he is a subject matter expert in several areas of information security, including application security, security management practice, certification and accreditation, secure infrastructure, and risk and compliance assessments. As a consultant, he has an extensive background in implementing information security programs in large environments. He has been credited with the development of several commercial software programs in accounting, military deployment, budgeting, marketing, and several IT methodologies currently in practice in security and application development.

Gerald L. Kovacich, PhD, CISSP, CFE, CPP, has over 37 years of industrial security, investigations, information systems security, and information warfare experience in the U.S. government as a special agent; in business as a technologist and manager for numerous technology-based, international corporations as an ISSO, security, audit, and investigations manager; and as a consultant to U.S. and foreign government agencies and corporations. He has also developed and managed several internationally based InfoSec programs for Fortune 500 corporations, and he managed several information systems security organizations, including providing service and support for their information warfare products and services.

Joe Kovara is CTO and the principal consultant of Certified Security Solutions Inc. He has more than 25 years in the security and IT industries with extensive experience in all aspects of information security and operating systems and networks as well as in the development and practical application of new technologies to a wide variety of applications and markets. He holds patents on self-configuring computer systems and networks. Prior to joining CSS in 2001, he was CTO of CyberSafe Corporation. He was a key contributor to CyberSafe's growth and in bringing several enterprise-security products to market and deploying them in mission-critical Fortune 100 environments. Prior to CyberSafe, he was a principal with the security-consulting firm of Kaplan, Kovara, & Associates.

David C. Krehnke, CISSP, CISM, IAM, is a principal information security analyst for Northrop Grumman Information Technology in Raleigh, North Carolina. He has more than 30 years experience in assessment and implementation of information security technology, policy, practices, procedures, and protection mechanisms in support of organizational objectives for various federal agencies and government contractors. He has also served the (ISC)^2 organization as a board member, vice president, president, and program director responsible for test development.

Mollie E. Krehnke, CISSP, CHS-II, IAM, is a senior information security consultant for Insight Global, Inc. in Raleigh, North Carolina. She and her husband, David Krehnke, are members of the inventor team for the Workstation Lock and Alarm System (U.S. Patent Number 6, 014, 746). She has served as an information security consultant for more than 15 years.

Kelly J. "KJ" Kuchta, CPP, CFE, is the president of Forensics Consulting Solutions in Phoenix, Arizona. He is formerly an area leader for Meta Security Group and Ernst & Young's Computer Forensics Services Group in Phoenix, Arizona. He is an active member of the High Technology Crime Investigation Association (HTCIA), Association of Certified Fraud Examiners (ACFE), the International Association of Financial Crime Investigators (IAFCI), and the American Society of Industrial Security (ASIS). He currently serves on the board of the ASIS Information Technology Security Council.

Paul Lambert is responsible for the development and implementation of Certicom's product strategy to meet and exceed current market demands, trends, and forecasts for cryptographic security technologies. He is currently a government appointee to a technical advisory committee for federal information processing and an active contributor to technical standards for such security technologies as digital signatures and network, e-mail, and LAN security. He was previously at Motorola where he served as a top security architect, designing the security architecture for a family of products to protect Internet communications. Prior to Motorola, he was director of security products at Oracle where he was responsible for the development and product management of core security technologies for all Oracle products. He has published numerous papers on key management and communication security, and he is the founder and co-chair of the IP security working group in the Internet Engineering Task Force.

Larry R. Leibrock, PhD, is with eForensics Inc.

Ross A. Leo, CISSP, is an information security professional for over 23 years with experience in a broad range of enterprises. He is currently the director of information systems and the chief information security officer at the University of Texas Medical Branch/Correctional Managed Care Division in Galveston, Texas. He has worked internationally as a systems analyst and engineer, IT auditor, educator, and security consultant for companies, including IBM, St. Luke's Episcopal Hospital, Computer Sciences Corporation, Coopers & Lybrand, and Rockwell International. Recently, he was the director of IT security engineering and the chief security architect for Mission Control at the Johnson Space Centre. His professional affiliations include (ISC)^2, ASIS and HCCO, and he is a member of the IT Security Curriculum Development and Advisory Board for Texas State Technical College. He is the editor of the *HIPAA Program Reference Handbook* (Auerbach Publications, 2004).

Ian Lim, CISSP, is a senior consultant in Accenture's global security consulting practice who has defined and deployed security architectures for Fortune 100 companies as well as contributed to Accenture's global privacy and policy framework.

Bill Lipiczky has practiced in the information technology and security arena for over two decades, beginning his career as a mainframe operator. As information technology and security evolved, he evolved as well. His experience includes networking numerous operating systems (*NIX, NetWare, and Windows) and networking hardware platforms. He is currently a principal in a security consulting and management firm as well as a lead CISSP instructor for the (ISC)^2.

David A. Litzau, CISSP, with a foundation in electronics and audio/visual, moved into the computer sciences in 1994. He has been teaching information security in San Diego for the past six years.

Perry G. Luzwick is the director of information assurance architectures at Northrop Grumman Information Technology for information warfare, information assurance, critical infrastructure protection, and knowledge management. He served as a lieutenant colonel in the U.S. Air Force, and he was Military Assistant to the Principal Deputy Assistant Secretary of Defense for Command, Control, Communications, and Intelligence; Deputy Director for Defensive IO, IO Strategy, and Integration Directorate; Chief, Information Assurance Architecture, Directorate for Engineering and Interoperability, Defense Information Systems Agency (DISA); Deputy Chief, Current Operations and Chief, Operations and Information Warfare Integration, Operations Directorate, DISA; Information Assurance Action Officer, Information Assurance Division (J6K), the Joint Staff; and Chief, JCS, CINC, and Defense Agency Communications-Computer Security Support, National Security Agency.

Franjo Majstor, CISSP, CCIE, is the EMEA senior technical director at CipherOptics Inc. where he is responsible for driving to market the latest generation of data protection solutions. Previously, as technical director EMEA at Fortinet, Inc., he was responsible for security products and solutions based on the modern perimeter security architecture. He is also an external CISSP instructor at (ISC)^2, and he is a mentor and recognized lecturer of an ICT audit and security postgraduate study, joint program between ULB, UCL, and Solvay Business School in Brussels, Belgium. As a member of several professional associations, he is a frequently invited speaker at worldwide technical conferences on network security topics. His public work references could be found on a private home page at www.employees.org/~franjo.

Thomas E. Marshall, PhD, is an associate professor of MIS, Department of Management, Auburn University, Alabama. He is a CPA, and he has been a consultant in the area of accounting information systems for over 20 years. His publications include *Information & Management, Information Systems Security, Information Management & Computer Security, Journal of Computer Information Systems, Journal of End User Computing, Information Resource Management,* and *Journal of Database Management.*

Bruce R. Matthews, CISSP, has been managing embassy technical security programs for U.S. government facilities worldwide for over 15 years. He is a security engineering officer with the U.S. Department of State, Bureau of Diplomatic Security. With the British, he is examining a wide range of technical security issues and how they impact IT security. As part of his work, he also conducts vulnerability assessments, IT security investigations, and forensic analysis. In previous assignments, he was head of the Department of State IT security training program and the chairman of the Security Standards Revision Committee for the Overseas Security Policy Board (OSPB). He has been published in magazines such as *Information Security* and *State,* and he is the author of *Video Surveillance and Security Applications: A Manager's Guide to CCTV* (Auerbach Publications, 2007).

George G. McBride, CISSP, CISM, is a director at Aon Consulting IT Risk Management organization in Eatontown, New Jersey, and he has worked in the network security industry for more than twelve years. He has spoken at conferences worldwide on topics such as penetration testing, risk assessments, and open source security tools. He has consulted numerous Fortune 100 companies on projects, including network architecture, application vulnerability assessments, and security organization and program development. He has contributed to *The Black Book on Corporate Security,* hosted several Webcasts, and contributed to several previous editions of the *Information Security Management Handbook.*

R. Scott McCoy, CPP, CISSP, CBCP, is the director of enterprise security for Xcel Energy where he is responsible for corporate security, IT security, and business continuity. He has 22 years of security experience, starting in 1984 in the U.S. Army, including four years on active duty as an explosive ordnance disposal technician, 10 years of security management experience with the last eight years in the electric and gas utility industry.

Samuel C. McClintock is a principal security consultant with Litton PRC, Raleigh, North Carolina.

Lowell Bruce McCulley, CISSP, has more than 30 years of professional experience in the information systems industry. His security credentials are complemented by an extensive background in systems development engineering that is primarily focused on critical systems along with experience in production operations, training, and support roles.

Lynda L. McGhie, CISSP, CISM, is the information security officer (ISO)/risk manager for Wells Fargo Bank, Private Client Services (PCS). She has over 25 years of information technology and information security experience, specializing in risk management and compliance, security engineering and design, business continuity planning (BCP) and crisis management, network security and identity management. She is formerly the CISO for Delta Dental and Lockheed Martin Corporation. In her current role, she is responsible for risk management and security for PCS within the Wells Fargo Corporation, and she has a dotted line responsibility to the corporate CISO/IT security governance. She regularly publishes articles on state of the art security topics/issues, and she is also a regular speaker for MISTI, ISSA, ISACA, and other IT security venues.

Laurie Hill McQuillan, CISSP, has been a technology consultant for 25 years, providing IT support services to commercial and federal government organizations. She is the vice president of KeyCrest Enterprises, a national security consulting company. She teaches graduate-level classes on the uses of technology for research and the impact of technology on culture. She is treasurer of the Northern Virginia chapter of the Information Systems Security Association (ISSA) and a founding member of CASPR, an international project that plans to publish Commonly Accepted Security Practices and Recommendations.

Jeff Misrahi, CISSP, is an information security manager at a large data and news organization in New York, where, among other tasks, he has responded to a plethora of client questionnaires and audit requests. His experience includes managing information security and risk at both large and small companies, as well as consulting. He is on the board of the New York Metro Chapter of the ISSA and can be reached at jmisrahi@nymissa.org.

James S. Mitts, CISSP, is a principal consultant with Vigilant Services Group who has over 18 years of demonstrated ability in managing, planning, implementing, and controlling complex projects involving numerous aspects of business continuity, disaster recovery, and information technology and security.

Ron Moritz, CISSP, is director of the Technology Office at Finjan Software, where he serves as primary technology visionary. As a key member of the senior management team interfacing between sales, marketing, product management, and product development, he helps establish and maintain the company's technological standards and preserve the company's leadership role as a developer of advanced Internet security solutions. He was instrumental in the organization of Finjan's Java Security Alliance, and he established and currently chairs Finjan's Technical Advisory Board. He has served in various capacities, including president, with both the North Coast chapter of the ISSA and the Northeast Ohio chapter of ISACA. He has lectured on Web security, mobile code security, computer ethics, intellectual property rights, and business continuity and resumption planning. Over the past year, his presentations on mobile code security have been well received at the European Security Forum (London), the FBI's InfraGuard Conference (Cleveland), CSI's NetSec (San Antonio), MISTI's Web-Sec Europe (London), and RSA Data Security (San Francisco).

Dorsey Morrow, JD, CISSP, is operations manager and general counsel for the International Information Systems Security Certification Consortium, Inc. (ISC)^2. He has served as general counsel to numerous information technology companies, and he also served as a judge. He is licensed to practice in Alabama, Massachusetts, the 11th Federal Circuit, and the U.S. Supreme Court.

William Hugh Murray, CISSP, is an executive consultant for TruSecure Corporation and a senior lecturer at the Naval Postgraduate School; he has more than fifty years experience in information technology and more than thirty years in security. During more than twenty-five years with IBM, his management responsibilities included development of access control programs, advising IBM customers on security, and the articulation of the IBM security product plan. He is the author of the IBM publication, *Information System Security Controls and Procedures.* He has made significant contributions to the literature and the practice of information security. He is a popular speaker on such topics as network security architecture, encryption, PKI, and secure electronic commerce. He is a founding member of the International Committee to establish the Generally Accepted System Security Principles (GASSP) as called for in the National Research Council's Report, *Computers at Risk.* He is a founder and board member of the Colloquium on Information System Security Education (CISSE). He has been recognized as a founder of the systems audit field and by *Information Security* as a Pioneer in Computer Security. In 1987, he received the Fitzgerald Memorial Award for leadership in data security. In 1989, he received the Joseph J. Wasserman Award for contributions to security, audit, and control. In 1995, he received a Lifetime Achievement Award from the Computer Security Institute. In 1999, he was enrolled in the ISSA Hall of Fame in recognition of his outstanding contribution to the information security community.

K. Narayanaswamy, PhD, is the chief technology officer and co-founder, Cs3, Inc. He is an accomplished technologist who has successfully led the company's research division since inception. He was the principal investigator of several DARPA and NSF research projects that have resulted in the company's initial software product suite, and he leads the company's current venture into DDoS and Internet infrastructure technology.

Matt Nelson, CISSP, PMP, ITIL Foundation**,** has spent several years as a programmer, network manager, and information technology director. He now does information security and business process consulting for International Network Services.

Man Nguyen, CISSP, is a security consultant at Microsoft Corporation.

Felicia M. Nicastro, CISSP, CHSP, is a principal consultant with International Network Services (INS). She has worked with various Fortune 500 companies in over the four years she has been with INS. Her areas of expertise include security policies and procedures, security assessments and security architecture planning, design, implementation, and operation. Prior to joining INS, she was a systems administrator for the Associated Press, and she was responsible for UNIX and security administration.

Keith Pasley, CISSP, is a security professional with over 20 years experience designing and building security architectures for both commercial and federal government. He has authored papers and taught security classes, and he is currently working as a regional security practice director.

Christopher A. Pilewski, BS 7799 Lead Auditor, NSA IAM/IEM, CCSA, GIAC, CPA/E, FSWCE, FSLCE, MCP, is a senior consultant for the international consulting and professional services firm Ajilon. He has over sixteen years of professional experience in consulting, audit, security, networking technology, and engineering. This experience spans compliance, audit, security, risk assessment and mitigation, business process, technical controls, business continuity, technical project leadership, design, and integration of network and information systems. Before joining Ajilon, he worked for consulting and audit firms as well as flagship communications companies where he led a wide variety of projects ranging from compliance efforts (Sarbanes-Oxley, HIPAA, VISA CISP, and others), audits, security assessments, implementation of security systems, secure network architecture, network management systems, quality control/assurance, protocol analysis, and technical marketing.

Ralph Spencer Poore, CFE, CISA, CISSP, CHS-III, CTM/CL, is the chief scientist at Innové LLC where he provides security, privacy, and compliance consulting services, continuing a 30-plus year distinguished career in information security as an inventor, author, consultant, CISO, CTO, educator, and entrepreneur.

Mike R. Prevost is the DBsign product manager at Gradkell Systems, Inc., in Huntsville, Alabama.

Sean M. Price, CISSP, is an independent information security consultant located in the Washington, D.C., area. He provides security consulting and engineering support for commercial and government entities. His experience includes nine years as an electronics technician in metrology for the U.S. Air Force. He is continually immersed in research and development activities for secure systems.

Anderson Ramos, CISSP, is an educational coordinator for Modulo Security, a leading information security and risk management company in Latin America. He is recognized as one of the most important professionals in Brazil and a key instructor for the country, having been responsible for training hundreds of security officers. Since 1998, he has been involved with dozens of projects for the public and private sector. A lead instructor for (ISC)^2 since 2001, he has presented official CISSP Review Seminars in several countries around the world. He served as a director of the Brazilian ISSA Chapter from 2004 to 2006. He possesses more than 20 certifications in the IT and security field, including the CISSP, CISA, SSCP, CCSI/E+, MCSE and CNE.

Anita J. Reed, CPA, is currently an accounting doctoral student at the University of South Florida, Tampa, and she has 19 years of public accounting experience.

David C. Rice, CISSP, recognized by the Department of Defense and industry as an information security expert, has spent seven years working on highly sensitive national information security issues and projects. He has held numerous professional certifications; developed and authored several configuration guides, including *Guide to Securing Microsoft Windows 2000 Active Directory, Guide to Securing Microsoft Windows 2000 Schema, and Microsoft Windows 2000 Group Policy Reference*; and won *Government Executive Magazine's* Technical Leadership Award. He is the founder and senior partner of TantricSecurity, LLC, an information security consultancy for government and private industry. In addition to his consultancy, research, and publications, he is an adjunct professor for the Information Security Graduate Curriculum at James Madison University, Harrisonburg, Virginia.

George Richards, CPP, is an assistant professor of criminal justice at Edinboro University of Pennsylvania. In addition to teaching criminal justice courses to undergraduates, he has an active research agenda that focuses primarily on crime prevention and security-related issues. He has published in several peer-reviewed and popular publications, among these being *The Journal of Contemporary Criminal Justice, Journal of Security Administration,* and *The American School Board Journal.*

Steve A. Rodgers, CISSP, the co-founder of Security Professional Services, has been assisting clients in securing their information assets for more than six years. He specializes in attack and penetration testing, security policy and standards development, and security architecture design.

Marcus K. Rogers, PhD, CISSP, CCCI, is the chair of the Cyber Forensics Program in the Department of Computer and Information Technology at Purdue University. He is an associate professor and also a research faculty member at the Center for Education and Research in Information Assurance and Security (CERIAS). He was a senior instructor for (ISC)^2, the international body that certifies information system security professionals (CISSP), is a member of the quality assurance board for (ISC)^2's SCCP designation, and is chair of the Law, Compliance, and Investigation Domain of International Common Body of Knowledge (CBK) committee. He is a former police detective who worked in the area of fraud and computer crime investigations. He sits on the editorial board for several professional journals, and he is a member of various national and international committees focusing on digital forensic science and digital evidence. He is the author of numerous book chapters and journal publications in the field of digital forensics and applied psychological analysis. His research interests include applied cyber forensics, psychological digital crime scene analysis, and cyber terrorism.

Georgina R. Roselli is a member of the faculty at the College of Commerce and Finance at Villanova University.

Ben Rothke, CISSP, CISM, is the director of Security Technology Implementation for AXA Technology Services. He has over 15 years of industry experience in the area of information systems security and privacy, and his areas of expertise are in risk management and mitigation, PKI, security and privacy regulation, design and implementation of systems security, encryption, and security policy development. Prior to joining AXA, he was with ThruPoint, Baltimore Technologies, Ernst & Young, and Citicorp, and he has provided security solutions to many Fortune 500 companies. He is the author of *Computer Security—20 Things Every Employee Should Know* (McGraw-Hill 2006), and a contributing author to *Network Security: The Complete Reference* (Osborne) and the *Information Security Management Handbook* (Auerbach). He writes a monthly security book review for *Security Management*, and he is a former columnist for *Information Security, Unix Review,* and *Solutions Integrator* magazines. He is a co-chairman (along with Warren Axelrod of Pershing) of the Information Security Policy Principles Working Group for the GAISP Project, and he is on the Experts Panel for Information Shield and an editorial board member for *Information Systems Security.* He is a member of ISSA, ISACA, ASIS, CSI and InfraGard.

Ty R. Sagalow is executive vice president and chief operating officer of American International Group eBusiness Risk Solutions, the largest of Internet risk insurance organization. Over the past 18 years, he has held several executive and legal positions within AIG.

Craig A. Schiller, CISSP-ISSMP, ISSAP, is the president of Hawkeye Security Training, LLC. He is the primary author of the first Generally Accepted System Security Principles (GASSP). He has been a contributing author to several editions of the *Handbook of Information Security Management* and a contributing author to *Data Security Management*. He co-founded two ISSA U.S. regional chapters: the Central Plains Chapter and the Texas Gulf Coast Chapter. He is a volunteer with the Police Reserve Specialists unit of the Hillsboro Police Department in Oregon. He leads the unit's Police-to-Business High-Tech speakers' initiative and assists with Internet forensics.

Thomas J. Schleppenbach is a senior information security advisor and security solutions and product manager for Inacom Information Systems in Madison, Wisconsin. With more than 16 years of IT experience, he provides information security and secure infrastructure design, and he acts in a strategic role helping organizations plan and build information security programs. He also sits on the Western Wisconsin Chapter of InfraGard planning committee, and he is the co-chair for the Wisconsin Kids Improving Security (KIS) poster contest, working with schools and school districts to educate kids on how to stay safe online.

Paul Serritella is a security architect at American International Group. He has worked extensively in the areas of secure application design, encryption, and network security.

Ken M. Shaurette, CISSP, CISA, CISM, IAM, is an engagement manager in Technology Risk Manager Services at Jefferson Wells, Inc. in Madison, Wisconsin. With over 25 total years of IT experience, he has provided information security and audit advice and vision for companies building information security programs for over 18 of those years. He is a founding member and past president of the Western Wisconsin Chapter of InfraGard; is past president and current vice president of ISSA-Milwaukee Chapter (International Systems Security Association); current president and founding member of ISSA-Madison Chapter. He chairs the Milwaukee Area Technical College's Security Specialist Curriculum Advisory Committee, is an active committee member on Herzing College Madison's Department of Homeland Security Degree Program, a member of the Wisconsin Association of Computer Crime Investigators (WACCI), a former chair of the HIPAA-COW (Collaborative of Wisconsin) Security Workgroup, and past co-chair of the Wisconsin InfraGard KIS (Kids Improving Security) Poster Contest. In addition to all that, he actually finds time to work.

Sanford Sherizen, PhD, CISSP, is president of Data Security Systems, Inc. in Natick, Massachusetts.

Brian Shorten, CISSP, CISA, has been involved in information security since 1986, working in financial institutions and telecommunications companies. He has held positions as data protection officer and business continuity manager. A member of the ISACA, the British Computer Society, and the Business Continuity Institute, he writes and presents on various aspect of information security and business continuity.

Carol A. Siegel, CISA, is the chief security officer of AmericanInternational Group. Siegel is a well-known expert in the field of information security, and she has been in the field for more than ten years.

Micah Silverman, CISSP and a Sun Certified Java programmer, is president of M*Power Internet Services, Inc. With over 13 years of experience, he has written numerous articles for industry journals, including *Information Security Magazine, Dr. Dobbs Journal, Java Developers Journal,* and *Linux Journal.*

He consults for corporations to architect software using agile development methods, to ensure that good security practices and policies are in place, and to train employees in the areas of information security and software development.

Janice C. Sipior, PhD, is a member of the faculty at the College of Commerce and Finance at Villanova University.

Valene Skerpac, CISSP, is past chairman of the IEEE Communications Society. Over the past 20 years, she has held positions at IBM and entrepreneurial security companies. She is currently president of iBiometrics, Inc.

Ed Skoudis, CISSP, is a senior security consultant with Intelguardians Network Intelligence. His expertise includes hacker attacks and defenses, the information security industry, and computer privacy issues. He has performed numerous security assessments, designed secure network architectures, and responded to computer attacks for clients in the financial, high-technology, healthcare, and other industries. He is a frequent speaker on issues associated with hacker tools and defenses, and he has published several articles on these topics and *Malware and Counter Hack*. He is also the author of the popular *Crack the Hacker Challenge* series that challenges information security professionals to learn from others' mistakes. Additionally, he conducted a demonstration of hacker techniques against financial institutions for the U.S. Senate. His prior work experience includes Bell Communications Research (Bellcore), SAIC, Global Integrity, and Predictive Systems.

Robert M. Slade, CISSP, is a data communications and security specialist from North Vancouver, British Columbia, Canada. He has both formal training in data communications and exploration with the BBS and network community, and he has done communications training for a number of international commercial seminar firms. He is the author of *Robert Slade's Guide toComputer Viruses.* He is the founder of the DECUS Canada Education and Training SIG.

Timothy R. Stacey, CISSP, CISA, CISM, CBCP, PMP, is an independent senior consultant with over twenty years of managerial and technical experience in system engineering and software development in a wide range of real-time and scientific applications. His primary area of focus for the last twelve years has been in the area of information security. His focus areas include IS audit, disaster recovery/business continuity planning, security risk analysis, and business impact assessment. Prior to becoming an independent consultant, he was a senior consultant with KPMG in its information risk management practice, a senior information security consultant in the Shell Services International's Global Information Security Team, and a senior software engineer with Science Application International Corporation supporting NASA/JSC.

Bill Stackpole, CISSP, is the regional engagement manager of Trustworthy Computing Services for Microsoft Corporation. He was a senior security consultant with Olympic Resource Management.

Stan Stahl, PhD, is the president of Citadel information Group, an information security management consultancy. An information security pioneer, his career began nearly 25 years ago on a wide range of advanced projects for the White House, various military branches, the National Security Agency, and NASA. He serves as vice president of the Los Angeles Chapter of the Information System Security Association, and he is on the Editorial Advisory Board of *Continuity Insights*, for whom he writes a bimonthly information security column.

Steve Stanek is a Chicago-based writer specializing in technology issues.

Christopher Steinke, CISSP, is an information security consulting staff member at Lucent World Wide Services, Dallas, Texas.

Carol Stucki is working as a technical producer for PurchasePro.com, a company that is an application service provider that specializes in Internet-based procurement. Her past experiences include working with GTE, Perot Systems, and Arthur Andersen as a programmer, system analyst, project manager, and auditor.

Samantha Thomas Cruz is the director of information security at the second largest public pension fund in the United States. She is a founding board member of the University of California at Davis Network Security Certificate Program, and she has developed curriculum for universities, institutes, and private industry, including ESPOCH Poly Technical University in Ecuador as well as presentations for MISTI North America and Sabre Corporation Global. She is a regularly requested keynote and think tank facilitator, and she has been a featured speaker in five European Union countries, South Africa, Australia, Mexico, and Papua New Guinea. Her writings, interviews, and quotations are published in international newspapers, magazines, and books. She served as a director elect on the International Board of ISSA and is past president of her local chapter where she serves as a board advisor.

Per Thorsheim is a senior consultant with PricewaterhouseCoopers in Bergen, Norway.

James S. Tiller CISM, CISA, CISSP, is the chief security officer and managing vice president of Security Services for International Network Services (INS). He has been with INS since 1998, and he has provided security solutions for global organizations for the past 13 years. He is the author of *The Ethical Hack: A Framework for Business Value Penetration Testing* and *A Technical Guide to IPSec Virtual Private Networks.*

Dr. Peter S. Tippett is chief technologist of TruSecure Corporation and chief scientist at ICSA Labs. He specializes in utilizing large-scale risk models and research to create pragmatic, corporate-wide security programs. Prior to joining TruSecure, Dr. Tippett was director of security and enterprise products at the Peter Norton Group of Symantec Corporation. He is credited with creating one of the first commercial antivirus products, which became Symantec's Norton AntiVirus. He was president and founder of Certus International Corporation, a publisher and developer of leading PC antivirus, security and enterprise management software. Dr. Tippett is the recipient of the 1998 Entrepreneur of the Year Award presented by Ernst & Young.

William Tompkins, CISSP, CBCP, is a system analyst with the Texas Parks and Wildlife Department in Austin, Texas.

James Trulove has more than 25 years experience in data networking with companies such as Lucent, Ascend, AT&T, Motorola, and Intel. He has a background in designing, configuring, and implementing multimedia communications systems for local and wide area networks using a variety of technologies. He writes on networking topics, and he is the author of *LAN Wiring, An Illustrated Guide to Network Cabling* and *A Guide to Fractional T1*, the editor of *Broadband Networking*, and the author of numerous articles on networking.

Michael Vangelos, CISSP, has over 23 years of IT experience, including 12 specializing in information security. He has managed the information security function at the Federal Reserve Bank of Cleveland for nine years, and he is currently the bank's information security officer. He is responsible for security policy development, security administration, security awareness, vulnerability assessment, intrusion detection, and information security risk assessment as well as incident response. He holds a degree in computer engineering from Case Western Reserve University.

Adriaan Veldhuisen is a senior data warehouse/privacy architect with Teradata, San Diego, California.

Burke T. Ward, PhD, is a member of the faculty at the College of Commerce and Finance at Villanova University.

Thomas Welch, CISSP, CPP, has over seventeen years in the information systems business, ten of which he designed and developed public safety-related applications. He served as a private investigator and information security consultant since 1988. He was actively engaged in consulting projects that included security assessments, secure architecture design, security training, high-tech crime investigations, and computer forensics. He is an author and frequent lecturer on computer security topics, including computer crime investigation/computer forensics.

Jaymes Williams, CISSP, is a security analyst for the PG&E National Energy Group and is currently the chapter secretary of the Portland, Oregon Chapter of ISSA. He has held security positions at other companies and served eight years in information security-related positions in the U.S. Air Force.

James M. Wolfe, MSM, is the senior virus researcher and primary technical contact for the Lockheed Enterprise Virus Management Group at Lockheed Martin Corporation. He is a member of the European Institute of Computer Antivirus Researchers (EICAR), the EICAR Antivirus Enhancement Program, the Antivirus Information Exchange Network, Infragard, and he is a reporter for the WildList Organization.

John O. Wylder, CISSP, has an extensive background in information technology and the financial services industry. Most recently, he has worked in the field of information security as a strategic security advisor for Microsoft Corporation. In that role, he discusses information security with a wide variety of businesses, providing guidance and also seeking their feedback. He writes on various topics for a wide variety of publications. He is very active in the business community working with organizations such as Infragard, and he is part of the advisory board of the Georgia Tech School of Economics. He is the author of *Strategic Information Security* (Auerbach Publications, 2003).

William A. Yarberry, Jr., CPA, CISA, is a principal with Southwest Telecom Consulting. He is the author of *Computer Telephony Integration* (Auerbach, 2002) and co-author of *Telecommunications Cost Management* (Auerbach, 2002).

Brett Regan Young, CISSP, CBCP, MCSE, and CNE, is the director of Security and Business Continuity Services for Detek Computer Services, Inc., in Houston, Texas. His background includes several years as an independent consultant in the information security and business continuity arenas, primarily for Houston-area companies. Prior to his work as a consultant, he managed the international network of a major oil and gas firm. He has also held various positions in the natural gas production, control, and processing environment. He has project management experience in the petroleum, banking, and insurance industries. He is a frequent contributor to several trade magazines as well as Texas newspapers on the subjects of risk management, security architecture, and business continuity planning and recovery.

Bits to Bytes to Boardroom

Micki Krause

> Picture this: You find yourself on the elevator with the CEO of your organization. You have approximately 90 s alone with the chief executive and a rare opportunity to convey a message, whatever that message is.
>
> Who are you? What do you do? What were the results of the recent penetration test? Why does the security program need additional funding? You think hard. What is my message? How do I convey it? How do I look? How am I perceived? Finally, do you succeed in grabbing his/her attention? Do you get your desired result at the end of the 90 s elevator ride? I wager that your answers to the questions above are not an overwhelming "yea verily." I also wager that the majority of us would be tongue-tied at best, incapable of uttering anything discernible at worst. And our only memory of the moment is "That was the longest 90 s I've ever spent!"

Why? Why? Why? We are each successful in our own right. We have achieved some sort of professional certification (or at least many of us have). We work hard. We try to do the right thing for our organizations. Why is it so difficult for the chief security officer or chief information security officer to get a seat at the right table?

During my tenure as a CISO, some of the best coaching I received came from an executive vice president who was personable enough to mentor me. I solicited his feedback relative to the first presentation I prepared for our Executive Management Committee relative to the status of the company's security program. The committee was composed of the senior-most executives of the business units and I knew the briefing had to be crisp and to the point. The message I wanted to convey was that, as a company, we were far behind the industry in security-essential practices and quite frankly, a lot of work was required to meet an adequate level for due diligence by industry standards.

The several page briefing I had originally assembled and shared with my mentor broke the program components into details segments and offered a lengthy description of each component. This kindly executive took one look at my painstaking effort and said, "Tell you what I would do…communicate your message in one page—a picture of a football player on the field with the caption 'We're on our own 10-yard line.'"

Bottom line: the briefing was a complete success, the message was conveyed (with additional talking points thrown in) and the program got top-down support. Required funding, project details, roles, responsibilities, policies, etc.—all important details—could be worked out later. I had gotten the nod at the top and the rest was (relative) gravy.

I am a sucker for a happy ending. Boy gets girl. Girl gets boy. Alien finds its way home. Security professional gets promoted and earns a seat in the boardroom.

OK, maybe I went one happy ending too far.

What is IT that gets a proficient information technology professional so far and then he or she hits the threshold and cannot move on or up in an organization? Regardless of the title of the position—whether chief information officer (CIO), IT security officer, or IT network engineer—something important is missing.

1.1 The Problem Statement

I submit that because CSOs, CISOs, and many CIOs (IT leaders face similar challenges to security professionals, as you will see from the several of the quotes that follow) typically grow up either in the information technology side of the house or law enforcement/the military, they often lack the "soft skills" and business acumen which are essential to being given credence and being accepted as part of the "mahogany row" team. What is required are the influence and communication skills to be on par with the decision makers. These skills include:

- Understanding the importance of assessing the culture of your organization
- Knowing how to assess the culture of your organization
- Knowing your place, i.e., clearly define your role
- Having the ability to check your passion at the door
- Knowing when and when not to tilt at windmills
- Identifying why alliances are essential to your success
- Assessing business risk and defer technical solutions

Not too long ago, organizations relied on technologists to assume the responsibility for securing the enterprise. Typically, "security officer" was just another hat worn by the IT engineers or administrators. This technical approach resulted in the installation of firewalls, the implementation of virus software, and possibly some sort of intrusion detection. With these defenses in place, we considered our domains safe from the archetypal intruder.

1.2 A New Paradigm is Needed

Industry publications decry the disconnect between the C suite and the CIO (typically one peg up from the IT security officer).

From a U.S. government report on the challenges ahead for CIOs: "As CIO's play a larger role in their agency's business decisions, the challenges they face are becoming more than technological" [1]. The report speaks to the changing focal point of IT towards a business model and states that people are beginning to understand that collaboration and working together not only makes sense, it tends to be a successful strategy.

A U.S. government survey of CIO priorities in 2005 reports that business expectations are forcing CIOs to transform their organizations and that now is the time for CIOs to deliver more value and become greater contributors to their organizations [2]. The survey reported that agency CIOs face three critical challenges, for which the fixes are all under their control.

- The CIO/CEO challenge: two-thirds of CIOs see themselves as "at risk" based on their CEO's view of IT and its performance.

- People and skills: only 39% of CIOs believe they have the right people to meet current and future business needs.
- The changing role of IT: the trend for IT operations to encompass greater involvement with business processes and the need for business intelligence poses a significant challenge for CIOs.

The report further goes on to say that the transformation into being a contributor to the business will require CIOs to excel at being a member of the executive team. This will require that CIOs, develop their business, technology, leadership, and personal skills.

According to a 2004 U.S. General Accounting Office report on federal CIOs' responsibilities, reporting relationships and tenure, government agency CIOs report they face major challenges in fulfilling their duties [3]. They cite as their biggest hurdles: communication, collaboration (both internally and externally), and managing change.

It is apparent that federal CIOS do not have what it takes, as the GAO report indicates that "their average time in office had a median tenure of about 2 years…" while noting that CIOs said it take three to five years to be effective. From this, the meaning of CIO was irreverently interpreted as "career is over."

Theories abound to explain the missing link. Studies indicate that the predominance of security officers rose from the technical ranks and can't shake the lingo. Further, security officers do not possess sufficient empathy for the business processes, which drive revenue, profit and loss. Not only are security officers challenged with explaining the risk in terms understandable to nontechnically savvy business people, their style is to move immediately to the conclusion, typically a technical solution to the problem, without being cognizant of cost considerations or business impact.

Business executives often complain about the propensity of security practitioners to have a knee-jerk response that is designed to mitigate security risk before a complete analysis occurs [4]. I have found myself in similar situations, once demanding that we purchase and implement an application firewall as a response to web-based vulnerabilities, while not having a clear and complete sense of important details such as:

1. How many web-based applications the company had
2. Which of those applications contained confidential or private information
3. What vulnerabilities existed within said applications
4. What compensating or mitigating controls already existed
5. The work effort required to resolve or remediate the critical vulnerabilities

Most IT people are analytical by nature and comfortable dealing in the bits and bytes. They tend to rely on their strengths, traits that make them valued players in IT, but limited them as players outside the IT realm. Some refer to this lack of proficiency as a "marketing thing." Some say technologists have to "become the business." SearchCIO.com assessed more than 250 Fortune 500 and Global 2000 IT organizations and compiled a list of the top issues and challenges facing IT executives [5]. Not surprisingly, four of the five largest issues identified were:

- IT operations not aligned with the business: "support cost center mindset versus customer solutions provider mindset"
- Systemic ineffective communication: communication is ineffective not only between IT and the business, but within IT and between IT and their vendors
- Organizational problems: technology-centric vs. services-centric perspectives
- People problems: the "genetic makeup" of technology workers with "little-to-no-focus on skills development, knowledge transfer and mentoring"

The large consulting organizations such as The Gartner Group perform regular studies on the state of the technical executive. In a 2004 report, the surveyed CIOs agreed that "the ability to communicate effectively, strategic thinking and planning and understanding business processes are critical skills for the

CIO position." They also concur that "the predominance of their rank and file lack these important skills" [6]. In fact, when they were asked to rank their greatest hurdles, the CIOs listed:

- The difficulty proving the value of IT
- Unknown expectations from the business
- Lack of alignment between business goals and IT efforts

In other words, the survey demonstrates that "they're not communicating. Worse yet, they realize they're speaking two very different languages with no hope of translation but don't appear to know what to do about the problem."

1.3 The Solution

We walk the aisles of Barnes and Noble or traverse the offerings of Amazon.com, seeking direction and wisdom. What we find: *Self Defeating Behaviors*, *Get Out of Your Own Way*, *Power of Positive Thinking*, *Awaken the Giant Within*, *Attitude is Everything*, and on and on. The book shelves are lined with volumes of gems on selling yourself and selling "up" in the organization. We drink in the message and subsequently spend a large part of our day conceiving plots and ploys to get the message across to those, we decry, who do not know and do not care about our life's work.

Fortunately, organizations are realizing that there is an urgent need for educational programs to provide the boost necessary for security professionals to be recognized among the ranks of the executive office. One program in particular that stands out is the Wharton/Association of Security (ASIS) Program for Security Executives. This program is a joint effort between the highly regarded Wharton School of Business, the Wharton School of the University of Pennsylvania and the ASIS. To gain insight about the program, I spoke with Michael Stack, the executive director of ASIS, Steve Chupa, director of security, Worldwide Security Group, at a Fortune 100 company and Arpid Toth, chief technologist for GTSI.com, a student in the initial Wharton offering.

According to Mr. Stack, over the past 20 years, there has been an increasing recognition that most physical security officers come from the ranks of law enforcement or the military and do not have the business acumen to go "toe to toe" with their C-level peers. This led ASIS leadership to seek out a renowned academic authority and form an alliance to jointly develop a program that would meet ASIS constituents' needs.

The ASIS/Wharton Program began in late 2004, "accelerated by 9–11 and a sense of urgency that, to achieve the highest levels of protection, a program such as this was imminent," according to Mr. Stack.

Steve Chupa, director of security in the Worldwide Security Group at a Fortune 100 company and president-elect of ASIS International, related that he worked with Wharton to develop the program as he experienced first-hand his companies' security officers and their stumbling attempts at communication. As Steve indicated, "over the years, I observed the Security staff briefs to the Board and watched that within 30 seconds, the board members' eyes glazed over and they had already moved on to the next subject on the agenda, leaving the Security Officer talking to the hand."

Looking back, Mr. Chupa and other ASIS leaders realized that their organization did a great job in bringing education and training to its members, but the offerings hit a wall at the middle management level. It was akin to coaching a football team to win the games leading up to the league championship, but not maintaining the drive, confidence and tools to win the gold ring. Association of Security education and training could not move its members to the ultimate goal: the boardroom.

Association of Security decided to partner with a great business school to develop an intensive curriculum that would bring critical skills to the table that could be applied practically and immediately. The dialog with Wharton began in 2002. Chupa relates that 9–11 was a significant driver. "It brought security to the front door, forcing companies to consider issues such as supply chain continuity, building safety and business continuity." The inaugural course was offered in November, 2004.

The focus of the ASIS/Wharton program is leadership within the framework of security. The curriculum is pragmatic, not theoretical, and it concentrates on providing tools to its students that can be applied immediately in the workplace. For example, Chupa indicated that "you can encourage your boss to modify his or her behavior to your advantage by observing your supervisor's behavior and listening to the phrases used when they communicate." "If your boss uses certain words or phrases," says Chupa, "begin to apply the same phrases in a positive manner. Suddenly, agreement on your ideas become the norm."

Arpad Toth, an alumni of this initial Wharton curriculum, shared that his primary motive for attending the program was to enhance his skills set relative to decision-making opportunities, that is, analyzing and digesting critical security scenarios to yield a logical structure and to gain a better understanding of the market.

According to Toth, he walked away with a much better understanding of the financial aspects of building a powerful and compelling business case. Toth appreciated the cross-pollination and sharing of ideas that occurred throughout the course of the program. He gained a better appreciation for decision-making opportunities, analyzing and digesting critical security scenarios to build a logical structure as well as a much better understanding of the key components of a successful business case relative to critical security scenarios.

The ASIS/Wharton program is offered in two nonconsecutive weeks. It is a certificate course, offering core business knowledge from one of the leading business schools. The courses are taught by many of the same faculty who have made Wharton's MBA program one of the top-ranked in the world.

According to Chupa, "Security executives need to become business partners. We sometimes are viewed as the people you call if you have a problem. We need to be seen as partners to make sure we contribute to the business. For example, we are working on issues such as counterfeiting, grey markets, and employment terminations, all of which address key security and business issues. We need to understand the directives and strategic objectives of the corporation and look out for the best interests of the company."

More details of the Wharton/ASIS program are available at http://education.wharton.upenn.edu/course.cfm?Program=ASIS.

At the time of this writing, I came across some additional information on the SANS website (http://www.sans.org) [7] relative to a program that the organization is providing for career enhancement for IT security professionals.

According to the 2005 Global Information Security Workforce Study sponsored by the International Information Systems Security Certification Consortium (ISC)2, IT security professionals are gaining increased access to corporate boardrooms. More than 70% of those surveyed said they felt they had increased influence on executives in 2005 and even more expect that influence to keep growing. "They are increasingly being included in strategic discussions with the most senior levels of management." Howard Schmidt, who serves on (ISC)2's board of directors, said "There's more attention and focus on IT security as a profession, as opposed to just a job." Companies are increasingly looking for employees who have not only security expertise, but experience in management and business as well. More than 4300 full-time IT security professionals provided responses for the study (http://www.techweb.com/wire/175800558).

Information Security Governance

Todd Fitzgerald

Increased corporate governance requirements have caused companies to examine their internal control structures closely to ensure that controls are in place and operating effectively. Organizations are increasingly competing in the global marketplace, which is governed by multiple laws and supported by various "best practices guidelines" (i.e., ITIL, ISO17799, COSO, COBIT). Appropriate information technology (IT) investment decisions must be made that are in alignment with the mission of the business. IT is no longer a back-office accounting function in most businesses, but rather is a core operational necessity to business, and it must have the proper visibility to the board of directors and management. This dependence on IT mandates ensuring the proper alignment and understanding of risks to the business. Substantial investments are made in these technologies, which must be appropriately managed. Company reputations are at risk from insecure systems, and trust in IT systems needs to be demonstrated to all parties involved, including shareholders, employees, business partners, and consumers. Information security governance provides mechanisms for the board of directors and management to have the proper oversight to manage the risks to the enterprise and keep them at an acceptable level.

2.1 Security Governance Defined

Although there is no universally accepted definition for security governance at this juncture, the intent of such governance is to ensure that the appropriate information security activities are being performed so that risks are being appropriately reduced, information security investments are being appropriately directed, the program has visibility to executive management and that management is asking the appropriate questions to determine the effectiveness of the information security program.

The IT Governance Institute™ (ITGI) defines IT governance as "a structure of relationships and processes to direct and control the enterprise in order to achieve the enterprise's goals by adding value while balancing risk versus return over IT and its processes." The ITGI proposes that information security governance should be considered part of IT governance, and that the board of directors become informed about information security, set direction to drive policy and strategy, provide resources to security efforts, assign management responsibilities, set priorities, support changes required, define cultural values related to risk assessment, obtain assurance from internal or external auditors, and insist that security investments be made measurable and reported on for program effectiveness. Additionally, the ITGI suggests that management: write security policies with business input, and ensure that roles and responsibilities are defined and clearly understood, threats and vulnerabilities are identified, security infrastructures are implemented, control frameworks (standards, measures, practices and procedures) are implemented after policy approved by governing body, timely implementation of priorities, monitoring of breaches, periodic reviews and tests are conducted, awareness education is viewed as critical and delivered, and that security is built into the systems development life cycle. These concepts are further delineated in this section.

2.2 IT Best Practices and Frameworks

Multiple frameworks have been created to support auditing of implemented security controls. These resources are valuable for assisting in the design of a security program, as they define the necessary controls for providing secure information systems. The following frameworks have each gained a degree of acceptance within the auditing and/or information security community and each adds value to information security investment delivery. Although several of the frameworks/best practices were not specifically designed to support information security, many of the processes within these practices support different aspects of confidentiality, integrity, and availability.

2.2.1 Committee of Sponsoring Organizations of the Treadway Commission

The Committee of Sponsoring Organizations of the Treadway Commission (COSO) was formed in 1985 to sponsor the National Commission on Fraudulent Financial Reporting, which studied factors that lead to fraudulent financial reporting and produced recommendations for public companies, their auditors, the Securities Exchange Commission and other regulators. COSO identifies five areas of internal control necessary to meet financial reporting and disclosure objectives. These areas include (1) control environment, (2) risk assessment, (3) control activities, (4) information and communication, and (5) monitoring. The COSO internal control model has been adopted as a framework by some organizations working towards Sarbanes–Oxley Section 404 compliance.

2.2.2 IT Infrastructure Library

The *IT Infrastructure Library* (ITIL) is a set of 44 books published by the British government's Stationary Office between 1989 and 1992 to improve IT service management. The framework contains a set of best practices for IT core operational processes such as change, release and configuration management, incident and problem management, capacity and availability management, and IT financial management. ITIL's primary contribution is showing how these controls can be implemented for service management IT processes. These practices are useful as a starting point, and can then be tailored to the specific needs of the organization. Their success in practice depends upon the degree to which they are kept updated and implemented on a daily basis. Achieving these standards is an ongoing process, whereby their implementation needs to be planned, supported by management, prioritized, and implemented in a phased approach.

2.2.3 Control Objectives for Information and Related Technology

Control Objectives for Information and Related Technology (COBIT) is published by the IT Governance Institute and contains a set of 34 high-level control objectives. There is one for each of a set of IT processes, such as Define a Strategic IT Plan, Define the Information Architecture, Manage the Configuration, Manage Facilities, and Ensure Systems Security. Ensure Systems Security has further been broken down into control objectives such as Manage Security Measures, Identification, Authentication and Access, User Account Management, Data Classification, Firewall Architectures, and so forth. The COBIT framework examines effectiveness, efficiency, confidentiality, integrity, availability, compliance and reliability aspects of the high-level control objectives. The model defines four domains for governance: Planning & Organization, Acquisition & Implementation, Delivery & Support, and Monitoring. Processes and IT activities and tasks are then defined within each domain. The framework provides an overall structure for IT control and includes objectives that can be utilized to determine effective security control driven from the business needs.

2.2.4 ISO17799/BS7799

The BS7799/ISO17799 standards can be used as a basis for developing security standards and security management practices within organizations. The DTI (U.K. Department of Trade and Industry) code of practice (CoP) for information security that was developed with support of industry in 1993 became British Standard 7799 in 1995. The BS 7799 standard was subsequently revised in 1999 to add certification and accreditation components, which became part 2 of the BS7799 standard. Part 1 of the BS7799 standard became ISO17799 and was published as ISO17799:2000 as the first international information security management standard by the International Organization for Standardization (ISO) and International Electrotechnical Commission (IEC).

The ISO17799 standard was modified in June, 2005 as ISO/IEC 17799:2005 and contains 134 detailed information security controls based upon the following 11 areas:

- Information security policy
- Organizing information security
- Asset management
- Human resources security
- Physical and environmental security
- Communications and operations management
- Access control
- Information systems acquisition, development, and maintenance
- Information security incident management
- Business continuity management
- Compliance.

The ISO standards are grouped by topic areas, and the ISO/IEC 27000 series has been designated as the information security management series. For example, the 27002 Code of Practice will replace the current ISO/IEC 17799:2005 *Information Technology—Security Techniques—Code of Practice for Information Security Management Document*. This is consistent with how ISO has named other topic areas, such as the ISO 9000 series for quality management.

ISO/IEC 27001:2005 was released in October, 2005, and specifies requirements for establishing, implementing, operating, monitoring, reviewing, maintaining and improving a documented information security management system taking into consideration the company's business risks. This management standard was based on the BS7799, part 2 standard and provides information on building information security management systems as well as guidelines for auditing those systems.

2.2.5 Ongoing Best Practices Testing

Ongoing testing of the security controls is necessary to ensure that the IT infrastructure remains secure. Changes such as mergers and acquisitions, staff turnover, new technologies, integration of new applications and new threats/vulnerabilities all affect the secure environment. Ensuring that appropriate patches are applied, antivirus controls are current and operational, and configuration settings are maintained according to baselines, are all critical. Testing controls can take the form of vulnerability assessments, which ascertain that the appropriate controls have been properly implemented on various platforms, and penetration testing that attempts to gain entry to the environment through limited initial knowledge of the infrastructure. Standards are important; however, testing is an important component to ensure ongoing compliance.

2.3 Organizational Dynamics

Organizations exist as a system of coordinated activities to accomplish organizational objectives. The larger the organization, the greater need for formalized mechanisms to ensure the stability of the operations. Formalized, written policies, standards, procedures, and guidelines are created to provide for the long-term stability of the organization, regardless of the identity of the incumbent occupying a position. Over time, those in leadership positions will change, as well as individuals within the workforce.

Organizational business processes are rationalized and logically grouped to perform the necessary work efficiently and effectively. Mergers and acquisitions frequently change the dynamics of the operating organization, frequently providing new opportunities to achieve synergies.

Work is typically broken down into subtasks, which are then assigned to an individual though specialization. When these tasks, such as systems security, database administration, or systems administration activities are grouped together, one or more individuals who can focus on those particular skill sets can perform them. This process of specialization creates greater efficiency within the organization, as it permits individuals to become very knowledgeable in particular disciplines and produces results more rapidly than if the tasks are combined with other responsibilities.

Organizations are also managed in a hierarchical manner, where the lower levels of the organization are assigned more defined, repetitive tasks with less discretion over resource allocation, including human and physical assets. In higher levels of the organization, through the chain of command, there are higher levels of authority and greater capabilities to reassign resources as necessary to accomplish higher-priority tasks.

2.4 Organizational Structure Evolution

The security organization has evolved over the past several decades with a variety of names, such as data security, systems security, security administration, information security, and information protection. These naming conventions are reflective of the emerging scope and expansion of the information security departments. Earlier naming conventions such as "data security" indicated the primary focus of the information security profession, which was to protect the information that was primarily created within the mainframe, data-center era. As technology evolved into distributed computing and the information has progressively moved outward from data-center "glass-house" protections, the scope of information security duties has increased to include these platforms. The focus in the 1970s was on the security between computers and the mainframe infrastructure, which evolved into the data security and information security in the 1980s, in recognition of the importance of protecting access to and integrity of the information contained within the systems. In the 1990s, as IT was being viewed as more fundamental to business success than ever before, and consumers became more aware of privacy issues regarding the protection and use of their information, concepts of enterprise security protection began to emerge.

Whatever naming convention is used within the organization, the primary focus of the information security organization is to ensure the confidentiality, availability, and integrity of business information. The size of the organization and the types of individuals necessary to staff the organization will depend upon the size of the overall organization, geographic dispersion, how centralized or decentralized are systems processing, the risk profile of the company, and the budget available for security. Each organization will be slightly different, as each operates within different industries with different threat profiles. Some organizations may be unwilling to take even the slightest risk if disclosure of the information that needs to be protected would be devastating to the long-term viability of the business. Organizations in the defense industry, financial institutions, and technical research facilities needing to protect trade secrets may fall into this category. Until recently, the healthcare and insurance industries have spent a small portion of the available funds on information security, as their primary expenditures were allocated to helping patients and systems that provide increased care as opposed to protecting patient/client information. In fact, in some hospital environments, making information "harder to retrieve quickly" was viewed as being detrimental to effective, timely care.

In the early centralized mainframe computing environments, a data security officer was primarily responsible for the account and password administration, granting access privileges to files, and possibly disaster recovery, administered the security function. The assets that the security officer was protecting were primarily IT assets in the mainframe computer systems, and did not include the hardcopy documents, people, facilities, or other company assets. These responsibilities resided within the IT department, and as such, the focus was on IT assets and limited in scope. The security officer was typically trained in mechanisms such as RACF, ACF2, TopSecret, and CICS/MVS, reflecting the scope of the position. As distributed, decentralized computing environments evolved to include internetworking between local-area network (LANs) and wide-area networks (WANs), email systems, data warehouses, and remote access capabilities, the scope of the responsibilities became larger and it became more difficult to find all these skills within one individual. Complicating the environment further was the integration of multiple disparate software applications and multiple vendor database management system environments, such as DB2, Oracle, Teradata, and SQL Server running on different operating systems such as MVS, Windows, or multiple flavors of UNIX. In addition, each application has individual user access security controls that need to be managed. It would not be realistic to concentrate the technical capability for each of these platforms within one individual, or a small set of individuals trained on all of the platforms. This provided the impetus for specialization of these skills to ensure that the appropriate training and expertise were present to adequately protect the environment. Hence, firewall/router administrators need the appropriate technical training in the devices that they are supporting, whereas a different individual or group may need to work with the Oracle database administrators to provide appropriate DBMS access controls, logging, and monitoring capabilities.

2.5 Today's Security Organizational Structure

There is no "one size fits all" for the structure of the information security department or assignment of the scope of the responsibilities. Where the security organization should report has also been evolving. In many organizations, the information systems security officer (ISSO) or chief information security officer (CISO) still reports to the chief information officer (CIO) or the individual responsible for the IT activities of the organization. This is due to the fact that many organizations still view the information security function as an IT problem and not a core business issue.

Alternatively, the rationale for this may be the necessity to communicate in a technical language, which is understood by IT professionals and not typically well understood by business professionals. Regardless of the rationale for placement within the organization, locating the individual responsible for information security within the IT organization could represent a conflict of interest, as the IT department is motivated to deliver projects on time, within budget and at a high quality. Shortcuts may be taken on security requirements to meet these constraints if the security function is reporting to the individual making these operational decisions. The benefit of having the security function report to the CIO is that the security department is more likely to be engaged in the activities of the IT department and be aware of the upcoming initiatives and security challenges.

A growing trend is for the security function to be treated as a risk-management function and as such, be located outside of the IT organization. This provides a greater degree of independence, as well as providing the focus on risk management vs. management of user IDs, password resets, and access authorization. Having the reporting relationship outside of the IT organization also introduces a different set of checks and balances for the security activities that are expected to be performed. The security function may report to the chief operating officer, CEO, general counsel, internal audit, legal, compliance, administrative services or some other function outside of IT. The function should report as high in the organization as possible, preferably to an executive-level individual. This reporting line ensures that the proper message about the importance of the function is conveyed to senior management, company employees see the authority of the department, and that funding decisions are made while considering the needs across the company.

2.6 Security Planning

Strategic, tactical, and operational plans are interrelated and each makes a different contribution towards enhancing the security of the organization. Planning reduces the likelihood that the organization will be reactionary concerning security needs. With appropriate planning, decisions on projects can be made taking into consideration whether they are supporting long-term or short-term goals and have the priority that warrants the allocation of more security resources.

2.6.1 Strategic Plans

Strategic plans are aligned with the strategic business and IT goals. These plans have a longer-term horizon (3–5 years or more) to guide a long-term view of the security activities. The process of developing a strategic plan emphasizes thinking about the company environment and the technical environment a few years into the future. High-level goals are stated to provide a vision for projects to achieve business objectives. These plans should be reviewed minimally on an annual basis, or whenever major changes to the business occur, such as a merger, acquisition, establishment of outsourcing relationships, major changes in the business climate, introductions of new competitors, and so forth. Technological changes will be frequent during a 5-year time period, so the plan should be adjusted regularly. A high-level plan provides organizational guidance to ensure that lower-level decisions are consistent with executive management's intentions for the future of the company. For example, strategic goals may consist of:

- Establish security policies and procedures
- Effectively deploy servers, workstations, and network devices to reduce downtime
- Ensure all users understand the security responsibilities and reward excellent performance
- Establish a security organization to manage security entity-wide
- Ensure that risks are effectively understood and controlled.

2.6.2 Tactical Plans

Tactical plans describe broad initiatives to support and achieve the goals specified in the strategic plan. These initiatives may include deployments such as establishing an electronic policy development and distribution process, implementing robust change control for the server environment, reducing the likelihood of vulnerabilities residing on the servers, implementing a "hot site" disaster recovery program, or implementing an identity management solution. These plans are more specific and may contain multiple projects to complete the effort. Tactical plans are shorter in length, typically from 6 to 18 months and are designed to achieve a specific security goal of the company.

2.6.3 Operational/Project Plans

Specific plans with milestones, dates, and accountabilities provide the communication and direction to ensure that individual projects are being completed. For example, establishing a policy development and communication process may involve multiple projects with many tasks:

- Conduct security risk assessment
- Develop security policies and approval processes
- Develop technical infrastructure to deploy policies and track compliance
- Train end users on policies
- Monitor compliance.

Depending upon the size and scope of the effort, these initiatives may be steps within a single plan, or they may consist of multiple plans managed through several projects. The duration of these efforts are typically short-term to provide discrete functionality at the completion of the effort. Traditional "waterfall" methods of implementing projects devoted a large amount of time to detailing the specific steps required to implement the complete project. Executives today are more focused on achieving some short-term, or at least interim results, to demonstrate the value of the investment along the way. Demonstrating value along the way maintains organizational interest and provides visibility to the effort, increasing the chances of sustaining longer-term funding. Executive management may grow impatient without seeing these early benefits.

2.7 Responsibilities of the Information Security Officer

The information security officer is responsible for ensuring the protection of all business information assets from intentional and unintentional loss, disclosure, alteration, destruction, and unavailability. The security officer typically does not have the resources available to perform all of these functions, and must depend upon other individuals within the organization to implement and execute policies, procedures, standards, baselines, and guidelines to ensure the protection of information. In this situation, the information security officer acts as the facilitator of information security for the organization.

2.7.1 Communicate Risks to Executive Management

The information security officer is responsible for understanding the business objectives of the organization, ensuring that a risk assessment is performed that takes into consideration the threats and vulnerabilities affecting the particular organization, and subsequently communicating those risks to executive management. The composition of the executive management team will vary from type of industry or government entity, but typically includes individuals with "C-level" titles such as the chief executive officer (CEO), chief operating officer (COO), chief financial officer (CFO), and chief information officer (CIO). The executive team also includes the first level reporting to the CEO such as the VP of sales and marketing, VP of administration, general counsel, and the VP of human resources.

The executive team is interested in maintaining the appropriate balance between acceptable risk and ensuring that business operations are meeting the mission of the organization. In this context, executive management is not concerned with the technical details of implementation, but rather with the cost/benefit of the solution and the residual risk that will remain after the safeguards are implemented. For example, the configuration parameters of installing a particular vendor's router are not as important as: (1) the real perceived threat (problem to be solved), (2) the risk (impact and probability) to business operations, (3) the cost of the safeguard, (4) be the residual risk (risk remaining after the safeguard is properly implemented and sustained), and (5) how long the project will take. Each of these dimensions must be evaluated along with the other items competing for resources (time, money, people, and systems).

The security officer has a responsibility to ensure that the information presented to executive management is based upon a real business need and that the facts are presented clearly. Ultimately, it is the executive management of the organization that is responsible for information security. Presentations should be geared at a high level to convey the purpose of the technical safeguard and should not be a detailed presentation of the underlying technology unless requested.

2.7.2 Budget for Information Security Activities

The information security officer prepares a budget to manage the information security program and ensures that security is included in various other departmental budgets such as the help desk, applications development, and computing infrastructure. Security is much less expensive when it is built into application design vs. added as an afterthought. Estimates range widely over the costs of adding security later in the life cycle, but it is generally believed that it is at least a factor of 10 to add security in the implementation phase vs. addressing it early in analysis phases. The security officer must work with the application development managers to ensure that security is being considered as a project cost during each phase of development (analysis, design, development, testing, implementation, and post-implementation). Systems security certification, or minimally holding walkthroughs to review security at each stage, ensures that the deliverables are being met.

In addition to ensuring that new project development activities appropriately address security, ongoing functions such as security administration, intrusion detection, incident handling, policy development, standards compliance, support of external auditors, and evaluations of emerging technology also need to be appropriately funded. The security officer will rarely receive all the funding necessary to complete all of the projects that he/she and team have envisioned, and these activities must usually be planned over a multi-year period. The budgeting process requires examination of current risks and ensuring that activities with the largest cost/benefit to the organization are implemented first. Projects exceeding 12–18 months in duration are generally considered to be long-term, strategic in nature and typically require more funding and resources or are more complex in their implementation than shorter projects. In the event that efforts require a longer timeframe, pilot projects to demonstrate near-term results on a smaller scale are preferable. Organizations lose patience with funding long-term efforts, as initial management supporters may change over time, as well as some of the team members implementing the change. The longer the payback period, the higher the rate of return on investment (ROI) expected by executive management. This is due primarily to the higher risk levels associated with longer-term efforts.

The number of staff, level of security protection required, tasks to be performed, regulatory requirements to be met, staff qualification levels, training required, and degree of metrics-tracking will also be parameters that will drive the funding required. For example, if the organization is being required through government regulation to increase the number of individuals with security certifications, whether that might be individual product-vendor or industry-standard certifications such as the CISSP, then the organization may feel an obligation to fund training seminars to prepare its employees and this will need to be factored into the budget process. This requirement may also be utilized to attract and retain security professionals to the organization through increased learning opportunities. As another example, the time required in complying with government mandates and laws may necessitate increased staffing to provide the appropriate ongoing tracking and responses to audit issues.

2.7.3 Ensure Development of Policies, Procedures, Baselines, Standards, and Guidelines

The security officer and his team are responsible for ensuring that the security policies, procedures, baselines, standards, and guidelines are written to address the information security needs of the organization. However, this does not mean that the security department must write all the policies in isolation. Nor should policies be written solely by the security department without the input and participation of other departments within the organization, such as legal, human resources, IT, compliance, physical security, the business units, and others that will be required to implement the resulting policy.

2.7.4 Develop and Provide Security Awareness Program

The security officer provides the leadership for the information security awareness program by ensuring that programs are delivered in a meaningful, understandable way to the intended audience. The program should be developed to “grab the attention” of participants, to convey general awareness of the security issues and what also reporting actions are expected when the end user notices security violations. Without promoting awareness, the policies remain as shelfware with little assurance that they will actually be practiced within the company.

2.7.5 Understand Business Objectives

Central to the security officer’s success within the organization is understanding the vision, mission, objectives/goals, and plans of the organization. Such understanding increases the security officer’s chances of success, as security issues can be introduced at the correct times during the project life cycle (to gain attention) and can enable the organization to carry out its business mission. The security officer needs to understand the competitive pressures facing the organization, its strengths, weaknesses, threats, and opportunities, and the regulatory environment within which the organization operates. This understanding increases the likelihood that appropriate security controls will be applied to areas with the greatest risk, thus resulting in an optimal allocation of scarce security funding.

2.7.6 Maintain Awareness of Emerging Threats and Vulnerabilities

The threat environment is constantly changing, and as such, it is incumbent upon the security officer to keep up with those changes. It is difficult for any organization to anticipate new threats, some of which come from the external environment and some from technological changes. Prior to the September 11, 2001, terrorist attacks in the U.S., few individuals perceived such attack as very likely. However, since then, many organizations have revisited their access-control policies, physical security precautions and business continuity plans. New technologies such as wireless networks and the low cost of removable media (writeable CDs/DVDs and USB drives) have created new threats to confidentiality and the disclosure of information, all which need to be addressed. While an organization tries to write policies to last for 2–3 years without change, depending upon the industry and the rate of change, policies addressing the threat environment may need to be revisited more frequently.

2.7.7 Evaluate Security Incidents and Response

Computer incident response teams (CIRTs) are groups of individuals with the necessary skills to evaluate an incident, including the damage caused by it, and providing the correct response to repair the system and collect evidence for potential prosecution or sanctions. Such a team should often includes management, technical staff, infrastructure, and communications staff. CIRTs are activated depending upon the nature of the incident and the culture of the organization. Security incidents need to be investigated and followed up on promptly, as this is a key mechanism in ensuring compliance with security policies. Sanctions for employees with appropriate disciplinary action, up to and including termination, must be specified and implemented for these policies to be effective. The security officer and the security department ensure timely response to such incidents.

2.7.8 Develop Security Compliance Program

Compliance is the process of ensuring that security policies are being followed. A policy and procedure regarding the hardening of the company's firewalls are not very useful if the activity is not being performed. Periodic compliance checks, whether though internal or external inspection, ensures that procedures, checklists, and baselines are documented and are followed in practice as well as in theory. Compliance by end users is also necessary to ensure that they and technical staff are trained and have read and apply security policies.

2.7.9 Establish Security Metrics

The security officer should design and collect measurements to provide information on long-term trends, the day-to-day workload caused by security requirements and to demonstrate the effect of noncompliance with them. Measurement of processes provides the ability to improve those processes. For example, measuring the number of tickets for password re-sets can be translated into workload hours and may provide justification for the implementation of new technologies permitting the end user to self-administer the reset process. Or, capturing the number of viruses found or reported may indicate a need for further education or improvement of the organization's anti-virus management process. Many decisions need to be made when designing and collecting metrics, such as who will collect the metrics, what statistics will be collected, when will they be collected, and what the thresholds are where variations are out of bounds and should be acted upon.

2.7.10 Participation in Management Meetings

Security officers must be involved on management teams and in planning meetings of the organization to be fully effective. Project directions are set and decisions made during these meetings, as well as gaining buy-in for security initiatives. Such meetings include board of director meetings (periodic updates), information technology steering committees, manager meetings, and departmental meetings.

2.7.11 Ensure Compliance with Government Regulations

Governments are continuously passing new laws, rules, and regulations, with which organizations must be compliant. Although many new laws overlap in their security requirements, new laws frequently provide more stringent requirements on a particular aspect of information security. Timeframes for coming into compliance with the new law may not always come at the best time for an organization, nor line up with its budget funding cycles. The security officer must stay abreast of emerging regulatory developments to enable the organization to respond in a timely manner.

2.7.12 Assist Internal and External Auditors

Auditors provide an essential role in information security by providing an independent view of the design, effectiveness, and implementation of security controls. Audit results generate findings that require corrective action plans to resolve issues and mitigate risks. Auditors request information prior to the start of audits to facilitate their reviews. Some audits are performed at a high level without substantive testing, while others perform pull samples to determine if a control was correctly executed. The security department cooperates with internal and external auditors to ensure that the control environment is both adequate and functional.

2.7.13 Stay Abreast of Emerging Technologies

The security officer must stay abreast of emerging technologies to ensure that appropriate solutions are in place for the company based upon their appetite for risk, culture, resources available, and the desire to be an innovator, leader or follower (mature product implementation) of security products and practices. Failure to do so could increase the costs to the organization by requiring maintenance of older, less effective products. Approaches to satisfying this requirement may range from active involvement in security industry associations, interaction with vendors, subscribing to industry research groups, or to reviewing printed material.

2.8 Reporting Model

The security officer and the information security organization should report in at as high a level in the organization as necessary to (1) maintain visibility of the importance of information security, and (2) limit the distortion or inaccurate translation of messages that occur due to hierarchical, deep organizations. The higher up in the organization the reporting occurs, the greater the ability of the information security officer to gain other senior management's attention to security matters, and the greater the information security officer's capability to compete for the appropriate budget and resources.

Where in the organization the information security officer reports has been the subject of debate for several years and depends upon the culture of the organization. There is no "one best model" that fits all organizations, but rather pros and cons associated with each placement choice. Whatever the chosen reporting model, there should be an individual chosen with the responsibility for ensuring information security at the enterprise-wide level to establish accountability for security issues. The discussion in the next few sessions should provide a perspective for making appropriate choice within the target organization.

2.8.1 Business Relationships

Wherever the ISO reports, it is imperative that he or she establish credible and good working relationships with executive management, middle management, and the end users who will be following security policies. Information gathered and acted upon by executive management is obtained through their daily interactions with many individuals, not just within the executive management team. Winning an executive's support may result from influencing a respected individual within the organization, possibly several management layers below the executive. Similarly, the relationship between senior executives and the ISO is important if security strategies are to be implemented. Establishing a track record of delivery and demonstrating the value of the protection to the business will build the relationship between the information security officer and executive management. If done properly, the security function will come to be viewed as an enabler of the business vs. a control point that slows innovation or provides roadblocks to implementation, and is seen as represents an overhead, cost function. Reporting to an executive who understands the need for information security and is willing to work to obtain funding is preferable.

2.8.2 Reporting to the CEO

Reporting directly to the CEO greatly reduces the message filtering of reporting further down the hierarchy and improves communication, as well as demonstrating to the organization the importance of information security. Firms that have high security needs, such as credit card companies, technology companies, and companies whose revenue stream depends highly upon internet website purchases, such as eBay or Amazon.com might utilize such a model. The downside to this model is that the CEO may be preoccupied with other business issues and may not have the interest, time, or enough technical understanding to devote to information security issues.

2.8.3 Reporting to Information Systems Department

In this model, the ISO reports directly to the CIO, director of information systems, the vice president for systems, or whatever the title of the head of the IT department is. Most organizations are utilizing this relationship, as this was historically where the data security function was placed in many companies. This is due to the history of security being viewed as only an IT problem, which it is not. The advantage of this model is that the individual to whom the security officer is reporting has the understanding of the technical issues and typically has sufficient clout with senior management to make desired changes. It is also beneficial because the information security officer and his or her department must spend a good deal of time interacting with the rest of the information systems department, and these interactions build appropriate awareness of project activities and issues, and builds business relationships. The downside of this reporting structure is the conflict of interest it can represent. When the CIO must make decisions about time to market, resource allocations, cost minimization, application usability, and project priorities, the ability exists to slight the information security function. The typical CIO's goals are more oriented toward delivery of application products to support the business in a timely manner than to information security. If there is a perception that implementation of the security controls may take more time or money, security considerations may not be given equal weight in the decision-making process. Reporting to a lower level within the CIO organization should be avoided, as because noted earlier, the more levels there are between the CEO and the ISO, the more challenges that must be overcome. Levels further down in the organization also have their own "domains of expertise" that they are focusing on, such as computer operations, applications programming, or computing infrastructure, and those can distract from the attention given to information security issues.

2.8.4 Reporting to Corporate Security

Corporate security is focused on the physical security and most often, individuals in this environment have backgrounds as former police officers or military, or were associated in some other manner with the criminal justice system. This reporting alternative may appear logical, but individuals from these organizations usually come from very different backgrounds from those of information security officers. Physical security is focused on criminal justice, protection, and investigation services, while information security professionals usually have different training in business and information technology. The language of these disciplines intersects in some areas, but is vastly different in others. Another downside of this reporting relationship may be that association of the information security staff with the physical security group may evoke a police-type mentality, making it difficult for the information security group to build relationships with business users. Establishing relationships with the end users increases their willingness to listen and to comply with security controls, as well as providing knowledge to the security department of potential violations.

2.8.5 Reporting to Administrative Services Department

Another option is reporting to the vice president of administrative services, which may also include the physical security, employee safety, and human resources departments. As in the model in which information security reports to the CIO, there is only one level in this model between the CEO and the information security department. The model may also be viewed as an enterprise function due to the association with the human resources department. It can also be attractive due to the focus on security for all forms of information (paper, oral, electronic) vs. residing in the technology department where the focus may tend to be more on electronic information. The downside of this model is that leaders of this area may be limited in their knowledge of IT and in their ability to communicate with the CEO on technical issues.

2.8.6 Reporting to the Insurance and Risk Management Department

Information intensive organizations such as banks, stock brokerages, and research companies may benefit from this model. The chief risk officer is already concerned with risks to the organization and with methods to control those risks through mitigation, acceptance, insurance, etc. The downside of this model is that the risk officer may not be conversant in information systems technology, nor in the strategic focus of this function, and thus may give less attention to day-to-day operational security projects.

2.8.7 Reporting to the Internal Audit Department

This reporting relationship can also create a conflict of interest, as the internal audit department is responsible for evaluating the effectiveness and implementation of the organization’s control structure, including those of the information security department. It would be difficult for the internal audit department to provide an independent viewpoint if meeting the security department’s objectives is also viewed as part of its responsibility. The internal audit department may have adversarial relationships with other portions of the company due to the nature of their role (to uncover deficiencies in departmental processes), and through association, the security department may develop similar relationships. It is advisable that the security department establishes close working relationships with the internal audit department to facilitate the control environment. The Internal Audit Manager most likely has a background in financial, operational and general controls and may have difficulty understanding the technical activities of the information security department. On the positive side, both areas are focused on improving the company’s controls. The internal audit department does have a preferable reporting relationship for audit issues through a dotted-line relationship to the company’s audit committee on the board of directors. It is advisable for the Information Security function to have a path to report security issues to the board of directors as well, either in conjunction with the internal audit department or through their own reporting line.

2.8.8 Reporting to the Legal Department

Attorneys are concerned with compliance with regulations, laws, ethical standards, performing due diligence, and establishing policies and procedures that are consistent with many of the information security department's objectives. The company's general counsel also typically has the respect or ear of the chief executive officer. In regulated industries, this reporting model may be a very good fit. On the downside, due to legal's emphasis on compliance activities, the information security department may end up performing more compliance-checking activities (vs. security consulting and support), which are more typically the domain of internal auditing. An advantage in this model is that the distance between the CEO and the ISO is only one level.

2.8.9 Determining the "Best Fit"

As indicated earlier, each organization must view the pros and cons of each of these possible relationships and develop its own appropriate relationship based upon the company's culture, type of industry, and what reporting relationship will provide the greatest benefit to the company. Conflicts of interest should be minimized, visibility maximized, funding appropriately allocated, and communication effective when the optimal reporting relationship is selected for the placement of the information security department.

2.9 Enterprise-Wide Security Oversight Committee

An enterprise-wide security oversight committee, sometimes referred to as a *security council*, serves as an oversight committee to the information security program. The vision of the security council must be clearly defined and understood by all members of the council.

2.9.1 Vision Statement

A clear security vision statement should exist that is in alignment with and supports the organization's vision. Typically, these statements draw upon security concepts of confidentiality, integrity, and availability to support business objectives. Vision statements are not technical, and focus on business advantages. People from management and technical areas will be involved in the council and have limited time to participate, so the vision statement must be something seen as worthwhile to sustain their continued involvement. The vision statement is a high-level set of statements, brief, to the point, and achievable.

2.9.2 Mission Statement

Mission statements are objectives that support the overall vision. These become the roadmap for achieving the organization's security vision and help the council clearly see the purpose of their involvement. Some groups may choose nomenclature such as goals, objectives, initiatives, etc. Effective mission statements need not be lengthy because their primary purpose is to communicate goals so both technical and nontechnical individuals readily understand them. The primary mission of the security council will vary by organization, but can include statements that address:

1. Provide security program oversight. By establishing this goal in the beginning, the members of the council begin to feel that they have some input and influence over the direction of the security program. This is key, because many security decisions will impact their areas of operation. This also is the beginning of management commitment at the committee level because the deliverables produced through the information security program now become "recommended or approved" by the security council vs. only by the information security department.

2. Decide on project initiatives. Each organization has limited resources (time, money, people) to allocate across projects to advance the business. The primary objective of information security projects is to reduce the organizational business risk through the implementation of reasonable controls. The council should take an active role in understanding the initiatives of the information security group and the resulting "business" impact.
3. Prioritize information security efforts. After the security council understands proposed project initiatives and the associated positive impacts to the business, they can be involved with the prioritization of the projects. This may be in the form of a formal annual process or may be through discussion and expressed support for individual initiatives.
4. Review and recommend security policies. Review of security policies should occur through a line-by-line review of the policies, a cursory review of procedures to support the policies, and a review of the implementation and subsequent enforcement of the policies. Through this activity, three key concepts are implemented that are important to sustaining commitment: (1) understanding of the policy is enhanced, (2) practical ability of the organization to support the policy is discussed, and (3) buy-in is established to subsequent support of implementation activities.
5. Champion organizational security efforts. After the council understands and accepts the information security policies, they serve as the organizational champions of the policies. Why? Because they were involved in the *creation* of the policies. They may have started reviewing a draft of a policy created by the information systems security department, but the resulting product was only accomplished through their review, input, and participation in the process. Their involvement in the creation creates ownership of the deliverable and a desire to see the security policy or project succeed within the company.
6. Recommend areas requiring investment. Members of the council have the opportunity to provide input from the perspectives of their individual business units. In this way, the council serves as a mechanism for establishing broad support for security investments. Resources within any organization are limited and are allocated to the business units with the greatest needs and with the greatest perceived returns on investment. Establishing support of members of the security council enhances the budgetary understanding of the other business managers, as well as the chief financial officer, and this is often essential to obtaining the appropriate funding to carry out projects.

A mission statement that incorporates the previous concepts will help focus the council and also provide a sustaining purpose for their involvement. The vision and mission statements should also be reviewed on an annual basis to ensure that the council is still functioning according to the values expressed in the mission statement, as well as to ensure that new and replacement members are in alignment with the objectives of the council.

2.9.3 Oversight Committee Representation

An oversight committee is composed of representatives from the multiple organizational units that are necessary to support information security policies in the long term. Participation by the human resources department is essential to provide knowledge of the existing code of conduct in the business, and of employment and labor relations, termination and disciplinary action policies, and other related practices that are in place. Participation by representatives from the legal department is needed to ensure that the language of policies states what is intended, and that applicable local, state and federal laws are appropriately followed. The IT department provides technical input and information on current initiatives and the development of procedures and technical implementations to support information security policies. Representation from individual business units is essential to understand how the policies relate carrying out the mission of the business and how practical they will be to implement. Compliance department representation provides insight on ethics, contractual obligations, and investigations that may require policy creation. And finally, the security officer, who typically chairs the council, should represent the information security department, and members of the security team, for specialized technical expertise.

The oversight committee is a management committee and, as such, is populated primarily with management-level employees. It is difficult to obtain the time commitment required to review policies at a detailed level by senior management. Reviewing policies at this level is a necessary step to achieve buy-in within management, but it would not be a good use of the senior management time in the early stages of policy development. Line management is very focused on their individual areas and may not have the organizational perspective necessary (beyond their individual departments) to evaluate security policies and project initiatives. Middle management appears to be in the best position to appropriately evaluate what is best for the organization, as well as possessing the ability to influence senior and line management to accept policies. Where middle management does not exist, then it is appropriate to include line management, as they are typically filling both of these roles (middle and line functions) when operating in these positions.

Many issues may be addressed in a single security council meeting that necessitates having someone to record the minutes of the meeting. The chairperson's role in the meeting is to facilitate the discussion, ensure that all viewpoints are heard, and drive the discussions to decisions where necessary. It is difficult to perform that function at the same time as taking notes. Recording the meeting can also be helpful, as it can capture key points that might have been missed in the notes, so that accurate minutes can be produced.

The relationship between the security department and the security oversight committee is a dotted-line relationship that may or may not be reflected on the organization chart. The value of the committee is to provide business direction and to increase awareness of security activities that are impacting the organization on a continuous basis. The frequency of committee meetings will depend upon the organizational culture (i.e., are monthly or quarterly oversight meetings held on other initiatives), the number of security initiatives, and the urgency of decisions that need input from business units.

2.10 Establishing Roles and Responsibilities

Many different individuals within an organization contribute to successful information protection. Security is the responsibility of everyone within the company. All end users are responsible for understanding policies and procedures applicable to their particular job function and adhering to the security control expectations. Users must have knowledge of their responsibilities and be trained to a level that is adequate to reduce the risk of loss. Although exact titles and scope of responsibility of individuals may vary by organization, the following roles support the implementation of security controls. An individual may be performing multiple roles when the processes are defined for the organization, depending upon existing constraints and organizational structure. It is important to provide clear assignments and accountability to designated employees for various security functions to ensure that the tasks are being performed. Communication of the responsibilities for each function, through distribution of policies, job descriptions, training, and management direction provides the foundation for execution of security controls by the workforce.

2.10.1 Security-Related Roles

2.10.1.1 End User

The end user is responsible for protecting information assets on a daily basis through adherence to the security policies that have been communicated. The end users represent many "windows" to the organization and, through their practices, security can either be strengthened through compliance or compromised. For example, downloading unauthorized software, opening attachments from unknown senders, or visiting malicious web sites could introduce back doors or Trojan horses into the environment. End users can also be the front-line eyes and ears of the organization and report security incidents for investigation. Creating this culture requires that these roles and responsibilities are clearly communicated and are understood by all.

2.10.1.2 Executive Management

Top management has overall responsibility for protection of information assets. Business operations are dependent upon information being available, accurate, and protected from individuals without a need to know. Financial losses can occur if the confidentiality, integrity, or availability of information is compromised. Members of the management team must be aware of the risks that they are accepting for the organization, either through explicit decision making or the risks they are accepting by failing to make decisions or to understand the nature of the risks inherent in the existing operation of the information systems.

2.10.1.3 Security Officer

As noted in the governance sections, the security officer directs, coordinates, plans and organizes information security activities throughout the organization. The security officer works with many different individuals, such as executive management, business unit management, technical staff, business partners, and third parties such as auditors and external consultants. The security officer and his/her team are responsible for the design, implementation, management and review of the organization's security policies, standards, procedures, baselines, and guidelines.

2.10.1.4 Information Systems Security Professional

Development of the security policies and the supporting procedures, standards, baselines, guidelines and subsequent implementation and review are performed by information security professionals. They provide guidance for technical security issues, and emerging threats are reviewed in the consideration of adoption of new policies. They are also responsible for the interpretation of government regulations, industry trends, and the placement of vendor solutions in the security architecture to advance the security of the organization.

2.10.1.5 Data/Information/Business Owners

A business executive or manager is responsible for the information assets of the business. These are the individuals who assign the appropriate classification to assets and ensure that business information is protected with appropriate controls. Periodically, data owners should review the classification and access rights associated with information assets. Depending upon the formalization of the process within the organization, data owners or their delegates may be required to approve access to information by other business units. Data owners also need to determine the criticality, sensitivity, retention, backups, and safeguards for information assets. Data owners or their delegates are responsible for understanding the policies and procedures used to appropriately classify the information.

2.10.1.6 Data Custodian

The data custodian is the individual (or function) who takes care of information assets on behalf of the data owner. These individuals ensure that the information is available to the end users and is backed up to enable recovery in the event of data loss or corruption. Information may be stored in files, databases, or systems; this technical infrastructure must be managed, typically by systems administrators or operations.

2.10.1.7 Information Systems Auditor

The information systems auditor determines whether systems are in compliance with adopted security policies, procedures, standards, baselines, designs, architectures, management direction, and other requirements. Auditors provide independent assurance to management on the appropriateness of the security objectives. The auditor examines information systems and determines whether they are designed, configured, implemented, operated, and managed in a way that the organizational objectives are being achieved. The auditors provide top company management with an independent view of the controls that have been adopted and their effectiveness. Samples are extracted to test the existence and effectiveness of information security controls.

2.10.1.8 Business Continuity Planner

This individual develops contingency plans to prepare for the occurrence of a major threat with the ability to impact the company's objectives negatively. Threats may include earthquakes, tornadoes, hurricanes, blackouts, and changes in the economic/political climate, terrorist activities, fire, or other major actions potentially causing significant harm. A business continuity planner ensures that business processes can continue through the disaster and coordinates those activities with the information technology personnel responsible for disaster recovery on specific platforms.

2.10.1.9 Information Systems/Information Technology Professionals

IT professionals are responsible for designing security controls into information systems, testing the controls, and implementing systems in production environments through agreed-upon operating policies and procedures. Information systems professionals work with business owners and security professionals to ensure that the designed solutions provide security controls commensurate with acceptable criticality, sensitivity, and availability requirements of the applications.

2.10.1.10 Security Administrator

Security administrators manage user access request processes and ensure that privileges are provided to those individuals who have been authorized for access by management. These individuals have elevated privileges; they and create and delete accounts and access permissions. Security administrators also terminate access privileges when individuals leave their jobs or transfer among company divisions. Security administrators maintain records of approvals as part of the control environment and provide these records to information systems auditors to demonstrate compliance with policies.

2.10.1.11 Systems Administrator

A systems administrator configures the hardware and operating systems to ensure that the information assets of the business can be available and accessible. The administrator runs software distribution systems to install updates and tested patches on company computers. The administrator tests and implements system upgrades to ensure continued reliability of the servers and network devices. Periodic usage of vulnerability testing tools, either through purchased software or open source tools tested in a separate environment, identifies areas needing system upgrades or patches to fix vulnerabilities.

2.10.1.12 Physical Security

The individual(s) assigned to the physical security role establishes relationships with external law enforcement, such as the local police agencies, state police, or the Federal Bureau of Investigations (FBI) to assist in incident investigations. Physical security personnel manage the installation, maintenance, and ongoing operation of CCTV surveillance systems, burglar alarm systems, and card reader access control systems. Guards are placed where necessary as a deterrent to unauthorized access and to provide safety for the company employees. Physical security personnel interface with systems security, human resources, facilities, legal, and business areas to ensure that all practices are integrated.

2.10.1.13 Administrative Assistants/Secretaries

This role can be very important to information security, as in many companies of smaller size, this may be the individual who greets visitors, signs packages in and out, recognizes individuals who desire to enter the offices, and serves as the phone screener for executives. These individuals may be subject to social engineering attacks, whereby the potential intruder attempts to solicit confidential information that may be used for a subsequent attack. Social engineers prey on the good will and good graces of the helpful individual to gain entry. A properly trained assistant will minimize the risk of divulging useful company information or providing unauthorized entry.

2.10.1.14 Help Desk Administrator

As the name implies, the help desk is there to handle questions from users that report system problems through a ticketing system. Problems may include poor response time, potential virus infections, unauthorized access, inability to access system resources, or questions on the use of a program. The help desk administrator contacts the computer incident response team (CIRT) when a situation meets the criteria developed by the team. The help desk resets passwords, resynchronizes/reinitializes tokens and smart cards, and resolves other problems with access control. These functions may alternatively be performed through self-service by the end-users (i.e., intranet-based solutions that establishes the identify of the end users and resets the password), or by another area such as the security administration, systems administrators, etc., depending upon the organizational structure and separation of duties principles in use at the business.

2.10.1.15 Other Roles

An organization may include other roles related to information security to meet the needs of the particular organization. Individuals within the different roles will require different levels of training. End users may require only security awareness training including activities that are acceptable, how to recognize when there may be a problem, and the mechanism for reporting problems to the appropriate security personnel for resolution. Security administrators need more in-depth training on access control packages to manage logon IDs, accounts, and log file reviews. Systems/network administrators need technical security training for specific operating systems (Windows, Unix, Linux, etc.) to competently set the security controls.

2.10.2 Establishing Unambiguous Roles

Establishing clear, unambiguous security roles has many benefits to the organization beyond providing information as to the duties to be performed and to whom they are assigned. The benefits may also include:

- Demonstrable executive management support for information security
- Increased employee efficiency by reducing confusion about who is expected to perform which tasks
- Team coordination to protect information as it moves from department to department
- Lowered risks to company reputation damage due to reduced security problems
- Capability to manage complex information systems and networks
- Established personal accountability for information security
- Reduced turf battles between and among departments
- Balancing of security with business objectives
- Supported disciplinary actions for security violations, up to and including termination where appropriate
- Increased communication for resolution of security incidents
- Demonstrated compliance with applicable laws and regulations
- Shielding of management from liability and negligence claims
- Development of roadmap for auditors to determine whether necessary work is being performed effectively and efficiently
- Support for continuous improvement efforts (i.e., ISO 9000)
- A foundation for determining the security and awareness training required.

Information security is a team effort requiring the skills and cooperation of many different individuals. Although executive management may have overall responsibility, and the security officer/director/manager may be assigned the day-to-day task of ensuring the organization is complying with the defined security practices, every person in the organization has one or more roles to contribute to ensuring appropriate protection of the information assets.

2.11 Future Organizational Competitiveness

Organizations that provide good management oversight and ensure that control frameworks are implemented will have a strategic advantage over those organizations that do not invest in these areas. It is much more expensive to clean up after major incidents have occurred, files were inadvertently deleted, information has been made unavailable, or sensitive information has been publicly disclosed, than if the appropriate controls were adhered to in the first place. Many individuals have good intentions, but organizations are dynamic in nature and "get busy" with other priorities. Security governance techniques reduce the risk that the appropriate controls will not be analyzed, designed or implemented to protect the organization's assets. The techniques also increase the probability that investments are allocated in such a way that permits the business to remain competitive, such as by prioritizing investments that provide support for new innovative company products, or by reducing the level of spending to sustain current infrastructure. Obtaining these revenue enhancers or cost reductions is dependent upon appropriate security management practices, which ensure the right actions that are in the best interest of the business are being performed in the most efficient and effective manner. Government regulations over the past few years have caused organizations and their senior management teams to understand the importance of information security and to allocate increased funding for thee efforts. To be successful and competitive in the long run with changing technologies, regulations, and opportunities, these governance structures must be in place to focus the appropriate management attention on them on a continual basis, beyond simply providing initial funding to achieve compliance.

Corporate Governance

David C. Krehnke

3.1 Introduction

3.1.1 The Need for Governance

Executive management needs to provide the leadership, organizational structures, strategies, and policies to ensure the organization sustains and extends its goals and objectives. Governance is the formal means by which the executive management discharges its responsibilities. Governance is driven by the need to manage risk and protect organization (shareholder or constituents) value. At its core, governance is concerned with two responsibilities: delivering value and mitigating risk. Governance equally applies to governmental, commercial, and educational institutions.

3.1.2 What is Governance?

Governance is leadership, organizational structure, and processes that manage and control the organization's activities to achieve its goals and objectives by adding value while balancing risk with return on investment. At the heart of governance is the concept that running an organization must be a well-organized activity carried out by trained professionals who accept full responsibility and accountability for their actions. The governance framework must be embedded in the organization and applied to all activities and processes such as planning, design, acquisition, development, implementation, and monitoring. The governance framework encompasses the governance environment, governance domains, and governance principles [1].

3.1.3 The Governance Environment

Governance takes place in the organizational environment that is determined by existing conditions and circumstances that include

- Federal and state laws, directives, and guidelines
- Industry regulations and governance practices
- Organization mission and strategies
- Organization risk tolerance
- Organization ethics, culture, and values
- Organization risk tolerance
- Organization mission, vision, and strategic plan
- Organization locations and management approach (centralized or decentralized)
- Organization policies, standards, processes, and procedures
- Organization roles and responsibilities
- Organization plans and reporting
- Organization monitoring for compliance [2]

3.1.4 The Governance Domains

The domains in the governance framework [3] are

- Strategic planning and alignment—the forethought and capabilities necessary to deliver organizational value
- Value delivery—generating the benefits promised on time and within budget
- Risk management—a continuous process that starts with identification of risk (threats and vulnerabilities) and their impact on assets, mitigation of the risk by countermeasures, and the formal acceptance of the residual risk by management
- Resource management—deploying the right capabilities (people, facilities, hardware, software, etc.) to satisfy organizational needs
- Performance measurement—providing feedback the organization needs to stay on track or take timely corrective measures

3.1.5 The Principles of Governance

The principles of governance [4] are

- Clear expectations
    - Clear values
    - Explicit policies and standards
    - Strong communication
    - Clear strategy
- Responsible and clear handling of operations
    - Competent organizational structure
    - Clearly defined roles and responsibilities
    - Orderly processes and procedures
    - Effective use of technology
    - Responsible asset management
- Proactive change management
- Timely and accurate disclosures
- Independent review and continuous improvement

3.2 It Governance

3.2.1 The Need for IT Governance

The pervasive use of information technology (IT) in today's organizations has created a critical dependency on IT that, in turns, calls for a specific focus on IT governance. Elevating IT from a pure managing level to the governance level is recognition of IT's pervasive influence on all aspects of an organization [5]. According to a recent global survey, chief information officers (CIOs) recognize the need for IT governance [6]. When properly implemented, IT governance can generate IT-related economies of scale and leverage synergies and standards throughout the organization. IT governance is mainly concerned with two responsibilities: delivering IT-related value and mitigating IT-related risks.

3.2.2 IT Governance Is Not IT Management

IT management is focused on IT services and products and the management of IT operations. IT governance is much broader and concentrates on what IT must do to meet the present and future demands of the business and its customers. IT governance is an integral part of organizational governance.

3.2.3 There Is No One-Size-Fits-All Approach for Employing IT Governance

IT governance can be deployed using a variety of structures, processes, and relational mechanisms. Designing IT governance for an organization is contingent on internal and external factors that are often conflicting, and what works for one organization may not work for another. Different organizations may need a different combination of structures, processes, and relational mechanisms.

3.2.4 Key IT Governance Domains, Structures, Processes, and Mechanisms

Key IT governance domains [7], structures, processes, and mechanisms include

- IT Strategic Planning and Alignment
  - *IT organization and reporting structure*. Effective IT governance is determined by the way the IT function is organized and where the decision-making authority is located within the organization. The dominant model is centralized infrastructure control and decentralized application control. This model achieves efficiency and standardization for the infrastructure and the effectiveness and flexibility for the development of applications.
  - *Roles and responsibilities*. Clear and unambiguous roles and responsibilities are a prerequisite for an effective IT governance framework. Roles and responsibilities must be effectively communicated and understood throughout the entire organization.
  - *IT Strategy Committee*. The IT Strategy Committee operates at the executive management level to align IT strategies with organizational strategies and objectives and set investment priorities to ensure IT investments align with business goals and objectives.
  - *IT Steering Committee*. The IT Steering Committee operates at the senior management level to determine the applications required to support organization initiatives, facilitate the determination of application criticality, allocate resources, and manage priorities and costs. The Steering Committee is charged with documenting high level issues and current priorities as well as how proposed investments in IT will serve business goals and objectives. Finally, the Steering Committee tracks projects and monitors the success and value added by the major IT initiatives.
  - *IT architecture review board*. The IT Architecture Review Board develops the high level IT architecture, maintains a close watch on new technologies, identifies key trends and issues, standardizes on the technology to be implement across the organization. Hardware and

software solutions should be limited to what is actually required to simplify installation, maintenance, and the help desk function. The IT Architecture Review Board tests and approves IT products for use within the infrastructure, determines a system development methodology (SDM) to manage the system life cycle, and monitors the implementation of standards and technology throughout the organization.
    - *Network connectivity review board*. The Network Connectivity Review Board manages all network connectivity to limit solutions and facilitate standardization.
    - *Information custodians*. Information custodians capture, process, and protect corporate information that includes the proper classification, handling, storage, retention, and destruction.

- IT Value Delivery
    - *Network operations*. Network operations designs, develops, integrates, documents, and manages information networks. Network operations establishes de-militarized zones (DMZs) and enclaves for sensitive and critical application systems. It also implements firewalls and other controlled interfaces, logical network access controls, network intrusion detection and prevention systems, and responsive patch management. Network operations blocks malicious code at the perimeter, and it develops network infrastructure recovery plans and network operations workgroup recovery plans.
    - *Computer operations*. Computer operations harden mainframes and servers and implement logical computer access controls, mainframe, and server intrusion detection/-prevention systems, end point security systems including personal firewalls, virus protection, screen savers, encryption, etc. Computer operations implement responsive patch management and a malicious code-free infrastructure on all platforms. Computer operations also develop mainframe and server recovery plans and workgroup recovery plans.
    - *Computer center management*. Computer center management implements physical access controls and environment protection mechanisms; develops emergency response plans, facility disaster recovery plans, and business continuity plans; and coordinates the development of computer center workgroup recovery plans. Computer center management implements a help desk function and production control systems for scheduling jobs and system backups.
    - *Application development*. Application development designs, develops, and documents application systems; tests application systems and implements backups; develops security plans and security test and evaluation plans; conducts risk assessments; develops application disaster recovery plans; and participates in the development of workgroup recovery plans.

- IT Risk Management
    - *IT risk management areas*. The need to evaluate the effectiveness of internal controls and to demonstrate sound value to customers and stake holders are the main drivers for increased emphasis on risk management. Risk assessments are conducted on main computer sites, the network infrastructure, and application systems.
    - *IT risk assessment methodology*. The risk assessment methodology is standardized and personnel are trained. The methodology identifies information assets, threats, potential vulnerabilities, and implemented or planned controls. The planned and implemented controls are analyzed against requirements and against the threats and potential vulnerabilities to determine the likelihood of occurrence of a given threat scenario and the impact on the assets of the organization. The likelihood of occurrence and the impact determine the level of risk. Next, possible additional controls and countermeasures are identified to further mitigate risk, and a cost benefit analysis can be conducted to determine the most cost effective of the additional controls. At this point,

    recommendations are presented to management who must decide among funding the recommendations, accepting the residual risk, or transferring the risk to another organization.

- IT Resource Management
    - *IT asset management*. The corporate asset inventory management program can be applied to IT assets. IT products that are not on the approved architecture list are phased out.
    - *IT capital budget*. The corporate capital budgeting process can be applied to manage IT capital assets.
    - *IT operating budget*. The corporate operating budgeting process can be applied to manage IT operations.
    - *IT resource allocation and planning*. The corporate resource allocation and planning process can be applied to IT resources to establish and deploy the right IT capabilities for business needs; i.e., judiciously introducing new technology and replacing obsolete systems.
    - *IT project tracking*. The corporate project tracking process can be applied to manage IT projects.
    - *IT contract management*. The corporate procurement and contract management process can be applied to IT contracts. IT hardware and software should be procured from approved vendors using corporate standard procurement contracts. Standard Service Level Agreements (SLAs) should be negotiated for all IT service contracts.
- *IT Performance Management*. Without establishing and monitoring performance measures, it is unlikely that previous domains will achieve their desired outcomes. The performance measurement domain closes the loop by providing timely feedback to keep the IT governance initiative on track [8].
    - Examples of regulatory compliance in the United States include
        - Paperwork Reduction Act—minimizes the burden from the collection of information by or for the federal government
        - Information Technology Management Reform Act (Clinger-Cohen)—exercises capital planning; improves acquisition, use, and disposal of technology; and provides guidelines for computer systems
        - Computer Fraud and Abuse Act—protects information in financial institutions and United States' government departments or agencies or information involved in interstate or foreign communications from access without authorization or exceeding authorized access
    - Policies—System development methodology, business continuity management, emergency response, and disaster recovery
    - Standards—Examples of IT standards include
        - CobiT, ITIL, SAS70
        - ITIL—Collection of best practices
        - Capability Maturity Model (CMM) for Software
        - Systems Engineering CMM
        - Integrated Product Development CMM
        - CMM Integration—Best practices for improving process
        - COSO—Internal control framework
        - BS 1500—Standard for IT service management
        - ISO 12207—Software lifecycle processes
        - ISO 15504—Standard on software process assessment
        - ISO 9000 and 9001—Quality management
        - ISO 13569—Banking and related services
        - TickIT—Software quality management certification

- Processes and procedures—System development methodology, business continuity management, backups, emergency response, and disaster recovery
- Quality assurance—Design reviews, code analysis, peer and independent code reviews, static code checkers, stress testing, application vulnerability testing, and runtime testing
- Metrics—Examples of IT metrics include
    - IT costs by category and by activity
    - Server and workstation costs
    - IT costs as a percentage of total operating costs
    - IT staff numbers by activity
    - Full-time versus contract staff
    - Outsourcing ratio
    - Number and cost of IT operation risk incidents [9]
    - Results of internal audits
    - Attainment of expense targets and unit cost targets such as lines of code
    - Business unit survey ratings
    - Staff turnover
    - Satisfaction survey scores
    - Implementation of lessons learned [10]

3.3 Information Security Governance

3.3.1 The Need for Information Security Governance

Computing in today's organizations is no longer conducted on a mainframe with hard wired terminals all housed in a secure data center environment with a well-defined physical and logical perimeter. Computing is now performed by servers, workstations, laptops, notebooks, personal digital assistants (PDA), BlackBerry devices, cell phones, cameras, watches, etc. from where ever an organization's employees, contractors, and business partners happen to be at the time. Employees, contractors, vendors, and business partners connect to the Intranet via the Internet, leased lines, dialup lines, and airwaves. Large amounts of data can be carried out of facilities in their pockets or transmitted out via instant messaging, email, and cell phones.

An organization's critical dependence on the confidentiality, integrity, and availability of its information calls for a specific focus on information security governance. Organizations need an information security architecture that enforces the infrastructure's secure state at every location and end point by enforcing policies for each information resource (device) and user. When properly implemented, information security governance can hone that architecture and generate economies of scale and leverage synergies and standards throughout the organization. Information security governance is mainly concerned with two responsibilities: delivering information security-related value and mitigating information security-related risks.

3.3.2 There Is No One-Size-Fits-All Approach for Employing Information Security Governance

Information security governance can be deployed using a variety of structures, processes, and relational mechanisms. Designing information security governance for an organization is contingent on internal and external factors that are often conflicting, and what works for one organization may not work for another. Different organizations may need a different combination of structures, processes, and relational mechanisms.

3.3.3 Key Information Security Governance Domains, Structures, Processes, and Mechanisms

Key information security governance domains, structures, processes, and mechanisms include

- Information Security Strategic Planning and Alignment
  - *Information security organization and reporting structure*. Effective information security governance is determined by the way the information security function is organized and where the decision-making authority is located within the organization. The information security function should not be reported to IT; rather, it should be reported at the same level or at a higher level in the organization.
  - *Roles and responsibilities*. Clear and unambiguous roles and responsibilities are a prerequisite for an effective information security governance framework. Roles should include information security officers, privacy officer, information custodians, executive sponsors for infrastructure components and application systems, certifier, and accreditor. Information security responsibilities should be documented in the job descriptions of employees at all levels. Roles and responsibilities should be effectively communicated and understood throughout the entire organization.
  - *IT architecture review board*. The information security organization should be a member of the IT Architecture Review Board to ensure new technologies can be securely implemented across the organization. The information security organization should participate in the security testing and approval of IT products for use within the infrastructure.
  - *Network connectivity review board*. The information security organization should be a member of or chair the Network Connectivity Review Board to ensure network connectivity is managed in a secure manner to limit the holes opened through the perimeter.
- Information Security Value Delivery
  - *Policy and process*. Information security policies and processes are developed for information privacy protection, sensitivity determination, criticality determination, information retention and archiving, archive protection, release of information to the public, and destruction. Information security documentation deliverables and check points are incorporated in the appropriate phases of the system's development life cycle. Policies and processes are also developed for authorization, identification, and authentication systems for controlling access.
  - *Standards*. Standards are developed for hardening servers and placing sensitive and critical applications in enclaves as well as the prevention, detection, containment, and cleanup from penetrations and malicious code including viruses, worms, bots, etc.
  - *Certification and accreditation*. Certification and accreditation processes are developed for infrastructure components and application systems. The certification and accreditation function coordinates the completion of a Business Impact Assessment (BIA) on infrastructure components or application systems to determine the information's sensitivity and criticality and the information security requirements required to protect the information based on that sensitivity and criticality level. The certification and accreditation function consults with the developing organization on information security requirements and possible controls that will satisfy those requirements and reviews risk assessments, security plans, security test and evaluation plans, business continuity plans, and disaster recovery plans. The certification and accreditation function certifies and accredits infrastructure components and application systems prior to production and ensures management accepts the residual risk associated with putting the infrastructure component or application system into production.

  - *Job descriptions and performance appraisals.* Information security responsibilities are included in job descriptions and in performance appraisals.
  - *Computer Incident and Response Team (CIRT).* The CIRT implements a standard information security incident response and reporting process.
  - *Public Key Infrastructure (PKI).* The PKI facilitates secure electronic data storage and exchange. Security is achieved by using public key cryptography. The types of security services provided by a PKI are
    - Confidentiality—transformation of data into a form unreadable by anyone without the proper key
    - Data integrity—addresses the unauthorized alteration of data by confirming its integrity or warning about changes
    - Authentication—proves users of information resources are who they claim to be
    - Non-repudiation—limits denial of previous commitments or actions
  - *Compliance.* The compliance function ensures information policies, processes, and standards are being followed throughout the organization, including the acceptable use of computing resources by users. The compliance function conducts site security reviews and penetration testing for compliance with information security requirements; reviews of firewall rules, developers, system administrators, and users for least privilege; monitors information resources, email, and Internet usage for acceptable use; establishes benchmarks; develops metrics to measure value, performance effectiveness, and organizational comparability; and implements a dashboard summary for ongoing top management program review.

- *Information Security Risk Management.* Site, infrastructure, and application system risk assessments should be reviewed to ensure that threats and vulnerabilities have been identified, the recommended controls implemented, and management has accepted the residual risk or transferred the risk to another organization.
- Information Security Resource Management
  - *Information security asset management.* The corporate asset inventory management program can be applied to information security assets. Plans should be developed to phase out information security products that are not on the approved architecture list.
  - *Information security capital budget.* The corporate capital budgeting process can be applied to manage information security capital assets.
  - *Information security operating budget.* The corporate operating budgeting process can be applied to manage information security operations. Best practices include clear budget ownership, control of actual spending, cost justification, and awareness of total cost of ownership.
  - *IT resource allocation and planning.* The corporate resource allocation and planning process can be applied to information security resources.
  - *Information security contract management.* The corporate procurement and contract management process can be applied to information security contracts. Information security hardware and software should be procured from approved vendors using corporate standard procurement contracts. Standard SLAs should be negotiated for all information security service contracts.

- Information Security Performance Management
  - Examples of regulatory compliance in the United States include
    - Privacy Act—protects the privacy of government employees and their contractors
    - Electronic Freedom of Information Act—provides visibility into government processes by allowing the public to request information

    - Government Paperwork Elimination Act—encourages the electronic submittal of information to federal agencies and the use of electronic signatures
    - Health Insurance Portability and Accountability Act (HIPAA)—protects patient identities and sensitive health and treatment information
    - Gramm-Leach-Bliley Act (GLBA)—protects financial information from unauthorized access
    - Children's Online Privacy Protection Act (COPPA)—protects children's personal identifiable information
    - Sarbanes-Oxley Act (SOX)—ensures the integrity of IT financial systems of publicly traded companies
    - Federal Information Security Management Act (FISMA)—provides a comprehensive framework for ensuring the effectiveness of information security controls in federal agencies
    - United States Patriot Act Customer Identification Program—requires that financial services firms operating in the United States obtain, verify, and record information that identifies each individual or entity opening an account
- Standards—Examples of information security standards include
    - ISO/IEC 27001:2005—Standard for Information Security Management Systems (ISMS) and the Foundation for Third-Party Audit and Certification
    - ISO/IEC TR 13335—Guideline for Management of IT Security
    - ISO/IEC 15408—Common Criteria for IT Security Product Evaluations
    - ISO 13569—Banking and Related Services: Information Security Guidelines
    - ISO 7816—Smart Card Standard
    - ISO 9001—Balanced Scorecard for Quality Assurance
    - NIST Special Publication 800-12—An Introduction to Computer Security: The NIST Handbook
    - NIST Special Publication 800-14—Generally Accepted Principles and Practices for Securing Information Technology Systems
    - NIST Special Publication 800-33—Guidelines for Security Certification and Accreditation of Federal Information Technology Systems
    - FIPS Pub 113—Computer Data Authentication
    - FIPS Pub 197—Advanced Encryption Standard
    - FIPS Pub 200—Minimum Security Requirements for Federal Information and Information Systems
    - IT Baseline Protection Manual—Standard Security Safeguards for Typical IT Systems
- Policies—Physical security, information security, privacy, personnel security, hardware security, software security, network security, wireless security, business continuity management, and incident handling
- Processes and procedures—Certification and accreditation, risk assessment, intrusion detection, penetration testing, emergency response, application disaster recovery, backups, facility disaster recovery, and incident response and reporting
- Quality assurance—security design review, security code review, and separate testing and production environments
- Metrics—Information security metrics include
    - Monthly CIRT operation hours by category, i.e., Web usage and data content review, incident response, spam, abuse, log review, and vulnerability reconnaissance
    - Monthly desktop intrusion prevention system blocked events by event category. The categories include spyware, network scans/probes, Web-related events, and virus and worm events.

- Monthly server intrusion prevention system blocked events by event category. The categories include spyware, network scans and probes, Web-related events, and virus and worm events.
- Monthly devices with desktop protection and server sensors report. This report reflects the percent of workstations and servers that are protected and delta showing those that are not protected.
- Monthly security vulnerability assessment (SVA) status report reflects the number of SVAs completed, in progress, and planned.
- Monthly certification and accreditation status report. This report reflects the number of certification and accreditation completed, in progress, and planned.

3.3.4 Costs of Poor Corporate, IT, and Information Security Governance

Costs of poor corporate, IT, and information security governance not reflected in profit and loss (P&L) statements include

- Fines for regulatory non-compliance
- Wasted resources because of duplicate projects, tasks, or code
- Lack of project prioritization, resulting in missed due dates
- Lack of standardized products, resulting in increase time to correct problems
- Lack of standardized processes and procedures, resulting in confusion and loss of momentum
- Lack of clear direction and objectives, resulting in lackluster leadership
- Lack of a defined SDM, resulting in haphazard applications development and poor documentation
- Lack of organization determined application criticality resulting in the unavailability of the most critical applications
- Disclosure of sensitive information, including personal identifiable information
- Improper use of information resources
- Barrage of information security threats, including intrusions, denial-of-service attacks, malicious code (e.g., viruses, Trojans, and worms) spyware, key-loggers, bots, phishing, content spoofing, spam, and related forms of electronic pestilence [11].

IT Governance Institute (ITGI) Overview

Mollie E. Krehnke

4.1 IT Governance Institute Purpose

Federal regulations, business competition, complex information and communication technologies, and expanded worldwide connectivity increase the risks associated with doing business. The IT Governance Institute (ITGI) was established to

- Raise awareness and understanding of enterprise business and technology risks
- Provide guidance and tools to those responsible for information technology (IT) at all levels
- Enable those professionals to conduct their responsibilities in such a manner that IT meets and exceeds internal (business) and external (federal) requirements
- Empower those professionals in the mitigation of their business process-related risks through the provision of pertinent publications based on extensive, focused, applied (as opposed to basic) research [1].

4.2 ITGI's Humble Beginnings

The ITGI was established by the Information Systems Audit and Control Association (ISACA) in 1976 as the Information Systems Audit and Control Foundation [2]. ISACA was formed in 1967 and incorporated in 1969 as the Electronic Data Processing (EDP) Auditors Association by a group of professionals who audited controls in the computer systems in their respective companies. In 2003, the ITGI was established to undertake large-scale research efforts to expand the knowledge and value of the IT governance and control field.

The new name reflects the expanded role of IT in the support of business enterprises—the enablement and transformation—of enterprise growth and (even) survival, and further embraces the many disciplines that are responsible for IT governance within the business enterprises such as audit, assurance, information security, control, and privacy.

4.3 ITGI Operations and Funding

ITGI accomplishes its objective as a 501(c)3 not-for-profit and vendor-neutral organization. Volunteers use their personal time to create, review, and publish the deliverables that are made available under the ITGI cognizance. No Information ISACA member dues are used to support the activities of ITGI. Personal and corporate contributions can be made to ITGI to offset the institute costs, and gifts of over U.S. $25 will be acknowledged as a contributor in the ISACA/ITGI annual report [3]. The various opportunities for contributions (affiliates, sponsors, and donors) are described on the ITGI web site.

4.4 ITGI Research Focus and Associated Deliverables

The research conducted by ITGI "contributes to a new level of excellence in practices worldwide, [by] evaluating and analyzing emerging guidelines for implementation and controls of new technologies and applications, capitalizing on technological advances to help enterprises achieve competitive advantage, bringing a global perspective to the critical issues facing senior management and providing practitioners a specialized viewpoint" [4].

The ITGI "strives to assist enterprise leadership in ensuring long-term, sustainable enterprise success and increased stakeholder value by expanding awareness of the need for and benefits of effective IT governance. The institute develops and advances understanding of the vital link between IT and enterprise governance, and offers best practice guidance on the management of IT-related risks" [5].

By conducting original research on IT governance and related topics, ITGI helps enterprise leaders understand the relationship of IT to business objectives and have the tools to ensure effective governance over IT within their enterprises. The resource center on the ITGI website includes articles, white papers, slide presentations, survey results, links, and other resources. Many publications are available in downloadable form, and hard copies are available from the ISACA bookstore. The major categories for the ITGI research are

- Security control and assurance
- Accounting, finance, and economics
- Business, management, and governance
- Contingency planning and disaster recovery
- Information technology
- Risk management [6].

ISACA members are granted a discount on the publications (generally $10–$100 per item) that, over time, can result in a substantial savings to an individual or to an organization. Academic and bulk discounts are also available to those who qualify. ISACA journals have a section in the back entitled *The ISACA Bookstore* that list new products and a description of those products and a bookstore price list for several hundred deliverables. The website provides a complete description for all deliverables at www.isaca.org/bookstore.

The content and scope of ITGI deliverables is continually expanding, and past research is enhanced to reflect new regulations, technologies, and changed business processes. An example of this would be CobiT 4.0, the newest Control Objectives for Information and related Technology (CobiT®). (Trademark registered by ISACA.) This version “emphasizes regulatory compliance, helps organizations to increase the value attained from IT, [and] enables and simplifies implementation of the CobiT Framework” [7].

4.5 Using ITGI Products to Guide and Support Initiatives

The number of ITGI products continues to expand, and the focus of many research deliverables is international in scope (and in language, including Japanese, German, and French). For example, a deliverable from the *CobiT Mapping* research project is *CobiT Mapping: Overview of International IT Guidance* that focuses on the business drivers for implementing international IT guidance documents and the risks of noncompliance. Another available resource is *A Guide to Cross-Border Privacy Impact Assessment* that addresses principles and questions associated with the collection, use, and disclosure of personally identifiable information that may be subject to regulation. The ITGI landmark study in 2003 and follow up survey in 2005 present IT governance perceptions and activities worldwide, as noted by senior IT executives and enterprise executives, entitled the *IT Governance Global Status Report*.

The best way to learn what is available is to routinely visit the ITGI and ISACA web sites. However, some product reviews are listed below to present a more detailed sampling of the offerings. ITGI makes excerpts available for review, so the reader can make a determination as to the usefulness of a product before purchasing it.

Members of the ISACA can read the book reviews in the *Information Systems Control Journal* to see if a particular product would be beneficial to their work. Examples of reviews of ITGI products are summarized below.

4.5.1 Information Security Governance

The Information Security Governance: *Guidance for Boards of Directors and Executive Management* document presents a big punch in a small package. The document defines management-level actions which ensure information security addresses the IT structure and the needs of the business and presents questions for directors and for management, best practices, and critical success factors to facilitate the deployment of the desired actions. The document also provides an information security governance maturity model that can be used to define an organization’s security ranking. The ranking can then be used as the focal point for determining future strategies for improvement of the security of the organization [8].

4.5.2 International Information Governance Practices

Strategies for IT Governance is a collection of research articles on IT governance written by academics and practitioners from different countries with a message of IT governance as a business imperative and a top management priority. The book presents case studies that show how IT governance can work in practice [9]. In addition, *CobiT* is considered to be a valuable resource in many countries as an organizational standard or guideline for multiple topics, including IT management, IT governance, and auditing. This is well presented in the text and figures in the article, “The Value to IT of Using International Standards,” by Ernst Jan Oud [10]. The article also discusses the value associated with the implementation of a de facto standard, or set of best practices, rather than developing standards from scratch; although, the need for customizing the practices to meet company objectives is strongly emphasized.

4.5.3 Network Security for Business Processes Governed by Federal Regulations

Network Security: *The Complete Reference* presents a broad spectrum of security topics, including return on security investment; security strategy and risk analysis; security policy development and security organizations; access control and physical security; biometrics; e-mail; network architecture; firewalls and Intrusion Detection Systems (IDSs); Virtual Private Network (VPNs); wireless security; disaster recovery; Windows, Linux, UNIX, and Novell; application and database security; and incident response. The book will be useful to security professionals, IT administrators, and software developers who are writing secure code for the J2EE and .NET platforms [11].

4.5.4 Secure Outsourcing of IT Functions

Outsourcing Information Security by C. Warren Axelrod is a risk-based approach to outsourcing according to the reviewer, Sarathy Emani, an IT professional with international experience. The book "explains the issues one needs to identify, quantify and analyze to make the right outsourcing decisions without sacrificing security." Topics included in the book are the history of IT outsourcing, internal and external security risks associated with outsourcing, motivations and justifications behind outsourcing, objectives of outsourcing, tangible and intangible costs and benefits, the outsourcing evaluation and decision process, and candidate security services for outsourcing. The book will be useful to managers, information security, and IT senior management professionals who are directly involved in outsourcing or business partner relationships [12].

4.5.5 Business Impacts for an Unavailable e-Commerce Service

The e-Commerce Security series, particularly *e-Commerce Security—Business Continuity Planning*, provides guidance to businesses and organizations in the creation of a plan to reduce the risk associated with such an event and to recover more quickly if resources are unavailable. The book addresses

- Business continuity planning and evaluation
- Business assessment
- Strategy selection
- Plan development
- Testing and maintenance

According to Linda Kinczkowski, it will be useful to business managers, security and audit professionals, and educators and students who have to address business continuity and disaster planning. The book also presents precautions and procedures that apply specifically to the e-commerce business component [13].

4.5.6 Financial Audit Processes

Auditing: A Risk Analysis Approach, 5th Edition, "offers an in-depth framework that addresses the relationships among audit evidence, materiality, audit risk and their concrete applications." In addition, the book provides resources that would be useful for anyone studying for the Certified Public Accountant (CPA) and Certified Internal Auditor (CIA) exams based on the review questions and essays provided at the end of each chapter and the computer audit practice case. Students, accountants, Chief Financial Officers (CFOs), CPAs, IT auditors, and faculty members teaching financial audit will find this to be a useful resource [14].

4.5.7 Internal Audit Processes

Managing the Audit Function: *A Corporate Audit Department Procedures Guide*, 3rd Edition, is very comprehensive, addressing all aspects of the internal auditing function. The procedural format provides a resource that could be used as a starting point for many organizations and includes audit plans, work papers, and descriptions of the roles and responsibilities for the audit team. The third edition, with its expanded focus on internal auditing, is applicable for internal audit managers and management for large and small businesses. The book also includes a discussion of other factors that impact corporate business processes, including the United States' Sarbanes–Oxley Act of 2002 and the Foreign Corrupt Practices Act. The reviewers felt that this book is an essential resource for every audit department [15].

4.5.8 Risk-Based Auditing Processes

Auditor's Risk Management Guide—Integrating Auditing and Enterprise Resource Management (ERM) is a guide for conducting a risk management-based auditing methodology and provides case studies that utilize the concepts presented. Topics include an overview of ERM; control-based, process-based, risk-based, and risk management-based auditing approaches; an integration of strategy into risk management-based auditing; and risk assessment quantification techniques. The book also includes a CD-ROM containing electronic versions of work programs, checklists, and other tools. The reviewer felt that this book is "outstanding in the way it is organized and the extent of details it covers and the presentation from generalities to specifics aids the reader in understanding the concepts being presented" [16].

4.5.9 Oracle Database Security, Privacy, and Auditing Requirements

Oracle Security Privacy Auditing addresses HIPAA technical requirements but is also "an excellent primer on Oracle database security, describing what is arguably best practice, which is why it is assessed as valuable even to a reader who is not specifically concerned with Health Insurance Portability and Accountability Act (HIPAA)." The authors are distinguished Oracle professionals, and the presentation enables the reader to skim through the text and read only the portions that are pertinent for a particular concern. However, the book is addressed to database administrators, architects, system developers, and designers, and the reader must be familiar with basic Oracle database concepts and Structured Query Language (SQL) [17].

4.5.10 IT Audit Tools for New Auditors

CobiT 4.0 is considered to be a vital tool for IT auditors, particularly in the "strong linkages to business objectives and goals to provide the drivers and rationale for the IT supporting process." The text, illustrations, and diagrams have been updated from earlier editions, and these changes have greatly enhanced the usability of the document, and the appendices provide additional IT governance processes and references [18] In an article by Tommie Singleton, "CobiT is the most effective auditing tool available today, which can be applied to a variety of IT audit-related functions." In support of this perspective, numerous process models (such as Committe of Sponsoring Organization [of the treadway Commission] (COSO), Information Technology Infrastructure Library (ITIL), British Standard 1500 (BS 1500), and Capability Maturity Model (CMM)) have been mapped to CobiT, at least in part because of the guidance it provides in assessing IT controls [19].

4.6 ITGI: A Leader and a Resource

The perspectives and actions of IT professionals, information security professionals, and auditors will impact the IT stance of an organization and the ability of IT to securely and consistently meet and exceed the objectives of an enterprise in a global community. ITGI has become a strategic force and a leading reference on IT-enabled business systems governance for the global business community. A corresponding effort relates to the ISACA perspective regarding the responsibilities of auditors or information security practitioners—those individuals are going to be required to support and become experts in IT governance. As a result, ITGI stands ready and continues in its research endeavors to support corporate enterprise in the utilization and protection of information resources to obtain business objectives. ISACA is prepared to provide resources to empower those individuals who must implement the enterprise objectives in their current (and future) job responsibilities [20].

Top Management Support Essential for Effective Information Security

Kenneth J. Knapp
Thomas E. Marshall

5.1 Introduction

As organizations become more dependent on information technology for survival, information security emerges as one of the most important concerns facing management. The increasing variety of threats and ferociousness of attacks has made protecting an organization's information resource a complex challenge. Improved knowledge of the critical issues underlying information security can help practitioners and researchers to understand and solve the most challenging problems. With this objective, the International Information Systems Security Certification Consortium $(ISC)^2$ teamed up with Auburn University researchers to identify and study the top information security issues in two sequential, but related, surveys. The first survey involved a worldwide sample of 874 certified information system security professionals (CISSPs) who ranked a list of 25 information security issues based on the most critical issues facing organizations today. The survey results produced some interesting findings. The criticality of top management support was demonstrated by the respondents who ranked it 1 of 25 issues. This finding suggests that top management support is the most critical element of an organization's information security program. As one study participant put it, "Management buy-in and increasing the security awareness of employees is key. Technology is great, but without…management's backing, all the bits in the world won't help." Based on the results of opinions, conclusions, and recommendations expressed or implied within are solely those of the authors and do not necessarily represent the views of USAFA, USAF, the DoD or any other government agency. This survey, gaining senior management support is arguably the most critical issue influencing information security effectiveness today.

In a follow-up survey, 740 CISSPs answered questions that tested some of the key relationships among the higher-ranked issues from the first survey. The findings suggest that management can significantly improve organizational security effectiveness by focusing primarily on four crucial areas

- Promoting strong user training programs
- Building a security-friendly culture
- Creating and updating security policies that are relevant to the business
- Adequately enforcing those policies

Although it is important that top management support a security program in its entirety, the survey's results suggest that focusing on these four areas are especially appropriate for senior management and will provide significant returns on security effectiveness. By studying the results of these two surveys, security professionals will gain a greater awareness and a better understanding of some the relationships among the most critical issues in information security.

5.2 Ranking the Top Information Security Issues

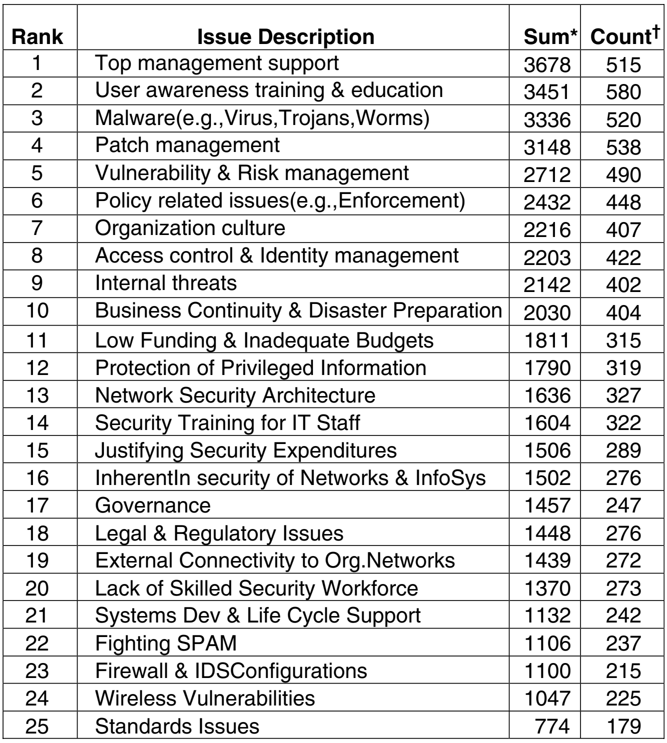
The web-based survey asked respondents to select 10 issues from a randomized list of 25 and rank them from 1 to 10. The 25 issues came from a preliminary study involving 220 CISSPs who responded to an open-ended question, asking for the top information security issues facing organizations today. Working with participants, the 25 most frequently mentioned of the issues for this web survey were identified. The ranking survey ran in 2004 with 874 CISSPs from over 40 nations participating.[1]

Top management support was the top ranked issue, and it received the highest average ranking of those participants who ranked the issue in their top ten. Although ranked 2, user awareness training and education was the most frequently ranked issue. An impressive 66 percent of the 874 survey respondents ranked this issue in their top ten. Exhibit 5.1 provides the complete results.

In this survey, it is noteworthy that many of the higher ranked issues are of a managerial and organizational nature. Managerial issues require management involvement to solve. This message is important because the protection of valuable information requires that security professionals and corporate executives make a commitment to information security. Information security is not only about the technology. Instead, information security programs also require both strong technological and managerial components. Although this should not surprise most information-security professionals, corporate executives may not realize that most critical information security challenges are largely organizational-centric issues. One of the reasons this may be the case is that corporate executives often get their information security news from the mainstream media that tend to publish stories focusing on the cyber side of computer security problems rather than the managerial side. During the 2006 RSA conference in California, the authors had a conversation with a well-placed media relations expert. This person confirmed that one of the bigger challenges the media face is convincing members of the top-tier media to publish more stories covering the managerial aspects of information security. As is often the case, technology issues tend to dominate the media headlines concerning information and computer security. Considering that many executives get their news from the top-tier media, security professionals may have an uphill battle convincing executives that information security is not just about the technology. Instead, information security involves complex organizational issues that demand top management's attention.

To highlight the point that top management support is essential for information security effectiveness, a number of direct quotations from study participants who responded to the open-ended question will be highlighted. The comments provided below articulate the types of issues faced by security professionals in their organizations. These comments will be limited to those directly relating to the highest ranked issue from the survey, top management support. By analyzing these comments, information security professionals can gain practical insight into many of the organizational complexities involving this issue.

[1] A comprehensive report of the study is available, upon request, from the first author.



Rank	Issue Description	Sum*	Count†
1	Top management support	3678	515
2	User awareness training & education	3451	580
3	Malware(e.g.,Virus,Trojans,Worms)	3336	520
4	Patch management	3148	538
5	Vulnerability & Risk management	2712	490
6	Policy related issues(e.g.,Enforcement)	2432	448
7	Organization culture	2216	407
8	Access control & Identity management	2203	422
9	Internal threats	2142	402
10	Business Continuity & Disaster Preparation	2030	404
11	Low Funding & Inadequate Budgets	1811	315
12	Protection of Privileged Information	1790	319
13	Network Security Architecture	1636	327
14	Security Training for IT Staff	1604	322
15	Justifying Security Expenditures	1506	289
16	InherentIn security of Networks & InfoSys	1502	276
17	Governance	1457	247
18	Legal & Regulatory Issues	1448	276
19	External Connectivity to Org.Networks	1439	272
20	Lack of Skilled Security Workforce	1370	273
21	Systems Dev & Life Cycle Support	1132	242
22	Fighting SPAM	1106	237
23	Firewall & IDSConfigurations	1100	215
24	Wireless Vulnerabilities	1047	225
25	Standards Issues	774	179

EXHIBIT 5.1 Issue ranking results (874 respondents). (*Sum is the summation of all the 874 participants ranking on a reverse scale. Example a #1 ranked issue reserved a score of ten, a#2 rankede issue received a score of nine etc.†Count is the number of participants who ranked the issue in their top ten.)

- "Without management support, resources will not be allocated, lower level staff will not believe security is important and policies will not be enforced."
- "Without top management support the information security program will become merely a suggestion. Because information security can often be considered as a nuisance, the suggestions will not be followed."
- "Without executive management support security doesn't receive proper attention, coordination across the business, coordination with business process, appropriate authority for enforcement, or appropriate funding."
- "Without top management support, the information security program and policies are just 'paper' (that is) not enforced."
- "With senior management support policies will receive the proper levels of communication and enforcement. Otherwise adoption of the policies will not be consistent throughout the organization and there would be too much variation from established security."
- "Without top management buy-in, your security program will never get off the ground."
- "Without leadership at the top, the effort is doomed to a dismal failure."
- "Without the complete support of management, a security program is little more than a stick used to beat the more egregious violators of policy. Minor policy violations get ignored, leading to an overall attitude that security is not a concern of each employee."
- "Demonstrated support from top management creates a security-conscious culture and shows everyone security is important."

- "If (management) doesn't support, encourage, and provide resources for a security program, the program won't have the ability to be effective nor well accepted by staff and other employees."
- "The absence of a culture where security is consistently applied and where management lives by example, security will not be effective."
- "Without upper management backing and support a security program will not be successful."
- "Success flows down through the organization. Management can promote security programs with organizational support and budget."
- "Without support and understanding of both management and employee an effective security program is impossible."
- "Senior management support and action is needed for an effective security program and that will be driven by a clear and accurate understanding of the threats, risks and safeguards."

These 15 quotations illustrate the criticality of top management support as well as some of the dependencies that issues such as policy enforcement have on obtaining top management support. In the next section, some of the relationships between top management support and other critical information security issues will be discussed.

5.3 Top Management Support: The Necessary but Insufficient Condition

Top management support is not an isolated information security issue nor is gaining support from senior management an end in itself. Instead, top management support has relationships with other key issues listed in Exhibit 5.1. A number of questions come to mind when thinking about top management support, mainly, what specifically should top management focus on to improve organizational security effectiveness? To answer this question, the list of top issues as well as the comments from the study participants are reviewed. A diagram (i.e., model) that illustrates the conceptual relationships among the major issues that had dominant managerial dimensions was created. The model allows for the argument that although necessary for information security effectiveness, top management support alone is insufficient. Specifically, this model suggests that four key issues mediate the relationship between top management support and

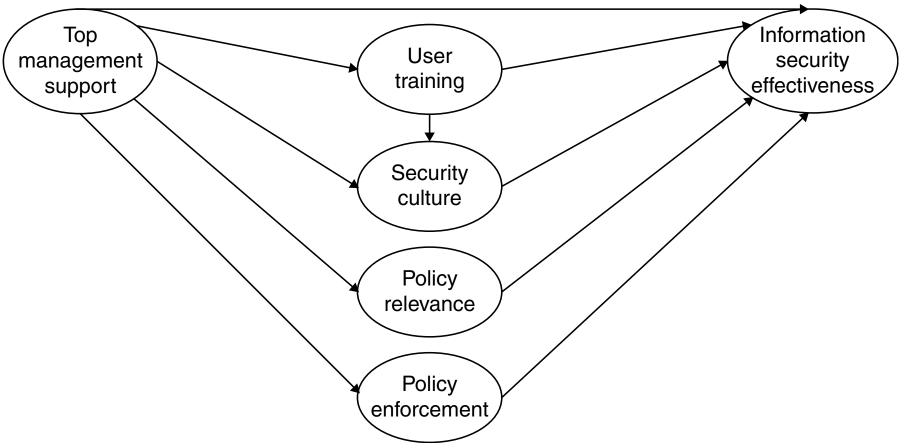


EXHIBIT 5.2 Conceptual relationship of top management support to other key issues. AMOS 5.0 structural equation modeling software. Adjusted chi-square = 2.27; GFI = .92; CFI = .97; RMSEA = .041. All paths significant at least at the .05 level. Alphas > .87.

security effectiveness: user training, security culture, policy relevance, and policy enforcement. After the model was created, an 80-question survey was developed that would statistically test the model.

In March 2005, 740 CISSPs completed the survey with results providing strong support for the model. Related survey questions were grouped into logical categories, and the model was then tested with statistical software. Exhibit 5.2 illustrates the model as a set of conceptual relationships. All relationships (represented by arrows) between the issues are statistically significant.

The model in Exhibit 5.2 is intended to encourage security professionals to think about the significant relationships among the critical issues impacting information security effectiveness. Understanding these key relationships can help better frame the issues. This is important because gaining top management support by will not solve organizational problems. Instead, top management must act through mediators in order to accomplish objectives. Certainly, other critical issues exist that top management can influence besides the four issues illustrated down the middle in Exhibit 5.2. Yet, these four mediating issues are especially appropriate for management to focus on in order to improve information security effectiveness.

At this point, each of the six constructs identified as critical by the study participants and displayed in Exhibit 5.2 will be discussed.

5.3.1 Top Management Support

Top management support refers to the degree that senior management understands the importance of the security function and the extent that management is perceived to support security goals and priorities. By virtue of their position, top management can significantly influence resource allocation and act as a champion of change in creating an organizational environment conducive to security goals. Support from top management has been recognized for at least four decades as necessary for effective computer security management. For example, Joseph Wasserman discussed the importance of executive support in a 1969 *Harvard Business Review* article stating, “Computer security thus involves a review of every possible source of control breakdown…one factor that has made the job more difficult is lack of awareness by many executives of new control concepts required for computer systems.” Although recognized as early as the 1960s as being critical, it is still difficult to get many executives to understand information security concepts. Four specific areas that are especially appropriate for senior management to focus on in support of their security programs are now addressed.

5.3.1.1 User Training

Training is a mechanism of organizational influence that serves to indoctrinate members to internalize important knowledge and skills so that workers make decisions consistent with organizational objectives. The goal of a security training and awareness program is to heighten the importance of information security as well as to make workers aware of the possible negative consequences of a security breach or failure. Awareness alerts employees to the issues of IT security and prepares them to receive the basic concepts of information security through a formal training program. Security awareness helps reinforce important security practices through initial as well as cyclical and ongoing training events. Consequently, training and awareness programs can also positively influence the culture of an organization so that workers have a favorable mindset about security practices in general. This is critical because many security incidents are the result of employees’ lack of awareness of cyber threats as well as the organizational policies and procedures aimed to minimize such threats.

The study participants emphasized the criticality of security training by ranking user awareness training and education as the second most critical of 25 issues (see Exhibit 5.1). One participant stated, “Training and end user awareness allows for dissemination of information…about best practices, methods for doing things, as well as raising awareness among the end user population about potential threats.” Another participant said, “Awareness training will do more for security effectiveness than any new firewall or instruction protection system.” Based on the study participants’ suggestions and comments, four key actions for management in support of training goals are offered. First, if one does not exist, management must champion a robust organizational security training program and support it with adequate resources. Second, management can provide leadership by example through attendance and completion of all one-time and cyclical training events as required by the program. Third, management should comply with organizational security policies and practice good security principles in their daily activities. Fourth, management can talk about the importance of security both formally and informally in the organization. By doing these things, management will be perceived by employees as supportive of not only security training but also the overall the security program.

5.3.1.2 Security Culture

Organizational culture is the set of beliefs, values, understandings, and norms shared by members of an organization. Culture is the unseen and directly unobservable influence behind the organizational activities that can be seen and observed. Some academics argue that the only thing of real importance that leaders can do is to create and manage a positive organizational culture. The security culture of an organization can be viewed as the shared beliefs and attitudes workers have toward security goals and practices. If most employees tend to resist and circumvent policies, for example, the security culture is poor. However, if most workers embrace security policies and view them as an integral part of their job, then the security culture is constructive. Culture can be influenced by the organization's training and awareness program. A strong training program will help build a culture favorable to security-minded thinking among employees.

The study participants ranked organizational culture as the seventh most critical of the 25 issues. One study participant articulated the overall importance of culture by stating, "Without a corporate culture solidly based on security, all the policies and procedures on the planet will not be effective at maintaining (security)." Another said, "The executive drives the company culture and the resources allocated. This is the primary factor, followed by the technical expertise of the people implementing security technologies." Management can help build either a security friendly or security resistant culture through its example. If management practices good security, employees will follow the lead. If managers practice poor security, employees will tend to do the same.

5.3.1.3 Policy Relevance

A policy is a general rule that has been laid down in an organization to limit the discretion of workers with top management typically promulgating the more important policies. In regards to security, policy defines an organization's high-level security philosophy and is the precondition to establishing effective security deterrents. Deterrents are important because they can ward off potential abusive acts by employees primarily through the fear of sanctions and unpleasant consequences. Security policies should be relevant and support the organization's business goals and objectives. One way to maintain relevant security policies is to establish a regular policy review process. Once established, the content of policy should be periodically reviewed to ensure it reflects current legal mandates (e.g., Sarbanes–Oxley Act of 2002), professional standards (e.g., ISO/IEC 17799 2005), and threats (e.g., risks associated with small storage devices).

Study participants ranked policy-related issues as the sixth most critical of the 25 issues. One participant stressed the value of conducting a risk assessment prior to developing and maintaining policy, "Part of consensus building is defining what a policy will cover that is actually pertinent to the organization as opposed to implementing security for security's sake. Just because it may be a best practice and good security to implement certain controls does not mean it is meaningful to a given organization. Consequently, risk analysis and vulnerability assessment must precede policy development." Another said, "Buy-in must be secured both from upper-management and the employees to ensure that policies are relevant, enforced, and properly updated with an eye on the needs of the organization as a whole." Many participants discussed the importance of regular (e.g., at least annual) review and updates of approved policies in order to maintain their relevance to current laws, professional standards, business objectives, and security threats. To encourage the relevance of security policies, top management must insist that approved policies are regularly reviewed to ensure continuous support of the needs of the business.

5.3.1.4 Policy Enforcement

Once management approves a set of relevant policies, they should be enforced. The phrase *to enforce* means to compel observance of or obedience for a policy. One way of enforcing policies is to administer monetary penalties to employees who violate policy. Management should consider dismissing employees who repeatedly violate policy. Yet, managers have a key role to play in designing monitoring and enforcement systems that are effective yet not viewed as too extreme or invasive by employees. In other words, an enforcement system should reach a balance between being viewed as too lenient or too onerous by the employees. If this balance is reached, employees not only tolerate the monitoring system, but they also understand and approve of it. Although only a few study participants commented on this specific aspect of policy enforcement, based on reading all of the participant responses from the study, results suggest that many organizations tend to err on being too lenient rather than too onerous in their monitoring and policy enforcement systems.

One study participant discussed the role of management in this area by stating, “Executive management must take an active role in the…enforcement of all corporate policies. Without this support from the organization’s leadership, any policies that do get distributed will not be totally effective.” Another participant summarized management’s responsibilities with, “Management must not only communicate the ‘contents’ of the policy, but also the need for it. Management should reinforce the need and importance with consistent enforcement as well as a clearly-defined process for updates and reviews.” Fortunately, automated tools are available to help monitor and log the cyber activities of employees and can facilitate the enforcement process. If an employee is caught violating a security policy, management must ensure that appropriate sanctions and penalties are applied. Another method of enforcement involves including security compliance metrics in an employee’s annual performance evaluation. If this evaluation factors into the organization’s promotion decision process, employees are more likely to take security policy seriously. Otherwise, as one participant stated, “A policy may become a ‘paper tiger’ with no ‘teeth’ if there is no enforcement.”

5.3.1.5 Information Security Effectiveness

The term *effective* means producing or capable of producing a desired outcome. In security, an effective program will minimize security risks, vulnerabilities, and the likelihood of costly security incidents. Effectiveness can also be viewed in terms of success. A successful security program, for example, should minimize or eliminate costly security breaches. Security effectiveness can be viewed from the individual as well as the team perspective. One participant stressed the importance of the individual by saying, “Ultimately, the success of security lies in the individual. Technology can facilitate security. Only individuals can ensure security.” Another participant stressed the necessity of teamwork, “Everyone (in the organization) must cooperate; only one (employee) not trying is enough to reduce the program to non-functionality.” Therefore, an effective information security program will have employees at all organizational levels practicing solid security principles while cooperating with corporate goals and policy.

It is worth discussing that information security professionals can measure effectiveness by using employee perceptions in addition to more quantifiable, objective measures. Problems can arise when attempting to measure security effectiveness exclusively using objective means. It can be difficult to know if hard data (e.g., number of incidents, financial losses) are accurate and complete considering that security incidents are sometimes underreported or completely undetected. Organizations that do report security incidents may be embarrassed and suffer a loss of reputation if the media discover and then report an incident. To avoid any public embarrassment, some organizational workers may be motivated to minimize the reporting of security breaches. Therefore, although collecting hard numbers may be helpful, they have limitations that may paint a misleading picture of the overall security effectiveness of an organization in that one can never know if the numbers are complete and accurate. An alternative way of evaluating security effectiveness is to measure employee perceptions of organizational security practices. For example, if employees notice that security is taken seriously and practiced at all organizational levels, measuring this perception can be a reliable indicator that the program is working and effective. Likewise, if employees perceive that they are properly trained and knowledgeable about cyber threats as well as the corporate policies that address these threats, this perception can also be an indicator that the security program is working and effective. In this manner, practitioners can use the proposed model from this study as a guide to help organizations evaluate the overall effectiveness of their information security program. In Exhibit 5.2, the illustrated model stresses a positive relationship between levels of top management support, user training, security culture, policy relevance, policy enforcement, and information security effectiveness. In general, higher levels of these constructs such as top management support and user training lead toward higher levels of effectiveness. Taken as a whole, measuring security effectiveness should be a multifaceted task involving the collection of both hard, objective data as well as soft, subjective perceptions.

5.4 Conclusion

This study began by analyzing the responses to an open-ended question and then conducting a ranking survey of the most frequently mentioned issues from the responses. Using this open-ended approach, results were not presumed or theorized. Yet, the findings from both surveys support the argument that top management support is the essential issue influencing the effectiveness of an information security program. In the first survey, the criticality of top management support was demonstrated by the 874 respondents who ranked it 1 of 25 issues. Based on this ranking, gaining senior management support is arguably the most critical issue influencing information security effectiveness in organizations today. In the second survey, top management support demonstrated statistically significant relationships with training, culture, and policy issues as a means of improving information security effectiveness. Management should focus on these critical issues when promoting information security in their organization.

Considering that many IT executives now consider security among their top issues, the findings of this study should be highly relevant to IT management. Results of this study suggest that levels of top management support, user training, security culture, and appropriate policy management are highly significant predictors of the effectiveness of an information security program. Because many current computer and information security problems require managerial solutions, the model proposed in this study can help management focus their efforts in the areas where they can make the most difference.

This study's findings are summarized by suggesting the following proposition: an organization's overall security health can be accurately predicted by asking a single question—does top management visibly and actively support the organization's information security program? The answer to this question is a strong indicator and predictor into the overall health and effectiveness of the organization's information security program. If answered in the affirmative, it is likely that an organization's information security program is achieving its goals. If answered in the negative, it is less likely the program is accomplishing its goals. The findings of this study support this proposition.

6

Managing Security by the Standards: An Overview and Primer

Bonnie A. Goins

6.1 What Is Security Management?

The definition of *security management* may take different forms, depending on the role of the organization or individual being asked. The definition of *security management* from Wikipedia states

> Security management: In network management, the set of functions (a) that protects telecommunications networks and systems from unauthorized access by persons, acts, or influences and (b) that includes many subfunctions, such as creating, deleting, and controlling security services and mechanisms; distributing security-relevant information; reporting security-relevant events; controlling the distribution of cryptographic keying material; and authorizing subscriber access, rights, and privileges.

Security management, as defined by the Information Technology Infrastructure Library (ITIL), follows:

> The ITIL-process Security Management describes the structured fitting of information security in the management organization. ITIL Security Management is based on the code of practice for information security management also known as ISO/IEC 17799 now ISO/IEC 27001. A basic concept of security management is the information security. The primary goal of information

> security is to guarantee safety of the information. Safety is to be protected against risks and security. Security is the means to be safe against risks. When protecting information, it is the value of the information that has to be protected. These values are stipulated by the confidentiality, integrity, and availability. Inferred aspects are privacy, anonymity and verifiability.

Note the inclusion of ISO/IEC 17799 in the definition of *security management*. The proper use of the standards is critical to an organization. Standards help to define and detail requirements for security management within an organization. As determined by the International Standards Organization in the standard BS ISO/IEC 27001:2005, management of security, in the form of implementation and certification of an information security management system, provides considerations for people, process, data, technology, and facilities. This standard prescribes a cohesive and mutually dependent framework that enables proper implementation of security management principles within an organization. As stated on the Standards Direct website, "ISO 27001 is a 'specification' for an ISMS (Information Security Management System), officially titled *Information Technology—Security Techniques—Information Security Management Systems—Requirements*." ISO 27001 replaces BS 7799-2:2002 that described the specification for ISMS prior. This standard is harmonized with the ISO 17799 that is regarded as a code of practice for information security and the BS 7799, of which the latest version, BS7799-3: 2005, is titled *Information Security Management Systems—Guidelines for Information Security Risk Management*. These standards will be discussed in more detail later in this chapter.

6.2 Why Is Security Management Important?

As can be seen by the above discussion, security management is essential to an organization that must protect its critical assets, including data, infrastructure, and people; in other words, security management is critical to every organization. Without a plan for security management, assets may be protected in an ad hoc, sporadic fashion or not all.

6.3 Who Performs Security Management?

In general, security is the entire organization's responsibility. On a more granular level, however, security management can be viewed as a primary responsibility for teams involved in risk management activities; infrastructure design, development, and maintenance (including network, server, and workstation architecture); application development; compliance; and safety and security. Senior management is also involved and as corporate officers are the owners of security within the business. In many organizations, individuals on these may also play a role on an interdisciplinary team, tasked with monitoring the security state for the organization jointly. A good example of this type of team is a forensics team who is tasked with investigating incidents and eradicating the consequences of such incidents for the organization.

6.4 How Does Security Management Partner With Business and Audit Functions?

6.4.1 A Business Partnership

In order for a group or an individual whose task is security management to protect an organization's assets, work must be conducted with the business units in the organization to help to determine the assets that exist; their relative value to the organization (understanding that some assets are intangible and will likely not have a dollar value. A good example is the organization's personnel or reputation); the threats, risks, vulnerabilities, and exposures that are present relative to the asset; the impact on the organization in the event of the asset's loss; identification of protection or controls that will transfer or mitigate the risk to the asset; and the proper implementation and documentation of these controls within the business unit.

If this list of security professional activities, relative to the performance of security management functions within the organization, sounds suspiciously like risk assessment/analysis, business continuity planning, remediation of vulnerabilities, and business impact assessment, then these activities are exactly what are happening. Security management is truly a macrocosm of those activities that are performed by a security professional, ensuring that the security program present in the organization is formally carried out.

It is important to note that it is very likely that the security professional will also require detailed knowledge of risk assessment/analysis, quality measurement, and infrastructure architecture methodologies and standards among others. These methods and standards may have already been discussed, or even implemented, within the organization. In this case, it is even more critical that the security professional participate as part of an interdisciplinary team so that controls can be properly identified and put in place.

6.4.2 An Audit Partnership

The discussion of the identification and implementation of proper controls presented above are points of commonality with the audit function within the organization. Given the very rigorous (and highly monitored) control framework that a regulated organization must create, implement, maintain, monitor, and enforce, it is clear that this function cannot be successfully performed by one group or individual alone. In many organizations, security professionals work hand-in-hand with the internal and/or external audit function to ensure that there are no gaps in the protection of assets, owing to the proper identification, design, implementation, and continuous tracking of appropriate controls.

It is important to note here that although the audit function may assist with recommendations, individuals tasked with auditing must maintain independence; that is, the audit function must not coincide with the remediation of gaps in protection within the environment. To do so would jeopardize the audit function's primary responsibility within the organization: oversight. It would put an individual in an uncomfortable position if he or she is required to evaluate his or her own work. It also puts the organization at risk because issues may indeed go unreported.

Many security professionals working in regulated industries and with companies bound by regulations such as those bound by Sarbanes-Oxley legislation (at present, this applies to public companies and companies that have chosen to opt in for business reasons) mistakenly believe that they are not able to consult with internal or external auditors for fear of violating the independence of the audit. Nothing could be farther from the truth. Dependent upon the audit team (that will absolutely weigh in if it feels its ability to maintain independence is in jeopardy), information may be shared about expectations for presentation of auditable evidence, sufficiency of documentation that is submitted by the organization to outline a policy, standard, procedure, guideline, or plan, or the detailing of the method that the auditors require the organization to submit its documentation or auditable evidence.

6.4.3 Standards and the Savvy Professional

Auditing is a discipline that is performed by individuals well-versed in generally accepted auditing principles (GAAP); information technology auditors may also be educated in generally accepted IT principles (GAIT). Because these individuals are predisposed to using well-established, highly defined methods for conducting audits, a security professional can assist himself or herself through the use of appropriate methodologies in accomplishing the protection of the organization's assets. Auditors are familiar with frameworks and can easily follow the standards.

An organization can opt to go a step farther and certify against a particular standard or method (as in the Capability Maturity Model for Integration (CMMI), a de facto standard). In some instances, certification may also be accepted as definitive proof of due diligence. Although certification is not yet considered definitive proof in the United States, it may still provide the organization with value. At present, there are more than 2000 organizations worldwide that have certified against the BS 7799 security standard. Reasons for certifying given by these organizations include enhanced reputation, expedited documentation of the security state, definitive direction regarding security best practices, etc. Regardless of whether the organization decides to pursue certification or not, aligning security practices with the standards available clearly makes good business sense.

6.5 Certification Organizations

6.5.1 British Standard Institution (BSI)

As stated on the BSI website, “founded in 1901, BSI has issued more than 35,500 registrations in over 90 countries. As the world’s first national standards body, and a founding member of the International Organization for Standardization (ISO), BSI facilitated and published the first commercial standards to address quality management systems, environmental management systems, occupational health and safety management systems, and project management.”

The following excerpt regarding the history of BSI is quoted directly from the BSI Global website.

6.5.1.1 History of the BSI Group

6.5.1.1.1 1901–1914 Making a start

On 26 April 1901 the first meeting of the Engineering Standards Committee took place.

By 1902 supporting finance could not keep up with demand for more standards. This led to the first government grant and by 1903 foundations were laid for the world’s first national standards organization. This was a voluntary body, formed and maintained by industry, approved and supported by Government for the preparation of technical standards.

The first 5 years saw the development of standards for: railway lines and engines, Portland cement, steam engines, telegraph and telephone material, electric cable and accessories.

By 1914, 64 British standards had been published.

By the end of the war there were 300 committees compared with 60 in 1914 and 31,000 copies of standards were sold in 1918 compared with less than 3,000 in 1914.

British Standards were being used by the Admiralty, the War Office, the Board of Trade, Lloyd’s Register, the Home Office, the Road Board, the London County Council and many colonial Governments.

The Committee changed its name to British Engineering Standards Association (BESA) in 1918.

During the 1920’s the standards message spread to Canada, Australia, South Africa and New Zealand. Interest was also developing in the USA and Germany.

The Mark Committee was formed in 1921 to grant licences to firms who wanted to show that their products conformed to the British Standard. The mark was registered in 1922 for all classes of product and the first licence was issued to the General Electric Company in 1926.

Against a background of economic slump the Association’s work was strongly praised in 1929. By now there were 500 committees and once again demand for standards was exceeding finance so the government grant was increased for the years 1930–1935.

On April 22, 1929, the Association was granted a Royal Charter that defined its main objectives as

> ‘To set up standards of quality and dimensions, and prepare and promote the general adoption of British Standard Specification and alter or amend these as required’
>
> ‘To register marks of all descriptions and to approve their fixing’.

A supplemental charter was granted in 1931, changing the name to British Standards Institution.

The Second World War gave a boost to industry standards and saw the start of consumer standards.

The Government officially recognised BSI as the sole organization for issuing national standards in 1942.

In 1946 the International Organization for Standardization (ISO) was set up.

International standards have had much success since 1946. Agreed sizes and shapes of items such as audio-cassettes, freight containers and credit cards have helped to encourage international exchange and co-operation.

The Cunliffe Report in 1951 set the direction for the Institution for the following two decades. Government's contribution was to equal that of industrial subscriptions, subscriptions were increased, membership was to be increased, there was to be more user representation on committees, wider certificate marking was to be encouraged and there was to be positive action to promote the understanding of standardization in the country.

Between 1950 and 1960, more standards were produced than in the entire previous 50 years.

In 1960 there began to be renewed interest in quality assurance schemes. Also BSI was to be sponsored by the then Ministry of Technology (now the DTI).

A major development during these years was the introduction of a standard for the quality of a company's management system. BS 5750 was introduced to help companies build quality and safety into the way they work so that they could always meet their customers' needs. The Registered Firm mark was introduced in 1979 to show that a company had been audited and registered to BS 5750.

August 1987 saw the publication of the dual numbered BSI/ISO standards in the BS 5750 / ISO 9000 series. From 1994, BS 5750 becomes known as BS EN ISO 9000. From now on a major part of BSI's work is in registering companies to the world's most popular management systems series: ISO 9000.

In 1991, BSI Inc. was established in Reston, Virginia, USA.

In 1992, BSI published the world's first environmental management standard, BS 7750. In due course this is adopted by the international standards community and is published as ISO 14001 in 1996.

In 1998, BSI formally went global.

6.5.2 BVQI

BVQI is the independent certification body of Bureau Veritas. According to the Bureau Veritas website, "Bureau Veritas is a professional services company specialising in independent verification and advice in the areas of Quality, Health and Safety, Environment and Social Accountability." BVQI, starting as a ship's registrar, offers certification against the BS 7799 (ISO 27001) as well. BVQI maintains offices in over 50 countries worldwide, and it has completed registrations around the globe.

6.6 Preparing for the Certification Effort

Once senior management has approved undertaking the certification effort, it is incumbent on the responsible security professional to recommend how the effort is to be carried out. First, it must be decided if the certification preparation will be internally carried out or if an external consultancy will be engaged to assist with the implementation of the information security management system. It is highly recommended that the standard be obtained from one of the registrars listed above. Standards can be purchased as stand-alone, with related standards, or as an implementation kit.

Once the standard and any related documentation has been obtained, the implementation team should review the standards and become completely familiar with the content. As reported on the Standards Direct website, components of the BS 7799-3: 2005 (Information Security Management Systems—Guidelines for Information Security Risk Management) include

- risk assessment
- risk treatment
- management decision making
- risk re-assessment
- monitoring and reviewing of risk profile
- information security risk in the context of corporate governance
- compliance with other risk based standards and regulations

Components of the ISO 17799 (Information Technology—Security Techniques—Code of Practice for Information Security Management) provide information regarding the implementation of proper controls surrounding an organization's assets. They include

- Introduction
- Scope
- Terms and Definitions
- Structure
- Risk Assessment
- Policy
- Organization of Information Systems
- Asset Management
- Human Resources Security
- Physical & Environmental Security
- Communications and Ops Management
- Access Control
- Information System Acquisition, Development, and Maintenance
- Incident Management
- Business Continuity Management
- Compliance

Components of the ISO27001 (Information Technology—Security Techniques—Information Security Management Systems (ISMS)—Requirements) that provide specifics around information security management systems and third party certification include

- Introduction
- Scope
- Terms and Definitions
- Normative References
- ISMS
- Management Responsibility
- Management Review
- ISMS improvement

The group or individual responsible for implementing the ISMS for certification (ISO 27001 that replaced BS7799-2:2002 in November 2005) should be familiar and facile with ISO 27001. This standard will explain how the ISMS is to be scoped, that is, the portion of the organization that is to be audited for certification. Scope can be as large or as small as desired with the rule being to right size the effort so that it is possible to certify but is not so small as to render the effort or the certification inconsequential. Many organizations that wish to certify in conjunction with regulatory efforts scope their certification efforts around the regulated space in the environment. This allows deliverables produced for the certification to be leveraged against audit efforts as well.

6.6.1 Personnel Requirements

Conducting certification and audit support activities is not a trivial task; fortunately, the skills required can be acquired through the receipt of external training, partnering with a registrar, or diligent study of the standards and their application to other organizations that have gone through the certification process. There are a number of resources available on the Internet, including an ISMS users' group that publishes a journal for consumption by the general public. It is highly recommended that external training with an experienced vendor be completed, if possible, for implementation of the ISMS.

Seasoned security professionals should have no issues with acquiring the skills necessary to complete this task; however, it is not recommended that junior security staff lead a project of this magnitude. Senior and junior staff could potentially partner to complete the certification process in an effective and timely fashion. It is important to note that this activity will require full attention and, as such, should be assigned dedicated resources that will be available for the duration of the implementation and the audit of the ISMS.

6.7 The Registration Process

The registration process describes the steps required for the successful completion of certification (i.e., registering the ISMS with the registrar). The steps follow, and they must be completed in the order presented:

Step 1: Use the standard (ISO 27001) to create the management framework for the ISMS. This work may take significant time and resources based on the scope of the ISMS and the skill set of the resources performing the implementation.

Step 2: Contact one of the registrars listed above to determine schedules, costs, and planning for assessment, audit, and registration activities.

Step 3: Obtain senior management approval for the project. Be certain to provide senior management with costs and benefits, risks and mitigation strategies, and a project plan that indicates all facets of the project that are tied to a timeline for completion.

Step 4: Schedule the project (assessment and audit activities) with the registrar.

Step 5: The registrar will request documentation surrounding the ISMS for review prior to coming onsite for the audit. The registrar may comment on deficiencies in the ISMS for correction prior to audit.

Step 6: The registrar conducts an on-site audit of the ISMS. This audit typically takes approximately two to three days, but the audit's length is at the discretion of the registrar.

Step 7: The organization will be notified by official mail of the audit results. In the event of a failure, deficiencies will be communicated to the organization. These deficiencies must be corrected prior to engaging a registrar for a new audit. When the organization successfully passes the audit, the registrar will transmit a formal certificate of registration to the organization. The organization is also allowed to use the watermark of the registrar on appropriate communications to indicate successful registration of the ISMS.

6.8 The Maturing Organization: Certification Mapping and Maintenance

Although this chapter has discussed security certification (registration) in detail, it is important to note that it is also possible to certify against other standards and best practices. A mature organization may desire multiple certifications to indicate its intention to promote due diligence and best practices across the organization and its functions. For example, ITIL security management was discussed early in this chapter. Certification of the organization against the ISO 20000 (was BS 15000) standard that the ITIL common body of knowledge and practices are related to is available as is certification against the Capability Maturity Model Integration (CMMI) (In 2000, the SW-CMM was upgraded to CMMI). Each of these standards has touched points in common; together, they can provide a more complete picture of an organization that is maturing in its processes, procedures, and practices.

6.9 Summary

Proper security management is paramount in an organization that has business and regulatory reasons for ensuring due diligence in protection of its assets. This due diligence can be documented though registration (certification) of the management framework for information security that is implemented in the form of an Information Security Management System (ISMS). This chapter gives both the organization and the security professionals performing the certification activities baseline knowledge to undertake this initiative; it also provides options for implementing proper security controls without moving to certification through alignment of security activities to a recognized international standard.

Information Security for Mergers and Acquisitions

Craig A. Schiller

7.1 Background and Establishment of Necessity of Information Security

A large global corporation was engaged in an aggressive merger and acquisition initiative. This company acquired a new business every other month. The information security office (IS) learned of the first acquisition upon receipt of the request to modify their firewall to include the acquired company's networks. Executive management was not pleased that IS declined to permit the new network connections until due diligence could be performed to IS standards.

Those responsible for information technology (IT) security should be included in the due diligence phase of mergers and acquisitions. The due diligence phase is required protocol whereby the acquirer verifies that the acquisition is a good investment. During due diligence, the acquiring company is allowed to examine the potential acquisition onsite. This is the perfect time for IT and IS to review the computer operations of the potential acquisition and alert management to any security concerns or IT-related challenges or expenses that may be encountered if the acquisition proceeds.

The policy and processes described below are the result of significant experience with this merger and acquisition initiative. In their first application, they hit the equivalent of a grand slam by preventing a very damaging action that could have significantly reduced the value of the acquisition. They were first applied during a hostile acquisition. The target company was being acquired for its resources and its customer base, not its employees. IS sent an assessment team to the corporate headquarters of the company to be acquired. They followed the policy and procedures described below, resulting in a security assessment that covered technical, organizational, and staff issues. From the results of the assessment, IS was able to determine what connectivity could be granted with minimal changes, what actions needed to be taken on the day of the merger, and what changes would be necessary for final network connectivity. With this information in hand, IS was able to work with business leaders, human resources (HR) and legal to develop a plan for the actual merger.

On the day of the acquisition, fifty percent of the target company's employees were terminated with equitable severance packages. The action plan was developed prior to the acquisition date. After reviewing the assessment data and conducting a meeting between HR, IT, and IS, HR arrived on-site with a list of employees, the times for their HR interviews, and the action planned for each individual. If the individual was being terminated, user administrators executed an action plan disabling access and transferring ownership of files.

Of particular interest was the senior network administrator. This individual managed the firewall prior to acquisition, but was not being retained. When this individual's exit interview began, the acquiring company's firewall administrator opened a new interface on the acquiring company's corporate firewall and changed the external DNS entries to point to a new IP address on this firewall. All traffic destined for the newly acquired company would come through the acquiring company's firewall and then be routed through a direct connection to the acquired company's network. The firewall administrator replicated the acquired company's existing firewall rule-set for all traffic destined for that interface.

The former network administrator accepted a new job the next day with the acquired company's closest competitor. It is likely that the individual promised the new employer access to the acquired company's customer project database. Had the competitor gained access to this database, much of the value of the acquisition would have been lost.

When the former network administrator realized it was no longer possible to gain access, that person tried to contact an employee who had been retained in an attempt to obtain the information. IS had briefed all retained employees about the possibility that former employees might call seeking proprietary information. Retained employees were given a number to call if they were contacted. The retained employee who was asked for the proprietary information followed this procedure and called IS. The legal team contacted the former employee to warn that continued efforts to secure the information would result in forfeiture of the previously granted severance check. The situation was resolved.

If IS had delayed taking precautionary steps, even a single day, the former network administrator would have been able to compromise the database and obliterate much of the value of the acquisition. From that point on, IS was given two weeks during the due diligence phase of mergers and acquisitions to conduct security assessments.

7.1.1 Merger and Acquisition Background

What is a merger? What is an acquisition? What are the differences between the two? The following are not legal definitions, but they will serve our purposes for this chapter.

A merger occurs when two companies, usually but not necessarily of approximately equal size, decide to join together to form a new organization combining functions from each original company.

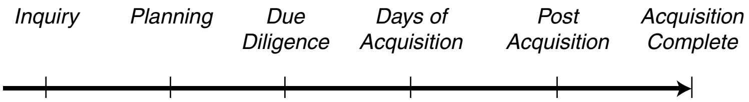

EXHIBIT 7.1 Merger and acquisition timeline.

An acquisition occurs when one company (usually the larger company) buys (takes over) another company or part of a company.

The difference between the two that is of interest from an IS perspective is that the discussions below are from the point of view of the acquiring company in the case of an acquisition and from the perspective of the composite merger team in the case of a merger. In an acquisition, it is the acquiring company's IS officer who gathers information about the company to be acquired. In a merger, both companies may be gathering information about each other, then meeting to discuss and agree upon a course of action.

In the course of a merger or acquisition, there are different phases of activities. The goals of each phase are different and, consequently, the goals and requirements for IS also change (Exhibit 7.1 and Exhibit 7.2).

7.2 Threats and Consequences Related to Mergers and Acquisitions

The threats related to acquisitions change over the life of the acquisition/merger.

7.2.1 Inquiry Phase Threats

During the inquiry phase, the primary concern is to prevent unauthorized or unintentional disclosure outside of the small group (inquiry team) considering acquisition/merger targets. Early publication of this information could affect the price of the acquisition/merger to the detriment of the acquirer. Others interested in the target may be able to mount a competitive offer or make a profit by selling the information to someone else who might do so. Publicity might also cause uncommitted key stakeholders to withhold support unless compensated. In some cases, public knowledge that a company is actively considering acquisition or merger possibilities is enough to change the market conditions such that any acquisition or merger would be difficult or more expensive. Some companies have enemies, groups that fundamentally oppose the nature of the business (such as logging or oil companies and environmentalist groups, abortion clinics or stem cell research labs and pro-life supporters, defense contractors and anti-war groups), that would use information of this type to harm the company, such as giving the information to the competition, publishing it in the news media, mounting a grass roots campaign to make the acquisition costly or to stop it entirely. Occasionally, the sensitive information is compromised through the carelessness of inquiry team members talking to friends and family about their work, inviting the team to a working lunch at a busy restaurant, or going out to a local bar to relax after a day of tense discussions where their conversations might be overheard.

The targets of inquiry phase threats:

- Information about the potential acquisitions or mergers
- Information about the inquiry team members
- Inquiry team members
- Systems storing inquiry team information
- Communications (email, Internet traffic, phone conversations, etc.) from or to inquiry team members
- Communications (email, Internet traffic, phone conversations, etc.) about inquiry team discussions, concerns, targets, etc.

EXHIBIT 7.2 Merger and Acquisition Phases

Phase	Description	Security Goal
Inquiry phase	Discussion at the executive or senior management level about the possibility of merger or acquisition	Protect the discussions for unauthorized and unintentional disclosure
Planning phase	A decision has been made to move forward. This may occur before or after formal documents have been filed that make aspects of the merger/acquisition public. More staff is brought in to gather more detail about the potential benefits and risks and to begin tentative plans	Gather information from the acquisition team about goals of the merger/acquisition, key players, personnel issues, information to be protected, and value estimates of that information, on-going litigation, intellectual property concerns (both sides, theirs and ours), and rules of engagement during "due diligence". Provide information about security involvement in due diligence. Provide security perspective research about the target acquisition
Due diligence phase	Due diligence occurs just prior (∼3–4 weeks) to the official date of merger/acquisition. This is the opportunity to inspect the merchandise. Functional departments (finance, engineering, manufacturing, security, etc.) are permitted to look in-depth at the target company. Due diligence is a formal requirement to satisfy stockholder concerns that the merger/acquisition is a considered decision rather than an emotional one. Following the review of due diligence reports, the business makes its final decision about the merger/acquisition	Determine if there are any security issues that could lessen or offset the value of the merger/acquisition. Gather information necessary to determine pre-acquisition requirements, plan the day of acquisition transition and the longer term permanent connectivity transition. Gather information to support day one of merger/acquisition actions. Pre-acquisition/pre-merger security requirements identified during this phase must be completed and validated as a precondition to beginning day of merger/acquisition actions
Day of acquisition/merger	Today's activities should be well-coordinated among HR, IT, information security, physical security, and legal. Management expects a smooth technical and personnel transition	Security should be able to complete all access actions for an individual during the HR interview. Network changes should be timely. All retained employees/users should be briefed about acceptable use and differences between the companies from a security perspective
Post-acquisition/merger phase	Goal is to complete all activities so that permanent connectivity can be deployed and all operations can return to normal	Security should monitor the progress of security projects required from the due diligence as a condition of permanent connectivity. Extended monitoring should be deployed for 30–90 days to ensure that all latent, potentially hostile resentment to the acquisition/merger has dissipated

7.2.2 Planning Phase Threats

During the planning phase, some information about the selected acquisition/merger target is made public. Care must be taken that only officially sanctioned and prepared information is released. The team grows so that more skills and knowledge can be brought to bear on the project. If this is the first attempt to involve IS in the acquisition/merger process, there will be resistance to the presence and involvement of these professionals. The security professional should be prepared to answer these objections and to sell the concept that it is necessary and valuable to address security in this phase. As information becomes more critical to corporations, the potential will increase that stockholders and courts will view the exclusion of security professionals from the planning and due diligence phases as negligent acts.

After public documents have been filed, the need for secrecy changes. At this point, the primary need for information focuses on accuracy and timing. The goal of confidentiality at this time for most information is to ensure control over the release of acquisition-related information. A few sets of information from the inquiry phase remain at the highly confidential level, such as estimates of the value of the company, aspects of the target that are desirable and undesirable, plans for eliminating duplication, etc. Existing employees of the company planning the acquisition/merger may feel threatened if they are insecure about their position in the company or about the future of their organization after an acquisition/merger. Some companies have divested themselves of business units prior to a merger to satisfy anti-trust regulators. Internal announcements should be carefully crafted.

The goal of this phase is to gather information, ensure the right people receive that information, and make plans for the subsequent phases, beginning with due diligence. Threats to that goal include inadequate or inaccurate information gathering, poor communication and distribution of the information, and poor or incomplete planning. The consequences of these threats might include:

- Providing bad information to decision makers
- Missing evidence of significant security concerns that might impact the value of the acquisition/merger
- Missing evidence of significant security concerns that would merit specific attention during due diligence
- Providing information to individuals who do not need to know
- Not providing necessary information to decision makers and planners
- Ineffectively communicating and distributing security information to those who need it
- Creating plans that do not meet the goals of due diligence and subsequent phases
- Inadequately staffing the plans from a resources or skills perspective.

7.2.3 Due Diligence Phase Threats

The phrase due diligence has come into common usage but has a specific meaning in regards to mergers and acquisitions (M&A). M&A lingo uses the phrase during due diligence. This refers to a required set of activities just prior to the actual consummation of the acquisition, in which the acquiring company is permitted an in-depth, usually onsite, examination of the company to be acquired. In common usage, the term due diligence has become synonymous with due care but, as you can see, due diligence during an M&A is both a phase and a set of care-related activities required during a merger or acquisition.

The goal of the due diligence phase is to satisfy stockholder concerns that the merger/acquisition is a rational decision rather than an emotional one and to support the final decision about the acquisition/merger.

For IS, the goal of the due diligence phase is to:

- Determine if there are any security issues that could lessen or offset the value of the acquisition/merger
- Gather information necessary to determine pre-acquisition requirements
- Plan the day of acquisition transition and the permanent network connectivity transition
- Gather information to support day of acquisition/merger actions
- Determine the level of pre-acquisition/pre-merger security requirements that must completed and validated as a pre-condition to beginning day of acquisition/merger actions.

Threats to these goals include inadequate or inaccurate information gathering, poor communication and distribution of the information, disclosure of sensitive information about the company to be acquired, and poor or incomplete planning. The consequences of these threats might include:

- Providing bad information to decision makers
- Missing evidence of significant security concerns that might impact the value of the acquisition/merger
- Missing evidence of significant security concerns that would affect decisions regarding security requirements for day-one connectivity and permanent network connectivity
- Providing information to individuals who do not need to know
- Distribution of information damaging to the company to be acquired to adversaries, competitors, or the media, such as findings of vulnerability assessments
- Providing inadequate information to decision makers and planners
- Ineffectively communicating and distributing security information to those who need it
- Creating plans that do not meet the goals of the subsequent phases
- Inadequately staffing the plans from a resources or skills perspective
- Failing to create plans for day one that address threats that were missed by due diligence analysis.

7.2.4 Day of Acquisition Threats

The goal of the day of acquisition activities is to achieve a well-coordinated, smooth technical and personnel transition.

The goals of IS for day one of the acquisition are to:

- Build team identity and acceptance of the new organization
- Complete all access actions for an individual during the HR interview
- Complete all network changes successfully and in a timely fashion
- Provide basic connectivity without subjecting the acquiring company to significant risk
- Brief all retained employees/users about acceptable use and differences between the companies from a security perspective
- Prevent intellectual property loss
- Prevent damage or loss from disgruntled or separated users
- Preserve the value of the acquired company.

Threats to these goals might include HR, legal, physical security, and IS transition plans created in silos (without coordination), ineffective attempts to build team identity and acceptance, computer access changes occurring prior to the HR exit interview, access changes occurring after a separated user has been notified, access changes not being made, incorrect network changes being implemented, intended network changes failing, failure to identify the business need for a network change, disgruntled or separated users exploiting day-one connectivity, tainting acquiring company intellectual property by contact with intellectual property under potential litigation, violation of industry required segregation of data (e.g., between commodities traders and producers of those commodities), and exposure of the acquiring company's systems to undetected compromises in the company to be acquired. Day one threats might have the following consequences:

- Loss of intellectual property
- Permitting connectivity to the acquired company's network that poses unacceptable risk
- Physical harm
- Loss in value of the acquired company

- Fines and regulatory sanctions
- Barriers to team building (or persistence of loyalty to the old company at the expense of the new) and resistance to changes related to the acquisition
- Periods of exposure due to gaps between actions of HR, legal, physical security, and IS
- Disciplinary action or loss of employees due to differences in expectations of acceptable computer use.

7.2.5 Post-Acquisition/Post-Merger Threats

The business goals are to complete all activities so that permanent connectivity can be deployed and all operations can return to normal.

The IS goals of this phase are to monitor the progress of security projects required by the due diligence phase as a condition of permanent connectivity and to monitor network traffic and logs for latent, potentially hostile, resentment of the acquisition/merger to determine if the threat has dissipated.

Threats to these goals include implementation of incorrect network changes, network changes failing, disgruntled or separated users exploiting the increased connectivity, and management relenting on the security requirements and allowing connectivity without mitigating risk appropriately. The consequences of these threats might include:

- Creation of exploitable vulnerabilities on firewalls and perimeter devices
- Loss of intellectual property
- Loss in value of the acquired company
- Increased maintenance costs through failure to standardize platforms or consolidate maintenance contracts
- Reduced IT performance due to failure to complete acquisition assimilation.

7.3 Policy Overview and Process Outline

I. Pre-merger/pre-acquisition security

A. Inquiry phase protection
B. Planning phase security
 1. Things to find out
 2. Things to provide
 3. Develop the due diligence security plan
C. Due diligence security
 1. Discovery
 2. Inventory information assets
 3. Value information
 4. Organization, policy and procedures security assessment
 5. Physical and technical vulnerability assessment
 6. Security attitude assessment
D. Analyze and report
 1. Security requirements for day one
 2. Report of the nature of day-one connectivity
 3. Security requirements for permanent connectivity
 4. Report on the nature of permanent connectivity
E. Plan transition projects
F. Plan day of merger/acquisition actions

G. Conduct pre-merger/pre-acquisition projects
H. Verify conditions met for initial connection
I. Train team for day of merger/acquisition

II. Day of merger/acquisition actions

A. Deploy and test initial connection
B. Execute access control project
C. Brief new users on awareness, policy, and merger/acquisition special topics
D. Extended monitoring

III. Post-merger/post-acquisition phase

A. Begin permanent connectivity projects
B. Conduct post-merger/post-acquisition projects
C. Verify conditions met for permanent connection
D. Deploy and test permanent connection configuration
E. Continue extended monitoring for X months

IV. Merger/acquisition project completion

A. Normal monitoring begins
B. Gather and record lessons learned
C. Merger/acquisition complete

7.4 Pre-Merger/Pre-Acquisition Security

7.4.1 Inquiry Phase Protection

Because IS is rarely a member of the acquisition and merger exploratory group, it is necessary to establish policy and procedures for this group, as well as logical and physical separation of these groups' information, to establish monitoring of key words on outbound and inbound network traffic, and to develop specific awareness and provide security training.

At the beginning of each inquiry team project, team members should be asked to disclose any relations with target companies, competitors, and opposing groups for themselves, former employers, friends, and relatives. The exercise itself will remind team members to be cautious in their discussions about the inquiry phase. Sensitive documents and reports of the inquiry team's work can each be given a unique identifying number and records kept of who was issued which document. The document number should be printed on every page of each document, in the meta data (properties section of the file) and some hidden in the file, if possible. These documents should be tracked and managed. New revisions should be provided upon surrender of old versions. Only originals should be produced. Dates and conditions of release (when each document can be may be made public) should be specified. Copying of these documents should be prohibited. Cross-hatch shredders should be available in the inquiry team's meeting room. Once a document is surrendered and recorded as such, it should be shredded. Any support (IT, admin, etc.) needs to be vetted in the same manner as actual inquiry team members. Support providers should be named individuals and not assigned as needed out of a pool. All of these procedures need to be established and in place prior to convening the group for consideration of potential acquisition and merger targets. During this phase, the accountability principle, confidentiality principle, and the principle of least privilege are key to meeting inquiry phase needs.

7.4.2 Planning Phase Security

If the company does not recognize the need for formal IS involvement during the planning phase, the IS office might learn of the acquisition/merger if a planning committee member has a task that will require a resource from IS. This may occur anytime from the beginning of the planning phase until the actual day of the merger/acquisition.

The most common case would be that IS does not become aware of the activity until the day of the merger/acquisition and IS is told to open access through the firewall for the new employees and special applications. The worst case would be that IS professionals learn of the acquisition in the enterprisewide announcement made after the completion of the sale. If the company does not recognize the need for formal IS involvement during the planning phase, an IS professional can use the occasion to raise the issue with management, perhaps citing the case described at the beginning of the chapter. Even in a friendly acquisition or merger, when both management teams are in favor of the move, employees may be unhappy with the change. “Between 60 and 90 percent of mergers and acquisitions fail to meet their desired objectives,” says Kate O’Sullivan in CFO Magazine in an article titled “Secrets of M&A Masters” (September 2005). If the one of the reasons for that failure rate is related to IS, then IS must be involved in the planning and due diligence phases to prevent or recover from the failure.

The following anecdote is another example of a situation where IS should have been involved during the planning and due diligence phases. In the late 1990s, a large corporation acquired a chemical engineering firm. IS first learned of the acquisition when the VP in charge of the acquisition demanded that the new acquisition be connected by the end of the week. IS politely but firmly refused the request, and declined to provide an explanation on the phone, opting instead to meet face-to-face with the VP at his earliest convenience. In the meeting, the VP assumed a confrontational posture, stating that this acquisition was very important to the corporation and that security must get in line and make the connection. The security officer calmly explained that the company that had just been acquired was responsible for the biggest intellectual property theft in the history of the acquiring company. The underlying reason driving the acquisition was that the acquiring company had brought suit against the acquired company and won, but indications were that the damages would not be recoverable. Executive staff had decided that the only way to regain any of the value was to take over the company. A possible complication was that the individual responsible for the original theft of intellectual property had recently left the acquired company; however, there was suspicion that he was attempting to take the intellectual property with him to a third company. Security had reason to believe that some employees still working for the acquired company were channeling intellectual property to that individual. IS and corporate security were conducting an active investigation with the FBI to gather evidence of the on-going illegal activity. Connecting the new acquisition’s computers to the acquiring company’s networks would have given them access to even more intellectual property and increased the complexity of the investigation. After this explanation, IS asked the VP if he still wanted to press for full connectivity by the end of the week. Not only did the VP change his position, but a stronger bond was created between the VP and the IS office.

If a company already recognizes the need for formal IS involvement during the planning phase of an acquisition or merger, then the IS office will be notified as part of the normal procedure of assembling planning committees for supporting the project. Ideally, the IS office would be expected to be a team leader and to present security requirements and awareness training to the team in the initial meeting.

7.4.2.1 Facts to Determine

To prepare for the due diligence phase and the day of acquisition event, IS requires certain information from the acquisition leadership team. Business leaders should be consulted to determine:

- Major goals of the acquisition from the business perspective
- Any relevant history, including current or pending litigation
- Intellectual property or trade secret concerns
- The location of intellectual property and trade secrets
- Status of IT assets such as hardware, software, networks, providers, etc.

- Requirements for Chinese wall protection (commodities trader restrictions, intellectual property under litigation and potential consequence of that litigation, export regulation requirements, strategic business plans to retain only a portion of the acquired company, etc.)
- Business function map of the two companies
- Key personnel from both companies and an explanation of their roles
- Agreed upon restrictions and prohibitions
- Extent of the merger or acquisition (whole or partial)
- Processes for decision making and communication during the transition
- Office locations, including international sites, staff at each location, and staff and office retention plans
- Management concerns about staff, technology, and processes
- The projected timetable of events, particularly due diligence and the day of merger/acquisition
- Budget implications for security activity during the transition

Additionally, legal and HR should be consulted regarding laws related to the acquisition/merger, as well as protocols to be followed.

The IS professional should gather open-source intelligence about the target. If there has been no public announcement about the potential merger/acquisition, then these efforts should not be made from a computer that can be recognized as being a corporate asset of the acquiring company. Too many inquiries made from identifiable corporate assets could raise suspicions.

Prior to the planning meeting, IS should investigate the target company. Consult Hoover's Online or some similar service to get the basics. With a subscription, it is possible to get information about the business, its leaders, its competitors, etc. Using Google or other search engines, it is possible to search the internet for references to the company. Be sure to search Usenet from google using @<target company's domain name> to find technical postings by the company's employees. The technical Usenet groups may reveal useful information about platforms, operating systems, applications, firewalls, etc., that the company is using or has used. It will also reveal the problems they have been having and whether they are looking for outside help.

From this information, broaden the search to vendor, technical, or user forums for the platforms or applications discussed on Usenet. With the list of intellectual property and trade secret concerns obtained from business leaders, target searches on any related public discussions. Remembering the above caution about inquiries prior to any public announcement, a good source of security relevant information for publicly traded companies is the investors' information page on the corporate website. Look for the company's SEC filings (e.g., annual reports). In the annual and quarterly reports, corporations are required to explain to their stockholders the risks they perceive and what steps are being taken to address those risks. This is a good place to find out what is important to a company and what worries it. If this has not already been done, IS professionals should attempt these searches on their own corporation and compare what they find to current security strategic and annual plans.

The results of these searches can be used to guide the creation of security assessment activity to be conducted during due diligence phase and planning for day of acquisition activities.

7.4.2.2 Infomation to Provide

- Awareness briefings about threats in each phase
- Overview of the due diligence phase IS assessments and associated processes
- Name and nature of each assessment
- Types of due diligence phase IS deliverables and their purpose
- Proposed locations where assessments will be performed
- Names or roles of individuals whose cooperation will be needed to conduct each assessment

- Number of staff and number of days needed to perform the assessments
- Budget estimate for the assessments
- Project plan for due diligence IS projects
- Acquisition/Merger information-handling guide derived from discussions with management about data that is important relative to the acquisition/merger.

Some of the information from the open-source intelligence gathering that might be useful to acquisition/merger planners and improve awareness regarding the need for protection during the acquisition/merger include the following.

Discussions about due diligence are made more difficult because the media and practioners use the term loosely. The phrase has been used to refer to taking an appropriate amount of care in a given situation. In the course of completing a merger or acquisition, it is clear that stockholders want the deal makers to be diligent and careful in all aspects of analysis and decision making regarding the deal. However, there is a time in the life cycle of a merger or acquisition in which the acquiring company is permitted to closely examine the target company. This usually involves onsite visits by a team from the acquiring company. Finance or auditors will look at the books, manufacturing will look at the factory, facilities will examine the physical plants, and IS will assess the security environment, architecture, and posture. Many involved in mergers and acquisitions call this timeframe during due diligence. The goal of this concentrated due diligence effort is three-fold:

- Identify any issue that could be considered a “deal breaker”
- Analyze material findings that could affect the price or be useful as negotiating points
- Discover and understand the nature, challenges, and complexity of the required integration.

It is amazing that, in today’s heavily information-dependent corporations, many businesses involved in mergers and acquisitions do not insist on an IS component of the due diligence phase. For U.S. companies, the regulatory environment of Sarbanes–Oxley, HIPAA, GLBA, and similar legal requirements may correct this oversight. Sarbanes–Oxley, for example, requires CEO’s and CFO’s to certify the presence and effectiveness of their internal controls. As part of the due diligence phase of a merger and acquisition, information security professionals should determine the impact of the target company’s internal control systems and disclosure controls on those of the acquiring company’s. In doing so, they should develop a transition plan for limiting damage to both entities while addressing deficiencies, inconsistencies, or incompatibilities. When the corporate infrastructures of two companies are connected, the resulting entity inheirits the vulnerabilities and exposures of both companies.

The cost of this transition may affect the perceived value of the merger or acquisition to the point that the deal may become untenable. For example, the acquiring company has standardized on a common server and desktop platform to reduce both costs and the vulnerability/exposure footprint. The target company has not standardized, and maintains a disorganized array of servers and desktops and perhaps differing brands of mainframes. If the acquiring company intends to keep the acquired company’s assets on a long-term basis, then the cost of replacing nonstandard desktops and servers, and the cost of porting critical applications from these to the common platforms needs to be considered. If the company does not intend to keep the assets in the long-term, then the cost of isolation or complex multi-platform patch and change management needs to be considered. The target company might also have been lax with respect to the use of licensed software or might have let maintenance contracts lapse. If any of these costs are significant, then the deal might be called off.

All three goals assist deal makers to make final decisions and to formulate negotiation strategies. The third goal contributes to planning for the day of acquisition and beyond. For this goal, a basic security assessment is needed. Because the audience for this assessment is the security officer, some of the presentation and formatting is unnecessary.

Based on the discussions during the planning Phase, the IS team can determine which of the target company’s sites should be visited as a part of the due diligence phase. Ideally, the team will gather the most information possible in the fewest possible site visits. The onsite portion of the due diligence phase may last between two and three weeks. Costs should be kept at a minimum, with one or two individuals involved in each site visit. In general, the onsite work will consist of discovery activities, followed by analysis and reporting to the acquiring company.

7.4.3 Discovery

The IS professional should request copies of external auditor findings, compliance audits (Sarbanes–Oxley, HIPAA, GLBA, CISP, EU or U.K. Data Protection, etc.), and work with legal to determine the laws, regulations, and standards to which the acquired company must maintain compliance.

7.4.3.1 Organization, Policy and Procedures Security Assessment

Obtain an organizational chart of all levels of management, IT, and all IS staff. Ask IT managers for the names of those outside of IS who are responsible for security-related tasks, such as enterprise virus server and desktop operations, patch management, asset management, firewall administration, and security baselines for platforms or applications. Obtain a list from IT managers containing IT resources that are not managed or operated by IT. Find out who manages these resources and obtain from them a set of policies and procedures they follow.

Prior to the site visit, request a copy of policies, procedures, standards, and work instructions from the HR and IT organization to be acquired. Develop a list of interviewees based on the existing documentation. Use a checklist for standards relevant to the acquired company's industry. A good general standard to use for security management is ISO 17799/27001. For due diligence purposes, a high level view of a company's security posture can be derived by transforming the requirements from the standards into questions. This will reveal a degree of coverage but cannot demonstrate effectiveness.

For each requirement, determine one or two appropriate interviewees who are able to speak of company efforts related to the requirement. In interviews and reviews of document inventory, watch for relevant policy, procedures, standards, and work instructions that were not listed in the document lists from IT and HR. Keep raw notes from each interview and graph the score of documented and implemented security requirements against the total security requirements in each domain in ISO 17799/27001. This will result in a radar plot with ten spokes, one for each domain in ISO 17799/27001 (Exhibit 7.3).

Obtain a history of security incidents, policy violations and records of their resolution. Check the help desk data base for incidents that might not have been included in the security incident data base.

7.4.3.2 Inventory Information Assets

Information asset inventories may have been gathered for finance asset management, for Sarbanes–Oxley documentation, for use as business continuity/disaster recovery records. To be useful in a due diligence setting, some additional information needs to be gathered. To assist in day of acquisition activities, information asset business owners must be established, if this has not already been done. Some business units may attempt to name multiple owners, but for accountability purposes, IS must insist that only one individual is named, and that all decisions regarding access and privilege should be referred to that person. IS will want to gather information beyond that for inclusion in the standard asset record. This should include information about lease expirations, maintenance contract levels and renewal dates, accounts, and contacts, version levels (for OS and applications), current applied patches, installed applications, and license keys. This additional information should note any special dependencies on IP addresses (e.g., license keys or maintenance contracts) that will need to be addressed in the long- or short-term.

Be sure to ask if any information assets are subject to, or may be subject to, intellectual property litigation. If intellectual property litigation is lost, then the courts may decide that the company must no longer use the technology in question. If the intellectual property in question has been incorporated into other systems, those systems may be prohibited from use or distribution. For this reason, any intellectual

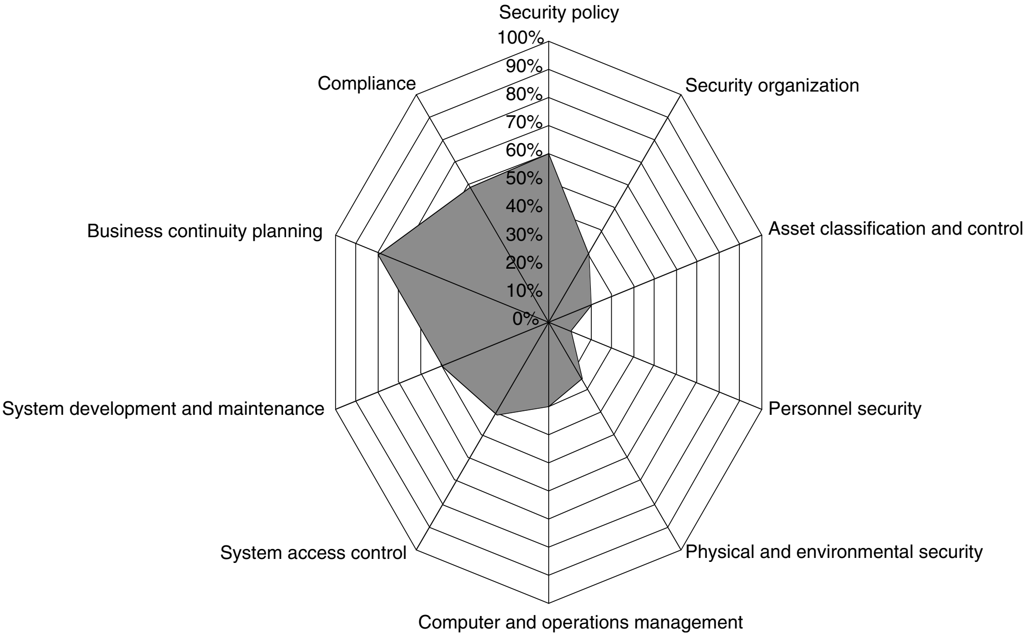

EXHIBIT 7.3 Organizational security assessment.

property that is currently or potentially subject to litigation should be isolated using Chinese wall techniques until the litigation is resolved.

Gather network architecture and topology diagrams for all sites of the acquired company. These diagrams should be analyzed as part of the technical vulnerability assessment.

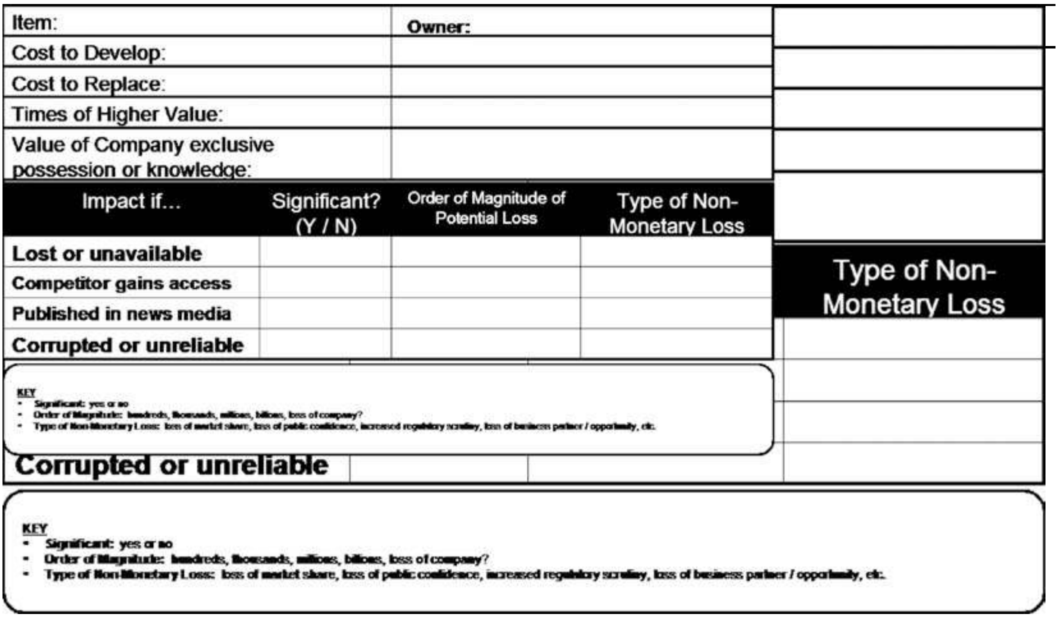
7.4.3.3 Value Information

When acquiring a new company it is important to know which information assets are important and which are not. Some information valuation may already be available from Sarbanes–Oxley or business continuity/disaster recovery work. If valuation information is not available, the IS professional can interview key staff using the general form provided below. When gathering value information, the security professional should keep in mind that each item represents different value to individuals with different perspectives. To illustrate, think about the penny. What is the value of a single penny? The most literal answer is one cent; however, in terms of the value of the its raw materials, the value of the penny varies with the era in which it was made. Since 1962, the composition of the penny is 2.4 percent copper and 97.6 percent zinc. The value of those materials in 2003 was two-tenths of one cent. However, if the penny in question was minted in 1922, its composition is 95 percent copper and 5 percent zinc. Additionally, if the 1922 penny is a 22 Plain from the Denver mint, it is valued at $85,000 if it is in mint condition. A penny may have many different values when viewed from different perspectives.

This same concept can be applied to information assets. What is the value of an information asset? Upon what is the value assessment based? There are several possible factors:

- Cost paid for it
- Cost to develop it
- Cost to recover it
- Potential for loss of market share
- Potential regulatory penalties for loss or corruption
- Potential loss of income if asset is unavailable.

EXHIBIT 7.4 Information Valuation Form



Item:	Owner:		
Cost to Develop:			
Cost to Replace:			
Times of Higher Value:			
Value of Company exclusive possession or knowledge:			
Impact if…	**Significant? (Y / N)**	**Order of Magnitude of Potential Loss**	**Type of Non-Monetary Loss**
Lost or unavailable			
Competitor gains access			
Published in news media			
Corrupted or unreliable			

KEY
- **Significant:** yes or no
- **Order of Magnitude:** hundreds, thousands, millions, billions, loss of company?
- **Type of Non-Monetary Loss:** loss of market share, loss of public confidence, increased regulatory scrutiny, loss of business partner / opportunity, etc.

Type of Non-Monetary Loss

Corrupted or unreliable

KEY
- Significant: yes or no
- Order of Magnitude: hundreds, thousands, millions, billions, loss of company?
- Type of Non-Monetary Loss: loss of market share, loss of public confidence, increased regulatory scrutiny, loss of business partner / opportunity, etc.

Once information assets have been divided into two categories, valuable and not valuable, the IS professional can gather information about the nature of the value of each asset using the form in Exhibit 7.4. It is particularly important to identify all intellectual property, trade secrets, and technology protected by export controls. IS should review all nondisclosure agreements, provided by legal, under which the acquired company must operate.

7.4.3.4 List of Users, Access and Authorization Information

Lists of those authorized to use information assets as well as their permissions and privileges must be made available to IS. The company to be acquired should perform account reconciliations to ensure that all accounts have one (and only one) owner and that all accounts for former users are removed by the day of acquisition. Additionally, an access reconciliation should be performed to ensure that all users have only the access needed for their current positions. Access reconciliation decisions should be made by either the user's manager or the application owner, depending upon the nature of the application.

7.4.3.5 Physical and Technical Vulnerability Assessment

The technical vulnerability assessment is the best understood of these due diligence measures. This is a tools-based evaluation of network- and host-centric vulnerabilities. The Open Source Security Testing Methodology Manual (OSSTM), located at http://www.OSSTMM.org is an excellent reference for the types of testing that might be considered as part of the technical vulnerability assessment. If the company to be acquired has recently performed a technical vulnerability assessment, IS may choose to leverage the results rather than performing an independent test. The decision criteria should be whether an independent examination is necessary.

The physical vulnerability assessment is a critical review of current physical security posture. If physical security is not part of the responsibilities of IS, then IS should partner with the physical security organization and review the IT-relevant portions of their findings. The presence or absence of adequate physical security can lower or raise IS concerns. Badged, accountable access for campus and restricted IT areas are significant components of a defense in-depth strategy. Alarms and video monitoring that cover all ingress and egress points can provide detection of potential breaches and permit post-event investigations. Entrances for nonemployees should be staffed with certified security staff. The security staff should be supplemented with silent alarm capability, local law enforcement drive-throughs for parking lot security, exterior lighting and video surveillance of the grounds and parking lots to reduce crime and the perception that the company is an easy target. This physical security assessment should also evaluate the fire detection and suppression system to determine if expensive changes will be required to bring the target company up to the acquiring company's standards. A reconciliation of the badged access system and physical key management system should be conducted to ensure that, on the day of acquisition, no former contractors or employees will have access.

7.4.3.6 Security Attitude Assessment

A hidden cost of an acquisition can come from the attitudes of the acquired company's user population. IS professionals can take a snapshot of an organization's security attitudes using a unique application of the Information Security Program Maturity Grid (see Exhibit 7.5, Part 1 and Part 2), described in a 1996 article by Timothy Stacey in Information Systems Security magazine. The grid is an adaptation for security of Philip Crosby's Quality Management Grid.

By distributing the grid to a sample of the user population and asking them to check the box in each row that best describes their attitude about security, an insight into the nature of security awareness training that will be required can be gained. Attitudes on the left side of the grid indicate that a great deal of awareness training and education will be required to gain acceptance for security measures.

The security professional can gain further utility from the grid by including checkboxes that permit individuals to mark whether they are end users, line managers, executive management, IT Staff or Security/Audit Staff. Including these indicators will give security professionals insights into the security attitudes of key groups within an organization. These insights can also be mapped to areas of the security awareness training and education programs that need to be addressed or emphasized.

7.4.3.7 Analyze and Report

The analysis and reports described in Exhibit 7.6, from the due diligence and planning phases will be used to produce the following reports.

7.4.3.8 Plan Transition Projects

To provide day-one connectivity, transition projects must be conducted at the acquired and acquiring companies. In the target company, the transition projects revolve around providing data needed for day of acquisition actions and projects to meet the security requirements that are a condition for day-one connectivity. These projects might include the completion of requests made during due diligence, such as the reconciliation efforts.

In the acquiring company, the transition projects are needed to support the new connectivity and the new systems. Some example tasks include making arrangements with external DNS providers to change contact information, transferring ownership of the domains, and changing mx records, IP addresses, etc., as required to support the day-one transition. The decision as to which records need to be changed on day one is part of the transition planning. Changing the external mx records would permit the acquiring company to have all email routed through the same external processing engine, where virus checking, spam filtering, and content monitoring can take place. Content monitoring is essential if the acquiring company is concerned about the potential loss of intellectual property during acquisition. In one of the examples in the introduction, it was necessary to move the connection to the Internet from the acquired company's firewall to the acquiring company's firewall. This was accomplished by changing the external DNS record and, on day one, physically shutting down the acquired company's firewall. This decision was driven by the hostile nature of the takeover, the risk associated with terminating the administrator of the firewall, and the fact that no one in the acquiring company had any experience with the brand of firewall used by the target company.

EXHIBIT 7.5 Information Security Maturity Grid

Measurement Categories	Stage I: Uncertainty	Stage II: Awakening	Stage III: Enlightenment	Stage IV: Wisdom	Stage V: Benevolence
			Part 1		
Management understanding and attitude	No comprehension of information security engineering as a protection mechanism. Tend to blame external forces (i.e., hackers, disgruntled employees, unreliability, equipment, etc.)	Recognizing that information security engineering may be of value but not willing to provide money or time to make it all happen. Rely on vendor supplied, “built-in” security	While going through security awareness training, learn more about information security engineering; becoming supportive, but provide only limited resources	Participating understanding absolutes of information security engineering. Making informed policy decisions	Consider information security engineering an essential part of the organization’s internal protection mechanisms. Provide adequate resources and fully support the computer security program
Security organization status	Information security engineering is decentralized, hidden in the line organization(s). Emphasis is on incident reporting	An organizational information security officer is appointed (but does not necessarily report to top management). Main emphasis is on centralized collection of incident reports and responding after-the-fact	The information security officer reports to top management. Information security officer develops corporate information security policy and implements an information security training program	Information security officer has an established infrastructure and adequate interfaces to other organizations (i.e., line management, product assurance, purchasing, etc.) for effective implementation of the security program	Information security officer regularly meets with top management. Prevention is the main concern. Security is a thought leader. Involved with consumer affairs and special assignments
Incident handling	Security incidents are addressed after they occur; recovery rather than a prevention strategy. Procedures for recovery are weak or nonexistant. Crisis management. Lots of yelling and accusations	Major security threats, based only on past security in Exhibit 7.1. Information security and maturity gridcidents are addressed. Procedures in place only for those frequently occurring crises	Formal reporting procedure. Reportable incidents are identified. An information security strategy is developed based on the past incidents and upon analysis of the threat population and the vulnerabilities of the assets	Threats are continually re-evaluated based on the continually changing threat population and on the security incidents. All security safeguards are open to suggestion and improvement. Legal actions are prescribed for each type of incident. Protected reporting chain.	Most incidents are reported. Causes are determined and corrective actions are prescribed and monitored. Incident data feeds back into risk management. Protected response chain

Part 2

Security economics	Prevention: none to minimal	Prevention: minimal plus waste on the wrong or incomplete safeguards supplied by vendors touting their "built-in" security	Prevention: initially managed and justified, but funding tends to be reduced through time as complacency sets in, if risks are not reassessed	Prevention: managed and continually justified due to reduced losses	Prevention: justified and reduced through its contribution to marketing
	Loss: unmanaged and unpredictable. Corporate mission could unknowingly be jeopardized	Loss: mismanaged and unpredictable, especially when loses do not follow the historical trend	Loss: managed through a baseline cost/benefit trade-off study (i.e., risk analysis)	Loss: managed through continual cost/benefit trade-offs (i.e., risk analysis) tied to change management system	Loss: minimal
Security improvement actions	No organized security awareness activities. No understanding of information security engineering and of risk reduction activities	The organizational information security officer attempts to assist organizations that have experienced security compromises. End-users view security restrictions as an "unnecessary hindrance." Security improved by mandate	Due to the thorough awareness and security training program, end users are more vigilant and tend to initiate more incident reports. End-users view security restrictions as "necessary." Management understands the "business case" for security. Information security engineering activities limited to training, risk analysis, risk reduction initiatives, and audits	Information security engineering research activities are initiated to keep up with the rapidly changing environment. Security awareness expanded to security training	Information security engineering activities (i.e., risk analysis, risk reduction initiatives, audits, research, etc.) are normal and continual activities. Desirable security improvement suggestions come from end-users and system owners
Summation of company information security posture	"We don't know why we have problems with information security" or "We don't have any information security problems."	"Is it absolutely necessary to always have problems with security?"	"Through management commitment and information security engineering improvement, we are identifying, prioritizing, and protecting our assets." or "We are actively looking for solutions to our security problems."	"Asset protection is a routine part of our operation." or "We know what to protect from what and we know what is most important to us."	"We know why we have secure systems." or "We know and understand our security systems and their interdependencies."

EXHIBIT 7.6 Due Diligence Analysis and Reports

Report of the nature of day-one connectivity	The nature of day-one connectivity is driven by two primary forces: (1) business need and (2) the security posture of the acquired company on day one
Security requirements for day one	This report describes the security requirements that must be met to provide day-one connectivity
Report of the nature of permanent connectivity	Because some security requirements may take longer to implement, a second phase of connectivity would provide the remaining connectivity. Permanent connectivity is not necessarily full connectivity. For example, a commodities trading company that also produces and some of the commodities it trades must maintain a "Chinese wall" between these two business units. This report describes the nature of connectivity in its final planned form
Security requirements for permanent connectivity	Describes the conditions and security requirements that must be met to provide permanent connectivity

For each project, management, IS, HR, and legal must determine if the project should be completed before, during, or after day one. The transition tasks include:

- Planning actions required on the day of merger or acquisition
- Conducting pre-merger or pre-acquisition projects
- Validating conditions have been met for initial connection
- Training team for day of merger or acquisition.

7.4.3.9 Planning Day of Merger or Acquisition Actions

The day of merger or acquisition will be a long day and detailed planning is essential to its success. The order of events will probably be dictated by HR. If there are layoffs involved, then the timing of actions is critical. Changing or disabling access should be coordinated to coincide with HR's notification of employees about their status. For individuals subject to layoff, no actions should take place prior to notification. After notification, the actions to terminate access should be completed prior to the individuals gathering their belongings. Some companies take the precaution of having someone gather the individuals' belongings during the notification.

It is important to remember to welcome and engage the retained members of the acquired company's staff. Each business area (including IT) involved in the acquisition will need to welcome its new members, listen to their concerns, answer their questions, lay out plans for the future, and provide the new members of the team with instructions on what to do if they are contacted by former employees seeking information. Retained staff must be assured that those who were not retained were treated fairly.

If a name change is part of the acquisition, then plans should be made to give the retained staff something with the new name—shirts, hats, etc. Although this is likely an HR initiative, IS will benefit if it is performed. This will begin the process of building the new team identity and reduce some resistance—and with it, the potential for latent hostile reactions.

Retained employees should be given a modified new employee security awareness briefing. The modifications will stress differences in policies, procedures, and acceptable use, if any, and will cover layoff-related concerns if appropriate.

Retained staff should be informed which policies and procedures to follow from the day of acquisition forward. Policy and procedures gathered during due diligence should be examined and analyzed so that this direction can be given on the day of acquisition. Policies are easier to exchange than procedures. It may be necessary to retain some day-to-day procedures until they can either be adapted or replaced by new procedures that comply with the acquiring company's policies.

If the acquisition does include layoffs, then it is likely that some of the acquired company's IT staff will also be laid-off. If any of the laid-off IT staff had access to root accounts, then the affected root passwords must be changed. If this is a more equal merger, then both companies usually conduct their layoffs prior to the day of acquisition.

Complex configuration changes should be prepared in advance in a manner that permits a single action to move pre-configured and tested changes into operation. For example, if the day of acquisition events include changes to the firewall, the changes should be set up as a complete set of firewall rules that will replace the existing rules at the appropriate time. This is opposed to editing the current firewall rules in real-time on the day of acquisition. Monitoring systems for IT and IS will need to be reconfigured to permit monitoring by the acquiring company's staff.

One rationale for having two phases of connectivity is to provide some isolation between the companies until sufficient time has passed for latent hostile reactions to the acquisition to manifest. While some connectivity is essential during the first phase of connectivity, increased monitoring vigilence is prudent. After a sufficient time has passed without significant concerns being raised (~30–90 days), then the permanent connectivity can be implemented if the prescribed security requirements for permanent connectivity have been met.

7.4.3.10 Conduct Pre-Merger or Pre-Acquisition Projects

In the course of the previous activities, many projects will be identified that need to be completed prior to the day of acquisition or that need to be ready to execute on that day. IS will have a project management responsibility for ensuring that their pre-acquisition projects complete successfully and on schedule.

7.4.3.11 Validate Conditions Have Been Met for Initial Connection

When the security requirements for day-one connectivity are defined, IS needs to establish a date by which the requirements must be met. The date should be set far enough in advance of day one that management has sufficient time to react if they are not met. The means of validation should be established at the same time the requirement is defined.

7.4.3.12 Train the Team for Day of Merger or Acquisition

Mistakes made on the day of acquisition can have significant consequences, including negation of the value of the acquisition. Some of these risks can be mitigated by providing training for the team that will be involved onsite for the day of acquisition.

HR, legal, and physical security should provide briefings to the team on:

- Preserving dignity and handling emotional responses
- Topics that should not be discussed with employees or contractors of the target company
- Who should handle questions about designated sensitive topics
- Issues of law and restrictions that must be observed on day one
- Handling violence, the threat of violence, and suspicion of the potential for violence.

If the acquisition crosses international boundaries, the acquiring company should provide cultural behavior briefings and native language "take me to my hotel/office" cards. The cultural briefings should cover key behaviors that are permitted in our culture that other cultures would find unacceptable or illegal. For example, a member of U.S. Military assigned for 30 days in Riyadh, Saudi Arabia was arrested when he went jogging outside U.S. compound. In Saudi Arabia, dressing only in jogging shorts and a T-shirt was considered indecent exposure. Training should also cover behaviors in business dealings that would be contrary to the acquiring company employee's expectations. For example, in many cultures it is not acceptable to tell your superior, "No." Managers, therefore need to be able to tell the difference between "Yes" and "Not yes."

From the IS perspective, the day-one team should be reminded that the list and schedule of access changes, like the list of who is to be retained and who is to be terminated, is very sensitive. The team should be told how to report suspected security incidents when onsite for day one. On this day, the normal help desk or security incident hot lines will not reach security staff onsite unless the process is modified for the event. Using the normal process may not be desireable for a number of reasons. The team needs to know what protocol to use instead.

The acquisition team leadership should provide clear guidance about the types of tasks that can be performed by the target company's staff and what should be handled only by the acquiring company's transition team.

7.5 Day of Merger or Acquisition Actions

All activities on the actual day of acquisition should be focused on executing the plan. If pre-acquisition planning has been sufficient, there will be few occasions that require ad hoc or arbitrary decisions.

7.5.1 Execute Access Control Project

The access control project, timed and coordinated with the HR notification process, is the first priority. IS will benefit if HR processes the target company's IT staff very early in the schedule. Password changes and deploying internal connectivity to the acquiring company must wait until after this occurs. As described above, IT should be advised by HR when an individual has entered the notification room. IT should begin taking the actions that have been pre-scripted for that individual's access. For individuals who are not being retained, HR should require them to sign a document prepared by legal which, among other concerns, makes their severance payment contingent upon honoring the terms of an intellectual property agreement.

Prior to initial connectivity, IS and IT staff must construct and deploy a Chinese wall if required for intellectual property litigation protection or if required by regulation.

7.5.2 Deploy and Test Initial Connection

Once IT notification is complete, the initial connection between the two companies can be deployed and tested. To the greatest extent possible, the changes should be packaged in a way that permits the entire set of changes for a system to be enabled at once. For a system such as a firewall, a safe approach to deployment would be to disconnect all cables from the internal interface, save the existing ruleset, execute a script that replaces the existing ruleset with the new pre-tested ruleset, change any other system configuration items, and then restart the firewall. Once restarted, the new ruleset can be tested to ensure that basic connectivity is restored and that the new ruleset functions as expected. If the tests are successful, then the internal interface can be reconnected.

This same cautious approach can be used for other changes to other systems required on day one.

7.5.3 Brief New Users on Awareness, Policy, and Merger and Acquisition Special Topics

As the notification process is completed all newly acquired users can be given the awareness presentation describe above.

7.5.4 Extended Monitoring

The monitoring process should be deployed as soon as possible upon arrival on-site for day one. to protect intellectual property and trade secrets as well as to protect the newly merged entity. The monitoring should include Internet and email content monitoring for key phrases related to intellectual property concerns or anything that could affect the value of the acquisition.

7.6 Post-Merger/Acquisition Phase

The post-merger or acquisition phase begins on the second day and continues until all merger or acquisition activities are complete. In mergers or acquisitions where IT and IS are not full participants, the IT aspects are often neglected. After a few acquisitions, IT service becomes expensive and the quality of service is reduced due to the complexity that grows when IT accumulates multiple platforms, operating systems, programming languages and applications. Add various versions and patch levels of each of the above and the quality of service drops significantly. Trying to keep maintenance contracts on all the diverse systems becomes very expensive, to the point where some companies begin dropping maintenance contracts to keep up the critical systems. Trying to maintain these diverse baselines increases the potential that one or more systems will have critical vulnerabilities that can be exploited.

The goal of the post-acquisition phase is to bring closure to the acquisition process and resume normal day-to-day operations.

7.6.1 Begin Permanent Connectivity Projects

The permanent connectivity projects are those that are required before the full, planned connectivity can be deployed. In addition to meeting the security requirements, IS and management need to agree that the potential for hostile reaction to the acquisition is negligible.

These projects may include re-IPing subnets that duplicate those in the acquiring company, merging internal DNS files, converting both companies to common anti-virus, anti-spyware, spam detection solutions, etc. It could also involve removing some legacy firewall open ports, establishing change control for critical systems, etc.

For each project, IS should establish a project with identified tasks, resources, and dates. IS should be responsible for tracking and ensuring that security-related projects are completed successfully and on time.

7.6.2 Conduct Post-Merger or Acquisition Projects

There are also post-acquisition projects that are not related to conditions for permanent connectivity. For example, the acquiring company may want to convert the acquired company to use the same physical access badging or video surveillance system. The acquiring company may also decide to consolidate maintenance contracts, lease agreements, or re-IP other subnets so that Class B or C addresses can be surrendered.

7.6.3 Validate Conditions Have Been Met for Permanent Connection

On the scheduled date, IS should formally review the results of projects that were intended to meet the conditions for permanent connection. IS should use a scorecard showing conditions that are met as they occur, to ensure that the projects to meet these conditions are being worked upon consistently throughout the project period rather than just in a rush when the projects are due. One primary condition is that, for every new port opened on the firewall, IS should establish an accountable owner who can make decisions regarding the port, such as who can use the port, or whether the port needs to remain an active open port.

7.6.4 Deploy and Test Permanent Connection Configuration

Once the conditions for permanent connectivity have been met, management and security can determine if or when sufficient time has transpired to cool and latent hostilities towards the acquisition. Similar to the process for day one, these changes should be pre-configured and tested before rolling out in the production environment. Following the same kind of process for day one, the changes should be carefully rolled out and tested before permitting permanent two-way traffic between the companies.

7.6.5 Continue Extended Monitoring for X Months

Following the deployment of permanent connection, IS should continue extended monitoring for some period of time set by security and management to ensure that the new connectivity has not opened targets for a patient adversary.

7.6.6 Merger/Acquisition Project Completion

This is the wrap-up portion of the acquisition project.

7.6.7 Normal Monitoring Begins

In this phase, extended monitoring ends and normal operations begins.

7.6.8 Gather and Record Lessons Learned

No acquisition or merger goes exactly as planned. If a company intends to do more acquisitions, it is prudent to document what worked and what did not, so as to not repeat the mistakes of the past and to benefit from past experience. Once lessons learned have been gathered and documented from all involved parties, then the acquisition is considered complete.

7.6.9 Merger/Acquisition Complete

A formal end of the acquisition can be declared, thus giving closure and focus to all task related to the acquisition.

7.7 Conclusion

This chapter seeks to make the case that IS should be included in the due diligence phase of mergers and acquisitions. The chapter describes the processes needed from the discovery phase through the completion of acquisition. Finally, a sample policy is provided that can be used by information security professionals to implement this capability.

8

Information Security Governance

Ralph Spencer Poore

> Governance: (1) government; exercise of authority; control; (2) a method or system of government or management.—*Random House Webster's Unabridged Dictionary*

8.1 Corporate Governance

Before describing information security governance, we need at least an overview of corporate governance as a context. Fundamentally, corporate governance concerns the means by which managers are held accountable to stakeholders (e.g., investors, employees, society) for the use of assets and by which the firm's directors and managers act in the interests of the firm and these stakeholders. Corporate governance specifies the relationships between, and the distribution of rights and responsibilities among, the four main groups of participants in a corporate body:

- Board of directors
- Managers
- Workers
- Shareholders or owners

The edifice of corporate governance comprises the national laws governing the formation of corporate bodies, the bylaws established by the corporate body itself, and the organizational structure of the corporate body. The objective of corporate governance is to describe the rules and procedures for making decisions regarding corporate affairs, to provide the structure through which the corporate objectives are set, to provide a means of achieving the set objectives, and to monitor the corporate performance against the set objectives.

The Committee of Sponsoring Organizations (COSO) of the Treadway Commission created a governance document entitled *Internal Control–Integrated Framework*. Originally published in 1985 and subsequently updated, this document provides a controls-based foundation for corporate governance. COSO also created additional guidance for boards of directors, executives, and other stakeholders that includes enterprise risk management guidelines. A comprehensive understanding of business risks is fundamental to proper governance.

Enron, Tyco, WorldCom, and Arthur Andersen are well-recognized examples of failed corporate governance, instances where the stakeholders were not well served. (For a longer list, see http://www.mywiseowl.com/articles/Accounting_scandals.) As a result of these high-visibility failures of voluntary corporate governance, new laws (e.g., the Sarbanes–Oxley Act of 2002 [107 H.R. 3763], signed into law on July 30, 2002) and regulations have raised the bar on corporate governance.

8.2 Information Technology Governance

Well before these scandals, however, we recognized the need for information technology (IT) governance within the context of corporate governance. The IT Governance Institute, a not-for-profit organization founded in 1998, grew from earlier efforts to identify structures and controls for information technology governance. Two important early reports, the 1992 Cadbury Report (*Report of the Committee on the Financial Aspects of Corporate Governance*) and the 1999 Turnbull Report (*Internal Control: Guidance for Directors on the Combined Code*), were influential in the maturation of IT governance. At its core, IT governance is concerned with two things:

- Delivery of value to the business
- Mitigation of information technology risks

Information technology governance plays an important role in information security governance, but the two are not congruent. IT governance addresses the application of technology to business problems and how and to what degree this application provides value to the business. Often, the efficiency of delivery of business applications and the choice of information technologies are in opposition to effective, efficient information security. For example, the accelerated deployment of off-the-shelf wireless networks running Web-based applications produced through rapid prototyping may permit IT to deploy a system that delivers value to the business but does not ensure confidentiality. We could argue that the IT governance requirement of “mitigation of information technology risks” is not met here. However, in practice, this concept reflects more the ideas of mean time between failures, technology obsolescence, and flexibility—issues of the technology rather than of the information itself.

8.3 Information Security Governance

Information has become many corporations’ most valuable asset. While human resources departments will doubtlessly argue that employees are the most valuable asset, few companies intentionally downsize their information assets or surrender them to other companies and remain in business. Information assets are bought and sold, used to generate capital, protect a company from personnel turnover, and provide competitive advantage. The information asset may also become a liability with negative value exceeding the investment the company had in it (for example, when a release of information constitutes a massive breach of privacy). Because the primary purpose of any governance within a corporation is to hold management accountable to the corporate stakeholders, information security governance must have as its primary purpose the process of holding management accountable for the protection and ethical use of information assets.

Whether information security governance is congruent with IT security governance is perhaps a matter of definition. The Information Systems Audit and Control Association (ISACA) organization published a document, *Information Security Governance: Guidance for Boards of Directors and Executive Management*, that makes no distinction. This author, however, views information security governance to be a superset with IT security governance a subset.

The central issue with information security governance is whether information security is essentially an information technology or whether information technology is essentially only one arena in which information security plays an important role. Part of this debate depends on the true nature and role of the chief information officer (CIO). Where the CIO is an executive responsible for information systems technology (i.e., effectively the manager over computers and computer applications), then the CIO lacks the scope necessary for information security governance. Exhibit 8.1 illustrates this point. Although Exhibit 8.1 depicts the more common role of CIO, it also depicts the more progressive role for the chief information security officer (CISO). The role of the CISO (often as only a subordinate manager) reflects a serious governance problem when the position reports through the CIO and the CIO's role is limited to automated systems. The CIO's role as a function of job description and formal policy may differ from the CIO's role in practice. A CIO wholly aligned with technology and rewarded on that basis will not act as the steward of the organization's overall information assets, regardless of the title.

Exhibit 8.2 presents the CIO as responsible for the information asset regardless of how it is processed. In this case, the CISO may legitimately report to the CIO without harm to information security governance. The reader will note that the CIO is responsible for paper records (i.e., manual information processing as well as automated information processing). Here, the information asset, not just the technology, is the scope of the CIO role. The CIO has responsibility for both information security and IT governance.

Organizational structure plays a significant role in governance. In addition to the accountability inherent in line reporting, matrices and other "dotted line" reporting structures can provide important means for keeping executive management informed and for keeping other organizational elements accountable for information security practices. Exhibit 8.3 depicts a more complex organizational structure supporting information security governance. In the example shown in Exhibit 8.3, information security reports directly through risk management, an organization that might include insurance, physical security, and investigations. Information security also has a dotted line reporting through the

CIO, who in this example has responsibility for all information assets. Further, as part of risk management, an additional reporting occurs to the audit committee of the board of directors. Such integral reporting assures, at least structurally, the best opportunity for successful information security governance.

Beyond organizational structure, information security governance requires metrics and means to monitor them. Traditional metrics, such as return on investment (ROI) and budget compliance, may prove problematic for several reasons. First, ROI requires an understanding of the investment made in information security and a method for capturing meaningful financial results (loss or gain) from such investment. Although information valuation techniques (e.g., as described in the *Guideline for Information Valuation*) may provide a valid basis for doing this—especially in conjunction with a quantitative risk assessment—this remains a daunting task. Second, managing to a budget is only proper information security governance if the budget reflects the organization's true requirements. Just as in IT governance, staying within budget is no assurance of delivering value to the business and mitigating risks. Similarly, going over budget does not indicate a failure to deliver value or to properly mitigate risk. Other metrics, such as the number of persons trained in security awareness, reduction in fraud losses, reduction in audit findings, and reduction in security incidents (e.g., computer viruses, reported unauthorized data releases), may better represent the effectiveness of the information security program.

Prioritization is a major function of good governance. An organization's resources are always limited. Determining priorities among the worthy potential investments a company must make is an act of

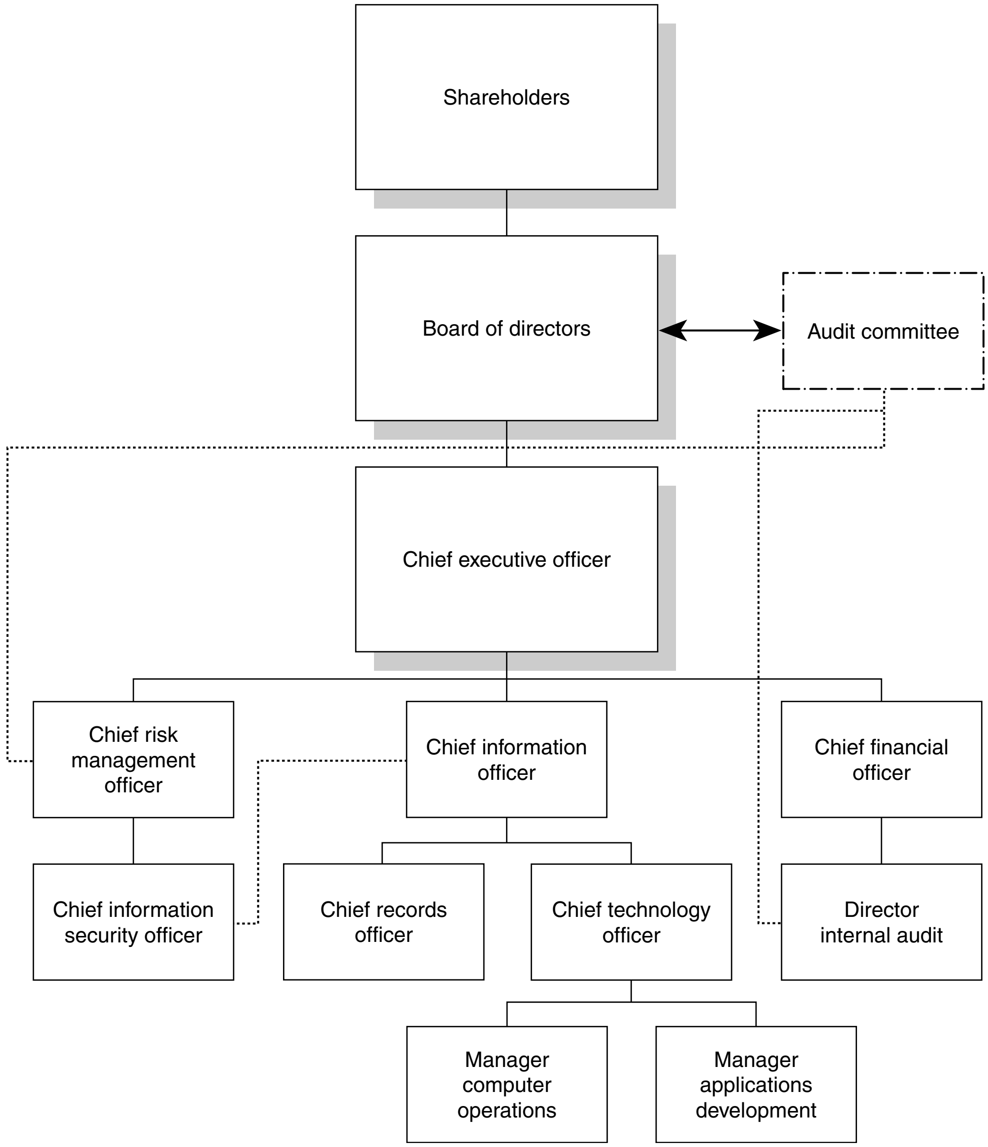

EXHIBIT 8.3 Complex information security governance organization.

governance. Although the creation of budgets inherently reflects these decisions (at some level), the political process associated with budgeting does not automatically support good governance. Information security governance is effectively infrastructure—essential to the success and survival of the company but not always clearly associated with profitability (except, perhaps, when it fails and wipes out profits). Information security is rarely a profit center with its own profit and loss. One way of participating in prioritization is to establish a committee with representatives from all business units and ask this committee to assign priorities. The process of educating the members on the need, impacts, costs, and benefits of information security and the process of listening to the business area needs are mutually instructive. The meetings should have formal minutes with action items. The documented consensus of the committee provides executive management with evidence of proper diligence and provides the basis for cooperation essential to any successful information security program.

Additional natural allies in information security governance include the corporate ethics program (generally included in corporate governance), regulatory compliance programs, privacy programs, and internal audit. A company's information security governance should include liaison roles with each of these organizational elements or programs.

8.4 Pitfalls in Information Security Governance

Politics is unavoidable. Many organizations have serious structural problems that make information security governance difficult or infeasible. As discussed earlier, if the information security function is organizationally buried within IT, an emphasis will be placed on administration of security technology, and information security overall will go unaddressed. However, independent reporting (e.g., reporting as a peer of the CIO) is no assurance that information security governance will provide an effective information security program. Political influence, the informal organization, may neutralize the formal structure that otherwise supports good information security governance. Effective information security must impact behavior. Depending on how entrenched poor security practices are, much inertia may have to be overcome. When the resources needed for these changes exist in other organizational budgets (e.g., the CIO's budget), success will require cooperative endeavors and political skill. Unless one's peers have a stake in the success of information security, formal information security governance may fall victim to informal organizational machinations.

8.5 Conclusion

Information security governance is an essential element in overall corporate governance. With laws at state and federal levels holding management and directors responsible for ethical conduct and accountable for proper use and protection of company assets, information security governance may have come of age. Good governance requires proper organizational structure, cross-enterprise cooperation, well-chosen metrics, and resource prioritization.

Belts and Suspenders: Diversity in Information Technology Security

Jeffrey Davis

Diversity in information security is a practice that can greatly improve the security of an organization's information assets. Using different techniques and controls can multiply the effectiveness of security controls in an increasingly diverse risk environment. Using overlapping controls can also provide redundancy that is important if a control should fail. Information technology security controls and response processes address different areas within an environment. These include network controls, operating system controls, and application level controls, as well as monitoring and responses to security events. Attention must also be paid to the coverage of the different controls, as the failure to provide protection for one piece of the application or service may lead to compromise of other areas. Providing adequate protection for all the pieces of an application will ensure its proper functioning and reduce the risk of its being compromised. It is also possible for one control to provide overlapping protection for other areas. Maximizing the overlapping protection and providing diversity within each one of these controls and processes are important to minimizing the risk of a security failure with regard to the information or services being protected. In addition, response and monitoring processes must also be able to address incidents and provide solutions in a timely manner. These controls and processes can also take advantage of diversity to reduce the risk of a single point of failure. Together, these controls and processes work to provide confidentiality, integrity, and availability of the information or service being secured.

9.1 Network Control Diversity

Controls can be classified into two basic types: preventive and detective. Preventive network controls prevent or block malicious network traffic, and detective network controls monitor the network for suspicious or malicious traffic that may require a response. One major function of preventive network controls is to allow only traffic necessary for the service to function. One way this can be accomplished is by using a firewall with access rules to control the network traffic. A way to provide diversity in this control is to implement the restriction not only via the firewall but also via access control lists on the routers that route the traffic within the network. This provides protection if the firewall is compromised or is bypassed maliciously. It can also provide a backup if a mistake is made in configuring the firewall. A drawback to this practice is that it does introduce an administrative burden and can make troubleshooting more difficult, and it is necessary to administer network access in more than one place.

Another method of providing diversity in network controls is to use multiple firewalls from different vendors. Various vendors may use different methods of implementing the control. This can prevent a weakness in one vendor's firewall from being exploited to bypass the network control it is implementing. If required, this can also be used to provide some separation of duties. This can be accomplished by having two different groups responsible for the administration of each firewall. If a change is required, it will require actions from both groups to be implemented.

Another security control used on a network is a network intrusion detection system. This is a detective type of control that is used to monitor the network for malicious traffic. The traffic is compared to signatures of known network attacks, and when a match is detected an alert is raised and some action may be taken. In some cases, an automated action may be taken to adjust an existing network control, like a firewall or router, to block any further traffic from getting to the target system. Another action may be to reset any resulting connection between the source of the traffic and the destination. If an automated action is not taken, then an appropriate incident response process should be in place to react to the alert and determine if any action is required. This control can complement other controls making their effectiveness visible. As a detective control, it can also be used to determine when another control has failed. This could be indicated by the presence of traffic that should not be there, such as an outbound connection attempt from a server in a protected network zone.

Network intrusion detection can also be implemented in a diversified fashion by using different types of vendors who employ various methods of detecting malicious traffic. In addition, most implementations use a list of traffic signatures that are known to be malicious. This signature list will vary in correctness and completeness. The correctness of the list is important in that, if a signature is not correct, it may result in generating false detection of the traffic or it may miss some malicious traffic completely. Utilizing multiple solutions will provide some protection against this. Some network intrusion detection prevention systems will also use heuristics or other methods to guess if particular network traffic may be malicious in nature. These implementations are vendor specific, and utilizing more than one vendor can also provide more assurance that the traffic that is identified as being malicious is a true indication of a problem.

Another type of network control is a network intrusion prevention device. This is a combination of a preventive control and a detective control. This type of control not only looks for known malicious network traffic but can also prevent it from reaching the system it is intended to attack. This is especially useful for single packet attacks or attacks that do not require a complete TCP handshake. This control is usually implemented as an inline device in the network. This means that all network traffic will flow through the device, and it can be configured to discard any traffic it considers malicious. These devices are similar to network intrusion devices in that they utilize a list of signatures of malicious traffic that is compared to the traffic flowing across the link they are monitoring. As with the network intrusion devices, it can be helpful to utilize multiple vendors in order to ensure the correctness of the signature list and any method of heuristics. In addition, because the device is usually implemented inline, it is important to consider redundancy in order to reduce the risk of an outage due to a single point of failure.

One other network control is the use of a host-based firewall. This is a firewall that is implemented directly on the system providing the application or service. This firewall limits connectivity to services on the system and can provide that protection if other network controls fail. One disadvantage of a host-based firewall is that it depends on the host to actually implement and control the rule set. If the host is compromised, then the firewall rules can be modified to bypass the controls, as has been demonstrated by a number of viruses. When the virus has infected a system, it has disabled the firewall controls to provide further access to the infected host or to allow the continued spread of the virus. Timely management of these firewalls is also important for them to be successful at mitigating attacks. To be effective in an enterprise setting, these firewalls should be centrally controlled. If they are centrally controlled, then the enterprise can react more quickly to new threats by adjusting the network access rules on the hosts to block malicious traffic. A host-based firewall can augment network controls and provide redundant control of network traffic.

One other important process in securing a system is running periodic vulnerability scans using a network vulnerability scanner. These are used to identify vulnerabilities that could be used to compromise a host or application. If it is necessary to secure a large enterprise, running a network vulnerability scan is one of the most effective ways of ensuring that the system has been kept up to date with patches. One way to increase this effectiveness is to use more then one scanner. Vulnerability scanners test for the presence of a vulnerability in different ways. Some will attempt to actually exploit the vulnerability, and others will simply determines that a vulnerability may exist by checking the version level in the software. Still others may just indicate the possibility that a system is vulnerable and might require further investigation to see if a vulnerability actually exists. The scanners will have to be periodically updated to reflect any new vulnerabilities that have been discovered. This is also where utilizing more then one scanner will be of benefit as some vendors may keep there software more current than others.

Another important tool for securing networks is the use of encryption technologies. Encryption is used to provide protection against eavesdropping by third parties by encrypting the traffic using an encryption algorithm. Encryption along with hashing algorithms can also be used to authenticate the traffic between two network connections. Two types of encryption algorithms are utilized to encrypt network traffic: symmetric and asymmetric. Symmetric algorithms use a shared key that is known to both parties to encrypt the traffic. They are much faster and require fewer computing resources than asymmetric algorithms. Algorithms of this type include the Advanced Encryption Standard (AES) and Triple-DES (formed from the Data Encryption Standard). An important factor in the implementation of symmetric encryption is the size of the shared keys that are being used. The size of this key determines the key space or range of values that the key can have. The size of the key space is an important factor in determining the strength of the implementation of an encryption system. One type of attack, called a brute force attack, attempts to decrypt the encrypted data by trying every possible key value in the key space. Larger key sizes are used to provide more protection against these attacks. It is important that the key space be of sufficient size so the amount of time and resources required to attempt all of the keys in the key space is large enough to make it impractical to try.

The second type of encryption algorithms is asymmetric, also known as public/private key encryption. These types of algorithms use two related keys. One key is private and must be kept secret, and the second key is public and can be distributed freely. Any data encrypted with one of the keys can only be decrypted using the other related key. Examples of these types of algorithms include RSA (named for its developers, R. L. Rivest, A. Shimir, and L. Adleman), Diffie–Hellman, and ElGamal. Asymmetric algorithms generally are used to provide key exchange and authentication functions for protocols such as Internet Protocol Security (IPSec) and Secure Sockets Layer (SSL). When an asymmetric algorithm has been used to pass a shared or session key between the connecting parties, then a more efficient symmetric algorithm can be used to encrypt the traffic. In addition to encrypting the data being passed between two parties, encryption can also be used to provide authentication between them. This is important to prevent a man-in-the-middle attack. A man-in-the-middle attack occurs when a third party is able to intercept traffic between two parties and is able to read or modify the traffic without the knowledge of either communicating party. Protection against this attack requires the ability to verify the identity of the source of the traffic and the ability to verify that it has not been modified. This is done by using encryption in combination with hashing algorithms.

Some commonly used algorithms include Message Digest 5 (MD5) and Secure Hashing Algorithm Version 1 (SHA1). These hashing algorithms take data as an input and output a message digest that by design of the hashing algorithm is unique for that particular input. This output can then be encrypted using the private key of a public/private key algorithm to form a digital signature. This allows the verification of the source of the data and that it has not been modified while in transit. Encryption controls and hashing algorithms have been found to have a number of weaknesses. One problem that has occurred in the past is the discovery of a mathematical weakness in an algorithm that is being utilized. One example of this is the Message Digest 2 (MD2) hashing algorithm. This algorithm was shown to be vulnerable to mathematical attacks that could allow two different inputs to produce the same hash result. When this weakness was discovered, the hashing algorithm could no longer be considered a secure one. To protect against a possible mathematical weakness in a specific algorithm, various algorithms can be utilized in different parts of the network. Client-to-Web network communications using SSL can use one algorithm, and server-to-server IPSec traffic can use a different one. Another technique is to encrypt the traffic first using an encryption system employing one algorithm and then encrypt the encrypted traffic again using a different algorithm. This technique is referred to as super-encryption. One example of super-encryption is using SSL over an IPSec virtual private network (VPN). The network traffic is first encrypted by the SSL implementation and is then encrypted by the IPSec implementation, thereby double encrypting the data. Utilizing more then one encryption algorithm reduces the risk of a weakness in a flawed algorithm that could compromise the security of an application.

Another problem that can occur with the use of encryption is in the actual implementation of the algorithm within a protocol. Protocols such as SSL use a random function to create a session key to encrypt the data. If the method used to generate that random key is flawed, it may be possible to guess the key or to reduce it down to a range of keys that can then be subject to a brute force attack that could succeed in a practical amount of time. Again, using various implementations that utilize different techniques will reduce the risk of a flawed implementation compromising an entire application. Another weakness in encryption systems can be in the mechanism used to protect the encryption keys. The most prevalent mechanism for protecting the key is to use a password scheme to encrypt the key and then storing it on the machine performing the encryption. In order to use the encryption key, the operator must supply the password to decrypt the key. A potential problem with this approach is that the password being used to protect the key may not be sufficiently complex. It could be subject to a guessing or dictionary attack, which uses lists of words to attempt to guess a password. It could also be intercepted and recorded by an attacker who has access to the machine on which it is used. To protect against this, complex passwords should be used, and every system should utilize a different password, so if one of the passwords is compromised then any potential damage will be limited only to that system.

Another mechanism for storing an encryption key is through the use of a smart card. This credit-card-sized card contains a chip that provides some protected storage and some simple encryption/decryption functions. It is also designed to be tamper resistant to protect against attempts to extract the information, even with physical access. When used to store encryption keys, a smart card can store the key and not allow it to be accessed unless a personal identification number (PIN) is supplied. This provides a much greater level of security as an attacker would have to have access to both the card and the PIN in order to compromise the encryption key. Using a combination of passwords and smart cards provides diversity in an encryption systems and lessens the risk of a failure in any part of the system leading to complete failure of the application.

These network controls can also complement other controls. Many major threats originate over the network, and good network controls can reduce the risk of the compromise of a system. If an operating system or application has a particular vulnerability to a network-based service, the network control can be adjusted to reduce or even eliminate the threat until an operating system or application can be patched or reconfigured. This is important, as the patching of these systems may take a long time and may require modification of the applications that are being run. Because the control is being implemented at the network, it can be implemented relatively quickly and provide protection against the threat. In addition, it is good security practice to allow only network traffic that is necessary to run the application or service to minimize the impact of new threats. Detective-type controls, such as network intrusion detection, can also help in determining the effectiveness of the other network controls by monitoring network traffic and assisting in determining if a network control has failed. Monitoring the log files of network controls is also important, as the logs produced by these controls can provide valuable information in determining when a machine has been compromised. Providing diversity within each network control and utilizing overlapping controls where possible can help in protecting and detecting network-based attacks and can lessen the risk of compromised applications.

9.2 Host Operating System Controls

Another important set of controls that can be used to protect an application or service exists on the host operating system of the system running the application or service. These controls support the confidentiality, integrity, and availability of the applications or services running on the host. Some of these mechanisms are built into the operating systems, and others are implemented by loading additional software. If implemented properly and with diversity, these controls can complement network and application controls to provide better security and reduce the threat to an application or service.

A major control provided by a host is authenticating access. This control is used to verify the identity of users of the host. This identification can then be used by other controls to provide access controls. The authentication method used to verify the identity of the users is important, as that method controls the extent to which the identity can be trusted to be authentic. A variety of methods can provide authentication. The most prevalent method is through the use of a password that is known by the person who is authenticating. This is known as one-factor authentication and uses something that only that person knows. Another method is through the use of a password that is generated by a hardware token or a certificate on a smart card. This is commonly used in conjunction with a PIN. This approach is referred to as two-factor authentication, as it combines something that the user knows and something that the user physically has (the token or smart card). A third method of authentication is through the use of biometric information that is unique to the person. Examples of these include fingerprints, hand geometry, and iris/retina scans. When a person has established his or her identity through authentication, then the appropriate access controls can be used to restrict that person to the appropriate data and functions.

Utilizing diverse authentication methods can greatly reduce the threat of an identity being compromised. Network controls can also be used to limit the network locations from which a user can gain access. The implementation of an access control list on a firewall can prevent access to the system unless the request comes from an approved network. This can reduce the threat of attempts at unauthorized access by limiting the access to better controlled networks. In addition, if users are only expected to access the system from a specific network, then monitoring can reveal when access is attempted from other unauthorized networks. Action can then be taken to investigate why the access was attempted.

When a user has been properly authenticated, then the access controls of the operating system can be used to limit the data and functions that can be accessed. This is done by granting or revoking privileges within the operating system. Some examples of these include allowing specific users to log in from the network, specifying times that a user is allowed to access the system, and, when a user has logged into the system, what resources that user can access. Functional privileges are another type of privilege that control what a user is allowed to do, such as having the ability to shut down the system, access another user's files, start or stop services, and even grant privileges to other users. Some operating systems support very granular control and allow the individual granting of privileges, whereas others only support the granting of either all privileges or none at all. Only allowing users the minimum privileges to perform their jobs is an important part of reducing the risk if that user is compromised. One way that overlapping controls can be used is in the case of a user who apparently has logged on via the network and is attempting to access other functions or areas that are unauthorized. This can indicate that the user's ID may have been compromised and the matter should be investigated. If the access is via the network, then network controls can help to locate, isolate, and subsequently block any further access attempts from that network. This is an example of how host controls and network controls can work in conjunction to detect and respond to threats to a system.

One other way to provide host access control to data is through the use of file encryption. This can be employed as part of the host operating system or can be a separate add-on application and can be implemented on a file-by-file basis or on an entire volume. This can complement and provide diversity to existing access controls by restricting access to authorized users only and also requiring that the user provide the key to decrypt the data. In addition, using encryption algorithms different from those used in other areas of the system can reduce the risk that a compromise in one algorithm will compromise the entire system. Encryption also provides protection against physical attacks on the host that would allow direct access to the protected data. Even if the host controls were bypassed, the risk of the data being compromised would be less as the data would still be protected by the encryption as long as the key remained secret. Furthermore, if the encryption scheme is implemented separate from the host operating system, it can provide a separate independent control that will reduce the risk of the data being accessed by an unauthorized individual.

Another control that is important to mention is the use of a host intrusion detection system. This is a collection of processes that run on a system to monitor for activity that may indicate an intrusion is occurring or has occurred. It can include various functions, such file integrity checking, monitoring of communications traffic, log file monitoring, and auditing of access rights. By performing these functions it can detect when an intrusion has occurred. When used in conjunction with other controls, such as network intrusion detection, it may be possible to pinpoint the source of the intrusion and take action to further investigate it or block any future intrusions. In addition, these controls can also provide important log information that may allow the organization to take legal action against the intruder.

One of the most important preventive host controls is provided by the addition of anti-virus software. Anti-virus software contains a number of features and functions that can help protect a system against compromise. One of the main functions of anti-virus software is the detection of malicious code in files. Most viruses will attempt to both install and run executable files or modify executable files that already exist on the system. These modifications can be used to provide unauthenticated access to the system or to spread the virus to other machines. Anti-virus software attempts to detect these infected files when they are accessed by the host system and prevent them from running. This is an important preventive control because it can provide protection against viruses and worms that use vulnerabilities that have not yet been patched on the host system. It may also be quicker to update the anti-virus signature files than to patch against the vulnerability used by the virus to spread.

Virus detection should also be used in other places to provide overlapping control. Although the most important place is on a host itself, another place that anti-virus software should be run is on e-mail servers. E-mail is one of the major methods or vectors used by viruses to spread from one system to another, so running anti-virus scanning software on the e-mail servers is an important control. It is important to implement diversity in this control, as well. Anti-virus implementations will use a variety of methods to detect viruses. Most implementations use signature files to identify the code used in a particular virus. This means that the virus signatures must be kept up to date in order to provide protection against the latest viruses. One way to provide extra protection through diversity is to utilize more then one anti-virus vendor solution. Anti-virus software companies can provide updates on different schedules. Some provide updates once a week, and others may provide them once a day. Also, anti-virus vendors will discover the virus and release their updates at different times. Utilizing multiple vendors allows an organization to take advantage of whichever vendor comes up with the detection and remediation first. When applied to e-mail solutions that use gateways and internal relays, this approach can be implemented by utilizing a different vendor's solution on the gateway than on the internal e-mail relays and, if possible, a third solution on the hosts themselves to provide even further diversity.

9.3 Application Controls

The next place where security controls can be implemented is in the application itself. Applications vary greatly in the amount of security controls that can be implemented. They can also be made up of diverse sets of systems such as browsers, Web servers, and databases. Each one of these pieces represents a place to attack the system as well as an opportunity to implement a control.

Applications rely on the system that is hosting the application in order to properly execute the application. If the underlying system that is hosting the application is compromised, then the application controls could be bypassed, making them ineffective. It is important to protect the system that is running the application. One way to reduce the risk of a system vulnerability being used to compromise an application is to use different types of systems to implement an application. If the application requires the use of multiple Web servers, possibly for load balancing, and can be run on more then one operating system, it is possible to take advantage of this and utilize two or more operating systems for those servers which can reduce the risk of a vulnerability in one operating system affecting the entire application. If a vulnerability is discovered, then the system that is vulnerable can be taken offline until it is patched or mitigated in some other manner, but the application can continue to function utilizing the other Web servers that use a different operating system. A drawback to this approach is that it greatly increases operating complexity by having to maintain and administer multiple operating systems; however, this complexity may be justified for critical applications that must be available all of the time.

Diversity should also apply to the clients used to access the applications. Particularly for Web-based applications, the application should support various browsers in order to prevent a flaw in any single browser from compromising the application or service. This can best be done by making sure the application does not depend on a specific feature of a specific browser to operate and uses standards that most browsers can support. This approach has some drawbacks in that the support of the application must be able to handle these multiple access platforms, and the application must be tested with them to ensure that it functions properly.

Applications may also provide their own authentication process that may be used either with the host authentication or as a totally separate authentication path. If the application authentication is done after a host authentication, then one way to reduce the threat of a compromise is to use a different method of authentication than that used by the host. This can prevent the compromise of the authentication method for the host from allowing access to the application.

Within applications, many access controls can be used to restrict access to functions and resources. For some enterprise applications, these can be very granular and can restrict access down to a particular transaction. Applications can also define roles or groups for its users that in turn define the type of access control, which can make it easier to administer these controls. These access controls can be used in the same manner as the host access controls to limit the functionality that is being accessed by users as well as combined with network controls to limit the sections of the network that can access a particular function within an application. An example of this combination control is not allowing high dollar transactions in a financial application to be initiated from the Internet. This can be done by limiting that functionality to an ID that can only be used to access the application from a controlled network. In addition, encryption can also be used to protect data within the application. Using encryption can prevent the disclosure of critical application data such as credit card numbers or other sensitive information that should be protected even from the administrators of the applications. Diverse access controls, including the use of encryption, can provide multiple layers of protection for the data that is contained within an application and reduce the risk of having the application data compromised.

Coordinating the use of network, host, and application controls can provide redundancy in protecting against compromises and detecting intrusions. This can be an administrative burden, as it requires the coordination of all the controls in order to provide appropriate access to authorized users, but combining all of these controls together can help in reducing the risk of a compromise due to a failure in any one of them.

9.4 Detection and Response

Detection and response are integral parts of any security plan. Although most plans attempt to prevent incidents from occurring, it is also necessary to react to any detected problems. A system that involves a number of diverse security controls can make it challenging to deal with all of the events being generated. It is possible to use diversity in response to improve the likelihood that the response will be timely and allow administrators to resolve the problem with a minimum of impact to the applications.

One tool that can be used to help monitor diverse security controls is a security event correlation system. These systems can take events and logs from various sources such as firewalls, network intrusion detection systems, anti-virus detection logs, host security logs, and many others type of logs and correlate them together. This then allows the events to be related together to determine if any action should be taken. An example of this is when a network intrusion detection system detects an attack against a system and the file integrity checker detects a change in a critical file. These events may be detected and responded to individually based only on the priority of that specific event occurring. If they are being processed by a security event correlation system, then it can recognize that these events may be related, and the priority of the events can be adjusted so they are addressed in a more timely manner. This can also help in managing the diversity of different events, as the security event correlation system can map the same type events from multiple sources to a common naming system or grouping of events. This is important, as multiple vendors may have different names for the same event, but this system allows events to be reacted to in the same fashion no matter what the source. This type of system is essential to an enterprise utilizing multiple diverse security controls and monitoring systems.

Another place where diversity can help is in the tools used in the alerting and response process. This can assist in ensuring that administrators will be able to respond to problems in a timely manner. Some alert processes rely on only one method of notification (usually e-mail to a pager). This can be a single point of failure, especially if the e-mail system or the network itself is the system that is affected by the problem. Utilizing other methods of notification, such as devices that will page directly from an event console, will increase the likelihood that the notification will occur in a timely manner. It is also important to protect the response tools and systems that run them as much as possible. These systems should be protected at the highest levels, as they are critical in assisting in containment, remediation, and recovery. Providing diversity for these tools is also a good idea. Being able to utilize tools that run on multiple operating systems is important, because the system that will be used to respond to the incident may be compromised by the same incident that is being responded to. It is also possible that the response system may not be accessible via the network because of the same incident. Having the ability to operate in many different environments will reduce an organization's dependency on any single system and increase the probability of being able to defend successfully against an attack.

Another place to practice diversity is in the actual tools required to respond. In some cases, a tool may not be able to function because the method it uses is blocked by a network control put in place to protect against the effects of an ongoing incident. An example of this was the Blaster worm. It used the Internet Control Messaging Protocol (ICMP) to locate other machines to infect. This resulted in massive amounts of ICMP traffic on networks with infected machines. A common practice was to block this protocol on those networks in order to allow the noninfected machines to communicate. A side effect of this was that it disabled a number of network tools, such as Ping and Tracert, that are commonly used to troubleshoot network issues. Other tools that did not use ICMP had to be utilized.

Another place where diversity is helpful is in the method of access that may be necessary to respond to an incident. For example, VPNs may be used to access the enterprise network from the Internet. If an incident has disabled that access, it will be necessary to have an alternative method available, such as dial-up or the ability to access the network directly by physically going to a location. This can also be useful if it is suspected that the normal method of access may be compromised or possibly is being monitored by an attacker.

9.5 Conclusion

The use of different security controls within an application environment can go a long way toward reducing the security risks of running the application. Utilizing diverse controls across the network, hosts, and applications, as well as the detection of and response to incidents, can provide multiple layers of protections. These layers can provide overlapping controls that will reinforce the security provided by each control. If one of the controls fails, then an overlapping control can still provide protection or detection. One drawback to using multiple overlapping controls is that administration of these controls requires more effort, which can be justified by the reduction of risk that these multiple controls can provide. Multiple controls can also provide some opportunities to separate critical duties in that different personnel can administer different controls, thereby not allowing any single person to compromise the entire application. Care must also be taken to implement the controls in an independent manner to reduce the risk that a failure in a single control will affect other controls. All in all, the implementation of multiple diverse controls that are layered throughout the network, host, and application can maximize the security of an organization's applications and minimize the risk of a compromise.

Building Management Commitment through Security Councils, or Security Council Critical Success Factors

Todd Fitzgerald

One of the most common concerns voiced at the various security conferences and security associations around the country is, "How do we get our management to understand the importance of information security?" These concerns are typically voiced by individuals that have been unable to secure the attention of or financial commitment from the senior leadership of their respective organizations. The question is usually accompanied with frustration as a result of multiple attempts to obtain budget dollars, only to be faced with flat budgets or even cuts to the current expenditure levels. Although each organization has different values, principles, and strategies to move the business forward, this article explores some techniques for building management commitment through the implementation of a successful information security council.

10.1 The Evolution of Information Security

Before we can accurately talk about today's information security environment, it is useful to explore how information security evolved to the current state. Exhibit 10.1 shows the evolution over the past 40 years as a progression of issues. In the early days of information security, the discipline was focused on the mainframe environment, where the information was controlled centrally through a single operating system. The view of information security at this time was that it was primarily an information technology (IT) issue. IT at that time was also seen as an overhead expense to support the accounting and back-end functions of the organization (*versus* operating as a core business enabler). Information technology was also viewed as being very technical and not well understood by senior executives within organizations, although they understood that it was necessary. To further distance information security from the senior executives, it was mainly viewed as the management of log-in IDs and passwords. As a result of these perceptions, information security was located within the IT departments and typically buried somewhere within the data center operations management.

Then along came minicomputers, the first mechanism to move information off of the mainframes and onto departmental processors. Moving the information to another platform required management of the information between the platforms and another level of log-in/password controls. These servers were still typically managed by the central IT departments, so information security was still predominantly addressed centrally. In the early 1980s, with the introduction of the personal computer and a move away from cathode ray terminals (CRTs), a significant change occurred for information security. Now information was being replicated from the previously centrally managed systems to individual workstations. The PCs were quickly organized into local area networks to share files and printers. This represented a real challenge for information security—although access to mainframe systems could be

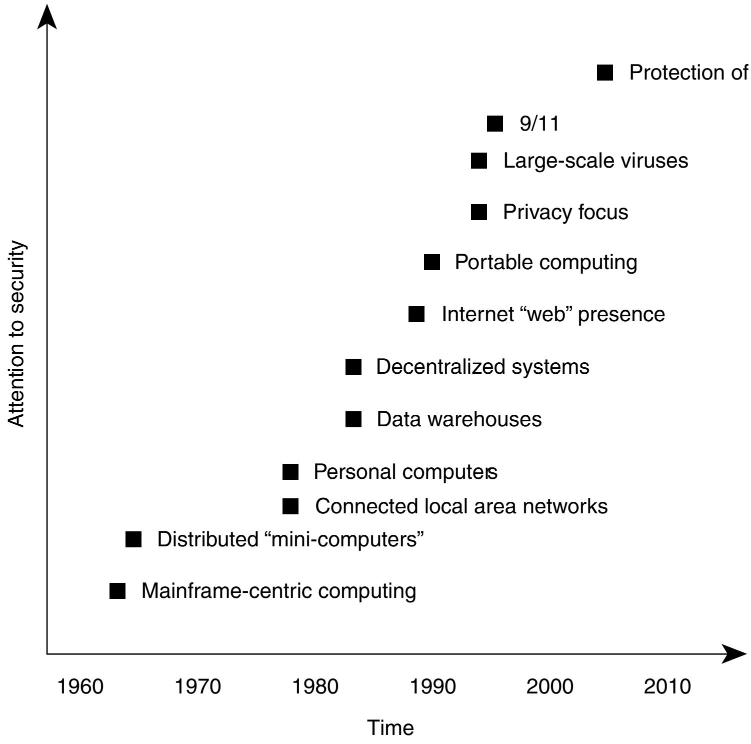

EXHIBIT 10.1 Attention to information security across technical/environmental changes.

controlled and access to the networks could be controlled through the network operating systems, what security controls were in place to protect the desktop? As history has shown us, very little has been done to protect the desktop in most organizations. What was the management view of information security at this time? There was some recognition that there was more to information security; however, it was still thought of as an IT issue and, more frequently, an impediment to integration of the networks. In other words, it was an obstacle that had to be overcome to be successful.

Beginning in the mid-1980s, organizations were making investments in data warehouses as the value of aggregating transactional information to support decision making was beginning to be realized. Organizations dealt with data ownership issues and who should have access to the decision-making information. Executives recognized the value of this information, but security was still viewed as an IT function, similar to systems analysis and design, database administration, infrastructure, computer programming, data center operations, and testing or quality assurance. However, the information was becoming significantly more meaningful, due to the aggregation, if viewed by inappropriate parties.

The next major change was the introduction of the Internet and specifically the Web. The Internet's beginnings can be traced back to the late 1960s/early 1970s, but usage at any scale beyond the research, education, and government communities did not occur until the mid-1990s. Today, the Internet is embedded in our culture as much as cell phones, minivans, sport utility vehicles, and expecting consistency in food quality from one chain restaurant to another. Systems that were once protected by the data center "glass house" subsequently moved to a shared network environment that was still connected within the organization. Wide area network (WAN) and local area network (LAN) technologies were utilized, but still there was exposure within the phone system; however, this was viewed as private within the organization, comprising lower risk. When the necessity to become connected to the Internet to establish a company presence, conduct electronic commerce, and provide access to the vast resources available, organizations increased their risk of intrusion significantly.

It is during this latest period that information security began to come to the forefront in leading organizations, albeit still being regarded as primarily an IT issue. Why? Because many organizations were positioning the Internet for customer service and order entry functions (beyond the earlier "Web presence" phase), their businesses were much more dependent on the availability of these systems. Additionally, communications were increasingly becoming dependent on electronic mail with external organizations due to the Internet connection. Computer viruses and worms such as Melissa, Ilove you, Goner, Blaster, Slammer, Sasser, and so on from the late 1990s to the present have served to compromise the availability of business systems. Senior executives were beginning to become concerned over reports of "external hackers" but were still were not completely knowledgeable as to the risks to the organization.

With the lower cost of producing portable computers in the late 1990s and the new millennium, these devices were becoming more common. The lower cost coupled with the Internet capabilities for accessing internal systems remotely served to proliferate the usage of laptop computers. New security concerns were introduced, as these devices created new entry points into the network. This was primarily viewed by senior management as an issue to be managed by the network and information security areas.

As organizations turned the corner on the new millennium, proposed rules emerged such as the Health Insurance Portability and Accountability Act (HIPAA), the Gramm-Leach-Bliley Act (GLBA), National Institute of Standards and Technology (NIST) guidance, and activity within California directed at individual privacy. Although several of these rules had been in development for many years, the general population was beginning to express greater concern about the privacy of their information, whether financial, health-related, or personal, and its being protected and viewed only by those with a legitimate need to know. Fears of their personal information being displayed on the Internet by a hacker or that their Social Security numbers could be compromised while conducting an online transaction came to the forefront. The threat of having their credit history damaged by identity theft became a reality to many individuals. Companies that were the subject of compromises gained unwanted attention in the press. Some of those organizations, such as Egghead, CDNow, and others were forced into bankruptcy as a result. Now, security was beginning to become a topic of boardroom discussion due to an increasing awareness of the risks to the business posed by an external or internal compromise and disclosure of confidential information. Somewhere between the widespread usage of the Internet and the attention being given to compliance regulations senior management in leading organizations began to recognize that the issue was one of business risk as opposed to an internal IT issue. As networks suffered outages due to worms and viruses, as inappropriate disclosures of company information occurred, and as trade secrets were suspected of being stolen through corporate espionage, attention to security began to move out of the IT department.

September 11, 2001, was a tragic day for our country. Senior management at many organizations began to ask: What if a tragic event happened to us? Are we prepared? Would we be able to sustain the business or go out of business? These questions again added to the perspective that information security was more than log-in IDs and passwords. The establishment of the Homeland Security department may not have had a significant, direct impact on most organizations, but the mere presence of and constant attention paid by the President to defeating the terrorists has increased the amount of attention paid to our critical infrastructures. Security has impacted the daily lives of each American—just consider the airport screening process today *versus* pre-911. Individuals are more understanding that security is here to stay, even though they may not like the inconvenience. Because individuals are now more security conscious, senior management is seeing security issues addressed more in the media and is beginning to understand the risks.

So, what does this quick tour of the history of information security all mean? Simply put, in many organizations, information security is viewed in a broader context than the establishment and termination of access controls by senior management. They understand, for the most part, that this is a business risk issue that requires some funding; however, protecting information is still largely viewed as an information technology issue, and the individuals responsible for information security still report within the IT organization or to the chief information officer (CIO), if they are fortunate. Some progressive organizations have recognized the business value of this function and have aligned the reporting with the legal, compliance, internal audit, and risk management functions.

10.2 Why Communication Fails

To have meaningful communication, it is imperative that the needs and perspective of the *listener* be understood by the person giving the presentation, trying to sell the idea, or advance the posture of information security. Let's try an exercise for a moment: Close your eyes, and envision the most technical person in your organization who understands security. Imagine that this person is having a conversation with the chief executive officer (CEO) of the company about why a new firewall is needed. What images come to mind? What are the key phrases that are communicated? What do you think the odds of success are? Okay, open your eyes now. Chances are this exercise produced either comfort or extreme discomfort. Let's examine some key concepts for making this interaction successful:

- *Avoid techno-babble*. Technical individuals are used to conversing among their peers about the latest technology, and it is many times necessary to communicate in this language to determine the appropriate solution. Sometimes techno-babble is used to make the individuals appear to be knowledgeable in the technology; however, throwing out vendor names and technical terms to senior executives such as the CISCO PIX 500 Series firewall, Active Directory organizational objects, stateful port inspections, or, worse yet, the vulnerabilities of port 139 or explaining why SSL encryption through port 443 is the way to go for this application is only a recipe for disaster! It is analogous to a new car salesman attempting to sell a car to someone by explaining the compression ratio specifications of the engine. Although these details may be important to the engineer designing the car to ensure that the car has the proper size engine for the weight and acceleration expectations of the car and may also be important to the manufacturer to ensure that the engine is built to the quality level desired, explaining these facts to most car buyers would be not only uninteresting but also rather irrelevant.

- *Understand the senior management view toward security*. Senior management's view of the importance of information security will guide the organization's view as well. If support for adopting security practices is currently lacking, this should be understood. Is there an uphill battle ahead, where every idea presented will have to be defended to obtain appropriate funding? Or does senior management have an understanding of the issue and are they willing to allocate some of the necessary funds? In the first case, more time will have to be spent educating senior management in terms of risk, as well as gaining champions of the effort, prior to actually selling information security to senior management.
- *Highlight business risks*. This does not mean dancing around like Chicken Little and proclaiming that the sky is falling. Yes, it is true that nothing grabs the attention of senior management better than a security incident; however, a strategy based on reacting to the latest security incidents is not conducive to establishing a long-term security program. Instead, it promotes the idea that security can be invested in only when major problems occur, which is contrary to the investment model desired. Risks must be communicated in business terms, such as the likelihood of occurrence, the impact of what will happen if the event does occur, what solutions can be implemented to mitigate the risk, and the cost of the solution. Whether the solution is the latest whiz-bang, leading-edge technology or the implementation of appropriate administrative controls, the real decision process involves answering the question of whether the organization can live with the risk or should make more investments. Understanding this perspective will reduce the possibility of presenting the idea in techno-babble terms, as previously mentioned. Many times people in technically oriented positions are very good at analyzing problems and formulating solutions to the problems, but their explanations are many times focused on the specific details of the technology. Although this is important and works for resolving those types of issues, it does not work as well when explaining positions to senior leaders that have limited time to address each individual issue.
- *Dress appropriately*. In today's business-casual environment, as well as its extension into certain dress-down days, it is easy to lose perspective of what is appropriate for the occasion. Notice how others in the organization dress and, specifically, how the executives dress. Are they blending with the workforce with business casual? Do they wear jeans or are they still clinging to their suits and ties? Because executives frequently have meetings with external parties, it is not uncommon in organizations that have adopted a business-casual policy for senior executives to be dressed in suits and ties for the external world. Alternatively, some executives may only dress up on those occasions when external meetings are required, so as to fit the team environment (which was the purpose of business-casual attire in the first place). Why should dress be important? If someone is to be taken seriously as an individual truly concerned about business risks, then dressing the part is necessary. Would jeans be appropriate to wear for a person's own wedding? Why do people rent tuxedos for the occasion? Because it is important, sacred, and special and deserves the appropriate attire. If selling security is important, then appropriate attire is in order.
- *Do your homework on other organizations*. Executives are interested in what other organizations are doing to resolve the issues. This is important, as an organization has limited resources (time, people, and money) to invest in the business and still remain profitable for shareholders and maintain the proper employee workload (to maintain morale, reduce turnover, and produce the necessary level of productivity). Because these resources are limited, they want to ensure that they are spending about the same as their competitors for investments that sustain the business and potentially more than their competitors for those investments that will gain competitive advantage. The psychology in this case is such that, as individuals, we do not want to be viewed as being less than anyone, as this is a negative. If information security is viewed as a necessary evil, as an overhead cost that must be absorbed, or as something that just has to be done, investments will never move beyond the *status quo* level of other organizations. If information security is viewed as being an enabler that allows the organization to add new

products and services, reduce costs, and promote its trustworthiness, then the investments are apt to exceed the *status quo* of other organizations. Again, the benefit must be clearly articulated in terms that the key decision makers can understand.

- *Keep presentations short and sweet.* The old adage that less is more definitely applies here. The business problem being addressed, the impact to the business, and the benefits and costs should be articulated within the first few slides. The first thought of the executives will be "Why am I here?" Then, they will ask: "What do they want from me? What will it cost?" The earlier in the presentation that these issues can be addressed, the better. Graphics and simple charts showing comparisons are also useful in communicating the message. The slides should be used as an aide but should not contain all the details, as these can be provided during the presentation if requested. Even in this case, answers to the question must be at the appropriate level for the executives. For example, if the decision makers are having difficulty understanding why information has to be encrypted to remain secure over an open network such as the Internet, diving into the details of Secure Sockets Layer, 128-bit encryption, digital certificates, and public key infrastructures is not going to address their concerns. The real questions being asked are "What are the business risks? What is the likelihood that one of these events will occur? Is it worth my investment? If the investment is made, what other problems (end-user training, inability to recover files, slower computer response time, etc.) are likely to occur?" Anticipating the answers to these business questions is the key to a successful presentation.

10.3 Critical Success Factors for Sustained Management Commitment

In the preceding sections, we reviewed the history of information security and why communication typically fails. Now it is time to define the essential steps to building a sustained management commitment throughout the organization. These steps may take months or years, depending on the size and challenges within the organization. Patience, perseverance, and incremental success will continually build the commitment. The chief security officer has to maintain the faith that the organization will enhance its security posture, especially under adverse circumstances.

10.3.1 Critical Success Factor 1: Communicating the Vision—One Manager at a Time

"Establishing buy-in" is a term first used in the 1980s/early 1990s when organizations recognized that teamwork was essential to obtain Total Quality Management (TQM). Although TQM experienced varying levels of success within organizations, the importance of getting those involved with the processes committed to the vision was a key assumption. Documented processes were of no use if they were not supported by the management charged with ensuring their compliance.

The same philosophy exists when implementing information security policies in that without line-level management concurrence with the vision, mission, and policies, they will not be consistently enforced within the workforce. So, how is this individual buy-in established? A technique that can be very successful with first-level supervisors, managers, and middle management is to have a brief, one-on-one, scheduled conversation with each employee. The four key concepts here are (1) brief, (2) individual, (3) scheduled, and (4) conversation. The meetings should be *brief*, as these are very busy individuals and security is not the only responsibility on their plate; in fact, it most likely is the furthest issue from their minds. Their days are filled with responding to strategic and daily operational, tactical issues. The meetings should be *individually focused*, as it is important to understand their individual issues and concerns. The one-on-one setting provides the opportunity to establish this relationship in an environment where the exchange of information can be open and honest. It is critical that the manager with whom the security officer is having the conversation views the discussion as being focused on how security can help that manager's business unit and the company achieve their business goals through the reduction of risk and enabling new services and products. The meetings must be *scheduled* to show appreciation for their time constraints. Technically oriented individuals are typically used to scheduling meetings at a moment's notice, as they are many times dealing with operational issues that must be resolved immediately. Although the management also has urgent issues, in their minds having a meeting to discuss their views of security would not qualify as an urgent issue that must be addressed today or tomorrow. Because many management personnel have meetings scheduled out weeks and months in advance, the meeting will have a greater chance of success if it is scheduled two to three weeks in advance. Flexibility is key also with last-minute schedule changes. When the manager says that the meeting has to be changed at the last minute, this does not mean that security is not important but rather that other priorities ("urgent items") have surfaced which must be addressed. Persistence in rescheduling will bring rewards, as the manager may end up paying greater attention to the message if the meeting was rescheduled. Finally, the meeting should be a *conversation*, not a one-sided security sales pitch. After all, the purpose of the meeting is to communicate the security vision, understand the individual's business needs, and, most importantly, establish buy-in.

Establishing management commitment throughout the organization is more of a grassroots effort among the management staff. Senior executives rely on their trusted advisors, or key management staff, to form their opinions about where the appropriate investments should be made. If the management staff is not on board with supporting the organizational security efforts, it may be difficult to bring the senior executive to support the security posture proposed by the security department. By establishing the relationships among the management staff prior to engaging the senior executive, the appropriate groundwork is laid to put forth the desired security program. If the senior executive is already a proponent of information security, then this can be leveraged in the discussions with that executive's management team, although this is often not the case.

Individuals are generally willing to help others, as it is human nature. The obstacles to helping have more to do with (1) other priorities, (2) time commitments, and (3) not understanding what help is needed. Sometimes, simply asking for help will go a long way. Individuals want to belong and feel that their contributions are important. As the discussions are being held with each manager, it is important to take time to understand their business needs and where they can feel that they are making a contribution to the company's efforts.

Finally, the question of "What's in it for me?" has to be answered for each manager. Each manager has many efforts to support, and in the end their sustained commitment to information security will be primarily determined by the business benefits that they see accruing to their areas. Is it to be in compliance with regulatory requirements? To ensure the integrity of their information? To reduce the time required to gain access to a system? To simplify the procedures required by a manager to bring on a new employee through role-based access? To reduce the risk of department reputation if a laptop is lost through laptop encryption? To ensure that productivity does not suffer when a system is down due to a virus? Communicating the benefits should be in their terms and should include the traditional goals of confidentiality, integrity; and availability (CIA). These terms may mean something to the manager but are more likely to be seen in an abstract sense that does not apply to them or, worse, something that the systems security or information technology departments take care of.

10.3.2 Critical Success Factor 2: Analyze Organizational Culture

As security professionals, we just *know* that investing money in security is a not only a good idea but also entirely necessary. In fact, the more the better, as it meets *our* goals. However, organizations are made up of many moving parts that, like parts of the human body, must all function together. What is the most important part of the human body? Think of a teenager running across the street in a hurry (we know how busy their lives are), not thinking to take the extra time to slow down or look both ways. Suddenly, a car comes speeding along. The driver ignores the stop sign in front of the crosswalk and hits the teenager. Is the brain important in making these split-second evaluations? Certainly. Or, maybe if the eyes had been more attentive or quicker to see what was happening on behalf of the driver and the pedestrian the accident could have been avoided. Or, maybe the most important part is the feet, which could have outrun the car or slammed on the brake pedal faster, again preventing the accident. Or, maybe the heart is the most important part, for if it had not kept on beating the teenager would have died. Or, maybe if the teenager's ears were stronger the teenager would have heard the car approaching. Hmmm, now what is the most important part of the body again?

Organizations are very much like the human body, as they have many parts that must function together in an integrated fashion to operate successfully. Fortunately, many security decisions are not life-and-death decisions that must be made in a split second, as in the scenario just mentioned; however, the different parts of the organization do interoperate simultaneously. Just as the parts of the body are moving in coordination with each other, organizations are not sequential but rather accomplish departmental missions at the same time. This is where the challenge comes in. Where is the "security part" operating within the organization? Is the "security part" part of the brain, analyzing the situation in real time and deciding how to proceed safely? Is the "security part" taking direction from some other organizational body part and moving as instructed (in a direction that may be right or wrong)? Is the "security part" listening to what is happening but has no control over the other organizational body parts running toward the street? Is security viewed as the pumping life blood of the organization, without which the organization could not exist? Or, is the "security part" an afterthought to be applied only when the ambulance and emergency medical technicians arrive? Relating the organization to the human body is useful in understanding the role of information security and the current level of cultural support.

Organizational culture is developed over time; however, the culture experienced is the present state, or something that is realized in the current moment. Cultures are also strongly influenced by the leaders of the organization and their actions. Thus, if the organization has experienced significant change in the senior leadership, the culture will also have difficulty sustaining the direction. The lesson learned from this is that security must be continually worked into the organization, as previous key supporters may have moved on to other positions or companies. This is also why it is necessary to build a broad base of support, so as leaders move on the security principles can be retained by those who move into their positions.

Organization cultural views toward information security can be viewed simplistically as high, moderate, and low. The following definitions could be utilized to assess the current cultural mindset:

- *High*. Senior management brings information security into the discussion on new projects. An information security officer is established at high levels within the organization, minimally at a director or vice president level. Information systems development projects incorporate information security within the systems analysis, design, testing, implementation, and maintenance phases of every major project. Information security professionals are engaged in the design of the applications. Updates are made on a periodic basis to the company board of directors. All employees are aware of the importance of information security and understand how to report incidents. Audit findings are minimal and are addressed through a managed process. Many times, the audit findings highlight previously known issues that have current project plans to address the vulnerability or weakness. Budgets are established with funding levels to support an ongoing security program along with the provision to review supplemental projects in the same process as other high-profile projects. Senior leadership considers security to be a business risk reducer and an enabler of new products or services and actively supports security efforts through their actions (participation, funding, authorizations).
- *Moderate*. People within the organization have received some training on information security. An individual has been assigned the information security role, usually at the supervisor or manager level buried within the information technology department, primarily because a regulation or auditor suggested that they have someone in this role. Security policies exist, but

they have been primarily created within the information technology department and may not have widespread support or knowledge of where they are located. Applications are developed with an understanding of security principles; however, not all applications are verified before moving to the next phase of development. Senior management has typically delegated the understanding of information security to the CIO and trusts that the CIO is keeping the environment secure. A staff is budgeted for information security and typically consists of security administration operational activities (e.g., account setups, password resets, file access) and a few security projects that are key for implementing a few critical organizational initiatives. Audit findings are responded to in a reactive fashion and typically become the impetus for change and obtaining support for future initiatives.

- *Low*. If security policies do exist, they are usually issued by a memo in reaction to an incident that has occurred. Policies may be created by copying one of the many canned policies without the means to enforce them or procedures in place to promote compliance. Information security is thought of as the log-in ID/password guys, the virus guys, and the guys who maintain the firewalls in the organization. Security is often sold by fear, anxiety, and doubt, with a technical person highlighting the latest hacker attack to explain why the organization needs to invest more money in information security. Auditors frequently locate missing paperwork for user requests, and the common initial password set and resets are equal to the log-in ID, TEMP 123, password, or Monday. Senior management intuitively knows that information security is important, but it assigns the same level of importance as ensuring that the computer system is up. Funding is not specific to information security and is usually part of a budget for network support, systems administration, or technical support.

Each organization has different priorities, and the current culture of the organization may be a decided upon position but most likely has just resulted from the level of attention (or lack of) paid to information security The good news is that, with the proper focus, organizations can move very quickly from low to high cultural levels.

10.3.3 Critical Success Factor 3: Establishing the Security Council

The information security council forms the backbone for sustaining organizational support. The security council serves as the oversight for the information security program. The vision of the security council must be clearly articulated and understood by all members of the council. Before the appropriate representation of the council can be determined, the purpose of the council must be decided. Although the primary purpose is to provide oversight for the security program and provide a mechanism to sustain the organizational security initiatives, the starting point for each organization will depend upon the current organizational culture as discussed in the preceding section.

A clear vision statement should exist that is in alignment with and supports the organizational vision. Typically, these statements draw upon the security concepts of confidentiality, integrity, and availability to support the business objectives. The vision statements are not technical and should focus on the advantages to the business. People will be involved in the council from management and technical areas and have limited time to participate, so the goal must be something that is viewed as worthwhile. The vision statement should be short and to the point and should drive the council toward an achievable, but stretch, goal.

Mission statements are objectives that support the overall vision. These become the roadmap to achieving the vision and help the council clearly view the purpose for their involvement. Some individuals may choose nomenclature such as goals, objectives, or initiatives. The important point is not to get hung up in differentiating between these but rather to ensure that the council has statements that help frame how the council can operate to successfully attain the vision. A sample mission statement is provided in Exhibit 10.2. Effective mission statements do not have to be lengthy, as the primary concern is to communicate the goals

EXHIBIT 10.2 Sample Security Council Mission Statement

The Information Security Council provides management direction and a sounding board for ACME Company's information security efforts to ensure that these efforts are:

Appropriately prioritized
Supported by each organizational unit
Appropriately funded
Realistic given ACME's information security needs
Balanced with regard to cost, response time, ease of use, flexibility, and time to market

The Information Security Council takes an active role in enhancing ACME's security profile and increasing the protection of its assets through:

Approval of organization wide information security initiatives
Coordination of various workgroups so security goals can be achieved
Promoting awareness of initiatives within their organizations
Discussion of security ideas, policies, and procedures and their impact on the organization
Recommendation of policies to ACME's Information Technology Steering Committee
Increased understanding of the threats, vulnerabilities, and safeguards facing the organization
Active participation in policy, procedure, and standard review

ACME's Information Technology Steering Committee supports the Information Security Council by:

Developing the strategic vision for the deployment of information technology
Establishing priorities and arranging resources in concert with the vision
Approving the recommended policies, standards, and guidelines
Approving major capital expenditures

that they are readily understood by technical and nontechnical individuals. The primary mission of the security council will vary by organization but should include statements that address:

- *Security program oversight*. By establishing this goal in the beginning, the members of the council begin to feel that they have some input and influence over the direction of the security program. This is key, as many security decisions will impact their areas of operation. This also is the beginning of management commitment at the committee level, as the deliverables produced through the information security program are now owned by the security council versus the information security department.
- *Decide on project initiatives*. Each organization has limited resources (time, money, people) to allocate across projects to advance the business. The primary objective of information security projects is to reduce the organizational business risk through the implementation of reasonable controls. The council should take an active role in understanding the initiatives and the resulting business impact.
- *Prioritize information security efforts*. When the security council understands the proposed project initiatives and the associated positive impact to the business, the members can be involved with the prioritization of the projects. This may be in the form of a formal annual process or may be through the discussion of and expressed support for individual initiatives.
- *Review and recommend security policies*. Review of the security policies should occur through a line-by-line review of the policy, a cursory review of the procedures to support the policies, and a review of the implementation and subsequent enforcement of the policies. Through this activity, three key concepts are implemented that are important to sustaining commitment: (1) understanding of the policy is enhanced, (2) the practical ability of the organization to support the policy is discussed, and (3) buy-in is established for subsequent support of implementation activities.
- *Champion organizational security efforts*. When the council understands and accepts the policies, they serve as the organizational champions behind the policies. Why? Because they were involved in the creation of the policies. They may have started reviewing a draft of the policy created by the information systems security department, but the resulting product was only accomplished through their review, input, and participation in the process. Their involvement in the creation creates ownership of the deliverable and a desire to see the security policy or project succeed within the company.

A mission statement that incorporates the previous concepts will help focus the council and also provide the sustaining purpose for their involvement. The vision and mission statements should also be reviewed on an annual basis to ensure that the council is still functioning according to the values expressed in the mission statement, as well as to ensure that new and replacement members are in alignment with the objectives of the council.

10.3.4 Critical Success Factor 4: Appropriate Security Council Representation

The security council should be made up of representatives from multiple organizational units that are necessary to support the policies in the long term. The human resources department is essential for providing information about the existing code of conduct, employment and labor relations, and the termination and disciplinary action policies and practices that are in place. The legal department is needed to ensure that the language of the policies states what is intended and that applicable local, state, and federal laws are appropriately followed. The information technology department provides technical input and information on current initiatives and the development of procedures and technical implementations to support the policies. Individual business unit representation is essential to developing an understanding of how practical the policies may be in terms of carrying out the mission of the business. Compliance department representation provides insight on ethics, contractual obligations, and investigations that may require policy creation. Finally, the information security department should be represented by the information security officer, who typically chairs the council, and members of the security team for specialized technical expertise.

The security council should be made up primarily of management-level employees, preferably middle management. It is difficult to obtain the time commitment required to review policies at a detailed level by senior management. Reviewing the policies at this level is a necessary step toward achieving buy-in within management; however, it would not be a good use of the senior management level in the early stages of development. Line management is very focused on their individual areas and may not have the organizational perspective necessary (beyond their individual departments) to evaluate security policies and project initiatives. Middle management appears to be in the best position to appropriately evaluate what is best for the organization, in addition to possessing the ability to influence senior and line management to accept the policies. Where middle management does not exist, it is appropriate to include line management, as they are typically filling both of these roles (middle and line functions) when operating in these positions.

The security council should be chaired by the information security officer (ISO) or the chief information security officer. The ISO is in a better position, knowledge-wise, to chair the council; however, politically it may be advantageous for the CIO to chair the council to communicate support through the information technology department. The stronger argument is for the council to be chaired by the ISO, as doing so provides for better separation of duties and avoids the "chicken in the henhouse" perception if the council is chaired by the CIO (even if the ISO does not report through the information technology organization). The CIO will have influence within the other IT-related steering committees. In addition to the ISO, the council should also have one or two members of the systems security department available to (1) provide technical security expertise, and (2) understand the business concerns so solutions can be appropriately designed.

10.3.5 Critical Success Factor 5: "Ing'ing" the Council—Forming, Storming, Norming, and Performing

Every now and then, an organization will recognize that collaboration is not taking place between the functional departments and it is time to talk about enhancing the team development process. This is usually the result of a problem of not communicating between the departments. Why wait for the problems to occur? When committees are formed, they are not magically functional the moment they are formed but rather must go through a series of necessary steps to become an operational team. The classical four phases of team development are forming, storming, norming, and performing. Let's visit each of the concepts briefly to see how they apply to the security council:

- *Forming*. This is the stage where the efforts are moving from an individual to a team effort. Individuals may be excited about belonging to something new that will make a positive change. The tasks at hand and role of the council are decided (as identified in critical success factor 3). Teams should be communicating openly and honestly about their likes and dislikes, deciding what information must be gathered to carry out their mission, and engaging in activities that build trust and communication with each other. It is critical to draw out the responses of those who may tend to remain silent during the meetings, as they may be thinking some very valuable thoughts but afraid at this stage that their ideas may be rejected.
- *Storming*. Now that the objectives are understood and the team has had the chance to discuss some of the challenges that they are tasked to resolve, doubt may settle in. Some members may become resistant to the tasks and return to their old comfort zones. Communication between members begins to erode, and different sections of the team form alliances to counter-positions. The team becomes divided, and minimal collaboration occurs between individuals. At this stage, it may be necessary to reestablish or change the rules of behavior for the council, negotiate the roles and responsibilities between the council members, and possibly return to the forming stage and answer any open questions about the purpose and clarity of the council. Finally, it is important to listen to the concerns of the council members and let them vent any frustrations, as they may have some very valid concerns that must be addressed to be successful.
- *Norming*. At this stage, the members of the council begin to accept their roles, the rules of behavior, and their role on the team and respect the individual contributions that others on the team can provide. Now, would not it be nice if the storming stage could be skipped, and the security council just moved on to this stage? Think of a child learning to ice skate. The concept of ice skating is explained in vague terms such as, "Put these skates on your feet, then stand up, and skate around the rink." The child has an idea of how this works because she has seen others skating and it looks pretty easy; however, when she stands up, she is in for a big surprise … boom! The same applies for teams. As much as individuals have seen other teams succeed and have worked on other teams, until the issues are actually addressed the team cannot understand how much the fall can hurt until this particular team actually falls down. As the forming stage progresses, competitive relationships may become more cooperative, more sharing occurs, the sense of being a team develops, and the team members feel more comfortable working together. This stage of development should focus on detailed planning, creating criteria for the completion of goals, and continuing to encourage the team and build on the positive behaviors demonstrated within the team and change the unhealthy ones.
- *Performing*. The team is now functioning as a unit focused on the objectives of the security council. The team has the best opportunity at this stage to meet deadlines, utilize each member's unique talents, and produce quality deliverables. The members of the team have gained insight into the unique contributions of everyone on the team and recognize that the team can accomplish much more than any one individual on the team.

The security council may be formed in a day but does not become a team in a day. Understanding the path that every team traverses can be helpful in knowing where the team is currently functioning, in addition to allowing the application of strategies to move the team to the next stage. Depending on the organizational culture and the individuals involved, the security council may become a functioning team within weeks or months. What is important is that the commitment to getting to the team stage has a level of persistence and perseverance equal to the passion to build a successful security program within the organization.

10.3.6 Critical Success Factor 6: Integration with Committees

As indicated earlier, management has limited time to be involved in efforts that may not seem to be directly related to their department. Examine the performance objectives and performance reviews of the management of most organizations, and it becomes readily apparent that the majority of the performance rewards are based on the objectives of the individual department goals. Typically, little incentive exists for participating to "enhance the corporate good," even though that may be communicated by the organization's vision, mission, and goals and objectives statements; therefore, committees that do not appear to provide a direct benefit or whose involvement is not seen as critical will be met with a lukewarm reception.

So, when the information security department decides to add a few more committees, this is likely to be met with resistance. A practical approach is to examine the committees that are already established, such as an information technology steering committee, electronic commerce committee, standards committee, senior management leadership committee, or other committee that has a history of holding regularly scheduled (and attended!) meetings. Tapping into these committees and getting 30 minutes on the agenda reserved specifically for security will provide ample airtime for security issues and the appropriate linkage to the company decision makers. In committees such as the information technology steering committee, many of the issues discussed have information security issues embedded within them and attendance provides the mechanism to be at the table during discussion of these issues.

Because the time allotment for discussing information security issues tends to decrease as the management chain is traversed to higher levels of management, it is important to ensure that the security council is established (as explained in critical success factor 3). Participation at the higher levels should be limited to review, discussion, and communication of initiatives and primarily decision making (approval of policies and projects). The senior management stamp of approval is necessary to win broad organizational support and is a key component for successful implementation. If the security council does not perceive that the recommendations are important to the senior leadership, it will lose interest. If the security policies are not approved by the senior leadership, organizational management and staff support will also dissipate; therefore, it is important to get on the agenda and stay on the agenda for every meeting. This also creates the (desired) perception that security is an ongoing business process necessary to implement the business objectives.

When it has been decided which committees would be the best candidates for integration, then the process for how the committees will function together has be decided. Is the IT steering committee the mechanism for policy and project approval? Does their approval depend on a dollar threshold? How are changes to the security policies made at this level? Do they go back to the security council for another review, or are they changed and considered final at this point? Much of this will depend upon each individual cultural norm of how teams and committees function.

10.3.7 Critical Success Factor 7: Establish Early, Incremental Success

Organizations tend to get behind individuals and departments that have demonstrated success in their initiatives because they believe that the next initiative will also be successful. Organizations lose patience with 15- to 18-month initiatives (these tend to be labeled as long-term strategies these days). Projects should be divided into smaller discrete deliverables as opposed to trying to implement the entire effort. This allows the organization to reap the benefits of an earlier implementation while waiting for the results of the longer term initiative. The early initiative may also help shape or redefine the longer term initiative through the early lessons learned.

The early initiatives should provide some benefit to the organization by making their processes easier, enabling new business functionality, providing faster turnaround, reducing paper handling, and making more efficient or effective processes. The primary objective should not be something that benefits the information security department but rather something that provides benefit to the business (although it most likely will provide information security benefit even though this is not the "sell"). Management may be skeptical that the investment in information security will produce an equal amount of benefits. Nothing helps future funding opportunities more than establishing a track record of (1) developing projects that contribute to the business objectives, (2) establishing cost-effective aggressive implementation schedules, (3) delivering on time, (4) delivering within budget, and (5) delivering what was promised (at a minimum).

10.3.8 Critical Success Factor 8: Let Go of Perfectionism

Imagine someone who has been a dancer for 15 years, dancing since she was 2-½ years old and practicing a couple of nights a week to learn jazz and ballet. Imagine the hours of commitment that were required to make movements that would be difficult for most of us appear to be purposeful and graceful and flow with ease. Imagine that it is the big night for showcasing this enormous talent—the recital—and the dancer is rightfully filled with excitement in anticipation of performing in front of friends and family. As the curtain rises, and the dancers are set to begin the performance, the dancer's hairpiece falls off. Oh, no! What to do? Should she stop and pick up the hairpiece? If she does not, will the other dancers have to keep an eye on the floor to avoid stepping on the hairpiece? Does the dancer break into tears? Does she stop and say, "I messed up?" No, none of the above. Although it is preferred that the dancers firmly attach their hairpieces and that is what was planned for and practiced, in the scope of the dance it is not a big deal. In fact, few people in the audience would actually notice it unless it was pointed out by the dancer. The dancer dances on, smiling with great pride, demonstrating the skill that she possesses to the audience's delight.

We should all strive to perform to the best of our ability. The argument could be made that the security profession is made up of many individuals who are control and detail oriented and are analytical and logical decision makers. These characteristics suit the profession very well, as these attributes are many times necessary to master the information security skills; however, another trait inherent to the profession is that of perfectionism, the need to get it right, to do the right thing. Security professionals often use the terms "must" and "will" *versus* "should" and "might?" For example, imagine a security policy written as, "As an employee, you may create an eight-character password made up of a combination of the alphabet, numbers, and special characters, or you may choose something less if you have a hard time remembering it. If KATE123 or your dog's name is easier to remember, then just use that?" That would be absurd—we tell users not only the rules but also how to implement them and that they *must* do that action. Carrying the perfectionist standard forward into every project is a recipe for failure. First of all, resulting project costs will be higher trying to get everything right. Second, the time to implement will be longer, and opportunities to create some business benefit may be missed.

When other individuals across the business units are asked to participate in security initiatives, they may not have a complete understanding of what is expected of them, and some tolerance for this gap in understanding should be accounted for. It may be that they believe that they are supplying the appropriate level of support or are completing the deliverables accurately, given their knowledge of what was communicated to them. The minimum expected deliverable for security initiatives should be that if 80 percent of the goal is completed, then the risk absorbed by the company is considered as reasonable. Achieving the remaining 20 percent should be viewed as the component which, if implemented, would return increased benefits and opportunities but is not necessary to achieve the minimum level of risk desired. Taking this posture allows the information security initiatives to drive toward perfection but does not require attainment of complete perfection to maintain a reasonable risk level. This approach keeps the costs of security implementations in balance with the reduction of risk objectives.

10.3.9 Critical Success Factor 9: Sustaining the Security Council

Humpty Dumpty sat on the wall, Humpty Dumpty had a great … Well, we know the rest of this story. Putting the pieces back together again is much more difficult than planning for the fall. As mentioned in the “ing’ing the council” critical success factor, the team will go through various stages. Frustration, boredom, impatience, and inertia may set in as the size of the effort is realized or the members’ roles in the process become blurred. When we know that something is likely to occur, it is much easier to deal with. Understanding that these events will occur can help the security council to continue its mission and not give up hope. The council may be viewed by members of the organization as a vehicle for resolving security issues. Alternatively, the council may be viewed as a committee that produces no tangible benefits and consumes the most valuable resource, time. The truth is that both views will exist simultaneously within the organization, depending on how the council affects each person individual role. At times, some council members will become disinterested, and it may be necessary to bring in some new blood, thereby expanding the knowledge of the council as well as injecting some new ideas and skills into the team. When this is done, it is important to revisit the mission and vision steps as this person and the rest of the team (with respect o the new individual) is repeating the forming, storming, forming, and performing process.

10.3.10 Critical Success Factor 10: End-User Awareness

The existence of the security council and its relationships with the other committees should be embedded in the security awareness training for every end user within the organization. By establishing the message that the security policies are business decisions (*versus* information technology decisions emanating from the information systems security department), greater acceptance for their implementation is likely. If the message is constructed in such a way that it is clear that middle management and senior management have reviewed and agree with all of the policies line by line, this can be a very powerful message. Line managers and supervisors are less likely to ignore the policies when they understand that the directives are coming from management and not another functional unit that they consider to be their peers. This assumes that the organization is following the necessary practice of training all management with the security training as well as the end users.

If multiple organizational units (e.g., IT steering committees, executive leadership team reviews, focused business or technical workgroups) are participating in the policy development and review process, in addition to the security council, then the relationships between these committees and their associated functions should be explained in concise terms at a high level. For example, if the role of the security council is to review and recommend policies to the IT steering committee, which approves the policies, then these basic functions should be stated so the end users understand the role. If the role of the security council is to establish the security strategy for the organization, prioritize projects, and implement the mission through these initiatives, then that should be stated as well. The advantage to having the end users understand the role of the security council is threefold in that it (1) helps them to understand how these policies are created, (2) conveys the message that their management is involved in the direction of information security (versus security mandates), and (3) provides incentive to keep their own management in line with the security policies.

Is end user awareness of the security council’s existence really a critical success factor? To answer that question, we need to look no further than what the ultimate goal of a security program should be—to have every user of an organization’s information protect it with the same diligence as if it was the purse on her shoulder or a wallet in his back pocket. The answer is you bet! While they may not need to understand the working dynamics of the security council, end users do need to understand that the organizational structure exists, is operating, and is effective at balancing the needs of security and the need to operate the business.

10.4 Conclusion

Security councils provide an excellent mechanism to serve as a sounding board for the information security program and test the vision, mission, strategies, goals, and objectives initiated by the security department. They are excellent mechanisms for establishing buy-in across middle management and subsequently senior management and the end users of the organization. Without them, the information security officer is working in isolation, trying to move initiatives forward, obtaining business management support one person at a time. Security councils are much more effective in establishing the necessary collaboration and ensuring that all points of view are provided a chance to be expressed.

The security council must produce some early successes in order to sustain the commitment of the individuals, each of whom has limited time which could be expended elsewhere. When it comes to committee involvement, people have a choice. Yes, it may be possible to get the individuals to physically show up for a few meetings, but to win their hearts and active participation the council must have a purpose that it is driving toward. At times, this purpose may not be clear, but the council must still be sustained by the leader's belief in the value of the council and the creation of activities when decisions are needed.

Establishing the security council may be seen as threatening to some managers at first, as it means that now some decisions will not be made by the security manager, director, or officer but rather by the security council. Some security leaders may not want that sort of insight into or control of their activities; however, to be truly effective and truly maintain management commitment, the continued participation by business unit managers is essential. This can also be established informally without a security council, but the time commitment is much greater and the collaboration between the business unit managers is less likely to occur.

The security council is not the answer to resolving all of the management commitment issues, as there will always be other business drivers impacting the decisions. Mergers and acquisitions may put security efforts on hold. Debates over the constraints of the technology on the business operations may stall projects. Budget constraints due to a drop in sales volume or public sector funding may preclude security investments. Acceptance of risk by insurance or outsourcing initiatives may change the company's security posture. Other company high-priority projects may consume the necessary internal resources for security projects. Each of these can serve to limit the information security focus and related investments. These are normal events in the course of business; however, consider the individual responsible for information security who has to address these issues alone (lack of management commitment) versus acting on these issues with the collaboration of the security council (supportive management commitment) and the advantages of the security council can be readily appreciated.

10.5 Final Thoughts

The word *commitment*, according to the Merriam-Webster *Dictionary of Law*, is defined as “an agreement or promise to do something in the future?” According to the Merriam-Webster *Medical Dictionary*, commitment is defined as “a consignment to a penal or mental institution?” As security practitioners, it is hoped that we could agree that the former definition is much preferred over the latter. Alternatively, if we fail to obtain the lawyers' definition of commitment, we might end up with the medical definition of commitment.

Management commitment is not something that can be held, touched, or seen; rather, it is a state of being. It is also a current state, subject to change at any moment. The level of commitment is arrived at by management's memory of historical events that led up to the present and pave the path for the future. If these experiences have not been good, then their commitment to spending large investments on future security initiatives will also not be good; therefore, appropriate care must be taken to deliver on the promises made through the security council by the security team, information technology departments, and the business unit representatives, or the next project will not be met with enthusiasm. Security councils are an essential element to building management commitment, and continued delivery provides the necessary oxygen to keep the council functioning.

Commitment is the two-way street. If commitment is expected from management, when it is obtained the security program must also be committed to deliver on the expectations agreed upon. Doing less results in withdrawals from the goodwill that has been established; doing more creates increased satisfaction and confirmation that the investment choices supported by management were, in fact, the right choice. This also increases their trust in their own ability to make decisions supporting the security program.

Finally, each security officer should evaluate his or her own commitment to enhancing the security of the organization and the current cultural view towards security. Where does the organization stand? It will feel uncomfortable at first to establish the council, but it is well worth the effort. So, assemble the security champions from legal, information technology human resources, and individual business units, and begin. Today.

11

Validating Your Business Partners

Jeff Misrahi

11.1 Introduction

Regulations and laws cause us to behave and act in a manner that we should adhere to, but for some reason, sometimes do not. Police enforce speed limits to help keep us driving safely. Similarly, there exist a growing number of governmental regulations that are designed to protect the consumer. Many large companies have information security policies designed to protect the company and its assets, and guide the employees to behavior that the management wishes to see.

Corporate policies, governmental regulations, and common sense drive us to know how our business partners handle and secure our data, and whether they follow and conform to the same information security standards that we do. If not, they might be the weak link in our security chain. Because that is all it takes—one weak link—we need to identify and assess that risk so it can be dealt with.

To find out whether our business partner or vendor is a security liability, we need to perform a simple risk assessment and find out what their security posture is; and determine whether the confidential data we may share with them will be protected in a manner with which we (our management and shareholders) are all comfortable. This risk assessment is ongoing and must be pragmatic. Every credible information security practitioner presents the business line with the risks and options so that intelligent business decisions are made that limit the company's risk.

11.2 Drivers

What are the drivers that cause information security practitioners to gather all this extra information? They actually come from different sources.

11.2.1 Corporate Policies

Best practices in establishing how to secure our enterprise are documented in policies, procedures, and guidelines. These dictate how assets and data are secured, outlining from a high conceptual level down to a detailed bits-and-bytes level. Many companies realize that the security domain that they have direct control over will exceed that of their vendor's. However, it is advisable to have policies that are implemented that state a couple of key points:[1]

- Vendors (contractors, business partners, etc.) must follow the organization's information security policies.
- The vendor must demonstrate that it has sound information security policies. This could be a check-off item during the vendor RFP process.

The information security professional must influence, negotiate, or pressure business partners to have similar standards of behavior. In reality however, changing their behavior in general is not likely to happen. It may be possible to correct some egregious behavior if it can be clearly articulated and defined. But unless you have some leverage, this is not likely to happen. Business relationships are made or vendors are chosen, based on price and product features, not on their information security policies. There are an alarming number of companies that still do not have their information security policies written down. For example, 73 percent of surveyed companies[2] in Britain last year did not have policies.

11.2.2 Regulatory/Legal Governances

External laws and regulations proliferate proportionally to computer crime and corporate fraud. Other legislation around the world will determine the scope of the influence one must exert over a security domain that exceeds what had previously been traditionally an internal matter only. The most relevant of these (at the time of press) that should cause information security practitioners to pay heed include ISO 17799, the Sarbanes-Oxley Act of 2002, California Law (S.B. 1386), and the Health Insurance Portability and Accountability Act (HIPAA).

11.2.3 ISO 17799

This international standard is based on the British Standard BS 7799 and provides detailed security guidelines that could form the basis of your organization's Information Security Management System (ISMS). ISO 17799 is organized into ten major sections that cover:

1. Security policy
2. Organization of assets and resources
3. Asset classification and control
4. Personnel security
5. Physical and environmental security
6. Communications and operations management
7. Access control
8. Systems development and maintenance
9. Business continuity management
10. Compliance

ISO 17799 is broad and technically agnostic but is geared toward information security in an organization. It is reasonable to measure yourself and your partners against this standard as it rapidly gains international recognition and acceptance. This ISO standards document can be purchased from a number of places, including www.iso.ch. If any part of one's IT business is outsourced, or third parties connect into your enterprise, you should apply these guidelines to them as well. By not being in compliance, they could be increasing your risk of accidental or deliberate data loss, breach of contract, or loss of market share to others who *are* in compliance. You increase your risk dramatically with each

[1] Charles Cresson Wood, Information Security Policies Made Easy.

[2] PricewaterhouseCoopers, Information Security Breach Survey 2002.

incremental external connection. In short, you have to know whom you are dealing with and whether they are at least as secure as you. Conversely, they should be looking at your security stance too.

11.2.3.1 Sarbanes-Oxley Act of 2002

This act requires the CEO and CFO of publicly traded companies to certify the effectiveness of internal controls as they relate to ensuring the accuracy of financial information. A good source for information on this law can be found at http://www.sec.gov/spotlight/sarbanes-oxley.htm. Company executives can be held personally responsible for the accuracy and security of the information that resides in their company. This sometimes trickles down to the IT directors and security officers being required to personally sign statements certifying that information systems that host financial records and systems are secure and under control. The most senior executive management has to rely on the controls the information security professional implements. The penalties for failure to comply are serious and include fines and imprisonment. As with the California Law discussed below, we must ensure that there are no weak links in the chain of security control, even with third parties or business partners. We must perform our due diligence with a risk assessment to determine, as best as possible, whether the security controls at all locations that could affect the financial records are in place. Possibly in this case, an independent third-party review may be in order.

11.2.3.2 California Law (S.B. 1386)

As of July 1, 2003, this law requires companies that conduct business in California to expediently notify their California customers when their personal data is accessed (or is believed to have been accessed) by unauthorized persons. There is clearly more to the law than this (politicians love to wax eloquent even more than information security professionals) but in essence the onus is on the information security team to detect and hopefully prevent unauthorized access to personal information. While our controls may be adequate, we may still need to pass personal data to another party, such as a payroll processing company. Should there be any indication of unauthorized access to the data, then the company must go public with the news of a security breach and face penalties of lawsuits and damages. The simplest ways to avoid this is by encrypting the personal data—although there is no mandate to use any particular encryption algorithm. This is an important fact to determine during the risk assessment and evidence of encryption and sound key management practices should be verified. More information on this and other California privacy legislation may be found at http://www.privacy.ca.gov/leg2002.htm.

11.2.3.3 Health Insurance Portability and Accountability Act (HIPAA)

The relevance of the HIPAA Act to the information security professional is that the act specifies that personal data (medical or personal records) must be reasonably protected in storage and transmission, both within and outside the company or institution. See http://www.cms.hhs.gov/hipaa/ for more information. Records must be protected to ensure the confidentiality, integrity, and availability of that data. Consider the company that outsources its data backups, for example. The backup media must be sanitized prior to that media being reused; data should be stored in encrypted format—these are both reasonable measures. Consequently, the onus is on the information security professional to check (and recheck) that business partners are working in conjunction with the organization to aid in its efforts to be in compliance.

11.3 Solutions

Each corporation needs to elicit information from potentially a myriad vendors and business partners as part of due diligence in making sure they are all doing the right thing. How can we most efficiently do this?

Information security professionals should be careful what they ask for—they may just get it. Whether with an audit or questionnaires, the information security professional may request all the documentation. If you do not want to wade through 600 pages of network diagrams, memoranda, and potential red herrings, be more specific in the requests.

11.3.1 Audits

Service providers (such as banks, ISPs, etc.) typically are inundated with requests to prove and demonstrate that their security and privacy meet acceptable standards. It is in their interest both in time and money to do this once and then leverage that effort. Third-party audits fulfill this function and can provide a level of comfort and assurance to both the company being audited and the partner that requests the validation. Having an independent third-party attest to the controls that the business partner is implementing should offer some solace to the information security professional. Utilizing a standard process to review these controls, organizations can determine their compliance against some recognized best practices standard, as well as compare and contrast other audited companies relative to their own (high) security standards. However, each consulting firm will often use its own processes.

Audits, like any other risk management tool, need to be repeated cyclically after vulnerabilities have been identified and mitigated. The more exhaustive audit should occur the second time around, when there are fewer issues to discover. Such audits are not cheap and can range in price; it is not uncommon for a large company to pay in excess of $600,000 for a broad-scope review of a complex environment. This cost is exacerbated by the fact that it covers only a one-year period and needs to be renewed at additional expense each year thereafter.

Because organizations can be measured and certified against different standards, this method is fundamentally flawed. Therefore, this author would opt for a standard certificate rather than a consultant's opinion. Three examples include:

1. Statement on Auditing Standards (SAS) No. 70, (from the AICPA)
2. SysTrust (from AICPA/CICA)
3. BS 7799-2

11.3.1.1 SAS 70

The Statement of Auditing Standards (SAS) number 70, from the American Institute of Certified Public Accountants (AICPA), is an internationally recognized auditing standard. Review http://www.aicpa.org for more information. An auditor will evaluate and issue an opinion on the business process and computer controls that an organization has in place. This opinion discloses the control activities and processes to its customers and its customers' auditors in a uniform reporting format. It is an excellent way to avoid over-auditing. It is done once and copies of the report can be handed out to business partners. The SAS 70 attestation comes in two flavors:

Type I: this audits the design of the controls at a given point in time.

Type II: this audits the design and tests the effectiveness of the controls over a period of time. The period of time is usually a year; although it is possible to have a shorter period of examination, say three months, if a subsequent one-year examination follows.

In the absence of anything else, the SAS 70 seems like a very useful tool. However, it is the customer organization, not the auditor that selects the controls to be examined. The SAS 70 does not present a predetermined, uniform set of control objectives or control activities against which service organizations are measured. The audited company may select the controls it wishes to be audited. For example, if the organization knows that the controls pertaining to the retention of backed-up media are weak, then this can simply be omitted from the list of controls being tested. The final report will be clean. SAS 70 Type II can be a meaningful document for the informed information security professional to read as long as what is not covered is examined as thoroughly as what *is* covered. It is in this regard that the lack of a complete checklist covering all the controls and processes is what negates the effectiveness of having this type of independent audit.

Second, members of the AICPA who perform the audit are primarily CPA-trained and not necessarily security-trained professionals. Of course, they can utilize staff members who have some information security knowledge, but typically they follow rigid guidelines and do not think or act out-of-the-box.

11.3.1.2 SysTrust

The SysTrust certification is slowly gaining popularity in the United States, much in the same way as BS 7799-2 certification is in the United Kingdom. It is broader and deeper than a SAS 70, but as with a SAS 70, the third party can still pick and choose the scope of what gets examined. However, there is more structure to the items being evaluated than an SAS 70, and it lends itself better to a more technical environment. It tests for reliability in four areas: security, integrity, availability, and maintainability. The premise is that an unreliable system can trigger a chain of events that could bring a corporation crashing down. Each section has multiple criteria to be evaluated (19, 14, 12, 13 items, respectively), making this a comprehensive and costly certification. It is difficult to determine how many SysTrust certificates have been issued, but it is estimated to be an order of magnitude less than BS 7799 certificates. The SysTrust principles and criteria are well documented[3] by the AICPA, at their site http://www.aicpa.org/assurance/systrust/princip.htm. Accounting firms tend to be the leading providers of this certification, which are only valid for one year.

11.3.1.3 BS-7799-2

There is no ISO equivalent for certification, so you need to use the British Standard BS 7799-2. ISO 17799 is only equivalent to the BS 7799-1 code of practice, and cannot be used as the basis for accredited certification because it is only a framework for describing areas that need to be assessed. A company could get a particular business function BS 7799 certified but not necessarily the entire infrastructure. Therefore, if it is crucial that your business partner be certified, you must carefully determine in what area, exactly, they are certified in. There are only 12 organizations listed with the United Kingdom Accreditation Service (UKAS) that are accredited to certify Information Security Management Systems. Not just any consulting or audit firm can provide this. The list of organizations that have been certified can be found at the ISMS International User Group site at http://www.xisec.com. The breakdown by country, as of September 2004, (version 100) is shown in Exhibit 11.1.

At this time, only a small percentage of the companies certified are located in the United States, a surprisingly low number for a country with a suite of state and federal legislation. However, the trend from month to month is increasing (there was a 20 percent increase in total certificates from February to

EXHIBIT 11.1 Breakdown by Country

Japan	408	China	8	Argentina	1
UK	156	Ireland	8	Colombia	1
India	51	Austria	4	Egypt	1
Korea	27	Sweden	4	Luxembourg	1
Taiwan	27	Switzerland	4	Macau	1
Germany	25	Brazil	3	Malaysia	1
Italy	17	Iceland	3	Netherlands	1
Hong Kong	15	Mexico	3	Qatar	1
Australia	11	Poland	3	Saudi Arabia	1
Singapore	11	Belgium	2	Slovenia	1
Finland	10	Denmark	2	South Africa	1
Hungary	9	Greece	2	Relative Total	855
Norway	9	Spain	2	Absolute Total	846
USA	9	UAE	2		

Note: The Absolute Total represents the actual number of certificates. The Relative Total reflects certificates that represent multi-nation registrations or are dual-accreditations. Further details of accredited ISMS/BS 7799 certificates can be found on the official International Register Web site www.xisec.com.

This table is copyright © ISMS International User Group 2002–2004 and is printed with permission from the ISMS International User Group. Please note that this information is updated regularly and the table used here is only current at the date of publication. More up-to-date figures can be found by going to the register Web site at www.xisec.com.

[3] AICPA/CICA SysTrust Principles and Criteria for Systems Reliability, Version 2.0.

March 2004, and the number of U.S. certificates almost doubled). At the same time, the number of certifications granted in Japan has increased substantially. It will be interesting to watch and see whether or not this is a continuing trend. BS 7799 is a standard that is becoming more widely known (considering there are so few standards, this is not difficult) and one would expect documented compliance to this standard to be a desirable commodity in the future. It is also important to note that the certificates are valid for three years, with frequent testing during this period.

11.3.2 On-Site Visits

An on-site visit must be seriously considered if your data is stored at a location not under your ownership or immediate control. This is in addition to any audit or questionnaire. Your policies might dictate that you validate that the controls securing your data are adequate. The third-party attestation (described above) may suffice. However, you should still "kick the tires" yourself. A visit to determine that there are locked doors, closed-circuit TV (CCTV) cameras, and ID badges is rudimentary and what is expected at a minimum. A visit should also be undertaken to establish rapport, view procedure manuals, and dig a little deeper into the processes rather than just the technology used to secure the facilities and data. Establishing rapport is more than just putting a face to a name. It might give you the opportunity to exchange ideas and methodologies. Managed security services companies routinely harden the operating systems. Your superb technical staff may do similar tasks internally and perhaps have a particular parameter set for improved security that the managed service missed. You should feel able to communicate technical information to each other for mutual benefit. Alternatively, you might be aware of some impending legislation that may have an impact on how data is backed up. It is better to be proactive and help guide your partners rather than react after the fact.

11.3.3 Questionnaires

Questionnaires may or may not be good tools to use—it depends on one's perspective. For security practitioners seeking information on their vendors, a common set of questions makes the most sense. Presumably these will be well thought out, meaningful, and consistent. It is in this regard that a specialized questionnaire should be developed that best addresses that company's needs. Consistency is most important when reviewing the responses. On the other hand, this will mean that questions will either be nonapplicable in many cases or target the lowest common denominator. Not all vendors operate under the same regulations. Not all vendors have or require the same level of security controls. This will tend to make it very difficult in reviewing the responses and prioritizing which vendor's risks are most meaningful and should be addressed.

It is a lot of work for the information security professional to issue questionnaires to business partners. You do this to solicit information and evaluate the responses to determine the risk level in doing business with that party. The level of effort involved in determining and mitigating the risk should be commensurate with the value of the asset being examined. This is why many companies do not audit or send out questionnaires to *every* third party that comes in contact with them, but select perhaps those that have a relationship above a certain dollar amount, say, $100,000. Everyone's threshold and acceptance level of risk is different, however. As mentioned earlier: one size does not fit all.

There are some simple guidelines in preparing questionnaires to send out, including:

- Avoid abbreviations that others may not understand. Although this may seem obvious, it is often overlooked. This is especially true for industry- or technology-specific terminology.
- Be thoughtful of the questions, make them relevant, but be more mindful of the answers that may be generated. It is best if the questions can be posed in such a way as to solicit a "Y" or "N" response. However, be aware that some questions may have the response of "Not Applicable." One example of this would be a bank that asked the question: "Is this project exempt from OTS notification?"

First, you would need to determine that OTS meant "Office of Thrift Supervision" (see the previous bullet). The respondent was neither a bank nor a thrift institution and was not regulated by them. To respond "N" would have implied they were subject to their regulation, but were exempt. To say "Y" would have been untrue. What was needed was "N/A."

- If there are areas of particular concern, then drill down and ask specific questions. Ask follow-up questions. For example, after asking "Do you have a backup site" and then not following up to find out where it is or how it is secured, is negligent. I know of one case where the main site was relatively secure but the backup server and data were located in the CEO's bedroom (it was a small company).
- Some of the better and more complete questionnaires are broken down into ten or more areas—mirroring the different domains of knowledge found in the CISSP courses or the components in ISO-17799. This proves useful because the recipient can easily pass the appropriate sections to other knowledgeable parties within the partner's company. It also demonstrates that the author has put some thought into the design and content of the questionnaire.
- Design the form so it has sufficient space for long answers and could expand and does not limit the responder.
- Send the questionnaires electronically. Faxed or paper copies are (a) slow to complete, and (b) waste natural resources. It also helps facilitate iterative editing sessions, should they be required.
- Make sure the responses are sent confidentially.
- Provide a contact name and number—there is no value in sending out a questionnaire anonymously. It is better for respondents to ask a clarifying question than it is for them to leave a question blank or incorrect because of a misunderstanding.
- If you are going to ask probing and deep questions, be prepared to have to sign a nondisclosure agreement.

When the questionnaire is completed and returned, you may have demonstrated a level of due diligence in complying with some of the regulations or policies. But most certainly, as an information security practitioner, you have only just started. Now comes the arduous work of examining the responses and determining whether or not there is an acceptable level of risk with this particular partner. Some larger banks have teams of five or more CISSP-certified people on staff dedicated to sending out and evaluating questionnaires, resolving issues with the third parties, and then explaining the risks to their own business lines' management. Some companies assign different risk weightings to the responses and end up with a final score that can indicate whether or not the company is above an acceptable risk level.

Do not rely on just filing the questionnaires when you receive them. And do not look for just the negative responses. Rather, read the entire document, and evaluate the respondent in the context of the business and the risks that were identified. Determine if there are mitigating controls and, most importantly, follow up on issues that might be considered of elevated risk.

11.4 Responding to Questionnaires

This is the other side of the coin. When responding to questionnaires, do not feel obligated to give all the information requested—just because it is being asked. For example, revealing that the data center is in an unmarked building in a particular city is adequate. But requests for the street address, floor plans, and locations of power and telephone outlets (as this author has been asked) is most certainly not going to solicit a response—even with an executed nondisclosure agreement in place.

Be wary of documents requiring a signature. You should seek legal advice, because signing the questionnaire responses may supersede existing master agreements you have with the business partner.

EXHIBIT 11.2 Example from a Simple Questionnaire

		A.Access Control	
Item #	Criteria	Response	Comments/Explanation
A.1	Are passwords used by the application?	Y	
A.2	Are passwords complex?	N	Biometric authentication used in conjunction with password.
A.3	Can passwords be forced to have a minimum length?	N	
		B.Disaster Recovery	
Item #	Criteria	Response	Comments/Explanation
B.1	Are there backup generators?		
B.2	How long can they run with the emergency fuel supply?		

Every questionnaire will be different; formats, level of detail, and questions will vary. The best solution to reduce your workload is to attempt to preempt this by publishing an information security FAQ (Frequently Asked Questions) that can be distributed. It would be prudent to run the FAQ by your Legal Department first. The questions in conjunction with the third-party attestation should be enough to assuage the fears of most risk managers. This, however, conflicts with the verifying company's need to request information on security that is in the format they want. Unfortunately, one size does not fit all, and the party with the biggest influence will probably prevail.

In the example in Exhibit 11.2, the response to question A.2 would normally be cause for concern (if the application were accessing data that needed a reasonable level of protection). However, the explanation given demonstrates a good mitigating control. Hence, it is valuable for both parties to provide this additional information. A red flag is not raised, so a subsequent communication is not necessary. However, it is not clear what kind of biometric authentication is used, or how it is applied or administered. The totally diligent information security professional may wish to obtain clarification on this. The point demonstrated here is the value of enticing additional comments, rather than responding with a binary response. Even with an additional response, the control may not be implemented correctly and your risk level is still high.

11.5 Conclusion

There is no singularly best solution for determining whether your business partner or vendor is a security liability. Much depends on the size and nature of the information security professional's organization; the nature of the data the vendor is exposed to; and to some extent, the size of the budget. Formal certifications tend to be expensive; filling out large numbers of questionnaires is draining on personnel resources. Evaluating incoming questionnaires is even more time consuming. Regardless of the role one plays, a significant effort needs to be expended.

Risk management, audit, information technology, legal, and procurement departments are all likely candidates for submitting or reviewing questionnaires. It does not matter which organization is involved as long as someone is and the results of the questionnaire are acted upon. But what does one do if the information received is unsatisfactory? The first step would be to understand the issue and then determine if there are any mitigating controls. Approach the vendor and determine if there are plans to rectify the issues at hand. A decision must be made on how to continue the business relationship and whether the risk to one's company is acceptable. Failing that, the information security professional needs to notify their management and the business line involved with this vendor/business partner.

Most information security professionals would like to rely on an independent certification or attestation that shows the controls of their business partner or vendor are sound and meet an industry-accepted level. However, these certifications are not widely used, presumably because they are expensive to obtain and equally expensive to maintain. Until certifications become affordable and widely adopted, there will be no uniform and convenient solution.

A combination of the methods described here will help identify and reduce the information security risks to your organization. What one does with the information gleaned is critical to your success.

If one can afford it, getting third party certification to a standard such as BS 7799 is desirable for your board of directors and shareholders. In other words, use it for internal use and for validating that the controls are sound. In this regard, certifying a particular one or two business functions may be all that is needed. It is unreasonable to expect all your business partners to have similar certifications so this author would use a detailed and customized questionnaire to solicit information from partners. One must then expect to follow up on the questionnaire by probing deeper where necessary to remediate issues.

Finally, be prepared to receive an FAQ in response to your questionnaire. This may be acceptable, depending on the breadth and depth of the FAQ. Information security professionals should always strive to obtain the information needed to manage their company's risks.

12 Measuring ROI on Security

Carl F. Endorf

Finding a return on investment (ROI) has never been easy; and for technology, it has been even more difficult. To make matters more complicated, the return on security investment (ROSI) has been nebulous at best. It is easy to say that a Web defacement or hack attack will cause a "loss of customer confidence," but what does that really mean? What is the financial impact on an organization if it experiences a loss of customer confidence? What needs to be determined is the causation of the financial impact and the event itself.[1] I believe that there are clear methods to do this.

The purpose of this chapter is to discuss the basic methods of finding the ROSI for an organization and the implications that this will have on the business of security. We also examine a seven-step analysis to help determine the ROI for security.

12.1 Understanding ROI

It is easy to get security money *after* you are attacked, but the problem is trying to get the money before that happens. How do you quantify what security gets you? If you spend an additional $3,000,000 this year on security, how do you justify it? What is the return on that investment? As a security professional, you see different vulnerabilities and attacks on a daily basis and it may be very clear to you that your enterprise needs to be more secure. But from a business perspective, it is not always that clear. Executives realize that threats are a reality, but they want some way to quantify these threats and know what the cost is for implementing a security measure or the financial consequences if they do not.

Many security managers rely on a soft return on investment (SROI) that is not based on actual data but on FUD (fear, uncertainty, and doubt) to sell the need for new security measures or the expansion of existing ones. The idea is that if you can scare enough people they will give you the money. The problem with this is that it can lead to implementing technology that is not always needed or that solves a problem where there is minimal risk of that threat.

Today more than ever, with a recession in the economy, it is difficult to justify with any solid evidence what security expenses are needed. For example, if you need to add three security people and update your firewalls, this will result in more uptime and less downtime on the network, which means the company will make more money; but where is the quantifiable value associated with staffing and firewalls?[2] The SROI will not help justify these costs.

This leads to the better answer of basing security expenditures on real numbers and obtaining a hard return on investment (HROI). The HROI will give a quantitative answer that will help justify the use of security and can help determine the operational cost of security.

Getting an HROI can be accomplished in much the same way a risk assessment is done. The following seven steps are involved in the process[3]:

1. Asset identification and valuation
2. Threat and vulnerability exposure factor (EF)
3. Determine the single loss expectancy (SLE)
4. Annualized rate of occurrence (ARO)
5. Compute the annual loss expectancy (ALE)
6. Survey controls
7. Calculate the ROSI

12.2 Asset Identification and Valuation

First, you need to list your organization's tangible and intangible assets. We define "tangible" as an asset that has physical form and "intangible" items as any item that does not have physical form, such as goodwill and intellectual property. Tangible items can usually be tracked easily in small organizations, but this becomes progressively more difficult as the size increases. Typically, larger organizations will have an asset management/tracking area that can provide a list. You will then need to assign a dollar value to each tangible asset, with depreciation taken into account. One way this can be done is as follows[4]:

$$\frac{\text{Cost} - \text{Salvage Value}}{\text{Useful Life}} = \text{Yearly Depreciation}$$

Next, make a list of intangible items. This can be subjective and is based on perceived value, but the following questions will help: "Knowing what you do about the asset, what would you pay to have that asset if you did not already own it?" and "What revenue will this asset bring to the organization in the future?"

Another possibility is to rank all your assets, both tangible and intangible, according to your perceived value of them. Given that you have values for the tangible assets, placement of the intangibles relative to the tangibles should help you in valuing the intangible assets.

12.3 Threat and Vulnerability Exposure Factor

Now that the assets have been identified, it is necessary to examine the possible threats to each of these assets. This is not a definite as there are many variables involved, but the subject matter experts for many of these assets can help identify exposures. This is an estimate; it cannot include everything possible because we do not know all the possible exposures.

The next step is to examine the threat and vulnerability exposure factor (EF). The EF is the percentage of loss a realized threat event would have on a specific asset, that is, the consequence. The EF can be a large number, as is the case of a major event such as a fire or a small number like the loss of a hard drive. It can be expressed from 0 to 100 percent of loss if exposed to a specific event. For example, if a virus brought down your Web farm, this may cause a 75 percent loss in the Web farm's functionality.

12.4 Determine the Single Loss Expectancy

The single loss expectancy (SLE) measures the specific impact, monetary or otherwise, of a single event. The following formula derives the SLE[5]:

$$\text{Asset value} \times \text{Exposure factor} = \text{SLE}$$

12.5 Annualized Rate of Occurrence

The annualized rate of occurrence (ARO) is the frequency with which a threat is expected to occur. The number is based on the severity of controls and the likelihood that someone will get past these controls.[6] ARO values fall within the range from 0.0 (never) to a large number.

The ARO is not a definite number and can be subjective. It is best based on probability from observed data, much like insurance. You will need to look at your organization's metrics on hardware, software, and past threats. For example, company X looks at the past five years' incident handling data and finds that there was an average of three attempts per external employee for the 100 external employees attempting unauthorized access. This would calculate to an ARO of 300, or 3 attempts × 100 external employees = 300.

12.6 Annual Loss Expectancy

The annual loss expectancy (ALE) can now be determined from the data collected. The following formula sets for the calculation needed:

$$\text{Single loss expectancy (SLE)} \times \text{Annual rate of occurrence (ARO)} = \text{ALE}$$

The ALE is the number you can use to justify your security expenditures. For example, you want to protect your payroll server within the company. The server itself will not cause a direct loss to the company if compromised, but will result in loss of reputation if exposed. The value of the system itself is \$10,000, and the information and loss of reputation is placed at \$250,000. The SLE has been placed at 75 percent and the ARO at 0.3. Using the formula above, we obtain an SLE of \$58,500 (\$260,000 × 0.75) × 0.3 = \$58,500. Once the ALE is known, it can be used by information security management to determine a cost-effective risk mitigation strategy.[3]

12.7 Survey Controls

It is now essential to survey the controls that you have in your existing security architecture and examine the SLE of those assets. If the loss expectancy is exceptionally high, you would want to consider new controls to mitigate those threats. For example, using the situation in the previous section, we have an SLE of \$58,000; but if we are spending \$100,000 a year to protect it, we are spending more than we need and new controls should be selected. It is best if each exposure has a control identified for it on a per-exposure basis.

12.8 Calculate Your ROSI

Now we are at the point of being able to calculate the ROSI. The basic calculation for ROI is the Return/Assets. Therefore, we can subtract the cost of what we expect to lose in a year for a specific asset from the annual cost of the control:

$$\text{Annual loss expectancy (ALE)} - \text{Current cost of control (CCC)} = \text{ROSI}$$

EXHIBIT 12.1 ROSI for Proprietary Confidential Data

Steps			Formula
Asset identification and valuation	**Asset:** proprietary confidential data	Valuation: $5,000,000	
Threat and vulnerability exposure factor (EF)	**Threat:** disclosure of data	**EF:** 90%	
Determine the single loss expectancy (SLE)	$5,000,000×.90=	**SLE:** $4,500,000	Asset Value×Exposure Factor=SLE
Annualized rate of occurrence (ARO)	Based on observed data, the probability is 1 in 20 years	ARO=0.05	
Compute the annual loss expectancy (ALE)	$4,500,000×.05=	**ALE**=$225,000	Single Loss Expectancy (SLE)×Annual Rate of Occurrence (ARO)=ALE
Survey controls	Current controls are costing $95,000	ROSI=$130,000	
Calculate ROSI	$225,000−$95,000		Annual loss expectancy (ALE)−Current cost of control (CCC)=ROSI

For example, if in the past we had a cost of $500,000 a year due to security breaches and we add an intrusion detection system (IDS) that costs the company $250,000 a year (this includes support, maintenance, and management) and is 80 percent effective, then we have a positive ROI of $150,000.

12.8.1 ROSI Example

Now apply the seven steps to the following situation. You are asked to protect a small database that contains critical business data. The data has been valued at $5,000,000 and has never been compromised. Based on recent events in similar companies with this type server and data, the probability of an attack has been estimated to happen about once every 20 years. You are asked to look at the current access controls in place that are costing the company $95,000 a year to maintain and see what the ROSI is on these controls.

As you can see from Exhibit 12.1, the total ROSI for the current access control gives the organization a positive ROSI of $130,000 per year.

12.8.2 Arguments against ROSI

One argument is that valuating the ROSI lacks precision and is based on approximations. This is true to an extent; but as more data is collected within your organization and the industry, the picture will become clearer, much like insurance actuarial tables can predict the probabilities of certain events. Another argument is that these hard numbers can give a company a false sense of security because the company feels these numbers are exact but needs to keep in mind that they need reevaluation. Another argument is that that the ROSI is immutable; but if it is made a part of the annual review process, this should not be the case.[3]

12.9 Conclusion

This chapter discussed a seven-step methodology to help determine the ROSI for an organization. The methods used were basic and could each be explained in much more depth, but they do illustrate that hard numbers can be obtained. These hard numbers help security managers to go away from using FUD and relying on better data. The data presented here is based on the principles of probability theory and statistics.

Although much of the data that the ROSI is based on is still in its infancy, it will likely take shape in the near future. The key is getting credible data to base the numbers on. We see this taking shape in the insurance industry as hacking insurance is being offered; these are steps in the right direction. It is likely that the insurance industry will be a driving force in the science of ROSI.[2]

13

The Human Side of Information Security

Kevin Henry

We often hear that people are the weakest link in any security model. That statement brings to mind the old adage that a chain is only as strong as its weakest link. Both of these statements may very well be true; however, they can also be false and misleading.

Throughout this chapter we are going to define the roles and responsibilities of people, especially in relation to information security. We are going to explore how people can become our strongest asset and even act as a compensating strength for areas where mechanical controls are ineffective. We will look briefly at the training and awareness programs that can give people the tools and knowledge to increase security effectiveness rather than be regarded as a liability and a necessary evil.

13.1 The Role of People in Information Security

First, we must always remember that systems, applications, products, etc. were created for people—not the other way around. As marketing personnel know, the end of any marketing plan is when a product or service is purchased for, and by, a person. All of the intermediate steps are only support and development for the ultimate goal of providing a service that a person is willing, or needs, to purchase. Even though many systems in development are designed to reduce labor costs, streamline operations, automate repetitive processes, or monitor behavior, the system itself will still rely on effective management, maintenance upgrades, and proper use by individuals. Therefore, one of the most critical and useful shifts in perspective is to understand how to get people committed to and knowledgeable about their roles and responsibilities as well as the importance of creating, enforcing, and committing to a sound security program.

Properly trained and diligent people can become the strongest link in an organization's security infrastructure. Machines and policy tend to be static and limited by historical perspectives. People can respond quickly, absorb new data and conditions, and react in innovative and emotional ways to new situations. However, while a machine will enforce a rule it does not understand, people will not support a rule they do not believe in. The key to strengthening the effectiveness of security programs lies in education, flexibility, fairness, and monitoring.

13.2 The Organization Chart

A good security program starts with a review of the organization chart. From this administrative tool, we learn hints about the structure, reporting relationships, segregation of duties, and politics of an organization. When we map out a network, it is relatively easy to slot each piece of equipment into its proper place, show how data flows from one place to another, show linkages, and expose vulnerabilities. It is the same with an organization chart. Here we can see the structure of an organization, who reports to whom, whether authority is distributed or centralized, and who has the ability or placement to make decisions—both locally and throughout the enterprise.

Why is all of this important? In some cases, it is not. In rare cases, an ideal person in the right position is able to overcome some of the weaknesses of a poor structure through strength or personality. However, in nearly all cases, people fit into their relative places in the organizational structure and are constrained by the limitations and boundaries placed around them. For example, a security department or an emergency planning group may be buried deep within one *silo* or branch of an organization. Unable to speak directly with decision makers, financial approval teams, or to have influence over other branches, their efforts become more or less philosophical and ineffective. In such an environment the true experts often leave in frustration and are replaced by individuals who thrive on meetings and may have limited vision or goals.

13.3 Do We Need More Policy?

Many recent discussions have centered on whether the information security community needs more policy or to simply get down to work. Is all of this talk about risk assessment, policy, roles and responsibilities, disaster recovery planning, and all of the other *soft* issues that are a part of an information security program only expending time and effort with few results? In most cases, this is probably true. Information security must be a cohesive, coordinated action, much like planning any other large project. A house can be built without a blueprint, but endless copies of blueprints and modifications will not build a house. However, proper planning and methodologies will usually result in a project that is on time, meets customer needs, has a clearly defined budget, stays within its budget, and is almost always run at a lower stress level. As when a home is built, the blueprints almost always change, modifications are done, and, together with the physical work, the administrative effort keeps the project on track and schedules the various events and subcontractors properly.

Many firms have information security programs that are floundering for lack of vision, presentation, and coordination. For most senior managers, information security is a gaping dark hole into which vast amounts of cash are poured with few outcomes except further threats, fear-mongering, and unseen results.

To build an effective program requires vision, delegation, training, technical skills, presentation skills, knowledge, and often a thick skin—not necessarily in that order.

The program starts with a vision. What do we want to accomplish? Where would we like to be? Who can lead and manage the program? How can we stay up-to-date, and how can we do it with limited resources and skills?

A vision is the perception we have of the goal we want to reach. A vision is not a fairy tale but a realistic and attainable objective with clearly defined parameters. A vision is not necessarily a roadmap or a listing of each component and tool we want to use; rather, it is a strategy and picture of the functional benefits and results that would be provided by an effective implementation of the strategic vision.

How do we define our vision? This is a part of policy development, adherence to regulations, and risk assessment. Once we understand our security risks, objectives, and regulations, we can begin to define a practical approach to addressing these concerns.

A recent seminar was held with security managers and administrators from numerous agencies and organizations. The facilitator asked the group to define four major technical changes that were on the horizon that would affect their agencies. Even among this knowledgeable group, the response indicated that most were unaware of the emerging technologies. They were knowledgeable about current developments and new products but were unaware of dramatic changes to existing technologies that would certainly have a major impact on their operations and technical infrastructures within the next 18 months. This is a weakness among many organizations. Strategic planning has been totally overwhelmed by the need to do operational and tactical planning.

Operational or day-to-day planning is primarily a response mechanism—how to react to today's issues. This is kindly referred to as crisis management; however, in many cases the debate is whether the managers are managing the crisis or the crisis is managing the managers.

Tactical planning is short- to medium-term planning. Sometimes, tactical planning is referred to in a period of up to six months. Tactical planning is forecasting developments to existing strategies, upgrades, and operational process changes. Tactical planning involves understanding the growth, use, and risks of the environment. Good tactical plans prevent performance impacts from over-utilization of hardware resources, loss of key personnel, and market changes. Once tactical planning begins to falter, the impact is felt on operational activity and planning within a short timeframe.

Strategic planning was once called long-term planning, but that is relative to the pace of change and volatility of the environment. Strategic planning is preparing for totally new approaches and technologies. New projects, marketing strategies, new risks, and economic conditions are all a part of a good strategic plan. Strategic planning is looking ahead to entirely new solutions for current and future challenges—seeing the future and how the company or organization can poise itself to be ready to adopt new technologies. A failure to have a strategic plan results in investment in technologies that are outdated, have a short life span, are ineffective, do not meet the expectations of the users, and often result in a lack of confidence by senior management (especially from the user groups) in the information technology or security department.

An information security program is not only a fire-fighting exercise; yet for many companies, that is exactly what they are busy with. Many system administrators are averaging more than five patch releases a week for the systems for which they are responsible. How can they possibly keep up and test each new patch to ensure that it does not introduce other problems? Numerous patches have been found to contain errors or weaknesses that affect other applications or systems. In October 2001, anti-virus companies were still reporting that the LoveLetter virus was accounting for 2.5 percent of all help desk calls—more than a year after patches were available to prevent infection.[1]

What has gone wrong? How did we end up in the position we are in today? The problem is that not any one person can keep up with this rapidly growing and developing field. Here, therefore, is one of the most critical reasons for delegation: the establishment of the principles of responsibility and accountability in the correct departments and with the proper individuals.

Leadership and placement of the security function is an ongoing and never-to-be-resolved debate. There is not a one-size-fits-all answer; however, the core concern is whether the security function has the influence and authority it needs to fulfill its role in the organization.

The role of security is to inform, monitor, lead, and enforce best practice. As we look further at each individual role and responsibility in this chapter, we will define some methods of passing on information or awareness training.

13.4 Security Placement

The great debate is where the security department should reside within an organization. There are several historical factors that apply to this question. Until recently, physical security was often either outsourced or considered a less-skilled department. That was suitable when security consisted primarily of locking doors and patrolling hallways. Should this older physical security function be merged into the technical and cyber-security group?

To use our earlier analogy of security being a chain, and the risk that one weak link may have a serious impact on the entire chain, it is probable that combining the functions of physical and technical security is appropriate. Physical access to equipment presents a greater risk than almost any other vulnerability. The trend to incorporate security, risk management, business continuity, and sometimes even audit under one group led by a chief risk officer is recognition both of the importance of these various functions and the need for these groups to work collaboratively to be effective.

The position of chief risk officer (CRO) is usually as a member of the senior management team. From this position, the CRO can ensure that all areas of the organization are included in risk management and disaster recovery planning. This is an extremely accountable position. The CRO must have a team of diligent and knowledgeable leaders who can identify, assess, analyze, and classify risks, data, legislation, and regulation. They must be able to convince, facilitate, coordinate, and plan so that results are obtained; workable strategies become tactical plans; and all areas and personnel are aware, informed, and motivated to adhere to ethics, best practices, policy, and emergency response.

As with so many positions of authority, and especially in an area where most of the work is administrative such as audit, business continuity planning, and risk management, the risk of gathering a team of paper pushers and “yes men” is significant. The CRO must resist this risk by encouraging the leaders of the various departments to keep each other sharp, continue raising the bar, and striving for greater value and benefits.

13.5 The Security Director

The security director should be able to coordinate the two areas of physical and technical security. This person has traditionally had a law enforcement background, but these days it is important that this person have a good understanding of information systems security. This person ideally should have certification such as the CISSP (Certified Information Systems Security Professional administered by ISC^2 [www.isc2.org]) and experience in investigation and interviewing techniques. Courses provided by companies like John E. Reid and Associates can be an asset for this position.

13.6 Roles and Responsibilities

The security department must have a clearly defined mandate and reporting structure. All of its work should be coordinated with the legal and human resources departments. In extreme circumstances it should have access directly to the board of directors or another responsible position so that it can operate confidentially anywhere within the organization, including the executive management team. All work performed by security should be kept confidential in order to protect information about ongoing investigations or erroneously damage the reputation of an individual or a department.

Security should also be a focus point to which all employees, customers, vendors, and the public can refer questions or threats. When an employee receives an e-mail that he suspects may contain a virus or that alleges a virus is on the loose, he should know to contact security for investigation—and not to send the e-mail to everyone he knows to warn them of the perceived threat.

The security department enforces organizational policy and is often involved in the crafting and implementation of policy. As such, this department needs to ensure that policy is enforceable, understandable, comprehensive, up-to-date, and approved by senior management.

13.7 Training and Awareness

The security director has the responsibility of promoting education and awareness as well as staying abreast of new developments, threats, and countermeasures. Association with organizations such as SANS (www.sans.org), ISSA (www.issa.org), and CSI (www.gocsi.org) can be beneficial. There are many other groups and forums out there; and the director must ensure that the most valued resources are used to provide alerts, trends, and product evaluation.

The security department must work together with the education and training departments of the organization to be able to target training programs in the most effective possible manner. Training needs to be relevant to the job functions and risks of the attendees. If the training can be imparted in such a way that the attendees are learning the concepts and principles without even realizing how much they have learned, then it is probably ideal. Training is not a "do not do this" activity—ideally, training does not need to only define rules and regulations; rather, training is an activity designed to instill a concept of best practice and understanding to others. Once people realize the reasons behind a guideline or policy, they will be more inclined to better standards of behavior than they would if only pressured into a firm set of rules.

Training should be creative, varied, related to real life, and frequent. Incorporating security training into a ten-minute segment of existing management and staff meetings, and including it as a portion of the new employee orientation process, is often more effective than a day-long seminar once a year. Using examples can be especially effective. The effectiveness of the training is increased when an actual incident known to the staff can be used as an example of the risks, actions, retribution, and reasoning associated with an action undertaken by the security department. This is often called *dragging the wolf into the room*. When a wolf has been taking advantage of the farmer, bringing the carcass of the wolf into the open can be a vivid demonstration of the effectiveness of the security program. When there has been an incident of employee misuse, bringing this into the open (in a tactful manner) can be a way to prevent others from making the same mistakes. Training is not fear mongering. The attitude of the trainers should be to raise the awareness and behavior of the attendees to a higher level, not to explain the rules as if to criminals that they had "better behave or else."

This is perhaps the greatest strength of the human side of information security. Machines can be programmed with a set of rules. The machine then enforces these rules mechanically. If prople are able to slightly modify their activity or use a totally new attack strategy, they may be able to circumvent the rules and attack the machine or network. Also—because machines are controlled by people—when employees feel unnecessarily constrained by a rule, they may well disable or find a way to bypass the constraint and leave a large hole in the rule base. Conversely, a security-conscious person may be able to detect an aberration in behavior or even attitude that could be a precursor to an attack that is well below the detection level of a machine.

13.8 Reacting to Incidents

Despite our best precautions and controls, incidents will arise that test the strength of our security programs. Many incidents may be false alarms that can be resolved quickly; however, one of the greatest fears with false alarms is the tendency to become immune to the alarms and turn off the alarm trigger. All alarms should be logged and resolved. This may be done electronically, but it should not be overlooked. Alarm rates can be critical indicators of trends or other types of attacks that may be emerging; they can also be indicators of additional training requirements or employees attempting to circumvent security controls.

One of the tools used by security departments to reduce nuisance or false alarms is the establishment of clipping levels or thresholds for alarm activation. The clipping level is the acceptable level of error before triggering the alarm. These are often used for password lockout thresholds and other low-level activity. The establishment of the correct clipping level depends on historical events, the sensitivity of the system, and the granularity of the system security components. Care must be exercised to ensure that clipping levels are not set too high such that a low-level attack can be performed without bringing in an alarm condition.

Many corporations use a tiered approach to incident response. The initial incident or alarm is recognized by a help-desk or low-level technical person. This person logs the alarm and attempts to resolve the alarm condition. If the incident is too complex or risky to be resolved at this level, the technician refers the alarm to a higher-level technical expert or to management. It is important for the experts to routinely review the logs of the alarms captured at the initial point of contact so that they can be assured that the alarms are being handled correctly and to detect relationships between alarms that may be an indication of further problems.

Part of good incident response is communication. To ensure that the incident is handled properly and risk to the corporation is minimized, a manner of distributing the information about the incident needs to be established. Pagers, cell phones, and e-mail can all be effective tools for alerting key personnel. Some of the personnel that need to be informed of an incident include senior management, public relations, legal, human resources, and security.

Incident handling is the expertise of a good security team. Proper response will contain the damage; assure customers, employees, and shareholders of adequate preparation and response skills; and provide feedback to prevent future incidents.

When investigating an incident, proper care must be taken to preserve the information and evidence collected. The victims or reporting persons should be advised that their report is under investigation.

The security team is also responsible for reviewing past incidents and making recommendations for improvements or better controls to prevent future damage. Whenever a business process is affected, and the business continuity plan is enacted, security should ensure that all assets are protected and controls are in place to prevent disruption of recovery efforts.

Many corporations today are using managed security service providers (MSSPs) to monitor their systems. The MSSP accumulates the alarms and notifies the corporation when an alarm or event of significant seriousness occurs. When using an MSSP, the corporation should still have contracted measurement tools to evaluate the appropriateness and effectiveness of the MSSP's response mechanisms. A competent internal resource must be designated as the contact for the MSSP.

If an incident occurs that requires external agencies or other companies to become involved, a procedure for contacting external parties should be followed. An individual should not contact outside groups without the approval and notification of senior management. Policy must be developed and monitored regarding recent laws requiring an employee to alert police forces of certain types of crimes.

13.9 The IT Director—The Chief Information Officer (CIO)

The IT director is responsible for the strategic planning and structure of the IT department. Plans for future systems development, equipment purchase, technological direction, and budgets all start in the office of the IT director. In most cases, the help desk, system administrators, development departments, production support, operations, and sometimes even telecommunications departments are included in his jurisdiction.

The security department should not report to the IT director because this can create a conflict between the need for secure processes and the push to develop new systems. Security can often be perceived as a roadblock for operations and development staff, and having both groups report to the same manager can cause conflict and jeopardize security provisioning.

The IT director usually requires a degree in electrical engineering or computer programming and extensive experience in project planning and implementation. This is important for an understanding of the complexities and challenges of new technologies, project management, and staffing concerns. The IT director or CIO should sit on the senior management team and be a part of the strategic planning process for the organization. Facilitating business operations and requirements and understanding the direction and technology needs of the corporation are critical to ensuring that a gulf does not develop between IT and the sales, marketing, or production shops. In many cases, corporations have been limited in their flexibility due to the cumbersome nature of legacy systems or poor communications between IT development and other corporate areas.

13.10 The IT Steering Committee

Many corporations, agencies, and organizations spend millions of dollars per year on IT projects, tools, staff, and programs and yet do not realize adequate benefits or return on investment (ROI) for the amounts of money spent. In many cases this is related to poor project planning, lack of a structured development methodology, poor requirements definition, lack of foresight for future business needs, or lack of close interaction between the IT area and the business units. The IT steering committee is comprised of leaders from the various business units of the organization and the director of IT. The committee has the final approval for any IT expenditures and project prioritization. All proposed IT projects should be presented to the committee along with a thorough business case and forecast expenditure requirements. The committee then determines which projects are most critical to the organization according to risk, opportunities, staffing availability, costs, and alignment with business requirements. Approval for the projects is then granted.

One of the challenges for many organizations is that the IT steering committee does not follow up on ongoing projects to ensure that they meet their initial requirements, budget, timeframes, and performance. IT steering committee members need to be aware of business strategies, technical issues, legal and administrative requirements, and economic conditions. They need the ability to overrule the IT director and cancel or suspend any project that may not provide the functionality required by the users, adequate security, or is seriously over budget. In such cases the IT steering committee may require a detailed review of the status of the project and reevaluate whether the project is still feasible.

Especially in times of weakening IT budgets, all projects should undergo periodic review and rejustification. Projects that may have been started due to hype or the proverbial bandwagon—“everyone must be E-business or they are out of business”—and do not show a realistic return on investment should be cancelled. Projects that can save money must be accelerated—including in many cases a piecemeal approach to getting the most beneficial portions implemented rapidly. Projects that will result in future savings, better technology, and more market flexibility need to be continued, including projects to simplify and streamline IT infrastructure.

13.11 Change Management—Certification and Accreditation

Change management is one of the greatest concerns for many organizations today. In our fast-paced world of rapid development, short time to market, and technological change, change management is the key to ensuring that a "sober second thought" is taken before a change to a system goes into production. Many times, the pressure to make a change rapidly and without a formal review process has resulted in a critical system failure due to inadequate testing or unanticipated or unforeseen technical problems.

There are two sides to change management. The most common definition is that change management is concerned with the certification and accreditation process. This is a control set in place to ensure that all changes that are proposed to an existing system are properly tested, approved, and structured (logically and systematically planned and implemented).

The other aspect of change management comes from the project management and systems development world. When an organization is preparing to purchase or deploy a new system, or modify an existing system, the organization will usually follow a project management framework to control the budget, training, timing, and staffing requirements of the project. It is common (and often expected, depending on the type of development life cycle employed) that such projects will undergo significant changes or decision points throughout the project lifetime. The decision points are times when evaluations of the project are made and a choice to either continue or halt the project may be required. Other changes may be made to a project due to external factors—economic climate, marketing forces, and availability of skilled personnel—or to internal factors such as identification of new user requirements. These changes will often affect the scope of the project (the amount of work required and the deliverables) or timing and budgeting. Changes made to a project in midstream may cause the project to become unwieldy, subject to large financial penalties—especially when dealing with an outsourced development company—or delayed to the point of impacting business operations. In this instance, change management is the team of personnel that will review proposed changes to a project and determine the cutoff for modifications to the project plan. Almost everything we do can be improved and as the project develops, more ideas and opportunities arise. If uncontrolled, the organization may well be developing a perfect system that never gets implemented. The change control committee must ensure that a time comes when the project timeline and budget are set and followed, and refuse to allow further modifications to the project plan—often saving these ideas for a subsequent version or release.

Change management requires that all changes to hardware, software, documentation, and procedures are reviewed by a knowledgeable third party prior to implementation. Even the smallest change to a configuration table or attaching a new piece of equipment can cause catastrophic failures to a system. In some cases a change may open a security hole that goes unnoticed for an extended period of time. Changes to documentation should also be subject to change management so that all documents in use are the same version, the documentation is readable and complete, and all programs and systems have adequate documentation. Furthermore, copies of critical documentation need to be kept off-site in order to be available in the event of a major disaster or loss of access to the primary location.

13.11.1 Certification

Certification is the review of the system from a user perspective. The users review the changes and ensure that the changes will meet the original business requirements outlined at the start of the project or that they will be compatible with existing policy, procedures, or business objectives. The other user group involved is the security department. This group needs to review the system to ensure that it is adequately secured from threats or risks. In this they will need to consider the sensitivity of the data within the system or that the system protects, the reliance of the business process on the system (availability), regulatory requirements such as data protection or storage (archival) time, and documentation and user training.

13.11.2 Accreditation

Once a system has been certified by the users, it must undergo accreditation. This is the final approval by management to permit the system, or the changes to a component, to move into production. Management must review the changes to the system in the context of its operational setting. They must evaluate the certification reports and recommendations from security regarding whether the system is adequately secured and meets user requirements and the proposed implementation timetable. This may include accepting the residual risks that could not be addressed in a cost-effective manner.

Change management is often handled by a committee of business analysts, business unit directors, and security and technical personnel. They meet regularly to approve implementation plans and schedules. Ideally, no change will go into production unless it has been thoroughly inspected and approved by this committee. The main exceptions to this, of course, are changes required to correct system failures. To repair a major failure, a process of emergency change management must be established. The greatest concern with emergency changes is ensuring that the correct follow-up is done to ensure that the changes are complete, documented, and working correctly.

In the case of volatile information such as marketing programs, inventory, or newsflashes, the best approach is to keep the information stored in tables or other logically separated areas so that these changes (which may not be subject to change management procedures) do not affect the core system or critical functionality.

13.12 Technical Standards Committee

Total cost of ownership (TCO) and keeping up with new or emerging tools and technologies are areas of major expenditure for most organizations today. New hardware and software are continuously marketed. In many cases a new operating system may be introduced before the organization has completed the rollout of the previous version. This often means supporting three versions of software simultaneously. Often this has resulted in the inability of personnel still using the older version of the software to read internal documents generated under the newer version. Configurations of desktops or other hardware can be different, making support and maintenance complex. Decisions have to be made about which new products to purchase—laptops instead of desktops, the minimum standards for a new machine, or type of router or network component. All of these decisions are expensive and require a long-term view of what is coming onto the horizon.

The technical standards committee is an advisory committee and should provide recommendations (usually to the IT steering committee or another executive-level committee) for the purchase, strategy, and deployment of new equipment, software, and training. The members of the technical standards committee must be aware of the products currently available as well as the emerging technologies that may affect the viability of current products or purchases. No organization wants to make a major purchase of a software or hardware product that will be incompatible with other products the organization already has or will require within the next few months or years. The members of the technical standards committee should consist of a combination of visionaries, technical experts, and strategic business planners. Care should be taken to ensure that the members of this committee do not become unreasonably influenced by or restricted to one particular vendor or supplier.

Central procurement is a good principle of security management. Often when an organization is spread out geographically, there is a tendency for each department to purchase equipment independently. Organizations lose control over standards and may end up with incompatible VPNs, difficult maintenance and support, loss of savings that may have been available through bulk purchases, cumbersome disaster recovery planning through the need to communicate with many vendors, and loss of inventory control. Printers and other equipment become untraceable and may be subject to theft or misuse by employees. One organization recently found that tens of thousands of dollars' worth of equipment had been stolen by an employee that the organization never realized was missing.

Unfortunately for the employee, a relationship breakdown caused an angry partner to report the employee to corporate security.

13.13 The Systems Analyst

There are several definitions for a systems analyst. Some organizations may use the term senior analyst when the person works in the IT development area; other organizations use the term to describe the person responsible for systems architecture or configuration.

In the IT development shop, the systems analyst plays a critical role in the development and leadership of IT projects and the maintenance of IT systems. The systems analyst may be responsible for chairing or sitting on project development teams, working with business analysts to determine the functional requirements for a system, writing high-level project requirements for use by programmers to write code, enforcing coding standards, coordinating the work of a team of programmers and reviewing their work, overseeing production support efforts, and working on incident handling teams.

The systems analyst is usually trained in computer programming and project management skills. The systems analyst must have the ability to review a system and determine its capabilities, weaknesses, and workflow processes.

Systems analysts should not have access to change production data or programs. This is important to ensure that they cannot inadvertently or maliciously change a program or organizational data. Without such controls, the analyst may be able to introduce a Trojan horse, circumvent change control procedures, and jeopardize data integrity.

Systems analysts in a network or overall systems environment are responsible for ensuring that secure and reliable networks or systems are developed and maintained. They are responsible for ensuring that the networks or systems are constructed with no unknown gaps or backdoors, that there are few single points of failure, that configurations and access control procedures are set up, and that audit trails and alarms are monitored for violations or attacks.

The systems analyst usually requires a technical college diploma and extensive in-depth training. Knowledge of system components, such as the firewalls in use by the organization, tools, and incident handling techniques, is required.

Most often, the systems analyst in this environment will have the ability to set up user profiles, change permissions, change configurations, and perform high-level utilities such as backups or database reorganizations. This creates a control weakness that is difficult to overcome. In many cases the only option an organization has is to trust the person in this position. Periodic reviews of their work and proper management controls are some of the only compensating controls available. The critical problem for many organizations is ensuring that this position is properly backed up with trained personnel and thorough documentation, and that this person does not become technically stagnant or begin to become sloppy about security issues.

13.14 The Business Analyst

The business analyst is one of the most critical roles in the information management environment. A good business analyst has an excellent understanding of the business operating environment, including new trends, marketing opportunities, technological tools, current process strengths, needs, and weaknesses, and is a good team member. The business analyst is responsible for representing the needs of the users to the IT development team. The business analyst must clearly articulate the functional requirements of a project early on in the project life cycle in order to ensure that information technology resources, money, personnel, and time are expended wisely and that the final result of an IT project meets user needs, provides adequate security and functionality, and embraces controls and separation of duties. Once outlined, the business analyst must ensure that these requirements are addressed and documented in the project plan. The business analyst is then responsible for setting up test scenarios to validate the performance of the system and verify that the system meets the original requirements definitions.

When testing, the business analyst should ensure that test scenarios and test cases have been developed to address all recognized risks and test scenarios. Test data should be sanitized to prevent disclosure of private or sensitive information, and test runs of programs should be carefully monitored to prevent test data and reports from introduction into the real-world production environment. Tests should include out-of-range tests, where numbers larger or smaller than the data fields are attempted and invalid data formats are tried. The purpose of the tests is to try to see if it is possible to make the system fail. Proper test data is designed to stress the limitations of the system, the edit checks, and the error handling routines so that the organization can be confident that the system will not fail or handle data incorrectly once in production. The business analyst is often responsible for providing training and documentation to the user groups. In this regard, all methods of access, use, and functionality of the system from a user perspective should be addressed. One area that has often been overlooked has been assignment of error handling and security functionality. The business analyst must ensure that these functions are also assigned to reliable and knowledgeable personnel once the system has gone into production.

The business analyst is responsible for reviewing system tests and approving the change as the certification portion of the change management process. If a change needs to be made to production data, the business analyst will usually be responsible for preparing or reviewing the change and approving the timing and acceptability of the change prior to its implementation. This is a proper segregation of duties, whereby the person actually making the change in production—whether it is the operator, programmer, or other user—is not the same person who reviews and approves the change. This may prevent either human error or malicious changes.

Once in production, business analysts are often the second tier of support for the user community. Here they are responsible to check on inconsistencies, errors, or unreliable processing by the system. They will often have a method of creating trouble tickets or system failure notices for the development and production support groups to investigate or take action.

Business analysts are commonly chosen from the user groups. They must be knowledgeable in the business operations and should have good communication and teamwork skills. Several colleges offer courses in business analysis, and education in project management can also be beneficial.

Because business analysts are involved in defining the original project functional requirements, they should also be trained in security awareness and requirements. Through a partnership with security, business analysts can play a key role in ensuring that adequate security controls are included in the system requirements.

13.15 The Programmer

This chapter is not intended to outline all of the responsibilities of a programmer. Instead, it focuses on the security components and risks associated with this job function. The programmer, whether in a mainframe, client/server, or Web development area, is responsible for preparing the code that will fulfill the requirements of the users. In this regard, the programmer needs to adhere to principles that will provide reliable, secure, and maintainable programs without compromising the integrity, confidentiality, or availability of the data. Poorly written code is the source of almost all buffer overflow attacks. Because of inadequate bounds, parameter checking, or error handling, a program can accept data that exceeds its acceptable range or size, thereby creating a memory or privilege overflow condition. This is a potential hole either for an attacker to exploit or to cause system problems due to simple human error during a data input function.

Programs need to be properly documented so that they are maintainable, and the users (usually business analysts) reviewing the output can have confidence that the program handles the input data in a consistent and reliable manner.

Programmers should never have access to production data or libraries. Several firms have experienced problems due to disgruntled programmers introducing logic bombs into programs or manipulating production data for their own benefit. Any changes to a program should be reviewed and approved by a business analyst and moved into production by another group or department (such as operators), and not by the programmer directly. This practice was established during the mainframe era but has been slow to be enforced on newer Web-based development projects. This has meant that several businesses have learned the hard way about proper segregation of duties and the protection it provides a firm. Often when a program requires frequent updating, such as a Web site, the placement of the changeable data into tables that can be updated by the business analysts or user groups is desirable.

One of the greatest challenges for a programmer is to include security requirements in the programs. A program is primarily written to address functional requirements from a user perspective, and security can often be perceived as a hindrance or obstacle to the fast execution and accessibility of the program. The programmer needs to consider the sensitivity of the data collected or generated by the program and provide secure program access, storage, and audit trails. Access controls are usually set up at the initiation of the program; and user IDs, passwords, and privilege levels are checked when the user first logs on to the system or program. Most programs these days have multiple access paths to information—text commands, GUI icons, and drop-down menus are some of the common access methods. A programmer must ensure that all access methods are protected and that the user is unable to circumvent security by accessing the data through another channel or method.

The programmer needs training in security and risk analysis. The work of a programmer should also be subject to peer review by other systems analysts or programmers to ensure that quality and standard programming practices have been followed.

13.16 The Librarian

The librarian was a job function established in a mainframe environment. In many cases the duties of the librarian have now been incorporated into the job functions of other personnel such as system administrators or operators. However, it is important to describe the functions performed by a librarian and ensure that these tasks are still performed and included in the performance criteria and job descriptions of other individuals.

The librarian is responsible for the handling of removable media—tapes, disks, and microfiche; the control of backup tapes and movement to off-site or near-line storage; the movement of programs into production; and source code control. In some instances the librarian is also responsible for system documentation and report distribution.

The librarian duties need to be described, assigned, and followed. Movement of tapes to off-site storage should be done systematically with proper handling procedures, secure transport methods, and proper labeling. When reports are generated, especially those containing sensitive data, the librarian must ensure that the reports are distributed to the correct individuals and no pages are attached in error to other print jobs. For this reason, it is a good practice to restrict the access of other personnel from the main printers.

The librarian accepts the certified and accredited program changes and moves them into production. These changes should always include a back-out plan in case of program or system problems. The librarian should take a backup copy of all programs or tables subject to change prior to moving the new code into production. A librarian should always ensure that all changes are properly approved prior to making a change.

Librarians should not be permitted to make changes to programs or tables; they should only enact the changes prepared and approved by other personnel. Librarians also need to be inoculated against social engineering or pressure from personnel attempting to make changes without going through the proper approval process.

13.17 The Operator

The operator plays a key role in information systems security. No one has greater access or privileges than the operator. The operator can be a key contributor to system security or a gaping hole in a security program. The operator is responsible for the day-to-day operations, job flow, and often the scheduling of the system maintenance and backup routines. As such, an operator is in a position that may have serious impact on system performance or integrity in the event of human error, job-sequencing mistakes, processing delays, backup execution, and timing. The operator also plays a key role in incident handling and error recovery. The operator should log all incidents, abnormal conditions, and job completions so that they can be tracked and acted upon, and provide input for corrective action. Proper tracking of job performance, storage requirements, file size, and database activity provides valuable input to forecasting requirements for new equipment or identification of system performance issues and job inefficiencies before they become serious processing impairments.

The operator should never make changes to production programs or tables except where the changes have been properly approved and tested by other personnel. In the event of a system failure, the operator should have a response plan in place to notify key personnel.

13.18 The System Owner and the Data Owner

History has taught us that information systems are not owned by the information technology department, but rather by the user group that depends on the system. The system owner therefore is usually the senior manager in the user department. For a financial system this may be the vice president of finance; for a customer support system, the vice president of sales. The IT department then plays the role of supporting the user group and responding to the needs of the user. Proper ownership and control of systems may prevent the development of systems that are technically sound but of little use to the users. Recent studies have shown that the gap between user requirements and system functionality was a serious detriment to business operations. In fact, several government departments have had to discard costly systems that required years of development because they were found to be inadequate to meet business needs.[2]

The roles of system owner and data owner may be separate or combined, depending on the size and complexity of the system. The system owner is responsible for all changes and improvements to a system, including decisions regarding the overall replacement of a system. The system owner sits on the IT steering committee, usually as chair, and provides input, prioritization, budgeting, and high-level resource allocation for system maintenance and development. This should not conflict with the role of the IT director and project leaders who are responsible for the day-to-day operations of production support activity, development projects, and technical resource hiring and allocation. The system owner also oversees the accreditation process that determines when a system change is ready for implementation. This means the system owner must be knowledgeable about new technologies, risks, threats, regulations, and market trends that may impact the security and integrity of a system.

The responsibility of the data owner is to monitor the sensitivity of the data stored or processed by a system. This includes determining the appropriate levels of information classification, access restrictions, and user privileges. The data owner should establish or approve the process for granting access to new users, increasing access levels for existing users, and removing access in a timely manner for users who no longer require access as a part of their job duties. The data owner should require an annual report of all system users and determine whether the level of access each user has is appropriate. This should include a review of special access methods such as remote access, wireless access, reports received, and *ad hoc* requests for information.

Because these duties are incidental to the main functions of the persons acting as data or system owners, it is incumbent upon these individuals to closely monitor these responsibilities while delegating certain functions to other persons. The ultimate responsibility for accepting the risks associated with a system rests with the system and data owners.

13.19 The User

All of the systems development, the changes, modifications, and daily operations are to be completed with the objective of addressing user requirements. The user is the person who must interact daily with the system and relies on the system to continue business operations. A system that is not designed correctly may lead to a high incidence of user errors, high training costs or extended learning curves, poor performance and frustration, and overly restrictive controls or security measures. Once users notice these types of problems, they will often either attempt to circumvent security controls or other functionality that they find unnecessarily restrictive or abandon the use of the system altogether.

Training for a user must include the proper use of the system and the reasons for the various controls and security parameters built into the system. Without divulging the details of the controls, explaining the reasons for the controls may help the users to accept and adhere to the security restrictions built into the system.

13.20 Good Principles—Exploiting the Strengths of Personnel in Regard to a Security Program

A person should never be disciplined for following correct procedures. This may sound ridiculous, but it is a common weakness exploited by people as a part of social engineering. Millions of dollars' worth of security will be worthless if our staff is not trained to resist and report all social engineering attempts. Investigators have found that the easiest way to gather corporate information is through bribery or relationships with employees.

There are four main types of social engineering: intimidation, helpfulness, technical, and name-dropping. The principle of intimidation is the threat of punishment or ridicule for following correct procedures. The person being "engineered" is bullied by the attacker into granting an exception to the rules—perhaps due to position within the company or force of character. In many instances the security-minded person is berated by the attacker, threatened with discipline or loss of employment, or otherwise intimidated by a person for just trying to do their job. Some of the most serious breaches of secure facilities have been accomplished through these techniques. In one instance the chief financial officer of a corporation refused to comply with the procedure of wearing an ID card. When challenged by a new security person, the executive explained in a loud voice that he should never again be challenged to display an ID card. Such intimidation unnerved the security person to the point of making the entire security procedure ineffective and arbitrary. Such a "tone at the top" indicates a lack of concern for security that will soon permeate through the entire organization.

Helpfulness is another form of social engineering, appealing to the natural instinct of most people to want to provide help or assistance to another person. One of the most vulnerable areas for this type of manipulation is the help desk. Help desk personnel are responsible for password resets, remote access problem resolution, and system error handling. Improper handling of these tasks may result in an attacker getting a password reset for another legitimate user's account and creating either a security gap or a denial-of-service for the legitimate user.

Despite the desires of users, the help desk, and administrators to facilitate the access of legitimate users to the system, they must be trained to recognize social engineering and follow established secure procedures.

Name-dropping is another form of social engineering and is often facilitated by press releases, Web page ownership or administrator information, discarded corporate documentation, or other ways that an attacker can learn the names of individuals responsible for research, business operations, administrative functions, or other key roles. By using the names of these individuals in conversation, a hacker can appear to be a legitimate user or have a legitimate affiliation with the corporation. It has been quoted that "The greater the lie, the easier it is to convince someone that it is true." This especially applies to a name-dropping type of attack. Despite the prior knowledge of the behaviors of a manager, a subordinate may be influenced into performing some task at the request of an attacker although the manager would never have contemplated or approved such a request.

Technology has provided new forms of social engineering. Now an attacker can e-mail or fax a request to a corporation for information and receive a response that compromises security. This may be from a person alleging to represent law enforcement or some other government department demanding cooperation or assistance. The correct response must be to have an established manner of contact for outside agencies and train all personnel to route requests for information from an outside source through proper channels.

All in all, the key to immunizing personnel against social-engineering attacks is to emphasize the importance of procedure, the correctness of following and enforcing security protocols, and the support of management for personnel who resist any actions that attempt to circumvent proper controls and may be an incidence of social engineering. All employees must know that they will never lose their job for enforcing corporate security procedures.

13.21 Job Rotation

Job rotation is an important principle from a security perspective, although it is often seen as a detriment by project managers. Job rotation moves key personnel through the various functional roles in a department or even between departments. This provides several benefits, such as cross-training of key personnel and reducing the risks to a system through lack of trained personnel during vacations or illnesses. Job rotation also serves to identify possible fraudulent activity or shortcuts taken by personnel who have been in the job for an extended time period. In one instance, a corporation needed to take disciplinary action against an employee who was the administrator for a critically important system, not only for the business but also for the community. Because this administrator had sole knowledge of the system and the system administrator password, they were unable to take action in a timely manner. They were forced to delay any action until the administrator left for vacation and gave the password to a backup person.

When people stay in a position too long, they may become more attached to the system than to the corporation, and their activity and judgment may become impaired.

13.22 Anti-Virus and Web-Based Attacks

The connectivity of systems and the proliferation of Web-based attacks have resulted in significant damage to corporate systems, expenses, and productivity losses. Many people recognize the impact of Code Red and Nimda; however, even when these attacks were taken out of the calculations, the incidence of Web-based attacks rose more than 79 percent in 2001.[3] Some studies have documented more attacks in the first two months of 2002 than were detected in the previous year and a half.[4]

Users have heard many times not to open e-mail attachments; however, this has not prevented many infections and security breaches from happening. More sophisticated attacks—all of which can appear to come from trusted sources—are appearing, and today's firewalls and anti-virus products are not able to protect an organization adequately. Instead, users need to be more diligent to confirm with a sender whether they intended to send out an attachment prior to opening it. The use of instant messaging, file sharing, and other products, many of which exploit open ports or VPN tunnels through firewalls, is creating even more vulnerabilities. The use of any technology or new product should be subject to analysis and review by security before the users adopt it. This requires the security department to react swiftly to requests from users and be aware of the new trends, technologies, and threats that are emerging.

13.23 Segregation of Duties

The principle of segregation of duties breaks an operation into separate functions so that no one person can control a process from initiation through to completion. Instead, a transaction would require one person to input the data, a second person to review and reconcile the batch totals, and another person (or perhaps the first individual) to confirm the final portion of the transaction. This is especially critical in financial transactions or error handling procedures.

13.24 Summary

This is neither a comprehensive list of all the security concerns and ways to train and monitor the people in our organizations, nor is it a full list of all job roles and functions. Hopefully it is a tool that managers, security personnel, and auditors can use to review some of the procedures they have in place and create a better security infrastructure. The key objective of this chapter is to identify the primary roles that people play in the information security environment. A security program is only as good as the people implementing it, and a key realization is that tools and technology are not enough when it comes to protecting our organizations. We need to enlist the support of every member of our companies. We need to see the users, administrators, managers, and auditors as partners in security. Much of this is accomplished through understanding. When the users understand why we need security, the security people understand the business, and everyone respects the role of the other departments, then the atmosphere and environment will lead to greater security, confidence, and trust.

Security Management

Ken Buszta

It was once said, "Information is king." In today's world, this statement has never rung more true. As a result, information is now viewed as an asset; and organizations are willing to invest large sums of money toward its protection. Unfortunately, organizations appear to be overlooking one of the weakest links for protecting their information—the information security management team. The security management team is the one component in our strategy that can ensure our security plan is working properly and takes corrective actions when necessary. In this chapter, we address the benefits of an information security team, the various roles within the team, job separation, job rotation, and performance metrics for the team, including certifications.

14.1 Security Management Team Justification

Information technology departments have always had to justify their budgets. With the recent global economic changes, the pressures of maintaining stockholder values have brought IT budgets under even more intense scrutiny. Migrations, new technology implementations, and even staff spending have been either been delayed, reduced, or removed from budgets. So how is it that an organization can justify the expense, much less the existence, of an information security management team? While most internal departments lack the necessary skill sets to address security, there are three compelling reasons to establish this team:

1. *Maintain competitive advantage*. An organization exists to provide a specialized product or service for its clients. The methodologies and trade secrets used to provide these services and products are the assets that establish our competitive advantage. An organization's failure to properly protect and monitor these assets can result in the loss of not only a competitive advantage but also lost revenues and possible failure of the organization.
2. *Protection of the organization's reputation*. In early 2000, several high-profile organizations' Web sites were attacked. As a result, the public's confidence was shaken in their ability to adequately protect their clients. A security management team will not be able to guarantee or fully prevent this from happening, but a well-constructed team can minimize the opportunities made available from your organization to an attacker.
3. *Mandates by governmental regulations*. Regulations within the United States, such as the Health Insurance Portability and Accountability Act (HIPAA) and the Gramm–Leach–Bliley Act (GLBA) and those abroad, such as the European Convention on Cybercrime, have mandated that organizations protect their data. An information security management team, working with the organization's legal and auditing teams, can focus on ensuring that proper safeguards are utilized for regulatory compliance.

14.2 Executive Management and the IT Security Management Relationship

The first and foremost requirement to help ensure the success of an information security management team relies on its relationship with the organization's executive board. Commencing with the CEO and then working downward, it is essential for the executive board to support the efforts of the information security team. Failure of the executive board to actively demonstrate its support for this group will gradually become reflected within the rest of the organization. Apathy toward the information security team will become apparent, and the team will be rendered ineffective. The executive board can easily avoid this pitfall by publicly signing and adhering to all major information security initiatives such as security policies.

14.3 Information Security Management Team Organization

Once executive management has committed its support to an information security team, a decision must be made as to whether the team should operate within a centralized or decentralized administration environment.

In a centralized environment, a dedicated team is assigned the sole responsibility for the information security program. These team members will report directly to the information security manager. Their responsibilities include promoting security throughout the organization, implementing new security initiatives, and providing daily security administration functions such as access control.

In a decentralized environment, the members of the team have information security responsibilities in addition to those assigned by their departments. These individuals may be network administrators or reside in such departments as finance, legal, human resources, or production.

This decision will be unique to each organization. Organizations that have identified higher risks deploy a centralized administration function. A growing trend is to implement a hybrid solution utilizing the best of both worlds. A smaller dedicated team ensures that new security initiatives are implemented and oversees the overall security plan of the organization, while a decentralized team is charged with promoting security throughout their departments and possibly handling the daily department-related administrative tasking.

The next issue that needs to be addressed is how the information security team will fit into the organization's reporting structure. This is a decision that should not be taken lightly because it will have a long-enduring effect on the organization. It is important that the organization's decision makers fully understand the ramifications of this decision. The information security team should be placed where its function has significant power and authority. For example, if the information security manager reports to management that does not support the information security charter, the manager's group will be rendered ineffective. Likewise, if personal agendas are placed ahead of the information security agenda, it will also be rendered ineffective. An organization may place the team directly under the CIO or it may create an additional executive position, separate from any particular department. Either way, it is critical that the team be placed in a position that will allow it to perform its duties.

14.4 Roles and Responsibilities

When planning a successful information security team, it is essential to identify the roles, rather than the titles, that each member will perform. Within each role, their responsibilities and authority must be clearly communicated and understood by everyone in the organization.

Most organizations can define a single process, such as finance, under one umbrella. There is a manager, and there are direct reports for every phase of the financial life cycle within that department. The information security process requires a different approach. Regardless of how centralized we try to make it, we cannot place it under a single umbrella. The success of the information security team is therefore based on a layered approach. As demonstrated in Exhibit 14.1, the core of any information security team lies with the executive management because they are ultimately responsible to the investors for the organization's success or failure. As we delve outward into the other layers, we see there are roles for which an information security manager does not have direct reports, such as auditors, technology providers, and the end-user community, but he still has an accountability report from or to each of these members.

It is difficult to provide a generic approach to fit everyone's needs. However, regardless of the structure, organizations need to assign security-related functions corresponding to the selected employees' skill sets. Over time, eight different roles have been identified to effectively serve an organization:

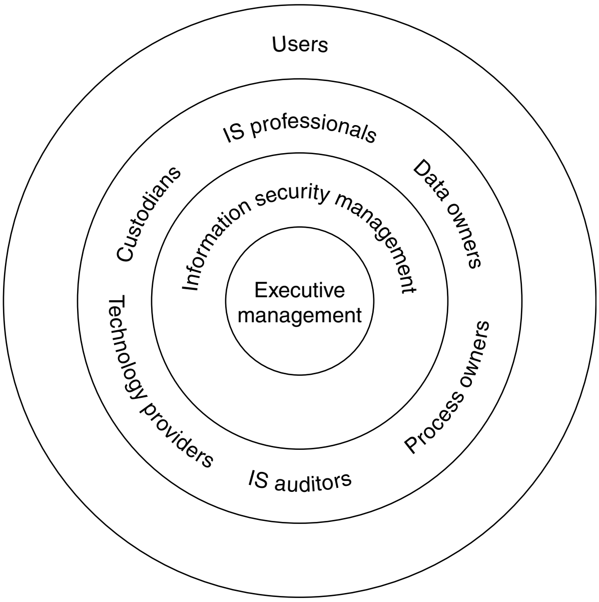

EXHIBIT 14.1 Layers of information security management team.

1. *Executive management.* The executive management team is ultimately responsible for the success (or failure) of any information security program. As stated earlier, without their active support, the information security team will struggle and, in most cases, fail in achieving its charter.
2. *Information security professionals.* These members are the actual members trained and experienced in the information security arena. They are responsible for the design, implementation, management, and review of the organization's security policy, standards, measures, practices, and procedures.
3. *Data owners.* Everyone within the organization can serve in this role. For example, the creator of a new or unique data spreadsheet or document can be considered the data owner of that file. As such, they are responsible for determining the sensitivity or classification levels of the data as well as maintaining the accuracy and integrity of the data while it resides in the system.
4. *Custodians.* This role may very well be the most under-appreciated of all. Custodians act as the owner's delegate, with their primary focus on backing up and restoring the data. The data owners dictate the schedule at which the backups are performed. Additionally, they run the system for the owners and must ensure that the required security controls are applied in accordance with the organization's security policies and procedures.
5. *Process owners.* These individuals ensure that the appropriate security, consistent with the organization's security policy, is embedded in the information systems.
6. *Technology providers.* These are the organization's subject matter experts for a given set of information security technologies and assist the organization with its implementation and management.
7. *Users.* As almost every member of the organization is a user of the information systems, they are responsible for adhering to the organization's security policies and procedures. Their most vital responsibility is maintaining the confidentiality of all usernames and passwords, including the program upon which these are established.
8. *Information systems auditor.* The auditor is responsible for providing independent assurance to management on the appropriateness of the security objectives and whether the security policies, standards, measures, practices, and procedures are appropriate and comply with the organization's security objectives. Because of the responsibility this role has in the information security program, organizations may shift this role's reporting structure directly to the auditing department as opposed to within the information security department.

14.5 Separation of Duties and the Principle of Least Privilege

While it may be necessary for some organizations to have a single individual serve in multiple security roles, each organization will want to consider the possible effects of this decision. By empowering one individual, it is possible for that person to manipulate the system for personal reasons without the organization's knowledge. As such, an information security practice is to maintain a separation of duties. Under this philosophy, pieces of a task are assigned to several people. By clearly identifying the roles and responsibilities, an organization will be able to also implement the Principle of Least Privilege. This idea supports the concept that the users and the processes in a system should have the least number of privileges and for the shortest amount of time needed to perform their tasks.

For example, the system administrator's role may be broken into several different functions to limit the number of people with complete control. One person may become responsible for the system administration, a second person for the security administration, and a third person for the operator functions.

Typical system administrator/operator functions include:

- Installing system software
- Starting up and shutting down the system

- Adding and removing system users
- Performing backups and recovery
- Mounting disks and tapes
- Handling printers

Typical security administrator functions include:

- Setting user clearances, initial passwords, and other security clearances for new users, and changing security profiles for existing users
- Setting or changing the sensitivity file labels
- Setting security characteristics of devices and communication channels
- Reviewing audit data

The major benefit of both of these principles is to provide a *two-person control* process to limit the potential damage to an organization. Personnel would be forced into collusion in order to manipulate the system.

14.6 Job Rotation

Arguably, training may provide the biggest challenge to management, and many view it as a double-edged sword. On the one edge, training is viewed as an expense and is one of the first areas depreciated when budget cuts are required. This may leave the organization with stale skill sets and disgruntled employees. On the other edge, it is not unusual for an employee to absorb as much training from an organization as possible and then leave for a better opportunity. Where does management draw the line?

One method to address this issue is job rotation. By routinely rotating the job a person is assigned to perform, we can provide cross-training to the employees. This process provides the team members with higher skill sets and increased self-esteem; and it provides the organization with backup personnel in the event of an emergency.

From the information security point of view, job rotation has its benefits. Through job rotation, the collusion fostered through the separation of duties is broken up because an individual is not performing the same job functions for an extended period. Further, the designation of additionally trained workers adds to the personnel readiness of the organization's disaster recovery plan.

14.7 Performance Metrics

Each department within an organization is created with a charter or mission statement. While the goals for each department should be clearly defined and communicated, the tools that we use to measure a department's performance against these goals are not always as clearly defined, particularly in the case of information security. It is vital to determine a set of metrics by which to measure its effectiveness. Depending upon the metrics collected, the results may be used for several different purposes, such as:

- *Financial.* Results may be used to justify existing or increasing future budget levels.
- *Team competency.* A metric, such as certification, may be employed to demonstrate to management and the end users the knowledge of the information security team members. Additional metrics may include authorship and public speaking engagements.
- *Program efficiency.* As the department's responsibilities are increased, its ability to handle these demands while limiting its personnel hiring can be beneficial in times of economic uncertainty.

While in the metric planning stages, the information security manager may consider asking for assistance from the organization's auditing team. The auditing team can provide an independent verification of the metric results to both the executive management team and the information security department.

Additionally, by getting the auditing department involved early in the process, it can assist the information security department in defining its metrics and the tools utilized to obtain them.

Determining performance metrics is a multi-step process. In the first step, the department must identify its process for metric collection. Among the questions an organization may consider in this identification process are:

- Why do we need to collect the statistics?
- What statistics will we collect?
- How will the statistics be collected?
- Who will collect the statistics?
- When will these statistics be collected?

The second step is for the organization to identify the functions that will be affected. The functions are measured as time, money, and resources. The resources can be quantified as personnel, equipment, or other assets of the organization.

The third step requires the department to determine the drivers behind the collection process. In the information security arena, the two drivers that affect the department's ability to respond in a timely manner are the number of system users and the number of systems within its jurisdiction. The more systems and users an organization has, the larger the information security department.

With these drivers in mind, executive management could rely on the following metrics with a better understanding of the department's accomplishments and budget justifications:

- Total systems managed
- Total remote systems managed
- User administration, including additions, deletions, and modifications
- User awareness training
- Average response times

For example, Exhibit 14.2 shows an increase in the number of system users over time. This chart alone could demonstrate the efficiency of the department as it handles more users with the same number of resources.

Exhibit 14.3 shows an example of the average information security response times. Upon review, we are clearly able to see an upward trend in the response times. This chart, when taken by itself, may pose some concerns by senior management regarding the information security team's abilities. However, when

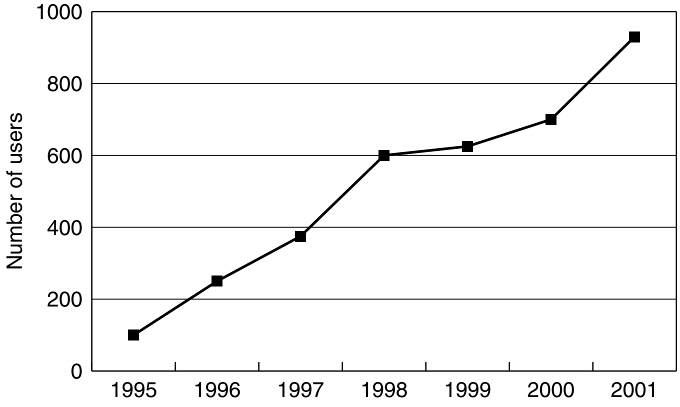

EXHIBIT 14.2 Users administered by information security department.

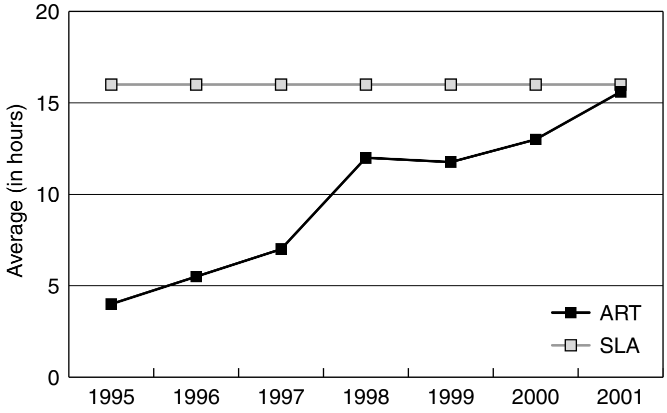

EXHIBIT 14.3 Average information security response times.

this metric is used in conjunction with the metrics found in Exhibit 14.2, a justification could be made to increase the information security personnel budget.

While it is important for these metrics to be gathered on a regular basis, it is even more important for this information to be shared with the appropriate parties. For example, by sharing performance metrics within the department, the department will able to identify its strong and weak areas. The information security manager will also want to share these results with the executive management team to perform a formal annual metric review and evaluation of the metrics.

14.8 Certifications

Using the various certification programs available is an effective tool for management to enhance the confidence levels in its security program while providing the team with recognition for its experience and knowledge. While there are both vendor-centric and vendor-neutral certifications available in today's market, we will focus only on the latter. (Note: The author does not endorse any particular certification program.)

Presently there is quite a debate about which certification is best. This is a hard question to answer directly. Perhaps the more important question is, "What do I want to accomplish in my career?" If based upon this premise, certification should be tailored to a set of objectives and therefore is a personal decision.

14.8.1 Certified Information Systems Security Professional (CISSP)

The CISSP Certification is an independent and objective measure of professional expertise and knowledge within the information security profession. Many regard this certification as an information security management certification. The credential, established over a decade ago, requires the candidate to have three years' verifiable experience in one or more of the ten domains in the Common Body of Knowledge (CBK) and pass a rigorous exam. The CBK, developed by the International Information Systems Security Certification Consortium (ISC)2, established an international standard for IS security professionals. The CISSP multiple-choice certification examination covers the following ten domains of the CBK:

Domain 1: Access Control Systems and Methodology
Domain 2: Telecommunications and Network Security
Domain 3: Security Management Practices
Domain 4: Applications and Systems Development Security

Domain 5: Cryptography
Domain 6: Security Architecture and Models
Domain 7: Operations Security
Domain 8: Business Continuity Planning (BCP) and Disaster Recovery Planning (DRP)
Domain 9: Law, Investigations and Ethics
Domain 10: Physical Security

More information on this certification can be obtained by contacting (ISC)2 through its e-mail address, info@isc2.org.

14.8.2 Systems Security Certified Practitioner (SSCP)

The SSCP certification focuses on information systems security practices, roles, and responsibilities defined by experts from major industries. Established in 1998, it provides network and systems security administrators with independent and objective measures of competence and recognition as a knowledgeable information systems security practitioner. Certification is only available to those individuals who have at least one year's experience in the CBK, subscribe to the (ISC)2 Code of Ethics, and pass the 125-question SSCP certification examination, based on seven CBK knowledge areas:

1. Access Controls
2. Administration
3. Audit and Monitoring
4. Risk, Response and Recovery
5. Cryptography
6. Data Communications
7. Malicious Code/Malware

14.8.3 GIAC

In 1999, the SANS (System Administration, Networking, and Security) Institute founded the Global Information Assurance Certification (GIAC) Program to address the need to validate the skills of security professionals. The GIAC certification provides assurance that a certified individual holds an appropriate level of knowledge and skill necessary for a practitioner in key areas of information security. This is accomplished through a twofold process: practitioners must pass a multiple-choice exam and then complete a practical exam to demonstrate their ability to apply their knowledge. GIAC certification programs include:

- *GIAC Security Essentials Certification* (*GSEC*). GSEC graduates have the knowledge, skills, and abilities to incorporate good information security practice in any organization. The GSEC tests the essential knowledge and skills required of any individual with security responsibilities within an organization.
- *GIAC Certified Firewall Analyst* (*GCFW*). GCFWs have the knowledge, skills, and abilities to design, configure, and monitor routers, firewalls, and perimeter defense systems.
- *GIAC Certified Intrusion Analyst* (*GCIA*). GCIAs have the knowledge, skills, and abilities to configure and monitor intrusion detection systems and to read, interpret, and analyze network traffic and related log files.
- *GIAC Certified Incident Handler* (*GCIH*). GCIHs have the knowledge, skills, and abilities to manage incidents; to understand common attack techniques and tools; and to defend against or respond to such attacks when they occur.
- *GIAC Certified Windows Security Administrator* (*GCWN*). GCWNs have the knowledge, skills, and

abilities to secure and audit Windows systems, including add-on services such as Internet Information Server and Certificate Services.
- *GIAC Certified UNIX Security Administrator* (*GCUX*). GCUXs have the knowledge, skills, and abilities to secure and audit UNIX and Linux systems.
- *GIAC Information Security Officer* (*GISO*). GISOs have demonstrated the knowledge required to handle the Security Officer responsibilities, including overseeing the security of information and information resources. This combines basic technical knowledge with an understanding of threats, risks, and best practices. Alternately, this certification suits those new to security who want to demonstrate a basic understanding of security principles and technical concepts.
- *GIAC Systems and Network Auditor* (*GSNA*). GSNAs have the knowledge, skills, and abilities to apply basic risk analysis techniques and to conduct a technical audit of essential information systems.

14.8.4 Certified Information Systems Auditor (CISA)

CISA is sponsored by the Information Systems and Audit Control Association (ISACA) and tests a candidate's knowledge of IS audit principles and practices, as well as technical content areas. It is based on the results of a practice analysis. The exam tests one process and six content areas (domains) covering those tasks that are routinely performed by a CISA. The process area, which existed in the prior CISA practice analysis, has been expanded to provide the CISA candidate with a more comprehensive description of the full IS audit process. These areas are as follows:

- Process-based area (domain)
- The IS audit process
- Content areas (domains)
- Management, planning, and organization of IS
- Technical infrastructure and operational practices
- Protection of information assets
- Disaster recovery and business continuity
- Business application system development, acquisition, implementation, and maintenance
- Business process evaluation and risk management

For more information, contact ISACA via e-mail: certification@isaca.org.

14.9 Conclusion

The protection of the assets may be driven by financial concerns, reputation protection, or government mandate. Regardless of the reason, well-constructed information security teams play a vital role in ensuring organizations are adequately protecting their information assets. Depending upon the organization, an information security team may operate in a centralized or decentralized environment; but either way, the roles must be clearly defined and implemented. Furthermore, it is crucial to develop a set of performance metrics for the information security team. The metrics should look to identify issues such as budgets, efficiencies, and proficiencies within the team.

15 It Is All about Control

Chris Hare

The security professional and the auditor come together around one topic: control. The two professionals may not agree with the methods used to establish control, but their concerns are related. The security professional is there to evaluate the situation, identify the risks and exposures, recommend solutions, and implement corrective actions to reduce the risk. The auditor also evaluates risk, but the primary role is to evaluate the controls implemented by the security professional. This role often puts the security professional and the auditor at odds, but this does not need to be the case.

This chapter discusses controls in the context of the Common Body of Knowledge of the Certified Information Systems Security Professional (CISSP), but it also introduces the language and definitions used by the audit profession. This approach will ease some of the concept misconceptions and terminology differences between the security and audit professions. Because both professions are concerned with control, albeit from different perspectives, the security and audit communities should have close interaction and cooperate extensively.

Before discussing controls, it is necessary to define some parameters. Audit does not mean security. Think of it this way: the security professional does not often think in control terms. Rather, the security professional is focused on what measures or controls should be put into operation to protect the organization from a variety of threats. The goal of the auditor is not to secure the organization but to evaluate the controls to ensure risk is managed to the satisfaction of management. Two perspectives of the same thing—control.

15.1 What Is Control?

According to *Webster's Dictionary*, control is a method "to exercise restraining or directing influence over." An organization uses controls to regulate or define the limits of behavior for its employees or its operations for processes and systems. For example, an organization may have a process for defining widgets and uses controls within the process to maintain quality or production standards. Many manufacturing facilities use controls to limit or regulate production of their finished goods. Professions such as medicine use controls to establish limits on acceptable conduct for their members. For example, the actions of a medical student or intern are monitored, reviewed, and evaluated—hence controlled—until the applicable authority licenses the medical student.

Regardless of the application, controls establish the boundaries and limits of operation.

The security professional establishes controls to limit access to a facility or system or privileges granted to a user. Auditors evaluate the effectiveness of the controls. There are five principle objectives for controls:

1. Propriety of information
2. Compliance with established rules
3. Safeguarding of assets
4. Efficient use of resources
5. Accomplishment of established objectives and goals

Propriety of information is concerned with the appropriateness and accuracy of information. The security profession uses integrity or data integrity in this context, as the primary focus is to ensure the information is accurate and has not been inappropriately modified.

Compliance with established rules defines the limits or boundaries within which people or systems must work. For example, one method of compliance is to evaluate a process against a defined standard to verify correct implementation of that process.

Safeguarding the organization's assets is of concern for management, the security professional, and the auditor alike. The term asset is used to describe any object, tangible or intangible, that has value to the organization.

The *efficient use of resources* is of critical concern in the current market. Organizations and management must concern themselves with the appropriate and controlled use of all resources, including but not limited to cash, people, and time.

Most importantly, however, organizations are assembled to *achieve a series of goals and objectives*. Without goals to establish the course and desired outcomes, there is little reason for an organization to exist.

To complete our definition of controls, Sawyer's *Internal Auditing, 4th Edition*, provides an excellent definition:

> Control is the employment of all the means and devices in an enterprise to promote, direct, restrain, govern, and check upon its various activities for the purpose of seeing that enterprise objectives are met. These means of control include, but are not limited to, form of organization, policies, systems, procedures, instructions, standards, committees, charts of account, forecasts, budgets, schedules, reports, checklists, records, methods, devices, and internal auditing.

Lawrence Sawyer
Internal Auditing, 4th Edition
The Institute of Internal Auditors

Careful examination of this definition demonstrates that security professionals use many of these same methods to establish control within the organization.

15.2 Components Used to Establish Control

A series of components are used to establish controls, specifically:

- The control environment
- Risk assessment
- Control activities
- Information and communication
- Monitoring

The *control environment* is a term more often used in the audit profession, but it refers to all levels of the organization. It includes the integrity, ethical values, and competency of the people and management. The organizational structure, including decision making, philosophy, and authority assignments are critical to the control environment. Decisions such as the type of organizational structure, where decision-making authority is located, and how responsibilities are assigned all contribute to the control environment. Indeed, these areas can also be used as the basis for directive or administrative controls as discussed later in the chapter.

Consider an organization where all decision-making authority is at the top of the organization. Decisions and progress are slower because all information must be focused upward. The resulting pace at which the organization changes is lower, and customers may become frustrated due to the lack of employee empowerment.

However, if management abdicates its responsibility and allows anyone to make any decision they wish, anarchy results, along with differing decisions made by various employees. Additionally, the external audit organization responsible for reviewing the financial statements may have less confidence due to the increased likelihood that poor decisions are being made.

Risk assessments are used in many situations to assess the potential problems that may arise from poor decisions. Project managers use risk assessments to determine the activities potentially impacting the schedule or budget associated with the project. Security professionals use risk assessments to define the threats and exposures and to establish appropriate controls to reduce the risk of their occurrence and impact. Auditors also use risk assessments to make similar decisions, but more commonly use risk assessment to determine the areas requiring analysis in their review.

Control activities revolve around authorizations and approvals for specific responsibilities and tasks, verification and review of those activities, and promoting job separation and segregation of duties within activities. The control activities are used by the security professional to assist in the design of security controls within a process or system. For example, SAP associates a transaction—an activity—with a specific role. The security professional assists in the review of the role to ensure no unauthorized activity can occur and to establish proper segregation of duties.

The *information and communication* conveyed within an organization provide people with the data they need to fulfill their job responsibilities. Changes to organizational policies or management direction must be effectively communicated to allow people to know about the changes and adjust their behavior accordingly. However, communications with customers, vendors, government, and stockholders are also of importance. The security professional must approach communications with care. Most commonly, the issue is with the security of the communication itself. Was the communication authorized? Can the source be trusted, and has the information been modified inappropriately since its transmission to the intended recipients? Is the communication considered sensitive by the organization, and was the confidentiality of the communication maintained?

Monitoring of the internal controls systems, including security, is of major importance. For example, there is little value gained from the installation of intrusion detection systems if there is no one to monitor the systems and react to possible intrusions. Monitoring also provides a sense of learning or continuous improvement. There is a need to monitor performance, challenge assumptions, and reassess information needs and information systems in order to take corrective action or even take advantage of opportunities for enhanced operations. Without monitoring or action resulting from the monitoring, there is no evolution in an organization. Organizations are not closed static systems and, hence, must adapt their processes to changes, including controls. Monitoring is a key control process to aid the evolution of the organization.

15.3 Control Characteristics

Several characteristics available to assess the effectiveness of the implemented controls are commonly used in the audit profession. Security professionals should consider these characteristics when selecting or designing the control structure. The characteristics are:

- Timeliness
- Economy
- Accountability
- Placement
- Flexibility
- Cause identification
- Appropriateness
- Completeness

Ideally, controls should prevent and detect potential deviations or undesirable behavior early enough to take appropriate action. The *timeliness* of the identification and response can reduce or even eliminate any serious cost impact to the organization. Consider anti-virus software: organizations deploying this control must also concern themselves with the delivery method and timeliness of updates from the anti-virus vendor. However, having updated virus definitions available is only part of the control because the new definitions must be installed in the systems as quickly as possible.

Security professionals regularly see solutions provided by vendors that are not *economical* due to the cost or lack of scalability in large environments. Consequently, the control should be economical and cost effective for the benefit it brings. There is little economic benefit for a control costing $100,000 per year to manage a risk with an annual impact of $1000.

The control should be designed to hold people *accountable* for their actions. The user who regularly attempts to download restricted material and is blocked by the implemented controls must be held accountable for such attempts. Similarly, financial users who attempt to circumvent the controls in financial processes or systems must also be held accountable. In some situations, users may not be aware of the limits of their responsibilities and thus may require training. Other users knowingly attempt to circumvent the controls. Only an investigation into the situation can tell the difference.

The effectiveness of the control is often determined by its *placement*. Accepted placement of controls are considered:

- *Before an expensive part of a process*. For example, before entering the manufacturing phase of a project, the controls must be in place to prevent building the incorrect components.
- *Before points of difficulty or no return*. Some processes or systems have a point where starting over introduces new problems. Consequently, these systems must include controls to ensure all the information is accurate before proceeding to the next phase.
- *Between discrete operations*. As one operation is completed, a control must be in place to separate and validate the previous operation. For example, authentication and authorization are linked but discrete operations.
- *Where measurement is most convenient*. The control must provide the desired measurement in the most appropriate place. For example, to measure the amount and type of traffic running through a firewall, the measurement control would not be placed at the core of the network.

- *Corrective action response time*. The control must alert appropriate individuals and initiate corrective action either automatically or through human intervention within a defined time period.
- *After the completion of an error-prone activity*. Activities such as data entry are prone to errors due to keying the data incorrectly.
- *Where accountability changes*. Moving employee data from a human resources system to a finance system may involve different accountabilities. Consequently, controls should be established to provide both accountable parties confidence in the data export and import processes.

As circumstances or situations change, so too must the controls. *Flexibility* of controls is partially a function of the overall security architecture. The firewall with a set of hard-coded and inflexible rules is of little value as organizational needs change. Consequently, controls should ideally be modular in a systems environment and easily replaced when new methods or systems are developed.

The ability to respond and correct a problem when it occurs is made easier when the control can *establish the cause* of the problem. Knowing the cause of the problem makes it easier for the appropriate corrective action to be taken.

Controls must provide management with the *appropriate* responses and actions. If the control impedes the organization's operations or does not address management's concerns, it is not appropriate. As is always evident to the security professional, a delicate balance exists between the two; and often the objectives of business operations are at odds with other management concerns such as security. For example, the security professional recommending system configuration changes may affect the operation of a critical business system. Without careful planning and analysis of the controls, the change may be implemented and a critical business function paralyzed.

Finally, the control must be complete. Implementing controls in only one part of the system or process is no better than ignoring controls altogether. This is often very important in information systems. We can control the access of users and limit their ability to perform specific activities within an application. However, if we allow the administrator or programmer a backdoor into the system, we have defeated the controls already established.

There are many factors affecting the design, selection, and implementation of controls. This theme runs throughout this chapter and is one the security professional and auditor must each handle on a daily basis.

15.4 Types of Controls

There are many types of controls found within an organization to achieve its objectives. Some are specific to particular areas within the organization but are nonetheless worthy of mention. The security professional should be aware of the various controls because he will often be called upon to assist in their design or implementation.

15.4.1 Internal

Internal controls are those used to primarily manage and coordinate the methods used to safeguard an organization's assets. This process includes verifying the accuracy and reliability of accounting data, promoting operational efficiency, and adhering to managerial polices.

We can expand upon this statement by saying internal controls provide the ability to:

- Promote an effective and efficient operation of the organization, including quality products and services
- Reduce the possibility of loss or destruction of assets through waste, abuse, mismanagement, or fraud

- Adhere to laws and external regulations
- Develop and maintain accurate financial and managerial data and report the same information to the appropriate parties on a timely basis

The term *internal control* is primarily used within the audit profession and is meant to extend beyond the limits of the organization's accounting and financial departments.

15.4.2 Directive/Administrative

Directive and administrative controls are often used interchangeably to identify the collection of organizational plans, policies, and records. These are commonly used to establish the limits of behavior for employees and processes. Consider the organizational conflict of interest policy.

Such a policy establishes the limits of what the organization's employees can do without violating their responsibilities to the organization. For example, if the organization states employees cannot operate a business on their own time and an employee does so, the organization may implement the appropriate repercussions for violating the administrative control.

Using this example, we can more clearly see why these mechanisms are called *administrative* or *directive* controls — they are not easily enforced in automated systems. Consequently, the employee or user must be made aware of limits and stay within the boundaries imposed by the control.

One directive control is legislation. Organizations and employees are bound to specific conduct based upon the general legislation of the country where they work, in addition to any specific legislation regarding the organization's industry or reporting requirements. Every organization must adhere to revenue, tax collection, and reporting legislation. Additionally, a publicly traded company must adhere to legislation defining reporting requirements, senior management, and the responsibilities and liabilities of the board of directors. Organizations that operate in the healthcare sector must adhere to legislation specific to the protection of medical information, confidentiality, patient care, and drug handling. Adherence to this legislation is a requirement for the ongoing existence of the organization and avoidance of criminal or civil liabilities.

The organizational structure is an important element in establishing decision-making and functional responsibilities. The division of functional responsibilities provides the framework for segregation of duties controls. Through segregation of duties, no single person or department is responsible for an entire process. This control is often implemented within the systems used by organizations.

Aside from the division of functional responsibilities, organizations with a centralized decision-making authority have all decisions made by a centralized group or person. This places a high degree of control over the organization's decisions, albeit potentially reducing the organization's effectiveness and responsiveness to change and customer requirements.

Decentralized organizations place decision making and authority at various levels in the company with a decreasing range of approval. For example, the president of the company can approve a $1 million expenditure, but a first-level manager cannot. Limiting the range and authority of decision making and approvals gives the company control while allowing the decisions to be made at the correct level. However, there are also many examples in the news of how managers abuse or overstep their authority levels. The intent in this chapter is not to present one as better than the other but rather to illustrate the potential repercussions of choosing either. The organization must make the decision regarding which model is appropriate at which time.

The organization also establishes internal policies to control the behavior of its employees. These policies typically are implemented by procedures, standards, and guidelines. Policies describe senior management's decisions. They limit employee behavior by typically adding sanctions for noncompliance, often affecting an employee's position within the organization. Policies may also include codes of conduct and ethics in addition to the normal finance, audit, HR, and systems policies normally seen in an organization.

The collective body of documentation described here instructs employees on what the organization considers acceptable behavior, where and how decisions are made, how specific tasks are completed, and what standards are used in measuring organizational or personal performance.

15.4.3 Accounting

Accounting controls are an area of great concern for the accounting and audit departments of an organization. These controls are concerned with safeguarding the organization's financial assets and accounting records. Specifically, these controls are designed to ensure that:

- Only authorized transactions are performed, recorded correctly, and executed according to management's directions.
- Transactions are recorded to allow for preparation of financial statements using generally accepted accounting principles.
- Access to assets, including systems, processes, and information, is obtained and permitted according to management's direction.
- Assets are periodically verified against transactions to verify accuracy and resolve inconsistencies.

While these are obviously accounting functions, they establish many controls implemented within automated systems. For example, an organization that allows any employee to make entries into the general ledger or accounting system will quickly find itself financially insolvent and questioning its operational decisions.

Financial decision making is based upon the data collected and reported from the organization's financial systems. Management wants to know and demonstrate that only authorized transactions have been entered into the system. Failing to demonstrate this or establish the correct controls within the accounting functions impacts the financial resources of the organization. Additionally, internal or external auditors cannot validate the authenticity of the transactions; they will not only indicate this in their reports but may refuse to sign the organization's financial reports. For publicly traded companies, failing to demonstrate appropriate controls can be disastrous.

The recent events regarding mishandling of information and audit documentation in the Enron case (United States, 2001–2002) demonstrate poor compliance with legislation, accepted standards, accounting, and auditing principles.

15.4.4 Preventive

As presented thus far, controls may exist for the entire organization or for subsets of specific groups or departments. However, some controls are implemented to prevent undesirable behavior before it occurs. Other controls are designed to detect the behaviors when they occur, to correct them, and improve the process so that a similar behavior will not recur.

This suite of controls is analogous to the prevent-detect-correct cycle used within the information security community.

Preventive controls establish mechanisms to prevent the undesirable activity from occurring. Preventive controls are considered the most cost-effective approach of the preventive-detective-corrective cycle. When a preventive control is embedded into a system, the control prevents errors and minimizes the use of detective and corrective techniques. Preventive controls include trustworthy, trained people, segregation of duties, proper authorization, adequate documents, proper record keeping, and physical controls.

For example, an application developer who includes an edit check in the zip or postal code field of an online system has implemented a preventive control. The edit check validates the data entered as conforming to the zip or postal code standards for the applicable country. If the data entered does not conform to the expected standards, the check generates an error for the user to correct.

15.4.5 Detective

Detective controls find errors when the preventive system does not catch them. Consequently, detective controls are more expensive to design and implement because they not only evaluate the effectiveness of the preventive control but must also be used to identify potentially erroneous data that cannot be effectively controlled through prevention. Detective controls include reviews and comparisons, audits, bank and other account reconciliation, inventory counts, passwords, biometrics, input edit checks, checksums, and message digests.

A situation in which data is transferred from one system to another is a good example of detective controls. While the target system may have very strong preventive controls when data is entered directly, it must accept data from other systems. When the data is transferred, it must be processed by the receiving system to detect errors. The detection is necessary to ensure that valid, accurate data is received and to identify potential control failures in the source system.

15.4.6 Corrective

The corrective control is the most expensive of the three to implement and establishes what must be done when undesirable events occur. No matter how much effort or resources are placed into the detective controls, they provide little value to the organization if the problem is not corrected and is allowed to recur.

Once the event occurs and is detected, appropriate management and other resources must respond to review the situation and determine why the event occurred, what could have been done to prevent it, and implement the appropriate controls. The corrective controls terminate the loop and feed back the new requirements to the beginning of the cycle for implementation.

From a systems security perspective, we can demonstrate these three controls.

- An organization is concerned with connecting the organization to the Internet. Consequently, it implements firewalls to limit (prevent) unauthorized connections to its network. The firewall rules are designed according to the requirements established by senior management in consultation with technical and security teams.
- Recognizing the need to ensure the firewall is working as expected and to capture events not prevented by the firewall, the security teams establish an intrusion detection system (IDS) and a log analysis system for the firewall logs. The IDS is configured to detect network behaviors and anomalies the firewall is expected to prevent. Additionally, the log analysis system accepts the firewall logs and performs additional analysis for undesirable behavior. These are the detective controls.
- Finally, the security team advises management that the ability to review and respond to issues found by the detective controls requires a computer incident response team (CIRT). The role of the CIRT is to accept the anomalies from the detective systems, review them, and determine what action is required to correct the problem. The CIRT also recommends changes to the existing controls or the addition of new ones to close the loop and prevent the same behavior from recurring.

15.4.7 Deterrent

The deterrent control is used to discourage violations. As a control itself, it cannot prevent them. Examples of deterrent controls are sanctions built into organizational policies or punishments imposed by legislation.

15.4.8 Recovery

Recovery controls include all practices, procedures, and methods to restore the operations of the business in the event of a disaster, attack, or system failure. These include business continuity planning, disaster recovery plans, and backups.

All of these mechanisms enable the enterprise to recover information, systems, and business processes, thereby restoring normal operations.

15.4.9 Compensating

If the control objectives are not wholly or partially achieved, an increased risk of irregularities in the business operation exists. Additionally, in some situations, a desired control may be missing or cannot be implemented. Consequently, management must evaluate the cost-benefit of implementing additional controls, called compensating controls, to reduce the risk. Compensating controls may include other technologies, procedures, or manual activities to further reduce risk.

For example, it is accepted practice to prevent application developers from accessing a production environment, thereby limiting the risk associated with insertion of improperly tested or unauthorized program code changes. However, in many enterprises, the application developer may be part of the application support team. In this situation, a compensating control could be used to *allow* the developer *restricted* (monitored and/or limited) access to the production system, *only when access is required*.

15.5 Control Standards

With this understanding of controls, we must examine the control standards and objectives of security professionals, application developers, and system managers. Control standards provide developers and administrators with the knowledge to make appropriate decisions regarding key elements within the security and control framework. The standards are closely related to the elements discussed thus far.

Standards are used to implement the control objectives, namely:

- Data validation
- Data completeness
- Error handling
- Data management
- Data distribution
- System documentation

Application developers who understand these objectives can build applications capable of meeting or exceeding the security requirements of many organizations. Additionally, the applications will be more likely to satisfy the requirements established by the audit profession.

Data accuracy standards ensure the correctness of the information as entered, processed, and reported. Security professionals consider this an element of data integrity. Associated with data accuracy is data completeness. Similar to ensuring the accuracy of the data, the security professional must also be concerned with ensuring that all information is recorded. Data completeness includes ensuring that only authorized transactions are recorded and none are omitted.

Timeliness relates to processing and recording the transactions in a timely fashion. This includes service levels for addressing and resolving error conditions. Critical errors may require that processing halts until the error is identified and corrected.

Audit trails and logs are useful in determining what took place after the fact. There is a fundamental difference between audit trails and logs. The audit trail is used to record the status and processing of individual transactions. Recording the state of the transaction throughout the processing cycle allows for the identification of errors and corrective actions. Log files are primarily used to record access to information by individuals and what actions they performed with the information.

Aligned with audit trails and logs is system monitoring. System administrators implement controls to warn of excessive processor utilization, low disk space, and other conditions. Developers should insert controls in their applications to advise of potential or real error conditions. Management is interested in information such as the error condition, when it was recorded, the resolution, and the elapsed time to determine and implement the correction.

Through techniques including edit controls, control totals, log files, checksums, and automated comparisons, developers can address traditional security concerns.

15.6 Control Implementation

The practical implementations of many of the control elements discussed in this chapter are visible in today's computing environments. Both operating system and application-level implementations are found, often working together to protect access and integrity of the enterprise information.

The following examples illustrate and explain various control techniques available to the security professional and application developer.

15.6.1 Transmission Controls

The movement of data from the origin to the final processing point is of importance to security professionals, auditors, management, and the actual information user. Implementation of transmission controls can be established through the communications protocol itself, hardware, or within an application.

For example, TCP/IP implementations handle transmission control through the retransmission of information errors when received. The ability of TCP/IP to perform this service is based upon error controls built into the protocol or service. When a TCP packet is received and the checksum calculated for the packet is incorrect, TCP requests retransmission of the packet. However, UDP packets must have their error controls implemented at the application layer, such as with NFS.

15.6.2 Sequence

Sequence controls are used to evaluate the accuracy and completeness of the transmission. These controls rely upon the source system generating a sequence number, which is tested by the receiving system. If the data is received out of sequence or a transmission is missing, the receiving system can request retransmission of the missing data or refuse to accept or process any of it.

Regardless of the receiving system's response, the sequence controls ensure data is received and processed in order.

15.6.3 Hash

Hash controls are stored in the record before it is transmitted. These controls identify errors or omissions in the data. Both the transmitting and receiving systems must use the same algorithm to compute and verify the computed hash. The source system generates a hash value and transmits both the data and the hash value.

The receiving system accepts both values, computes the hash, and verifies it against the value sent by the source system. If the values do not match, the data is rejected. The strength of the hash control can be improved through strong algorithms that are difficult to fake and by using different algorithms for various data types.

15.6.4 Batch Totals

Batch totals are the precursors to hashes and are still used in many financial systems. Batch controls are sums of information in the transmitted data. For example, in a financial system, batch totals are used to record the number of records and the total amounts in the transmitted transactions. If the totals are incorrect on the receiving system, the data is not processed.

15.6.5 Logging

A transaction is often logged on both the sending and receiving systems to ensure continuity. The logs are used to record information about the transmission or received data, including date, time, type, origin, and other information.

The log records provide a history of the transactions, useful for resolving problems or verifying that transmissions were received. If both ends of the transaction keep log records, their system clocks must be synchronized with an external time source to maintain traceability and consistency in the log records.

15.6.6 Edit

Edit controls provide data accuracy and consistency for the application. With edit activities such as inserting or modifying a record, the application performs a series of checks to validate the consistency of the information provided.

For example, if the field is for a zip code, the data entered by the user can be verified to conform to the data standards for a zip code. Likewise, the same can be done for telephone numbers, etc.

Edit controls must be defined and inserted into the application code as it is developed. This is the most cost-efficient implementation of the control; however, it is possible to add the appropriate code later. The lack of edit controls affects the integrity and quality of the data, with possible repercussions later.

15.7 Physical

The implementation of physical controls in the enterprise reduces the risk of theft and destruction of assets. The application of physical controls can decrease the risk of an attacker bypassing the logical controls built into the systems. Physical controls include alarms, window and door construction, and environmental protection systems. The proper application of fire, water, electrical, temperature, and air controls reduces the risk of asset loss or damage.

15.8 Data Access

Data access controls determine who can access data, when, and under what circumstances. Common forms of data access control implemented in computer systems are file permissions. There are two primary control methods—discretionary access control and mandatory access control.

Discretionary access control, or DAC, is typically implemented through system services such as file permissions. In the DAC implementation, the user chooses who can access a file or program based upon the file permissions established by the owner. The key element here is that the ability to access the data is decided by the owner and is, in turn, enforced by the system.

Mandatory access control, also known as MAC, removes the ability of the data owner alone to decide who can access the data. In the MAC model, both the data and the user are assigned a classification and clearance. If the clearance assigned to the user meets or exceeds the classification of the data and the owner permits the access, the system grants access to the data. With MAC, the owner and the system determine access based upon owner authorization, clearance, and classification.

Both DAC and MAC models are available in many operating system and application implementations.

15.9 Why Controls do not Work

While everything present in this chapter makes good sense, implementing controls can be problematic. Overcontrolling an environment or implementing confusing and redundant controls results in excessive human/monetary expense. Unclear controls might bring confusion to the work environment and leave people wondering what they are supposed to do, delaying and impacting the ability of the organization to achieve its goals. Similarly, controls might decrease effectiveness or entail an implementation that is costlier than the risk (potential loss) they are designed to mitigate.

In some situations, the control may become obsolete and effectively useless. This is often evident in organizations whose polices have not been updated to reflect changes in legislation, economic conditions, and systems.

Remember: people will resist attempts to control their behaviors. This is human nature and very common in situations in which the affected individuals were not consulted or involved in the development of the control. Resistance is highly evident in organizations in which the controls are so rigid or overemphasized as to cause mental or organizational rigidity. The rigidity causes a loss of flexibility to accommodate certain situations and can lead to strict adherence to procedures when common sense and rationality should be employed.

Personnel can and will accept controls. Most people are more willing to accept them if they understand what the control is intended to do and why. This means the control must be a means to an end and not the end itself. Alternatively, the control may simply not achieve the desired goal. There are four primary reactions to controls the security professional should consider when evaluating and selecting the control infrastructure:

1. *The control is a game*. Employees consider the control as a challenge, and they spend their efforts in finding unique methods to circumvent the control.
2. *Sabotage*. Employees attempt to damage, defeat, or ignore the control system and demonstrate, as a result, that the control is worthless.
3. *Inaccurate information*. Information may be deliberately managed to demonstrate the control as ineffective or to promote a department as more efficient than it really is.
4. *Control illusion*. While the control system is in force and working, employees ignore or misinterpret results. The system is credited when the results are positive and blamed when results are less favorable.

The previous four reactions are fairly complex reactions. Far more simplistic reactions leading to the failure of control systems have been identified:

- *Apathy*. Employees have no interest in the success of the system, leading to mistakes and carelessness.
- *Fatigue*. Highly complex operations result in fatigue of systems and people. Simplification may be required to address the problem.
- *Executive override*. The executives in the organization provide a "get out of jail free" card for ignoring the control system. Unfortunately, the executives involved may give permission to employees to ignore all the established control systems.
- *Complexity*. The system is so complex that people cannot cope with it.
- *Communication*. The control operation has not been well communicated to the affected employees, resulting in confusion and differing interpretations.
- *Efficiency*. People often see the control as impeding their abilities to achieve goals.

Despite the reasons why controls fail, many organizations operate in very controlled environments due to business competitiveness, handling of national interest or secure information, privacy, legislation, and other reasons. People can accept controls and assist in their design, development, and implementation. Involving the correct people at the correct time results in a better control system.

15.10 Summary

This chapter has examined the language of controls, including definitions and composition. It has looked at the different types of controls, some examples, and why controls fail. The objective for the auditor and the security professional alike is to understand the risk the control is designed to address and implement or evaluate as their role may be. Good controls do depend on good people to design, implement, and use the control.

However, the balance between the good and the bad control can be as simple as the cost to implement or the negative impact to business operations. For a control to be effective, it must achieve management's objectives, be relevant to the situation, be cost effective to implement, and easy for the affected employees to use.

Acknowledgments

Many thanks to my colleague and good friend, Mignona Cote. She continues to share her vast audit experience daily, having a positive effect on information systems security and audit. Her mentorship and leadership have contributed greatly to my continued success.

Patch Management 101: It Just Makes Good Sense!

Lynda L. McGhie

You don't need to apply every patch, but you do need a process for determining which you will apply!

16.1 Introduction

Information technology (IT) continues to grow and develop in complexity, and thus even small to medium-sized firms have evolved into diverse, complex, and unique infrastructures. One size no longer fits all, and what works in one environment does not necessarily work in another. So while the underlying IT infrastructure becomes more challenging to maintain, the threats and vulnerabilities introduced through today's "blended" exploits and attacks also grows exponentially.

This tenuous state of affairs, contributing to and sometimes actually defining a snapshot in time security posture for an organization, leads most security managers to conclude that the development, implementation, and ongoing maintenance of a vigorous patch management program is a mandatory and fundamental requirement for risk mitigation and the management of a successful security program. The rise of widespread worms and malicious code targeting known vulnerabilities on unpatched systems, and the resultant downtime and expense they bring, is probably the biggest justification for many organizations to focus on patch management as an enterprise IT goal.

Remember January 25, 2003? The Internet was brought to its knees by the SQL Slammer worm. It was exploiting a vulnerability in SQL Server 2000, for which Microsoft had released a patch over six months prior. Code Red, one of the most well-known Internet worms, wreaked havoc on those companies that were not current with software patch updates. According to the Cooperative Association for Internet Data Analysis (CAIDA), estimates of the hard-dollar damage done by Code Red are in excess of $2.6 billion, with a phenomenal 359,000 computers infected in less than 14 hours of the worm's release.

According to data from the FBI and Carnegie Mellon University, more than 90 percent of all security breaches involve a software vulnerability caused by a missing patch of which the IT department is already aware. In an average week, vendors and other tracking organizations announce about 150 alerts. Microsoft alone sometimes publishes five patches or alerts each week. Carnegie Mellon University's CERT Coordination

Center states that the number of vulnerabilities each year has been doubling since 1998. According to the Aberdeen Group, the number of patches released by vendors is increasing for three main reasons:

1. Vendors are releasing new versions of software faster than ever, and thus are devoting less time than ever to testing their products.
2. More complex software makes bulletproof security impossible.
3. Hackers are more sophisticated and continually find new ways to penetrate software and disrupt business.

If IT departments know about these risks ahead of time, why do these vulnerabilities exist and why do they continue to be exploited on a global scale? IT administrators are already shorthanded and overburdened with maintenance and systems support. Patching thousands of workstations at the current rate of patches released each week is almost impossible, especially utilizing manual methods. Gartner estimates that IT managers now spend up to two hours every day managing patches. And when Microsoft alone issues a new patch about every fifth day, how can anyone keep up?

The complexity and the labor-intensive process of sorting through growing volumes of alerts, figuring out applicability to unique IT environments and configurations, testing patches prior to implementing, and finally orchestrating the process of timely updates begins to overwhelm even the most resource-enabled IT organizations. Overtaxed system administrators do not have the bandwidth to deal with the torrent of patches and hot fixes.

Without a disciplined, repeatable, and auditable patch management process, unapplied patches mount up and some never get applied. Systems administrators do not want to spend all their time dealing with the constant review and application of patches. Some systems have become so kludged together over time that the very thought of introducing any change invokes fear and hesitation on the part of support personnel. The introduction of a new patch could ultimately result in causing more trouble than it solves.

In an interconnected world, it is critical for system administrators to keep their systems patched to the most secure level. The consequences of failing to implement a comprehensive patch management strategy can be severe, with a direct impact on the bottom line of the organization. Mission-critical production systems can fail and security-sensitive systems can be exploited, all leading to a loss of time and subsequent business revenue.

So why do all large organizations not have a comprehensive patch management strategy? Because there is no coherent solution, and patch management has become an increasingly onerous issue for IT organizations to grapple with in terms of people, process, and technology.

The same technologies that have enabled, organized, and streamlined businesses also have the potential to cause havoc and extreme financial loss to those same businesses—and others. Because software defects, inappropriate configurations, and failure to patch have been at the root cause of every major attack on the Internet since 1986, the solution requires a solid patch management process that protects IT investments.

A good patch management program consists of several phases. The number of phases may be unique to an individual company based on its IT infrastructure and other key components such as size; diversity of platforms, systems and applications; degree of automation and modernization; whether IT is centralized or decentralized; and resource availability.

To ensure the successful implementation of a security patch management program, an organization must devise a robust patch management life-cycle process to ensure timely and accurate application of security patches across the enterprise. While patch management processes are maturing and merging to other key IT operations and support processes, such as change management, system management, and asset management, there still remains a lot of up-front work to plan, design, integrate, and implement an effective and responsive program.

A sample phased patch management life-cycle process, combining and expanding several shorter methodologies, is outlined below. There are also longer processes available. The basic core components are assess, apply, and monitor. With a clear understanding of your company's environment, current tool set, and resources, one can devise a practical and unique patch management process for an organization. One can also walk before one runs and establish a baseline process with the intent to continue to expand as resources grow or interdependent projects are completed (e.g., systems management, MS Active Directory, asset management, etc.).

16.2 Patch Management Life Cycle

1. Develop a baseline software inventory management system:
   - Implement update and change processes to ensure that the inventory system remains current.
   - Identify other automated or manual systems that need to interface with the inventory management system, such as asset management, change management, system configuration and management, etc. Create interfaces and document processes.
   - Identify what information you want to capture on each entry/object (e.g., hardware platform, vendor, operating system, release level and versions, IP address, physical location of device, system administrator, owner, criticality of the system, role of the computer, contact information, etc.).
   - Utilize scanning tools to inventory your system on a regular basis once you have established your baseline system.
2. Devise a plan to standardize on software configurations across the enterprise:
   - Ensure that all systems are maintained to the same version, release, and service pack level. Standard configurations are easier and more cost effective to manage. If you know what software and what applications are resident on your systems, you can quickly analyze the impact of critical patches to your environment.
   - Ensure your system is up-to-date and that any change made on the system is captured and recorded in your database.
   - Every time you make any change to the system, capture the following information: name/version number of the update, patch or fix installed, functional description of what was done, source of the code (where it was obtained), date the code was downloaded, date the code was installed, and the name of the installer.
   - Create a patch installation cycle that guides the normal application of patches and updates to the system. This cycle will enable the timely application of patch releases and updates. It is not meant for emergency use or just the application of critical patches, but should be incorporated into the systems management system.
3. Determine the best source for information about alerts and new software updates:
   - Subscribe to security alert services, assign an individual responsible for monitoring alerts, and ensure that the process/system for collecting and analyzing the criticality and the applicability of patches is reliable and timely. A combination of automated notification and in-house monitoring is optimal.
   - Partner with your vendors for auto-alerts and patch notification.
   - Check with peers within the industry as to what they are doing and how they are interpreting the risk and criticality of applying a new patch. Ask a question as to who has applied the patch and what impact it had on their system.
   - Check the vendor's Web site to see if anyone has reported a problem applying the patch. If nothing is reported, post inquiries.
   - Compare these reported vulnerabilities with your current inventory list.
4. Assess your organization's operational readiness:
   - Determine if you have the skilled personnel to staff a patch management function.
   - Is there an understanding of and support for the value of the patch management function?
   - Are there, operational processes in place and documented?
   - Do processes exist for change management and release management?
   - Is there currently an emergency process for applying critical updates/patches?
5. Assess the risk to your environment and devise a critical patch rating system:
   - Assess the vulnerability and likelihood of an exploit in your environment. Perhaps some of your servers are vulnerable, but none of them is mission critical. Perhaps your firewall already blocks the

service exploited by the vulnerability. Even the most obscure patch can be an important defense against worms and system attackers.
   - Consider these three factors when assessing the vulnerability: the severity of the threat (the likelihood of its impacting your environment, given its global distribution and your inventory control list, etc.); the level of vulnerability (e.g., is the affected system inside or outside perimeter firewalls?); and the cost of mitigation or recovery.
   - Check the vendor's classification of the criticality of the risk.
   - Consider your company's business posture, critical business assets, and system availability.
6. Test all patches prior to implementation:
   - Once you have determined that a patch is critical and applicable in your environment, coordinate testing with the proper teams. Although patching is necessary to securing the IT infrastructure, patches can also cause problems if not tested and applied properly. Patch quality varies from vendor to vendor and from patch to patch.
   - If you do not have a formal test lab, put together a small group of machines that functions as a guinea pig for proposed patches.
   - Validate the authenticity of the patch by verifying the patch's source and integrity.
   - Ensure that the patch testing process combines mirror-image systems with procedures for rapidly evaluating patches for potential problems.
   - There are automated tools emerging that will test patches, but there is no substitute for evaluating patches on a case-by-case basis utilizing a competent and experienced IT staff familiar with the company's IT and business infrastructure.
7. Implement a patch installation and deployment strategy:
   - Implement a policy that only one patch should be applied at a time.
   - Propose changes through change control.
   - Read all the documentation about applying the patch before you begin.
   - Back up systems, applications, and data on those systems to be patched. Back up configuration files for a software package before applying a patch to it.
   - Have a back-out plan in case the patch causes problems. Do not apply multiple patches at once.
   - Know who to contact if something goes wrong. Have information available when you call for help, what is the patch reference information that you were trying to apply, what is the system and release level of the system that you were trying to apply the patch to, etc.
   - Automate the deployment of patches to the extent possible. In most shops, this will probably utilize any number of automated tools such as SMS, scripts, management systems, or a patch management product. Although the process is automated, ensure that the patch does not negatively impact a production system.
8. Ensure ongoing monitoring and assessment to maintain compliance:
   - Periodically run vulnerability tracking tools to verify that standard configurations are in place and the most up-to-date patches are applied and maintained.
   - Timely management reporting is the key to any successful enterprise patch management system. The following reports will be helpful: installation reporting, compliance reporting, and inventory reporting.

16.3 Policies and Procedures

Establish policies and procedures for patch management. Assign areas of responsibility and define terminology. Establish policies for the timing and application of updates. Noncritical updates on noncritical systems will be performed on a regularly scheduled maintenance window. Emergency updates will be performed as soon as possible after ensuring patch stability. These updates should only be applied if they fix an existing problem. Critical updates should be applied during off-hours as soon as possible after ensuring patch stability.

Establish policies for standard configurations and ensure that all new workstations are imaged with the most recent version, including all patch updates. Enforce standard configurations and ensure compliance with ongoing and scheduled use of discovery and scanning tools. Establish a policy and criteria for enforcement for noncompliant machines.

A policy should be created for security advisories and communication. The policy should define the advisory template to ensure consistency and reduce confusion. The template should include the type of vulnerability, the name of the vulnerability, the affected application or platform with versions and release levels, how the vulnerability is exploited, and detailed instructions and steps to be taken to mitigate the vulnerability.

16.4 Roles and Responsibilities

- *Computer Emergency Response Team* (*CERT*). This team manages the analysis and management of security vulnerabilities. The CERT is authorized to assemble subject matter experts (SMEs) from other parts of the organization. The CERT provides ongoing monitoring of security intelligence for new vulnerabilities and recommends the application of fixes or patches.
- *Product managers*. Product managers are responsible for a specific product or application (e.g., Windows, UNIX, etc.). Product managers are also responsible for providing SMEs to the CERT team and responding quickly to all alerts and patches. Product managers participate in the testing and release of patches and make recommendations on the remediation approach.
- *Risk managers*. Risk managers are responsible for ensuring the data they are responsible for is secured according to corporate security policy. In some organizations, the Chief Information Security Officer (CISO) performs this function. The risk manager assists the CERT in defining critical systems and data, and in assessing the potential risk and vulnerability to their business resulting from the application of a patch.
- *Operations managers*. Operations managers are usually responsible for deploying the patch on the vulnerable systems. They are important members of the security patch management life cycle process and the CERT because they must coordinate the implementation efforts. They assist the CERT in preparing the implementation plan and scheduling the implementation.

16.5 Conclusion

An outside service can also be engaged to assist with the patch management process. Services include monitoring alerts, running assessment and inventory tools, notification of vulnerabilities and patches, testing patches, and preparing installation builds and ongoing monitoring to ensure that systems remain patched and secure. Some vendors are already moving in this direction and are attempting to provide update or patch automation for systems and applications. While this trend works well for home users, corporations need to approach this alternative with caution due to the complexity of a single production enterprise. Even if the patches are rigorously tested in the vendor environment, it does not mean that they will necessarily work in your environment.

Security teams need to work together throughout the industry to share information relative to threats, vulnerability announcements, patch releases, and patch management solutions. With the number of bugs to fix and systems to continually update, patch management becomes a key component of a well-planned and well-executed information security program. It is not, however, free. And because it is a "pay now or pay later" situation, it is cheaper to invest up front in a solid patch management process. This is simply something that you have to do, like preparing for Y2K problems and business continuity planning (as evidenced by 9/11).

17

Security Patch Management: The Process

Felicia M. Nicastro

17.1 Introduction

A comprehensive security patch management process is a fundamental security requirement for any organization that uses computers, networks, or applications for doing business today. Such a program ensures the security vulnerabilities affecting a company's information systems are addressed in an efficient and effective manner. The process introduces a high degree of accountability and discipline to the task of discovering, analyzing, and correcting security weaknesses.

The patch management process is a critical element in protecting any organization against emerging security threats. Formalizing the deployment of security-related patches should be considered one of the important aspects of a security group's program to enhance the safety of information systems for which they are responsible.

17.2 Purpose

The goals behind implementing a security patch management process cover many areas. It positions the security management process within the larger problem space—vulnerability management. It improves the way the organization is protected from current threats and copes with growing threats. Another goal of the security patch management process is to improve the dissemination of information to the user community, the people responsible for the systems, and the people responsible for making sure the affected systems are patched properly. It formalizes record keeping in the form of tracking and reporting. It introduces a discipline, an automated discipline that can be easily adapted to once the process is in place. It also can allow a company to deal with security vulnerabilities as they are released with a reduced amount of resources, and to prioritize effectively. It improves accountability within the organization for the roles directly responsible for security and systems. With this in mind, the *security group* within an organization should develop a formal process to be used to address the increased threats represented by known and addressable security vulnerabilities.

17.2.1 Background

Information security advisory services and technology vendors routinely report new defects in software. In many cases, these defects introduce opportunities to obtain unauthorized access to systems. Information about security exposures often receives widespread publicity across the Internet, increasing awareness of software weaknesses, with the consequential risk that cyber-criminals could attempt to use this knowledge to exploit vulnerable systems. This widespread awareness leads vendors to quickly provide security patches so they can show a response to a vulnerability that has been publicized and avoid erosion of customer confidence in their products.

Historically, most organizations tend to tolerate the existence of security vulnerabilities and, as a result, deployment of important security-related patches is often delayed. Most attention is usually directed toward patching Internet-facing systems, firewalls, and servers, all of which are involved in data communications with business partners and customers. These preferences resulted from two fundamental past assumptions:

1. The threat of attack from insiders is less likely and more tolerable than the threat of attack from outsiders.
2. A high degree of technical skill is required to successfully exploit vulnerabilities, making the probability of attack unlikely.

In the past, these assumptions made good, practical sense and were cost-effective given the limited scope of systems. However, both the threat profile and potential risks to an organization have changed considerably over time. Viruses can now be delivered through common entry points (such as e-mail attachments), automatically executed, and then search for exploitable vulnerabilities on other platforms.

The following information was taken from the Symantec Internet Security Threat Report Volume III, February 2003. This report documented the attack trends for Q3 and Q4 of 2002. In 2002, Symantec documented 2524 vulnerabilities affecting more than 2000 distinct products. This total was 81.5 percent higher than the total documented in 2001. Perhaps of even more concern is the fact that this rise was driven almost exclusively by vulnerabilities rated as either moderately or highly severe. In 2002, moderate and high severity vulnerabilities increased by 84.7 percent, while low severity vulnerabilities only rose by 24.0 percent.

Gartner has also released a substantial amount of information pertaining to patches over the past year. The following is a quote from Gartner from a report entitled "Patch Management Is a Fast Growing Market," published May 30, 2003. "Gartner estimates that it cost $300K a year to manually deploy patches to 1000 servers. Whereas a patch management solution may cost only $50K a year (tools)."

The following information surrounding the threats to organizations today are based on Symantec's latest report released in September 2003, entitled "Symantec Internet Security Threat Report, Executive Summary."

> Blended threats, which use combinations of malicious code to begin, transmit, and spread attacks, are increasing and are among the most important trends to watch and guard against this year. During the first half of 2003, blended threats increased nearly 20 percent over the last half of 2002. One blended threat alone, Slammer, disrupted systems worldwide in less than a few hours. Slammer's speed of propagation, combined with poor configuration management on many corporate sites, enabled it to spread rapidly across the Internet and cause outages for many corporations.
>
> Blaster used a well-known Microsoft security flaw that had been announced only 26 days before Blaster was released. This fact supports our analysis that the time from discovery to outbreak has

> shortened greatly. During the first half of 2003, our analysis shows that attackers focused on the newer vulnerabilities; of all new attacks observed, 64 percent targeted vulnerabilities less than one year old. Furthermore, attackers focused on highly severe vulnerabilities that could cause serious harm to corporations; we found that 66 percent targeted highly severe vulnerabilities. That attackers are quickly focusing on the attacks that will cause the most harm or give them the most visibility should be a warning to executives.

To summarize the information that Symantec has provided, there are three main trends we are seeing with patches, and the vulnerabilities associated with them. First, the speed of propagation is increasing; secondly, time from discovery to outbreak has shortened; and finally, attackers are focusing on highly severe vulnerabilities.

17.2.2 Types of Patches

System patches are generally broken down into three types:

1. *Security patches*: those that correct a known vulnerability
2. *Functionality patches*: those that correct a known functional issue—not related to security
3. *Feature patches*: those that introduce new features or functions to an existing operating system or application

In most cases, a patch management process concerns itself with security patches, versus functionality (or feature) patches. Usually, developers deploy the latter during the testing phases of an application. They can also be deployed during a software update, but not typically within the patch management process itself.

17.3 Process Life Cycle

A security patch management process describes best practices that should be employed in any major organization to govern how to respond to security-related vulnerabilities. Updating patches on a system is not the only method by which to protect a company's asset from a threat. However, it is the most common, and is one that is often overlooked or underemphasized. This process is initiated whenever the organization becomes aware of a potential security vulnerability, which is followed up with a vendor release, or hot fix, to address the security vulnerability. Exhibit 17.1 shows a high-level walkthrough of the patch management process. It will be broken down into further detail in the following sections.

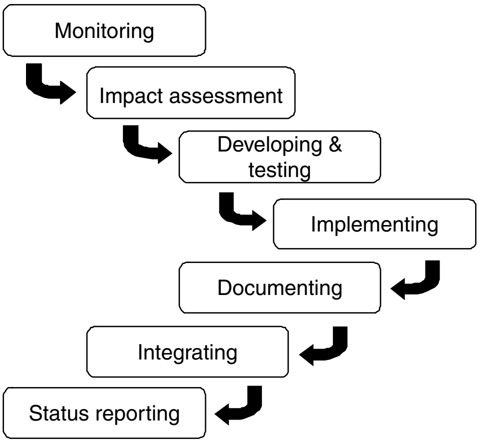

EXHIBIT 17.1 High-level patch management flow diagram.

The process covers the following key activities:

- Monitoring for security vulnerabilities from security intelligence sources
- Completing an impact assessment on new security vulnerabilities
- Developing and testing the technical remediation strategy
- Implementing the technical remediation strategy on all affected hosts
- Documenting the life cycle of each vulnerability, including reporting and tracking of remediation measures implemented by each line of business
- Integrating the patch or configuration changes into the related application/system baseline and standard build
- All of these activities will be subject to status reporting requirements

The security patch management process contains multiple highlights that need to be taken into consideration during development within the organization. The security patch management process should be centrally managed. In a smaller organization, this can be a simple task, as the security department may only consist of a few individuals. In other larger organizations, IT and the security group may be decentralized, making it more difficult to ensure that all groups are following the security patch management procedure in the same manner. Even if the IT department is decentralized, there should always be a centralized Security Committee that oversees the security posture of the entire organization. It is within this group that the patch management process would be included.

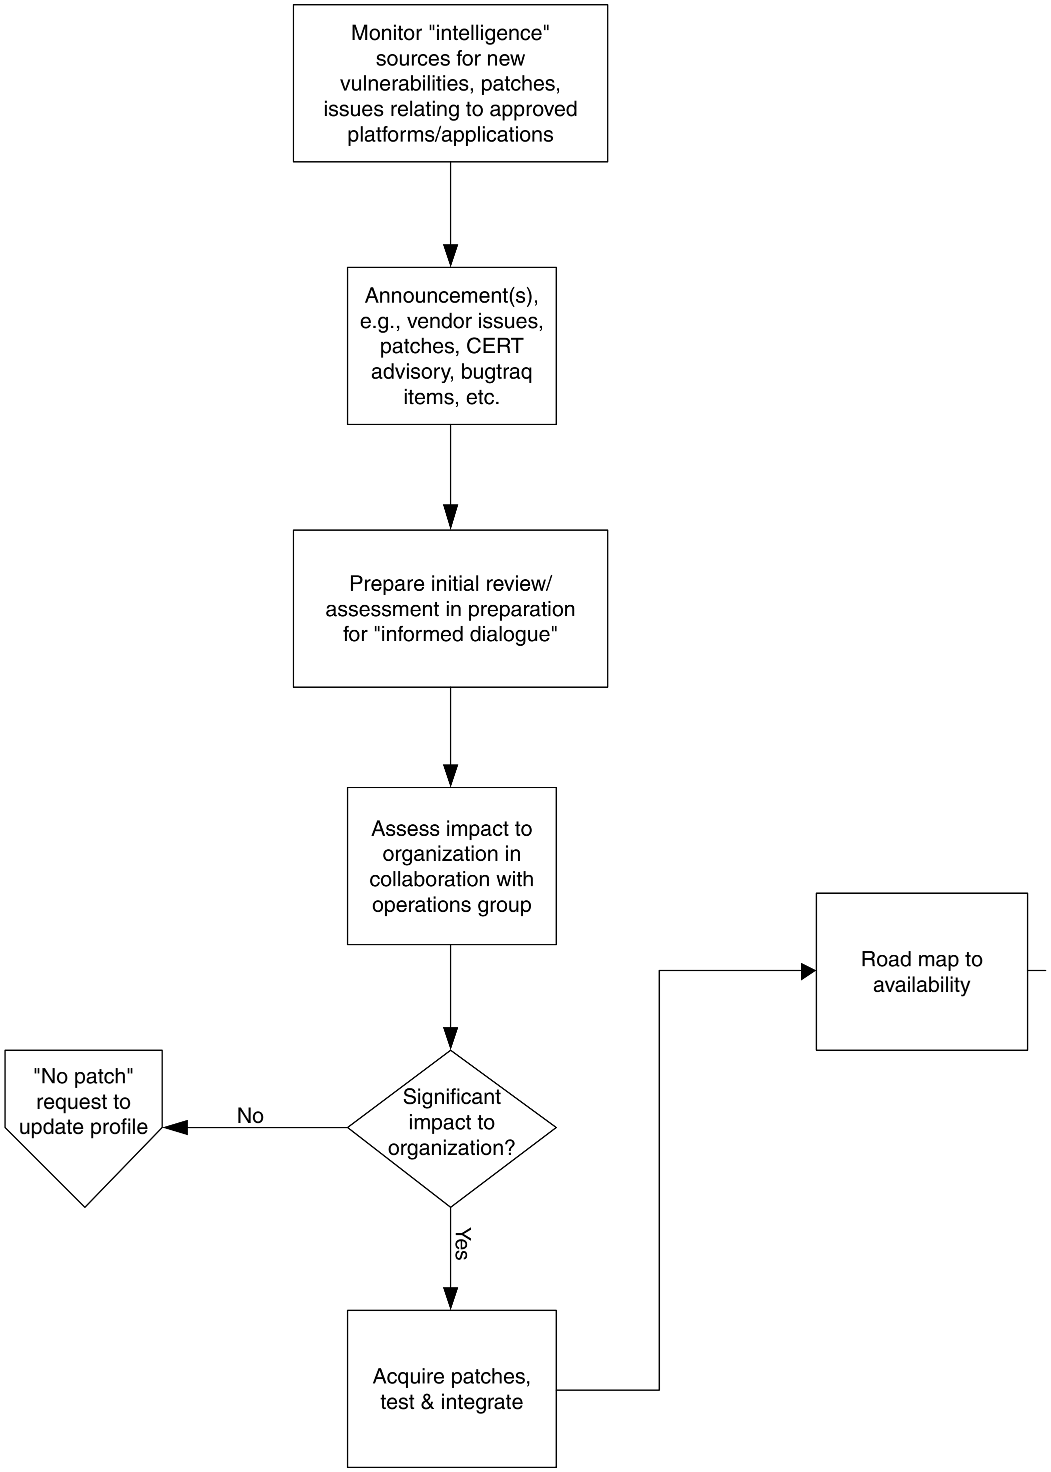
One of the primary reasons why the patch management process fails is the absence of a supportive culture. Whether the security group consists of one person or ten, collaboration between the security group as well as the other individuals, which are explained in detail later in this chapter, is required, and it is built into the process. This raises the level of communication between various groups, which may not exist until a procedure such as this is put into place. Because security vulnerabilities affect many different systems and applications, all entities must be willing to work with each other, ensuring that the risk is mitigated. Frequent meetings also take place during the process, which again promotes interaction between various people.

Formal processes are tied into the patch management process, including IT operations, change and configuration management, intelligence gathering, retention of quality records, communication, network/systems/application management reporting, progress reports, testing, and deploying security-related patches. Having these processes defined in a formal manner ensures consistency and the success of the patch management process.

Another crucial step in implementing patch management is taking an inventory of the entire IT infrastructure. IT infrastructure inventory will provide an organization with the systems that make up the environment, operating systems and applications (including versions), what patches have been applied, and ownership and contact information for each system and device.

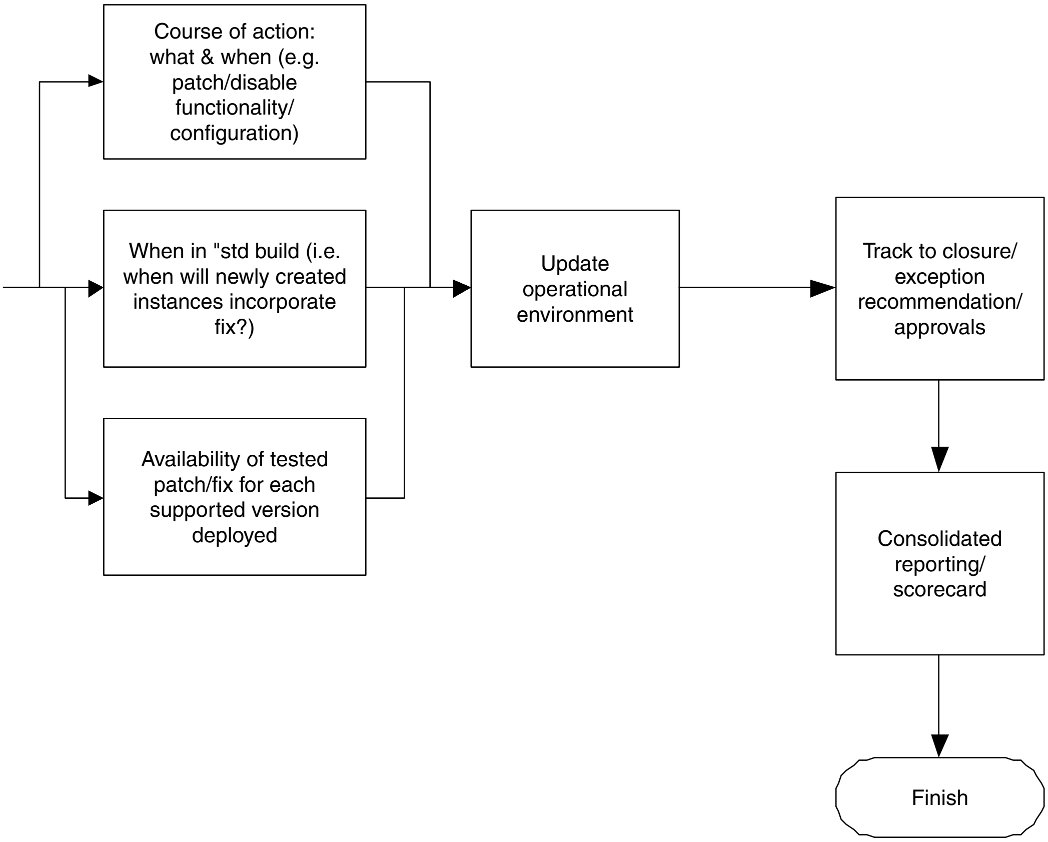
A security patch management process not only requires centralization, collaboration, and formalization, but also requires employees to take accountability into consideration. It requires prioritizing for not only the security group, but also the product and operations managers. In some organizations, these roles can be tied to the same entity, or to multiple employees spread over various departments. Placing a priority on a security vulnerability ensures that the organization is protected not only against significant vulnerabilities, but also against critical security-related patches. A waiver process is also put in place in case there is a significant reason that would prohibit the organization from implementing a security-related patch when it is released. Disputes can also arise, especially when it comes to business-critical systems, which warrants formalizing procedures for dealing with such disputes.

Exhibit 17.2 shows the detailed patch management process flow, which is broken down and explained in the following sections.



Monitor "intelligence" sources for new vulnerabilities, patches, issues relating to approved platforms/applications
Announcement(s), e.g., vendor issues, patches, CERT advisory, bugtraq items, etc.
Prepare initial review/ assessment in preparation for "informed dialogue"
Assess impact to organization in collaboration with operations group
Significant impact to organization?
No
"No patch" request to update profile
Yes
Acquire patches, test & integrate
Road map to availability

EXHIBIT 17.2 Security patch management flow diagram.



Course of action: what & when (e.g. patch/disable functionality/ configuration)
When in "std build (i.e. when will newly created instances incorporate fix?)
Availability of tested patch/fix for each supported version deployed
Update operational environment
Track to closure/ exception recommendation/ approvals
Consolidated reporting/ scorecard
Finish

EXHIBIT 17.2 (continued)

17.3.1 Roles and Responsibilities

The patch management process should define the roles and responsibilities of groups and individuals that will be involved in the remediation of a known vulnerability. A description of these groups and individuals follows.

17.3.1.1 Security Group

Typically, the patch management process falls under the responsibility of the security group within an organization. However, this depends on how the organization's groups and responsibilities are defined. Regardless, within the security group, or the persons responsible for security, a centralized Computer Incident Response Team (CIRT) should be established and defined. The CIRT manage the analysis and management of security vulnerabilities. The CIRT can contain as little as one member, and up to a dozen. This number depends on the size of the organization, the number of business-critical applications, and the number of employees within the company who can be dedicated to this full-time responsibility.

The CIRT's responsibilities include:

- Monitoring security intelligence sources for new security vulnerabilities
- Responding within 24 hours to any request from any employee to investigate a potential security vulnerability
- Defining and promoting awareness of escalation chains for reporting security vulnerabilities

- Engaging employees or contractors to play lead roles in:
  - Vulnerability analysis
  - Patch identification
  - Test plan development
  - Formal testing
  - Development of action plans
- Coordinating the development of action plans with timetables for addressing vulnerabilities
- Coordinating the approval of security-related patches
- Notifying all groups about tools and implementation and back-out plans
- Managing documentation

17.3.1.2 Operations Group

The operations group within the organization is usually responsible for deploying the patch on the vulnerable systems. They are important members of the security patch management process because they must coordinate the patch implementation efforts. The operations group responsibilities should include:

- Assisting the CIRT in development of action plans, and timeframes for completion
- Be involved during the development and testing phase to monitor progress and provide insight
- Be responsible for deployment of the remedial measure to eliminate security vulnerabilities

It is assumed that when the operations group receives the course of action plan for the security vulnerability, they are aware of what systems need to be updated and where they are located. In larger organizations, the IT group can contain product managers (PMs) who are responsible for a specific product or application (e.g., Windows, UNIX, Apache, and MySQL). The PM's responsibilities can include:

- Responding within 24 hours to requests from the CIRT to assist in the analysis of security vulnerabilities and the development of a suitable response
- Maintaining a list of qualified employees within an organization to act as subject matter experts (SMEs) on different technologies
- Calling and attending relevant meetings, as required, to determine the impact of new vulnerabilities on the systems for which they are responsible
- Leading the development and testing of remedial measures throughout their engineering groups
- Ensuring evaluation of the testing results prior to patching or solution implementation
- Making recommendations on the approach to remediation, especially when a vendor patch is not currently available—and until it becomes available

If PMs are not defined within an organization, their responsibilities would fall under the operations group. For the purpose of this reading, the PM's responsibilities are included in the operations group throughout. If a PM is defined within the organization, these tasks can be broken out through the different parties.

17.3.1.3 Network Operations Center (NOC)

The NOC plays an important role in the patch management process. NOC personnel are responsible for maintaining the change, configuration, and asset management processes within the organization. Therefore, all activity that affects any of these processes must be coordinated through them.

17.3.2 Analysis

17.3.2.1 Monitoring and Discovery

Once established within an organization, the CIRT is responsible for daily monitoring of all appropriate security intelligence sources for exposures that may impact platforms or applications utilized by the organization. Whether the organization decides to implement a CIRT of one, two, or five people, one specific person (with an appropriate backup) should be dedicated to monitoring the security intelligence sources on a daily basis. In some cases, if multiple people are completing the same tasks, overlaps can occur, as well as missing an important announcement because the schedule of monitoring is not clearly communicated. Another inclusion is that rotation of duties must be implemented so that more than one employee knows how to monitor the intelligence sources, should the primary not be available.

New security advisories and vulnerabilities are released frequently; therefore, diligence on the part of the CIRT will be required at all times.

Intelligence sources will normally publish a detailed, formal announcement of a security vulnerability. These announcements usually provide a description of the vulnerability, the platform or application affected, and the steps necessary (when available) to eliminate the risk. In addition, employees or contractors outside of the CIRT may become aware of vulnerabilities through personal sources, including hands-on experience and word of mouth. They should be encouraged through security awareness training and regular communications to report these to the CIRT.

The following Web sites and mailing lists are examples of security intelligence sources:

- General security:
  - SecurityFocus.com: http://www.securityfocus.com
  - InfoSysSec: http://www.infosyssec.net
- Mailing lists:
  - Bugtraq Archive: http://www.securityfocus.com/archive/1
  - NT Bugtraq: http://www.ntbugtraq.com
- Advisories:
  - Computer Emergency Response Team: http://www.cert.org
  - SecurityFocus.com: http://www.securityfocus.com
  - Common Vulnerabilities and Exposures: http://cve.mitre.org
- Vendor security resources:
  - Microsoft: http://www.microsoft.com/security
  - Sun Microsystems: http://sunsolve.sun.com
  - Hewlett-Packard: http://www.hp.com
  - IBM: http://www.ibm.com
  - Linux Security: http://www.linuxsecurity.com

17.3.2.2 Initial Assessment

Once a vulnerability that affects a platform or application in use within the environment has been identified, the CIRT should perform an initial review to establish the resources required to perform adequate analysis of the vulnerability and to establish an initial level of exposure. This should be completed within 48 hours of the vulnerability being identified.

If a vulnerability is released that drastically affects business-critical systems within the organization, a lead analyzer may be called in to assess the vulnerability immediately for these systems. In other cases, the normal CIRT team would assess the vulnerability and make a determination of whether or not the organization is impacted. The vulnerability should be thoroughly analyzed to determine if the organization is susceptible. For example, it may only impact an older version of software, which the company has since migrated off of, therefore leaving them unaffected by the newly released vulnerability.

The initial assessment phase is a task headed by the CIRT; however, additional resources may be called in to assist in the process. These resources would include other groups from within the company, primarily the operations group and SMEs from other groups, but will often also include product vendors. The initial assessment phase also begins the documenting process in which the security patch management process should engage. This includes a spreadsheet, or other tracking mechanism, that details which vulnerabilities were released, and to which vulnerabilities the organization is susceptible and which ones it is not. In some cases, the initial assessment may prove that the company does not run that version of software; therefore, the company is not affected by the new vulnerability. However, the vulnerability announcement and the conclusion would be tracked in this tracking mechanism, whether it is a database or spreadsheet.

17.3.2.3 Impact Assessment

Once the initial assessment is completed, the CIRT and the operations group should assess the impact of the vulnerability on the environment. The operations group is included in this phase of the process because they have product engineering responsibility and a detailed technical understanding of the product. An important step in the impact assessment phase is to complete a cost/benefit analysis, which immediately analyzes whether or not the cost of implementing the remediation plan is less than the value of the asset itself.

Typically, the following steps are completed in the impact assessment phase:

1. Assess the need for remediation.
2. Hold meetings and discuss, if needed.
3. Form the vulnerabilities response team.
4. Conduct more in depth analysis, if needed.
5. Document the results of the analysis.
6. Rate the relevance and significance/severity of the vulnerability.

Assessing the impact requires developing a risk profile, including the population of hosts that are vulnerable, the conditions that need to be satisfied to exploit the vulnerability, and the repercussions to the company if it were to be exploited. Holding meetings with the appropriate personnel, including the CIRT, operations group, and NOC manager(s) to discuss the vulnerability and the impact it has on the organization will be required. The vulnerabilities response team usually consists of members of the CIRT, the operations group team, and the NOC's team, which all then work together to remediate the vulnerability at hand.

In some cases, further in-depth analysis needs to be completed. Some factors to be considered in the impact assessment include:

- *Type and delivery of attack.* Has an exploit for the vulnerability been published? Is the vulnerability at risk of exploitation by self-replicating, malicious code?
- *Exploit complexity.* How difficult is it to exploit the vulnerability? How many conditions must be met in order to exploit it? What infrastructure and technical elements must exist for the exploit to be successful?
- *Vulnerability severity.* If the vulnerability is exploited, what effect will this have on the host?
- *System criticality.* What systems are at risk? What kind of damage would be caused if these systems were compromised?
- *System location.* Is the system inside a firewall? Would it be possible for an attacker to use a compromised host as a beachhead for further attacks into the environment?
- *Patch availability.* Are vendor-supported patches available? If not, what steps can be taken to lessen or eliminate the risk?

Once the impact assessment has been completed, the results of the analysis are documented in the same fashion as was completed during the initial assessment phase. To conclude, the vulnerability is rated based on relevance, significance, and severity, taking into consideration the results of the cost/benefit analysis. If both the CIRT and the operations group conclude that the security vulnerability has no impact on the environment, no further action is needed. A record of all information gathered to date would be stored by the CIRT for future reference.

17.3.2.4 Security Advisory

Once an appropriate course of action has been agreed upon, the CIRT will release an internal Security Advisory to the persons responsible for the systems, whether it is within the operations group or members of the organization impacted by the vulnerability. The Security Advisory is always issued using the template provided in order to show consistency and reduce confusion. Each Security Advisory contains the following information:

- *Vulnerability description*: the type of vulnerability, the affected application or platform versions, and the methods used to exploit it.
- *Implementation plan*: detailed instructions on the steps required to mitigate the vulnerability, including the location of repositories containing executable programs, patches, or other tools required.
- *Back-out plan*: details on how to address unexpected problems caused by the implementation of the remedial measures.
- *Deployment timeframe*: a deadline for applying remedial measures to vulnerable systems. Systems with different levels of risk may have different timeframes to complete the deployment.

The audience that receives a notification will depend on the nature of the advisory. Security Advisories should also be developed in a consistent format. This ensures that an advisory is not overlooked but, instead, is easily recognized as an item that must be addressed.

17.3.3 Remediation

17.3.3.1 Course of Action

Once the impact assessment phase is completed and the risk or exposure is known and documented, the operations group would then develop a course of action for the vulnerability to be remediated on every platform or application affected. This will be performed with the involvement of the CIRT.

A suitable response (Security Advisory) to the persons responsible for the identified systems would be designed and developed—a response that details the vulnerability and how it impacts the organization. The importance of eliminating the vulnerability is also included in the response, which is based on the results of the impact analysis. These are usually sent out in the form of e-mail; however, they can also be sent in an attached document. Each organization can tailor the response to fit its needs; the example responses are included as guidelines. The vulnerability response team, which was discussed in the impact assessment phase, should also be formed and working on the *course of action* with the operations group, the NOC, and the CIRT.

The course of action phase consists of the following steps:

1. Select desired defense measures.
2. Identify, develop, and test defensive measures:
   - Test available security-related patches or influence vendors in developing needed patches.
   - Develop and test back-out procedure.
3. Apply a vendor-supplied patch, either specific to the vulnerability or addressing multiple issues.
4. Modify the functionality in some way, perhaps by disabling a service or changing the configuration, if appropriate.
5. Prepare documentation to support the implementation of selected measures.

The desired defense measure is usually in the form of a patch or a hot fix from the vendor. It is usually selected, or chosen, based on the release of the vulnerability. In some cases, the defense measure is a manual configuration change; but in most cases, it is in the form of a patch or hot fix. Where a vulnerability affects a vendor-supplied product and the vendor has not supplied an appropriate patch or workaround, the product manager will work with the vendor to develop an appropriate mitigation strategy. Regardless of the vendor's recommendation, the operations group needs to determine and document the course of action that is to be taken. Where a vendor-supplied patch is to be used, the operations group will be responsible for retrieving all relevant material from the vendor.

Once the defense measure is chosen, it must be tested to ensure that it will function properly in the organization's current environment. Usually, testing is done in a development environment, where implementing, testing, and creating back-out procedures can all be accomplished. This ensures a smooth transition when implementing the defense measure on all the systems affected. A procedural document is created to assist in the smooth implementation, which is then provided to the operations group to follow when implementing the fix. However, the operations group should be involved in the testing of the patch, or configuration change, to ensure that what is being documented can accurately be used on the systems in production.

17.3.3.2 Testing

Testing is coordinated through the operations group and the NOC, and includes services from appropriate SMEs and access to necessary resources (e.g., test labs). The CIRT, along with the primary party within the operations group, is responsible for preparing a detailed implementation plan and performing appropriate testing in a representative lab environment. A formal plan and documentation to govern the testing will be generated based on the type of system and vulnerability. Formal testing is conducted, and documented test results are provided to the CIRT. A back-out plan should also be developed and tested to ensure that if the patch adversely affects a production system, it can be quickly reversed and the system restored to its original state.

Back-out procedures could include:

- Vendor-specific procedures to remove the patch or fix
- Other backup and restore procedures to bring a disrupted system back to its original state

The operations group manager is responsible for approving the implementation plan for production use based on the test results and recommendations from SMEs and information security professionals. The operations group must also validate that the patch is protected from malicious activity before it is installed on the system. This is usually done in the form of MD5 hash functions implemented by the vendor prior to distribution.

17.3.3.3 Standard Build

Standard builds, or operating system images, are often overlooked in the patch management process. When a standard build for a platform or application is impacted by a vulnerability, it must be updated to avoid replication of the vulnerability. This ensures that any future implementation of a platform or application has the modifications necessary to eliminate the vulnerability.

A timeframe for deploying the updates into the build must be determined in the remediation phase. It must be carefully set to ensure that a build is not updated too frequently, risking the validity of appropriate testing, and not too infrequently, such that new implementations are installed without the fix or update to address the security vulnerability.

17.3.3.4 Critical Vulnerabilities

In situations where a vulnerability introduces a significant threat to the organization, awareness must be promoted. This will include a staged release of notifications with the intent of informing the persons responsible for the affected systems before awareness of the vulnerability is promoted to others. Other stakeholders within the business areas will generally be notified shortly after the discovery of a vulnerability that requires a response from the organization.

17.3.3.5 Timeframe

The CIRT, in conjunction with the operations group, would need to define a timeframe for the deployment of the security patch based on the criticality of the vulnerability and any other relevant factors. The NOC will also affect the timeframe determined, because all activity must be coordinated through them in regard to deployment of the patch. This falls under the change management procedures that are set in place within the organization.

17.3.4 Update Operational Environment

Updating the operational environment is no easy task. There are many steps involved, and the response team must ensure that all processes and procedures are adhered to when making updates to this environment. In the Security Advisory, the steps for implementation are included at a high level, which kicks off the implementation of the remediation plan. In the Security Advisory; a timetable is defined that dictates how long the persons responsible for the systems and the operations group has before the patch (or fix) is implemented. To ensure that these parties can meet their timetable, the CIRT and operations group must have the material available that supports remediation of the vulnerability before the Security Advisory is sent. The security-related patches are usually stored in a repository provided by the NOC (or within the operations group) once they have received them from the appropriate vendor (if applicable).

The CIRT may choose to send out a more general notification regarding the vulnerability to the general user population, depending on the severity of the vulnerability. This is only done on an "as-needed" basis that is determined during the impact assessment phase. However, the notification would go out *after* the Security Advisory is sent. The reason for this is that the CIRT and operations group must know how to fix the vulnerability and have an implementation plan developed *prior* to causing concern with the general user population. The operations group, which is responsible for making the updates, must follow all corporate change and configuration management procedures during the update. This is coordinated through the NOC. This includes not only patching the vulnerable systems, but also conducting any additional testing.

There are also instances where an operations group may choose to not implement a patch. In these cases, a waiver request can be completed, which is used to process requests for exemptions. If the waiver request is not agreed to by the CIRT, operations group, and corresponding responsible party, a dispute escalation process can be followed to resolve it. Included in the Security Advisory is a reporting structure. Each responsible party and the operations group must provide progress reports to the CIRT on the status of implementing the required fix. This ensures that the timetable is followed and the Security Advisory is adhered to.

17.3.4.1 Distribution

The operations group distributes all files, executable programs, patches, or other materials necessary to implement the mitigation strategy to the appropriate operations manager using an internal FTP or Web site. The operations group is responsible for ensuring that the data is transmitted via a secure method that meets integrity requirements. For integrity requirements, SHA-1 should be used when distributing information in this manner. If SHA-1 is not feasible, the minimum acceptable level should be MD5, which is also commonly used by external vendors.

17.3.4.2 Implementation

The operations group team, or persons identified with the operations group, will apply patches in accordance with established change management procedures. The NOC has the change management procedures defined that must be followed when implementing the patch. The NOC also maintains the configuration management procedure, which also must be updated once the patch has been implemented. Following the implementation, the operations group is responsible for testing production systems to ensure stability. Production systems may experience disruption after a security patch has been applied. If this occurs, the defined back-out procedures should be implemented.

17.3.4.3 Exceptions

In exceptional cases, a business unit (BU) may be unable or unwilling to implement mitigating measures within the required timeframe for the following reasons:

- The system is not vulnerable to the threat due to other factors.
- The vulnerability is considered a limited threat to the business.
- The security-related patch is determined to be incompatible with other applications.

In such cases, the BU can submit an action plan to the CIRT to pursue alternate mitigation strategies. If a BU wants to delay the implementation of the security patch, the BU must complete a risk acceptance form, which details any risks resulting from the failure to deploy the patch. The risk acceptance form is presented to the CIRT.

In some instances, the CIRT and operations group may not be able to come to an agreement on whether or not the organization is susceptible to the vulnerability, or the criticality of the vulnerability itself. This can become a common occurrence within any organization; therefore, a distinct dispute resolution path must be defined to clearly dictate how they are resolved. This can also be known as an escalation path.

When a dispute cannot be resolved properly, the CIRT manager (or lead) should escalate the dispute to the Chief Information Risk Officer (CIRO), or CIO if no CIRO exists. The CIRO (or CIO) would then consult with the CIRT manager and operations group, hearing both sides of the impact assessment phase before resolving the dispute.

17.3.4.4 Tracking

It is necessary to ensure that any security vulnerability is properly mitigated on all platforms or applications affected throughout the environment. The operations group is essentially responsible for tracking the progress in updating the operational environment during the security patch management process. However, the NOC's change and configuration procedures would track this information according to predefined processes.

The tracking process includes detailing each vulnerable system, the steps taken to eliminate the risk, and confirming that the system is no longer vulnerable. Any exception made to a vulnerable system must also be included in the tracking process. A standardized form will be specified for use to record when a system has been patched. The tracking results will be reported to the CIRT in accordance with the timetable set out in the Security Advisory.

Included in the tracking process, typically in a "comments" section, are the lessons learned and recommendations to improve the process. This allows for feedback from the operations group and the persons responsible for the affected systems on the security patch management process itself, and it gives constant feedback on how to update or improve the process. The security patch management process should be reviewed and updated on a bi-yearly basis, or at existing predefined procedural review intervals. The CIRT is responsible for taking the feedback into consideration when making changes to the overall process.

17.3.4.5 Reporting

The CIRT will maintain consolidated reporting on each security vulnerability and affected system. For each vulnerability, the following documentation will be maintained by the CIRT:

- Vulnerability overview with appropriate references to supporting documentation
- Test plan and results for relevant security-related patches or other remedial measures
- Detailed mitigation implementation and back-out plans for all affected systems
- Progress reports and scorecards to track systems that have been patched

All supporting documentation for a processed security vulnerability is stored in the CIRT database.

Note: This database should be a restricted data storage area, available only to the CIRT members and designated information security specialists.

The CIRT publishes a list of security-related patches that have been determined to be necessary to protect the organization. This list is reissued whenever a new security-related patch is sanctioned by the CIRT.

An online system is used to report status. System owners are required to report progress when deploying required remedial measures. When feasible, the CIRT monitors vulnerable systems to ensure that all required remedial measures have been successfully implemented.

A scorecard is used in the reporting process to ensure that any vulnerable system is, in fact, fixed. The CIRT is responsible for creating and maintaining the accuracy of the scorecard for each system affected by the vulnerability. The scorecard must be monitored and kept up-to-date to ensure there are no outstanding issues.

17.3.4.6 Tools

Up to this point, the patch management process itself has been discussed. However, organizations are looking for a method to streamline or expedite the patch implementation part of the process. Typically, this is done through the use of a software-based tool. Tools, although not required, do assist organizations in deploying patches in a more timely manner, with reduced manpower, thereby eliminating the vulnerability in a shorter timeframe. This method reduces the organization's risk to an exploit being released due to the vulnerability. If an organization does not have a clearly defined patch management process in place, then the use of tools will be of little or no benefit to the organization. Prior to leveraging a tool to assist in the patch management process, organizations must ask themselves the following questions:

- What is the desired end result of using the tool?
- What tools are in place today within the organization that can be leveraged?
- Who will have ownership of the tool?

In many organizations, an existing piece of software can be used to expedite the deployment of patches, whether it is for the desktop environment or for servers as well. Therefore, putting a patch distribution tool in place solely for use on the desktops provides them with the most value.

17.4 Challenges

When trying to implement a security patch management process, there are numerous challenges an organization will face. Some of the most common ones are explained in this section.

Senior management dictates the security posture of an organization. Getting their approval and involvement is important in the success of a company's overall security posture. A clear understanding that the security patch management process is part of the vulnerability management process enables the company to not only address non-security-related patches, but also those that pose a risk to the security posture of the company. Implementing a security patch management process is not a simple task, especially because there are groups and people involved in the process that may not today collaborate on such items.

The next set of challenges relates to assessing the vulnerability and the course of action taken against the security-related patch. Determining when and when not to patch can also be a challenge. This is why a cost/benefit analysis is recommended. If system inventory is not available for all the systems within the organization's network infrastructure, it can be difficult to determine whether or not they need the patch. The system inventory must be kept up-to-date, including all the previous patches that have been installed on every system. This avoids any confusion and errors during the security patch management process. A challenge faced during the patch testing phase is dealing with deployment issues, such as patch dependencies. This emphasizes why the testing phase is so important: to make sure these items are not overlooked or missed altogether. Documentation of the installation procedures must also be completed to ensure a smooth transition. Usually, documentation is the last step in any process; however, with security patch management, it must be an ongoing process.

Accountability can pose a challenge to a strong security posture. The accountability issue is addressed through the CIRT, the operations group, the PMs (if applicable), and the NOC. Because each entity plays a major role in the security patch management process, they must all work together to ensure that the vulnerability is addressed throughout the organization. The Security Advisory, along with the tracking and report functions, ensures that accountability is addressed throughout each vulnerability identified.

17.5 Conclusion

For an organization to implement a sound security patch management process, time and dedication must be given up front to define a solid process. Once the process has been put in place, the cycle will begin to take on a smoother existence with each release of a security vulnerability. Sometimes, the most difficult hurdle is determining how to approach a security patch management process. Of course, in smaller organizations, the CIRT may actually be a single individual instead of a team, and the tasks may also be broken down and assigned to specific individuals instead of in a team atmosphere. With the release of vulnerabilities today occurring at a rapid rate, it is better to address a vulnerability before an exploit is executed within your infrastructure. The security patch management process can reduce the risk of a successful exploit, and should be looked at as a proactive measure, instead of a reactive measure.

Appendix A

There are many patch management tools available today. Below is a list of the most widely used patch management tools, along with a short description of each.

Vendor	Product	Pricing	Description
BigFix	BigFix Enterprise Suite	List cost: $2500 for server, $15/node for the first year, $500 per year maintenance	BigFix Patch Manager from BigFix Inc. stands out as one of the products that is most capable of automating the Patch Management process BigFix allows administrators to quickly view and deploy patches to targeted computers by relevancy of the patch *Summary*: BigFix delivers patch information to all systems within an infrastructure and Fixlet, which monitors patches and vulnerabilities in each client and server
PatchLink	PatchLink update	List cost: $1499 for update server, $18 per node	PatchLink's main advantage over competition is that for disaster recovery, the administrator is only required to re-install the same serial number on the server, which then automatically re-registers all the computers with the PatchLink server PatchLink also has the ability to group patches by severity level and then package them for deployment PatchLink allows the update server to connect back to the PatchLink Master Archive site to download and cache all the updates for future use

APPENDIX A (continued)

Vendor	Product	Pricing	Description
			Summary: PatchLink provides administrators with the ability to customize patch rollouts by setting up parameters for patch installations, such as uninstall/rollback and force reboots
Shavlik Technologies	HFNetChkPro	List cost: HFNetChkPro customers get 50 percent off, $2100 for server, $21 per node	HFNetChkPro has an extensive list of software prerequisites that must be installed for it to function properly. It also requires installation of the NET Framework component The inventory for HFNetChkPro and its interface assists administrators in quickly identifying deficiencies within the network. All the necessary patch information is identified and listed One of the features that HFNetChkPro lacks is that the software does not offer real-time status of deployment and patch inventory *Summary*: HFNetChkPro offers command-line utilities that provide administrators with the option to check server configurations and validate that they are up-to-date
St. Bernard	UpdateExpert	List cost: $1499 for update server, $18 per node	St. Bernard Update is the only product in this list that can be run with or without an agent The UpdateExpert consists of a Management Console and a machine agent For organizations that limit the use of Remote Procedures Calls (RPCs), UpdateExpert can use an optional “Leaf Agent” to bypass the use of RPCs *Summary*: Overall, the UpdateExpert console interface is easy to use and navigate. The multiple operator console installation and leaf agent options are the best features of this product

Configuration Management: Charting the Course for the Organization

Mollie E. Krehnke
David C. Krehnke

Configuration management (CM) supports consistency, completeness, and rigor in implementing security. It also provides a mechanism for determining the current security posture of the organization with regard to technologies being utilized, processes and practices being performed, and a means for evaluating the impact of change on the security stance of the organization. If a new technology is being considered for implementation, an analysis can determine the effects from multiple standpoints:

- Costs to purchase, install, maintain, and monitor
- Positive or negative interactions with existing technologies or architectures
- Performance
- Level of protection
- Ease of use
- Management practices that must be modified to implement the technology
- Human resources who must be trained on the correct use of the new technology, as a user or as a provider

CM functions serve as a vital base for controlling the present—and for charting the future for an organization in meeting its goals. But looking at CM from a procedural level exclusively might result in the omission of significant processes that could enhance the information security stance of an organization and support mission success.

The Systems Security Engineering Capability Maturity Model (SSE–CMM)[1] will serve as the framework for the discussion of CM, with other long-standing, well-accepted references used to suggest key elements, policies, and procedural examples.

18.1 An Overview of the SSE–CMM

The SSE–CMM describes the essential characteristics of an organization's security engineering process that must exist to ensure good security engineering and thereby protect an organization's information resources, including hardware, software, and data. The SSE–CMM model addresses:

- The entire system life cycle, including concept definition, requirements analysis, design, development, integration, installation, operations, maintenance, and decommissioning activities
- The entire organization, including management, organizational, and engineering activities, and their staffs, including developers and integrators, that provide security services
- Concurrent interactions with other disciplines, such as systems, software, hardware, human factors, and testing engineering; system management, operation, and maintenance
- Interactions with other functions, including acquisition, system management, certification, accreditation, and evaluation
- All types and sizes of security engineering organizations—commercial, government, and academia[2]

18.1.1 SSE–CMM Relationship to Other Initiatives

Exhibit 18.1 shows how the SSE–CMM process relates to other initiatives working to provide structure, consistency, assurance, and professional stature to information systems security and security engineering.

[1] The Systems Security Engineering Capability Maturity Model (SSE–CMM) is a collaborative effort of Hughes Space and Communications, Hughes Telecommunications and Space, Lockheed Martin, Software Engineering Institute, Software Productivity Consortium, and Texas Instruments Incorporated.

[2] SSE–CMM, Version 2.0, April 1, 1999, pp. 2–3.

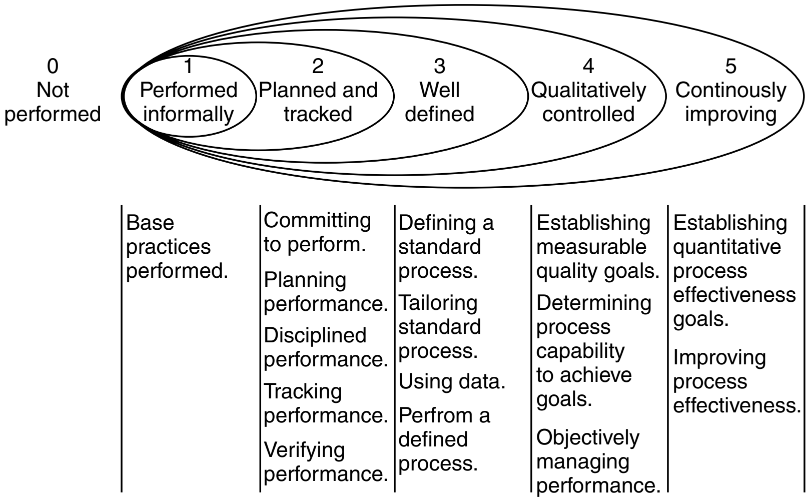
EXHIBIT 18.1 Information Security Initiatives

Effort	Goal	Approach	Scope
SSE–CMM	Define, improve, and assess security engineering capability	Continuous security engineering maturity model and appraisal method	Security engineering organizations
SE–CMM	Improve the system or product engineering process	Continuous maturity model of systems engineering practices and appraisal method	Systems engineering organizations
SEI CMM for software	Improve the management of software development	Staged maturity model of software engineering and management practices	Software engineering organizations
Trusted CMM	Improve the process of high-integrity software development and its environment	Staged maturity model of software engineering and management practices, including security	High-integrity software organizations
CMM1	Combine existing process improvement models into a single architectural framework	Sort, combine, and arrange process improvement building blocks to form tailored models	Engineering organizations
Sys. Eng. CM (EIA731)	Define, improve, and assess systems engineering capability	Continuous system engineering maturity model and appraisal method	System engineering organizations
Common criteria	Improve security by enabling reusable protection profiles for classes of technology	Set of functional and assurance requirements for security, along with an evaluation process	Information technology
CISSP	Make security professional a recognized discipline	Security body of knowledge and certification test for security profession	Security practitioners
Assurance frameworks	Improve security assurance by enabling a broad range of evidence	Structured approach for creating assurance arguments and efficiently producing evidence	Security engineering organizations
ISO 9001	Improve organizational quality management	Specific requirements for quality management process	Service organizations
ISO 15504	Improve software process and assessment	Software process improvement model and appraisal methodology	Software engineering organizations
ISO 13335	Improve management of information technology security	Guidance on process used to achieve and maintain appropriate levels of security for information and services	Security engineering organizations

18.1.2 CMM Framework

> A CMM is a framework for evolving an security engineering organization from an ad hoc, less organized, less effective state to a highly structured effective state. Use of such a model is a means for organizations to bring their practices under statistical process control in order to increase their process capability. The SSE–CMM was developed with the anticipation that applying the concepts of statistical process control to security engineering will promote the development of secure systems and trusted products within anticipated limits of cost, schedule, and quality.
>
> —SSE–CMM, Version 2.0, April 1, 1999

A process is a set of activities performed to achieve a given purpose. A well-defined process includes activities, input and output artifacts of each activity, and mechanisms to control performance of the activities. A defined process is formally described for or by an organization for use by its security



0
Not performed

4
Qualitatively controlled
5
Continously improving
Base practices performed.
Committing to perform.
Planning performance.
Disciplined performance.
Tracking performance.
Verifying performance.
Defining a standard process.
Tailoring standard process.
Using data.
Perfrom a defined process.
Establishing measurable quality goals.
Determining process capability to achieve goals.
Objectively managing performance.
Establishing quantitative process effectiveness goals.
Improving process effectiveness.

EXHIBIT 18.2 Capability levels of a security engineering organization.

> professionals and indicates what actions are supposed to be taken. The performed process is what the security professionals actually do.…[P]rocess maturity indicates the extent to which a specific process is explicitly defined, managed, measured, controlled, and effective. Process maturity implies a potential for growth in capability and indicates both the richness of an organization's process and the consistency with which it is applied throughout the organization.
>
> —SSE–CMM, Version 2.0, April 1, 1999, p. 21

18.1.3 Capability Levels Associated with Security Engineering Maturity

There are five capability levels associated with the SSE–CMM maturity model (see Exhibit 18.2) that represent increasing organizational capability. The levels are comprised of generic practices ordered according to maturity. Therefore, generic practices that indicate a higher level of process capability are located at the top of the capability dimension.

> The SSE–CMM does not imply specific requirements for performing the generic practices. An organization is generally free to plan, track, define, control, and improve their processes in any way or sequence they choose. However, because some higher level generic practices are dependent on lower level generic practices, organizations are encouraged to work on the lower level generic practices before attempting to achieve higher levels.
>
> —SSE–CMM, Version 2.0, April 1, 1999

18.1.4 CMM Institutionalization

Institutionalization is the building of an infrastructure and corporate culture that establishes methods, practices, and procedures, even after those who originally defined them are gone. The process capability side of the SSE–CMM supports institutionalization by providing practices and a path toward quantitative management and continuous improvement.[3] A mature, and continually improving, CM process and the associated base practices can result in activities with the following desirable qualities.

[3] *Ibid.*, p. 22.

- *Continuity*: knowledge acquired in previous efforts is used in future efforts
- *Repeatability*: a way to ensure that projects can repeat a successful effort
- *Efficiency*: a way to help both developers and evaluators work more efficiently
- *Assurance*: confidence that security needs are being addressed[4]

18.1.5 Security Engineering Model Goals

The SSE–CMM is a compilation of the best-known security engineering practices and is an evolving discipline. However, there are some general goals that can be presented. Many of these goals are also supported by the other organizations noted in Exhibit 18.1 that are working to protect an organization's information resources.

- Gain an understanding of the security risks associated with an enterprise.
- Establish a balanced set of security needs in accordance with identified risks.
- Transform security needs into security guidance to be integrated into the activities of other disciplines employed on a project and into descriptions of a system configuration or operation.
- Establish confidence or assurance in the correctness and effectiveness of security mechanisms.
- Determine that operational impacts due to residual security vulnerabilities in a system or its operation are tolerable (acceptable risks).
- Integrate the efforts of all security engineering disciplines and specialties into a combined understanding of the trustworthiness of a system.[5]

18.2 Security Engineering

While information technology security is often the driving discipline in the current security and business environment, the more traditional security disciplines should not be overlooked. These other security disciplines include the following:

- Operations security
- Information security
- Network security
- Physical security
- Personnel security
- Administrative security
- Communications security
- Emanation security
- Computer security

18.2.1 Security Engineering Process Overview

The security engineering process is composed of three basic areas: risk management, engineering, and assurance. The risk management process identifies and prioritizes dangers inherent in the developed product or system. The security engineering process works with the other engineering disciplines to determine and implement solutions to the problems presented by the dangers. The assurance process establishes confidence in the security solutions and conveys this confidence to customers or to

[4] *Ibid.*, p. 6.

[5] *Ibid.*, p. 26.

management. These areas work together to ensure that the security engineering process results achieve the defined goals.

18.2.1.1 Risk Management

Risk management involves threats, vulnerabilities, and impacts. As an SSE–CMM process, risk management is the process of identifying and quantifying risk, and establishing an acceptable level of risk for the organization. The security practice areas in support of the risk management process are assess security risk, assess impact, and assess vulnerability.[6]

18.2.1.2 Engineering

Security engineers work with the customer to identify the security needs based on the identified risks, relevant laws, organizational policies, and existing information configurations. Security engineering is a process that proceeds through concept, design, implementation, test, deployment, operation, maintenance, and decommission. This process requires close cooperation and communication with other parts of the system engineering team to coordinate activities in the accomplishment of the required objectives, ensuring that security is an integral part of the process. Once the security needs are identified, security engineers identify and track specific requirements.[7]

The security practice areas in support of the engineering process are specify security needs, provide security input, administer security controls, and monitor security posture. Later in the life cycle, the security engineer is called on to ensure that products and systems are properly configured in relation to the perceived risks, ensuring that new risks do not make the system unsafe to operate.[8]

18.2.1.3 Assurance

Assurance is the degree of confidence that the security needs are satisfied. The controls have been implemented, will function as intended, and will reduce the anticipated risk. Often, this assurance is communicated in the form of an argument and is evident in documentation that is developed during the normal course of security engineering activities.

18.2.2 Security Engineering Basic Process Areas

The SSE–CMM contains approximately 60 security base practices, organized into 11 process areas that cover all major areas of security engineering, and represent the best existing practices of the security engineering community. Base practices apply across the life cycle of the enterprise, do not overlap with other base practices, represent a best practice of the security community (not a state-of-the-art technique), apply using multiple methods in multiple business contexts, and do not specify a particular method or tool. The 11 SSE–CMM process areas are listed below in alphabetical order to discourage the association of a practice with a life cycle phase.

- Administer security controls
- Assess impact
- Assess security risk
- Assess threat
- Assess vulnerability
- Build assurance argument
- Coordinate security
- Monitor security posture
- Provide security input

[6] *Ibid.*, p. 31.

[7] *Op cit.*

[8] SSE–CMM, Version 2.0, April 1, 1999, p. 32.

- Specify security needs
- Verify and validate security

18.2.3 Security Engineering Project and Organizational Practices

There are also 11 process areas related to project and organizational practices:

- Ensure quality
- Manage configuration
- Manage project risk
- Monitor and control technical effort
- Plan technical effort
- Define organization's system engineering process
- Improve organization's system engineering process
- Manage product line evolution
- Manage systems engineering support environment
- Provide ongoing skills and knowledge
- Coordinate with suppliers[9]

The base practices and the project and organizational practices were presented to provide the reader with a perspective for the focus of this chapter on the utilization and implementation configuration management—the topic of this chapter.

18.3 Configuration Management

This chapter follows the base practices associated with SSE–CMM PA 13—Configuration Management to discuss policies, procedures, and resources that support this process in the establishment, implementation, and enhancement of security of an organization's information resources.

18.3.1 Configuration Management Description

The purpose of CM is to maintain data on and status of identified configuration units, and to analyze and control changes to the system and its configuration units. Managing the system configuration involves providing accurate and current configuration data and status to developers and customers. The goal is to maintain control over the established work product configurations.[10]

18.4 Configuration Management Base Practices

The following are the base practices considered essential elements of good security engineering CM:

- Establish CM methodology
- Identify configuration units
- Maintain work product baselines
- Control changes to established configuration units
- Communicate configuration status[11]

[9] *Ibid.*, p. 38.
[10] *Ibid.*, p. 211.
[11] *Ibid.*, p. 211.

EXHIBIT 18.3 BP.13.01—Establish CM Methodology

Description

Three primary trade-off considerations will have an impact on the structure and cost of CM, including:

- Level of detail at which the configuration units are identified
- Time when the configuration units are placed under CM
- Level of formalization required for the CM process

Example of Work Products

- Guidelines for identifying configuration units
- Timeline for placing configuration units under CM
- Selected CM process
- Selected CM process description

Notes

Selection criteria for configuration units should address interface maintenance, unique user requirements, new versus modified designs, and expected rate of change.

Source: SSE–CMM, Version 2.0, April 1, 1999, pp. 213–214.

Each of these base practices is discussed below. The format presents the SSE–CMM description, example work products, and notes. Then a discussion of other references and resources that can be utilized to implement the base practice is presented.

18.5 Establish Configuration Management Methodology

18.5.1 Relationship to Other Security References

Choosing a CM tool to support the CM process will depend on the business processes being supported and the associated resources to be configured (see Exhibit 18.3). "Any information which may impact safety, quality, schedule, cost, or the environment must be managed. Each activity within the supply chain must be involved in the management process…. The best CM process is one that can best accommodate change and assure that all affected information remains clear, concise, and valid."[12]

18.5.1.1 Electronic Industries Alliance (EIA-649)

The Department of Defense and the Internal Revenue Service have adopted EIA-649 as their CM standard.

The CM process must relate to the context and environment in which it is to be implemented. Related activities include assignment of responsibilities, training of personnel, and determination of performance measurements. The Configuration Management Plan (CMP) can help to correlate CM to the International Standards Organization (ISO) 9000 series of quality systems criteria. The plan can also facilitate the justification of required resources and facilities, including automated tools.[13]

18.5.2 Automated Tools

18.5.2.1 Institute of Configuration Management

There are several tools that have been certified by the Institute of Configuration Management (ICM)[14] because they can support a (new) configuration methodology (indicated as CMII) as defined by the ICM. The tools are listed in Exhibit 18.4.

[12] To Fix CM Begins with Proper Training, *ICM Views*, ICM Web site, Institute of Configuration Management, P.O. Box 5656, Scottsdale, AZ 85261-5656, (840) 998-8600, info@icmhq.com.

[13] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 9–12.

[14] Institute of Configuration Management, P.O. Box 5656, Scottsdale, AZ 85261-5656, (840) 998-8600, info@icmhq.com.

EXHIBIT 18.4 ICM's CMII Certified Automated Tools

System Type	System Name	Release/Version	Provider Name/Site	Date Certified
PDM	Metaphase	3.2	SDRD/Methphase www.SDRD.com	May 12, 2000
PDM	Axalant-CM	1.4	Usb/Eigner + Partner www.usbmuc.com www.ep-ag.com	December 8, 2000

The ICM certification signifies that:

- The tool supports achievement of the core elements of CMII functionality.
- The tool has the potential to be robust in all areas of functionality needed by that type of tool.
- The developer understands and agrees with the tool's strengths and weaknesses relative to CMII.
- The developer plans to make enhancements that will overcome those weaknesses.
- ICM agrees with the developer's priorities for doing so.[15]

18.5.2.2 Other Automated Tools

Another automated software management tool that is used in the IBM mainframe environment is ENDEVOR. The product can automate the transfer of all program source code, object code, executable code (load modules), interpretable code, control information, and the associated documentation to run a system. This includes source programs written in high-level programming language, job control or other control language, data dictionary, operating system, database components, online teleprocessing system, and job procedures.[16]

Two other commercially available online CM tools are UNIX's Source Code Control System (SCCS) and Revision Control System (RCS).[17]

18.5.3 Configuration Management Plan and Configuration Control Board as "Tools"

18.5.3.1 Computer Security Basics

This reference states that a manual tracking system can also be used for CM throughout a system's life cycle. Policies associated with CM implementation include:

- Assigning a unique identifier to each configuration item
- Developing a CMP
- Recording all changes to configuration items (either online or offline)
- Establishing a Configuration Control Board (CCB)[17]

18.5.3.2 EIA-649

Configuration identification is the basis of unique product identification, definition, and verification; product and document identification marking; change management; and accountability. The process enables a user to distinguish between product versions and supports release control of documents for baseline management.[18]

[15] *Configuration Management (CM) Resource Guide*, edited by Steve Easterbrook, is available at http://www.quality.org/config/cm-guide.html.

[16] *CISSP Examination Textbooks, Volume 1: Theory*, first edition, Rao Vallabhaneni, S. SRV Professional Publications, 2000, p. 135.

[17] Russell, Deborah and Gangemi Sr., G. T. *Computer Security Basics*, 1991, p. 146. O'Reilly & Associates, Inc.

[18] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 14.

18.5.3.3 Information Systems Security Engineering Handbook

CM is a process for controlling all changes to a system (software, hardware, firmware, documentation, support/testing equipment, and development/maintenance equipment). A CCB should be established to review and approve any and all changes to the system. Reasons for performing CM throughout the life cycle of the information system include:

- Maintaining a baseline at a given point in the system life cycle
- Natural evolution of systems over time—they do not remain static
- Contingency planning for catastrophes (natural or human)
- Keeping track of all certification and accreditation evidence
- Use of the system's finite set of resources will grow through the system's life cycle
- Configuration item identification
- Configuration control
- Configuration accounting
- Configuration auditing[19]

18.5.3.4 NCSC-TG-006, A Guide to Understanding Configuration Management in Trusted Systems

The CMP and the human resources that support the CM process via the CCB should also be considered "tools." Effective CM should include a well-thought-out plan that should be prepared immediately after project initiation. The CMP should describe, in simple, positive statements, what is to be done to implement CM in the system.[20] CCB participants' roles should also be defined in the CMP. The responsibilities required by all those involved with the system should be established and documented in the CMP to ensure that the human element functions properly during CM.[21] A portion of the CMP should also address required procedures, and include routine CM procedures and any existing "emergency" procedures. Because the CMP is a living document, it should have the capability for additions and changes, but should be carefully evaluated and approved and then completely implemented to provide the appropriate assurances.

Any tools that will be used for CM should be documented in the CMP. These tools should be "maintained under strict configuration control." These tools can include forms used for change control, conventions for labeling configuration items, software libraries, as well as any automated tools that may be available to support the CM process. Samples of any documents to be used for reporting should also be contained in the CMP, along with a description of each.[21]

18.5.3.5 Information Systems Security Engineering Handbook, National Security Agency, Central Security Service

Ensuring that a CM process is in place to prevent modifications that can cause an increase in security risk to occur without the proper approval is a consideration in the information system's life cycle, certification/accreditation, and recertification/reaccreditation activities after system activation.[22]

EXHIBIT 18.5 BP.13.02—Identify Configuration Units

Description

A configuration unit is one or more work products that are baselined together. The selection of work products for CM should be based on criteria established in the selected CM strategy. Configuration units should be selected at a level that benefits the developers and customers, but that does not place an unreasonable administrative burden on the developers.

Example of Work Products

- Baselined work product configuration
- Identified configuration units

Notes

Configuration units for a system that has requirements on field replacement should have an identified configuration unit at the field-replacement unit level.

Source: —SSE–CMM, Version 2.0, April 1, 1999, p. 215.

EXHIBIT 18.6 Examples of Configuration Units

The following examples of configuration units are cited in BP.01.02—Manage Security Configuration:

- *Records of all software updates*: tracks licenses, serial numbers, and receipts for all software and software updates to the system, including date, person responsible, and a description of the change.
- *Records of all distribution problems*: describes any problem encountered during software distribution and how it was resolved.
- *System security configurations*: describes the current state of the system hardware, software, and communications, including their location, the individual assigned, and related information.
- *System security configuration changes*: describes any changes to the system security configuration, including the name of the person making the change, a description of the change, the reason for the change, and when the change was made.
- *Records of all confirmed software updates*: tracks software updates, which includes a description of the change, the name of the person making the change, and the date made.
- *Periodic summaries of trusted software distribution*: describes recent trusted software distribution activity, noting any difficulties and action items.
- *Security changes to requirements*: tracks any changes to system requirements made for security reasons or having an effect on security, to help ensure that changes and their effects are intentional.
- *Security changes to design documentation*: tracks any changes to the system design made for security reasons or having an effect on security, to help ensure that changes and their effects are intentional.
- *Control implementation*: describes the implementation of security controls within the system, including configuration details.
- *Security reviews*: describes the current state of the system security controls relative to the intended control implementation.
- *Control disposal*: describes the procedure for removing or disabling security controls, including a transition plan.

Source: SSE–CMM, Version 2.0, April 1, 1999, p. 115–116.

18.6 Identify Configuration Units

See Exhibit 18.5 and Exhibit 18.6.

18.6.1 Relationship to Other Security References

18.6.1.1 AR25-3, Army Life Cycle Management of Information Systems

CM focuses on four areas: configuration identification, configuration control, configuration status accounting, and configuration audit. CM should be applied throughout the life cycle of configuration items to control and improve the reliability of information systems.[23]

[23] AR25-3, Army Life Cycle Management of Information Systems, 9 June 1988, p. 36.

18.6.1.2 British Standards (BS7799), Information Security Management, Part 1, Code of Practice for Information Security Management Systems

A lack of change control is said to be a "common cause of system or security failures." Formal management and practice of change control are required for equipment, software, or procedures.[24]

18.6.1.3 Computer Security Basics

CM items also include documentation, test plans, and other security-related system tools and facilities.[25]

18.6.1.4 DOD-STD-2167A, Defense System Software Development

Although this military standard has been canceled, the configuration identification units are a familiar concept to many system developers: computer software configuration items (CSCIs) and the corresponding computer software components (CSCs) and the computer software units (CSUs). Documentation established the Functional, Allocated, and Product Baselines. Each deliverable item had a version, release, change status, and other identification details. Configuration control was implemented through an established plan that was documented and then communicated through the implementation of configuration status accounting.

18.6.1.5 EIA-649

Unique identifiers support the correlation of the unit to a process, date, event, test, or document. Even documents must be uniquely identified to support association with the proper product configuration. The baseline represents an agreed-upon description of the product at a point in time with a known configuration. Intermediate baselines can be established for complex products. Baselines are the tools to match the need for consistency with the authority to approve changes. Baselines can include requirements, design releases, product configurations, operational, and disposal phase baselines.[26]

18.6.1.6 "Information Classification: A Corporate Implementation Guide," *Handbook of Information Security Management*

Maintaining an audit/history information that documents the software changes, "such as the work request detailing the work to be performed, who performed the work, and other pertinent documentation required by the business" is a vital software control.[27]

18.7 Maintain Work Product Baselines

See Exhibit 18.7.

18.7.1 Relationship to Other Security References

18.7.1.1 EIA-649

Recovery of a configuration baseline (or creation after the fact, with no adequate documentation) will be labor intensive and expensive. Without design and performance information, configuration must be determined via inspection, and this impacts operational and maintenance decisions. Reverse-engineering is a very expensive process.[26]

[24] BS7799, British Standards 7799, Information Security Management, Part 1, Code of Practice for Information Security Management Systems, 1995, Section 6.2.4.

[25] Russell, Deborah and Gangemi Sr., G. T. *Computer Security Basics*, 1991, p. 145. O'Reilly & Associates, Inc.

[26] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 18–22.

[27] Information Classification: A Corporate Implementation Guide, in *Handbook of Information Security Management*, 1999, p. 344.

EXHIBIT 18.7 BP13.03—Maintain Work Product Baselines

Description

This practice involves establishing and maintaining a repository of information about the work product configuration. …capturing data or describing the configuration units … including an established procedure for additions, deletions, and modifications to the baseline, as well as procedures for tracking/monitoring, auditing, and the accounting of configuration data … to provide an audit trail back to source documents at any point in the system life cycle.

Example of Work Products

- Decision database
- Baselined configuration
- Traceability matrix

Notes

Configuration data can be maintained in an electronic format to facilitate updates and changes to supporting documentation.[38]

Source: SSE–CMM, Version 2.0, April 1, 1999, p. 216.

18.7.1.2 "Information Classification: A Corporate Implementation Guide," *Handbook of Information Security Management*

This chapter emphasizes the importance of version and configuration control, including "versions of software checked out for update, or being loaded to staging or production libraries. This would include the monitoring of error reports associated with this activity and taking appropriate corrective action."[28]

18.7.1.3 New Alliance Partnership Model (NAPM)

NAPM is a partnership model that combines security, configuration management, and quality assurance functions with an overall automated information system (AIS) security engineering process. NAPM provides insight into the importance of CM to the AISs of the organization and the implementation of an effective security program.

> CM provides management with the assurance that changes to an existing AIS are performed in an identifiable and controlled environment and that these changes do not adversely affect the integrity or availability properties of secure products, systems, and services. CM provides additional security assurance levels in that all additions, deletions, or changes made to a system do not compromise its integrity, availability, or confidentiality. CM is achieved through proceduralization and unbiased verification, ensuring that changes to an AIS and/or all supporting documentation are updated properly, concentrating on four components: identification, change control, status accounting, and auditing.[29]

18.8 Control Changes to Established Configuration Units

See Exhibit 18.8.

[28] Information Classification: A Corporate Implementation Guide, in *Handbook of Information Security Management*, 1999, p. 344.

[29] Systems Integrity Engineering, in *Handbook of Information Security Management*, 1999, p. 634.

EXHIBIT 18.8 BP.13.04—Control Changes to Established Configuration Units

Description

Control is maintained over the configuration of the baselined work product. This includes tracking the configuration of each of the configuration units, approving a new configuration, if necessary, and updating the baseline. Identified problems with the work product or requests to change the work product are analyzed to determine the impact that the change will have on the work product, program schedule and cost, and other work products. If, based on analysis, the proposed change to the work product is accepted, a schedule is identified for incorporating the change into the work product and other affected areas. Changed configuration units are released after review and formal approval of configuration changes. Changes are not official until they are released.

Example of Work Products

- New work product baselines

Notes

Change control mechanisms can be tailored to categories of change. For example, the approval process should be shorter for component changes that do not affect other components.

Source: SSE–CMM, Version 2.0, April 1, 1999, p. 217.

18.8.1 Relationship to Other Security References

18.8.1.1 British Standards (BS7799), Information Security Management, Part 1, Code of Practice for Information Security Management Systems

The assessment of the potential impact of a change, adherence to a procedure for approval of proposed changes, and procedures for aborting and recovering from unsuccessful changes play a significant role in the operational change process.[30] Policies and procedures to support software control and reduce the risk of operational systems corruption include:

- Program library updates by the nominated librarian with IT approval
- Exclusion of nonexecutable code
- In-depth testing and user acceptance of new code
- Updating of program source libraries
- Maintenance of an update audit log for all operational program libraries
- Retention of previous versions of software for contingencies[31]

18.8.1.2 British Standards (BS7799), Information Security Management, Part 2, Specification for Information Security Management Systems

Formal change control procedures should be implemented for all stages of a system's life cycle, and these changes should be strictly controlled.[32]

18.8.1.3 EIA-649

> The initial baseline for change management consists of the configuration documentation defining the requirements that the performing activity (i.e., the product developer or product supplier) has agreed to meet. The design release baseline for change management consists of the detail design documentation used to manufacture, construct, build, or code the product. The product configuration baseline for change management consists of the detailed design documentation from the design release baseline which defines the product configuration that has been proven to meet the requirements for the product. The product configuration is considered [to be] a mature

[30] British Standards (BS7799), Information Security Management, Part 1, Code of Practice for Information Security Management Systems, 1995, p. 19.

[31] Ibid., p. 36.

[32] British Standards (BS7799), Information Security Management, Part 2, Specification for Information Security Management Systems, 1998, p. 8.

> configuration. Changes to the current requirements, design release, or product configuration baselines may result from discovery of a problem, a suggestion for product improvement or enhancement, a customer request, or a condition dictated by the marketplace or by public law.
>
> Changes should be classified as major or minor to support the determination of the appropriate levels of review and approval. A major change is a change to the requirements of baselined configuration documentation (requirements, design release or product configuration baselines) that has significant impact. It requires coordination and review by all affected functional groups or product development teams and approval by a designated approval authority.... A minor change corrects or modifies configuration documentation (released design information), processes or parts but does not impact...customer requirements.
>
> To adequately evaluate a request for change, the change request must be clearly documented. It is important to accurately describe even minor changes so that an audit trail can be constructed in the event that there are unanticipated consequences or unexpected product failures. Saving the cost of the research involved in one such incident by having accurate accessible records may be sufficient to fully offset diligent, disciplined change processing.[33]

Technical, support, schedule, and cost impacts of a requested change must also be considered prior to approval and implementation. The organizational areas that will be impacted by the change or have the responsibility for implementing the change must be involved in the change process. Those organizations may have significant information (not available to other organizations) that could impact the successful implementation of a change. Change considerations must include the timeline and resource requirements of support organizations, as well as those of the primary client organization (e.g., update of support software, availability of spare and repair parts, or revisions to operating and maintenance instructions) and urgency of the change. The change must be verified to ensure that the product, its documentation, and the support elements are consistent. The extent to which the verification is implemented will depend on the quantity of units changed and the type of change that is implemented. Records must be maintained regarding the verification of changes and implementation of required support functions. Variances to required configuration must be approved and documented.[33]

18.8.1.4 FIPS PUB 102, Guideline for Computer Security Certification and Accreditation

The change control process is an implicit form of recertification and reaccreditation. It is required during both development and operation. For sensitive applications, change control is needed for requirements, design, program, and procedural documentation, as well as for the hardware and software itself.

The process begins during development via the establishment of baselines for the products listed above. Once a baseline is established, all changes require a formal change request and authorization. Every change is reviewed for its impact on prior certification evidence.

An entity sometimes formed to oversee change control is the CCB. During development, the CCB is a working group subsidiary to the Project Steering Committee or its equivalent. Upon completion of development, CCB responsibility is typically transferred to an operations and maintenance office. There should be a security representative on the CCB responsible for the following:

- Deciding whether a change is security relevant
- Deciding on a required security review and required levels of recertification and reaccreditation

[33] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 24–34.

- Deciding on a threshold that would trigger recertification activity
- Serving as technical security evaluator, especially for minor changes that might receive no other security review

For very sensitive applications, it is appropriate to require approval and testing for all changes. However minor, a record must be kept of all changes as well as such pertinent certification evidence as test results. This record is reviewed during recertification.[33]

> As security features of a system or its environment change, recertification and reaccreditation are needed…. CM is a suitable area in which to place the monitoring activity for these changes.[34]

Information Systems Security Engineering Handbook

> A change or upgrade in the system, subsystem, or component configuration (e.g., incorporation of new operating system releases, modification of an applications program for data management, installation of a new commercial software package, hardware upgrades or swapouts, new security products, change to the interface characteristics of a "trusted" component) … may violate its security assumptions.[35] The strongest configuration control procedures will include provisions for periodic physical and functional audit on the actual system in its operational environment. They will not rely solely on documentation or known or proposed changes. Changes frequently occur that are either not well known, or not well documented. These will only be detected by direct inspection of the system hardware, software, and resident data.[36]

NCSC-TG-006, A Guide to Configuration Management in Trusted Systems. CM maintains control of a system throughout its life cycle, ensuring that the system in operation is the correct system, and implementing the correct security policy. The Assurance Control Objective can be applied to configuration management as follows:

> Computer systems that process and store sensitive or classified information depend on the hardware and software to protect that information. It follows that the hardware and software themselves must be protected against unauthorized changes that could cause protection mechanisms to malfunction or be bypassed entirely. Only in this way can confidence be provided that the hardware and software interpretation of the security policy is maintained accurately and without distortion.[36]

18.9 Communicate Configuration Status

The status of the configuration is vital to the success of the organization (see Exhibit 18.9). The information that an organization uses must be accurate. "What is the sense of building the product to Six Sigma[37] when the blueprint is wrong?"[38] Changes must be documented and communicated in an expeditious and consistent manner.

[34] FIPS PUB 102, Performing Certification and Accreditation, Section 2.7.3, Change Control, p. 54.

[35] FIPS PUB 102, p. 9.

[36] *Information Systems Security Engineering Handbook*, Release 1.0, National Security Agency, Central Security Service, February 28, 1994, p. 3–49.

[38] What is Software CM?, ICM Views, ICM Web site, *Op.cit.*

EXHIBIT 18.9 BP.13.05—Communicate Configuration Status

Description

Inform affected groups of the status of configuration data whenever there are any status changes. The status reports should include information on when accepted changes to configuration units will be processed, and the associated work products that are affected by the change. Access to configuration data and status should be provided to developers, customers, and other affected groups.

Example of Work Products

- Status reports

Notes

Examples of activities for communicating configuration status include providing access permissions to authorized users, and making baseline copies readily available to authorized users.

Source: SSE–CMM, Version 2.0, April 1, 1999, p. 218.

18.9.1 Relationship to Other Security References

18.9.1.1 EIA-649

Configuration management information about a product is important throughout the entire life cycle, and the associated CM processes (planning and management, identification, change management, and verification and audit). "Configuration status accounting (CSA) correlates, stores, maintains, and provides readily available views of this organized collection of information…. CSA improves capabilities to identify, produce, inspect, deliver, operate, maintain, repair, and refurbish products."[39] CSA also provides "a source for configuration history of a product and all of its configuration documentation."

This CSA information must be disseminated to those who have a need to know throughout the product's life cycle. Examples of CSA life cycle documentation by phase include the following.

- *Conception phase*: requirements documents and their change history
- *Definition phase*: detailed configuration documents (e.g., specifications, engineering drawings, software design documents, software code, test plans and procedures) and their change history and variance status
- *Build phase*: additional product information (e.g., verified as-built unit configuration) and product changes, and associated variances
- *Distribution phase*: information includes customers and dates of delivery, installation configuration, warranty expiration dates, and service agreement types and expiration
- *Operation phase*: CSA varies, depending on the type of product and the contractual agreements regarding CM responsibilities, but could include product as-maintained and as-modified configurations, operation and maintenance information revision status, change requests and change notices, and restrictions
- *Disposal phase*: CSA information varies with the product and whether disposing of a product could have adverse implications, or if there are legal or contractual statues regarding retention of specific data[40]

18.9.1.2 "Systems Integrity Engineering," Handbook of Information Security Management

This chapter emphasizes the importance of configuration management plans to convey vital system-level information to the organization. Distributed system CM plans must document:

[39] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 34.

[40] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 35–38.

- System-level and site-level policies, standards, procedures, responsibilities, and requirements for the overall system control of the exchange of data
- The identification of each individual's site configuration
- Common data, hardware, and software
- The maintenance of each component's configuration

Distribution controls and audit checks to ensure common data and application versions are the same across the distributed system in which site-level CM plans are subordinate to distributed-level CM plans. The change control authority(ies) will need to establish agreements with all distributed systems on policies, standards, procedures, roles, responsibilities, and requirements for distributed systems that are not managed by a single organizational department, agency, or entity.[41]

18.10 Conclusions

18.10.1 Change Is Inevitable

Change is inevitable in an organization. Changes in an information system, its immediate environment, or a wider organizational environment can (and probably will) impact the appropriateness of the information system's security posture and implemented security solutions. Routine business actions or events that can have a significant impact on security include:

- A mission or umbrella policy driven change in information criticality or sensitivity that causes a changes in the security needs or countermeasures required
- A change in the threat (e.g., changes in threat motivation, or new threat capabilities of potential attackers) that increases or decreases systems security risk
- A change in the application that requires a different security mode of operation
- A discovery of a new means of security attack
- A breach of security, a breach of system integrity, or an unusual situation or incident that appears to invalidate the accreditation by revealing a security flaw
- A security audit, inspection, or external assessment
- A change or upgrade in the system, subsystem, or component configurations
- The removal or degradation of a configuration item
- The removal or degradation of a system process countermeasure (i.e., human interface requirement or other doctrine/procedure components of the overall security solution)
- The connection to any new external interface
- Changes in the operational environment (e.g., relocation to other facilities, changes in infrastructure/environment-provided protections, changes in external operational procedures)
- Availability of new countermeasures technology that could, if used, improve the security posture or reduce operating costs
- Expiration of the information system's security accreditation statement[42]

18.10.2 Change Must Be Controlled

With the concept of control comes the concept of prior approval before changes are made. The approval is based on an analysis of the implications if the changes are made. It is possible that some changes may inadvertently change the security stance of the information system.

[41] Systems Integrity Engineering, in *Handbook of Information Security Management*, 1999, p. 628.

[42] *Information Systems Security Engineering Handbook*, Release 1.0, National Security Agency, Central Security Service, February 28, 1994, p. 3–47.

CM that is implemented according to an established plan can provide many benefits to an organization, including:

- Decisions based on knowledge of the complete change impact
- Changes limited to those that are necessary or offer significant benefits
- Effective cost-benefit analysis of proposed changes
- High levels of confidence in the product information or configurations
- Orderly communication of change information
- Preservation of customer interests
- Current system configuration baselines
- Configuration control at product interfaces
- Consistency between system configurations and associated documentation
- Ease of system maintenance after a change[43]

Change control must also be implemented within the computing facility. Every computing facility should have a policy regarding changes to operating systems, computing equipment, networks, environmental facilities (e.g., air conditioning, water, heat, plumbing, electricity, and alarms), and applications.[44]

18.10.3 Configuration Management as a Best Practice

The European Security Forum has been conducting systematic case studies of companies across various economic sectors for a number of years. A recent study addressed organizing and managing information technology (IT) security in a distributed environment. Change management for live systems was the fifth most important security practice worthy of additional study indicated by those organizations queried. Although the practice was well established and deemed of high importance by all respondents—as reported by the IT security manager, the IT manager, and a business manager of a functional area for each company—their comments resulted in the following finding. "While examples of successful practice exist, the general feeling that change management was an area where even the best organization recognized the need for improvement."[45]

18.10.4 Configuration Management as a Value-Adding Process

CM as a process enables an organization to tailor the process to address the context and environment in which the process will be implemented and add value to the resulting product. Multiple references reviewed for this chapter emphasized the need for consistency in how the process is implemented and its repeatability over time. It is better for an organization to consistently repeat a few processes over time than to inconsistently implement a multitude of activities once or twice. With standardization comes the knowledge of the status of that process. With knowledge of the status and the related benefits (and drawbacks), there can be a baseline of the process and its products. Effectively implementing configuration management can result in improved performance, reliability, or maintainability; extended life for the product; reduced development costs; reduced risk and liability; or corrected defects. The attributes of CM best practices include planned, integrated, consistent, rule/workflow-based, flexible, measured, and transparent.[46]

[43] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 23.

[44] Systems and Operations Controls, *Handbook of Information Security Management*, 1993, p. 399.

[45] Best Business Practice: Organising and Managing IT Security in a Distributed Environment, *European Security Forum*, September 1991, p. 38.

[46] EIA-649, National Consensus Standard for Configuration Management, Electronic Industries Alliance, August 1998, p. 11.

Security advantages of CM include protection against unintentional threats and malicious events. Not only does CM require a careful analysis of the implications of the proposed changes and approval of all changes before they are implemented, but it also provides a capability for reverting to a previous configuration (because previous versions are archived), if circumstances (e.g., a faulty change) require such an action. Once a reviewed program is accepted, a programmer is not permitted to make any malicious changes, such as inserting trapdoors, without going through the change approval process where such an action should be caught.[47]

18.10.5 Implementing Configuration Management

When implementing configuration management, the security professional should:

- Plan CM activities based on sound CM principles
- Choose a CM process that fits the environment, external constraints, and the product's life cycle phases
- Choose tools that support the CM process; tools can be simple and manual, or automated, or a combination of both
- Implement CM activities consistently across project and over time
- Use the CM plan as a training tool for personnel, and a briefing tool to explain the process to customers, quality assurance staff, and auditors
- Use enterprise CM plans to reduce the need for complete CM plans for similar products
- Ensure resources are available to support the process in a timely and accurate manner
- Ensure a security representative is on the CCB to evaluate the security implications of the proposed changes
- Ensure the changed system is tested and approved prior to deployment
- Ensure support/service areas are able to support the change
- Ensure configuration information is systematically recorded, safeguarded, validated, and disseminated
- Perform periodic audits to verify system configurations with the associated documentation, whether hardcopy or electronic in format.

Information Classification: A Corporate Implementation Guide

Jim Appleyard

19.1 Introduction

Classifying corporate information based on business risk, data value, or other criteria (as discussed later in this chapter), makes good business sense. Not all information has the same value or use, or is subject to the same risks. Therefore, protection mechanisms, recovery processes, etc. are—or should be—different, with differing costs associated with them. Data classification is intended to lower the cost of protecting data, and improve the overall quality of corporate decision making by helping ensure a higher quality of data upon which the decision makers depend.

The benefits of an enterprise wide data classification program are realized at the corporate level, not the individual application or even departmental level. Some of the benefits to the organization include:

- Data confidentiality, integrity, and availability are improved because appropriate controls are used for all data across the enterprise.
- The organization gets the most for its information protection dollar because protection mechanisms are designed and implemented where they are needed most, and less costly controls can be put in place for noncritical information.
- The quality of decisions is improved because the quality of the data upon which the decisions are made has been improved.

- The company is provided with a process to review all business functions and informational requirements on a periodic basis to determine priorities and values of critical business functions and data.
- The implementation of an information security architecture is supported, which better positions the company for future acquisitions and mergers.

This chapter will discuss the processes and techniques required to establish and maintain a corporate data classification program. There are costs associated with this process; however, most of these costs are front-end start-up costs. Once the program has been successfully implemented, the cost savings derived from the new security schemes, as well as the improved decision making, should more than offset the initial costs over the long haul, and certainly the benefits of the ongoing program outweigh the small, administrative costs associated with maintaining the data classification program.

Although not the only methodology that could be employed to develop and implement a data classification program, the one described here has been used and proved to work.

The following topics will be addressed:

- Getting started: questions to ask
- Policy
- Business Impact Analysis
- Establishing classifications
- Defining roles and responsibilities
- Identifying owners
- Classifying information and applications
- Ongoing monitoring

19.2 Getting Started: Questions to Ask

Before the actual implementation of the data classification program can begin, the Information Security Officer (ISO)—whom for the purposes of this discussion is the assumed project manager—must ask some very important questions, and get the answers.

Is there an executive sponsor for this project?

Although not absolutely essential, obtaining an executive sponsor and champion for the project could be a critical success factor. Executive backing by someone well respected in the organization who can articulate the ISO's position to other executives and department heads will help remove barriers, and obtain much needed funding and buy-in from others across the corporation. Without an executive sponsor, the ISO will have a difficult time gaining access to executives or other influencers who can help sell the concept of data ownership and classification.

What are you trying to protect, and from what?

The ISO should develop a threat and risk analysis matrix to determine what the threats are to corporate information, the relative risks associated with those threats, and what data or information are subject to those threats. This matrix provides input to the business impact analysis, and forms the beginning of the plans for determining the actual classifications of data, as will be discussed later in this chapter (see Exhibit 19.1 for an example Threat/Risk Analysis table).

EXHIBIT 19.1 Threat/Risk Analysis

Application	Platform	Threat	Risk	Consequences of Loss
Application				

Are there any regulatory requirements to consider?

Regulatory requirements will have an impact on any data classification scheme, if not on the classifications themselves, at least on the controls used to protect or provide access to regulated information. The ISO should be familiar with these laws and regulations, and use them as input to the business case justification for data classification, as well as input to the business impact analysis and other planning processes.

Has the business accepted ownership responsibilities for the data?

The business, not IT, owns the data. Decisions regarding who has what access, what classification the data should be assigned, etc. are decisions that rest solely with the business data owner. IT provides the technology and processes to implement the decisions of the data owners, but should not be involved in the decision-making process. The executive sponsor can be a tremendous help in selling this concept to the organization. Too many organizations still rely on IT for these types of decisions. The business manager must realize that the data is his data, not IT's; IT is merely the custodian of the data. Decisions regarding access, classification, ownership, etc. resides in the business units. This concept must be sold first, if data classification is to be successful.

Are adequate resources available to do the initial project?

Establishing the data classification processes and procedures, performing the business impact analysis, conducting training, etc. requires an up-front commitment of a team of people from across the organization if the project is to be successful. The ISO cannot and should not do it alone. Again, the executive sponsor can be of tremendous value in obtaining resources such as people and funding for this project that the ISO could not do. Establishing the processes, procedures, and tools to implement good, well-defined data classification processes takes time and dedicated people.

19.3 Policy

A useful tool in establishing a data classification scheme is to have a corporate policy implemented stating that the data are an asset of the corporation and must be protected. Within that same document, the policy should state that information will be classified based on data value, sensitivity, risk of loss or compromise, and legal and retention requirements. This provides the ISO the necessary authority to start the project, seek executive sponsorship, and obtain funding and other support for the effort.

If there is an Information Security Policy, these statements should be added if they are not already there. If no Information Security Policy exists, then the ISO should put the data classification project on hold, and develop an Information Security Policy for the organization. Without this policy, the ISO has no real authority or reason to pursue data classification. Information must first be recognized and treated as an asset of the company before efforts can be expended to protect it.

Assuming there is an Information Security Policy that mentions or states that data will be classified according to certain criteria, another policy—Data Management Policy—should be developed which establishes data classification as a process to protect information and provides:

- The definitions for each of the classifications
- The security criteria for each classification for both data and software
- The roles and responsibilities of each group of individuals charged with implementing the policy or using the data

Below is a sample Information Security Policy. Note that the policy is written at a very high level and is intended to describe the "what's" of information security. Processes, procedures, standards, and guidelines are the "hows" or implementation of the policy.

Sample Information Security Policy

> All information, regardless of the form or format, which is created or used in support of company business activities is corporate information. Corporate information is a company asset and must be protected from its creation, through its useful life, and authorized disposal. It should be maintained in a secure, accurate, and reliable manner and be readily available for authorized use. Information will be classified based on its sensitivity, legal, and retention requirements, and type of access required by employees and other authorized personnel.
>
> Information security is the protection of data against accidental or malicious disclosure, modification, or destruction. Information will be protected based on its value, confidentiality, and/or sensitivity to the company, and the risk of loss or compromise. At a minimum, information will be update-protected so that only authorized individuals can modify or erase the information.

The above policy is the minimum requirement to proceed with developing and implementing a data classification program. Additional policies may be required, such as an Information Management Policy, which supports the Information Security Policy. The ISO should consider developing this policy, and integrating it with the Information Security Policy. This policy would:

- Define information as an asset of the business unit
- Declare local business managers as the owners of information
- Establish Information Systems as the custodians of corporate information
- Clearly define roles and responsibilities of those involved in the ownership and classification of information
- Define the classifications and criteria that must be met for each
- Determine the minimum range of controls to be established for each classification

By defining these elements in a separate Information Management Policy, the groundwork is established for defining a corporate information architecture, the purpose of which is to build a framework for integrating all the strategic information in the company. This architecture can be used later in the enablement of larger, more strategic corporate applications.

The supporting processes, procedures, and standards required to implement the Information Security and Information Management policies must be defined at an operational level and be as seamless as possible. These are the "mechanical" portions of the policies, and represent the day-to-day activities that must take place to implement the policies. These include but are not limited to:

- The process to conduct a Business Impact Analysis
- Procedures to classify the information, both initially after the BIA has been completed, and to change the classification later, based on business need
- The process to communicate the classification to IS in a timely manner so the controls can be applied to the data and software for that classification
- The process to periodically review:
  — Current classification to determine if it is still valid
  — Current access rights of individuals and/or groups who have access to a particular resource
  — Controls in effect for a classification to determine their effectiveness
  — Training requirements for new data owners
- The procedures to notify custodians of any change in classification or access privileges of individuals or groups

The appropriate policies are required as a first step in the development of a Data Classification program. The policies provide the ISO with the necessary authority and mandate to develop and implement the program. Without it, the ISO will have an extremely difficult time obtaining the funding and necessary support to move forward. In addition to the policies, the ISO should solicit the assistance and support of both the Legal Department and Internal Audit. If a particular end-user department has some particularly sensitive data, their support would also provide some credibility to the effort.

19.4 Business Impact Analysis

The next step in this process is to conduct a high-level business impact analysis on the major business functions within the company. Eventually this process should be carried out on all business functions, but initially it must be done on the business functions deemed most important to the organization.

A critical success factor in this effort is to obtain corporate sponsorship. An executive who supports the project, and may be willing to be the first whose area is analyzed, could help persuade others to participate, especially if the initial effort is highly successful and there is perceived value in the process.

A Study Team comprised of individuals from Information Security, Information Systems (application development and support), Business Continuity Planning, and Business Unit representatives should be formed to conduct the initial impact analysis. Others that may want to participate could include Internal Audit and Legal.

The Business Impact Analysis process is used by the team to:

- Identify major functional areas of information (i.e., human resources, financial, engineering, research and development, marketing, etc.)
- Analyze the threats associated with each major functional area. This could be as simple as identifying the risks associated with loss of confidentiality, integrity, or availability, or get into more detail with specific threats of computer virus infections, denial of service attacks, etc
- Determine the risk associated with the threat (i.e., the threat could be disclosure of sensitive information, but the risk could be low because of the number of people who have access, and the controls that are imposed on the data)
- Determine the effect of loss of the information asset on the business (this could be financial, regulatory impacts, safety, etc.) for specific periods of unavailability—one hour, one day, two days, one week, a month
- Build a table detailing the impact of loss of the information (as shown in Exhibit 19.2—Business Impact Analysis)
- Prepare a list of applications that directly support the business function (i.e., Human Resources could have personnel, medical, payroll files, skills inventory, employee stock purchase programs, etc.) This should be part of Exhibit 19.2

From the information gathered, the team can determine universal threats that cut across all business functional boundaries. This exercise can help place the applications in specific categories or classifications with a common set of controls to mitigate the common risks. In addition to the threats and their

EXHIBIT 19.2 Business Impact Analysis

Function	Application	Type Loss (CIA)	Cost after 1 Hour	Cost after 2 Hours	Cost after 1 Day	Cost after 1 Week	Cost after 1 Month

		Integrity					
		Availability					
	Medical	Confidentiality					
		Integrity					
		Availability					

associated risks, sensitivity of the information, ease of recovery, and criticality must be considered when determining the classification of the information.

19.5 Establish Classifications

Once all the risk assessment and classification criteria have been gathered and analyzed, the team must determine how many classifications are necessary and create the classification definitions, determine the controls necessary for each classification for the information and software, and begin to develop the roles and responsibilities for those who will be involved in the process. Relevant factors, including regulatory requirements, must be considered when establishing the classifications.

Too many classifications will be impractical to implement; most certainly will be confusing to the data owners and meet with resistance. The team must resist the urge for special cases to have their own data classifications. The danger is that too much granularity will cause the process to collapse under its own weight. It will be difficult to administer and costly to maintain.

On the other hand, too few classes could be perceived as not worth the administrative trouble to develop, implement, and maintain. A perception may be created that there is no value in the process, and indeed the critics may be right.

Each classification must have easily identifiable characteristics. There should be little or no overlap between the classes. The classifications should address how information and software are handled from their creation, through authorized disposal. See Exhibit 19.3, Information/Software Classification Criteria.

Following is a sample of classification definitions that have been used in many organizations:

- **Public**—Information, that if disclosed outside the company, would not harm the organization, its employees, customers, or business partners.
- **Internal Use Only**—Information that is not sensitive to disclosure within the organization, but could harm the company if disclosed externally.
- **Company Confidential**—Sensitive information that requires "need to know" before access is given.

It is important to note that controls must be designed and implemented for both the information and software. It is not sufficient to classify and control the information alone. The software, and possibly the hardware on which the information and/or software resides, must also have proportionate controls for each classification the software manipulates. Below is a set of minimum controls for both information and software that should be considered.

19.5.1 Information—Minimum Controls

- **Encryption**—Data is encrypted with an encryption key so that the data is "scrambled." When the data is processed or viewed, it must be decrypted with the same key used to encrypt it. The encryption key must be kept secure and known only to those who are authorized to have access to the data. Public/private key algorithms could be considered for maximum security and ease of use.
- **Review and approve**—This is a procedural control, the intent of which is to ensure that any

EXHIBIT 19.3 Information/Software Classification Criteria

Classification	Storage Media	Minimum Data Controls	Minimum Software Controls	Transmission Considerations	Destruction Mechanisms
Application					

change to the data is reviewed by someone technically knowledgeable to perform the task. The review and approval should be done by an authorized individual other than the person who developed the change.

- **Backup and recovery**—Depending on the criticality of the data and ease of recovery, plans should be developed and periodically tested to ensure the data is backed up properly, and can be fully recovered.
- **Separation of duties**—The intent of this control is to help ensure that no single person has total control over the data entry and validation process, which would enable someone to enter or conceal an error that is intended to defraud the organization or commit other harmful acts. An example would be not allowing the same individual to establish vendors to an Authorized Vendor File, then also be capable of authorizing payments to a vendor.
- **Universal access: none**—No one has access to the data unless given specific authority to read, update, etc. This type of control is generally provided by security access control software.
- **Universal access: read**—Everyone with access to the system can read data with the control applied; however, update authority must be granted to specific individuals, programs, or transactions. This type of control is provided by access control software.
- **Universal access: update**—Anyone with access to the system can update the data, but specific authority must be granted to delete the data. This control is provided by access control software.
- **Universal access: alter**—Anyone with access to the system can view, update, or delete the data. This is virtually no security.
- **Security access control software**—This software allows the administrator to establish security rules as to who has access rights to protected resources. Resources can include data, programs, transactions, individual computer IDs, and terminal IDs. Access control software can be set up to allow access by classes of users to classes of resources, or at any level of granularity required to any particular resource or group of resources.

19.5.2 Software—Minimum Controls

- **Review and approve**—The intent of this control is that any change to the software be reviewed by someone technically knowledgeable to perform this task. The review and approval should be an authorized individual other than the person who developed the change.
- **Review and Approve Test Plan and Results**—A test plan would be prepared, approved, documented, and followed.
- **Backup and recovery**—Procedures should be developed and periodically tested to ensure backups of the software are performed in such a manner that the most recent production version is recoverable within a reasonable amount of time.
- **Audit/history**—Information documenting the software change such as the work request detailing the work to be performed, test plans, test results, corrective actions, approvals, who performed the work, and other pertinent documentation required by the business.
- **Version and configuration control**—Refers to maintaining control over the versions of software checked out for update, being loaded to staging or production libraries, etc. This would include the monitoring of error reports associated with this activity and taking appropriate corrective action.
- **Periodic testing**—Involves taking a test case and periodically running the system with known data that has predictable results. The intent is to ensure the system still performs as expected, and does not produce results that are inconsistent with the test case data. These tests could be conducted at random or on a regular schedule.
- **Random checking**—Production checking of defined data and results.

- **Separation of duties**—This procedural control is intended to meet certain regulatory and audit system requirements by helping ensure that one single individual does not have total control over a programming process without appropriate review points or requiring other individuals to perform certain tasks within the process prior to final user acceptance. For example, someone other than the original developer would be responsible for loading the program to the production environment from a staging library.
- **Access control of software**—In some applications, the coding techniques and other information contained within the program are sensitive to disclosure, or unauthorized access could have economic impact. Therefore, the source code must be protected from unauthorized access.
- **Virus checking**—All software destined for a PC platform, regardless of source, should be scanned by an authorized virus-scanning program for computer viruses before it is loaded into production on the PC or placed on a file server for distribution. Some applications would have periodic testing as part of a software quality assurance plan.

19.6 Defining Roles and Responsibilities

To have an effective Information Classification program, roles and responsibilities of all participants must be clearly defined. An appropriate training program, developed and implemented, is an essential part of the program. The Study Team identified to conduct the Business Impact Analysis is a good starting point to develop these roles and responsibilities and identify training requirements. However, it should be noted that some members of the original team, such as Legal, Internal Audit, or Business Continuity Planning, most likely will not be interested in this phase. They should be replaced with representatives from the corporate organizational effectiveness group, training, and possibly corporate communications.

Not all of the roles defined in the sections that follow are applicable for all information classification schemes and many of the roles can be performed by the same individual. The key to this exercise is to identify which of the *roles* defined is appropriate for your particular organization, again keeping in mind that an individual may perform more than one of these when the process is fully functional.

- **Information owner**—Business executive or business manager who is responsible for a company business information asset. Responsibilities include, but are not limited to:
  — Assign initial information classification and periodically review the classification to ensure it still meets the business needs
  — Ensure security controls are in place commensurate with the classification
  — Review and ensure currency of the access rights associated with information assets they own
  — Determine security requirements, access criteria, and backup requirements for the information assets they own
  — Perform or delegate, if desired, the following:
    - Approval authority for access requests from other business units or assign a delegate in the same business unit as the executive or manager owner
    - Backup and recovery duties or assign to the custodian
    - Approval of the disclosure of information act on notifications received concerning security violations against their information assets

- **Information custodian**—The information custodian, usually an information systems person, is the delegate of the information owner with primary responsibilities for dealing with backup and recovery of the business information. Responsibilities include the following:
  — Perform backups according to the backup requirements established by the information owner
  — When necessary, restore lost or corrupted information from backup media to return the application to production status

- — Perform related tape and DASD management functions as required to ensure availability of the information to the business
- — Ensure record retention requirements are met based on the information owner's analysis

- **Application owner**—Manager of the business unit who is fully accountable for the performance of the business function served by the application. Responsibilities include the following:
  - — Establish user access criteria and availability requirements for their applications
  - — Ensure the security controls associated with the application are commensurate with support for the highest level of information classification used by the application
  - — Perform or delegate the following:
    - Day-to-day security administration
    - Approval of exception access requests
    - Appropriate actions on security violations when notified by security administration
    - The review and approval of all changes to the application prior to being placed into the production environment
    - Verification of the currency of user access rights to the application
- **User manager**—The immediate manager or supervisor of an employee. They have ultimate responsibility for all user IDs and information assets owned by company employees. In the case of nonemployee individuals such as contractors, consultants, etc., this manager is responsible for the activity and for the company assets used by these individuals. This is usually the manager responsible for hiring the outside party. Responsibilities include the following:
  - — Inform security administration of the termination of any employee so that the user ID owned by that individual can be revoked, suspended, or made inaccessible in a timely manner.
  - — Inform security administration of the transfer of any employee if the transfer involves the change of access rights or privileges.
  - — Report any security incident or suspected incident to Information Security.
  - — Ensure the currency of user ID information such as the employee identification number and account information of the user ID owner.
  - — Receive and distribute initial passwords for newly created user IDs based on the manager's discretionary approval of the user having the user ID.
  - — Educate employees with regard to security policies, procedures, and standards to which they are accountable.
- **Security administrator**—Any company employee who owns a user ID that has been assigned attributes or privileges associated with access control systems, such as ACF2, Top Secret, or RACF. This user ID allows them to set system-wide security controls or administer user IDs and information resource access rights. These security administrators may report to either a business division or Information Security within Information Systems. Responsibilities include the following:
  - — Understand the different data environments and the impact of granting access to them.
  - — Ensure access requests are consistent with the information directions and security guidelines.
  - — Administer access rights according to criteria established by the Information Owners.
  - — Creat and remove user IDs as directed by the user manager.
  - — Administer the system within the scope of their job description and functional responsibilities.
  - — Distribute and follow up on security violation reports.
  - — Send passwords of newly created user IDs to the manager of the user ID owner only.
- **Security analyst**—Person responsible for determining the data security directions (strategies, procedures, guidelines) to ensure information is controlled and secured based on its value, risk of loss or compromise, and ease of recoverability. Duties include the following:
  - — Provide data security guidelines to the information management process.

  - Develop basic understanding of the information to ensure proper controls are implemented.
  - Provide data security design input, consulting and review.

- **Change control analyst**—Person responsible for analyzing requested changes to the IT infrastructure and determining the impact on applications. This function also analyzes the impact to the databases, data-related tools, application code, etc.
- **Data analyst**—This person analyzes the business requirements to design the data structures and recommends data definition standards and physical platforms, and is responsible for applying certain data management standards. Responsibilities include the following:
  - Design data structures to meet business needs.
  - Design physical data base structure.
  - Create and maintain logical data models based on business requirements.
  - Provide technical assistance to data owner in developing data architectures.
  - Record metadata in the data library.
  - Create, maintain, and use metadata to effectively manage database deployment.
- **Solution provider**—Person who participates in the solution (application) development and delivery processes in deploying business solutions; also referred to as an integrator, application provider/programmer, IT provider. Duties include the following:
  - Work with the data analyst to ensure the application and data will work together to meet the business requirements.
  - Give technical requirements to the data analyst to ensure performance and reporting requirements are met.
- **End user**—Any employees, contractors, or vendors of the company who use information systems resources as part of their job. Responsibilities include:
  - Maintain confidentiality of log-on password(s).
  - Ensure security of information entrusted to their care.
  - Use company business assets and information resources for management approved purposes only.
  - Adhere to all information security policies, procedures, standards, and guidelines.
  - Promptly report security incidents to management.
- **Process owner**—This person is responsible for the management, implementation, and continuous improvement of a process that has been defined to meet a business need. This person:
  - Ensures data requirements are defined to support the business process.
  - Understands how the quality and availability affect the overall effectiveness of the process.
  - Works with the data owners to define and champion the data quality program for data within the process.
  - Resolves data-related issues that span applications within the business processes.
- **Product line manager**—Person responsible for understanding business requirements and translating them into product requirements, working with the vendor/user area to ensure the product meets requirements, monitoring new releases, and working with the stakeholders when movement to a new release is required. This person:
  - Ensures new releases of software are evaluated and upgrades are planned for and properly implemented.
  - Ensures compliance with software license agreements.
  - Monitors performance of production against business expectations.
  - Analyzes product usage, trends, options, competitive sourcing, etc. to identify actions needed to meet project demands of the product.

19.7 Identifying Owners

The steps previously defined are required to establish the information classification infrastructure. With the classifications and their definitions defined, and roles and responsibilities of the participants articulated, it is time to execute the plan and begin the process of identifying the information owners. As stated previously, the information owners *must* be from the business units. It is the business unit that will be most greatly affected if the information becomes lost or corrupted; the data exists solely to satisfy a business requirement. The following criteria must be considered when identifying the proper owner for business data:

- Must be from the business; data ownership is *not* an IT responsibility.
- Senior management support is a key success factor.
- Data owners must be given (through policy, perhaps) the necessary authority commensurate with their responsibilities and accountabilities.
- For some business functions, a multi-level approach may be necessary.

A phased approach will most likely meet with less resistance than trying to identify all owners and classify all information at the same time. The Study Team formed to develop the roles and responsibilities should also develop the initial implementation plan. This plan should consider using a phased approach—first identifying from the risk assessment data those applications that are critical or most important by orders of magnitude to the corporation (such as time-critical business functions first, etc.). Owners for these applications are more easily identified and probably are sensitized to the mission criticality of their information. Other owners and information can be identified later by business functions throughout the organization.

A training program must also be developed and be ready to implement as the information owners and their delegates are named. Any tools such as spreadsheets for recording application and information ownership and classification and reporting mechanisms should be developed ahead of time for use by the information owners. Once the owners have been identified, training should commence immediately so that it is delivered at the time it is needed.

19.8 Classify Information and Applications

The information owners, after completing their training, should begin collecting the meta data about their business functions and applications. A formal data collection process should be used to ensure a consistency in the methods and types of information gathered. This information should be stored in a central repository for future reference and analysis. Once the information has been collected, the information owners should review the definitions for the information classifications, and classify their data according to that criteria. The owners can use the following information in determining the appropriate controls for the classification:

- Audit information maintained: how much and where it is, and what controls are imposed on the audit data.
- Separation of duties required: yes or no; if yes, how is it performed.
- Encryption requirements.
- Data protection mechanisms; access controls defined based on classification, sensitivity, etc.
- Universal access control assigned.
- Backup and recovery processes documented.
- Change control and review processes documented.

- Confidence level in data accuracy.
- Data retention requirements defined.
- Location of documentation.

The following application controls are required to complement the data controls, but care should be taken to ensure all controls (both data and software) are commensurate with the information classification and value of the information:

- Audit controls in place.
- Develop and approve test plans.
- Separation of duties practiced.
- Change management processes in place.
- Code tested, verified for accuracy.
- Access control for code in place.
- Version controls for code implemented.
- Backup and recovery processes in place.

19.9 Ongoing Monitoring

Once the information processes have been implemented and data classified, the ongoing monitoring processes should be implemented. The internal audit department should lead this effort to ensure compliance with policy and established procedures. Information Security, working with selected information owners, Legal, and other interested parties, should periodically review the information classifications themselves to ensure they still meet business requirements.

The information owners should periodically review the data to ensure that it is still appropriately classified. Also, access rights of individuals should be periodically reviewed to ensure these rights are still appropriate for the job requirements. The controls associated with each classification should also be reviewed to ensure they are still appropriate for the classification they define.

19.10 Summary

Information and software classification is necessary to better manage information. If implemented correctly, classification can reduce the cost of protecting information because in today's environment, "one size fits all" will no longer work within the complexity of most corporation's heterogeneous platforms that make up the IT infrastructure. Information classification enhances the probability that controls will be placed on the data where they are needed the most, and not applied where they are not needed.

Classification security schemes enhance the usability of data by ensuring the confidentiality, integrity, and availability of information. By implementing a corporate-wide information classification program, good business practices are enhanced by providing a secure, cost-effective data platform that supports the company's business objectives. The key to the successful implementation of the information classification process is senior management support. The corporate information security policy should lay the groundwork for the classification process, and be the first step in obtaining management support and buy-in.

20 Ownership and Custody of Data

William Hugh Murray

This chapter introduces and denes the concepts of data owner and custodian; their origins and their emergence; and the rights, duties, privileges, and responsibilities of each. It describes how to identify the data and the owner and to map one to the other. It discusses the language and the tools that the owner uses to communicate his intention to the custodian and the user. Finally, it makes recommendations about how to employ these concepts within your organization.

20.1 Introduction and Background

For a number of years now we have been using the roles of data owner and custodian to assist us in managing the security of our data. These concepts were implicit in the way the enterprise acted, but we have only recently made them sufficiently explicit that we can talk about them. We use the words routinely as though there is general agreement on what we mean by them. However, there is relatively little discussion of them in the literature.

In the early days of mainframe access control, we simply assumed that we knew who was supposed to access the data. In military mandatory access control systems, the assumption was that data was classified and users were cleared. If the clearance of the user dominated the classification of the user, then access was allowed. There was the troublesome concept of need-to-know; but for the life of me, I cannot remember how we intended to deal with it. I assume that we intended to deal with it in agreement with the paper analogy. There would have been an access control matrix, but it was viewed as stable. It could be created and maintained by some omniscient privileged user, but no one seemed to give much thought to the source of his knowledge. (I recall being told about an A-level system where access could not be changed while the system was operational. This was not considered to be a problem because the system routinely failed about once a week. Rights were changed while it was offline.)

In time-sharing systems, access was similarly obvious. Most data was accessed and used only by its author and creator. Such sharing of his data as occurred was authorized in a manner similar to that in modern UNIX. That is, the creator granted privileges to the file system object to members of his own affinity group or to the world. While this is not sufficiently granular for today's large group sizes and populations, it was adequate at the time.

ACF2, the first access control for MVS, was developed in a university setting by systems programmers and for systems programmers. It was rules-based. The default rule was that a user could access data that he created. To facilitate this, the creator's name was forced as the high-level qualifier of the object name. Sharing was based upon the rules database. As with the access control matrix, creation and maintenance of this database required both privilege and omniscience. In practice, the privilege was assigned to a systems programmer. It was simply assumed that all systems programmers were omniscient and trustworthy; they were trusted by necessity. Over time, the creation and maintenance of the ACF2 rules migrated to the security staff. While I am sure that we had begun to talk about ownership by that time, none of these systems included any concept of or abstraction for an object owner.

In reviewing my papers, the first explicit discussion of ownership that I find is in 1981; but by that time it was a fairly mature concept. It must have been a fairly intuitive concept to emerge whole without much previous discussion in the literature.

What is clear is that we must have someone with the authority to control access to data and to make the difficult decisions about how it is to be used and protected. We call this person the *author*. It is less obvious, but no less true, that the person who makes that decision needs to understand the sensitivity of the data. The more granular and specific that knowledge, the better the decision will be.

My recollection is that the first important system to externalize the abstraction of owner was RACF. (One of the nice things about having lived to this age is that the memories of your contemporaries are not good enough for them to challenge you.) RACF access control is list-based. The list is organized by resource. That is, there is a row for each object. The row contains the names of any users or defined and named groups of users with access to that resource and the type of access (e.g., create, read, write, delete) that they have. Each object has an owner and the name of that owner is explicit in the row. The owner might be a user or a group, that is, a business function or other affinity group. The owner has the implicit right to grant access or to add users or groups to the entry. For the first time we had a system that externalized the privilege to create and maintain the access control rules in a formal, granular, and independent manner.

20.2 Definitions

> **Owner**, n. One who owns; a rightful proprietor; one who has the legal or rightful title, whether he is the possessor or not.
>
> **— Webster's Dictionary, 1913**

> **Owner**, n. Principal or agent who exercises the exclusive right to use.
> **Owner**, n. The individual manager or representative of management who is responsible for making and communicating judgments and decisions on behalf of the organization with regard to the use, identification, classification, and protection of a specific information asset.
>
> **— Handbook of Information Security Management**
> **Zella G. Ruthberg and Harold F. Tipton, Editors, 1993**

> **Ownership**, n. The state of being an owner; the right to own; exclusive right of possession; legal or just claim or title; proprietorship.
> **Ownership**, n. The exclusive right to use.
> **Custodian**, n. One that guards and protects or maintains; especially: one entrusted with guarding and keeping property or records or with custody or guardianship of prisoners or inmates.
>
> **— Merriam-Webster's Collegiate Dictionary**

> **Custodian**. A designated person who has authorized possession of information and is entrusted to provide proper protection, maintenance, and usage control of the information in an operational environment.
>
> **— Handbook of Information Security Management**
> **Zella G. Ruthberg and Harold F. Tipton, Editors, 1993**

20.3 Policy

It is a matter of policy that management makes statements about the level of risk that it is prepared to take and whom it intends to hold accountable for protection. Owners and custodians are useful abstractions for assigning and distinguishing this responsibility for protection. Policy should require that owners be explicitly identified; that is, that the responsibility for protection be explicitly identified. While ownership is implicit, in the absence of requiring that it be made explicit, the responsibility for the protection of information is often overlooked. Similarly, policy should make it explicit that custodians of data must protect it in accordance with the directions of the owner.

20.4 Roles and Responsibilities

20.4.1 Owner

At one level, the owner of institutional data is the institution itself. However, it is a fundamental characteristic of organizations that they assign their privileges and capabilities to individual members of the organization. When we speak of owner, we refer to that member of the organization to whom the organization has assigned the responsibility for a particular asset. (To avoid any possible confusion about the real versus the virtual owner of the data, many organizations eschew the use of *owner* in favor of some other word such as agent, steward, or surrogate. For our purposes, the owner is the assigned agent.)

This individual exercises all of the organization's rights and interests in the data. These include:

- Judging the asset's importance, value, and sensitivity
- Deciding how and by whom the asset may be used
- Specifying the business controls
- Specifying the protection requirements for the asset
- Communicating decisions to others (e.g., labeling the object with its classification)
- Acquiring and operating necessary automated controls over the assets
- Monitoring compliance and initiating corrective action

Note that these duties are not normally separable. That is to say that all must be assigned to the same agent. Specifically, the right to use cannot be separated from the responsibility to protect.

We should keep in mind that others might have some interest in an information asset. For example, while the institution may own a copy of information such as employee name and address in the pay record, the employee still has a proprietary interest in the data. While this interest may not rise to the level of ownership, it is still a material interest. For example, the employee has an interest in the accuracy and confidentiality of the data. In exercising its interest, the institution and its agents must honor these other interests.

20.4.2 Custodian

Even the dictionary definition recognizes that the idea of custodian includes one who is responsible for protecting records. This responsibility includes:

- Protecting the data in accordance with owner direction or agreement with the owner
- Exercising sound business judgment in the protection of data
- Reporting to the data owner on the discharge of his responsibilities

Suppliers of data processing services and managers of computers and storage devices are typically custodians of application data and software processed or stored on their systems. This may include paper input documents and printed reports.

Because it is these custodians who choose, acquire, and operate the computers and storage, they must provide the necessary access controls. The controls chosen must, at a minimum, meet the requirements specified by the owners. Better yet, they should meet the real requirements of the application, regardless of whether the owner of the data is able to recognize and articulate those requirements. Requirements to which the controls must answer include reliability, granularity, ease of use, responsiveness, and others.

20.4.3 Administrator

The owner may wish to delegate the actual operation of the access controls to a surrogate. This will be particularly true when the amount of special knowledge required to operate the controls exceeds the amount required to make the decisions about the use of the data.

Such an administrator is responsible for faithfully carrying out the intent of the owner. He should act in such a way that he can demonstrate that all of his actions were authorized by the responsible owner and that he acted on all such authorizations. This includes keeping records of what he did and the authorizations on which he acted.

20.4.4 User Manager

The duties of user management include:

- Enrolling users and vouching for their identities
- Instructing them in the use and protection of assets
- Supervising their use of assets
- Noting variances and taking corrective action

While the list of responsibilities is short, the role of user management may be the most important in the enterprise. This is because user management is closer to the use of the resources than any other managers.

20.4.5 User

Users are responsible for:

- Using the enterprise information and information processing resources only for authorized and intended purposes
- Effective use and operation of controls (e.g., choice of passwords)
- Performance of applicable owner and custodian duties
- Compliance with directions of owners and management
- Reporting all variances to owners, managers, and staff

Variances should be reported to at least two people. This reduces the probability that the variance is called to the attention of only the individual causing it. The owner of the resource and the manager of the user would be likely candidates for notification. Otherwise, use one line manager and one staff manager (e.g., audit or security staff).

20.5 Identifying the Information

Identifying the data to be protected might seem to be a trivial exercise. Indeed, before computers, it really was. The enterprise focused on major and persistent documents and on major functional files such as those of payroll records or payables. Focus was placed on those files that were special to the industry or enterprise. In banking, one worried about the records of deposits and loans; in insurance, one worried about policy master records. Managers focused on departmental records and used file cabinets as the objects of control and protection. Even when computers emerged, one might still have facused on the paper printout of the data rather than on the record on magnetic tape. When a megabyte was the size of a refrigerator, one identified it and protected its contents similarly to how one protected the contents of a file cabinet. As magnetic storage became sufficiently dense that the storage object was shared across a large number of data objects, we started to identify data sets. While we often think of a data set as analogous to the modern file, in fact it was a collection of logically related files that shared a name. The input file to a job, the output file from the job, and the archival version of that file might all be part of the same logical data set. The members of a data set were related in a formal way. While there are a small number of different types of data sets (e.g., partitioned, sequential, VSAM), members of all data sets within a type were related in a similar way. The information about the relationships was recorded in the metadata for the data set.

Therefore, for protection purposes, one made decisions about the named data set rather than about the physical objects that made them up. The number of data sets was sufficiently small that identifying them all was not difficult.

In modern systems, the data objects of interest are organized into (tree-structured) directories and files. A data set in a mainframe might correspond to a file or to all the files in a directory. However, the relationship between a directory and the files and other directories that are stored in it may be totally arbitrary. There are conventions, but there are no fixed rules that can be consistently used to reduce the number of objects over which one must make decisions. For example, in one directory, programs and data may be stored together; while in the next one, programs and data may be stored in separate named subdirectories. A file name may be qualified by the name of the directory in which it is stored — and then again, it may not.

Therefore, for protection purposes, a decision may have to be made over every directory entry and possibly every file. The number of objects expands, perhaps even faster than the quantity of data. This is complicated further by the rapidly falling cost of storage. Cheap storage enables one to keep data longer and otherwise encourages growth in the number of data objects.

Data sets also had the advantage that the names tended to be unique within a system and, often, by convention, across an enterprise. In modern practice, neither objects nor names are unique even within a system, much less across an enterprise.

In modern systems, there is no single reference or handle that one can use to identify all data within an enterprise. However, most of them require some enterprise procedures or conventions. For example, one can store data according to its kind and, by inference, its importance.

- Enterprise data versus departmental, personal, or other
- Changeable versus fixed (e.g., balances versus transactions; programs versus data; drafts versus published documents; images versus text)
- Documents versus other
- Permanent versus temporary

- Business functional applications versus other (e.g., payroll, payables, sales) versus other (e.g., correspondence)
- Active versus archival
- Other enterprise-specific categories

Each of these distinctions can be useful. Different procedures may be required for each.

20.6 Identifying the Owner

Prior to the use of the computer, management did not explicitly identify the owners of information. This was, in part, because the information of interest was the functional data of the organization. This information included pay records, customer records, sales records, etc. Ownership and custody of the information were almost always in the same hands. When the computer came along, it separated custody from ownership. The computer function found itself with custody of the information. Management did not even mind very much until decisions needed to be made about the care of the records.

Management was particularly uncomfortable with decisions about access and security. They suddenly realized that one standard of care was not appropriate for all data and that they did not know enough about the data to feel comfortable making all the decisions. Everyone wanted discretion over the data but no one wanted responsibility. It was obvious that mistakes were going to be made. Often, by the time anyone recognized there was a problem, it was already a serious problem and resolving it was difficult.

By this time, there was often so much data that discovering its owner was difficult. There were few volunteers. It was not unusual for the custodians to threaten to destroy the data if the owner did not step forward and take responsibility.

20.6.1 Line Manager

One useful way to assign ownership is to say that line managers are responsible for all of the resources allocated to them to accomplish their missions. This rule includes the responsibility to identify all of those assets. This ensures that the manager cannot escape responsibility for an asset by saying that he did not know.

20.6.2 Business Function Manager

Although this is where the problem got out of hand, it is the easiest to solve. It is not difficult to get the managers of payroll or payables to accept the fact that they own their data. It is usually sufficient to simply raise the question. When we finally got around to doing it, it was not much more difficult than going down the list of information assets.

20.6.3 Author

Another useful way to assign ownership is to say that the author or creator of a data object is its owner until and unless it is reassigned. This rule is particularly useful in modern systems where much of the data in the computer is created without explicit management direction and where many employees have discretion to create it. Like the first rule, it works by default. This is the rule that covers most of the data created and stored on the desktop.

20.6.4 Surrogate Owners

Even with functional data, problems still arise with shared data, as for example in modern normalized databases. One may go to great pains to eliminate redundant data and the inevitable inconsistencies, not to say inaccuracies, that go with it. The organization of the database is intended to reflect the relationships of the entities described rather than the organization of the owners or even the users. This may make mapping the data to its owners difficult.

An example is a customer master record that is shared by three or four different business functions. If one of the functions assumes ownership, the data may be operated for their benefit at the expense of the others. If it is not well managed, the other functions may start keeping their own copies with a loss of both accuracy and efficiency.

One solution to this problem is to create a surrogate function to act as the owner of the data. This surrogate acts as agent for his principals; he satisfies their ownership requirements while exercising their discretion. He is motivated to satisfy all of his customers equally. When conflicts arise between the requirements of one customer and another, he negotiates and resolves them.

In modern systems, shared functional data is usually stored in databases rather than in ?at files. Such systems permit more granular control and more choices about the assignment of ownership. Control is no longer limited by the physical organization of the data and storage.

20.7 Classification and Labeling

One way for the owner to communicate his intentions about how to treat the information is to write instructions as metadata on the data object. A classification scheme provides an efficient language in which to write those instructions. The name of the class is both an assertion about the sensitivity of the data and the name of the set of protective measures to be used to protect it. The owner puts the label on the data object, and the custodian uses the associated protective measures.

The number of classes must be must be small enough for one to be able to habitually remember the association between the name of the class and the related controls. It must be large enough to ensure that all data receives the appropriate protection, while expensive measures are reserved to the data that really requires them.

We should prefer policies that enable us to detect objects that are not properly classified or labeled. Policies that require that all objects be labeled, even the least sensitive, make it easy to recognize omissions. Many organizations do not require that public data be labeled as such. This makes it difficult to distinguish between public data and data over which no decision has been made.

While paper feels natural and comfortable to us, it has severe limitations not shared by more modern media. It is bulky, friable, flammable, resistant to timely update, and expensive to copy or back up. On the other hand, it has an interesting kind of integrity; it is both tamper-resistant and tamper-evident. In paper systems, the label is immutably bound to the object and travels with it, but the controls are all manual. In automated systems, the label is no more reliable than the system and does not travel with the object beyond the system. However, controls can be based upon the label and automatically invoked. In mandatory access control systems, both the label and the controls are reliable. In discretionary access control systems, both the labels and the controls are less reliable but adequate for many applications and environments.

Cryptographic systems can be used to bind the label to the object so that the label follows the object in such a way that the object can only be opened in environments that can be relied upon to enforce the label and the associated controls. Certain high-integrity imaging systems (e.g., Adobe Acrobat) can bind the label in such way that the object cannot be displayed or printed without the label.

20.8 Access Control

The owner uses access controls to automatically direct and restrain who sees or modifies the data. Mandatory access controls ensure consistent application of management's policy across an entire system while minimizing the amount of administrative activity necessary to achieve it. Discretionary controls enable owners to implement their intent in a flexible way. However, consistent enforcement of policy may require more management attention and administrative activity.

20.9 Variance Detection and Control

It must be possible for the owner to observe and measure how custodians and others comply with his instructions. He must have visibility. This visibility may be provided in part by alarms, messages, confirmations, and reports. It may be provided in part by feedback from such staffs as operations, security administration, and audit.

The owner is interested in the reliability of the user identification and authentication (I&A) scheme. He is most likely to look to the audit report for this. Auditors should look at the fundamental strength of the I&A mechanism, log-on variances, the security of password change procedures where used, and weak passwords where these are possible.

The owner is also likely to look to the audit report for information on the integrity of the access control system and the authorization scheme. The auditors will wish to look to the suitability of the controls to the applications and environment. Are they application-specific or provided by the system? Are the controls appropriately granular and responsive to the owner? They will be interested in whether the controls are mandatory or discretionary, rules-based or list-based. They will wish to know whether the controls have been subjected to third-party evaluation, how they are installed and operated, and how they are protected from late change or other interference. They will want to know the number of privileged users of the system and how they are supervised.

Periodically, the owner may want to compare the access control rules to what he thinks he authorized. The frequency of this reconciliation will be a function of the number of rules and the amount of change.

The owner will be interested in denied attempts to access his data; repeated attempts should result in alarms. Some number of denied attempts are probably intended to be authorized and will result in corrections to the rules. Others may require follow-up with the user. The user will want to be able to detect all accesses to the data that he owns so that he can compare actual access to what he thinks he authorized. This information may be in logs or reports from logs.

20.10 Recommendations

- Policy should provide that ownership of all assets should be explicitly assigned. This helps to avoid errors of omission.
- Ownership of all records or data objects should be assigned to an appropriate level of granularity. In general, this means that there will be an owner for each document, file, folder, or directory, but not necessarily for each record or message.
- The name of the owner should be included in the metadata for the object.
- The classification or other reference to the protective measures should be included in the metadata for the object.
- Because few modern systems provide abstractions or controls for data classification or owner, this metadata should be stored in the object name or in the object itself.
- The owner should have responsive control over access. This can be through automated controls, administrators, or other surrogates.
- There should be a clear agreement between the owner and the custodian as to how the data will be protected. Where a classification and labeling system exists, this can be the basis of sensitivity labels on the object.
- Consider written agreements between owners and custodians that describe the protective measures to be used. As a rule, these agreements should be based upon offers made by the custodians.
- The owner should have adequate visibility into the operation and effectiveness of the controls.
- There should be prompt variance detection and corrective action.

20.11 Conclusion

The ideas of ownership and custody are fundamental to any information protection scheme. They enable management to fix responsibility and accountability for deciding how an object is to be protected and for protecting it in accordance with that decision. They are essential for avoiding errors of omission. They are essential for efficiency; that is, for ensuring that all data is appropriately protected while reserving expensive measures only for the data that requires them.

While management must be cautious in assigning the discretion to use and the responsibility to protect so as not to give away its own rights in the data, it must be certain that control is assigned with sufficient granularity that decisions can be made and control exercised. While identifying the proper owner and ensuring that responsibility for all data is properly assigned are difficult, both are essential to accountability.

Owners should measure custodians on their compliance, and management should measure owners on effectiveness and efficiency.

21 Information Security Risk Assessment

Samantha Thomas Cruz

21.1 Forward

Since very early in the information security industry, risk management has had many concepts. Some have been based on applied management strategy (such as portfolio management), old warring tactics (scenario planning), and modern day economics (feasibility studies and cost to market). Most of these attempts at risk management have been created and implemented by professionals in a specific industry, areas of academia and consulting firms, not the actual business areas dealing with the risks. Little attention has been paid to the complex processes taking place among work producers, business decision makers, applying a risk management concept and then managing the concept itself.

21.2 Opening Remarks

This chapter describes how organizations create, adopt, fail, and succeed at marrying their information security risk management processes with root management concepts of the business. There are many different observations made and several suggestions provided on the relationship among business drivers, those doing the work of the business, and the political and cognitive processes within a company. Finally, this chapter assimilates and summarizes a process model that interplays a few crucial factors during the cycle of risk management concepts and core values in management within organizations.

21.3 Traditional Information Security Risk Management: Assessment and Analysis

Historically, in the information security industry, there has been a universally agreed upon standard of how to quantitatively manage information security risk. Organizationally, for many companies, risk management is a sub-program within an information security program and will have resources exclusively dedicated to the task of trying to reduce information security risk. The process may involve identifying crucial business information, threats, vulnerabilities, risks, and ranking or weighting those risks. It may also involve annual loss expectancy, single loss expectancy, probabilities, costs of controls and mitigation measures, residual risks, uncertainty, and risk acceptance. These traditional processes are tried, true, and still work as a productive method for information security risk assessment and analysis. This chapter reviews the process highlights, offers suggestions for variations to traditional processes, and provides alternative methods for identifying the different parts necessary to conduct an analysis.

21.4 Traditional Process: Business Problems and Opportunities

21.4.1 A Traditional Process

It is practical for any business program, information security or otherwise, to occasionally conduct a risk assessment and then to analyze the components within that assessment. Most information security risk assessments begin by the information security organization meeting with the different business areas in their company to conduct a discovery. During this discovery, the business area and information security team work together to identify the most crucial information and assets that are required for them to successfully conduct business.

21.4.1.1 Business Problem

Often, these meetings are the first occasion other business areas will have to directly interact with information security staff. These discovery meetings are often facilitated by information security teams who typically have no training or professional experience facilitating a group of adults.

21.4.1.2 Opportunity

These meetings are often the only one-on-one chance to create an affirmative image directly with others in the company, and it is the responsibility of the information security organization to make the most of this chance to create and instill a positive, professional impression to its internal customers. In most of today's consultative-type information security organizations, it is imperative that facilitation and communication skills be developed and maintained. Most information security organizations pride themselves on hiring the most qualified individuals in their field, and they continually enhance their information security skills through regular education. Usually, this education does not include the areas of active listening, communication, or facilitation. However, to create and maintain the professional respect of staff outside of the information security organization, the valuable information security skills of the team must be articulated and expressed to create a positive, trusted image with internal customers. Active listening and communication delivery skills must be honed and a foundation set in standard business and management terms, not information security jargon. This opportunity of polished facilitating is an entry to another opportunity in the discovery process, that of the discovery meetings themselves. When the information security team has the chance to meet with other internal customers, an opportunity arises to create partnerships and alliances with other members of the organization. Finally, these initial meetings give leeway for demonstrating and articulating the different ways a risk assessment discovery process adds value to the business area by providing an avenue to re-examine their information, assets, and processes that support them. That is the opportunity these teams have purely by the mechanics and outcomes of the discovery process.

21.4.2 Traditional Process

Once the business area has identified and documented its information and assets, the teams identify what information is crucial enough to be considered for the rest of the risk management process and how that chosen information flows into and out of their specific organizational area.[1]

21.4.2.1 Problem

This problem is three-fold. First, there is often no documented classifications of information, no formalized processes, and there usually is not a significant amount of identified information or assets from which the team can glean the information it needs to have a productive meeting. Therefore, the team will try to classify and document its processes or identify its information and assets during the discovery meeting. This is also a potential problem that can occur during this process. When this occurs, the team usually attempts to identify the future state of its information and assets versus the here and now or very near future. During any of these three problem points, discussions tend to stray into the area of solving business problems for issues that are simply changing too quickly to foresee a static future. This is not a good path as drivers such as profits, regulations, and technology are all areas that change often, and in turn, will not align with attempts to document information and assets with a crystal ball approach.

21.4.2.2 Opportunity

In many cases, using a value chain[2] method can be helpful. The value chain is a model that can help business areas and information security practitioners through these rough patches of business. The approach allows teams to identify and document drivers, activities, outputs, and outcomes to work through an information security risk assessment. These processes will be addresses later in this chapter.

21.4.3 Traditional Process

After crucial business information and the way it flows into and out of a specific organizational area have been identified, most teams begin to identify and assess threats, vulnerabilities, and recognize risks. There are different ways a business can set about executing these tasks. The more popular choices seem to be software products that are populated with a variety of different databases and mathematical equations that can ultimately perform scenario queries, consulting firms that assign a team to conduct research and analysis on similar industry and international trends, one-on-one style contractors who conduct deep-business research and tailor the process specifically for an organization, or a combination of these three choices.

21.4.3.1 Problem

The problem here is two-fold: one problem is as the areas of business risk management and information security risk management evolve into a part of every manager's *role*, the actual *responsibility* of identifying threats and vulnerabilities in the area of information security has not evolved with it. So the responsibility still tends to fall into the lap of the information security organization.

21.4.3.2 Opportunity

For the crucial information in their area, business managers need to be responsible for identifying some, if not the majority of, information security threats and vulnerabilities. Using the value chain mentioned

[1] Other factors that are usually considered in the process include different values such as replacement, business continuity, maintenance, etc.

[2] Based on work by Michael E. Porter of Harvard Business School and Rene' Ewing.

above, business areas will be able to ask themselves the “why” and “how” related to threats and vulnerabilities, and ultimately risks, in their business areas without having to be seasoned information security practitioners. This does not mean the information security organization stops playing a vital role in the process; it means the business takes one step closer to ultimately owning and managing its own information security risk. The other problem is that although most information security practitioners understand the difference, most lay business managers and staff will confuse the semantics of information security threat, vulnerability and risk and use them interchangeably.

21.4.4 Further Opportunity

This is an important error to correct and come to consensus on clear definitions with the team. One way to work through this process is to agree that a threat is a source of harm, a vulnerability is a handicap, and a risk is a combination of the two culminating in an undesired consequence or action. The following definitions, which we use in CISSP CBK Review course, would be appropriate here. *Threat*—any potential danger to information or an information system, including its supporting infrastructure. *Exposure*—instance of being exposed to losses from a threat. *Vulnerability*—an information system weakness that could be exploited. *Countermeasures and safeguards*—an entity that mitigates the potential risk. *Risk*—likelihood of an unwanted event occurring. *Residual risk*—the portion of the risk that remains after implementation of countermeasures.

A simple example: fire can be a threat, an office constructed of wood can be a vulnerability, and the burning/loss of information can be the undesired consequence or action. Fire alone does not cause risk, nor does the office constructed of wood cause alone risk. The risk is the undesirable consequence or action of the two placed together. Therefore, in its simplest form, a risk can be described as requiring the combination of both a threat and a vulnerability. Not clarifying and agreeing on the simplest of definitions for these three significant words—threat, vulnerability, and risk—can be an expensive error. Companies may waste valuable resources reducing the probabilities of a vulnerability when no likely threat exists or visa versa, and they attempt to place into motion controls to protect themselves from a threat where no likely vulnerability exists. During these clarification of terms discussions, it will be important for the teams to understand and agree that with appropriate balance of mitigation measures and controls in certain situations, threats can actually evolve into business enablers and vulnerabilities in fact into cost savings. For example, using the last illustration of the threat of fire, a mitigation control of purposefully starting a fire in a controlled space such as a fireplace in a lobby entry may create the desired public image with a side benefit of heat in the winter. The vulnerability of an office made of wood with the mitigation control of smoke alarms and fire suppression may allow the building of the office with a cost savings of wood in lieu of a more expensive building material. This is an area where information security risk management can reap valuable results by making good points with business area colleagues.

21.4.4.1 Traditional Process

To rank the identified information security risks into categories of high, medium, and low and apply weights and values.

21.4.4.2 Problem

Often, there are too many unbalanced variables on the criteria used to rank, weigh, and value the risks. Variables include the cost of creating information, purchasing an asset, replacement values, weighing in skills of staff to maintain a low vulnerability threshold, future value, etc.

21.4.4.3 Opportunity

This point in the risk analysis process provides an occasion for including all management to agree on key issues most important for identifying and applying criteria. To keep things simple an either–or path can be explored; have the senior management team agree on one system of categorizing the risks—rank, weight, or value, not all three. To springboard this overarching categorization, an often overlooked opportunity is to use the organization's core values. Along with being the identified cornerstone of a company, a noteworthy advantage of using core values is the implicit support of the executive management and board of directors. By using the organization's core values, the information security team also positions itself to have the information security risk management decisions made by the team in a manner that can be measured up the path of the organization's strategic plan, align with its mission, compliment the company vision, etc.

21.4.5 Traditional Process

To identify cost effective compliance-based mitigation measures and controls, and a plan for their creation, execution and maintenance.

21.4.5.1 Problem

By the time a team begins wrestling with this area, it often embarks on the path of least resistance by examining best practices. The problem with best practices is that they are usually created two to five years earlier. Therefore, while the team has identified its business problems of today, it is looking to apply best practices of yesterday. Implementing best practices is acceptable as a precursor to continued exploration of mitigation measure and controls specific to an organization's needs. However, outdated best practices can actually create an inaccurate mitigation measure or control implemented for a risk that was not realized during the same time period the best practice become best. Therefore, the business team will be recommending the implementation of a control that is not appropriate for the risk and that, in and of itself, can create a new set of risks.

21.4.5.2 Opportunity

With correct questioning by the facilitator, the business teams, along with help from technical specialists and the information security team, should first be led through a path of legal compliance. This typically sets the tone for working out tradeoffs with those who have the authority to accept risk, residual risks, and uncertainty. During this process, sometimes a roadblock for information security practitioners is to acknowledge that if they so choose, the business teams can accept each and every risk identified in a risk analysis effort (usually their senior leadership), even those risks identified as non-compliant with regulations, statues, etc. This normally does not happen, but it is important to mention as it brings about one of the most important aspects of an information security risk management program and that is information security is subservient to the business itself. Information security exists because of the business, not the other way around.

There are other aspects of risk assessment and analysis such as categorized impact, percentage of value, expected loss per event or year, localized threats, information ownership, control effectiveness, etc., that this writing purposefully does not address—firstly, because of the intention to create a foundation for opening one's mind to accept a more business-centric approach for conducting information security risk assessments, and secondly, because such specifics have been written in precise detail many times over in other books.

21.5 An Alternative Strategic Approach

An organization's risk management processes—operational in approach—can be critical for specific areas of the company to better understand how risks affect their business performance. High performing organizations integrate planning processes where clear linkages exist between internal operations and the overall strategic plan of the company. The following will introduce these characteristics and linkages for an information security risk assessment and illustrate how to move through the linkages in the business chain to better ensure real business risks are being addressed and in a manner consistent with the company's core values and overarching enterprise wide business strategy.

21.5.1 Value Chain Model

A chain-of-value approach can be built to address and manage the strategic responsibilities of the business areas involved with the information security risk assessment. Advantages to using this value chain method is that it guides business teams to address core information security issues and does so in an illustrative manner. Another advantage is the premise of business teams working, sometimes for the first time, with information security experts, and instead of being met with the expectation of understanding industry lingo, are requested to examine their business by asking themselves the simple questions “why” and “how” when examining their information security risks in the value chain model. For the purposes of this chapter, the value chain discussed includes five perspectives: drivers, ultimate outcomes, intermediate outcomes, outputs, and actionable items. This value chain (Exhibit 21.1) can be used as a type of strategic map, guiding staff to identify not only the goal of information security risk reduction, but also the ultimate outcome of supporting the core values and mission of its organization.

To facilitate a move up the value chain, one asks why the value in that box is important. Likewise, to facilitate a move down the value chain, one asks how that particular item is achieved. The ultimate significance of using the value chain for information security risk assessment and analysis is not to identify detailed threats, vulnerabilities, and risks, but more the supporting actions an organization can take to allow information security risk reduction to be influenced by the core values and drivers of the business, thus holistically perpetuating a transformation of a risk reduction culture within the entire organization.

Drivers: These are actions outside an organization’s sphere of influence that cause things to happen inside an organization; examples include sharply increased computer virus outbreaks, modifications to disclosure laws, change in company stock holders, board strategy and direction, etc.

Ultimate Outcome: These are the highest levels of performance. It is the most difficult area to quantify, but the most meaningful to an organization in having information security decisions and actions made lower on the value chain actually meeting the company mission and aligning with core values.

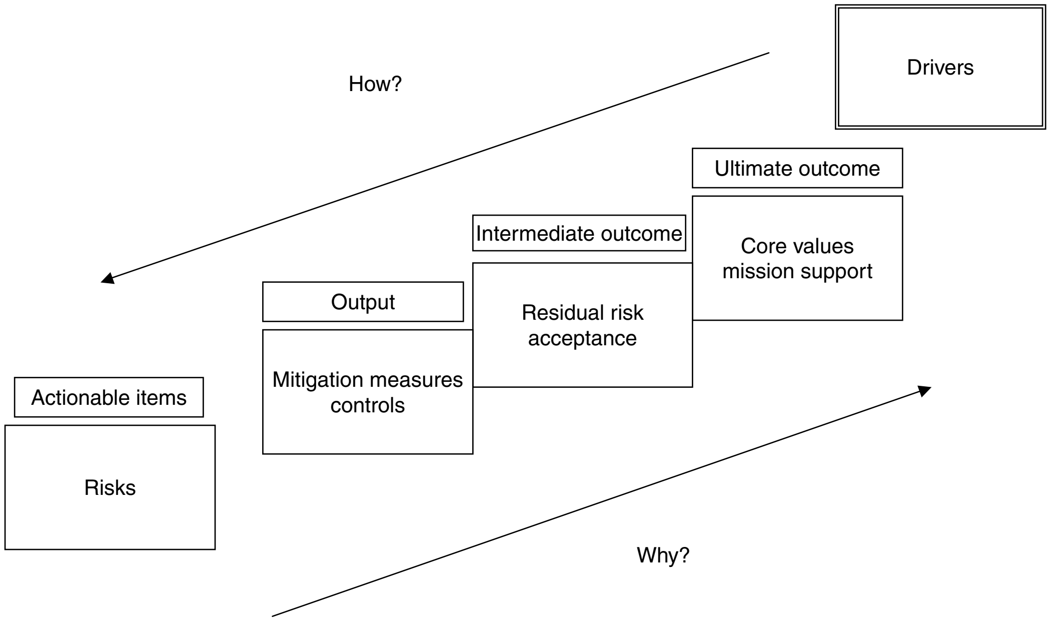

EXHIBIT 21.1 The value chain model.

Intermediate Outcome: These items are a step higher above outputs. They are based on the impact the value chain thread has on behavior changes, overall satisfaction of the problem of the risk addressed by acceptance, a business need met, system or process changes, etc.

Outputs: As a result of the actionable items (risk), certain outputs are generated. Outputs are the most common perspective type item seen examined and analyzed in organizations because the information is usually easy to capture. As this information is usually easy to capture, it is the area most reported. This is unfortunate because the real value of information security supporting the core values and mission of the organization are higher up on the value chain.

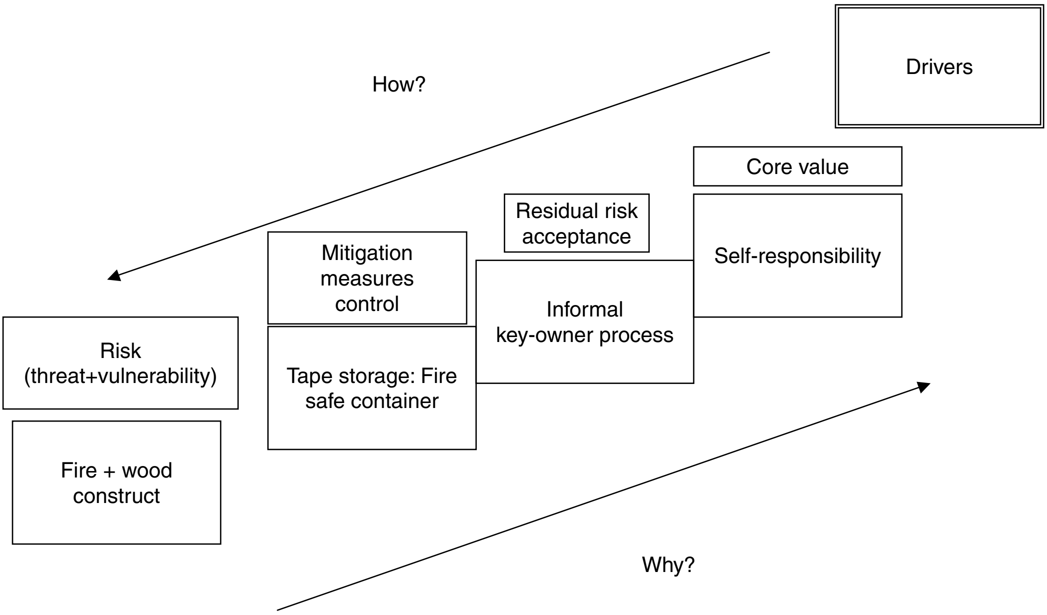
Actionable Items: Here, the risks are identified and act as the catalyst that drives all of the other items up the value chain. They are the root by which all other items in the value chain derive their why.

This value chain can provide the architecture for an information security risk assessment and analysis. Using the ultimate outcome of the reduction of information security risk to support the core values and mission of an organization, one can supplant assessment and analysis items in the different boxes and move up and down through the value chain. An example can be seen in Exhibit 21.2.

As with any sort of information security risk assessment, beginning with current and quality threat and vulnerability information is important for the ultimate outcomes to be meaningful. At most large enterprises, the information that business and information security teams often have access to is 60 or 90 days prior and somewhat sanitized by the time it reaches senior management. The problem here is that without transparent access to the current state of their business threats and vulnerabilities, the ultimate information security risk acceptance by executives may not be the most prudent business decisions as these choices will be made to accept/solve yesterday's problems.

21.5.2 Problem: Business Ownership

Having a new, illustrative, and simple-to-use method is not enough. Often mitigation measures and controls take too long to develop, and by the time a company is ready to implement them, they are no longer effective because the business has changed. Therefore, the execution piece is a key element. There are factors in business that can make a mitigation measure or control difficult to execute. The pace of



How?
Drivers
Core value
Residual risk acceptance
Self-responsibility
Mitigation measures control
Informal key-owner process
Risk (threat+vulnerability)

Fire + wood construct
Why?

EXHIBIT 21.2 Example of value chain use for risk assessment.

internal change continues to evolve quickly but is not communicated effectively as technology upgrades and the diversity of how staff interacts within a business (a more mobile work force and the use of temporary specialized talent) are more prevalent than ever before. But fundamentally, it is difficult to execute mitigation measures and controls today because the way business is conducted is different than it was as little as ten years ago when the traditional information security risk assessment and analysis methods were taking a strong hold in the industry. The adage of moving from the industrial age to the information age and now to the knowledge age has been heard. Businesses have moved from production-driven, top-down silos to customer-centric, information security sensitive leadership.

21.5.3 Opportunity: Value Chain

As more businesses are embracing the balanced score card[3] to chart and measure their performance, the value chain is a same-type support tool that can assist moving information security risk management into, the mainstream of business. It is a process based on a model for measurements that most business areas are familiar to using for performance; therefore, it is a process that internal business customers can understand and embrace as a user-friendly tool. Using the value chain approach for information security risk assessments with business teams can also decrease the use of some foreign sounding information security terms such as annualized rate of occurrence and single-loss expectancy. Although these traditional terms are valuable in conducting the finer aspects within the risk analysis portion of an assessment, using the value chain allows teams to use mostly business language, and it leaves the security terms more to the information security organization for the detailed work that requires the knowledge and skills of an information security professional. Another benefit of using a value chain for information security risk assessments is that after a team of business and information security staff work through an initial assessment using a value chain approach, the business can try using the same approach on its own to independently work through some low risks without the hand holding of the information security organization. Although mitigation measure and control results of such endeavors should be reviewed by the information security team, allowing the business to try and work through some low risk areas allows it to own part of the process, incorporating information security risk management into its business. By owning this new management process, it becomes part of the fabric by which that business area operates. Therefore, as an operational item in their business, information security risk management becomes woven into their strategy, by the business, for the business. A key feature here is that now the value chain has assisted in making information security risk management happen continually, not just per assessment.

21.6 Conclusion

For many organizations, the accelerated pace of change, increased expectations, staff turnover, and pressures from decreased budgets create significant daily pressures. As information security responsibilities expand beyond the confines of the traditional information security role, it is imperative that information security organizations have tools in place to share with their internal customers to help them reach their full risk reduction potential. Although senior managers have complimentary but separate roles in promoting risk management efforts, when supported by an interconnected information security business value chain, they have greater opportunity to make their information security risk management decision more visible. The value chain is a business-modern tool that enables leadership to fulfill its obligation for incorporating information security risk management into its business areas, throughout its organization, and align information security risk management with its core values.

[3] Balanced score card management practices were developed in the early 1990s by Drs. Robert Kaplan (Harvard Business School) and David Norton.

22

Developing and Conducting a Security Test and Evaluation

Sean M. Price

22.1 Introduction

System security is a composition of people, processes, and products. People are system users, administrators, and managers. Processes represent the operational aspects of the system which are manual or automated. Products are the physical and intangible attributes such as facilities and the hardware and software components that make up a system. Generally, each of these groups is subject to the same security requirements; however, each grouping faces its own unique challenge regarding consistent compliance with established requirements. People may not know, understand, or follow security rules. Processes sometimes become antiquated or have flaws in them that expose a system to a threat. Product implementations are challenged by security patch updates and insecure configurations. Interaction between these groups forms a basis of productivity within an organization. This interaction creates a complex situation when each group interacts with another aspect.

Each group is dynamic in nature. The activities of each can change on a regular basis. People come and go in organizations. Processes are changed to adapt to new operational environments. Hardware and software are changed with the advance of technology. With every change comes the possibility of nonconformance with security requirements. This gives rise to a need to perform comprehensive system security reviews on a periodic basis.

A security test and evaluation (ST&E) is a validation of system compliance with established security requirements. The ST&E is a snapshot in time of the overall security posture. It is an important security management tool used to assess system conformance to established security requirements. The scope of an ST&E includes people, processes, and products affected by security. Although security requirements may seldom change, the system configuration, users, applications, and architecture might be in continual flux. The ST&E is an audit of implementation of the security policy by the system and a validation of the proper operation of the implemented security controls.

A properly conducted ST&E provides management with an objective view of the security posture of a system. Individuals conducting the ST&E should not have management, administrative, or development responsibilities on the system. Appropriate separation of duties ensures the integrity of the ST&E process. The test procedures and results should also be clearly documented. The associated documentation should be in enough detail to give subsequent evaluators the ability to reproduce tests conducted and obtain similar results if the system has not changed.

Several other types of security reviews are commonly conducted on systems, including vulnerability assessments, risk assessments, and penetration testing. The purpose of a vulnerability assessment is to determine if a system has exposed vulnerabilities. Typically, a vulnerability assessment is conducted using host- and network-based scanners. These tools usually look for misconfigured or unpatched system components. Vulnerability scans are helpful in determining weaknesses or noncompliance of system products with security requirements. Risk assessments use quantitative and qualitative measurements to determine the potential loss that might occur if a threat takes advantage of a weak control. These assessments are tools used by management to allocate resources to protect systems and data. Risk assessments do not validate that a system does or does not support a particular requirement; however, identification of an unacceptable risk in a given area of people, processes, or products may generate new security requirements. Penetration testing is an overt or covert attempt to gain access to a system. Properly planned penetration tests implement a variety of processes but generally make use of *ad hoc* procedures to accomplish their goals. Penetration testing can identify weaknesses in people, processes, and products; however, penetration testing is not comprehensive and is based more on verifying best-business practices or combating popular attack methods than on validating system conformance to a security policy or requirements. Each of the aforementioned types of reviews serves a valuable purpose, but none of them fully validates conformance to all established security requirements.

22.1.1 Why Do a Security Test and Evaluation?

A properly conducted ST&E provides organizational and systems managers with a comprehensive audit of the security controls of a system. Performing a security audit provides organizations with evidence that can be reviewed by external entities. Many organizations within the United States are bound by laws and regulations that require some type of security review. Laws such as the Sarbanes–Oxley (SOX) Act, Health Insurance Portability and Accountability Act (HIPAA), Federal Information Security Management Act (FISMA), and Gramm–Leach–Bliley Act (GLBA) require some form of security review for the entities affected by these regulations. Beyond the legal requirements, business needs and requirements may dictate that a system provide some level of confidentiality, integrity, and availability. A comprehensive review of the controls provides management with some level of assurance regarding the security posture of the system. Where security controls are lacking or excessive, management can make risk-based decisions regarding which controls to implement or forego. Management decisions regarding the security controls to implement shape the security requirements necessary for a given system.

22.2 Security Test and Evaluation Methods

An ST&E requires a comprehensive review of the interaction among people, processes, and products with regard to identified security requirements. This is accomplished through interviews, observations, and document and technical reviews. Each requirement identified is tested with the appropriate review:

- *Interviews*—Users, managers, and system administrative personnel are asked questions regarding system security processes. Interviews support the gathering of abstract data that is not likely to be found on a system. For example, there may be a requirement such as “all users must participate in security awareness training annually." This requirement may be monitored electronically, but it is more likely that it is not. Organizational personnel may be asked if they have received or given the required training. The results might be corroborated by further by having users answer questions that demonstrate they have received the training.

- *Observations*—Some security requirements may be implemented in a manual process. To illustrate consider the requirement that "all users must secure their workstations prior to departing the immediate area." This may be interpreted to mean that users must log off or lock their sessions prior to leaving the facility. This requirement could be tested through interviews but is more appropriately assessed by physically observing workstations before, during, and after working hours. Partial or noncompliance with the security requirement would be noted if a session was not secured and the user had left the facility. Additionally, some physical and environmental security requirements are tested through observations. Limiting access to servers and the implementation of fire suppression equipment are examples of physical security and environmental requirements that are validated through observations.
- *Document reviews*—The implementation of a security requirement can involve the generation of security-relevant documentation. Some examples of required documentation include memoranda, system security plans, configuration guides, risk assessments, accreditation packages, or security agreements. Documentation should be reviewed for conformance, completeness, and accuracy. Artifact documents, such as batch completion reports and audit logs, produced through business operations should also be included in document reviews.
- *Technical reviews*—Systems should be designed and implemented to support security requirements. A review of the hardware and software controls demonstrates system compliance with the identified requirements. This review consists of all technical aspects regarding design, configuration, and update management of a system.

22.3 Security Requirements

The first step in developing an ST&E is to identify all applicable security requirements. Policies, procedures, standards, and guides within an organization provide the principle source of security requirements. Other sources include government laws and regulations, parental organization policies, industry standards, best business practices, previous risk assessments, and system security or engineering documentation. Ultimately, organizational and system management must determine what constitutes the system security requirements. For the remainder of this chapter, the term *policy documents* refers to the list of all documents, regardless of origin or type, that are used to derive security requirements.

Security requirements are decomposed from the identified policy documents. Each sentence in the document indicating a required implementation is a policy statement. Policy statements may be decomposed into one or more security requirements. To illustrate consider the following:

> The audit mechanism must be configured to record the following types of events: Log-on and log-off activities, object access, deletion of objects, administrator actions, and other security relevant events. The audit record must identify for each event: the date and time of the event, user, type of event, success or failure of the event, terminal, and user identification.

Each sentence is considered a policy statement; however, each policy statement has multiple parts. The first sentence could be accepted in its entirety as a security requirement, or it could be decomposed into the following requirements:

- AUD1—The audit mechanism must be configured to record:
  AUD1.1, Log-on activities
  AUD1.2, Log-off activities

AUD1.3, Object access

AUD1.4, Object deletion

AUD1.5, Administrator activities

AUD1.6, Other security-relevant events

- AUD2—Each audit record must contain:
  AUD2.1, Date of the event
  AUD2.2, Event time
  AUD2.3, Terminal identification
  AUD2.4, User identification

At first glance, the decomposition process seems straightforward, but various interpretations must be considered; for example, does "object access" also mean object creation? This requirement may be interpreted two different ways. First, it may be interpreted that any access that may include the creation of an object must be recorded in the audit record. Second, it could be interpreted to suggest that object access applies only to objects that already exist, excluding the need to record object creation events. This quandary may seem trivial, but a more difficult issue resides in the last requirement.

What exactly constitutes *other security relevant events*? How should this be interpreted? Clearly, an interpretation of these requirements must be made and documented. Documenting interpretations provides subsequent reviewers with the ability to more accurately repeat the tests conducted and understand the reasoning behind the content. Furthermore, it provides consistency within the security tests conducted by different individuals in the same organization abiding by the same requirements.

Another important aspect of policy interpretation is its scope. To what extent should a policy statement span a given system? Returning to our audit requirement example provides us with more points of view to consider in a given system. For example, a system with a Web-based front end for a database has at least four important aspects: network devices such as routers, firewalls, operating systems, and a database management system (DBMS). Each system component indicated may have an audit mechanism capability. With the exception of the workstation and server, each component also has a unique audit format. With regard to the audit requirement, where should auditing be required? Conservatively, each component monitors separate types of events and objects in the system and thus would require auditing at each level. The router logs connections. The firewall monitors ports and protocols. The server handles system authentication, and the DBMS can audit individual record access. Clearly, these diverse components provide a multitude of audit points within the system; however, some may interpret the requirement more liberally to say that auditing is only required on the server because it is the primary mediator for system access.

It is possible that a requirements analysis will reveal gaps in the policy. In this situation, a recommendation should be given to management identifying the issue and proposing a new requirement in the form of a policy.

22.3.1 Grouping Requirements

It is advisable to group requirements according to their focus. Grouping requirements is a way to manage policy statements from diverse sources. A suggested strategy is to group requirements into management, operational, and technical groups:

- *Management*—This group represents those requirements that are primarily people orientated. Management in this sense refers to the nontechnical aspects of people security management. It is, in essence, security management of people and oversight requirements for system managers and owners. Examples of management requirements include security documentation, rules of behavior, and manager reporting and oversight responsibilities. Most of the tests conducted for this group involve interviews and document reviews.

- *Operational*—Requirements involving processes should be placed in this group. Some activities that are security processes include anti-virus signature updates, system backups, patch management, and audit log review and analysis. Testing of operational security requirements should primarily involve documentation reviews and observations.
- *Technical*—The technical group includes those requirements that are product orientated. Security requirements that are directly related to a product configuration or implementations should be in this group. Examples, of technical requirements supported by a system include audit log settings and password expiration settings. Typically, technical and observation types of tests are conducted for this group.

Decomposing requirements takes time, attention to detail, patience, and, more importantly, peer review. Development of a security requirements testing matrix should be a group effort whenever possible. The final product should be supported by upper management.

22.4 Security Test Development and Implementation

Security testing validates a systems conformance with established security requirements. The ultimate purpose of a test is to determine if a control is implemented correctly to support or enforce a security requirement established by policy. Mapping test procedures to requirements is necessary to manage the testing process. One way to do this is to establish a security requirements testing matrix (SRTM). The SRTM is a security requirements management tool that has two parts. The first part is used to manage the life cycle of a security requirement. As requirements or tests change, it is helpful to know the history of a particular requirement or procedure. This can be done through the use of a matrix. The following suggested components of a matrix provide a way of developing a central management repository for security requirements:

- *Requirement number*—Each requirement with a given interpretation is matched to a single test or group of tests.
- *Start date*—Start date is the first date this requirement implementation becomes effective.
- *End date*—End date is the retirement date of the implementation.
- *Supercede number*—This corresponds to an implemented requirement that supercedes this requirement. This date is only entered when a requirement has an end date. Identifying requirement succession provides external reviewers with a record of changes in security management practices.
- *Requirement*—This is the requirement statement extracted from the policy.
- *Primary source*—This is the identification information demonstrating the source of the requirement statement.
- *Related requirements*—This is a list of the locations of related requirements from other sources.
- *Dependent requirement numbers*—This is a list of requirement numbers that would result in an automatic noncompliance if the system is found to be noncompliant with this requirement:
  - *I*—Identifies a test that requires interviews.
  - *D*—Demonstrates the need for a documentation review for the security test.
  - *O*—Indicates that an observation type of test procedure is required.
  - *T*—Technical testing procedures are used to satisfy this requirement.
- *System applicability*—This is a list of system names or identifications that must support the requirement.
- *Interpretation*—This provides an area to record management interpretations of policy statements.
- *Procedures*—This is a list of procedure numbers that must be performed to validate system compliance with the requirement.

The second part of the SRTM is used to manage procedures. Each procedure developed should be tracked in a similar manner as requirements. The following headers are suggested for each procedure tracked in the SRTM:

- *Procedure number*—Each procedure has a given assumption and methodology.
- *Start date*—Start date is the first date the procedure becomes effective.
- *End date*—End date is the retirement date of the implementation.
- *Supercede number*—The supercede number corresponds to an implemented superceding procedure. This date is only entered when a procedure has an end date. Identifying procedure succession provides external reviewers with a record of changes in a security testing process.
- *Requirement numbers*—This is a listing of requirement numbers utilizing this procedure.
- *Test type*—Test type identifies the test as being an interview, document review, observation, or technical test.
- *Assumptions*—This describes any assumptions that are used to validate test results.
- *Methodology*—Methodology provides a detailed explanation of how to conduct the test.
- *Tools*—This is a list of manual or automated tools used to conduct the test.

22.4.1 Developing Test Procedures

Documented security requirements represent a collection of codified controls that a system must support. From this collection a determination regarding a match between existing controls and those identified as security requirements must be made. Testing a requirement may involve one or more tests to validate compliance.

Two important attributes of a well-constructed security test are its repeatability and completeness. These two attributes provide consistency to the testing process. Clear and concise test procedures provide repeatability. Documented procedures should not be so vague as to cause different individuals with varying skill levels to perform the test in different manners. This would likely result in the testers selecting different test points and possibly losing the ability to obtain repeatable results. Likewise, complicated procedures that are difficult to follow may result in similar anomalies. Procedures should be as concise as possible, be easy to read, and accommodate a variety of skill and system knowledge levels of potential testers. Documented procedures should completely test a requirement. It is best to associate only one procedure per requirement. Although this may result in a long procedure, it reduces the likelihood that procedures have dependencies on other procedures. In this case, the testing process may become complicated and cumbersome. In contrast, it is not unreasonable to associate one procedure with multiple requirements. Using one procedure to validate multiple requirements typically occurs with the use of automated testing methods. Lengthy procedures are best kept in separate documents from the SRTM. Simply reference the appropriate procedure document in the SRTM.

When developing tests, some considerations must be given to the resources and tester skills required. Security practitioner labor and tools used for testing and monitoring comprise the bulk of these resources. Security resources are frequently in short supply and must be carefully distributed where they will provide the most effective return. Resources should be allocated according to the results of system risk assessments and the security practitioners' judgment. Areas of a system, as identified in a risk assessment or practitioner experience, deemed to have greater risk should receive sufficient testing to identify any vulnerabilities present. System risk assessments do not always thoroughly examine the people and process aspects of information security; therefore, the security practitioner developing the test procedures must determine the depth and breadth of testing necessary to identify moderate- to high-risk areas. Different procedures require varying skills to perform each task. Procedures requiring specialized skills should be kept to a minimum. This is not to say that they should be avoided, but rather consideration should be given to the possibility that a requirement might be tested without the need for specialized skills. Generally, tests that are complicated and difficult to perform will likely raise costs over time. The skill necessary to perform a procedure is typically related to the test method implemented. Interviews are considered the easiest, whereas some manual and technical methods are the most difficult.

Another consideration in procedure development is the sample size of the test. Sample size refers to the number of like items to be tested. Should a test be done for each point on the system supporting the requirement, or should it be some fraction thereof? For example, testing the audit settings on 100 geographically dispersed servers in a system is likely not too difficult if it can be automated. In contrast, suppose that 15,000 geographically dispersed users are required to acknowledge a security agreement in writing on an annual basis. Reviewing 15,000 signed documents is neither practical nor feasible. In this instance, it is reasonable to select a fraction of the total to obtain a level of confidence regarding compliance with the requirement. No hard and fast rules exist with regard to selecting an appropriate sample size. Indeed, cost is a consideration for obtaining and reviewing the sample. Likewise, the judgment of the security practitioner again comes into play. Generally, management will dictate the sampling size, but the tester should retain the flexibility to select which locations or devices are to be tested. It is advisable to select those areas that are suspected or known to have compliance issues. Alternatively, the areas could be selected at random; however, this may result in missing areas known to have issues. Purposefully selecting weak areas is not considered overbearing but rather identifies weaknesses and provides management with the opportunity to enhance the overall security posture of the system through corrective actions.

The last consideration in test development refers back to the scope of the requirement. Procedures should be specific to the people, process, or product being reviewed. Consider an interpretation of our audit requirement such that it is only applicable to servers, routers, and firewalls. In this case, it will be necessary to have procedures for each type of server, router, and firewall in the system. Each test procedure should be unique to the product being tested; therefore, it is likely that a requirement will have multiple procedures associated with it.

22.4.2 Test Methods

Testing is conducted through manual, automated, and *ad hoc* methods. These methods do not represent the use or nonuse of tools but rather indicate a degree of automation and adherence to predefined procedures. Manual methods imply that a given test is conducted by the evaluator in a step-by-step process. The strength of the manual process is in its thoroughness. Manual tests conducted with detailed procedures give the tester complete control over the testing process. Evaluation of people and processes is primarily conducted through manual methods. The downside of manual tests is the speed with which they can be accomplished. These tests can be labor intensive, time consuming, and therefore costly.

In contrast, automated tests provided consistent and repeatable test methods. Automated tests represent the automation of a manual process. Automated tests provide a high degree of efficiency. Tools used for automated tests may or may not be complicated to configure and operate. In either case, they have the ability to rapidly test predefined controls. Two major issues regarding the use of automated tools could potentially reduce the completeness of a test. First, an automated tool is limited to testing the parameters for which it was designed. Tools with the flexibility to allow user-defined parameters are inherently more complicated to configure and operate and thus are a trade off. Second, it may be difficult to map the use of a tool to all of the necessary requirements. Vulnerability assessment tools should be used with caution. These tools will report items that are not compliant with the rule set used to evaluate the system. In some cases, a tool may identify an open port, protocol in use, or system configuration as a vulnerability when in fact the identified issue is a normal function of the system. Furthermore, identifying the requirements tested with the tool may not be an easy task. Mapping the capabilities of a robust tool to system security requirements can initially be a difficult task. Automated tools are extremely helpful, but generally do not test all of the variations in technical controls present on a given system and require a through understanding of the tool functions as well as the system architecture.

Ad hoc testing is a valuable method of testing. Testers may encounter situations where existing test procedures are inadequate or incomplete regarding a system being evaluated; therefore, it is sometimes necessary to perform additional tests to validate system compliance with the identified requirements. The strength in the *ad hoc* test is evident in the flexibility it provides. In contrast, *ad hoc* testing represents a deviation from established procedures and therefore requires additional information from the tester. The tester should document how the test was conducted as well as the results to retain the repeatability attribute of the test.

22.4.3 Conducting Tests

An ST&E should be performed according to written procedures agreed to by management; however, it is important to be on the lookout for weaknesses in the testing process. Poorly worded, inaccurate, or ambiguous test procedures hamper the tester and reduce the likelihood that the test will be repeatable. For this reason, a tester should not blindly follow a procedure but instead should consider the context of the written procedure and internally determine its sufficiency. Flawed test procedures may introduce inaccuracies or inconsistencies into the testing process. For this reason it is important to correct flawed procedures and document that the changes occurred.

It is likely that a generic set of test procedures will not identify all key testing points for a given system. The tester should be continuously cognizant of the testing process and look for areas that might be missed. For example, a new application recently integrated into a system that opens new ports and introduces new protocols might not be securely configured or implemented. Furthermore, the parameters of the new application may be outside existing security test procedures. Not testing the conformance of the system as a whole to the established requirements is a weakness in the testing process and may neglect to identify an existing vulnerability. For this reason, a tester should be familiar enough with the system to determine if additional procedures should be developed and conducted.

The last step in conducting a test is to document the results. The amount of detail necessary when documenting the result of a test is generally dictated by management. At a minimum, it is advisable that compliance with a requirement be acknowledged as passing and that tests resulting in noncompliance include the actual result of the test. Returning to our previous auditing example, suppose that the host operating system has the capability to audit the use of administrative privileges; however, in our example, the system is configured to audit only failed attempts to use administrative privileges. Although the system is configured to perform auditing of a failed attempted use of administrative privileges, it is not compliant with our AUD1.5 administrator activities requirement. This is because the root of the requirement states that "AUD1: The audit mechanism must be configured to record" and then AUD1.5 identifies administrative activities.

Let's consider a reverse situation. Suppose that in our example the host operating system is configured to audit successful attempts of the use of administrative privileges; however, it is not configured to identify failed attempts. Would this result in a failure? From a conservative standpoint it would not because the system is meeting the minimum wording of the requirement. It is configured to audit successful administrator actions; however, consider our requirement reworded to state "AUD1.5: Successful and unsuccessful administrative activities." Then certainly our latter example would result in a noncompliance because only successful auditing is configured.

In this case, it is clear that high-level security requirements will involve some need for interpretation or assumptions. Organizations can ease this situation by developing system-specific configuration guides. The settings found in the configuration guides are added to the SRTM to provide more precise testing parameters. For technical tests, it is important to have the tests be as technology specific as possible to avoid the preceding situation.

22.5 Results Analysis

In general, four outcomes of a security test are possible: (1) The system complies with the requirement, (2) it does not comply, (3) it partially complies, or (4) the test is not applicable to the given system. A system is said to be compliant with a security requirement when a test is conducted and the system completely passes the test with no issue. A system is said not to be compliant with a requirement when the system in part or as a whole fails a test. Alternatively, a system could be said to be partially compliant when some aspects of the test procedure pass. Suppose one server out of a hundred is not properly configured. It seems more reasonable to say the system is partially compliant as opposed to indicating a complete lack of compliance. Noncompliance should be used in all circumstances when evidence of any compliance with the requirement is lacking; however, use of the term *partially compliant* is left up to the discretion of management. In the course of conducting a test, it may be determined that some requirements do not apply to the system being tested. This is a common situation for some government systems, where systems processing classified information have other requirements in addition to those that process unclassified information.

The identification of people, processes, or products not complying with a security requirement results in a vulnerability. The generally accepted definition of a vulnerability is a weakness or flaw in a system; however, this does not adequately address the issues of failed tests regarding people and processes. With respect to an ST&E, we need to modify the definition of a vulnerability to accommodate the other two aspects of system information security; therefore, vulnerabilities result from misconfigurations, policy violations, and system flaws.

Noncompliance issues identified in an ST&E arise from misconfigurations, policy violations, and system flaws. Misconfigurations are identified when a system clearly does not follow documented configuration requirements. Misconfigurations are product-specific issues. Policy violations could involve all three aspects of system information security. Policy violations from people arise from ignorance, complacency, or disregard for security requirements by users, administrators, or system managers. Products can also have policy violations when they do not have the capability or capacity to support a security requirement. System flaws are the result of design errors in products and processes. Flaws are corrected by reworking the product or process so it conforms to its intended or designed operation. Systems are fixed through product updates or security patches. Processes may require some changes in procedures to shore up any shortcomings; for example, suppose a process of reviewing security audit logs is solely delegated to the administrator of the system. This is a typical situation in small organizations. This situation violates the concept of separation of duties because the administrator is providing security oversight of his or her own activities; therefore, this process or practice is flawed. In this situation, it is not the system that has a security issue, but the process implemented by people that weakens the security posture as a whole.

The identification of new vulnerabilities may impact prior risk and vulnerability assessments. Prior to an ST&E management may have assumed that the system properly supported the necessary requirements. The discovery of new vulnerabilities can radically alter the perception of operating risk of the system. Identified vulnerabilities should be matched against the assumptions and findings of prior risk and vulnerability assessments to reassess the security posture of the system. Vulnerabilities noted that represent significant exposures of the system should be reported to management.

Newly identified vulnerabilities may also have an impact on the security documentation of the system. Vulnerabilities arising from flaws may require system reengineering or design efforts to correct deficiencies. System security configuration and design documents may have to be updated to establish new baselines. The resulting updates to the documentation will likely result in new security requirements for the system.

22.6 Summary

Developing an ST&E involves the collection and analysis of security requirements that affect the people, processes, and products associated with an IT system. Security requirements are gathered from organizational policies, procedures, guides, risk assessments, and system security engineering documentation. Requirement statements are decomposed from the security documentation into individual security requirements. These requirements are further grouped into management, operation, and technical groups. Vague requirements are interpreted for clarification. Each requirement is analyzed to determine the most appropriate type of test to be conducted. Management is notified when requirements are lacking so the gaps can be filled with new policy.

Procedures are developed to test each requirement collected. Procedures should completely test the associated requirement. Likewise, the procedure should be detailed enough to give subsequent reviewers the ability to repeat a test conducted and obtain similar results. Assumptions made regarding each test are documented. Assumptions that are inadequate may necessitate the development of new requirements.

System compliance with identified requirements is evaluated through interviews, observations, document reviews, and technical evaluations. Testing methods include manual, automated, and *ad hoc* processes. The testing process should follow the established procedures. Gaps in procedures or policies are identified and reported to management for appropriate action. Results are documented as compliant, partially compliant, noncompliant, or not applicable. Partially or noncompliant issues occur when a component of the system does not follow policy or is misconfigured or flawed. Resulting vulnerabilities are reported and may require management to provide new policies or guidance to correct the issue.

22.7 Definitions

Applicability—An identified requirement applies to a given system.

Assumption—Assumptions are essentially testing shortcuts. An assumption can serve to reduce the amount of low-level testing detail necessary. For example, viewing the lock on Internet Explorer and the “https” in the address bar is sufficient to prove that a session is encrypted, rather than analyzing network traffic packet headers when observing the handshake process for the Secure Sockets Layer (SSL); however, this may not be the case for other applications that do not provide visual indications that SSL is in use. Assumptions are used to trust that other processes, products, or people are performing other necessary tasks. In essence, making an assumption requires deciding that some other requirement or situation is true or not true.

Completeness—Security test procedures are said to be complete when they fully test a given requirement.

Duplicity—The redundancy of testing procedures; duplicity among tests should be reduced. Tests that satisfy multiple requirements should be identified.

Dependencies—Dependencies occur when a requirement relies on or is subordinate to the implementation of another. This situation usually results in a cascade of failures during security testing. Where dependencies exist, it should be noted so unnecessary tests can be avoided. This will reduce the time required to conduct a system test. Also, the results that cascade can point to the parent test that failed, thus reducing the amount of repetition necessary to account for a top-level failure.

Feasibility—The extent to which a requirement can be implemented by the people, product, or process.

Interpretation—Rephrasing or restating a security requirement such that it is more clear or applicable to the system being tested; aspects of a requirement that may be interpreted include scope and applicability.

Repeatable—The attribute of a security test that allows different testers to reproduce the same or similar results if the test point has not changed.

Sample size—The number of test points selected within a system for a given requirement.

Scope—The depth and breadth of the applicability of a policy or security test.

23

Enterprise Security Management Program

George G. McBride

Before a chapter discussing enterprise security management (ESM) can be written, an acceptable definition must be made as a basis for further discussion. Ironically, this process has turned out to be a difficult one because several different, equally valid, and generally accepted definitions are used in the security industry today. To further cloud the issue, other concepts, systems, and programs exist that are similar in nature and often used interchangeably, such as enterprise risk management (ERM) and security information/event management (SIM/SEM). ERM focuses on the identification, measurement, mitigation, and monitoring of risks in areas such as economic, business, and information technology. As we will see, a valuable input to a successful ESM program is a successful ERM program that provides a majority of the required inputs, such as real-time information regarding the assets and vulnerabilities of an enterprise. Additionally, an SIM or SEM tool is generally concerned with the collection, consolidation, analysis, reporting, and alerting of security-related data such as logs, alerts, and processes. This tool is often the one used to provide the requisite input into the ESM program, as detailed later in this chapter. Some product-based companies offer software systems (or sometimes both hardware and software) based on ESM solutions. These are generally centralized collection and analytical software-based tools that collect security event data from any number of heterogeneous devices. Likewise, consulting organizations offer the development of an ESM-based program that fully introduces and incorporates the ESM system functionality into the security organization.

23.1 Enterprise Security Management Definition

Throughout this chapter, the definition proposed for enterprise security management (ESM) is *a comprehensive, enterprise-wide security management program that supports the protection of assets by collecting, analyzing, reporting, and alerting on critical activities such as potential security incidents and* *security information*. This program includes the composition and structure of the ESM functions, the scope of coverage, roles and responsibilities, governance, compliance issues, use of software-based tools, and relevant metrics to ensure that the program is operating to its fullest capacity. Although an ESM system can exist within an organization without an official program, a program adds value to the ESM system by fully incorporating it into the infrastructure.

In addition to defining ESM, this chapter also addresses why an enterprise may need an ESM system by discussing the drivers behind ESM, the implementation challenges, and some of the traditional goals and expectations of an ESM program. A typical ESM program is also described to highlight the major ESM program elements and how they fit into an organization. Finally, before concluding the chapter, the advantages and disadvantages of a typical ESM program are reviewed to give readers an unbiased view to help determine whether an ESM program should be rolled out in their organizations.

Today, innovative and progressive organizations recognize that risk is not something that must be avoided at all cost but rather something that can be utilized as a business enabler. A company that can accurately measure the level of risk of an application and knows the levels of risk with which it is comfortable can make educated and informed decisions that companies without a complete ESM solution cannot make. For example, a progressive organization may chose to roll out a customer-facing Web portal to provide a service to its customers that no other competitor has provided. Clearly, this service provides an advantage over its competitors, and, if the risks have been identified, measured, and monitored, then the service will not cause everybody in the IT security organization to cross their fingers. Instead, they will understand the balance between business enablement and acceptable risk.

Risk can be thought of as an equation involving just a few variables:

$$\text{Risk} = (\text{Threats} \times \text{Vulnerabilities})/\text{Controls}$$

The threats component is comprised of the likelihood of occurrence and the impact to the asset or to the overall business. Threats are the agents that are capable of affecting an asset (usually negatively). A number of different threat parameters must be considered, including whether the threat is intentional or accidental, logical or physical, active or passive. A vulnerability is generally considered to occur in the absence of effective controls, resulting in exposure of an asset or offering a potential avenue of attack. The controls are the safeguards that are inherent or built into an asset to provide protection against threats by mitigating the vulnerabilities. Assets can include a server, an application, a critical business process, a building, intellectual property, or the corporate plane.

As mentioned before, companies today should not attempt to drive the risk of an asset or business process down to zero but instead should drive the risk down to at or below an acceptable level of risk. This reduction of measured risk can be made in any number of traditional ways, such as mitigation, transferal, or removal of the asset. The acceptable level of risk has many factors, such as:

- The corporation’s reactions to previous security-related incidents or the perceived reaction based on company stature, industry, or visibility
- Regulatory and legal restraints, such as Sarbanes–Oxley or Gramm–Leach–Bliley, that limit the risk an organization may take
- Corporate image and the effect a negative (or potentially negative) event would have on the organization
- Organizational and personnel risk tolerance, which may dictate or influence the amount of risk an organization is willing to take

If a company can measure the risk of an asset (such as a Web server) and has determined what the corporation’s acceptable level of risk is, an educated decision can be made as to whether or not the device should be deployed. Neither the measured level of risk for an asset nor the acceptable level of risk for that asset can be determined in an afternoon; however, they both can be measured, albeit qualitatively, to allow educated comparisons and decisions to be made.

23.2 The Need for Enterprise Security Management

Levels of risk are continuously changing, as every enterprise is a dynamic entity with controls being added and deleted, ports in the firewalls being opened, services and systems being added, architectures being redeveloped, and acquired companies being added to the network. Additionally, vulnerabilities and threats, introduced external to the organization, will affect the level of risk of an organization and must be captured and measured. Rather than measure the risk of each asset every time the infrastructure changes, an ESM program incorporated with an ERM program can provide that functionality almost continuously based on the inputs that the system receives.

The continuous availability of updated data positions the ESM system to serve as an optimized dashboard of the company's risk posture. In fact, the dashboard function is often one of the most compelling business advantages to an organization when considering the deployment of an ESM program. In addition, the security and risk posture can be used to measure compliance with a number of regulatory and legal requirements such as:

- The Sarbanes–Oxley Act, which requires an annual assessment of internal controls over financial reporting systems
- The Health Insurance Portability and Accountability Act (HIPAA), which applies to all healthcare providers, as well as payment and clearing centers, and ensures the confidentiality, integrity, and availability of ell electronic personally identifiable health information
- The Gramm–Leach–Bliley Act, which applies to any company regulated by the U.S. Office of the Comptroller of Currency and ensures that financial institutions ensure the security and confidentiality of customer personal information against "reasonably foreseeable" threats
- The European Union (EU) Data Protection Directive, which stipulates appropriate technical controls to protect against personal data loss, modification, access, or disclosure of data that flows among EU states

Assuming that proper, accurate, and complete inputs are part of the ESM program, the system can provide a number of different parameters to help determine the security posture of the individual assets as well as holistically across the entire company. By having a complete picture of its security posture, an organization can monitor and measure its compliance with regulatory, legal, and industrial compliance issues.

23.3 Enterprise Security Management Challenges

A successful ESM implementation is not without its challenges. ESM programs are solely dependent on the input data that arrives through a number of systems and programs that support the programs. The first two challenges listed below refer to specific system-based challenges, and the third challenge is one that may affect a typical ESM program:

- The proper sensors are incorporated in the ESM architecture.
- The proper data is collected from the sensors.
- The proper actions are performed based on ESM output.

Just as the saying goes, "Garbage in, garbage out." As with any enterprise-wide implementation, the data that is processed, analyzed, reported on, and sometimes alerted on is only as good as the data that has been received. In general, ESM solutions deploy sensors (also called collectors or agents) at various network segments that have been reviewed and identified as critical.

Enterprise security management sensors can utilize proprietary collectors; they can be integrated with existing collection devices such as intrusion detection system (IDS) units, firewalls, and hosts; or they can be hybrids of both. In any event, it is as important to capture the required information to identify and process incidents as it is to transmit the minimal amount of data from the sensor to the server or console. It is not uncommon to generate thousands of events per second (EPS) in a typical environment. Forwarding all of the alert data from a sensor to a server will reduce the EPS because the network will quickly become saturated and normal business traffic will be impeded. It is equally important to ensure that the required information is captured by the ESM to be analyzed. Not providing the requisite data to an ESM system is equally detrimental, as incidents may not be detected and investigations may not have all of the data that is required.

One of the most important aspects of the data forwarded from the sensor to the server is that something must be done with that data. Although this sounds obvious, too many times the proposed solution forwards data to a collector that will never be reviewed or be included in an investigation. For example, if the system is transmitting all internal successful File Transfer Protocol (FTP) transfers from a critical server but is only generating an alert on the fifth unsuccessful log-on attempt, why transmit the successful transfer data to the server? Only information that will be used as part of the ESM monitoring or alerting should be transmitted, as the other data is best suited to remaining local. Today's advanced ESM systems can pull the data automatically later or the incident response team can obtain the data manually later.

The types of sensors, locations, data collected, and alert triggers all factor into the false positives and false negatives generated. False positives identify actions that are not truly security incidents and, by doing so, can reduce the alertness of the incident response team. False negatives are valid security incidents that are not detected. Through sensor and analysis tuning, analyzing past performance feedback, and adjusting alerting triggers, the false positives and negatives can be managed.

23.4 Enterprise Security Management Components

As mentioned previously, a successful ESM solution is comprised of two integral and related components. A software-based solution is generally used to receive, analyze, report, and alert on the data, and the ESM program complements the system by defining staffing, roles and responsibilities, metrics, etc. Although an ESM system will provide an advantage over an organization that does not have one, the true differentiator will be an effective ESM program that allows the organization to fully leverage the system. This section discusses both the ESM program and the system.

Before an ESM program can be deployed, a risk assessment of the enterprise should be performed. This assumes that a risk management program, a critical and required component of any ESM program (and the introduction of which could require an entire book), is in place within the organization. The risk management program, which includes the identification of assets, the identification of the risk equation components, the measurement of risk, and determining how the risk is managed, is a formal program that should also detail governance, roles and responsibilities, organizational structure, metrics, etc. Through the risk assessment, a comprehensive view of business operations as well as the physical and logical infrastructure can be developed. As part of the risk assessment, the critical assets and business processes are identified, and the assets that require protection are prioritized. Likewise, the risk assessment identifies the threats and vulnerabilities that must be protected against by the ESM program. This often overlooked but critical step will often help develop the requirements of the ESM system, as a particular ESM system may have certain strengths regarding particular threats and vulnerabilities that other systems may not have.

This review process should be a collaborative effort that includes business units, information systems (IS), information technology (IT), IS/IT security, the compliance officer, and the chief security officer, as well as the incident response and forensics teams if they are considered separate entities. The goal of the sensor placement exercise is to ensure that a significant majority agree on where the critical assets of the enterprise exist (assuming that everyone knows what they are), where high-risk network segments exist, and where gateways exist.

Additionally, as part of the ESM program deployment, the organization should take the time to update (or create) a security roadmap. The roadmap is a forward-looking plan that identifies the types of assets within an organization that must be protected against evolving threats and vulnerabilities. The roadmap also highlights how the security organization will evolve and adapt to meet those threats and how the ESM program will be incorporated into the enterprise.

23.5 Enterprise Security Management System

No single ESM architecture works better than any other ESM architecture for every organization. When an organization's requirements have been identified, the organization will be able to reach out to the various ESM vendors to determine which architecture is the best fit for that particular enterprise. When developing the ESM system, it is important to understand how it will fulfill the requirements of the ESM program. Whether the ESM system drives the program or *vice versa*, the two are tightly coupled, as we will see in the next few sections.

As part of the data collection process, data collectors are dispersed throughout the network. These collectors include such network elements as:

- Firewalls, including desktop and gateway
- Routers
- Critical servers, such as Web servers, application servers, and transaction servers
- Network and media gateways
- Intrusion detection systems (IDSs) or intrusion prevention systems (IPSs)
- Authentication servers
- Anti-virus consoles and desktop engines
- Pure "collectors," which act as network "sniffers"

These collectors can push the data to an intermediary collector, or the data can be pulled by the collector. In a smaller environment, only a few collectors within the enterprise may receive and process data. In a larger environment, the hierarchical architecture may include numerous collectors. Generally, at some point is a centralized ESM manager, which is remotely accessed through an administrator graphical user interface (GUI) or via a Web-based interface. Although every solution may propose a different architecture, redundancy and minimization of data transfer are two key goals of an ESM solution.

As such, data retention and available network bandwidth generally stipulate where the complete set of data will remain. Although having a centralizing collector to store all of the event data is preferable from a backup perspective, available network bandwidth may prevent thousands of collectors from sending information to a single point. As such, intermediary collectors are generally utilized and serve as a focal point for data collection and backup.

Several particular features of any ESM system under consideration by an enterprise should be part of the evaluation criteria. Optimally, these features should be considered requirements to the solution to ensure that it can grow as the enterprise grows. These items are detailed below.

The ESM manager should provide for multiple levels of user roles, such as administrator, analyst, investigator, IT staff, and IT/IS security. Following the concept of least privilege, only the minimal information required for each role to complete its task should be displayed. Likewise, modification of data should be restricted by technical mechanisms, and cryptographic hashes or checksums to identify any modified data should be utilized. Should the need for a forensics investigation that ultimately makes it to the judicial system emerge, this requirement will prove essential to ensuring that no data has been tampered with.

The architecture should be scaleable to grow with the enterprise's never-ending changes through acquisitions, divestitures, adoption of new technologies, and the retirement of old technologies. The architecture should also be scaleable through bandwidth growth to incorporate emerging technologies such as gigabit Ethernet, Intelligent Multimedia Subsystems (IMSs), and Voice over IP (VoIP). Likewise, the solution should provide for timely and rapid deployments and integration of sensors into the ESM infrastructure.

Management consoles sometimes require additional resources above and beyond what is required by the vendor. For example, hidden costs may be associated with the use of storage devices, such as storage area networks (SANs). Although quite expensive to deploy, a SAN provides an effective mechanism to store the large volumes of data that will be collected. Whether or not a SAN is used, data storage and data backups must be considered when identifying the requirements. Likewise, some vendors may choose to utilize a back-end database that is not fully supported by the vendor or may not have the full capacity and processing capabilities of the full product suite. In certain events, it may be necessary to obtain the enterprise version of certain products to fully support and maintain the ESM system.

The architecture chosen should be able to support the growing trend to deploy security operations centers (SOCs) managed internally and through third parties. An optimal solution, but perhaps not a requirement, would be integration with a trouble ticketing system to address any issues or anomalies that are detected. With true integration, the tracking of incidents from detection to resolution can be managed from a single platform and will simplify the collection and generation of metrics data.

The architecture should be technology and vendor neutral to be able to optimally mix vendors' equipment and provide a best-in-class solution in a heterogeneous environment. The best ESM solution should be able to aggregate data from any sensor capable of providing relevant data. The solution must be able to satisfy any requirements regarding how quickly alerts are generated after a suspicious activity is recorded. Finally, an organization may require that particular types of alerts be automatically squelched after surpassing some threshold.

The ESM console should have an efficient solution to provide for backup capabilities to support any ongoing or future forensics investigation needs. The solution should provide for data retrieval and playback in the familiar console format. Additionally, data retention should meet or exceed any regulatory compliance or industry best practices while still complying with any corporate policies.

One of the most significant benefits of providing a holistic perspective across the enterprise is the ability to normalize the data that is aggregated. The ESM system should be able to normalize the data over the enterprise to adjust alert reactions as the implementation scope increases and the threat environment changes. Additionally, the reporting functions should be granular enough to provide for administrator override when it becomes necessary to focus on particular network segments, threats, or alerts.

23.6 Enterprise Security Management Program

The ESM system is only one piece of an effective ESM program. In order to effectively leverage that system, a program should be implemented that includes the following:

- Program charter
- Governance
- Implementation (as required) and integration with other programs
- Organization roles and responsibilities
- Regulatory and compliance reporting
- Metrics
- Enterprise security policy

The ESM program charter should be typical of other organizational and program charters that already exist within the organization. For example, the charter will define the governance requirements, the organizational structure and roles and responsibilities at a high level, and interfaces of the ESM program such as human resources or other IT organizations. Additionally, the charter may be used to introduce the program and its role and responsibilities to the organization and the corporate board. It defines the purpose of the ESM program, how it will support the organization, and the authority that the ESM program has to carry out its mission.

The governance of the ESM program depends on how the program is managed within the organization. Governance ensures that the program is administered properly, that the appropriate persons are doing the appropriate activities, that the program is efficient and effective, and, to an extent, that the program provides some value to the organization. For governance to be effective, it should be managed from outside of the ESM program, perhaps by the chief risk officer, chief security officer, or chief information security officer.

It is important to ensure that certain programs within the enterprise are reviewed and integrated with the ESM program as applicable. Although the incident response program may be an obvious program to integrate with the ESM, integrating the change management and configuration management programs may not be as obvious. By integrating the change management program, changes to the infrastructure will be noted and will not create any false alarms. Likewise, any infrastructure changes documented in the change management program can be incorporated immediately into the ESM program. An effective configuration management program will allow the ESM program and personnel to know the exact configurations of any assets under question to understand if risks are applicable given its current state. Finally, the risk management program is a critical and essential component of any ESM program.

Other enterprise wide programs should be integrated into the ESM program. An effective patch management system requires accurate asset inventory and configuration management components to deploy the appropriate patches, hot fixes, and updates to systems as required. Like the configuration management database, all of these programs can share a common asset database, configuration management database, and change management database as centralized repositories.

It is important to note that these other programs (e.g., risk management or change management) can feed data to the ESM program, and in turn the ESM program can provide data and support to the other programs. Whether through maintaining a centralized repository or data feeds, each program can support the others to create a system of checks and balances to ensure an accurate repository within the enterprise.

The ESM program should highlight the roles and responsibilities of those that manage and support the program. This may also include the roles that are required, how many people are required in each role, and the job descriptions and responsibilities for every role. Initial and ongoing training requirements should also be specified, as well as an organization structure that highlights the reporting hierarchy and includes persons outside of the formal ESM program who are still part of the infrastructure (e.g., IT, forensics team). Each position from ESM analyst to director should be detailed.

The actual organizational structure will be highly dependent on the infrastructure of the enterprise, including its size, complexity, and scope. Typically, several analysts are used to monitor system consoles, receive alarms and alerts, and support the help desk. The primary responsibility of a tier II or tier III analyst may be to review tickets and issues that cannot be immediately resolved and interface with the IT/IS security personnel, the forensics group, or the incident response team. As part of this effort, IS/IT support personnel may be tasked to provide support to temporarily extend logging capabilities, install network sniffers, or provide expert guidance on the identified traffic.

Depending on the size of the organization as well as the monitoring times (e.g., 24/7 or Monday through Friday 9–5), some managers may be required to support the analysts. Likewise, these managers may report to an ESM director who may then report to the chief security officer, chief information security officer, or the director of IT security. Depending on the existing structure, the ESM director may have additional support staff as direct or dotted line reports.

Additionally, due to the sensitivity of the data managed by the ESM organization, additional physical security requirements may be required, such as the use of a separate room with additional card-key access requirements, and permanent IS/IT personnel may be used to support the program. Furthermore, the ESM systems will house some of the most sensitive information regarding such as attacks, vulnerabilities, and risks. It is imperative that IS/IT security be involved with the ESM system requirements, evaluations, trials, and deployment to ensure that all security issues related to the ESM system are mitigated prior to deployment.

As part of an organization's compliance with acts such as Sarbanes–Oxley and Gramm–Leach–Bliley, organizations may be required to prepare certain documents for the auditors. Although some higher level audits may be satisfied with organizational structure charts and a cursory review of the policy framework, other audits and compliance reviews may require additional details and inputs into the program. As an example, certain firms may be required to produce documentary evidence of any intrusion detection attempts and their process to follow the investigative process through to and including notification of the offender's Internet Service Provider (ISP).

Metrics, or the measurements of certain parameters of the program, are necessary for determining the effectiveness of the program, identifying areas that require improvements, and detecting any overall trends that may not be noticed in everyday operation. In general, a commonly accepted practice is to generate only actionable metrics; that is, the metrics will identify areas that may be of concern so the appropriate changes can be made to improve the program. Metrics should be simple, and this is where a dashboard approach is better than a detailed in-depth analysis. Typical ESM program metrics will differ based on architecture and program maturity. For example, during the ESM system roll out, a metric may be the number of collectors deployed, whereas a more mature program may include metrics such as the number of events detected, number of false alarms, and number of events closed by tier I personnel. As part of the governance program, the ESM-based metrics should be regularly reported to the governing body.

The final key component of the ESM program is an enterprise security policy that is able to support the program. An effective security policy should address what must be done within the organization, how often it must be done, by whom, how it is to be done, and why it must be done. The policy must be written by somebody who understands the organization, the types of users within the organization, the industry in which it is competing, and, most importantly, the goals and mission of the enterprise. Any external drivers—regulatory, industrial, or legal—both current and pending should also be considered. The policy must be well defined in scope up front to set any expectations, and it should explicitly detail what information will be found in policies, standards, practices, and procedures. Also, the policy must be written with the thought of the standards, practices, and procedures logically falling into place in a hierarchical manner.

The policy must be readable and available to the population in the enterprise that needs access (usually everybody), and it should have a formal version control and back-up system. The policy should have the buy-in from key business unit and corporate center personnel and should have a formal documented process to address any changes or updates, as the policy documentation framework is a living document that has to be updated as technology changes.

To ensure an effective, enforceable, and applicable policy framework, the policy development team must be composed of persons who are intimately familiar with the enterprise, architecture, business, and technology. When the policy framework has been drafted, reviewed, and approved, the policy team or an awareness team must then promote the awareness program policy throughout the enterprise. This promotion should include a general population program as well as a targeted approach to raise awareness in certain roles, such as system administrators and security personnel.

23.7 Enterprise Security Management Advantages and Disadvantages

Deploying an ESM solution has its advantages and disadvantages. Spanning the personnel, technical, and business realms, this section highlights some of the pros and cons an organization must be aware of when considering the deployment of an ESM program. The ESM system generates a tremendous amount of information through reports and a number of different types of alerts, all of which require different reactions. Without an adequate program in place to manage those alerts, an organization will be quickly overwhelmed with data and alerts that must be addressed immediately. A true ramp-up process will give an organization the opportunity to manage the frequency of alerts, how they are managed, what actions to take when a true security incident is detected, and how the reports can be used to increase efficiency.

The organization that is tasked to manage the ESM system and program will require additional resources to support the efforts. ESM systems require a significant initial capital expense (e.g., several hundred thousand dollars) for a global enterprise rollout. Factor in yearly maintenance and upgrade costs, and the cost increases significantly, and the personnel costs attributable to the ESM program can exceed the system costs.

The ESM system will require tuning that can only take place within the infrastructure where it is placed. Although vendors can recommend settings and provide guidance on the tuning process, only when the equipment and personnel are in place can the system be tuned to manage, for example, alerts, false positives, and automatic trouble ticketing.

The ESM system should provide for a number of different methods of alerting and reporting depending on the frequency and type of incident detected and recorded. Although these are highly enterprise specific, some general guidelines usually fall into place. For example, almost all security incidents are logged. This ensures being able to identify where an incident occurred, when it occurred, and any other incidents within some agreed-upon period. Although some of the more advanced sensors have long-term memory that allows them to recall identical (or similar) incidents within a longer time frame, such as several weeks, most normalize over a period of several days and may miss some of the more determined malicious users whose primary mission is to avoid detection, not complete the job quickly.

Determining which incidents actually generate an alert is a difficult task. Two approaches to where to start are (1) alert on almost nothing and increase alerting as time goes on, or (2) alert on almost everything until the false positives are removed or the incident response team collapses. The first alternative—alerting on nothing initially and closely monitoring the console for some period of time—is probably preferable. After reviewing baseline traffic (being careful not to baseline malicious traffic), alerts can be added based on malicious traffic that is not normally seen after investigating some of the malicious traffic that may be fairly regular in the enterprise.

When the organization supplies the required time, resources, funding, and personnel to support the ESM system, some tremendous benefits will be realized and will continue to grow as the organization becomes familiar with the ESM system operation and benefits. The ESM program will reveal the real-time, dynamically updated risk posture of the organization. With the proper reporting tools, the risk posture at the asset, business unit, regional, and corporate level can be part of the dashboard to quickly identify hot spots and areas that require additional controls or other corrective actions. Also, the ESM system can identify network bottlenecks, faulty devices, and other poor configurations that may be adversely affecting network performance.

Finally, through proper operation and management, the ESM program allows an organization to manage effectively the overall risk of that organization and its assets and business processes and to make educated decisions with regard to what controls to deploy, what systems to implement, and what corrective actions must be taken. As a business enabler, the ESM program provides an advantage over organizations that cannot dynamically measure their risk as they deploy new services and applications ahead of their competition.

23.8 Conclusion

No "silver bullet" can eliminate the security risks of an enterprise, and no package or program can automatically mitigate every identified risk, but an effective ESM program will allow the enterprise to make educated business decisions and manage risk within an acceptable risk range. Although that single advantage often justifies the expense of the ESM program, it is not the only one, as other advantages include the security management dashboard and a holistic view of the risk components that can secure an early return on investment for the organization. Finally, no program with such tremendous benefits can come without a proportionate demand on effort, resources, and funds. To design and implement an effective ESM program, additional personnel will have to be hired and trained, systems purchased, programs developed and integrated, policies updated, and more; however, for those corporations willing to make the commitment, the benefits, return on investment, and increased security will clearly become business differentiators.

24

Technology Convergence and Security: A Simplified Risk Management Model

Ken M. Shaurette

24.1 Introduction

How do we balance the correct amount of security with the appropriate use of technological solutions? Every industry today from consulting to manufacturing, finance to healthcare is witnessing the convergence of technology. Banks are doing away with paper check reconciliation, replacing it with scanning or imaging canceled checks to reduce physical storage requirements and mailing costs to customers. Hospitals are using radiofrequency identification (RFID) and bar code scanning to match prescriptions to the correct patients to reduce medication errors. Educational institutions are populated with students carrying laptops, and some schools have even gone as far as issuing IP-based phones to their students as part of their residency on campus. They can use the phone for making calls anywhere on campus, as though they were in their dorm, as well as access directories and specialized Web applications. The increased productivity, cost savings, and even life-saving opportunities that the convergence of technology is making possible are very exciting but also very scary.

Someday we might hear: “Oh, no, someone hacked my grade book from my cell phone!” Already, in 2005, we have seen cell phones hacked (*e.g.*, one owned by Paris Hilton), and a BlueSniper rifle demonstrated at Defcon Las Vegas in 2004 is able to extract information off vulnerable Bluetooth-enabled cell phones. Or, we might someday hear: “Oh, no, someone hacked my cell phone from my grade book!”

24.2 The McDonald’s/Burger King Mentality

Why do I bring all this up in a chapter about a risk analysis model? Consider the convergence of technology and ease of use we are experiencing in technology today. Technology has created a dependency, a requirement beyond just a nice-to-have situation. This dependency and craving or starving for technology have a cost that goes beyond just the dollars and cents to purchase the cool new toys. Demand is driving access anytime, anywhere and an “I want it now” attitude among the user communities. I call this the McDonald’s mentality, because we no longer have any patience; we expect it fast just like we expect our fast food. Why McDonald’s? This social change brought on by the immediacy of going to fast food restaurants has caused us to want *everything* quickly, not just our Big Mac. We expect fast food on every corner, and now Burger King has introduced the concept of being able to have it our way, so we expect quality as well. Similarly, we are beginning to expect split-second response time on our networks and access to e-mail and the Web in airports and hotels, even as we walk down the street. We have Web-enabled phones and personal data assistants, and when our reception is bad we are not very patient with our service companies. The ease of using these technologies has rapidly improved in the last few years to meet consumer demand. On the flip side, we must consider the impact of this convergence of technology on our demand for the latest and greatest. Some examples would include 911 systems being hacked or the posting of personal telephone numbers from Paris Hilton’s cell phone. Theoretical challenges, such as the example of the grade book being hacked from a cell phone, must be addressed. How do we as organizations gauge our levels of risk? What can we do to manage risk? Is there an easy way to determine how much risk we have and what impact we can make by managing the risk?

24.3 A Prediction

Before jumping into my simplified illustration of risk, let’s first talk about a prediction made by Gartner in 2002. Gartner stated that 75 percent of organizations that fail to plan and build a secure infrastructure will have at least one security breach in the next five years that will disrupt strategic services. Mark Chapman, former Director of Information Security for Omni Corporation of Pewaukee, WI, and I modified that prediction a bit in a presentation for the Ohio Higher Education Conference (OHEC) that same year. We stated that *all* organizations that fail to plan and build a secure infrastructure will have at least one security breach in the next five *months* that will disrupt strategic services. I think history shows that our modified prediction was actually more accurate.

24.4 Convenience

What happens to confidentiality, integrity, and availability (CIA) as convenience increases? The CIA security triad, as it is often referred to, in my opinion circles around liability (see Exhibit 24.1). A lack of diligence and adequate management of risk increases liability because each element of the triad is impacted. This lack exposes data to disclosure, affecting privacy (the confidentiality element). It exposes the data to inappropriate modification, bringing to question the integrity of any information. Finally, either the overall vulnerabilities in systems and their data expose them to undesirable things, such as

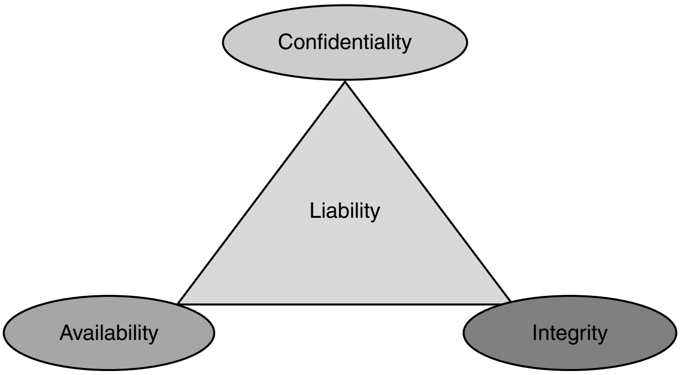

EXHIBIT 24.1 The CIA security triad and liability.

malicious code, or the systems that are not patched risk their data not being available when access to it is desired.

24.5 Risk *versus* Convenience

Lack of diligence and attention to security will result in an inadequate amount of appropriate security controls, which increases liability. The legislation passed in recent years represents an attempt by the government to force companies to implement reasonable controls or face liability. Sarbanes–Oxley, the most recent legislation, directly holds chief executive personnel responsible and as a result liable for inaction regarding ensuring that proper technology controls are in place. The federal organizational sentencing guidelines were updated in 2004 to better account for technology, specifically identity theft. Convenience often has a very direct impact on risk (see Exhibit 24.2).

Six components are illustrated in this risk analysis model, and each can have a very dramatic effect on risk. The model is divided into two categories, each containing three of the components. The *risk management* portion includes those components that help manage risk—security awareness, security spending, and the acceptance of security by the user community. To understand this relationship, refer to Exhibit 24.3. The *risk factor* portion also has three components—embracing technology (leading edge), threat exposure, and asset value (or what the information assets are worth). For our simplified risk analysis, we will use a numeric scale of 1 to 3 for each of the six components. We will begin our discussion with the risk factor portion of the model.

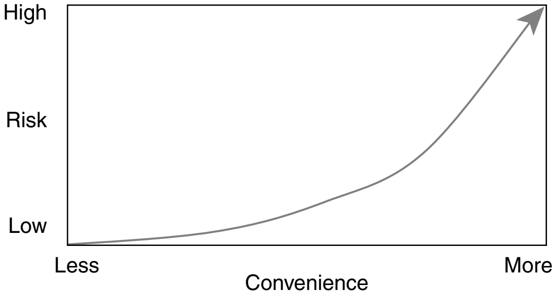

EXHIBIT 24.2 Convenience with a direct impact on risk.

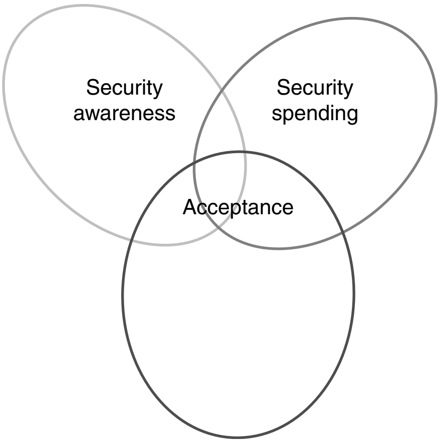

EXHIBIT 24.3 Security awareness, security spending, and acceptance of security.

24.6 Risk Factor

24.6.1 Embracing Technology

Does your organization rush out to buy the latest and greatest of new technologies, or does it still use those green/amber screen terminals from the 1980s? Many organizations are seeing an increase in the advancement and adoption of new technology by their user communities. Many systems and network administrators are finding themselves faced with departments that have decided they require new technology in their area, both hardware and software. This is very often the result of a great job of sales by some vendor who has convinced them that they need a particular technology that will provide some immediate benefit. Another potential situation is that personnel have heard about this new technology from their peers and just think it would be cool to use. If your organization finds itself often getting into the newest, latest, and greatest technology as an early adopter, give yourself a value of 3 for your embracing technology component. If you find that everyone is still doing it the way they've always done it, then give yourself a value of 1. If you feel that your organization is in the middle of the pack with regard to adopting new technology, neither early nor late, use a value of 2 (see Exhibit 24.4).

24.6.2 Threat Exposure

The next component in the risk factor is your organization's level of threat, vulnerabilities, or exposures. How likely are you to be attacked? Does your organization deal in extremely valuable materials or is it perhaps an organization that works with controversial chemicals? Perhaps your organization's name is well known and viewed as a target for malicious activity. Educational organizations, as an example, could find themselves exposed due to, for example, the courses offered, the mix of students, research grants, size, visibility, or maybe even tuition. For an organization that believes it is greatly exposed, give yourself a value of 3, a value of 1 if your organization is not very highly exposed, or a value of 2 for something in between (see Exhibit 24.5).

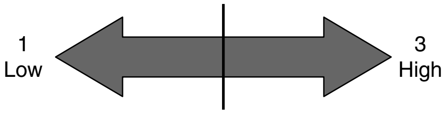

EXHIBIT 24.4 Is your technology on the leading edge?

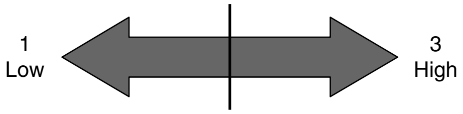

EXHIBIT 24.5 Threats: how exposed is the organization?

24.6.3 Relationship

What is the combined effect of your scores? Your leading edge or embracing technology score (1, 2, or 3) and your threat exposure score (1, 2, or 3) can often be changed by making modifications in your organization. What impact or potential impact might there be on your organization if it always uses the newest in technology and is also a very high-profile organization. Maybe that latest in technology is what makes the organization a desirable target, or perhaps using that new technology, which has not been in the industry long enough for the bugs to be worked out, has created a greater chance for your organization to be attacked.

24.6.4 Asset Value

The next aspect of this analysis is one that often cannot be changed to improve or affect the risk factor. That component is asset value. Think about this in very simple terms. Take into account the value of your organization's information assets from the perspective of the CIA triad. How valuable would your customer list be if stolen? Do you maintain research data or other proprietary formulas that, if modified, would greatly impact your business? Would an outage involving some of your organization's most critical systems, such as an Internet E-commerce Web site, jeopardize company finances or its ability to conduct business? Perhaps just having your network unavailable for a significant time would impact your customers. Also, think about the liability that might be associated with the confidentiality, integrity, or availability of those assets. Once again, give yourself a score of 1, 2, or 3 to represent the value of your information assets, where 1 represents low-value assets and 3 represents high-value assets (see Exhibit 24.6).

24.6.5 The Risk Factor Equation

This model makes it very easy to establish an organization's risk factor. Simply multiply your embracing technology (*ET*) or leading edge score (1, 2, or 3) by the exposure threat (*T*) score (1, 2, or 3) and by the asset value (*AV*) score (1, 2, or 3). The resulting number is your risk factor, or *RF*:

$$RF = ET \times T \times AV$$

The maximum possible risk factor would be 27. This number is a representation of your organization's risk. Now let's shift into how well we are doing as an organization to manage that risk.

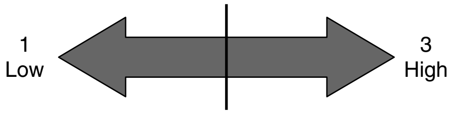

EXHIBIT 24.6 How valuable are the assets?

24.7 Risk Management

24.7.1 Security Spending

First, let's begin by giving your organization's security budget a value of 1, 2, or 3. This value should represent how willing management is to budget adequate funds for security (1, willing; 3, not very willing). Do they provide a sizable budget to handle most things that come along, or are they conservative, believing that security is not all that important? (See Exhibit 24.7.)

24.7.2 Security Awareness

Now let's account for the level of security awareness in your organization using the same scoring system as before. Choose 1 (very aware), 2, or 3 (not at all aware) to represent how aware or not aware users in your organization are of the importance of protecting information (see Exhibit 24.8).

24.7.3 Acceptance of Controls

This aspect of risk management can be helped by increasing security awareness. An effective awareness program can help to improve acceptance of security controls by people in the organization. Security awareness has become a component of holistic security programs that require more focus than in the past. Regulations such as the Health Insurance Portability and Accountability Act (HIPAA) have specifically identified awareness as a required element for regulatory compliance. For years, security awareness, although identified in every complete security program, was never given the funding or attention that it deserved. Too often, the individuals most involved with security would look for technical controls they could implement, and it was not uncommon to hear system administrators complain about how stupid their users were because they could not even follow simple instructions to change their password or remember the new passwords when they did change them.

Finally, whether because security programs have managed to obtain all the security technology they needed and have gotten it implemented or because the new regulations have actually been able to put the necessary emphasis on awareness, security awareness programs have become a critical component of information security. These programs are educating users throughout the organization not only on the importance of policy but also how to interact or better leverage technology-based security controls. Simple controls, such as choosing a good password, or more complex requirements, such as knowing how and when to encrypt confidential data or to deal with e-mail attachments to avoid scams such as phishing or pharming, are required. *Phishing*, as defined by Webopedia, is "the act of sending an e-mail to a user falsely claiming to be an established legitimate enterprise in an attempt to scam the user into surrendering private information that will be used for identity theft." *Pharming*, by comparison, is similar but, as defined by Webopedia, it seeks "to obtain personal or private (usually finance-related)

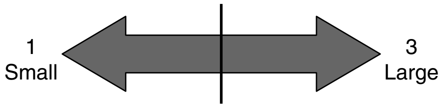

EXHIBIT 24.7 How large is the budget?

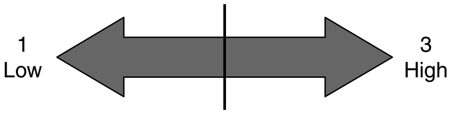

EXHIBIT 24.8 How security aware are your users?

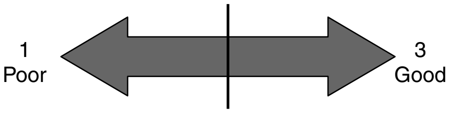

EXHIBIT 24.9 How well are security controls accepted as a requirement?

information through domain spoofing." Rather than spamming with malicious and mischievous e-mail requests to visit spoof Web sites that appear legitimate, pharming poisons a Domain Name System (DNS) server by infusing false information into the server, resulting in a user's request being redirected elsewhere (see Exhibit 24.9).

24.7.4 The Risk Management Equation

How you can effect a change in the management of risks to data in your organization is a factor of accepting the technology-based controls and policies and being more security aware:

$$RM = SA \times CA \times B$$

where *RM* is risk management, *SA* is security awareness (1, 2, or 3), *CA* is controls acceptance (1, 2, or 3), and *B* is the budget (1, 2, or 3). The result of this equation is a numeric value from 1 to 27 that illustrates how well an organization is managing risk. Exhibit 24.10 provides a sample matrix of risk factor and risk management.

24.8 What To Do?

An organization has several options. For years, executives used a "bury their heads in the sand" technique. They often figured if they did not know about security issues, they could avoid fixing them or could even ignore their responsibility to budget for and fix them. This often made it very difficult to get a vulnerability assessment or overall security risk assessment completed in an organization.

The events of September 11, 2001, changed that forever. The tragedy of that day woke up the world to the importance of security in our airports. The importance of having disaster recovery plans became apparent, but most importantly that day created an awareness of and alertness to security vulnerabilities like no event ever before. The issues of not just the physical aspects of security, which were compromised by the terrorists, but also the vulnerabilities that exist in every organization's information security or cyber security are written about in nearly every issue of any technology trade magazine. Prior to that tragic day, the attention and awareness given to security were not nearly as great as after. This more than anything has made it impossible for organization executives to plead ignorance regarding the importance of security and their direct responsibility for due diligence to ensure adequate controls in their organization.

EXHIBIT 24.10 Risk Factor and Risk Management Matrix

Risk Factor	Value	Risk Management	Value
Embracing technology	3	Security spending	2
Threat exposure	2	Security awareness	2
Asset value	3	Acceptance of security controls (buy-in)	1

An unrealistic alternative for improving our risk factor is to go back to pen and paper and manual methods that existed before the technology and the convergence of technology that exist today. Or, we could simply accept the risk as a cost of doing business. Organizations accept risk every day, but it is still necessary to identify, categorize, and prioritize the risk. Vulnerabilities in systems and networks can be identified by implementing a vulnerability assessment. Such an assessment can also categorize vulnerabilities as high, medium, or low risk. When the risks are known and categorized, they can be prioritized by identifying the ones that require more immediate attention *versus* those that can wait or maybe can be accepted. When accepting a risk, it is important to document the decision to assume that risk and the justification for doing so. This documentation will be critical in an audit and in demonstrating diligence in making a conscious business decision to manage this risk.

Not yet popular would be a process for handling risk known as transferring the risk, also known as insurance. The statistical sampling of cyber security events and loss is insufficient for insurance company actuaries to be sure how to set a reasonable premium to insure against these kinds of events. Premiums tend to be too high for most organizations to justify when they can find this insurance. More common is to take out insurance against the more physical aspects of security, such as insurance covering loses from fire, damage to computers, or theft of systems.

The most common method for dealing with and managing risk is to mitigate risk. This includes putting together a comprehensive security program that considers technology security controls as well as the people and process aspects. It may mean adding additional layers of depth to the corporate security, eliminating vulnerabilities with patch management, and enforcing security policy or educating users in security awareness.

24.9 Solving the New Paradigm

For the purposes of our simplified risk management model, let's briefly discuss a way to reduce risk using three of the components in our model: embracing technology, threat exposure, and asset value. Together, these comprise our risk factor. We can easily improve our score (and reduce our risk) by lowering any of the values of any of the components of the risk factor. As we noted, the asset value is pretty much a set factor so we can really only improve on the other two. We can choose to be less bleeding edge in our choice of technology, instead choosing to put a bit more time in the market before becoming the company with all the newest widgets.

The other factor in our model is risk management. We can equally improve our security situation by making changes to any of the components of the risk management equation: increase security spending, add to our security awareness program, or increase user acceptance of controls.

Using our model, let's walk through a sample illustration to show management how improving on one area can improve the entire security situation. If we focus our current security awareness program on educating users to better accept controls that we have already implemented, we can show a significant improvement in our managing of risk just by increasing our factor by 1. By doing this we hope to be able to get management to support security funding and resources. Simply improving the user buy-in from 1 to 2 greatly improves our risk management. We cannot really change the value of our assets, so we must focus on our use of technology to directly reduce risk throughout the organization. By rating the organization's use of bleeding edge technology as being not quite as aggressive, we can reduce our score from 3 to 2, lowering our risk factor by nearly 25 percent.

In conclusion, we have determined that the convergence and convenience of technology directly correspond to risk. A simplified way to analyze risk is to work through two equations comprised of important factors that impact the protection of an organization's information assets. The factors for risk management that we used consisted of budget, security awareness, and how well users accept security controls. It is possible to swap out other aspects of your security program for any of these components, if you wish, but these are the best for illustrating impacts on risk. Factors that increase exposure in an organization include the use of leading edge technology, specific threats within the organization, and the value of the assets being protected.

We have many ways to improve the security state of our organization. In today's world of technology convergence, it all comes down to managing risk to maintain a successful business.

25

The Role of Information Security in the Enterprise Risk Management Structure

Carl B. Jackson
Mark Carey

25.1 Driving Information Security Management to the Next Level

The purpose of this chapter is to discuss the role of information security business processes in supporting an enterprise view of risk management and to highlight how, working in harmony, the ERM and information security organizational components can provide measurable value to the enterprise people, technologies, processes, and mission. This chapter also briefly focuses on additional continuity process improvement techniques.

If not already considered a part of the organization's overall enterprise risk management (ERM) program, why should business information security professionals seriously pursue aligning their information security programs with ERM initiatives?

25.2 The Role of Enterprise Risk Management

The Institute of Internal Auditors (IIA), in their publication entitled *Enterprise Risk Management: Trends and Emerging Practices,*[1] describes the important characteristics of a definition for ERM as:

- Inclusion of risks from all sources (financial, operational, strategic, etc.) and exploitation of the *natural hedges* and *portfolio effects* from treating these risks in the collective.
- Coordination of risk management strategies that span:
  - Risk assessment (including identification, analysis, measurement, and prioritization)
  - Risk mitigation (including control processes)
  - Risk financing (including internal funding and external transfer such as insurance and hedging)
  - Risk monitoring (including internal and external reporting and feedback into risk assessment, continuing the loop)
  - Focus on the impact to the organization's overall financial and strategic objectives

According to the IIA, the true definition of ERM means dealing with uncertainty and is defined as "A rigorous and coordinated approach to assessing and responding to all risks that affect the achievement of an organization's strategic and financial objectives. This includes both upside and downside risks."

It is the phrase "coordinated approach to assessing and responding to all risks" that is driving many information security and risk management professionals to consider proactively bundling their efforts under the banner of ERM.

25.2.1 Trends

What are the trends that are driving the move to include traditional information security disciplines within the ERM arena? Following are several examples of the trends that clearly illustrate that there are much broader risk issues to be considered, with information security being just another mitigating or controlling mechanism.

- *Technology risk.* To support mission-critical business processes, today's business systems are complex, tightly coupled, and heavily dependent on infrastructure. The infrastructure has a very high degree of interconnectivity in areas such as telecommunications, power generation and distribution, transportation, medical care, national defense, and other critical government services. Disruptions or disasters cause ripple effects within the infrastructure, with failures inevitable.
- *Terrorism risk.* Terrorists have employed low-tech weapons to inflict massive physical or psychological damage (e.g., box cutters and anthrax-laden envelopes). Technologies or tools that have the ability to inflict massive damage are getting cheaper and easier to obtain every day and are being used by competitors, customers, employees, litigation teams, etc. Examples include *cyber-activism* (the *Electronic Disturbance Theater* and *Floodnet* used to conduct virtual protests by flooding a particular Web site in protest) and *cyber-terrorism* (NATO computers hit with e-mail bombs and denial-of-service attacks during the 1999 Kosovo conflict, etc.).
- *Legal and regulatory risk.* There is a large and aggressive expansion of legal and regulatory initiatives, including the *Sarbanes–Oxley Act* (accounting, internal control review, executive verification, ethics, and whistleblower protection); *HIPAA* (privacy, information security, physical security, business continuity); *Customs-Trade Partnership Against Terrorism* (process control, physical security, personnel security); and *Department of Homeland Security initiatives*, including consolidation of agencies with various risk responsibilities.
- *Recent experience.* The grounds of corporate governance have been shaken with recent events, including those proclaimed in headlines and taking place at such luminary companies as *Enron, Arthur Andersen, WorldCom, Adelphia, HealthSouth*, and *GE*. These experiences reveal and amplify some underlying trends impacting the need for an *enterprise* approach to risk management.

25.2.2 Response

Most importantly, the information security practitioner should start by understanding the organization's value drivers, those that influence management goals and answer the questions as to how the organization actually works. Value drivers are the forces that influence organizational behavior; how the management team makes business decisions; and where they spend their time, budgets, and other resources. Value drivers are the particular parameters that management expects to impact their environment. Value drivers are highly interdependent. Understanding and communicating value drivers and the relationship between them are critical to the success of the business to enable management objectives and prioritize investments.

In organizations that have survived events such as 9/11, the War on Terrorism, Wall Street rollercoasters, world economics, and the like, there is a realization that ERM is broader than just dealing with insurance coverage. The enterprise risk framework is similar to the route map pictured in Exhibit 25.1

25.3 The Enterprise Risk Management Framework

Explanations of the key components of this framework are as follows.

25.3.1 Business Drivers

Business drivers are the key elements or levers that create value for stakeholders and, particularly, shareholders. Particular emphasis should be placed on an organization's ability to generate excess cash,

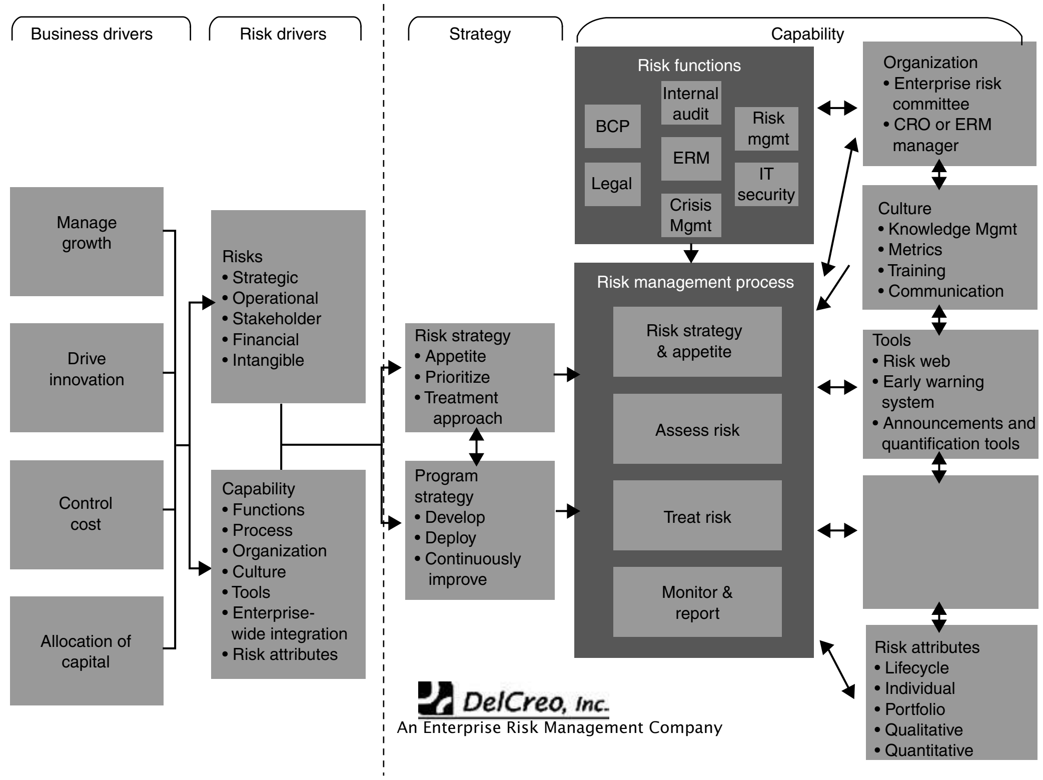

EXHIBIT 25.1 Enterprise risk management framework.

and the effective use of that cash. Business drivers vary by industry; however, they will generally line up in four categories:

1. *Manage growth.* Increasing revenue or improving the top line is achieved in many ways, such as expanding into new markets, overseas expansion, extending existing product lines, and developing new product areas and customer segments.
2. *Drive innovation.* The ability to create new products, markets, etc. through product innovation, product development, etc. New products and markets often give the creator a competitive advantage, leading to pricing power in the market, and allowing the company to generate financial returns in excess of their competition's.
3. *Control costs.* Effectively managing cost increases the competitive positioning of the business, and increases the amount of cash remaining.
4. *Allocate capital.* Capital should be effectively allocated to those business units, initiatives, markets, and products that will have the highest return for the least risk. These are the primary business drivers. They are what the organization does and by which it expects to be measured.

25.3.2 Risk Drivers

Both the types of risk and the capability of the organization to manage those risks should be considered.

- *Risk types.* The development of a risk classification or categorization system has many benefits for an organization. The classification system creates a common nomenclature that facilitates discussions about risk issues within the organization. The system also facilitates the development of information systems that gather, track, and analyze information about various risks, including the ability to correlate cause and effect, identify interdependencies, and track budgeting and loss experience information. Although many risk categorization methods exist, Exhibit 25.2 provides examples of a risk types and categories.
- *Risk capability.* The ability of the organization to absorb and manage various risks. This includes how well the various risk management related groups work together, what the risk process is within the enterprise, what organizational cultural elements should be considered, etc. The key areas of risk capability are discussed in greater detail below.

EXHIBIT 25.2 Risk Types and Categories

Strategic	Operational	Stakeholder	Financial	Intangible
Macro trends	Business interruption	Customers	Transaction fraud	Brand/reputation
Competitor	Privacy	Line employees	Credit	Knowledge
Economic	Marketing	Management	Cash management	Intellectual property
Resource allocations	Processes	Suppliers	Taxes	Information systems
Program/project	Physical assets	Government	Regulatory compliance	Information for decision making
Organization structure	Technology infrastructure	Partners	Insurance	
Strategic planning	Legal	Community	Accounting	
Governance	Human resources			
Brand/reputation				
Ethics				
Crisis				
Partnerships/JV				

25.3.3 Risk Strategy

The strategy development section focuses management attention on both risk strategy and program strategy.

25.3.3.1 Risk Appetite

Of critical importance in developing the risk strategy is to understand management's appetite for risk. "Risk appetite" is a term frequently used throughout the risk management community. It seems, however, that there is a real lack of useful information on its application outside of financial risk. *Risk appetite, at the organizational level, is the amount of risk exposure, or potential adverse impact from an event, that the organization is willing to accept or retain.*

Once the risk appetite threshold has been breached, risk management treatments and business controls are implemented to bring the exposure level back within the accepted range.

To establish the organization's risk appetite and determine the acceptable level of risk, the following questions must be asked and answered:

- Where do we feel we should allocate our limited time and resources to minimize risk exposures? Why?
- What level of risk exposure requires immediate action? Why?
- What level of risk requires a formal response strategy to mitigate the potentially material impact? Why?
- What events have occurred in the past, and at what level were they managed? Why?

Each of these questions is followed by a *Why?* because the organization must be made to articulate the quantitative and qualitative basis for the appetite, or it runs the potential for appearing backward-looking (based only on historical events) or even arbitrary.

25.3.3.2 Prioritization

Based on the risk level, the inventory of risks should be prioritized and considered for the treatment approach.

25.3.3.3 Treatment Approach

Although most information security professionals focus on reducing risk through contingency planning, many alternatives exist and should be thoroughly considered.

- *Accept risk:* management decides to continue operations as-is, with a consensus to accept the inherent risks.
- *Transfer risk:* management decides to transfer the risk, for example, from one business unit to another or from one business area to a third party (e.g., insurer).
- *Eliminate risk:* management decides to eliminate risk through the dissolution of a key business unit or operating area.
- *Acquire risk:* management decides that the organization has a core competency managing this risk, and seeks to acquire additional risk of this type.
- *Reduce risk:* management decides to reduce current risk through improvement in controls and processes.
- *Share risk:* management attempts to share risk through partnerships, outsourcing, or other risk-sharing approaches.

25.3.4 Risk Capabilities

The risk management capability speaks to the ability of the organization to effectively identify and manage risk. Many elements can make up the risk management capability; some of the key elements are discussed below.

25.3.4.1 Risk Functions

Various risk management functions must participate, exchange information and processes, and cooperate on risk mitigation activities to fully implement an ERM capability. Some of these risk management functions might include:

- Business continuity planning
- Internal audit
- Insurance
- Crisis management
- Privacy
- Physical security
- Legal
- Information security
- Credit risk management

25.4 Defining Risk Management Processes

Effective risk management processes can be used across a wide range of risk management activities, and include the following:

- Risk strategy and appetite:
  - — Define risk strategy and program.
  - — Define risk appetite.
  - — Determine treatment approach.
  - — Establish risk policies, procedures, and standards.
- Assess risk:
  - — Identify and understand value and risk drivers.
  - — Categorize risk within the business risk framework.
  - — Identify methods to measure risk.
  - — Measure risk.
  - — Assemble risk profile and compare to risk appetite and capability.
- Treat risk:
  - — Identify appropriate risk treatment methods.
  - — Implement risk treatment methods.
  - — Measure and assess residual risk.
- Monitor and report:
  - — Continuously monitor risks.
  - — Continuously monitor risk management program and capabilities.
  - — Report on risks and effectiveness of risk management program and capabilities.

25.4.1 The Risk Organization

A Chief Risk Officer (CRO), an Enterprise Risk Manager, or even an Enterprise Risk Committee can manage enterprise risk management activities and would interface with the information security function. CRO duties would typically include:

- Providing risk management program leadership, strategy, and implementation direction
- Developing risk classification and measurement systems

- Developing and implementing escalation metrics and triggers (events, incidents, crisis, operations, etc.)
- Developing and monitoring early warning systems, based on escalation metrics and triggers
- Developing and delivering organization wide risk management training
- Coordinating risk management activities; some functions may report to CRO, while others will be coordinated

25.4.2 Culture

Creating and maintaining an effective risk management culture is challenging. Special consideration should be given to the following areas:

- *Knowledge management.* Institutional knowledge about risks, how they are managed, and experiences by other business units should be effectively captured and shared with relevant peers and risk managers.
- *Metrics.* The accurate and timely collection of metrics is critical to the success of the risk management program. Effort should be made to connect the risk management programs to the Balanced Scorecard, EVA, or other business management/metrics systems.
  — *Balanced Scorecard*[2]: a management system (not only a measurement system) that enables organizations to clarify their vision and strategy and translate them into action. It provides feedback around both the internal business processes and external outcomes to continuously improve strategic performance and results. When fully deployed, the Balanced Scorecard transforms strategic planning from an academic exercise into the reality of organizational measurement processes. (*Source:* http://www.balancedscorecard.org/basics/bsc1.html)
  — *EVA (Economic Value Added):* net operating profit minus an appropriate charge for the opportunity cost of all capital invested in an enterprise. As such, EVA is an estimate of true *economic* profit, or the amount by which earnings exceed or fall short of the required minimum rate of return that shareholders and lenders could get by investing in other securities of comparable risk. Stern Stewart developed EVA to help managers incorporate two basic principles of finance into their decision making. The first is that the primary financial objective of any company should be to maximize the wealth of its shareholders. The second is that the value of a company depends on the extent to which investors expect future profits to exceed or fall short of the cost of capital. (*Source:* http://www.sternstewart.com/evaabout/whatis.php)
- *Training.* Effective training programs are necessary to ensure that risk management programs are effectively integrated into the regular business processes. For example, strategic planners will need constant reinforcement in risk assessment processes.
- *Communication.* Frequent and consistent communications regarding the purpose, success, and cost of the risk management program are a necessity to maintain management support and to continually garner necessary participation of managers and line personnel in the ongoing risk management program.
- *Tools.* Appropriate tools should be evaluated or developed to enhance the effectiveness of the risk management capability. Many commercial tools are available, and their utility across a range of risk management activities should be considered. Quality information about risks is generally difficult to obtain, and care should be exercised to ensure that information gathered by one risk function can be effectively shared with other programs. For example, tools used to conduct the business impact assessment should facilitate the sharing of risk data with the insurance program.

- *Enterprisewide integration.* The ERM and InfoSec programs should effectively collaborate across the enterprise and should have a direct connection to the strategic planning process, as well as the critical projects, initiatives, business units, functions, etc. Broad, comprehensive integration of risk management programs across the organization generally leads to more effective and efficient programs.

25.5 Risk Attributes

Risk attributes relate to the ability or sophistication of the organization to understand the characteristics of specific risks, including their life cycle, how they act individually or in a portfolio, and other qualitative or quantitative characteristics.

- *Life cycle.* Has the risk been understood throughout its life cycle, and have risk management plans been implemented before the risk occurs, during the risk occurrence, and after the risk? This obviously requires close coordination between the risk manager and the continuity planner.
- *Individual and portfolio.* The most sophisticated organizations will look at each risk individually, as well as in aggregate, or in portfolio. Viewing risks in a portfolio can help identify risks that are natural hedges against themselves, as well as risks that amplify each other. Knowledge of how risks interact as a portfolio can increase the ability of the organization to effectively manage the risks at the most reasonable cost.
- *Qualitative and quantitative.* Most organizations will progress from being able to qualitatively assess risks to being able to quantify risks. In general, the more quantifiable the information about the risk, the more treatment options available to the organization.

25.6 The Importance of Understanding Risk Appetite

In the January 2004 issue of *Optimize Magazine,*[3] a survey of organizational executives revealed that 40 percent of the executives interviewed identified the CIO as the most likely executive to own enterprise risk management. The percentage spread was as follows: CIO (40 percent), CFO (23 percent), CEO (13 percent), division president (7 percent), chief information security officer (7 percent), and chief risk management officer (3 percent).

Admittedly, this was an IT-focused survey, and so it is likely that the types of people interviewed tended to focus on IT; but even if the survey population was skewed, the implications are large either way. Many IT departments may be initiating ERM programs, some may partially duplicate existing ERM activities in the company, and some may actually be leading the charge.

There are a few noteworthy items referenced in the article, including:

- 82 percent of the respondents said risk management has increased in importance for their CIO or other senior IT executive in the past 12 months.
- 57 percent believe that the approach to managing risks across IT and business functions at their companies is inconsistent.
- Survey participants were asked to identify the “biggest challenges your company faces in managing IT risk.” The top four responses were:
  - — Budget/cost restraints
  - — Ambiguous strategy about risk management
  - — Lack of risk management tools
  - — Poor training in risk management issues

25.6.1 Methodology for Determining Organizational Risk Appetite

The following is a suggested methodology and strategic approach that can assist organizations—as well as the security, risk, and control functions contained therein—in developing and articulating their risk appetite. The key deliverable in this process is the Risk Appetite Table (see Exhibit 25.3).

The approach to completing the Risk Appetite Table has two key inputs:

1. Impact Table
2. Likelihood Table

Recent changes in global regulations that encompass security, risk, and control implications have raised awareness concerning the concept of risk appetite, particularly among the management team. Many organizations, from the board level down, are currently struggling with risk management in general, and understanding and implementing meaningful processes, metrics, and strategies in regard to risk appetite.

The process used here to articulate the risk appetite for an organization or a function is described in the sections that follow.

At first glance, the process described here might look like a typical risk mapping exercise; in fact, this exercise should be applied to risks previously identified in a risk mapping project. The manner in which one designs an appetite and implements follow-up risk management processes will carry incident management, business management, and strategic implications that go far beyond a risk identification activity.

25.6.2 Developing the Impact Table

Development of the Impact Table depends on determining the organization's status on the following.

25.6.2.1 Identification of Stakeholders

The first step in developing your organization's approach is to identify the key stakeholders. Stakeholders can be any person, group, or entity who can place a claim on the organization's attention, resources, or output, or is affected by that output. Stakeholders tend to drive decision making, metrics, and measurement, and, of course, risk appetite. They may be internal or external, and do not neglect stakeholders who have a direct impact on your salary and performance reviews. Once stakeholders have been identified, list the interests, benefits, and outputs that stakeholders demand from your organization, such as:

- Shareholder value
- Compliance with regulations
- Product safety
- Privacy of personal information

25.6.2.2 Value Drivers

The interests, benefits, and outputs that stakeholders demand are often defined at a high level, thus making it difficult to articulate the direct impacts your function has on the outcome. For example,

EXHIBIT 25.3 Risk Appetite Table

Escalation Level	Risk Level	Risk Score	Action/Response	Deadlines for Required Actions
C level	Crisis	12–16		
Director level	High	9–11		
Risk management function	Medium	5–8		
Within business	Low	1–4		

shareholders are interested in increasing shareholder value. It is difficult to know that you are directly impacting shareholder value with a particular risk management activity. However, managing costs effectively and reducing the number of loss events can ensure that you positively impact shareholder value. Ultimately, business and function strategies are designed with the intent of creating value for key stakeholders. Value drivers are the key elements (performance measures) required by the organization to meet key stakeholder demands; value drivers should be broken down to the level where they can be managed. Each organization should identify potential value drivers for each key stakeholder group; however, seek to limit the value drivers to those that your security, risk, or control program can impact in a significant way. The core element of the Risk Appetite Table is determining how you will describe and group potential impacts and the organization's desire to accept those impacts.

25.6.2.3 Key Risk Indicators

Key risk indicators are derived from the value drivers selected. Identification of key risk indicators is a three-step process.

Step 1: Identify and understand value drivers that may be relevant for your business or function. Typically, this will involve breaking down the value drivers to the level that will relate to your program.

Step 2: Select the key risk indicator metric to be used.

Step 3: Determine appropriate thresholds for each key risk indicator. For example:

— Value driver breakdown:
— Financial
— Increase revenue
— Lower costs
— Prevent loss of assets
— Key risk indicators:

- Increase revenue—lost revenue due to business interruption
- Lower costs—incremental out-of-budget costs
- Prevent loss of assets—dollar value of lost assets

— Thresholds:

- Incremental out-of-budget cost:
    - Level 1 threshold: 0 to 50K
    - Level 2 threshold: 51 to 250K
    - Level 3 threshold: 251K to 1M
    - Level 4 threshold: 1M+

One of the more challenging aspects of defining risk appetite is creating a diverse range of key risk indicators, and then level-setting each set of thresholds so that comparable impacts to the organization are being managed with comparable attention. For example, how do you equate a potential dollar loss with the number of customers unable to receive customer support for two days? Or even more basic, is one dollar of lost revenue the equivalent of one dollar of incremental cost?

25.6.2.4 Threshold Development

It is equally important to carefully consider how you establish your thresholds from an organizational perspective. You should fully consider whether you are establishing your program within the context of a single business unit, a global corporation, or from a functional perspective. Each threshold should trigger the next organizational level at which the risk needs to be managed. This becomes an actual manifestation of your risk appetite as risk management becomes more strictly aligned with management and the board's desire to accept certain levels of risk. These thresholds, or impact levels, should be commensurate with the level at which business decisions with similar implications are managed.

For example, a Risk Appetite Impact Table being defined for the Insurance and Risk Financing Program might be broken down as follows:

Threshold Level 1: manage risk or event within business unit or function.
Threshold Level 2: risk or event should be escalated to the Insurance and Risk Financing Program.
Threshold Level 3: risk or event should be escalated to the corporate treasurer.
Threshold Level 4: risk or event should be escalated to the Corporate Crisis Management Team or the Executive Management Team.

25.6.3 Developing the Likelihood Table

The Likelihood Table reflects a traditional risk assessment likelihood scale. For this example, it will remain simple.

Level 1: low probability of occurring
Level 2: medium probability of occurring
Level 3: high probability of occurring
Level 4: currently impacting the organization

There is a wide range of approaches for establishing likelihood metrics, ranging from simple and qualitative (as in the example above) to complex quantitative analyses (such as actuarial depictions used by the insurance industry).

25.6.4 Developing the Risk Appetite Table

The resulting Risk Appetite Table helps an organization align real risk exposure with its management and escalation activities. An event or risk is assessed in the Risk Appetite Table and assigned a Risk Score by multiplying the Impact and Likelihood scores. Ranges of Risk Scores are then associated with different levels of management attention. The escalation levels within the Risk Appetite Table will be the same as the levels in the Impact Table. The actual ranking of a risk on the Risk Appetite Table will usually be lower than its ranking on the Impact Table—this is because the probability that the risk will occur has lowered the overall ranking. Incidents or events that are in process will have a 100 percent chance of occurring; therefore, their level on the Risk Appetite Table should equal the ranking on the Impact Table.

For example:

Score between 1 and 4: manage risk or event within business unit or function.
Score between 5 and 8: risk or event should be escalated to the Insurance and Risk Financing Program.
Score between 9 and 11: risk or event should be escalated to the corporate treasurer.
Score between 12 and 16: risk or event should be escalated to the Corporate Crisis Management Team or the Executive Management Team.

25.6.5 Risk Appetite: A Practical Application

The following provides a practical application of the Risk Appetite Table. This example uses the Risk Appetite of an information security department.

- *Determine the impact score.* Vulnerability is identified in Windows XP Professional. Consider the impact on the organization if this vulnerability is exploited. You should factor in your existing controls, risk management treatments, and activities, including the recently implemented patch management program. You decide that if this vulnerability were to be exploited, the impact to the organization would be very significant because every employee uses Windows XP on his or her workstations. You have assigned the event an impact score of 4 out of 4.

EXHIBIT 25.4 Completed Risk Appetite Table

Escalation Level	Risk Level	Risk Score	Action/Response	Deadlines for Required Actions
C level	Crisis	12–16	Notify and escalate to CFO level.	Immediately
Director level	High	9–11	Notify and escalate to director level immediately. Depending on nature of the risk event, relevant risk functions should be notified.	Within 2 hours
Risk management function	Medium	5–8	Manage in information security program.	Within 12 hours
Within business	Low	1–4	Manage in relevant business unit or risk function. If escalation attempt is made, deescalate to the business unit or function to manage per their standard operating procedures.	Within 24 hours

- *Determine the likelihood score.* Consider the likelihood of the event occurring within the context of your existing controls, risk management treatments, and activities. Because of the availability of a patch on the Microsoft Web site and the recent success of the patch management program, you are certain that the number of employees and, ultimately, customers who are likely to be impacted by the vulnerability is Low. You assign a likelihood score of 2 out of 4.
- *Determine risk score and management response.* Simply multiply the impact score by the likelihood score to calculate where this event falls on the Risk Appetite Table. In this case, we end up with a Risk Score of 8 and thus continue to manage the event in the information security patch management program. If, at any point, it becomes apparent that a larger number of employees or customers might be impacted than was originally thought, consideration should be given to a more significant escalation up the management chain. A completed Risk Appetite Table is shown in Exhibit 25.4.

The Risk Appetite Table is *only* a risk management tool. It is not the sole decision-making device in assessing risk or events. At all times, professional judgment should be exercised to validate the output of the Risk Appetite Table. Also, it is critical that the tables be reviewed and evolve as your program and your overall business model matures.

Having completed the development of the Risk Appetite Table, there is still a lot of work ahead. You need to do the following things:

1. Validate the Risk Appetite Table with your management team.
2. Communicate the Risk Appetite Table to business units, as well as your peers within the security, risk, and control functions of your organization, and develop incident management and escalation procedures based on your risk appetite.
3. Test your Risk Appetite Table. Does it make sense? Does it help you determine how to manage risks? Does it provide a useful framework for your team?

25.6.5.1 Program Strategy

Information security programs, like all other risk management programs, require strategic planning and active management of the program. This includes developing a strategic plan and implementation of workplans, as well as obtaining management support, including the required resources (people, time, and funding) to implement the plan.

25.7 Summary

Lack of suitable business objectives-based metrics has forever plagued the information security profession. We, as information security professionals, have for the most part failed to sufficiently define and articulate a high-quality set of metrics by which we would have management gauge the success of information security business processes. So often, we allow ourselves to be measured either by way of fiscal measurements (e.g., security technology, full-time head count, awareness program expenses, etc.), or in terms of successful or non-successful parameter protection or in the absence of unfavorable audit comments.

Rather than being measured on quantitative financial measures only, why should the information security profession not consider developing both quantitative *and* qualitative metrics that are based on the value drivers and business objectives of the enterprise? We should be phrasing information security business process requirements and value contributions in terms with which executive management can readily identify. Consider the issues from the executive management perspective. They are interested in ensuring that they can support shareholder value and clearly articulate this value in terms of business process contributions to organizational objectives. As we recognize this, we need to begin restructuring how the information security processes are measured. Many organizations have, or are in the process of redefining, information security as part of an overarching ERM structure. The risks that information security processes are designed to address are just a few of the many risks that organizations must face. Consolidation of risk-focused programs or organizational components—such as information security, business continuity planning, environmental health and safety, physical security, risk management, legal, insurance, etc.—makes sense, and in many cases capitalizes on economies-of-scale.

A true understanding of business objectives and their value-added contributions to overall enterprise goals is a powerful motivator for achieving success on the part of the information security manager. There are many value drivers—*strategic* (competitive forces, value chains, key capabilities, dealing with future value, business objectives, strategies and processes, performance measures); *financial* (profits, revenue growth, capital management, sales growth, margin, cash tax rate, working capital, cost of capital, planning period and industry-specific subcomponents, etc.); and *operational value* (customer or client satisfaction, quality, cost of goods, etc.)—that the information security professional should focus on, not only during the development of successful information security strategies, but also when establishing performance measurements.

The information security business processes should be in support of an enterprise view of risk management and should work in harmony with the ERM. Jointly, these functions can provide measurable value to the enterprise people, technologies, processes, and mission. It is incumbent upon both InfoSec managers and enterprise risk managers to search for a way to merge efforts to create a more effective and efficient risk management structure within the enterprise.

A Matter of Trust

Ray Kaplan

There is a continuous stream of security-related bug reports permeating the news these days. With all the noise, it is difficult to spot the core issue, let alone to keep one's eye on it. The simple questions of what one trusts and why one trusts it are often ignored. Moreover, the need to define both inter- and intra-infrastructure trust relationships is often overlooked. The core question of what trust is and its importance is usually forgotten altogether. Security is a matter of trust. This chapter explores the nature of trust and trust relationships, and discusses how one can use trust to build a secure infrastructure.

26.1 A Matter of Trust?

Trust is the core issue in security. Unfortunately, simply understanding that is not going to get one very far when one has an infrastructure to secure. The people in an organization, its customers, and their customers are depending on the security of one's infrastructure. Strangely enough (and do not take this personally), they probably should not. The reality is that people make poor decisions about trust all the time, and often engage in relationships based on flawed trust decisions.

Before exploring this further, it is important to understand what trust is and how it is used to build and maintain a trustworthy infrastructure. One can start with the definition of trust—what it is and what it is not. Then this chapter explores how to build and maintain a trustworthy infrastructure.

26.1.1 Trust Defined

The dictionary variously defines trust as a *firm belief or confidence in the honesty, integrity, reliability, justice, etc., of another person or thing*. It goes on to talk about confident expectation, anticipation or hope, imparting responsibility, and engendering confidence. This allows for the development of relationships. Consider committing something or someone to someone else's care, putting someone in charge of something, allowing something to take place without fear, and granting someone credit. All these things are examples of how most people operate—as individuals, as citizens, as organizations, and as a society (locally, nationally, and internationally).

In matters of real-world models of trust for the Internet, law, E-commerce, linguistics, etc., one base definition applies:

> Trust is that which is essential to a communication channel but cannot be transferred from source to destination using that channel.[1]

One can look to information theory as an anchor:

> In Information Theory, information has nothing to do with knowledge or meaning. In the context of Information Theory, information is simply that which is transferred from a source to a destination, using a communication channel.[2]

Think of trust as a value attached to information.

Examples of where people rely on trust in matters of security are everywhere in computing and networking. For example, the scheduler of an operating system trusts the mechanism that is giving it entities to schedule for execution. A TCP/IP network stack trusts that the source address of a packet can be trusted to be its originator (unless a security mechanism demands proof of the source's identity). Most users trust their browsers and the Web sites they access to automatically "do the right thing" security-wise. In doing so, they trust the operating system schedulers and network stacks on which they rely. The NSA sums it up best when it says that a trusted system or component is one with the power to break one's security policy. However, most organizations do not consider trust in this context.

It is extraordinarily important to understand how this puzzle fits together because everything concerning the security of the distributed systems being developed, deployed, and used depends on it. Consider PKIs and operating systems with distributed trust models such as Windows NT and Windows 2000 as examples.

26.1.2 What Trust Is Not

It is also important to talk about what trust is not. In his works on trust, Dr. E. Gerck explains that trust is not transitive, distributive, associative, or symmetric except in certain instances that are very narrowly defined.[3] Gerck uses simple examples, mathematical proofs, and real-world experience to illustrate trust. Because practical experience in security agrees with him, it is comforting to know that Gerck begins his work with a quote from the Polish mathematician Stanislaw Leshniewski:

> A theory, ultimately, must be judged for its accord with reality.[4]

Because rules regarding trust are regularly ignored, people are going to continue to have heartburn as they deal with trust between UNIX systems, build out Public Key Infrastructures (PKIs) and distributed infrastructures, and deal with the practical aspects of Microsoft Windows 2000's new security model. Note that these are just a few of the problem areas.

[3] Gerck, E. *Overview of Certification Systems: X.509, CA, PGP and SKIP* http://www.mcg.org.br/cert.htm#CPS; Gerck, E. e-mail message titled: *Towards a Real-World Model of Trust*, http://www.mcg.org.br/trustdef.txt; Gerck, E., e-mail message titled: *Re: Trust Properties*, http://www.mcg.org.br/trustprop.txt.

[4] Leshniewski, Stanislaw, (1886–1939) http://www-groups.dcs.st-and.ac.uk/~history/Mathematicians/Leshniewski.html.

Before beginning, a note is in order; this is NOT an exercise in demeaning Windows 2000. However, Windows 2000 provides excellent examples of:

- How trust rules are broken with alacrity
- How detailed things can get when one sets about the task of evaluating a trust model
- The problems presented by trust models that break the rules

Take one of Gerck's assertions at a time, using simple examples based on research, mathematical proofs, and real-world experience—starting with an introduction to the problem with the basic Windows 2000 trust model: transitivity.

26.1.2.1 Trust Is Not Transitive

If X trusts Y and Y trusts Z, X cannot automatically trust Z. That is, the simple fact that I trust you is not reason for me to trust everyone who you trust. This is a major limiting factor in "web-of-trust" models such as that of PGP. This is quite understandable because PGP was developed as e-mail security software for a close group of friends or associates who would handle trust management issues.[5] Within a "closed group," trust is transitive only to the extent that each group member allows it to be. Outside a "closed group," there is no trust. A problem arises when the group is large and its members do not restrict the trust they place in the credentials presented to them by a "trusted" group member. Consequently, a problem results when systems rely on "relative" references. Windows 2000 is such a system because it has a model based on transitive trust. Simply the way that transitive trust is expected to be used in a Windows 2000 system is problematic, as illustrated by the following descriptions of how it works.

First, excerpts from the Windows NT Server Standards documentation that discuss Primary and Trusted Domains point out the differences between Windows NT 4.0 and Windows 2000:

> …A trusted domain is one that the local system trusts to authenticate users. In other words, if a user or application is authenticated by a trusted domain, its authentication is accepted by all domains that trust the authenticating domain.

On a Windows NT 4.0 system, trust relationships are one-way and must be created explicitly. Two-way trust is established explicitly by creating two one-way trusts. This type of trust is nontransitive, meaning that if one trusts a domain, one does not automatically trust the domains that domain trusts.

> On a Windows NT 4.0 workstation, a Trusted Domain object is used to identify information for a primary domain rather than for trusted domains…
>
> …on a Windows 2000 system, each child domain automatically has a two-way trust relationship with the parent. By default, this trust is transitive, meaning that if you trust a domain, you also trust all domains that domain trusts.[6]

Second, an excerpt from a Microsoft NT Server Standards document:

> Windows 2000 Domains can be linked together into an ADS "tree" with automatic two-way transitive trust relationships. ADS (Active Directory Server) "trees" can also be linked together at

[5] Gerck, E. taken together: E-mail message titled: *Towards a Real-World Model of Trust*, http://www.mcg.org.br/trustdef.txt and e-mail message titled: Re: Trust Properties, Gerck, E. http://www.mcg.org.br/trustprop.txt; Gerck, E. *Summary of Current Technical Developments Near-Term Perspectives for Binarily-Secure Communications*, http://www.mcg.org.br/report98.htm.

[6] *Primary and Trusted Domains, Local Security Authority Policy Management*, Microsoft MSDN Online Library, http://msdn.microsoft.com/library/default.asp?URL=/library/psdk/lsapol/lsapol_2837.htm.

> their roots into an “enterprise” or “forest,” with a common directory schema and global catalog server by setting up static “site link bridges,” which are like manual trust relationships.[7]

Finally, an excerpt from the Microsoft 2000 Advanced Server Documentation:

> Because all Windows 2000 domains in a forest are linked by transitive trust, it is not possible to create one-way trusts between Windows 2000 domains in the same forest.
>
> …All domain trusts in a Windows 2000 forest are two-way transitive trusts.[8]

The Microsoft 2000 Advanced Server Documentation explains that all the domains in the forest trust the forest’s root domain, and all the interdomain trust paths are transitive by definition. Note that all of this stands in stark contrast to what we know: trust is not transitive except in certain, narrowly defined cases. Suffice it to say, the implications of this dependence on transitive trust and the accompanying default behavior present significant challenges. Consider a classic example: the Human Resources (HR) department’s domain. Due to the sensitive nature of HR information, it is not clear that an automatic, blanket, transitive interdomain trust relationship with every other domain in the infrastructure is appropriate. For example, HR may be segregated into its own domain to prevent non-HR network administrators from other domains from accessing its resources and protected objects (such as files.)

Other examples of inappropriate transitive trust abound. Examples of why it is a problem, how it must be handled, and the problems associated with it in the UNIX environment can be found in Marcus Ranum’s explanation of transitive trust in the UNIX NFS (Network File System) and rlogin (remote login) facilities.[9]

26.1.2.2 Trust Is Not Distributive

If W and Y both trust Z, W cannot automatically trust Y and Z as a group.

Suppose your organization and your biggest competitor both get certificates from a Certification Authority (CA). Sometime later, that competitor buys that CA, thereby gaining access rights to all of your information. One cannot automatically trust that your biggest competitor would not revoke your certificate and access all of your information.[10] Practically speaking, such a situation might be met with a lawsuit (if your contract with the CA has been breached, for example). However, this is likely to be difficult because agreements with CAs may not provide for this eventuality.

One could also merely change one’s behavior by:

- No longer trusting the offending CA or the credentials that it issued to you
- Ensuring that these, now untrustworthy credentials are revoked
- Getting new credentials from a CA with which one has a viable trust relationship

[10] Gerck, E. e-mail message titled: *Towards a Real-World Model of Trust*, http://www.mcg.org.br/trustdef.txt.

26.1.2.3 Trust Is Not Associative

If X trusts the partnership formed with Y and Z for some specific purpose, X cannot automatically trust Y and Z individually.

Just because one trusts a group (that presumably was formed for some specific purpose) does not mean that one can trust each member of that group. Suppose one trusts the partnership formed between two competitors for some specific purpose. That, in and of itself, does not mean that one can trust them individually, even in a matter that has do with the business of the partnership.

26.1.2.4 Trust Is Not Symmetric

Just because X trusts Y, Y cannot automatically trust X. That is, trust relationships are not automatically bidirectional or two-way. Trust is unidirectional or asymmetric. Just because I trust you, you cannot automatically trust me.

As illustrated several times in the preceding discussion, the trusting party decides the acceptable limits of the trust. The only time trust is transitive, distributive, associative, or symmetric is when some type of "soft trust" exists—specifically where the trusting party permits it.[11] Practically speaking, many trusting parties do not limit the scope of the trust they place in others. Accordingly, those trust relationships are ill-founded. This is a problem—not a benefit.

26.1.3 Trustworthiness

Whereas trust means placing one's confidence in something, trustworthiness means that one's confidence is well-founded. Trusting something does not make it trustworthy. This is the pay dirt of the trust business.

While many systems and networks can be trusted, few are trustworthy. A simple example will help tease this out. Suppose you live far from your job in a metropolitan area that has little or no mass transit. Chances are that you will commute to work by automobile. You may trust your automobile to get you to and from work just fine without ever experiencing a hitch. However, you may not trust it to get you across Death Valley in the middle of a hot summer day. The reason might be that help is only a cell phone call away in the metropolitan area and you know that a breakdown will not be life-threatening. On the other hand, help might be very difficult to find on the journey across Death Valley, and if you break down, dehydration is a threat. You have decided that your car is trustworthy for commuting to work, whereas it is not trustworthy for long journeys through hostile environments. That is, for the purposes of commuting within your own metropolitan area, you trust your automobile for transportation.

Simply put, trust is situational. That is, one decides to trust something in certain, specific circumstances. Trust is about confidence.

One can consider systems and networks to be trustworthy when they have been shown to perform their jobs correctly in a security sense. That is, one has confidence in them under specific circumstances. Accordingly, this encompasses a wide spectrum of trustworthiness. On one end of this spectrum are the so-called trusted systems that require formal assurance of this assertion based on mathematical proofs. On the other end of this spectrum lie bodies of anecdotal evidence gathered over a long period of time that seems to say "the system is doing its job."

As a practical example of how all this fits together, consider one of Dr. Ed Gerek's notes on the definition of trust, which refers to the American Bar Association's Digital Signature Guidelines:[12]

[11] Gerck, E. Summary of Current Technical Developments Near-Term Perspectives for Binarily-Secure Communications, http://www.mcg.org.br/report98.htm.

[12] American Bar Association, Legal Infrastructure for Certification Authorities and Secure Electronic Commerce, 1996, http://www.abanet.org/scitech/ec/isc/dsgfree.html.

> Trust is not defined per se, but indirectly, by defining "trustworthy systems" (or, systems that deserve trust) as "Computer hardware, software, and procedures that: (1) are reasonably secure from intrusion and misuse; (2) provide a reasonably reliable level of availability, reliability and correct operation; (3) are reasonably suited to performing their intended functions; and (4) adhere to generally accepted security principles." This definition is unfortunate in that it confuses trust with fault-tolerance, especially so because fault-tolerance is objective and can be quantitatively measured by friends and foes alike—whereas trust is the opposite.[13]

As can be seen, one tries to define trust (trustworthiness) as a measurable quantity in many ways. On the technical side of security, there are several ways to accomplish this, including:

- Formal criteria such as the *Trusted Computer Security Evaluation Criteria* (TCSEC, also known as the *Orange Book*) and its successor the Common Criteria and accompanying formal methods of test
- Less formal testing that is performed by the commercial product testing labs such as those that certify firewalls
- So-called "challenge sites" that seek to prove themselves trustworthy by demonstrating that they can withstand attacks
- Penetration testing that seeks to exhaustively test for all known vulnerabilities
- Assessments that seek to show where vulnerabilities exist past those that can be found using purely technical means
- Alpha, beta, and pre-releases of software and hardware that attempt to identify problems before a final version of a product is shipped

All of these are designed to demonstrate that we can trust systems or networks *under certain circumstances*. The object of all of them is to build trust and confidence and thereby to arrive at a level of trust—circumstances under which the systems or networks are trustworthy. For example, among the many things one finds in the so-called *Rainbow Series* of books that contains the *Orange Book* of the TCSEC are *Guidelines for Writing Trusted Facility Manuals*[14] and *A Guide to Understanding Trusted Facility Management*[15] that discuss how a trusted system must be deployed. Quoting the manual:

> *Guidelines for Writing Trusted Facility Manuals* provides a set of good practices related to the documentation of trusted facility management functions of systems.

"Trusted facility management" is defined as the administrative procedures, roles, functions (e.g., commands, programs, interfaces), privileges, and databases used for secure system configuration, administration, and operation.

Before one can trust a system to be secure, the facility in which the system is deployed must be managed in such a way that it can be trusted. Before giving up on this military-style thinking, consider that commercial systems and network components such as routers must be treated in the same way before one can trust them.

Note that these theories and various testing methods are limited; they do not always work in practice. However, one generally uses adherence to criteria and high scores on tests as measures of trustworthiness.

[13] Gerck, E. Towards a Real-World Model of Trust, E. Gerck, http://www.mcg.org.br/trustdef.htm, also Gerck, E. in a 1998 e-mail message defining trust, http://www.sandelman.ottawa.on.ca/spki/html/1998/winter/msg00077.html which references the *American Bar Association Digital Signature Guidelines*, http://www.abanet.org/scitech/ec/isc/dsgfree.html.

[14] National Computer Security Center, *Guidelines for Writing Trusted Facility Manuals*, NCSC-TG-016.

[15] National Computer Security Center, *A Guide to Understanding Trusted Facility Management*, NCSC-TG-015.

Another way to look at it is that one mitigates as many risks as one can and accepts the remaining risks as residual risk. Nothing is risk-free, including systems and networks. Hence, our job in security is risk management. Eliminate the risks that one can and accept the rest. The reason for this is that it would be much too expensive to eliminate all risks; even if this were possible, one usually cannot identify absolutely all of them.

26.1.4 Why Is Trust Important?

It is easy to see why trust and trustworthiness are important. Start with a global view. The best articulation of this global view that this author has found is in Francis Fukuyama's *Trust, The Social Virtues & The Creation of Prosperity.* One quote seems to apply to everything we do in life and everything we do in computing and networking, including security:

> A nation's well-being, as well as its ability to compete, is conditioned by a single pervasive cultural characteristic: the level of trust inherent in the society.[16]

Consider that the well-being of our enterprises, including their ability to compete, is conditioned on a single pervasive characteristic of their infrastructures and those on which they depend: the level of inherent trust. Simply put, if one cannot trust one's infrastructure, all bets are off. Consider your own desktop system. How comfortable will you be in using it if you cannot trust it?

As a Ph.D. candidate in 1990, Dr. David Cheriton commented:

> The limit to distributed systems is not performance, it is trust.[17]

Cheriton's statement is especially applicable in an age where everything, including toasters, has computing power and the network accoutrements necessary to connect it to everything else in our lives. The interconnectivity aspect of this developing complexity is best illustrated by the following quote from Robert Morris, Sr.:

> To a first approximation, everything is connected to everything else.[18]

This can be a very scary thought. Increasingly, people are trusting more and more of what they are, have, and know, to parties they may not even know, much less have a basis upon which to establish trust. Trust is becoming increasingly important, but most individuals and organizations do not realize or appreciate this until assets are lost or compromised.

26.1.5 Why Do People Trust?

As previously discussed, there are many reasons why people trust. It is important to note that most people never get to the point where they consider any of the reasons in the trustworthiness spectrum. There is only one reason that most of us trust: blind faith. The reasons seem to include:

- Evidence that "things seem to be doing their jobs"
- Lack of evidence to the contrary
- Anecdotal evidence from others in the community

[16] Fukuyama, Francis. 1995. *Trust, The Social Virtues & the Creation of Prosperity,* ISBN 0-02-910976-0, The Free Press, New York.

[17] From a presentation on security in distributed systems by David Cheriton in a Computer Science Department colloquium at the University of Arizona in the early 1990s.

[18] A comment made by NSA computer security researcher Robert Morris, Sr., at a National Computer Security Conference in the early 1990s. He was explaining why he has to work so hard on such things as eliminating covert channels in order to protect the 1000 bit keys that could unleash a nuclear war. (He is the father of Robert T. Morris, who was responsible for the 1988 Internet Worm.)

Moreover, the nature of people in many cultures of the world is to trust first and ask questions later—if ever. This is a little confusing because there is often much evidence to the contrary. Nevertheless, it seems to remain a key part of many cultures.

26.1.6 Why Should People Not Trust?

Perhaps the best way to show the importance of trust is to talk about distrust: the lack of trust, faith, or confidence, doubt or suspicion.

The scary part is that most of what people trust is beyond their control. By way of illustration, consider only one dimension of the problem: complexity. In his musings about complexity, Marcus Ranum observes that Web browsers themselves have become tools for managing complexity. Consider that most every browser is in the business of hiding the complexity of having to deal with the myriad of protocols that most of them support (such as HTTP, FTP, Telnet, etc.). Ranam asks how many of us know all of the features and hooks of the cool, new Web apps that continue to pop up. He posits that probably the only people who know are the ones who coded them. Moreover, the details of the security of such protocols are not published and change from version to version.[19]

As an example that gives life to this, consider this discussion of the "Smart Browsing" feature that showed up in version 4.06 of the Netscape browser:[20]

> Netscape Communications Corporation's release of Communicator 4.06 contains a new feature, 'Smart Browsing,' controlled by a new icon labeled What's Related, a front end to a service that will recommend sites that are related to the document the user is currently viewing. The implementation of this feature raises a number of potentially serious privacy concerns, which we have examined here.
>
> Specifically, URLs that are visited while a user browses the Web are reported back to a server at Netscape. The logs of this data, when used in conjunction with cookies, could be used to build extensive dossiers of individual Web users, even including their names, addresses, and telephone numbers in some cases.

If one is having trouble with this, one can easily make a headache worse by trying to get one's arms around all of the trust questions that surround PKIs and Windows 2000 if not already doing so. Consider that the problem of figuring out how to build and maintain a long-lived trust model with Windows 2000 pales when compared to the problem of figuring out how to trust Windows 2000 itself. This, since it reportedly has 27–40 million lines of code,[21] some half or more of which are reportedly new to the initial release. The number of security-related bug fixes is likely to be just as astounding.

Complexity and protocol issues notwithstanding, there is no reason for most people and organizations to trust their infrastructures. The reasons to distrust an infrastructure are legion. Very few infrastructures are trustworthy. Given Marcus Ranum's observation about complexity and what the author of this chapter knows about how things work (or do not work), this author has trouble trusting his own infrastructures much of the time.

Finally, there are the continual reminders of purposeful deceit that confront us every day. These begin with virus, worm, and Trojan horse writers foisting their wares on us, continue through the daily litany of

[19] Ranum, Marcus, *The Network Police Blotter*, *Login*: (the newsletter of USENIX and SAGE), February 2000, Volume 25, Number 1, http://pubweb.nfr.net/%7Emjr/usenix/ranum_1.pdf.

security problems that flood past us on lists such as Bugtraq,[22] and end with the malice of forethought of attackers. Clever competitors, in either business or war, will deceive people at every available opportunity. For an instruction manual, I recommend Sun-Tzu's *On the Art of War* for your study.[23] Your adversaries, be they your competitors in business or those who would attack your infrastructure, are likely out to deceive you at every opportunity.

What justifies the trust placed in an infrastructure? Most of the time, there is only one answer: We have never considered that question. However, the absence of justification for trusting infrastructure does not stop there. Some people—and entire organizations—deceive themselves. The *Skeptic's Dictionary*[24] aptly describes this situation: "The only thing infinite is our capacity for self-deception." Better yet: "There is no accounting for self-delusion."[25]

26.2 Securing One's Infrastructure

Now one is down to the nub of the matter. There is only one question left to ask: "Where to from here?" Thankfully, the answer is relatively straightforward. Not to say that it will not take some work. However, it is easy and intuitive to see how to attain trust in one's infrastructure:

1. Decide to approach the problem of gaining trust as an exercise in risk management.
2. Develop a plan.
3. Implement the plan.
4. Assess the plan's effectiveness.
5. Modify the plan if necessary.
6. Go to step 1.

This is a sure-fire recipe for success—guaranteed. Barring total disaster outside the control of whomever is following the instructions (e.g., the company going out of business), it has never failed in this author's experience. That is because it is simply a basic problem-solving model. One can fill in the details, starting with risk management.

26.3 Risk Management 101

Risk management is an exercise in which one balances a simple equation. Exhibit 26.1 presents a simple picture of how the process of risk management works. A few definitions will help make it readable, starting with security. The *American Heritage Dictionary offers* several definitions, including:

> Freedom from risk or danger; safety.

Accepting this as a starting point presents the first challenge. How does one define risk, danger, and safety for a computing infrastructure? Start with some terminology.

26.3.1 Vulnerabilities, Threats, Risks, and Countermeasures

Sticking with commonly accepted security terminology, one can build a list that is oddly self-referential:

- *Vulnerability*: a weakness that can be exploited. Alternatively, a weakness in system security procedures, design, implementation, internal controls, etc., that could be exploited to violate a security policy.

[22] The bugtraq forum on http://www.securityfocus.com.

[23] Tsu, Sun, *On the Art of War, The Oldest Military Treatise in the World*, an easily accessible version, can be found at http://www.chinapage.com/sunzi-e.html.

[24] *The Skeptic's Dictionary*, http://skepdic.com/.

[25] Connie Brock.

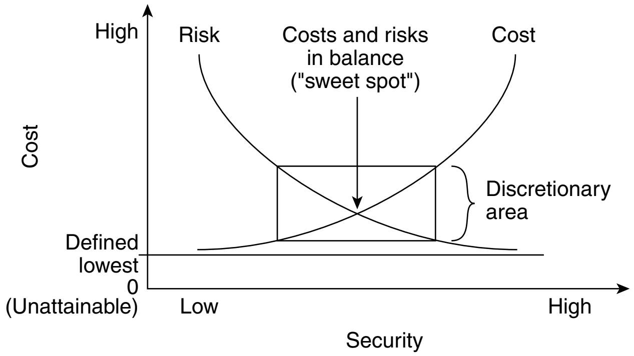

EXHIBIT 26.1 Balancing cost and security.

- *Threat*: anything or anyone that can exploit a vulnerability. Alternatively, any circumstance or event with the potential to cause harm to a system in the form of destruction, disclosure, modification of data, or denial-of-service.
- *Risk*: the likelihood and cost of a particular event occurring. Alternatively, the probability that a particular threat will exploit a particular vulnerability of a system.
- *Countermeasure*: a procedure or mechanism that reduces the probability that a specific vulnerability will be exploited or reduces the damage that can result from a specific vulnerability's exploit. Alternatively, a technique, an action, device, or other measure that reduces an infrastructure's vulnerability. (All of these are risks.)

The game is to balance the expense of incurring risk with the expense of mitigating (not merely mediating) risk by applying just the right amount of countermeasures to offset the vulnerabilities that exist.

Another way to look at this is from the point of view of cost. Exhibit 26.1 illustrates how costs and risk relate to each other. In addition, it shows how one can determine the optimum amount to spend on security. It plots the cost of security against the amount of security one is able to attain for that expenditure.

Perhaps one can now begin to see some of the challenges ahead. All by itself, building a common vocabulary is problematic. One can tackle each of these terms to see how to mold infrastructure security out of them.

These three concepts are logically related and can be grouped together for the sake of discussion. Using them, securing an infrastructure can be as simple as following three simple steps:

1. Identify a vulnerability
2. Identify the threats that can exploit it
3. Design and implement a countermeasure that will reduce the likelihood (risk) that a specific threat can exploit this vulnerability.

Seems simple enough. However, most infrastructures have enough different components in them to make this approach a truly daunting task. Nevertheless, it is an iterative process that uses these steps over and over again. In an ideal situation, every threat, vulnerability, and countermeasure is considered for every infrastructure component in an iterative process. Experience shows that unless one examines every component of an infrastructure in this manner, one simply cannot secure the infrastructure at large.

Practically speaking, however, this is impossible for all but the smallest organizations. Imagine stopping the business of an organization while one goes through this process. After all, the infrastructure is probably in place to support an organization's business needs—not the other way around.

The only exceptions to this rule are where good security is a design goal and there is a resource commitment to go with it. For example, an opportunity certainly exists when brand-new components or entirely new infrastructure are being installed.

Most people seem to believe that this thinking is restricted to so-called military-grade security. However, most segments of the economy are concerned enough about protecting their information assets to get serious about security. This includes most commercial, industrial, and educational organizations.

One problem is outdated thinking about threats and vulnerabilities. This is being overcome by new thinking that takes a fresh look at them, such as Donn Parker's new framework. It lists several dimensions of threats and vulnerabilities alongside asset categories.[26]

Take a look at how to solve the practical problem of how to complete this risk management exercise without stopping the business of the organization.

26.3.2 Analysis and Quantification

It seems almost obvious to say that the keys to finding and fixing vulnerabilities are analysis and quantification. Only almost, because most organizations do not approach security from a business or technical engineering perspective. Moreover, many organizations run off and buy security technology before they have even identified the problem. Suffice it to say, this sort of thinking is a trap.

To the experienced business or technical problem-solver, there is no other way to proceed. Given a well-stated problem, one simply has to analyze it and quantify the results as the first step.

So, how does one analyze and quantify vulnerabilities, threats, and countermeasures? Were it not for the maturity of the discipline of securing information systems, one would have an impossible task. As it is, this problem is well understood, and there are tools and techniques available. However, it is important to note that no tool is complete. In any case, most successful approaches use another one of the concepts in our basic vocabulary: risk.

Before taking even one step forward from here, a word of caution is in order:

> Quantification of risk is a hard problem.[27] In fact, all attempts to develop reasonable methods in this area have utterly failed over the last several decades. Donn Parker explains exactly how this happened in the 1998 edition of his book *Fighting Computer Crime*.[28] One might succeed in quantifying specific ratings in a narrowly defined area using an arbitrary ranking scale. However, experience shows that reconciling these ratings with others that use equally arbitrary ranking is impossible, especially on the scale of a contemporary, large, highly distributed organization.

One can use quantitative risk assessment methods. However, experience shows that one will end up using some form of qualitative measure in many areas. Consider the evaluation of a security program at large. One will likely want to score it based on an opinion of how well it is able to do its job for its own organization. Clearly, this requires a qualitative rating scale such as one that ranges from "poorly" to "superbly."

[26] Parker, Donn. 1998. *Fighting Computer Crime*, John Wiley & Sons, Inc., Chapter 11, Information Security Assessments, in particular. A summary of risk assessment failure begins on p. 277 of this chapter.

[27] There are two styles of risk analysis: Quantitative and qualitative. Dictionary definitions imply how they work: Quantification—"to determine, express, or measure the quantity of," qualitative—"of, relating to, or involving quality or kind," *WWWebster WWW Dictionary*, http://www.m-w.com/. In his book *Fighting Computer Crime*, Donn Parker presents a complete tutorial on them and why quantitative methods have failed.

[28] Parker, Donn. 1998. *Fighting Computer Crime*, John Wiley & Sons, Inc., Chapter 11, Information Security Assessments, in particular. A summary of risk assessment failure begins on p. 277 of this chapter.

26.3.3 Dealing with Risks

Anytime probability or likelihood is mentioned, most people get nervous. After all, there are systems and networks to secure. One does not need to get lost in "the possibilities." However, there is an intuitive appeal to quantifying things—especially when one has to ask for a budget to support one's security-related efforts. Management and bean counters have little tolerance for pure speculation, and techies and engineers want details. Everyone wants something concrete to work with. Therein lies the rub.

Given ample time and resources, all system and network managers worth their salt can identify security problems. The missing piece is the ability to quantify the effect of identified security problems in terms of their likelihood. This problem is discussed shortly. In the meantime, take a brief look at how risks are analyzed and quantified.

First, one must seek precise problem definition, analysis, and quantification. In addition, experienced problem-solvers will always ask about their goals. A good way to characterize problem solution goals is to rank them according to completeness:

- *Necessary*. These are the essential elements required to solve a problem. Necessary elements can be viewed as fundamental, cardinal, mandatory, or prerequisite.
- *Sufficient*. These are the additional elements that move a problem solution to completeness by making it adequate, ample, satisfactory, and complete.

Experience with security in commercial, industrial, and educational organizations shows that the essence of picking a reasonable security solution is found in the business and technical *artistry* of combining necessity and sufficiency. In this arena, it is not a science. However, high levels of security are only achieved through the rigor of mathematical proof and the application of rigid rules that strictly control their variables. Here, necessity is assumed and sufficiency is a baseline requirement.

The idea of introducing these concepts at this point is to focus on the cost of security. Properly chosen countermeasures mediate risks. However, in the same way that it takes money to make money, it takes money to provide security. Identifying needed countermeasures does no good if those countermeasures cannot be implemented and maintained because they are dismissed as too expensive.

26.3.4 Where the Rubber Meets the Road

There are few—if any—hard numbers surrounding security. This is especially bothersome when a system or network manager tries to explain to management exactly why those extra person-weeks are needed to properly configure or test the security-related aspects of infrastructure components. While a management team can usually quantify what a given information resource is worth to the business, it is nearly impossible for a system or network manager to translate this valuation directly into hard numbers for a security budget. Some relief is found in longtime security pundit Bob Courtney's summary:

> You never spend more than something is worth to protect it.

The problem is determining how much something is worth. The answer is achieving an appropriate balance between cost and risk. Exhibit 26.1 presents a time-honored graphic view of how this works in practice.

As one can see, the balance point between the amount of security one has and its cost (the risks or lack of security) is identified as the *Sweet Spot*. Also note that there is a box labeled *Discretionary Area* that includes an area around the *Sweet Spot*. This is the area in which the amount of security and its cost can be in balance. This is based on the fact that perfectly balancing the risk that one incurs with what it costs to maintain that level of security is very difficult, if not impossible. In other words, there is some discretion in the amount of risk one incurs before either the risks or the high costs being incurred would be considered out of hand by some commonly accepted standard.

For example, one will never be able to buy a virus scanner that protects against all viruses. Thus, one incurs more risk. On the other hand, one might operate under a conservative policy that severely restricts what can be executed. Thus, one incurs less risk because there are presumably fewer ways for a virus to propagate in one's environment.

Another way to think about this is that the *Discretionary Area* is an area in which both risks and expenditures are "reasonable." Generally speaking, points on the risk curve to the right of the *Sweet Spot* represent overspending (more security than is needed). Points of the risk curve to the left of the *Sweet Spot* represent underspending (less security than is needed).

26.3.5 Limits

A careful inspection of Exhibit 26.1 reveals that neither of the curves ever reach zero and that there are two zeros identified. Two important points about limits explain this:

1. One must define zero points. Infrastructures with absolute zero risk and security with absolute zero cost do not exist and cannot be created.
2. One must define maximums. One can spend as much as one has and still end up with an insecure infrastructure.

Keep it simple. In general, the less one spends, the more risk one incurs. The trick is to identify the level of risk that is acceptable. Again, this is the area Exhibit 26.1 identifies as *Discretionary.*

All of this begs the questions: how does one know what is reasonable?, and how does one determine the risks that exist? Take a look at one time-honored approach.

26.3.6 A Do-It-Yourself Kit

Exhibit 26.2 adds several ways to evaluate risk to the *x*-axis (security level) of Exhibit 26.1. These risk evaluation criteria are alternative scales on which to measure risk. Each scale includes labels that suggest how the cost of mitigating risk at this level is thought of by commonly accepted standards of due care.

Note that the additional information under the *x*-axis (security level) is in a box labeled *Apparent Choices*, *Alternatives*, *Opportunities*, and *Pitfalls*. This box encloses the acceptable ranges of risk (listed horizontally on the bottom of the diagram), just as the box labeled *Discretionary Area* did in Exhibit 26.1. These ranges are determined by various risk evaluation criteria (listed next to the right of their respective risk ranges on the bottom of the diagram).

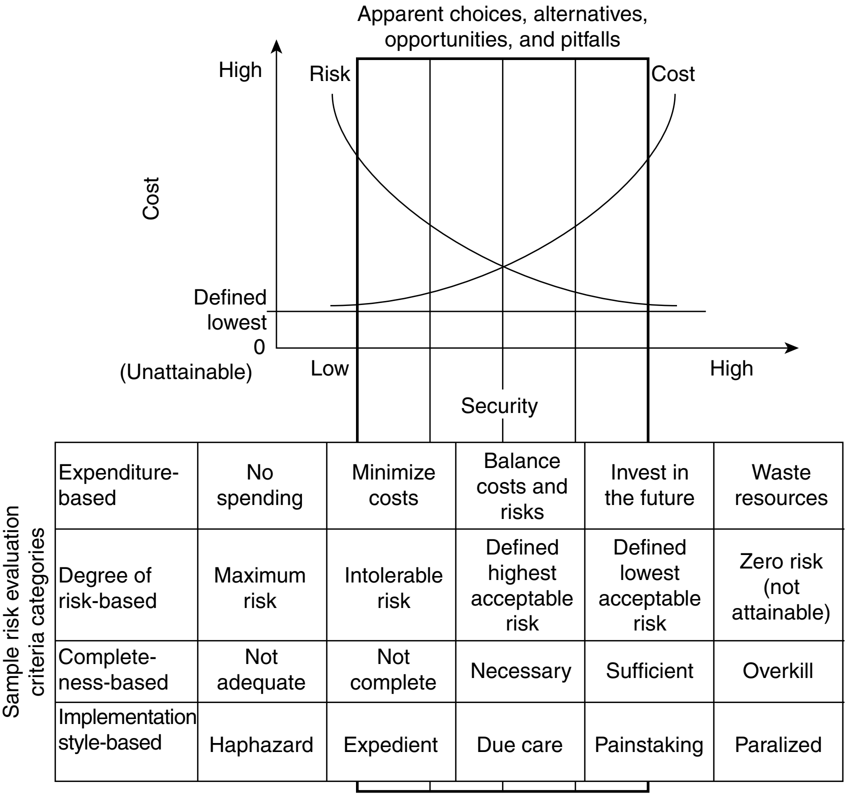
For example, look at *Expenditure-Based* risk evaluation criteria. To judge how much risk is acceptable, one can see that *No Spending* and *Waste Resources* are both outside of the box. No *Spending* is underkill, and *Waste Resources* is considered overkill—just as one would expect them to be. Using *Implementation Style Based risk* evaluation criteria, one can see that the *Apparent Choices*, *Alternatives*, *Opportunities*, *and Pitfalls* box encloses the range from *Expedient* to *Due Care* to *Painstaking*. Again, this is just as one would expect it to be.

One can add most any criteria one chooses. These are only examples to get started.

A note of caution is in order:

> Attempts to come up with a method to quantify risks have been largely unsuccessful and those that exist are problematic to use, at best. This is not an attempt to provide a quantitative approach to risk analysis past what is necessary for you to see how all of the factors affecting risk interact. In fact, one can see that the risk evaluation criteria that are listed below the *x*-axis (level of security) are actually a mix of quantitative and qualitative measures.

Asking what is important and how it will be measured is the best place to start. Once that is done, one can consider the various risk evaluation criteria that are available. While there are many considerations to choose from, those that matter to a particular organization are the most important.



Apparent choices, alternatives, opportunities, and pitfalls
High
Risk
Cost
Cost
Defined lowest
0
(Unattainable)
Low
High
Security
Sample risk evaluation criteria categories

Expenditure-based	No spending	Minimize costs	Balance costs and risks	Invest in the future	Waste resources
Degree of risk-based	Maximum risk	Intolerable risk	Defined highest acceptable risk	Defined lowest acceptable risk	Zero risk (not attainable)
Complete-ness-based	Not adequate	Not complete	Necessary	Sufficient	Overkill
Implementation style-based	Haphazard	Expedient	Due care	Painstaking	Paralized

EXHIBIT 26.2 Risk evaluation criteria.

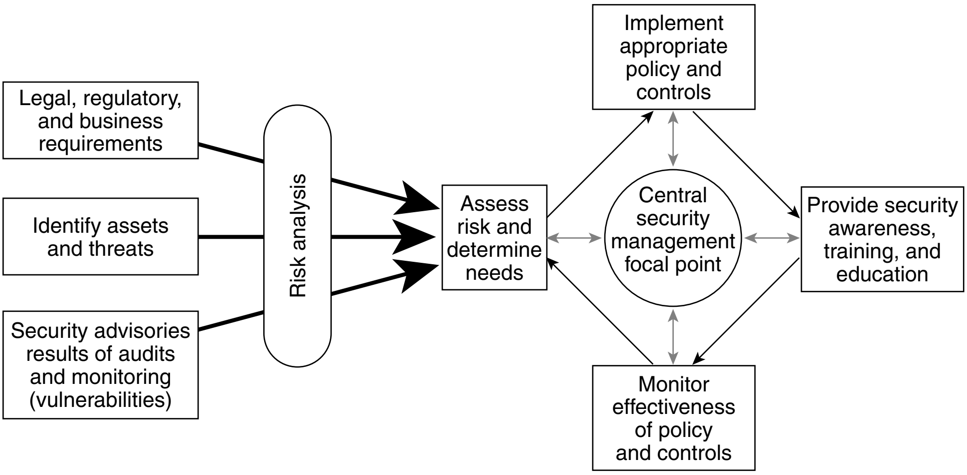
Surrounding an organization's unique concerns, there are standards of due care, common practice, and compliance that can be used as risk evaluation criteria—both from the point of view of industry-specific measures and measures that are common to all organizations. Auditors and other security professionals practiced in doing audits and assessments for a particular industry can provide the industry-specific standards that are important to an organization, as well as what is considered to be due care and common practice in general. For example, some industries such as defense contracting are required to do certain things and there is wide agreement in the security industry about what it takes to protect specific systems such as NT, UNIX, routers, etc., in general.

One will also have to find risk evaluation criteria that match the management style and culture of one's organization. Certainly, one would like to have risk evaluation formulae, models that implement them, and tools that automatically do all this according to Exhibit 26.2 suggestions. However, the state-of-the-art for analysis and quantification in security is quite far from point-and-click tools that do everything. No point-and-click tools do it all. Most of the tools that exist are basically spreadsheets that are elaborately scripted. Unfortunately, these tools help maintain a facade of value for quantitative risk assessment methods.

For now, risk assessment is still very much a job that falls to creative and experienced security professionals to sort out—one little, ugly detail at a time.

26.3.7 The Bottom Lines

Despite the apparent complexity, the process of securing one's infrastructure is quite well-understood and widely practiced. There is hope. The trick is to look at the information system and network



Legal, regulatory, and business requirements
Identify assets and threats
Security advisories results of audits and monitoring (vulnerabilities)
Risk analysis
Assess risk and determine needs
Implement appropriate policy and controls
Central security management focal point
Provide security awareness, training, and education
Monitor effectiveness of policy and controls

EXHIBIT 26.3 A plan for gaining trust.

infrastructures from a business point of view with a plan. Here are the steps to take and a framework in which one can operate—a time-tested way to approach the problem:

1. Identify the vulnerabilities and threats that the infrastructure faces.
2. Translate these vulnerabilities and threats into statements about the risks that they represent.
3. Organize the risks in a hierarchy that reflects the business needs of the organization.
4. Identify the countermeasures that are required to balance them.
5. Start working on a plan of attack for this list of risks.
6. Start working on reducing the biggest risks—today.

Now that one has a handle on risk, one can proceed to discuss how to gain trust in an infrastructure.

26.3.8 Gaining Trust

The reader will be happy to know that gaining trust in an infrastructure is a well-understood process. It is well-documented and widely practiced. In fact, the literature is ripe with examples. A good reference to the process is found in *Learning from Leading Organizations*.[29] Do not let the fact that it is a government document turn you away. It is an excellent reference, based on processes successfully applied by leading private-sector and government organizations. This author has used a modified version of this model to do security assessments (that is how I know it works so well). This GAO model has been extended to include some of the steps that precede one of the steps in the process. This is represented in Exhibit 26.3 as part of a methodology that works in practice.

In examining Exhibit 26.3, one sees that it includes an iterative loop. The assessment phase of the model has been expanded into a risk assessment and the parts that feed it:

- *Legal, Regulatory, and Business Requirements*: the process of sorting through an organization to identify its constraints (e.g., laws and oversight that determine how it must behave)
- *Identify Assets and Threats*: the process of sorting through an organization's priorities to find what is important and then isolating the threats to those assets
- *Security Advisories and Results of Audits and Monitoring*: the process of identifying the infrastructure's vulnerabilities

[29] U.S. General Accounting Office, *Executive Guide, Information Security Management, Learning from Leading Organizations*, GAO/AIMD-98-68, Information Security Management, http://www.gao.gov/special.pubs/pdf_sing.pdf.

The gory details of gaining trust in specific components of the infrastructure are a story for another dissertation. Suffice it to say, following a model such as that presented in the GAO report (as presented in Exhibit 26.3) to identify and mediate risks is a tried and true way to gain trust in one's infrastructure.

Acknowledgments

This chapter was originally an Invited Paper for the *Spring 2000 Internet Security Conference*, http://tisc.corecom.com/. Charlie Payne, Tom Haigh, Steve Kohler, Tom Markham, Rick Smith, Dan Thompson, and George Jelatis of Secure Computing; Randy Keader, Lori Blair, Bryan Koch, and Andrea Nelson of Guardent, Inc.; and Dave Piscitello of Core Competence, Inc., contributed to this paper.

Notes

URLs have been included for as many references as possible. Due to the volatile nature of the Web, these may change from time to time. In the event that a URL does not work, using the title of the reference as the search string for a capable search engine such as http://www.google.com should produce the page or a suitable substitute.

Trust Governance in a Web Services World

Daniel D. Houser

The problem space of trust governance is discussed, and five business drivers for trust governance are detailed, including the rise of Web Services, SAML, and Cross-Company Authentication. Xota^{SM}, a protocol for providing lightweight standards-based trust assertions, is introduced, as well as a framework for utilizing trusted third parties for generating trust assertions. With these in place, enterprise and division security postures can be dynamically evaluated for trustworthiness at the time each transaction or connection is made.

27.1 Introduction

Web Services are rapidly changing the face of E-business, while the trust models we use for conducting commerce remain largely unchanged. Cross-company authentication and portals are also increasing interdependence on business partner trustworthiness, while many trust models are built on houses of cards. Many organizations have little means of determining and evaluating the trustworthiness of business partners and their divisions aside from error-prone, expensive, and time-consuming processes. This chapter further outlines the business drivers in this space, and includes analysis of how hacker insurance and changing security attack patterns will likely lead to a regulated industry. With business drivers firmly in place and the problem space defined, a new open protocol for establishing trustworthiness at the transaction and message level is provided (Xota), which permits a dynamic assessment of a business partner's trust status at business application execution time, instead of months earlier. To deliver this protocol, a framework for utilizing trusted third-party assertions is also detailed, along with likely implementation plans for dynamic trust analysis in the B2B and B2C environment.

27.2 Prologue: A Story of E-Business and Trust Governance

The thought came to me one day as I reflected on meetings I had attended that morning. In two consecutive meetings, I was asked to provide a time estimate for my team's involvement to secure a data feed to a business partner. This straightforward, everyday IT project meeting had two very different outcomes because of a simple but significant difference. In the first meeting, I asked the business partner what kind of cryptography he provided to protect the data stream. His clear-cut answer described secure, well-proven means for protecting data. We heard names we trusted: PGP, SSL, RSA, VeriSign. I asked a few more questions and determined the protocols and modes he supported, and got solid answers. Finally, he was forthcoming with a vulnerability assessment from a reputable information security consulting firm, which included an assessment of the application. In five questions, I had determined enough to permit a comfortable level of trust in the strength of his data protection, because trusted third parties had done most of the work for us.

In the next meeting, it was "déjà vu all over again," to quote Yogi Bera. We had a similar discussion about a virtually identical product and process, and I asked the same questions but received starkly different answers. The second business partner had developed proprietary cryptography using its own homegrown algorithms. It had also spurned using a cryptographic toolkit for development, and used native C++ code, with its own random number generator. From a security perspective, this was a disaster! Proprietary cryptography is usually a very poor substitute for the real thing, and often easy to break. The costs to hire acryptographer, plus our team's involvement of 180–250 hours to certify the proprietary cryptography, would cost more than the expected profits. We could not trust this cryptography.

As I reflected back on these events at the end of the day, the stark contrast between the two meetings struck me. The first partner had enabled me to determine the risk of the transaction with just a few questions. By using protocols, toolkits, and a certificate authority that met our standards, and then wrapping it in a completed assessment delivered by a reliable third party, we had enough information to make a decision about the trustworthiness of their application. Then it hit me—what if trust assertions, during E-business transactions, could be driven down to this level of simplicity? How might that change the process for determining vendor trustworthiness?

27.3 Business Driver 1: Acceleration of E-Business through Web Services

In case you have been asleep for the past ten years, business acceleration through technology is moving at an incredible rate. Where formerly a typesetter could produce a book in three to six months, the same book can now be printed on-demand and bound in five minutes. Business formerly done through a handshake over dinner at the club is now brokered autonomously through EDI. Massive diversification, outsourcing, insourcing, and merger and acquisition fragmentation constantly shift the way industries and partners connect their networks together. In this arena, the latest force that promises to revolutionize the speed and ease of doing business is Web Services.

Consider the business and trust decisions that are made through conducting E-business in a Web Services transaction. Web Services offerings provide a near "instant-on" delivery of services and information through interoperable lightweight protocols: largely HTML, XML, and SOAP. Web Services transactions are ideally conducted through flexible interfaces that permit corporations to provide adaptable and extensible access portals for their legacy business logic and processes. Read the previous sentence again. It is not rhetoric; it is sincere. Consider the power of being able to broker a Web Service to a partner by providing an interface to the same object model that rests at the core of your business application. When you roll out new business functions for your business application, providing that same interface through your Web Service portal is a relatively simple operation. Imagine how quickly your business could pivot and respond to market changes if you remove the need to create and update yet another presentation and application layer each time you make a change. At long last, object technology is making a difference on the bottom line as competitive advantage is achieved by slashing time-to-market. This is a powerful force that is driving business to the speed of thought.

However, it is not just B2B (business-to-business) reaping the benefits of Web Services. Since mobile computing is driving the computing power of the individual to this ubiquitous edge, Web Services promise to deliver instant menus on-demand to handhelds when standing down the street, or perhaps instant call-ahead reservations for your table two minutes from now. These, however, are low-trust transactions, as there is little harm in a menu item being left off, or a reservation for four being dropped to two. In contrast, consider the trust necessary to conduct stock trades through the same device. This type of transaction requires a starkly different trust model for conducting instant business, particularly in B2C (business-to-commerce).

The need to provide stated trust levels for instant services executed on behalf of others is one of the driving forces behind the Security Assertions Markup Language (SAML), although it may not be immediately apparent. Most consumers do not have digital certificates, so consumers cannot easily assert their identity through a third party. Consumers' authentication is necessarily going to be brokered for B2B2C transactions for the foreseeable future. If you need that translated, brokered authentication equates to cross-realm authentication, or cross-company authentication. This is also referred to in some industry groups as "federated identity." With apologies to entities and organizations that do not call themselves a "company" (e.g., the FBI, the Republican Party, and UCLA), I will refer to this authentication as cross-company authentication, or CCA. Although CCA can carry substantial risks, because you are permitting another organization to manage the authentication credentials to your site, CCA is one of the drivers promising single sign-on between business partners and portals. There are already a substantial number of CCA projects that have been implemented in finance, government, and other industries, largely through proprietary (expensive) protocols. As an example, when consumers connect to Travelocity to book airfare on America West Airlines, they do not have to log in to Sabre or America West. Rather, Travelocity provides that authentication for them, as a brokered authentication session for that transaction conducted on their behalf. Through proprietary protocols, Travelocity asserts the identity of the consumer to Sabre, and Sabre asserts the identity of Travelocity to America West. This is a familiar model, but expensive to replicate, due to the proprietary protocols. Resolving this expensive implementation is the promise of SAML, as it provides the ability to ensure that the trust inherent in transactions is asserted through an interoperable authentication assertion protocol. Because it is interoperable, it is repeatable.

Web Services and cross-company authentication drive business to the cusp of instantaneous trust decisions because E-business and E-commerce trust decisions must be delivered within a very short click-stream. Remember: your customers may only tolerate ten seconds of Internet lag before they jump to a competitor's site, and connecting with the Web Service interface has already spent 15 percent of that time, so your model must be able to make a trust decision in two seconds or less.

Before you make that trust decision, there are some things to consider, not least of which is determining what you are trusting. Smart and well-meaning IT and business professionals are often far too loose with how they use the term "trust." If you listen to the Root Certificate Authorities discuss trust, many of them call their certificates "trust," which is over-simplified. Trust, at its core, is derived from "trustworthiness." The trust extended by a digital certificate through SSL is merely trust in the identification of the party on the other end of the SSL tunnel, which is *session trust*.

There are multiple levels of trust that must be embraced to conduct E-business, and digital certificates cannot provide trust in individual transactions/messages, business functions, or corporations (see Exhibit 27.1). Unfortunately, there are many companies that have trustworthy digital certificates about untrustworthy transactions or their untrustworthy corporations. I am sure that WorldCom

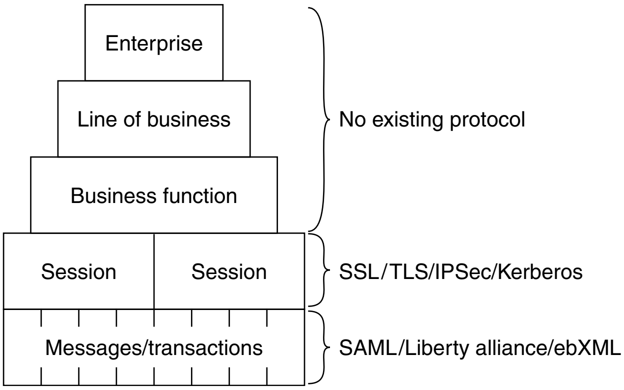

EXHIBIT 27.1 Protocols providing trust.

stockholders can help sharply differentiate the "trust" embodied in the SSL session that the lock icon in their browser assured them of as they connected to AOL and the trust they had in WorldCom after news of their financial scandal was made public.

It is this core differentiation, between the trustworthiness of a session and the trustworthiness of an organization, that is so problematic in the paradigm of Web Services, where instant trust decisions are necessary for trusted transactions. If this trust decision is further permitting outsourced authentication through CCA, the criticality of this trust is even more acute. How is it that you can determine, instantly, at the moment a Web Service transaction is occurring, if you can trust the security and privacy posture of a business partner or vendor?

If you do not think this is a problem, there are even stronger business drivers for trust governance.

27.4 Business Driver 2: Death by 1000 Cuts

When establishing new business relationships, companies must determine a number of things about their new partner, including their security posture, financial strength, and a number of other factors that help measure the trustworthiness of the organization. Because of the need to attest to the security of a partner organization, most organizations have reverted to making determinations of security posture through large proprietary checklists of questions that are exchanged and completed. Typically, after asking hundreds (or thousands) of probing questions, security and privacy analysts review the answers, score the organization's security posture, and make some report of findings. Based on the report, management is able to make some basic decision regarding the trustworthiness of the organization. As organizations become more interconnected with business partners and vendors, these stacks of checklists arrive more frequently. Many organizations have had to hire multiple employees to do nothing more than manage incoming and outbound ad-hoc security assessments. Furthermore, the margin of error after completing hundreds of manual and subjective assessments makes it likely that a few untrustworthy organizations were given a clean bill of health. However, that is only a small part of the problem. If the security policy of your company changes, many of your assessments are no longer valid. If your policy is strengthened, all the assessments you performed were measured against an old standard that was weaker, so your trust models are no longer valid. Your business practices at that point could be construed as no longer providing due diligence in protecting your information assets, because your effective security policy is less than your stated policy. If you have instead relaxed your security policy, all the assessments you provided to other organizations have been invalidated, which could represent liability.

27.5 Business Driver 3: Trust Erosion

Imagine that you moved to a new city six months ago, and your car's air conditioning goes out. How do you find a mechanic you can trust? Of course, you ask your neighbor, a friend at work, or a buddy at the gym where you can find a trustworthy mechanic. Five years later, their recommendation is now stale. If you did not return to the garage for five years, how would you know that that garage could still be trusted? This is one of the problems of trust, which degrades over time.

Security assessments, like any audit function, are out-of-date the minute they are performed. Simply put, an assessment from yesterday or last year cannot provide any trustworthiness in a vendor's current or future security posture. Assessments are also largely undertaken during the intense scrutiny brought about through purchasing, merger and acquisition, and contract negotiation activities, and may never be conducted again at that level of diligence. Very few organizations will undertake the expense of performing monthly, quarterly, or even annual audits of all business partners and vendors, so their partners' security postures are unknown at any given point. You certainly have a contract with various vendors who manage some of your customer, employee, or financial data. If one of those vendors eliminates employee bonding and drug testing, removes most firewalls, moves its hosting servers from a data center to a warehouse, and converts long-term debt into junk bonds, would your organization ever know?

At this point, lawyers will interject that contracts should protect the organization, if they have required that the business partner provide a stated level of security. This is true, but contracts can rarely provide adequate compensation for reputation and consequential damages from a serious security breach. There is no monetary salve that can erase your company's name from bad press.

27.6 Business Driver 4: Lack of Common Standards

Corporations today are inundated with a variety of organizations asking them to attest to their level of security in dozens of unique and proprietary ways, and there is no single security standard used in all organizations to provide a measurement of trust. Although many fine standards exist, such as ISO 17799, COBIT, GASSP, and the Common Criteria, they are so massive and stringent that few organizations can be 100-percent compliant with any one of them, and could never hope to achieve compliance with more than one. Some of these standards, such as the Common Criteria, make generalities about a corporation's recommended security stance, regardless of industry, which is patently false. To expect that all industries could (or should) have similar security standards and policies is ludicrous. While most U.S. financial organizations conduct drug tests and background checks when hiring, most higher education institutions would likely consider such measures heavy-handed, and might instead focus on evaluating employee curriculum vitae and transcripts. At the other end of the spectrum, the CIA, NSA, and defense contractors commonly use lifestyle polygraph tests on employees holding sensitive positions, security measures that would certainly not be viable for most organizations.

By contrast, other standards, such as GASSP, are such a generalized framework that compliance with GASSP is largely subjective. An assessment that asserted compliance with GASSP would not be useful to another entity because the underlying principles of best practice necessary to ensure compliance with GASSP are largely open to interpretation.

Clearly, a common standard or framework is needed so that assessments, conducted by one company's auditors, can be easily evaluated by partner companies to save expense and provide a better determination of trust.

27.7 Business Driver 5: Security Standard Regulation

At the RSA 2002 Conference, Bruce Schneier proposed a vision of the future that I found startling. It took several months for me to realize his vision was sound, although I disagreed with his forecasted end-result.

Schneier related the following timeline, which I present with my revisions:

- The "hacker insurance" market will continue to grow as CEOs look for ways to transfer risk.
- Small security events, such as the SQL Slammer attack of February 2003, will dramatically increase interest in acquiring hacker insurance.
- Many insurers will aggressively enter the hacker insurance market, seeking lucrative policies.
- Massive security events like Melissa and Code Red are evolving to resemble worldwide weather patterns and acts of God, rather than focused or targeted attacks. Just like weather-induced floods and earthquakes, these massive security events will attack quickly, universally, and cause widespread damage.
- A massive security event of Code Red proportion will overwhelm networks worldwide, and cause widespread, actual damage to corporate information through a destructive payload. Billions in damages will be registered, and several insurance companies will face crippling losses or go out of business.
- Just as insurers formed Underwriters Laboratories (UL) in the 1890s because they were tired of paying for electrical fires, insurers will again turn to UL and ask them to establish security standards that will be required for hacker insurance coverage.
- UL standards for security best practice will be published, and will start to appear in contracts as a base requirement to protect participants, just as ISO 9000 showed substantial growth through pressure by Fortune 500 companies on their supply chains.
- Eventually, UL standards will become codified by various government bodies and gain the rule of law, similar to the adoption of UL wiring and fire suppression standards that have been codified through municipal building codes.

Although some industries might welcome this regulation of security standards, many others would rather develop and police their own standards to ensure they were meeting their particular needs, rather than the needs of the insurers. We must either develop our own standards (soon!) and police ourselves, or the choices on how we secure our company data may be forced upon us, just as privacy law has done.

27.8 The Trust Governance Answer: Certified Trust Assertions

We return now to the original story, about the two business partners with starkly different cryptography solutions, and the idea it sparked in my brain.

I realized that if industries developed a simplified set of standards, perhaps they could simply state, with 100–300 statements, enough indicators about their security posture to enable others in the same industry to determine their trust status. They might be able to say six things about how they secure firewalls, five things about their host server hardening, five statements about their CIRT, three statements about hiring practices, etc. Once you have these answers, you can readily determine the high-level trustworthiness of a partner in the same industry. Perhaps 50 common questions could be established across all industries, and several more questions would provide the industry-specific standards.

This industry-specific security standard solves the problem of a common standard that can be evaluated, but does not address the timeliness of trust decisions. However, that model is even easier to provide. The same consortium that establishes the standard 100–300 questions also establishes the standards that certified auditors must meet in testing and reporting compliance with those standards. When an assessment is completed, the auditor, likely a major accounting firm, would generate a score and statement of scope. With this information, an organization would only need to know the answer to five questions to determine trustworthiness:

1. Who provided the audit?
2. What standard was used?

EXHIBIT 27.2 Example of What a Xota Assertion Would Look Like

Standard:	ISO17799-ABCDE
Score:	6.7.19.22.8.5.9.4.2.5.6.x.x.x.x.x.x.x.x.x
Score (Raw):	CACEADD9F7BFF7FDFF7B6D90E7D8CA04106C8B70
ORG:	O= EXAMPLE ORG; C=US; OU=BANKING; CN=CCU_APP
Included:	OU=BANKING
Excluded:	NONE
Date:	20020103101411.2Z

3. What was the score?
4. What was the scope of the audit?
5. What date was the audit conducted?

These questions cover everything a relying party needs to know, provided they trust the standard and the auditor, and have established scoring criteria for their organization. However, the real power is yet to come. As a required deliverable of the assessment, the auditing party would issue a digital signature that contains these five fields of information, and is issued by a trusted Root Certificate Authority. Because an X.509 certificate can be readily verified, such credentials would be nearly impossible to forge.

When connecting to a business application, part of the connection negotiation would require exchange of digital certificates to establish secure communications, and the trust assertion certificate could be included in this handshake (see Exhibit 27.2). The relying party can then extract the information, verify the public key, ensure that the integrity of the information is intact, and that the digital certificate has not been revoked. That process takes sub-seconds to perform, and is a time-honored process currently used in SSL.

For each business application, all organizations taking part in the transaction would establish minimal scoring standards for that application, aligned with the stipulations in the contractual agreement. The trust assertion analysis process then checks those baseline standards against the assertions, represented as the answers to those five questions detailed above (see Exhibit 27.3).

Again, because these standards are an extension of contractual obligations stipulated in the agreement between the two companies, the terms should be clear to all involved, and the trust analysis merely reflects the trust embodied in the contract. Because the standard and scope are flexible, each business application can determine what level and scope are required for the trust posture necessary for the application. Scope can readily be defined through embedded XML in the certificate, providing a pointer to LDAP-compliant Fully Distinguished Names (FDNs) and Relative Distinguished Names (RDNs). This would permit the application to determine how much of the infrastructure was covered by the auditor's assessment.

EXHIBIT 27.3 Answers to the Five Questions

Q1: Who provided the audit?
A1: "PDQ Audit Solutions" provided the audit.
Our business accepts them. Passed.

Q2: What standard was used?
A2: The standard was ISO 17799-ABCDE.
That's a standard we support. Passed.

Q3: What was the score?
A3: The score was 6.7.19.22.8.5.9.4.2.5.6.
Minimum for ISO 17799-ABCDE is 5.5.17.22.8.2.9.3.2.3.3. Passed.

Q4: What was the scope of the audit?
A4: The scope was the OU=Banking.
Business app is in Banking Division. Passed.

Q5: What date was the audit conducted?
A5: The date was 1/3/2002.
Maximum age is 18 months. Failed. Untrusted state.

In addition to providing scoring ranges for quick compliance scoring, the answer to each compliance question would also be communicated in hexadecimal notation (00-FF), providing a compact means of conveying assessment information, to facilitate very granular compliance analysis. For example, "FC" represents scoring answers of 11111100, which indicates the company is compliant with requirements 1 through 6, but is not compliant with standards 7 and 8.

Basing Certified Trust Assertions on X.509 is not an accident, because Certificate Revocation List (CRL) checking becomes an integral control of the methodology. If a security score downgrade is determined through an audit, event, or discovery, the auditor would be required to revoke the prior certificate and reissue the new one (which is a simple process). For a security score upgrade, a new certificate would be issued without revoking the "weaker" assertion, to avoid a denial-of-service in ongoing transactions using trust assertions. Checking certificate revocation against Certificate Revocation Lists ensures that the trust rating is still viable, and provides protection against fraud. Further, it permits all other parties relying on that trust assertion to know, near instantaneously, that the trust model has changed for that transaction.

This methodology, of determining trustworthiness through exchange of standards-based assertions of trust from third parties, is the core of the recently developed Xota protocol. Xota—eXtensible Organizational Trust Assertions—is the combination of the methodology and practices, which use trusted third parties, with the lightweight protocol to report the scope and standard used during the assessment, and the "score" of that assessment.

Because the trust assertion is provided via lightweight and ubiquitous X.509 digital certificates, nearly any system designed to provide authentication could readily request and analyze trust assertions. Both traditional client/server E-commerce and Web Services business applications can dynamically determine session trust, application trust, and entity trust, all at execution time. The same technology could be embedded in SSH to determine trustworthiness for logins, to protect file transfers and terminal emulation sessions. By placing trust assertion processing in e-mail gateways, spam can be deflected or routed based on the trust assertions embedded with the message, either by mail router trust assertions or those from the author's systems.

Trustworthiness of executables could also be governed if a secure kernel would not only verify the integrity against known, signed hashes, but would also perform trust assertion validation. By performing an assessment of the executable's Xota trust assertion, most importantly by assessing the viability of the certificate against a CRL, the kernel would be able to determine if the executable had lost its certification, perhaps because vulnerabilities had been published against that version of the application. Implementing such a methodology would require some serious shoring up of the certification and vetting process to ensure that a bogus CRL did not cause a massive denial-of-service attack, but still presents useful extensions for a trustworthy computing environment, particularly in a government or military application requiring certified executables.

Xota trust modeling is also viable for the B2C environment, and could be built into a browser quite easily to provide a security assessment automatically, just as PGP does for privacy. Java applets, ActiveX controls, JavaScript, VBScript, and embedded components could be required not only to be signed, but also to include a trust assertion for the application. Consumers would be able to determine the trustworthiness of the application, company, and privacy controls automatically at download, which could be a very powerful tool for consumers to identify malicious payloads, spyware, and untrustworthy companies.

27.9 Conclusion

The technical challenges to building a Xota-compliant trust assertion model are minimal, as all the necessary components exist today. Common standards would be helpful, but merely provide implementation lubrication to remove barriers and expense from implementation. Most of the assessments are already being conducted as part of vulnerability assessments, SAS 70 audits, and regulatory compliance assessments. The process could technically be implemented tomorrow by using an existing standard (e.g., ISO 17799), although it will almost certainly take the establishment of a consortium to develop standards that will evoke trust by participants. Additionally, the consortium should develop auditing standards and auditing certification processes to ensure that issuers of trust assertions follow the standards.

The benefits realized from developing this system speak directly to the five business drivers introduced earlier. Presuming adoption of the Xota protocol by business partners within one or more industries, what might trust governance look like within these paradigms?

27.9.1 Acceleration of E-Business through Web Services

By utilizing Xota trust assertions as an integral component of their Web Services offerings, business partners can now interconnect their Web Services very quickly. UDDI and WSDL are two protocols that permit Web Services and their interfaces to be published in a meta-directory, and hold the promise of "drag-and-drop" Web Services interface deployment. However, they are currently only used for referencing low-value transactions, due to the lack of trust and contractual assurances. By utilizing Xota trust assertions, UDDI and WSDL could also be used for high-value Web Services transactions. This would mean that the only remaining barrier for instant-on Web Services is contract negotiation. Business partners can now react very quickly to market changes by rolling out Web Services interfaces to existing and new partners in days instead of months, because the security and interface barriers can be identified within minutes instead of weeks.

Several consortiums and business groups are currently working to create "circles of trust" within industries, to permit Single Sign-on through federated identity management. However, these circles of trust are constrained when they cross industry, country, and other trust barriers. If these business trust models use Xota trust assertions to provide a common language and framework for trust modeling, these circles of trust may no longer be constrained to single industries or circles, but can now enable the rapid deployment of cross-industry E-business.

27.9.2 Death by 1000 Cuts

The most striking effect from implementation of trust governance lies in the compliance and assessment functions within organizations. By implementing rapid assessments with the Xota protocol, the tasks of establishing, assessing, and governing business trust models becomes an automated process. Further, by moving the trust assessments to the transaction point, compliance with the business trust model is provided automatically and proactively. Trust assertions can easily be forwarded to a central repository for further compliance analysis.

Once Xota trust modeling is implemented, compliance organizations can shift compliance workers from a cost to a revenue basis. Instead of the drudgery of assessing and reporting on security models, security knowledge workers can focus on building and extending trust models. Security assessments become a key business enabler, rather than a cost sink. Further, the hidden costs of continuous assessments and governance are converted into hard-dollar infrastructure and application costs that can be included in budgets for projects that implement those risks, rather than being borne by the security and compliance organizations as overhead. The risk posture of partnerships can also be determined and evaluated at the point of project initiation, rather than weeks later. By attaching costs and risks to the projects that generate them, senior management can make more-informed decisions on project return on investment (ROI) and return on risk.

27.9.3 Trust Erosion

Although most contracts today include verbiage that permits a periodic or unscheduled on-site visit by one or both parties of the contract, this assessment is rarely executed, due to the high cost of such assessments. However, with the availability of continuous determinations of trust compliance, these components of contract compliance are now verified automatically. If the contracts are structured to require periodic third-party assessments and Xota assertions, the trust models can be self-regulated through ongoing analysis of the trust assertions.

27.9.4 Common Standards

Through the creation of a common framework and language for discussing standards compliance, Xota permits translations of assessments across international and industry boundaries. If an assessment was provided against the Common Criteria standard, but the organization has based its policies and trust models on BS 7799, the assessment can still be used by the business partners. The relying organization would have to assess the individual answers to all the questions of the "new" standard, and then determine what its requirements would be within that business context. Once completed, the organization would have a template that can be used to translate Common Criteria to BS 7799, and this could be extended to other trust models in the organization. Although Xota does not provide a common standard, it does provide a common language for interpreting standards, and permits wide reuse of assessments across many isolated contexts.

27.9.5 Security Regulation

Security regulatory proponents primarily cite the need for regulation to establish and enforce common standards. With industry-wide adoption of Xota and the underlying standards, regulators can assess the compliance of organizations within their jurisdictional purview without the need to create yet another security standard. Insurers could likewise determine the risk posture of policyholders, and reward security diligence (or punish poor security) through a tiered pricing structure. By moving industries to a common language for communicating compliance with existing standards, the need to regulate security evaporates. Governing and regulatory bodies are able to provide compliance metrics and oversight without the need to enforce monolithic standards across the industry, and organizations are able to report their security posture without necessarily migrating to yet another security standard.

The power of Xota as the language of trust governance extends from the ability to make a clear determination of trustworthiness with five simple questions that can be dynamically assessed. The instant payoff from implementation is the ability to determine the trustworthiness of business partners without long checklists and expensive manual processes; and by ensuring that businesses, divisions, and applications are trustworthy at the point that messages and transactions are processed.

28

Risk Management and Analysis

Kevin Henry

Why risk management? What purpose does it serve and what real benefits does it provide? In today's overextended work environments, it can easily be perceived that "risk management and analysis" is just another hot buzzword or fashionable trend that occupies an enormous amount of time, keeps the "administrative types" busy and feeling important, and just hinders the "technical types" from getting their work done.

However, risk management can provide key benefits and savings to a corporation when used as a foundation for a focused and solid countermeasure and planning strategy.

Risk management is a keystone to effective performance and for targeted, proactive solutions to potential incidents. Many corporations have begun to recognize the importance of risk management through the appointment of a Chief Risk Officer. This also recognizes that risk management is a key function of many departments within the corporation. By coordinating the efforts and results of these many groups, a clearer picture of the entire scenario becomes apparent. Some of the groups that perform risk management as a part of their function include security (both physical and information systems security groups), audit, and emergency measures planning groups.

Because all of these areas are performing risk analysis, it is important for these groups to coordinate and interleave their efforts. This includes the sharing of information, as well as the communication of direction and reaction to incidents.

Risk analysis is the science of observation, knowledge, and evaluation—that is, keen eyesight, a bit of smarts, and a bit of luck. However, it is important to recognize that the more a person knows, the harder they work, often the luckier they get.

Risk management is the skill of handling the identified risks in the best possible method for the interests of the corporation.

Risk is often described by a mathematical formula:

$$\text{Risk} = \text{Threat} * \text{Vulnerability} * \text{Asset value}$$

This formula can be described and worked quite readily into the business environment using a common practical example. Using the example of the bully on the playground who threatens another child with physical harm outside the school gates after class, one can break down each component as follows:

- The threat is that of being beat up, and one can assign a likelihood to that threat. In this case, say that it is 80 percent likely that the bully will follow up on his threat unless something else intervenes (a countermeasure—discussed later).
- The vulnerability is the other child's weakness. The fact that the other child is unable to defend himself adequately against this physical attack means that the child is probably 100 percent likely to be harmed by a successful attack.
- The asset value is also easy to calculate. The cost of a new shirt or pants, because they will probably be hopelessly torn or stained as a result of an altercation and the resultant bloody nose, puts the value of the assets at $70.00.

Therefore, the total risk in this scenario is:

$$\text{Risk} = 80\% * 100\% * \ \$\ 70.00.$$

$$\text{Risk} = \ \$\ 56.00$$

Now one can ask: what is the value of this risk assessment? This assessment would be used to select and justify appropriate countermeasures and to take preventative action. The countermeasures could include hiring a bodyguard (a firewall) at a cost of $25.00, not going to school for the day (like shutting the system down and losing business), or taking out insurance to cover losses. The first of these primarily deals with strengthening the weakness(es) or vulnerabilities, while the third protects the asset value. Preventative action would include methods of reducing the threats, perhaps by befriending the bully, working out or learning karate, or moving out of town.

Thus, from this example, it is easy to describe a set of definitions in relation to risk management.

- Risk is any event that could impact a business and prevent it from reaching its corporate goals.
- Threat is the possibility or likelihood that the corporation will be exposed to an incident that has an impact on the business. Some experts have described a threat both in a positive sense as well as in a negative sense. Therefore, it is not certain that a threat will always have a negative impact; however, that is how it is usually interpreted.
- A vulnerability is the point of weakness that a threat can exploit. It is the soft underbelly or Achilles' heel where, despite the tough armor shielding the rest of the system, the attack is launched and may open the entire system or network to compromise. However, if risk is viewed as a potentially positive scenario, one should replace the term "vulnerability" with the term "opportunity" or "gateway." In this scenario, the key is to recognize and exploit the opportunity in a timely manner so that the maximum benefit of the risk is realized.
- The asset is the component that will be affected by the risk. From the example above, the asset was described as the clothing of the individual. This would be a typical quantitative interpretation of risk analysis. Quantitative risk analysis attempts to describe risk from a purely mathematical viewpoint, fixing a numerical value to every risk and using that as a guideline for further risk management decisions.

28.1 Quantitative Risk Analysis

Quantitative risk analysis has several advantages. It provides a rather straightforward result to support an accounting-based presentation to senior managers. It is also fairly simple and can easily follow a template type of approach. With support and input from all of the experts in the business groups and supporting research, much of the legwork behind quantitative analysis can be performed with minimal prior experience. Some of the steps of performing risk analysis are addressed later in this chapter.

However, it is also easy to see the weaknesses of quantitative risk analysis. While it provides some value from a budget or audit perspective, it disregards many other factors affected by an incident. From the previous example, how does one know the extent of the damage that would be caused by the bully? An assumption was made of generally external damage (clothing, scrapes, bruises, bloody nose), but the potential for damage goes well beyond that point. For example, in a business scenario, if a computer system is compromised, how does one know how far the damage has gone? Once the perpetrator is into a system and has the mind to commit a criminal act, what limits the duration or scope of the attack? What was stolen or copied? What Trojan horses, logic bombs, or viruses were introduced. What confidential information was exposed? And in today's most critical area, what private customer details or data were released. Because these factors are unknown, it is nearly impossible to put a credible number on the value of the damage to the asset.

This chapter, like most published manuscripts these days, is biased toward the perception of risk from a negative standpoint. On the other hand, when risk is regarded in a potentially positive situation, there is the difficulty of knowing the true benefit or timing of a successful exploitation of an opportunity. What would be the effect on the value of the asset if a person reacts today rather than tomorrow, or if the opportunity is missed altogether and the asset (corporation) thereby loses its leading-edge initiative and market presence? A clear example of this is the stock market. It can be incredibly positive if a person or company knows the ideal time to act (seize a risk); however, it can be devastating to wait a day or an hour too long.

Some of the factors that are difficult to assess in a quantitative risk analysis include the impact on employees, shareholders or owners, customers, regulatory agencies, suppliers, and credit rating agencies.

From an employee perspective, the damage from a successful attack can be severe and yet unknown. If an attack has an effect on morale, it can lead to unrealized productivity losses, skilled and experienced employee retention problems, bad reactions toward customers, and dysfunction or conflict in the workplace. It can also inhibit the recruitment of new, skilled personnel.

Shareholders or owners can easily become disillusioned with their investments if the company is not performing up to expectations. Once a series of incidents occur that prevent a company from reaching its goals, the attraction to move an investment or interest into a different corporation can be overpowering. Despite the best excuses and explanations, this movement of capital can significantly impact the financial position of the corporation.

Customers are the key to every successful endeavor. Even the best product, the best sales plans, and the best employees cannot overcome the failure to attract and retain customers. Often, the thought can be that the strength of a company can rest in a superior product; however, that is of little value if no one is interested in the services or products a company is trying to provide. A company with an inferior product will often outperform the company with superior products that gets some "bad press" or has problems with credibility. A lifetime warranty is of no value if the company fails because the billing system being used is insecure.

Regulatory agencies are often very vulnerable to public pressure and political influence. Once a company has gained a reputation for insecure or vulnerable business processes, the public pressure can force "kneejerk" reactions from politicians and regulatory agencies that can virtually handcuff a firm and cause unreasonable costs in new controls, procedures, reports, and litigation.

One of the best lessons learned from companies that have faced serious disasters and incidents is to immediately contact all major customers and suppliers to reassure them that the company is still viable and business processes are continuing. This is critical to maintaining confidence among these groups. Once a company has been exposed to a serious incident, the reluctance of a supplier to provide new raw materials, support, and credit can cripple a firm from re-establishing its market presence.

Because of the possible impact of an incident on all of these groups, and the difficulty in gauging a numerical value for any of these factors, it has been asserted by many experts that a purely quantitative risk analysis is not possible or practical.

28.2 Qualitative Risk Analysis

The alternative to quantitative risk analysis is qualitative risk analysis. Qualitative risk analysis is the process of evaluating risk based on scenarios and determining the impact that such an incident would have.

For qualitative risk analysis, a number of brief scenarios of potential incidents are outlined and those scenarios are developed or researched to examine which areas of the corporation would be affected and what would be the probable extent of the damage experienced by those areas in the event that this scenario ever occurred. This is based on the best estimates of the personnel involved.

Instead of a numerical interpretation of a risk as done in a quantitative risk analysis, a ranking of the risk relative to the affected areas is prepared. The risk analysis team will determine what types of incidents may occur, based on the best knowledge they can gain about the business environment in which the company operates. This is similar to the financial modeling done by strategic planning groups and marketing areas. By rolling out the scenario and inputting the variables that influence the event, the risk analysis team will attempt to identify every area that might be affected by an incident and determine the impact on that group based on a simple graph like "High Impact," "Medium Impact," "Low Impact"—or through a symbolic designation like 3,2,1 or 0 for no impact. When all of the affected areas are identified, the value for each area is summarized to gauge the total impact or risk to the company of that scenario occurring. In addition to purely financial considerations, some of the areas to include in this analysis are productivity, morale, credibility, public pressure, and the possible impact on future strategic initiatives.

Whenever doing a risk analysis of an information system, it is important to follow the guidelines of the AIC triad. The risk analyst must consider the availability requirements of the system. Is it imperative that it operates continuously, or can it be turned down for maintenance or suffer short outages due to system failure without causing a critical failure of the business process it supports? The integrity of the data and process controls and access controls around the systems and the underlying policies they are built on also need a thorough review. Probably no area has received as much negative publicity as the risk of data exposure from breaches of confidentiality in the past few years. A large, well-publicized breach of customer private information may well be a fatal incident for many firms.

One of the best methods to examine the relationship between the AIC triad and risk analysis is to perform general computer controls checks on all information systems. A short sample of a general computer controls questionnaire appears in Exhibit 28.1. This is a brief survey compiled from several similar documents available on the Internet. A proper general computer controls survey (see Exhibit 28.1) will identify weakness such as training, single points of failure, hardware and software support, and documentation. All of these are extremely valuable when assessing the true risk of an incident to a system.

However, qualitative risk analysis has its weaknesses just like quantitative risk analysis does. In the minds of senior managers, it can be too loose or imprecise and does not give a clear indication of the need or cost benefit analysis required to spur the purchase of countermeasures or to develop or initiate new policies or controls.

For this reason, most companies now perform a combination of these two risk analysis methodologies. They use scenario-based qualitative risk analysis (see Exhibit 28.2) to identify all of the areas impacted by an incident, and use quantitative risk analysis to put a rough dollar figure on the loss or impact of the risk according to certain assumptions about the incident. This presumes, of course, a high level of understanding and knowledge about the business processes and the potential risks.

EXHIBIT 28.1 General Computer Controls Guideline Questionnaire

Objective:

When an Auditor is involved in the analysis of a system or process that involves a software tool or computer system or hardware that may be unique to that department, we are requesting that the Auditor fill out this questionnaire, if possible, during the performance of the audit.

This will allow us to identify and monitor more of the systems in use throughout the company, and especially to assess the risk associated with these systems and indicate the need to include these systems in future audit plans.

Thanks for your assisance; if you have any questions, please contact either Alan or myslf.

System Name and Acronym: ______________________________

Key Contact Person: ____________________________________

Area where system is used: ______________________________

Questions for initial meeting:

Please describe the system function for us: ______________________________________

____

What operating platform does it work on (hardware)? ___________________________

Is it proprietary software? Yes ____ No ____ Who is the supplier? _________________

Does MTS have a copy of the source code? Yes ____ No ____

In which department? ____

Who can make changes to the source code?______________________________________

Are backups scheduled and stored offsite? Yes ____ No ____

How can we obtain a list of users of the systems
and their privileges? ____

Is there a maintenance contract for software and hardware? Yes ____ No ____

Can we get a copy? Yes ____ No ____

Separation of Duties:

Can the same person change security and programming or
perform data entry? Yes ____ No ____

Completeness and accuracy of inputs/processing/outputs:

Are there edit checks for inputs and controls over totals to ensure
that all inputs are entered and processed correctly? Yes ____ No ____

Who monitors job processing and would identify job failures? ____________________

Who receives copies of outputs/reports? ____

Authorization levels

Who has high-level authorization to the system? _________________________________

Security — physical and configuration

Are the hardware and data entry terminals secure? Can just
anyone get to them, especially high-level user workstations? Yes ____ No ____

Maintenance of tables

Are there any tables associated with the system
(i.e., tax tables, employee ID tables)? Yes ____ No ____

Who can amend these tables? ____

EXHIBIT 28.1 (Continued)

Documentation

Is the entire system and process documented? Yes ____ No ____

Where are these documents stored? ____

Training of end users

Who trains the users? ____

Who trains the system administrator? ____

Is there a knowledgeable backup person? ____

DRP of System

Has a Disaster Recovery Plan for this system been prepared and filed with Corporate Emergency Management? Yes ____ No ____

Please provide an example of an input/output. ____

Any other comments:

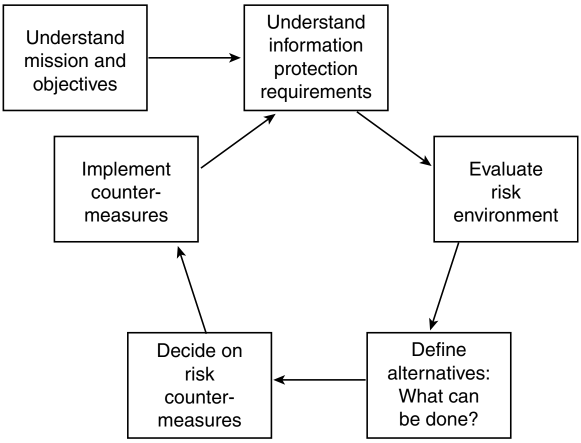
28.3 The Keys

If one were to describe three keys to risk analysis, they would be knowledge, observation, and business acumen.

28.3.1 Knowledge

Effective risk analysis depends on a thorough and realistic understanding of the environment in which a corporation operates. The risk manager must understand the possible threats and vulnerabilities that a corporation faces. These managers must have a current knowledge of new threats, trends, and system



Understand mission and objectives
Understand information protection requirements
Evaluate risk environment
Define alternatives: What can be done?
Decide on risk counter-measures
Implement counter-measures

EXHIBIT 28.2 Risk analysis/management process.

components, tools, and architectures in order to separate the hype and noise from the true vulnerabilities and solutions to their organization. To gain the cooperation of the business areas to perform risk analysis, and to be able to present the resulting credible recommendations to senior managers, the manager must be able to portray a realistic scenario of possible threats and countermeasures. This knowledge is gained through the continuous review of security bulletins, trade journals, and audits. For this reason, a Chief Risk Officer should also sit on the senior management team so that he or she has knowledge of corporate strategic direction and initiatives. The Chief Risk Officer should also receive regular updates of all ongoing incidents that may have an impact on the corporation.

28.3.2 Observation

Observation is the second key. We live in an age of overwhelming data and communication. Observation is the ability and skill to see through all of the outside influences and understand the underlying scenarios. Observation is to review all tools and reports routinely to notice if any abnormal conditions are being experienced. It is noteworthy that many excellent audit logs and output reports from tools are sitting unused on shelves because it is too difficult and time-consuming for most individuals to pick out the details. When a person first installs an intrusion detection system on his home PC, he suddenly becomes aware of the number of scans and hits he is exposed to. Did those just commence when he installed his IDS? No, it is just that he was able to observe them once he had purchased the correct tools. Therefore, observations and the use of tools are critical to understanding the characteristics and risks of the environment in which they operate.

28.3.3 Business Acumen

The main reason for risk analysis is to get results. Therefore, the third key is business acumen, that is, the ability to operate effectively in the business world—to sense and understand the methods and techniques to use to achieve the desired results. Business acumen separates the average manager from the effective manager. With business acumen, they know how to get things done, how to make powerful and credible presentations, when to cry wolf, and when to withdraw. Because the whole foundation of risk analysis is based on understanding and addressing the mission of the business, risk managers must have the ability to set aside their traditional biases and understand the perspective of the business area managers at the same time they are evaluating risk and countermeasures. An ideal risk management solution requires the support of the users, the business area managers, and effective administration. This means that the solution must not be seen as too intrusive or cumbersome for the users nor having a significant performance or productivity impact on the supporting business systems or processes.

28.4 Risk Management

This is where the science of risk management comes into effect. Risk management is the careful balance between placing controls into the business processes and systems to prevent, detect, and correct potential incidents, and the requirement that the risk management solution not impede or restrict the proper flow and timeliness of the business.

Once the risk assessment has been completed, the result should be a concise overview of all possible threats to the organization. Included in this review will be a listing of all identified threats, areas potentially impacted by a threat, estimated cost or damage from an exposure (a threat actually being realized or occurring), and the key players in each business group.

From this assessment, the risk managers must evaluate whether or not the risk identified supports the adoption of some form of countermeasure. Usually, these countermeasures can be grouped into three categories: reduce, assign, and accept.

28.4.1 Reduce

To reduce the risk, most often some new control is adopted. These controls can be either administrative (balancing, edits, ID control, process change, or physical access rules) or technical (intrusion detection systems, firewalls, architecture, or new tools). By evaluating the true extent of the risk and the business requirements, the risk manager will develop a list of possible solutions to the risks. These solutions will then be evaluated on the basis of cost, effectiveness, and user acceptance before being presented for approval and implementation.

By this time in the risk analysis and management process, some of the initial fear or excitement that was driving the risk analysis process may be starting to wane. Personnel are moving on to new issues and can become desensitized to the threats that caused them sleepless nights only a few weeks before. This is where many risk management processes become derailed. Solutions are proposed and even purchased, but now the impetus to implement them dries up. The new tools sit ignored because no one has the time to look at them and learn all of their features. The controls are relaxed and become ineffective, and the budget does not provide the funding to continue the administrative support of the controls effectively. These can be dark days for the risk manager, and the result is often an incomplete risk analysis and management process. Now, at the very verge of implementation, the project silently subsides.

This is a challenge for the risk manager. The manager must rise to the occasion and create an awareness program, explain the importance of the new controls, and foster an understanding among the user community of how this risk solution can play a critical role in the future health of their department and the corporation.

28.4.2 Outsourcing

One alternate solution being explored by many companies today is a hybrid between the adoption of risk management tools and the assignment of risk management. This is the concept of outsourcing key areas of the risk management process. It is difficult for a corporation to maintain a competent, knowledgeable staff to maintain some of the tools and products needed to secure an information system. Therefore, they leverage the expertise of a vendor that provides risk management services to several corporations and has a skilled and larger staff that can provide 24-hour support. This relieves the corporation from a need to continually update and train an extensive internal staff group and at the same time can provide some proof of due diligence through the independent evaluation and recommendations of a third party. This does have significant challenges, however. The corporation needs to ensure that the promised services are being delivered, and that the knowledge and care of the corporate network entrusted to a third party are kept secure and confidential. Nothing is worse than hiring a fox to guard the chicken house. Through an outsourcing agreement, the risk manager must maintain the competence to evaluate the performance of the outsourcing support firm.

28.4.3 Assign

To assign the risk is to defer or pass some of the risk off to another firm. This is usually done through some insurance or service level agreement. Insurers will also require a fairly thorough check of the risks to the corporation they are ensuring to verify that all risks are acknowledged and that good practices are being followed. Such insurance should be closely evaluated to confirm that the corporation understands the limitations that could affect a reimbursement from the insurer in the event of a failure. Some of the insurance that one will undoubtedly be seeing more of will be denial-of-service, E-business interruption, and Web site defacement insurance.

28.4.4 Accept

When a risk is either determined to be of an insignificant level, or it has been reduced through countermeasures to a tolerable level, acceptance of the residual risk is required. To accept a level of risk, management must be apprised of the risk analysis process that was used to determine the extent of the risk. Once management has been presented with these results, they must sign off on the acceptance of the risk. This presumes that a risk is defined to be at a tolerable level, either because it is of insignificant impact, countermeasure costs or processes outweigh the cost of the impact, or no viable method of risk prevention is currently available.

28.5 Summary

Risk analysis and management is a growing and exciting area. The ability of a corporation to identify risks and prevent incidents or exposures is a significant benefit to ensuring continued business viability and growth even in the midst of increasing threats and pressures. The ability of the risk managers to coordinate their efforts alongside the requirements of the business and to keep abreast of new developments and technologies will set the superb risk managers apart from the mundane and ineffective.

For further research into risk analysis and management, see the Information Assurance Technical Framework (IATF) at www.iatf.net.

New Trends in Information Risk Management

Brett Regan Young

Corporations have increased their investment in information security because critical business systems have moved into increasingly hostile territory. As the enterprise has embraced new technologies such as EDI/EFT, remote access, and sales automation, confidential data has gradually found itself in ever-riskier venues. Moving to the Internet is the latest—and riskiest—frontier. Nevertheless, forward-looking companies are willing to face the growing and unpredictable body of risks on the Internet to create competitive advantage.

Management of information risk is a new discipline, following on the heels of electronic information systems in general. To date, in the majority of organizations, information risk management has been done largely with a "seat of the britches" approach. The opinions of experts are often sought to assist with current protection needs while divining future threats. Electronic fortifications have been erected to improve an organization's defensive position. These measures, while allowing businesses to operate within the delicate balance of controls and risks, have had mixed success. This is not to say that organizations have not been hit by computer crime. The extent and frequency of such crimes have been historically low enough to give the impression that IS departments and security teams were managing information risk sufficiently well.

29.1 A Traditional Approach

Conventional risk analysis is a well-defined science that assists in decision support for businesses. The most common use of risk analysis is to lend order to apparently random events. By observing the frequency of an event factored by the magnitude of the occurrences, one can predict, with more or less accuracy, when and to what degree something might happen. Thus, one might expect ten earthquakes of a 7 magnitude to strike Yokohama within 100 years. When information is available to indicate the projected expense of each episode, then one can ascertain the ALE (annual loss expectancy). Conventional risk analysis is a powerful tool for managing risk, but it works best when analyzing static or slowly evolving systems such as human beings, traffic patterns, or terrestrial phenomena. Incidents that cause the loss of computing functions are difficult to map and even more difficult to predict. Two reasons for this are:

1. Trends in computing change so rapidly that it is difficult to collect enough historical data to make any intelligent predictions. A good example of this can be found in the area of system outages. An observer in California might predict that a server farm should suffer no more than one, three-hour outage in ten years. In 1996, that was plausible. Less than five years later and after an extended power crisis, that estimate was probably off by a factor of ten.
2. There is a contrarian nature to computer crime. Criminals tend to strike the least protected part of an enterprise. Because of the reactive nature of information security teams, it is most likely that one will add protection where one was last hit. This relationship between attackers and attacked makes most attempts to predict dangerously off-track.

While information risk shares aspects with other types of business risks, it is also unique, making it difficult to analyze and address using conventional methods.

29.2 Doing Our Best

To protect their E-commerce operations, most businesses have relied primarily on an “avoidance” strategy, focusing on components such as firewalls and authentication systems. Daily reports of Internet exploits have shown that these avoidance measures, while absolutely essential, are not a sufficient defense. Avoidance strategies offer little recourse when incursions or failures do occur. And despite an organization’s best efforts to avoid intrusions and outages, they will occur. In the high-stakes world of E-commerce, would-be survivors must understand this and they need to prepare accordingly.

Reports of Internet intrusions are frequent—and frightening enough to get the attention of management. Tragically, the most common response from corporate management and IS directors is a simple redoubling of current efforts. This reaction, largely driven by fear, will never be more than partially successful. It is simply not possible to out-maneuver Internet thugs by tacking new devices onto the perimeter.

The most telling metric of failed security strategies is financial. According to one source, funding for defensive programs and devices will increase an estimated 55 percent during the two years leading up to 2004, growing to a projected $19.7 billion for U.S. entities alone.[1] Keeping pace with rising computer security budgets are the material effects of computer crime. Dramatic increases in both the frequency and extent of damage were reported in the most recent annual Computer Security Institute (CSI)/FBI computer crime survey. The 273 respondents reported a total of $265 million in losses. These figures were up from the $120 million reported the previous year.[2] While the survey results are not an absolute measure of the phenomenon, it is a chilling thought to imagine that the enormous increases in security spending may not be keeping up with 50 percent and greater annual increases in material damage suffered as a result of computer-related crime.

The composite picture of rising costs for security chasing rising damages casts a dark shadow on the future of electronic commerce. Left unchecked, security threats coupled with security mismanagement could bring otherwise healthy companies to ruin. The ones that escape being hacked may succumb to the exorbitant costs of protection.

29.3 Common Sense

29.3.1 Who Let the Cows Out?

During the 1990 s, a trend emerged among IS management to focus intensely on prevention of negative security events, often to the exclusion of more comprehensive strategies. There were three distinct rationales behind this emphasis:

1. *Experience has consistently shown that it is cheaper to avoid a negative incident than to recover from it.* This is most often expressed with a barnyard metaphor: "like shutting the gate after the cows are gone." The implication is that recovery operations (i.e., rounding up livestock after they have gotten loose) is infinitely more trouble than simply minding the latch on the gate.
2. *Loss of confidentiality often cannot be recovered, and there is, accordingly, no adequate insurance for it.* Valuing confidential information poses a paradox. All of the value of some types of confidential information may be lost upon disclosure. Conversely, the value of specific information can shoot up in certain circumstances, such as an IPO or merger. Extreme situations such as these have contributed to an "all-or-nothing" mentality.
3. *The "bastion" approach is an easier sell to management than recovery capability.* Information security has always been a hard sell. It adds little to the bottom line and is inherently expensive. A realistic approach, where contingencies are described for circumvented security systems, would not make the sale any easier.

The first argument makes sense: avoidance is cheaper than recovery in the long run. In theory, if new and better defenses are put in place with smarter and better-trained staff to monitor them, then the problem should be contained. The anticipated results would be a more secure workplace; however, precisely the opposite is being witnessed, as evidenced by the explosive growth of computer crime.

The bastion approach has failed to live up to its expectations. This is not because the technology was not sufficient. The problem lies in the nature of the threats involved. One constant vexation to security teams charged with protecting a corporation's information assets is the speed with which new exploits are developed. This rapid development is attributable to the near-infinite amount of volunteer work performed by would-be criminals around the world. Attacks on the Internet are the ultimate example of guerilla warfare. The attacks are random, the army is formless, and communication between enemy contingents is almost instantaneous. There is simply no firewall or intrusion detection system that is comprehensive and current enough to provide 100 percent coverage. To stay current, a successful defense system would require the "perps" to submit their exploits before executing them. While this may seem ludicrous, it illustrates well the development cycle of defensive systems. Most often, the exploit must be executed, then detected, and finally understood before a defense can be engineered.

Despite the media's fascination with electronic criminals, it is the post-event heroics that really garner attention. When a high-volume E-commerce site takes a hit, the onlookers (especially affected shareholders) are less interested in the details of the exploit than they are in how long the site was down and whether there is any risk of further interruption. Ironically, despite this interest, spending for incident response and recovery has historically been shorted in security and E-commerce budgets.

It is time to rethink information protection strategies to bring them more in line with current risks. Organizations doing business on the Internet should frequently revise their information protection strategies to take into account the likelihood of having to recover from a malicious strike by criminals, a natural disaster, or other failures. Adequate preparation for recovery is expensive, but it is absolutely necessary for businesses that rely on the Internet for mission-critical (time-critical) services.

Exhibit 29.1 illustrates a simple hierarchy of information security defenses. The defenses garnering the most attention (and budget dollars) are in the lower three categories, with avoidance capturing the lion's

EXHIBIT 29.1 Information Protection Model

Level	Examples
Recovery	Incident response, disaster recovery
Detection	Intrusion detection
Assurance	Vulnerability analysis, log reviews
Avoidance	Firewalls, PKI, policy and standards

Courtesy of Peter Stephenson of the Netigy Corporation.

share. Organizations will need to include recovery and bolster assurance and detection if they are to successfully protect their E-commerce operations.

29.4 A Different Twist: Business Continuity Management

Business continuity management (BCM) is a subset of information security that has established recovery as its primary method of risk management. Where other areas of information security have been preoccupied with prevention, BCM has focused almost exclusively on recovery. And just as security needs to broaden its focus on post-event strategies, business continuity needs to broaden its focus to include pre-event strategies. BCM in the E-commerce era will need to devise avoidance strategies to effectively protect the enterprise. The reason for this is time.

A review of availability requirements for Internet business reveals an alarming fact: there often is not enough time to recover from an outage without suffering irreparable damage. Where BCM has historically relied heavily on recovery strategies to maintain system availability, the demands of E-commerce may make recovery an unworkable option. The reason for this is defined by the fundamental variable of maximum tolerable downtime (MTD). The MTD is a measure of just how much time a system can be unavailable with the business still able to recover from the financial, operational, and reputational impacts.

E-commerce has shortened the MTD to almost nil in some cases. A few years back, a warehousing system might have had the luxury of several days' recovery time after a disaster. With the introduction of 24/7 global services, an acceptable downtime during recovery operations might be mere minutes. In this case, one is left with a paradox: the only workable alternatives to recovery are avoidance strategies.

Referring again to the information protection model, shown in Exhibit 29.1, BCM now requires more solutions at the lower avoidance area of the hierarchy. Discussing these solutions is not within the scope of this chapter, but examples of enhancing availability include system redundancy, duplexing, failover, and data replication across geographical distances. Another indication of the shift in focus is that business continuity now requires a greater investment in assurance and detection technologies. In 2002, was likely that a company's Web presence would fail as a result of a malicious attack because it is from a physical failure. Business continuity teams once relied on calls from end users or the helpdesk for notification of a system failure; but today, sophisticated monitoring and detection techniques are essential for an organization to respond to an attack quickly enough to prevent lasting damage.

The makeup of business continuity teams will likewise need to change to reflect this new reality. A decade ago, business continuity was largely the domain of subject matter experts and dedicated business continuity planners. The distributed denial-of-service attacks witnessed in February 2000 spawned ad hoc teams made up of firewall experts, router jocks, and incident management experts. The teams tackled what was, by definition, a business continuity issue: loss of system availability.

29.5 Reworking the Enterprise's Defenses

One only needs to look back as far as the mid-1990 s to remember a time when it seemed that we had most of the answers and were making impressive progress in managing information risk. New threats to organizational security were sure to come, but technological advances would keep those in check—it was hoped. Then the rigorous requirements of protecting information within the insecurity of a wired frontier jarred us back to reality. Waves of malicious assaults and frequent outages suggest that it may be a long time before one can relax again. But one should take heart. A thorough review of the current risk terrain, coupled with renewed vigilance, should pull us through. It is quite clear, however, that organizations should not expect to improve the protection of their environments if they continue to use the same strategies that have been losing ground over the past several years. Coming out on top in the E-commerce age will require one to rethink positions and discard failed strategies.

It should be encouragement to us all that reworking the enterprise's defenses requires more rethinking than retooling. Many of the requisite techniques are already resident in the enterprise or can be readily obtained. In recommending a review of an organization's defensive strategy, four principal areas of analysis need to be applied. They are presented below.

29.5.1 Security Architecture

Building an appropriate security architecture for an organization requires a thorough understanding of the organization's primary business functions. This understanding is best obtained through interviews with business leaders within the organization. Once discovered, the primary business functions can be linked to information technology services. These, in turn, will require protection from outside attack, espionage, and systems outage. Protecting IS services and systems is accomplished using security practices and mechanisms. Thus, the results of a security architecture study relate the activities of the information security group back to the primary business of the company.

The results of a security architecture study are particularly enlightening to businesses that have recently jumped onto the Internet. Quite often, businesses will have security processes and mechanisms protecting areas of secondary criticality while new business-critical areas go unprotected. Devising an effective architecture model allows an organization to allocate sufficient resources to the areas that need the most protection.

An additional benefit of the results of a security architecture study lies in its bridging function. Security architecture tracks relationships between information security and business functions that it protects, demonstrating the value of information security to the enterprise. The resultant insights can prove quite valuable as a support tool for budgetary requests.

29.5.2 Business Impact Analysis

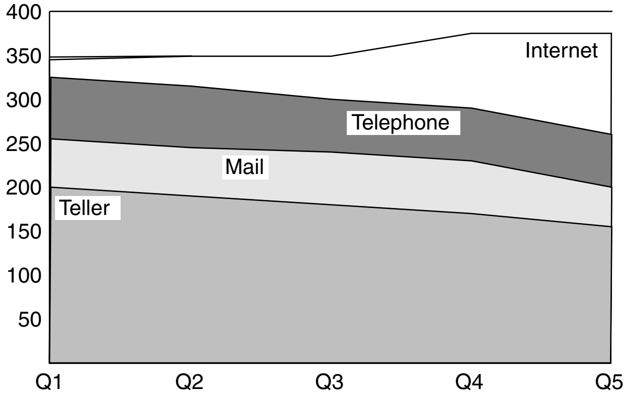
Business impact analysis (or BIA) has been used as an essential component of business continuity planning for some years. The BIA estimates the cost per time unit of an outage of a specific system. Once this cost is known for a specific system (e.g., $100,000 per day), then informed decisions can be made concerning the system's protection. In addition to the practical uses for such information, the cost of a potential outage is the type of information that makes corporate management less reluctant to budget for protective measures.

The BIA has been a tool employed almost exclusively by business continuity planners until very recently. As malicious attacks on E-commerce availability have become a costly form of computer crime, the BIA is receiving a broader base of attention.

Two points must be made with respect to doing a BIA on E-commerce systems. First, as the MTD approaches zero, the potential business impact will appear absolute and infinite—much like an asymptote. Some understanding of the actual workings of the system may be indicated here. Unfortunately, because so many systems connected to the Internet host real-time activities, such as stock trading, the impact of a specific system outage may indeed be immediately devastating. This might be the case with a back-office, host-based system that previously had a more relaxed recovery requirement. Moving to a real-time Internet business model may put 7×24 requirements on legacy systems. The resulting dilemma may force decisions regarding the ability of the enterprise to run its business on certain platforms.

Second, a BIA that uses multiple revenue streams as a source of potential lost profit will need to be updated frequently as business shifts to the Internet. This is to say, for example, that a company trying to replace a telephone center with an Internet-based alternative should weight impacts to the telephone center with decreasing importance. This can be accomplished by frequently updating the BIA or by extrapolating future numbers using projections. An example for a bank transitioning to online services is shown in Exhibit 29.2.

The results of a BIA fasten perceived risks to a concrete anchor—money. As with a security architecture review, the information returned suggests a very potent tool. Obtaining resources to protect a business-critical system or process is far easier when the costs of an outage have been tallied and presented to management.



A bank's transaction totals are shown in millions of dollars per quarter. Four types of transactions are added to obtain the total. As revenue streams shift from one revenue source to another, material impacts to the bank for failed systems in each of the four areas should increase or decrease in proportion to the change. Thus, the numbers used in a BIA must be extrapolated in anticipation of the changes.

EXHIBIT 29.2 Banking services over time.

29.5.3 Risk Analysis

Risk analysis isolates and ranks individual risks to a specific system or process. In the past, quantitative risk analysis was time-consuming and not terribly accurate. In the area of E-commerce, risk analysis needs to be swift and decisive to be useful. In industries where marketing goals and production are expected to shift quickly to maximize profitability, risk analysis is the key to avoiding dangerous situations. It can provide the candid observations and raw ideas necessary to devise strategies to avoid and to resist threats.

The method known as facilitated risk analysis, taught by the CSI, offers a rapid, straightforward approach to ascertaining risks without getting bogged down in unnecessary details. Using this approach, a facilitator directs a small group (usually six to twelve people) through a series of questions designed to evoke the participant's impression of the threats to a particular system. Ideally, those participating will represent a diverse group of people, each having a unique view of the system. The process resembles a group interview, in that real-time peer review of each person's comments takes place. The results are a synthesized picture of the system's significant risks and a number of suggested controls for mitigating the risks.

As a process, the facilitated risk analysis is sufficiently lightweight that it could be repeated as often as required without overly taxing the affected group. Effective information security management depends on having a current, realistic assessment of risks to the enterprise's information. It also serves as a check to ensure that the mission of the information security team is in line with the customer's expectations.

29.5.4 Incident Response

Twenty years ago, incident response was exclusively the domain of disaster recovery and corporate (physical) security. If the incident was a massive system failure, the recovery team invoked a detailed, formal plan to recover the information asset. Had there been a reason to suspect wrongdoing, a fraud investigator would be enlisted to investigate the alleged crime.

Client/server and PC networks brought in their wake a wide range of vulnerabilities requiring proactive mechanisms to protect internal networks and hosts. As IS shops raced forward in the waves of new technologies, avoidance remained the preferred strategy—but ad hoc recovery became the new reality. In truth, most organizations make a dreadful mess of recovering from incidents.

In most shops today, incident response is the weakest tool of information defense. Incident recovery is the ability to detect and respond to an unplanned, negative incident in an organization's information systems. Most companies are woefully unprepared to respond to an incident because of their unwavering faith in avoidance. The approach of building an invincible wall around a trusted network was sold so well in the past decade that many organizations felt that spending on detection and recovery from computer crime was a frivolous waste of money. This is the same mix of technological faith and naiveté that supplied lifeboats for only half the passengers on the Titanic.

The appalling lack of incident response capability in most corporate environments is especially salient when one looks at a particularly embarrassing segment of computer crime: insider crime. The CSI/FBI computer crime survey presents an alarming picture of corporate crime that has not deviated very much over the past few years. The survey indicates that corporate insiders perpetrate approximately 70 percent of incidents reported in the survey. Even if overstated, the numbers underscore the need for increased detection and response capabilities. The criminals in these cases were found on the "friendly" side of the firewall. These threats are largely undeterred by the recent increases in funding for Internet security, and they require mechanisms for detection and response expertise to resolve.

Incident response brings an essential element to the arsenal of information security; that is, the organizational skill of having a group rapidly assess a complex situation and assemble a response. Properly managed, an incident response program can save the organization from disaster. The team needs a wide variety of experts to be successful, including legal, networking, security, and public relations experts. And the organization needs to exercise the team with frequent drills.

29.6 Conclusion

While the demand for security goods and services is experiencing boundless growth, the total cost of computer crime may be outpacing spending. This should prompt a thorough review of defensive strategies; instead, corporate IS managers seem prepared to increase funding to still higher levels in a futile attempt to build stronger perimeters. There is little reason for optimism for this program, given recent history.

The Internet now hosts live transaction business processes in almost every industry. Hitherto unthinkable exposures of technical, financial, and corporate reputations are the daily grist of the 21st-century information workers. Information risk management was once feasible with a small number of decision makers and security technicians. Those days are gone. Risk management in an atmosphere that is so fraught with danger and constantly in flux requires clear thought and a broad base of experience. It requires that one take extraordinary measures to protect information while preparing for the failure of the same measures. It also requires wider participation with other groups in the enterprise.

It is incumbent on those who are in a position of influence to push for a more comprehensive set of defenses. Success in the Internet age depends on building a robust infrastructure that avoids negative incidents and is positioned to recover from them as well. Risk management in the 21st-century will require adequate attention to both pre-event (avoidance and assurance) measures as well as post-event (detection and recovery) measures. While the task seems daunting, success will depend on application of techniques that are already well-understood—but lamentably underutilized.

Cyber-Risk Management: Technical and Insurance Controls for Enterprise-Level Security

Carol A. Siegel

Ty R. Sagalow

Paul Serritella

Traditional approaches to security architecture and design have attempted to achieve the goal of the elimination of risk factors—the complete prevention of system compromise through technical and procedural means. Insurance-based solutions to risk long ago admitted that a complete elimination of risk is impossible and, instead, have focused more on reducing the impact of harm through financial avenues—providing policies that indemnify the policyholder in the event of harm.

It is becoming increasingly clear that early models of computer security, which focused exclusively on the risk-elimination model, are not sufficient in the increasingly complex world of the Internet. There is simply no magic bullet for computer security; no amount of time or money can create a perfectly hardened system. However, insurance cannot stand alone as a risk mitigation tool—the front line of defense must always be a complete information security program and the implementation of security tools and products. It is only through leveraging both approaches in a complementary fashion that an organization can reach the greatest degree of risk reduction and control. Thus, today, the optimal model requires a program of understanding, mitigating, and transferring risk through the use of integrating technology, processes, and insurance—that is, a risk management approach.

The risk management approach starts with a complete understanding of the risk factors facing an organization. Risk assessments allow for security teams to design appropriate control systems and leverage the necessary technical tools; they also are required for insurance companies to properly draft and price policies for the remediation of harm. Complete risk assessments must take into account not only the known risks to a system but also the possible exploits that might develop in the future. The completeness of cyber risk management and assessment is the backbone of any secure computing environment.

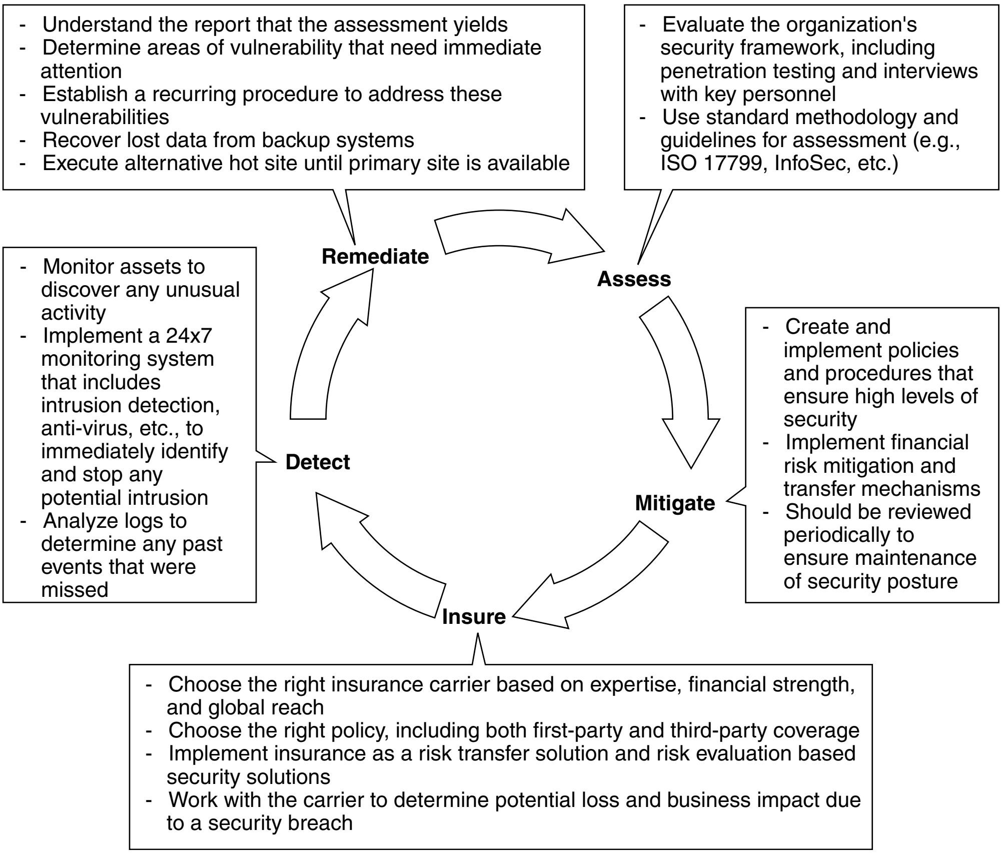
After a risk assessment and mitigation effort has been completed, insurance needs to be procured from a specialized insurance carrier of top financial strength and global reach. The purpose of the insurance is threefold: (1) assistance in the evaluation of the risk through products and services available from the insurer, (2) transfer of the financial costs of a successful computer attack or threat to the carrier, and (3) the provision of important post-incident support funds to reduce the potential reputation damage after an attack.

30.1 The Risk Management Approach

As depicted in Exhibit 30.1, risk management requires a continuous cycle of assessment, mitigation, insurance, detection, and remediation.

30.1.1 Assess

An assessment means conducting a comprehensive evaluation of the security in an organization. It usually covers diverse aspects, ranging from physical security to network vulnerabilities. Assessments should include penetration testing of key enterprise systems and interviews with security and IT



- Understand the report that the assessment yields
- Determine areas of vulnerability that need immediate attention
- Establish a recurring procedure to address these vulnerabilities
- Recover lost data from backup systems
- Execute alternative hot site until primary site is available

- Evaluate the organization's security framework, including penetration testing and interviews with key personnel
- Use standard methodology and guidelines for assessment (e.g., ISO 17799, InfoSec, etc.)

- Monitor assets to discover any unusual activity
- Implement a 24x7 monitoring system that includes intrusion detection, anti-virus, etc., to immediately identify and stop any potential intrusion
- Analyze logs to determine any past events that were missed

- Create and implement policies and procedures that ensure high levels of security
- Implement financial risk mitigation and transfer mechanisms
- Should be reviewed periodically to ensure maintenance of security posture

- Choose the right insurance carrier based on expertise, financial strength, and global reach
- Choose the right policy, including both first-party and third-party coverage
- Implement insurance as a risk transfer solution and risk evaluation based security solutions
- Work with the carrier to determine potential loss and business impact due to a security breach

EXHIBIT 30.1 Risk management cycle.

management staff. Because there are many different assessment formats, an enterprise should use a method that conforms to a recognized standard (e.g., ISO 17799, InfoSec—Exhibit 30.2). Regardless of the model used, however, the assessment should evaluate people, processes, technology, and financial management. The completed assessment should then be used to determine what technology and processes should be employed to mitigate the risks exposed by the assessment.

An assessment should be done periodically to determine new vulnerabilities and to develop a baseline for future analysis to create consistency and objectivity.

30.1.2 Mitigate

Mitigation is the series of actions taken to reduce risk, minimize chances of an incident occurring, or limit the impact of any breach that does occur. Mitigation includes creating and implementing policies that ensure high levels of security. Security policies, once created, require procedures that ensure compliance. Mitigation also includes determining and using the right set of technologies to address the threats that the organization faces and implementing financial risk mitigation and transfer mechanisms.

30.1.3 Insure

Insurance is a key risk transfer mechanism that allows organizations to be protected financially in the event of loss or damage. A quality insurance program can also provide superior loss prevention and analysis recommendations, often providing premium discounts for the purchase of certain security products and services from companies known to the insurer that dovetail into a company's own risk assessment program. Initially, determining potential loss and business impact due to a security breach

EXHIBIT 30.2 The 11 Domains of Risk Assessment

Security Policy: During the assessment, the existence and quality of the organization's security policy are evaluated. Security policies should establish guidelines, standards, and procedures to be followed by the entire organization. These need to be updated frequently.

Organizational Security: One of the key areas that any assessment looks at is the organizational aspect of security. This means ensuring that adequate staff has been assigned to security functions, that there are hierarchies in place for security-related issues, and that people with the right skill sets and job responsibilities are in place.

Asset Classification and Control: Any business will be impacted if the software and hardware assets it has are compromised. In evaluating the security of the organization, the existence of an inventory management system and risk classification system have to be verified.

Personnel Security: The hiring process of the organization needs to be evaluated to ensure that adequate background checks and legal safeguards are in place. Also, employee awareness of security and usage policies should be determined.

Physical and Environmental Security: Ease of access to the physical premises needs to be tested, making sure that adequate controls are in place to allow access only to authorized personnel. Also, the availability of redundant power supplies and other essential services has to be ensured.

Communication and Operations Management: Operational procedures need to be verified to ensure that information processing occurs in a safe and protected manner. These should cover standard operating procedures for routine tasks as well as procedures for change control for software, hardware, and communication assets.

Access Control: This domain demands that access to systems and data be determined by a set of criteria based on business requirement, job responsibility, and time period. Access control needs to be constantly verified to ensure that it is available only on a need-to-know basis with strong justification.

Systems Development and Maintenance: If a company is involved in development activity, assess whether security is a key consideration at all stages of the development life cycle.

Business Continuity Management: Determining the existence of a business continuity plan that minimizes or eliminates the impact of business interruption is a part of the assessment.

Compliance: The assessment has to determine if the organization is in compliance with all regulatory, contractual, and legal requirements.

Financial Considerations: The assessment should include a review to determine if adequate safeguards have to be implemented to ensure that any security breach results in minimal financial impact. This is implemented through risk transfer mechanisms—primarily insurance that covers the specific needs of the organization.

allows organizations to choose the right policy for their specific needs. The insurance component then complements the technical solutions, policies, and procedures. A vital step is choosing the right insurance carrier by seeking companies with specific underwriting and claims units with expertise in the area of information security, top financial ratings, and global reach. The right carrier should offer a suite of policies from which companies can choose to provide adequate coverage.

30.1.4 Detect

Detection implies constant monitoring of assets to discover any unusual activity. Usually this is done by implementing a 24/7 monitoring system that includes intrusion detection to immediately identify and stop any potential intrusion. Additionally, anti-virus solutions allow companies to detect new viruses or worms as they appear. Detection also includes analyzing logs to determine any past events that were missed and specification of actions to prevent future misses. Part of detection is the appointment of a team in charge of incident response.

30.1.5 Remediate

Remediation is the tactical response to vulnerabilities that assessments discover. This involves understanding the report that the assessment yields and prioritizing the areas of vulnerability that need immediate attention. The right tactic and solution for the most efficient closing of these holes must be chosen and implemented. Remediation should follow an established recurring procedure to address these vulnerabilities periodically.

In the cycle above, most of the phases focus on the assessment and implementation of technical controls. However, no amount of time or money spent on technology will eliminate risk. Therefore, insurance plays a key role in any risk management strategy. When properly placed, the insurance policy will transfer the financial risk of unavoidable security exposures from the balance sheet of the company to that of the insurer. As part of this basic control, companies need to have methods of detection (such as intrusion detection systems, or IDS) in place to catch the cyber-attack when it takes place. Post incident, the insurer will then remediate any damage done, including finance and reputation impacts. The remediation function includes recovery of data, insurance recoveries, and potential claims against third parties. Finally, the whole process starts again with an assessment of the company's vulnerabilities, including an understanding of a previously unknown threat.

30.2 Types of Security Risks

The CSI 2001 Computer Crime and Security Survey[2] confirms that the threat from computer crime and other information security breaches continues unabated and that the financial toll is mounting. According to the survey, 85 percent of respondents had detected computer security breaches within the past 12 months; and the total amount of financial loss reported by those who could quantify the loss amounted to $377,828,700—that is, over $2 million per event.

One logical method for categorizing financial loss is to separate loss into three general areas of risk:

1. *First-party financial risk*: direct financial loss not arising from a third-party claim (called first-party security risks).
2. *Third-party financial risk*: a company's legal liabilities to others (called third-party security risks).
3. *Reputation risk*: the less quantifiable damages such as those arising from a loss of reputation and brand identity. These risks, in turn, arise from the particular cyber-activities. Cyber-activities can

[1] The views and policy interpretations expressed in this work by the authors are their own and do not necessarily represent those of American International Group, Inc., or any of its subsidiaries, business units, or affiliates.

[2] See http://www.gocsi.com for additional information.

include a Web site presence, e-mail, Internet professional services such as Web design or hosting, network data storage, and E-commerce (i.e., purchase or sale of goods and services over the Internet).

First-party security risks include financial loss arising from damage, destruction, or corruption of a company's information assets—that is, data. Information assets—whether in the form of customer lists and privacy information, business strategies, competitor information, product formulas, or other trade secrets vital to the success of a business—are the real assets of the 21st century. Their proper protection and quantification are key to a successful company. Malicious code transmissions and computer viruses—whether launched by a disgruntled employee, overzealous competitor, cyber-criminal, or prankster—can result in enormous costs of recollection and recovery.

A second type of first-party security risk is the risk of revenue loss arising from a successful denial-of-service (DoS) attack. According to the Yankee Group, in February 2000 a distributed DoS attack was launched against some of the most sophisticated Web sites, including Yahoo, Buy.com, CNN, and others, resulting in $1.2 billion in lost revenue and related damages. Finally, first-party security risk can arise from the theft of trade secrets.

Third-party security risk can manifest itself in a number of different types of legal liability claims against a company, its directors, officers, or employees. Examples of these risks can arise from the company's presence on the Web, its rendering of professional services, the transmission of malicious code or a DoS attack (whether or not intentional), and theft of the company's customer information.

The very content of a company's Web site can result in allegations of copyright and trademark infringement, libel, or invasion of privacy claims. The claims need not even arise from the visual part of a Web page but can, and often do, arise out of the content of a site's metatags—the invisible part of a Web page used by search engines.

If a company renders Internet-related professional services to others, this too can be a source of liability. Customers or others who allege that such services, such as Web design or hosting, were rendered in a negligent manner or in violation of a contractual agreement may find relief in the court system.

Third-party claims can directly arise from a failure of security. A company that negligently or through the actions of a disgruntled employee transmits a computer virus to its customers or other e-mail recipients may be open to allegations of negligent security practices. The accidental transmission of a DoS attack can pose similar legal liabilities. In addition, if a company has made itself legally obligated to keep its Web site open on a 24/7 basis to its customers, a DoS attack shutting down the Web site could result in claims by its customers. A wise legal department will make sure that the company's customer agreements specifically permit the company to shut down its Web site for any reason at any time without incurring legal liability.

Other potential third-party claims can arise from the theft of customer information such as credit card information, financial information, health information, or other personal data. For example, theft of credit card information could result in a variety of potential lawsuits, whether from the card-issuing companies that then must undergo the expense of reissuing, the cardholders themselves, or even the Web merchants who later become the victims of the fraudulent use of the stolen credit cards. As discussed later, certain industries such as financial institutions and healthcare companies have specific regulatory obligations to guard their customer data.

Directors and officers (D&Os) face unique, and potentially personal, liabilities arising out of their fiduciary duties. In addition to case law or common-law obligations, D&Os can have obligations under various statutory laws such as the Securities Act of 1933 and the Securities and Exchange Act of 1934. Certain industries may also have specific statutory obligations such as those imposed on financial institutions under the Gramm-Leach-Bliley Act (GLBA), discussed in detail later.

Perhaps the most difficult and yet one of the most important risks to understand is the intangible risk of damage to the company's reputation. Will customers give a company their credit card numbers once they read in the paper that a company's database of credit card numbers was violated by hackers? Will top employees remain at a company so damaged? And what will be the reaction of the company's shareholders? Again, the best way to analyze reputation risk is to attempt to quantify it. What is the

EXHIBIT 30.3 First- and Third-Party Risks

Activity	First-Party Risk	Third-Party Risk
Web site presence	Damage or theft of data (assumes database is connected to network) via hacking	Allegations of trademark, copyright, libel, invasion of privacy, and other Web content liabilities
E-mail	Damage or theft of data (assumes database is connected to network) via computer virus; shutdown of network via DoS attack	Transmission of malicious code (e.g., NIMDA) or DoS due to negligent network security; DoS customer claims if site is shut down due to DoS attack
E-commerce	Loss of revenue due to successful DoS attack	Customer suits
Internet professional services		Customer suits alleging negligent performance of professional services
Any		Claims against directors and officers for mismanagement

expected loss of future business revenue? What is the expected loss of market capitalization? Can shareholder class or derivative actions be foreseen? And, if so, what can the expected financial cost of those actions be in terms of legal fees and potential settlement amounts?

The risks just discussed are summarized in Exhibit 30.3.

30.2.1 Threats

The risks defined above do not exist in a vacuum. They are the product of specific threats, operating in an environment featuring specific vulnerabilities that allow those threats to proceed uninhibited. Threats may be any person or object, from a disgruntled employee to an act of nature, that may lead to damage or value loss for an enterprise. While insurance may be used to minimize the costs of a destructive event, it is not a substitute for controls on the threats themselves.

Threats may arise from external or internal entities and may be the product of intentional or unintentional action. External entities comprise the well-known sources—hackers, virus writers—as well as less obvious ones such as government regulators or law enforcement entities. Attackers may attempt to penetrate IT systems through various means, including exploits at the system, server, or application layers. Whether the intent is to interrupt business operations, or to directly acquire confidential data or access to trusted systems, the cost in system downtime, lost revenue, and system repair and redesign can be crippling to any enterprise. The collapse of the British Internet service provider (ISP) Cloud-Nine in January 2002, due to irreparable damage caused by distributed DoS attacks launched against its infrastructure, is only a recent example of the enterprise costs of cyber-attacks.[3]

Viruses and other malicious code frequently use the same exploits as human attackers to gain access to systems. However, as viruses can replicate and spread themselves without human intervention, they have the potential to cause widespread damage across an internal network or the Internet as a whole.

Risks may arise from non-human factors as well. For example, system outages through failures at the ISP level, power outages, or natural disasters may create the same loss of service and revenue as attackers conducting DoS attacks. Therefore, technical controls should be put in place to minimize those risks. These risks are diagrammed in Exhibit 30.4.

Threats that originate from within an organization can be particularly difficult to track. This may entail threats from disgruntled employees (or ex-employees), or mistakes made by well-meaning employees as well. Many standard technical controls—firewalls, anti-virus software, or intrusion detection—assume that the internal users are working actively to support the security infrastructure. However, such controls

[3] Coverage provided in *ISPreview*, ZDNet.

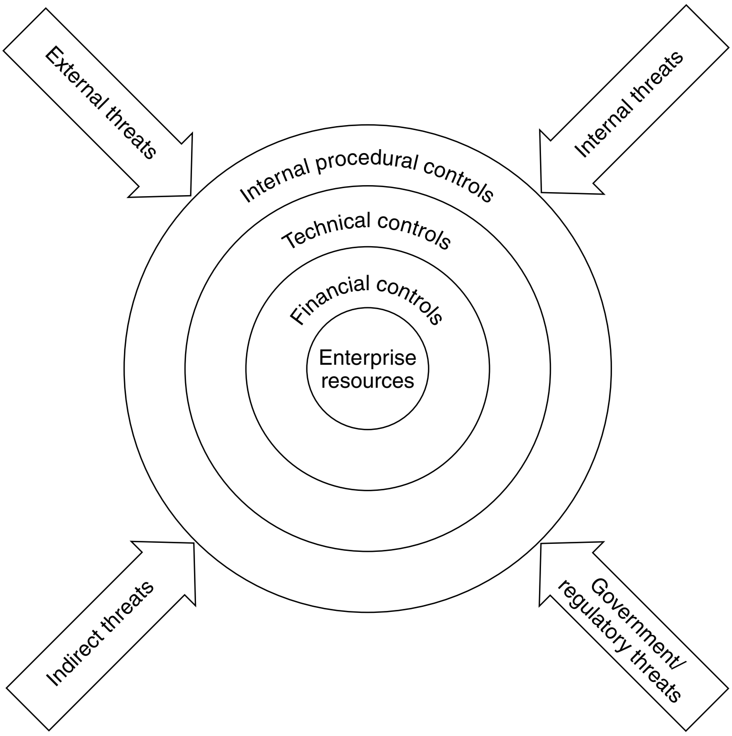


EXHIBIT 30.4 Enterprise resource threats.

EXHIBIT 30.5 Threat Matrix

	Threat	Description	Security Risk	Controls
External	System penetration (external source)	Attempts by external parties to penetrate corporate resources to modify or delete data or application systems	Moderate	Strong authentication; strong access control; ongoing system support and tracking
	Regulatory action	Regulatory action or investigation based on corporate non-compliance with privacy and security guidelines	Low to moderate	Data protection; risk assessment and management programs; user training; contractual controls
	Virus penetration	Malicious code designed to self-replicate	Moderate	Technological: anti-virus controls
	Power loss or connectivity loss	Loss of internet connectivity, power, cooling system; may result in large-scale system outages	Low	Redundant power and connectivity; contractual controls with ISP/hosting facilities
Internal	Intellectual property violation	Illicit use of third-party intellectual property (images, text, code) without appropriate license arrangements	Low to moderate	Procedural and personnel controls; financial controls mitigating risk
	System penetration (internal source)	Malicious insiders attempting to access restricted data	Moderate	Strong authentication; strong access control; use of internal firewalls to segregate critical systems

are hardly sufficient against insiders working actively to subvert a system. Other types of risks—for example, first-party risks of intellectual property violations—may be created by internal entities without their knowledge. Exhibit 30.5 describes various threats by type.

As noted, threats are comprised of motive, access, and opportunity—outsiders must have a desire to cause damage as well as a means of affecting the target system. While an organization's exposure to risk can never be completely eliminated, all steps should be taken to minimize exposure and limit the scope of damage. Such vulnerabilities may take a number of forms.

Technical vulnerabilities include exploits against systems at the operating system, network, or application level. Given the complexity and scope of many commercial applications, vulnerabilities within code become increasingly difficult to detect and eradicate during the testing and quality assurance (QA) processes. Examples range from the original Internet Worm to recently documented vulnerabilities in commercial instant messaging clients and Web servers. Such weaknesses are an increasing risk in today's highly interconnected environments.

Weaknesses within operating procedures may expose an enterprise to risk not controlled by technology. Proper change management processes, security administration processes, and human resources controls and oversight, for example, are necessary. They may also prove disruptive in highly regulated environments, such as financial services or healthcare, in which regulatory agencies require complete sets of documentation as part of periodic auditing requirements.

30.2.2 GLBA/HIPAA

Title V of the Gramm-Leach-Bliley Act (GLBA) has imposed new requirements on the ways in which financial services companies handle consumer data. The primary focus of Title V, and the area that has received the most attention, is the sharing of personal data among organizations and their unaffiliated business partners and agencies. Consumers must be given notice of the ways in which their data is used and must be given notice of their right to opt out of any data-sharing plan.

However, Title V also requires financial services organizations to provide adequate security for systems that handle customer data. Security guidelines require the creation and documentation of detailed data security programs addressing both physical and logical access to data, risk assessment, and mitigation programs, and employee training in the new security controls. Third-party contractors of financial services firms are also bound to comply with the GLBA regulations.

On February 1, 2001, the Department of the Treasury, Federal Reserve System, and Federal Deposit Insurance Corporation issued interagency regulations, in part requiring financial institutions to:

- Develop and execute an information security program.
- Conduct regular tests of key controls of the information security program. These tests should be conducted by an independent third party or staff independent of those who develop or maintain the program.
- Protect against destruction, loss, or damage to customer information, including encrypting customer information while in transit or storage on networks.
- Involve the board of directors, or appropriate committee of the board, to oversee and execute all of the above.

Because the responsibility for developing specific guidelines for compliance was delegated to the various federal and state agencies that oversee commercial and financial services (and some are still in the process of being issued), it is possible that different guidelines for GLBA compliance will develop between different states and different financial services industries (banking, investments, insurance, etc.).

The Health Insurance Portability and Accountability Act (HIPAA) will force similar controls on data privacy and security within the healthcare industry. As part of HIPAA regulations, healthcare providers, health plans, and clearinghouses are responsible for protecting the security of client health information. As with GLBA, customer medical data is subject to controls on distribution and usage, and controls must be established to protect the privacy of customer data. Data must also be classified according to a standard classification system to allow greater portability of health data between providers and health plans. Specific guidelines on security controls for medical information have not been issued yet. HIPAA regulations are enforced through the Department of Health and Human Services.

As GLBA and HIPAA regulations are finalized and enforced, regulators will be auditing those organizations that handle medical or financial data to confirm compliance with their security programs. Failure to comply can be classified as an unfair trade practice and may result in fines or criminal action. Furthermore, firms that do not comply with privacy regulations may leave themselves vulnerable to class-action lawsuits from clients or third-party partners. These regulations represent an entirely new type of exposure for certain types of organizations as they increase the scope of their IT operations.

30.2.3 Cyber-Terrorism

The potential for cyber-terrorism deserves special mention. After the attacks of 9/11/01, it is clear that no area of the world is protected from a potential terrorist act. The Internet plays a critical role in the economic stability of our national infrastructure. Financial transactions, running of utilities and manufacturing plants, and much more are dependent upon a working Internet. Fortunately, companies are coming together in newly formed entities such as ISACs (Information Sharing and Analysis Centers) to determine their interdependency vulnerabilities and plan for the worst. It is also fortunate that the weapons used by a cyber-terrorist do not differ much from those of a cyber-criminal or other hacker. Thus, the same risk management formula discussed above should be implemented for the risk of cyber-terrorism.

30.3 Insurance for Cyber-Risks

Insurance, when properly placed, can serve two important purposes. First, it can provide positive reinforcement for good behavior by adjusting the availability and affordability of insurance depending upon the quality of an insured's Internet security program. It can also condition the continuation of such insurance on the maintenance of that quality. Second, insurance will transfer the financial risk of a covered event from a company's balance sheet to that of the insurer.

The logical first step in evaluating potential insurance solutions is to review the company's traditional insurance program, including its property (including business interruption) insurance, comprehensive general liability (CGL), directors and officers insurance, professional liability insurance, and crime policies. These policies should be examined in connection with a company's particular risks (see above) to determine whether any gap exists. Given that these policies were written for a world that no longer exists, it is not surprising that traditional insurance policies are almost always found to be inadequate to address today's cyber-needs. This is not due to any *defect* in these time-honored policies but simply due to the fact that, with the advent of the new economy risks, there comes a need for specialized insurance to meet those new risks.

One of the main reasons why traditional policies such as property and CGL do not provide much coverage for cyber-risks is their approach that *property* means *tangible property and not data*. Property policies also focus on physical perils such as fire and windstorm. Business interruption insurance is sold as part of a property policy and covers, for example, lost revenue when your business burns down in a fire. It will not, however, cover E-revenue loss due to a DoS attack. Even computer crime policies usually do not cover loss other than for money, securities, and other *tangible* property. This is not to say that traditional insurance can *never* be helpful with respect to cyber-risks. A mismanagement claim against a company's directors and officers arising from cyber-events will generally be covered under the company's directors' and officers' insurance policy to the same extent as a non-cyber claim. For companies that render professional services to others for a fee, such as financial institutions, those that fail to reasonably render those services due to a cyber-risk may find customer claims to be covered under their professional

EXHIBIT 30.6 First- and Third-Party Coverage

	First-Party Coverage	Third-Party Coverage
Media		Web content liability
E&O		Professional liability
Network security	Cyber-attack caused damage, destruction and corruption of data, theft of trade secrets or E-revenue business interruption	Transmission of a computer virus or DoS liability; theft of customer information liability; DoS customer liability
Cyber-extortion	Payment of cyber-investigator	Payment of extortion amount where appropriate
Reputation	Payment of public relations fees up to $50,000	
Criminal reward	Payment of criminal reward fund up to $50,000	

liability policy. (Internet professional companies should still seek to purchase a specific Internet professional liability insurance policy.)

30.3.1 Specific Cyber-Liability and Property Loss Policies

The inquiry detailed above illustrates the extreme dangers associated with relying upon traditional insurance policies to provide broad coverage for 21st-century cyber-risks. Regrettably, at present there are only a few specific policies providing expressed coverage for all the risks of cyberspace listed at the beginning of this chapter. One should be counseled against buying an insurance product simply because it has the name *Internet* or *cyber* in it. So-called Internet insurance policies vary widely, with some providing relatively little *real coverage*. A properly crafted Internet risk program should contain multiple products within a *suite concept* permitting a company to choose which risks to cover, depending upon where it is in its Internet maturity curve.[4] A suite should provide at least six areas of coverage, as shown in Exhibit 30.6.

These areas of coverage may be summarized as follows:

- *Web content liability* provides coverage for claims arising out of the content of your Web site (including the invisible metatags content), such as libel, slander, copyright, and trademark infringement.
- *Internet professional liability* provides coverage for claims arising out of the performance of professional services. Coverage usually includes both Web publishing activities as well as pure Internet services such as being an ISP, host, or Web designer. Any professional service conducted over the Internet can usually be added to the policy.
- *Network security coverage* comes in two basic types:
  - *Third-party coverage* provides liability coverage arising from a failure of the insured's security to prevent unauthorized use of or access to its network. This important coverage would apply, subject to the policy's full terms, to claims arising from the transmission of a computer virus (such as the Love Bug or Nimda virus), theft of a customer's information (most notably including credit card information), and so-called denial-of-service liability. In the past year alone, countless cases of this type of misconduct have been reported.
  - *First-party coverage* provides, upon a covered event, reimbursement for loss arising out of the altering, copying, misappropriating, corrupting, destroying, disrupting, deleting, damaging, or theft of information assets, whether or not criminal. Typically the policy will cover the cost of replacing, reproducing, recreating, restoring, or recollecting. In case of theft of a trade secret (a broadly defined term), the policy will either pay or be capped at the endorsed negotiated amount. First-party coverage also provides reimbursement for lost E-revenue as a result of a

[4] One carrier's example of this concept can be found at www.aignetadvantage.com

covered event. Here, the policy will provide coverage for the period of recovery plus an extended business interruption period. Some policies also provide coverage for dependent business interruption, meaning loss of E-revenue as a result of a computer attack on a third-party business (such as a supplier) upon which the insured's business depends.

- *Cyber-extortion coverage* provides reimbursement of investigation costs, and sometimes the extortion demand itself, in the event of a covered cyber-extortion threat. These threats, which usually take the form of a demand for "consulting fees" to prevent the release of hacked information or to prevent the extortion from carrying out a threat to shut down the victims' Web sites, are all too common.
- *Public relations or crisis communication coverage* provides reimbursement up to $50,000 for use of public relation firms to rebuild an enterprise's reputation with customers, employees, and shareholders following a computer attack.
- *Criminal reward funds coverage* provides reimbursement up to $50,000 for information leading to the arrest and conviction of a cyber-criminal. Given that many cyber-criminals hack into sites for "bragging rights," this unique insurance provision may create a most welcome chilling effect.

30.3.2 Loss Prevention Services

Another important feature of a quality cyber-risk insurance program is its loss prevention services. Typically these services could include anything from free online self-assessment programs and free educational CDs to a full-fledged, on-site security assessment, usually based on ISO 17799. Some insurers may also add other services such as an internal or external network scan. The good news is that these services are valuable, costing up to $50,000. The bad news is that the insurance applicant usually has to pay for the services, sometimes regardless of whether or not it ends up buying the policy. Beginning in 2001, one carrier has arranged to pay for these services as part of the application process. This is welcome news. It can only be hoped that more insurers will follow this lead.

30.3.3 Finding the Right Insurer

As important as finding the right insurance product is finding the right insurer. Financial strength, experience, and claims philosophy are all important. In evaluating insurers, buyers should take into consideration the factors listed in Exhibit 30.7.

In summary, traditional insurance is not up to the task of dealing with today's cyber-risks. To yield the full benefits, insurance programs should provide and implement a purchase combination of traditional and specific cyber-risk insurance.

EXHIBIT 30.7 Finding the Right Insurer

Quality	Preferred or Minimum Threshold
Financial strength	Triple-A from standard and poor's
Experience	At least 2 years in dedicated, specialized unit composed of underwriters, claims, technologists, and legal professionals
Capacity	Defined as amount of limits single carrier can offer; minimum acceptable: $25,000,000
Territory	Global presence with employees and law firm contacts throughout the United States, Europe, Asia, Middle East, South America
Underwriting	Flexible, knowledgeable
Claims philosophy	Customer focused; willing to meet with client both before and after claim
Policy form	Suite permitting insured to choose right coverage including eight coverages described above
Loss prevention	Array of services, most importantly including FREE on-site security assessments conducted by well-established third-party (worldwide) security assessment firms

EXHIBIT 30.8 Physical Controls

Physical Control	Description	Role
Access control	Grants access to physical resources through possession of keys, cards, biometric indicators, or key combinations; multi-factor authentication may be used to increase authentication strength; access control system that requires multiple-party authentication provide higher levels of access control	Securing data center access in general, as well as access to core resources such as server rooms; media—disks, CD-ROMs, tapes—should be secured using appropriate means as well; organizations should model their access control requirements on the overall sensitivity of their data and applications
Intrusion detection	Detection of attempted intrusion through motion sensors, contact sensors, and sensors at standard access points (doors, windows, etc.)	At all perimeter access points to the data center, as well as in critical areas
24/7 Monitoring	Any data center infrastructure should rely on round-the-clock monitoring, through on-premises personnel and off-site monitoring	Validation to existing alarm and access control systems

30.4 Technical Controls

Beyond insurance, standard technical controls must be put in place to manage risks. First of all, the basic physical infrastructure of the IT data center should be secured against service disruptions caused by environmental threats. Organizations that plan to build and manage their own data centers should implement fully redundant and modular systems for power, Internet access, and cooling. For example, data centers should consider backup generators in case of area-wide power failures, and Internet connectivity from multiple ISPs in case of service outages from one provider.

In cases where the customer does not wish to directly manage its data center, the above controls should be verified before contracting with an ASP or ISP. These controls should be guaranteed contractually, as should failover controls and minimum uptime requirements.

30.4.1 Physical Access Control

Access control is an additional necessity for a complete data center infrastructure. Physical access control is more than simply securing entrances and exits with conventional locks and security guards. Secure data centers should rely on alarm systems and approved locks for access to the most secure areas, with motion detectors throughout. More complex security systems, such as biometric[5] or dual-factor authentication (authentication requiring more than one proof of identity; e.g., card and biometric), should be considered for highly secure areas. Employee auditing and tracking for entrances and exits should be put in place wherever possible, and visitor and guest access should be limited. A summary of potential controls is provided in Exhibit 30.8.

If it is feasible to do so, outside expertise in physical security, like logical security, should be leveraged wherever possible. Independent security audits may provide insight regarding areas of physical security that are not covered by existing controls. Furthermore, security reports may be required by auditors, regulators, and other third parties. Audit reports and other security documentation should be kept current and retained in a secure fashion.

Again, if an organization uses outsourced facilities for application hosting and management, it should look for multilevel physical access control. Third-party audit reports should be made available as part of the vendor search process; security controls should be made part of the evaluation criteria. As with environmental controls, access controls should also be addressed within the final service agreement such that major modifications to the existing access control infrastructure require advance knowledge and approval. Organizations should insist on periodic audits or third-party reviews to ensure compliance.

[5] Biometrics authentication comprises many different measures, including fingerprint scans, retinal or iris scans, handwriting dynamics, and facial recognition.

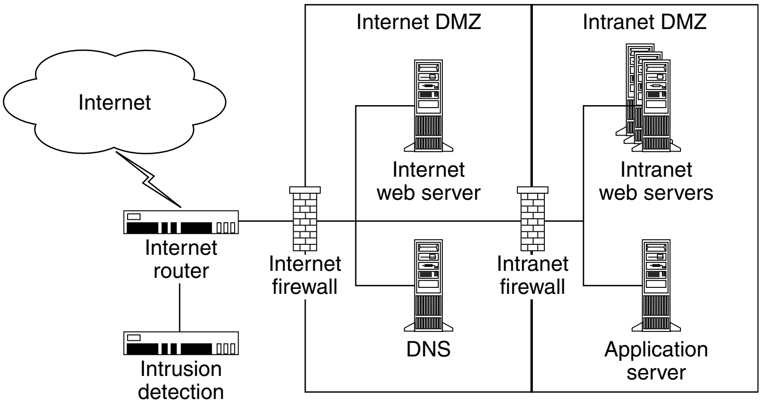

EXHIBIT 30.9 Demilitarized zone architecture.

30.4.2 Network Security Controls

A secure network is the first layer of defense against risk within an E-business system. Network-level controls are instrumental in preventing unauthorized access from within and without, and tracking sessions internally will detect and alert administrators in case of system penetration. Exhibit 30.9 conceptually depicts the overall architecture of an E-business data center.

Common network security controls include the following features.

30.4.2.1 Firewalls

Firewalls are critical components of any Internet-facing system. Firewalls filter network traffic based on protocol, destination port, or packet content. As firewall systems have become more advanced, the range of different attack types that can be recognized by the firewall has continued to grow. Firewalls may also be upgraded to filter questionable content or scan incoming traffic for attack signatures or illicit content.

For any infrastructure that requires access to business data, a multiple-firewall configuration should be used. An Internet demilitarized zone (DMZ) should be created for all Web-accessible systems—Web servers or DNS servers—while an intranet DMZ, separated from the Internet, contains application and database servers. This architecture prevents external entities from directly accessing application logic or business data.

30.4.2.2 Network Intrusion Detection Systems

Networked IDSs track internal sessions at major network nodes and look for attack signatures—a sequence of instructions corresponding to a known attack. These systems generally are also tied into monitoring systems that can alert system administrators in the case of detected penetration. More advanced IDSs look for only "correct" sequences of packets and use real-time monitoring capabilities to identify suspicious but unknown sequences.

30.4.2.3 Anti-Virus Software

Anti-virus gateway products can provide a powerful second level of defense against worms, viruses, and other malicious code. Anti-virus gateway products, provided by vendors such as Network Associates, Trend Micro, and Symantec, can scan incoming HTTP, SMTP, and FTP traffic for known virus signatures and block the virus before it infects critical systems.

As described in Exhibit 30.10, specific design principles should be observed in building a stable and secure network. Exhibit 30.11 provides a summary of the controls in question.

EXHIBIT 30.10 Secure Network Design Principles

Redundancy. Firewall systems, routers, and critical components such as directory servers should be fully redundant to reduce the impact of a single failure.

Currency. Critical network tools must be kept up-to-date with respect to patch-level and core system operations. Vulnerabilities are discovered frequently, even within network security devices such as firewalls or routers.

Scalability. An enterprise's network security infrastructure should be able to grow as business needs require. Service outages caused by insufficient bandwidth provided by an ISP, or server outages due to system maintenance, can be fatal for growing applications. The financial restitution provided by cyber-risk coverage might cover business lost during the service outage but cannot address the greater issues of loss of business, consumer goodwill, or reputation.

Simplicity. Complexity of systems, rules, and components can create unexpected vulnerabilities in commercial systems. Where possible, Internet-facing infrastructures should be modularized and simplified such that each component is not called upon to perform multiple services. For example, an organization with a complex E-business infrastructure should separate that network environment from its own internal testing and development networks, with only limited points of access between the two environments. A more audited and restricted set of rules may be enforced in the former without affecting the productivity of the latter.

EXHIBIT 30.11 Network Security Controls

Network Control	Description	Role
Firewall	Blocks connections to internal resources by protocol, port, and address; also provides stateful packet inspection	Behind Internet routers; also within corporate networks to segregate systems into DMZs
IDS	Detects signature of known attacks at the network level	At high-throughput nodes within networks, and at perimeter of network (at firewall level)
Anti-virus	Detects malicious code at network nodes	At Internet HTTP and SMTP gateways

Increasingly, organizations are moving toward managed network services rather than supporting the systems internally. Such a solution saves the organization from having to build staff for managing security devices, or to maintain a 24/7 administration center for monitoring critical systems. Such a buy (or, in this case, hire) versus build decision should be seriously considered in planning your overall risk management framework. Organizations looking to outsource security functions can certainly save money, resources, and time; however, organizations should look closely at the financial as well as technical soundness of any such vendors.

30.4.3 Application Security Controls

A successful network security strategy is only useful as a backbone to support the development of secure applications. These controls entail security at the operating system level for enterprise systems, as well as trust management, encryption, data security, and audit controls at the application level.

Operating systems should be treated as one of the most vulnerable components of any application framework. Too often, application developers create strong security controls within an application, but have no control over the lower level exploits. Furthermore, system maintenance and administration over time is frequently overlooked as a necessary component of security. Therefore, the following controls should be observed:

- Most major OS suppliers—Microsoft, Sun, Hewlett–Packard, etc.—provide guidelines for operating system hardening. Implement those guidelines on all production systems.
- Any nonessential software should be removed from production systems.
- Administer critical servers from the system console wherever possible. Remote administration should be disabled; if this is not possible, secure log-in shells should be used in place of less secure protocols such as Telnet.

- Host-based intrusion detection software should be installed on all critical systems. A host-based IDS is similar to the network-based variety, except it only scans traffic intended for the target server. Known attack signatures may be detected and blocked before reaching the target application, such as a Web or application server.

Application-level security is based on maintaining the integrity and confidentiality of the system as well as the data managed by the system. A Web server that provides promotional content and brochures to the public, for example, has little need to provide controls on confidentiality. However, a compromise of that system resulting in vandalism or server downtime could prove costly; therefore, system and data integrity should be closely controlled. These controls are partially provided by security and the operating system and network levels as noted above; additional controls, however, should be provided within the application itself.

Authentication and authorization are necessary components of application-level security. Known users must be identified and allowed access to the system, and system functions must be categorized such that users are only presented with access to data and procedures that correspond to their defined privilege level.

The technical controls around authentication and authorization are only as useful as the procedural controls around user management. The enrollment of new users, management of personal user information and usage profiles, password management, and the removal of defunct users from the system are required for an authentication engine to provide real risk mitigation.

Exhibit 30.12 provides a summary of these technologies and procedures.

30.4.4 Data Backup and Archival

In addition to technologies to prevent or detect unauthorized system penetration, controls should be put in place to restore data in the event of loss. System backups—onto tape or permanent media—should be in place for any business-critical application.

Backups should be made regularly—as often as daily, depending on the requirements of the business—and should be stored off-site to prevent loss or damage. Test restores should also be performed regularly to ensure the continued viability of the backup copies. Backup retention should extend to at least a month, with one backup per week retained for a year and monthly backups retained for several years. Backup data should always be created and stored in a highly secure fashion.

Finally, to ensure system availability, enterprise applications should plan on at least one tier of redundancy for all critical systems and components. Redundant systems can increase the load-bearing

EXHIBIT 30.12 Application Security Controls

Application Control	Description	Role
System hardening	Processes, procedures, and products to harden operating system against exploitation of network services	Should be performed for all critical servers and internal systems
Host-based intrusion detection	Monitors connections to servers and detects malicious code or attack signatures	On all critical servers and internal systems
Authentication	Allows for identification and management of system users through identities and passwords	For any critical systems; authentication systems may be leveraged across multiple applications to provide single sign-on for enterprise
Access control	Maps users, by identity or by role, to system resources and functions	For any critical application
Encryption	Critical business data or non-public client information should be encrypted (i.e., obscured) while in transit over public networks	For all Internet-based transactional connectivity; encryption should also be considered for securing highly sensitive data in storage

capacity of a system as well as provide increased stability. The use of enterprise-class multi-processor machines is one solution; multiple systems can also be consolidated into server farms. Network devices such as firewalls and routers can also be made redundant through load balancers. Businesses may also wish to consider maintaining standby systems in the event of critical data center failure. Standby systems, like backups, should be housed in a separate storage facility and should be tested periodically to ensure stability. These backup systems should be able to be brought online within 48 h of a disaster and should be restored with the most recently available system backups as well.

30.5 Conclusion

The optimal model to address the risks of Internet security must combine technology, process, and insurance. This risk management approach permits companies to successfully address a range of different risk exposures, from direct attacks on system resources to unintentional acts of copyright infringement. In some cases, technical controls have been devised that help address these threats; in others, procedural and audit controls must be implemented. Because these threats cannot be completely removed, however, cyber-risk insurance coverage represents an essential tool in providing such nontechnical controls and a major innovation in the conception of risk management in general. A comprehensive policy backed by a specialized insurer with top financial marks and global reach allows organizations to lessen the damage caused by a successful exploit and better manage costs related to loss of business and reputation. It is only through merging the two types of controls that an organization can best minimize its security threats and mitigate its IT risks.

31

Committee of Sponsoring Organizations (COSO)

Mignona Cote

31.1 Introduction

COSO stands for the Committee of Sponsoring Organizations and, by simple definition, is a control framework that provides guidance on internal control areas that could be incorporated in business processes. The objective of COSO is to provide a common understanding of internal control as *internal control* has diverse meanings across different groups and work disciplines. COSO establishes this common definition and identifies the internal control objectives, the components, and the criteria that controls can be evaluated against. This chapter provides an overview of COSO, highlights its components and criteria, and identifies current ways COSO is being used.

31.2 History

The Committee of Sponsoring Organizations consists of the following organizations:

- American Institute of Certified Public Accountants (AICPA)
- American Accounting Association

- Financial Executives Institute (FEI)
- Institute of Internal Auditors (IIA)
- Institute of Management Accountants.

During the late 1980s, several financial situations such as the savings and loans corruptions led to these groups' convening to create a definition and framework for internal control. These groups formed the Treadway Commission that is described later in this chapter.

Prior to the 1980s, controls were prevalent in business processes. Focus on controls has been evident throughout history with recorded activities noted in the United States dating back to the colonial period. COSO highlights the 1940s as a significant period as public accounting firms and internal auditors published many definitions and guidelines on internal control during this time. Management began emphasizing the use of financial and non-financial information to control the business environments.

Legislative and regulatory bodies began focusing on the impact of internal controls as a result of the Watergate investigations during the mid 1970s. The investigations highlighted the illegal campaign contributions and questionable payments made by corporations to domestic and foreign government officials. The enactment of the Foreign Corrupt Practices Act of 1977 (FCPA) was to address anti-bribery, accounting, and internal controls. Within the act, internal controls are presented to provide an effective deterrent to illegal payments.

Several other governing commissions provided input into the internal control evolution. This input included

- Studies to determine auditor's responsibilities
- Rules for mandatory reports on an entity's internal accounting controls
- Guidance on evaluating internal controls
- New and redefined professional standards in the auditing profession.

By 1985, after several noteworthy business and audit failures such as those within the savings and loans area, focus on internal controls gained heightened attention. A congressional subcommittee began hearings to investigate several public companies and activities regarding managements' conduct, the proprietary of financial reporting, and the effectiveness of independent audits. Additional legislation was introduced to require a public company's management to report on the effectiveness of internal control and independent auditors to provide an opinion on management's report. This legislation was not enacted; however, a subcommittee was established with an expanded scope to consider additional aspects of internal control.

The Treadway Commission was established in 1985 with sponsorship by the five previously mentioned organizations. The Treadway Commission's objective was to identify the factors leading to fraudulent financial reporting and make recommendations to reduce such activities. The Treadway report issued in 1987 made several recommendations to address internal control. This report led to the five organizations' continuing to define and document internal control concepts and to create a common reference point. The outcome presented by the five organizations is COSO.

31.3 Defining COSO

The foundation of COSO lies with the definition of *control*. *Control*, as defined by COSO, is "Internal control is a process, effected by an entity's board of directors, management and other personnel, designed to provide reasonable assurance regarding the achievement of objectives in the following categories: effectiveness and efficiency of operations; reliability of financial reporting; and compliance with applicable laws and regulations."

Within the COSO report, the definition is expanded and further explained, identifying certain fundamental concepts. These concepts are

- Internal control is a process. It is a means to an end, not an end itself.
- Internal control is affected by people. It is not merely policy manuals and forms, but it is people at every level of an organization.
- Internal control can be expected to provide only reasonable assurance, not absolute assurance, to an entity's management and board.
- Internal control is geared to the achievement of objectives in one or more separate but overlapping categories.

This definition provides the foundation to emphasize to practitioners that controls include both people and process. It expands beyond financial reporting to incorporate operational effectiveness, efficiency, and compliance.

In regards to process, COSO highlights, "internal control is not one event or circumstance, but is a series of actions that permeate an entity's activities."

In other words, the process is the series of actions or steps taken to complete a function. Within this series of steps, controls are built-in to support the quality of the function. These built-in controls contribute to successful execution, and they often help manage costs and response times.

People execute the process and also impact the definition and outcome of the control. The tone of control execution is set by the board of directors, management, and personnel by what they say and do. Each person within an organization maintains a unique set of skills and experiences that affect their interpretation and adherence to the control. Communication and alignment must occur to ensure the control operates as designed. COSO also notes how internal control affects the behavior of people. The control, the understanding of the control, and the enforcement contribute to the person's behavior in regards to the control environment.

Thorough examination of the control definition reveals that internal control only provides reasonable assurance to achieving objectives; absolute assurance that controls are working as intended cannot be guaranteed. The effectiveness of internal controls is affected by external factors, human error, and intentional non-adherence. External factors could include regulatory or market changes, natural disasters, or other unforeseen events. Human error may result from poor judgment, lack of experience, time constraints, or mistakes. Intentional non-adherence typically occurs when needed decisions to expedite a process or compensate for some other event do not occur, and in cases of fraud or collusion.

The definition of *internal control* specifies that the intent of control is to lead to achieving objectives. Objectives establish the goals an organization or function is trying to accomplish. COSO presents three categories for control objectives: operations, financial reporting, and compliance. External parties such as regulators may impose the requirements the organizational objectives are to meet; whereas, the internal control framework further defines how these objectives will be met. These categories may overlap, so an objective may fall into more than one category. For example, a control objective may be defined to address a regulatory requirement but also impact an operation of a process.

31.4 The COSO Components

Committee of Sponsoring Organizations identifies five internal control components. They are

- Control environment
- Risk assessment
- Communication
- Control activities
- Monitoring.

These components represent the actions needed to meet the internal control objectives previously described, namely operations, financial reporting, and compliance. COSO states, "The five components should be considered when determining whether an internal control system is effective." Within the COSO report, examples on how to evaluate each component are provided.

Each control component breaks down into factors. These factors highlight the consideration areas when evaluating the component. Specific to the organization, the factors will be implemented in varying degrees. Overall, seventeen factors exist, and each should be considered when evaluating the control components. The factors, as listed below, present factors supporting each control component. Of special note is that control activities are regarded as a factor rather than having additional factors. Control activities comprise the hard controls within an environment that typically are audited.

Control environment	Integrity and ethical values
	Commitment to competence
	Board of directors or audit committee
	Management philosophy and operating style
	Organizational structure
	Assignment of authority and responsibility
	Human resource policies and practices
Risk assessment	Entity-wide objectives
	Activity-level objectives
	Risks
	Managing change
Control activities	
Information and communication	Information
	Communication
Monitoring	Ongoing monitoring
	Separate evaluations
	Reporting deficiencies

31.5 Control Environment

Important to the control infrastructure is the control environment that is defined by COSO as "The core of any business is its people—their individual attributes, including integrity, ethical values and competence—and the environment in which they operate. They are the engine that drives the entity and the foundation on which everything rests." The control environment sets the tone for the how well the organization will adhere to the controls based on management's direction. The control environment component influences overall business operations and references people as its basis.

The factors within the control environment include integrity and ethical values; commitment to competence; board of directors or audit committee; management's philosophy and operating style; organizational structure; assignment of authority and responsibility; and human resource policies and practices.

Integrity and ethical values address the manner in which an entity's objectives are met. A combination of individual past experiences, preferences, and operating styles coupled with the overall control environment set the direction for integrity and ethical values. Leadership must display integrity and balance fairness across conflicting activities. The organization affects its industry reputation through its ethical behavior, especially during the course of adverse events. Reputation impacts the overall stock price and the health of the organization.

The COSO Control Framework provides a supplemental guide, *Evaluation Tools*, that provides samples of tools that can be used to evaluate an entity's control environment using the principles outlined in COSO. The specific criteria to test for, as previously described, are called factors. Several factors to test integrity and ethical values are listed below with suggested considerations for evaluation as provided in the COSO Evaluation Tools:

- Existence of a code of conduct. Within this area, the tools highlight insurance that the code is comprehensive, periodically acknowledged by all employees, and understood by employees in terms of behavior. If a written code does not exist, management culture emphasizes the importance of integrity and ethical values.

- Establishment of "tone at the top." Tone at the top provides guidance on what is right and wrong and considers effective communications throughout the enterprise regarding commitment to integrity and ethics, and management deals appropriately with signs of problems such as defective products or hazardous waste.
- Dealings with associates on a high ethical plane. These associates include employees, suppliers, customers, investors, creditors, insurers, competitors, and auditors; business dealings are based on honesty and fairness.
- Remedial action is taken when departure from policy or the code of ethics occur. Areas to consider include management's response to violations and the disciplinary actions taken as a result of the violations.
- Management's attitude to the intervention or overriding established controls. Areas to consider include management-provided guidance on situations when intervention is needed, intervention is documented and explained, override is prohibited, and deviations are investigated.
- Pressure to meet unrealistic targets, especially to gain short-term results. Areas to consider include conditions where incentives exist that can test people's adherence to ethical values; compensation and promotions are based on achievement of these short-term performance goals; and controls are in place to reduce temptations (COSO Evaluation Tools, pp. 5, 6).

Another key factor within the control environment is commitment to competence. Commitment to competence requires the organization establish appropriate skills and worker knowledge to accomplish tasks. The level of competence should be defined to ensure both overqualified and under qualified talent is used for execution of a role. Areas to be considered include ensuring that formal or informal job descriptions are available and communicated and that analysis of the knowledge and skills needed to perform the job are adequate.

Examination of the board of directors requires the board is active and provides oversight as management maintains the ability to override controls. As the top leadership for the company, the board of directors must operate in a specific fashion. The evaluation tools used to verify these key areas include

- Maintaining independence between the board and management. This independence fosters appropriate scrutiny over the strategic initiatives, major transactions, and past performance of management. As well, alternative views are highlighted.
- Using the board when deeper attention is required for specific matters.
- Ensuring directors have sufficient knowledge and industry experience.
- Meetings occur with key management at the correct frequency. The audit committee meets with internal and external auditors to discuss controls, the reporting process, and significant comments and recommendations. Also, the audit committee reviews the scope of internal and external audit activities.
- Providing sufficiently detailed and timely information to the board to allow monitoring of objectives and strategies.
- Providing sensitive information to the board such as investigations and improper acts.
- The board provides oversight on the determination of executive compensation.
- The board maintains a role in establishing tone at the top; for example, the board evaluates the effectiveness of the tone at the top. It takes steps to ensure the tone is appropriate, and it addresses management's adherence to the code of conduct.

- Actions taken by the board as a result of findings presented to them. Considerations include the directives the board gives and also ensuring appropriate follow-up. (COSO Evaluation Tools, pp. 8, 9).

Management's philosophy and operating style are key factors of the control environment, addressing the unique cultures by which key decisions are made and executed. For example, some management styles may easily accept risks when executing strategic decisions or critical transactions; whereas, others may perform detail and cautious analytics.

Personnel turnover effectively gauges management style such as excessive turnover, unexpected resignations, and a pattern of turnover. For example, high turnover in executive internal audit and key financial positions may indicate management's view on internal controls. Organizations suffering from a higher turnover rate in these areas may have a poor view of the importance of internal controls. That is not to say, however, an organization with little or no turnover has a perfect internal control implementation.

Management's view toward data processing, accounting, and financial reporting accuracy also signifies their perspective on controls. Considerations including the accounting principles chosen by the organization and management's decision to implement the practice of reporting the highest income are important topics to review. Another consideration is management's requirements regarding sign-offs in the decentralized accounting department. If sign-offs are insufficient, it may be possible for departments in different areas to use different practices and sign off on their own work as being accurate. Additionally, how management protects intellectual property and other valuable assets from unauthorized access is an indicator of internal controls.

Organizational structure represents another internal control evaluation factor. The organizational structure defines the framework the organization uses to achieve its goals. Some areas to examine include the organizational structure's appropriateness, adequate definition of key manager's roles, adequacy of knowledge and experience of key managers in light of their responsibility, and the appropriateness of reporting relationships. For example, it may not be appropriate for a director in Internal Audit to report to the Chief Financial Officer when it is the finance area where most scrutiny is directed. Such a reporting structure could result in the Chief Financial Officer's applying direct pressure to inappropriately adjust internal audit reports.

Furthermore, changes in organizational structure as market and business conditions change along with an adequate span of control or number of employees per manager is important. Managers must have sufficient time and people to execute their responsibilities. Teams with too many people burden the manager with excessive people management responsibilities, possibly affecting their ability to execute the other tasks in their role.

Assignment of authority and responsibility provides the basis for accountability and control. This factor involves the level of empowerment allowed within the ranks of an organization. Delegation is important with attention to both the level of delegation employed and ensuring only the level of delegation required to reach the objective is implemented. Assignment of authority and responsibility should be established and consistently assigned throughout an organization. The level of delegation assigned to each manager at the same organizational level should be appropriate and consistent. Responsibility must be related to the assignment, and proper information should be considered in setting the level of authority.

Control-related standards such as job descriptions with specific references to control-related responsibilities should be considered. Many organizations do not implement clearly defined job descriptions, responsibilities, and control requirements, leaving these decisions to each individual manager or employee. This can have a significantly negative impact on the effectiveness of the control infrastructure, weaken management's effectiveness, and limit the ability to reach the organization's goals. Additionally, the entity should have an adequate workforce to carry out its mission. Finally, the job role should be defined to create the boundaries of which an employee executes prior to involving higher management.

The final factor within the control environment is human resources policies and practices. Human resource departments manage the standards and hiring practices within a company along with relaying messages to employees regarding expected ethical behaviors and required competence levels. Human resource policies ensure skilled resources are recruited and retained while also ensuring consistent behavior is attained throughout the employee population. Just as job descriptions and responsibilities are an important control factor, the human resources department is critical in establishing the job classifications and ensuring the organization maintains current job descriptions for hiring and performance evaluation purposes. Essential evaluation factors include adequate policies and procedures for hiring, training, promoting, and compensating employees.

Other considerations may be clarity in supporting a person's role within an organization. A person should know his or her role, including specific requirements, responsibilities, and authority levels, and the employee should also be subjected to periodical reviews of job performance. Remedial action should be consistently taken when employees fail to meet their objectives and for non-adherence to policies. Employees should understand the consequences they will face if they do not perform their work. Failing to ensure this understanding may expose the organization to legal implications through lawsuits and court designated penalties.

Overall review of the adequacy of employee background checks, employee retention, and promotion criteria should occur as well. Practices may include specific focus on candidates with frequent job changes and gaps in work history, although the specific nature of these gaps should be carefully considered as these do not specify a problem; they only identify the need for improved examination. Also, hiring practices may require background checks for criminal records, bankruptcies, or financial history, depending upon the nature of the job. These checks require uniform application and clear understanding on the part of the job candidate of the requirement.

The seven factors in the control environment presented here establish the entire control framework for an organization. When conducting a review of the control environment, all seven factors are reviewed across the entire organization. Performing reviews of these factors in smaller subsections of the organization may not identify problems, or they may indicate problems where none exist. Additionally, each factor has several criteria for evaluating the control; however, each specific component may be applicable to unique organizations. Each company must develop its own evaluation criteria to effectively measure and monitor the control framework. Companies may use what is presented in the tools provided by COSO or rely on these as examples and develop their own.

31.6 Information and Communication

The introduction within COSO to the information and communication component states, "Every enterprise must capture pertinent information—financial and non-financial, relating to external as well as internal events and activities. The information must be identified by management as relevant to managing the business. It must be delivered to people who need it in a form and timeframe that enables them to carry out their control and other responsibilities."

Information, as defined by COSO, is the data required to run the business, and *communication* is the manner used to disseminate the data to the appropriate personnel. Information and communication cross operational, financial, and compliance categories and are the glue that holds the organization together.

Information is stored and processed in information systems. Information systems incorporate the processing of internal data transactions and provide external information such as market data or other areas that may impact operations. The reports produced by these systems are used to ensure effective operations and are critical for management decisions. Information systems produce reports used for monitoring the environment. Information systems and the functions they provide have become strategic in nature to the overall success of organizations. These systems are heavily integrated into the operations of companies and enable the processing of large volumes of data.

Data quality is critical to the information and value of the knowledge derived from it. The information must be accurate and reliable. Because of the heavy reliance on information, several components of this information must be incorporated into information systems to ensure appropriateness, timeliness, currency, accuracy, and accessibility. Each of these impacts the overall ability to use the data for operations and key strategic decisions.

Communication occurs both internally and externally. Communication expands beyond the sharing of data generated by information systems, and it incorporates the setting of expectations and ensuring responsibilities are understood. Internal communications should include messages from the top regarding the value of internal controls and how their activities relate to the work of others. For example, if the company's CEO advises employees of the importance of ethics and operating with integrity, it is not only an example of internal communications, but it is also of a type indicating the value placed on internal controls. External communications involve open communication channels with suppliers and customers through press announcements, media articles, etc. Communications with external parties such as external auditors and regulators can provide valuable information regarding the overall effectiveness of controls.

Committee of Sponsoring Organizations separates information and communication into two factors with each having several focus points. When evaluating the information area, significant factors include

- Mechanisms are in place to obtain and report appropriate data to management from both external and internal sources.
- Information is provided to the right people with sufficient detail.
- Information systems are strategically linked to the organization with emphasis on ensuring objectives are met and attention is paid to emerging information needs.
- Management supports development of information systems as evidenced with appropriate human and financial resources.

The evaluation of communication may consider

- An employee's responsibilities are effectively communicated.
- Communication channels for reporting suspected improprieties.
- Receptiveness of management to employees' suggestions in regards to improving operations.
- Adequacy of information across the organization to enable an employee to discharge his or her responsibilities.
- Openness of communication channels with suppliers, customers, and other external parties.
- Extent to which outside parties are made aware of the entity's ethical standards.
- Proper follow-up action occurs resulting from communications from external sources.

Communication and information should be evaluated across the entity and within the business functions. Each is crucial to ensure goals and objectives are understood. Once understood, then the next component, monitoring, should occur to ensure that the controls are understood and working as intended.

31.7 Monitoring

Monitoring is the fifth component COSO requires for examination. Monitoring involves the review of internal control processes through ongoing activities or separate evaluations. Management may establish processes within the controls that effectively enable the control to monitor itself. These processes may be mechanized reports or other tools that identify when the control is not working. This ongoing monitoring incorporates regular management and supervisory activities. The more effective a control is, as presented by ongoing monitoring, the less frequent a separate evaluation of that control is needed. Separate evaluations may occur by management, but more often, by other groups such as internal audit.

The frequency of separate evaluations should be set based on risk assessment as well as overall effectiveness of the control. For example, controls with a higher exception or failure rate may need more frequent review until the problem is corrected.

Examination of the monitoring component occurs both corporate wide and within individual business units. Three factors should be considered: ongoing monitoring, separate evaluations, and reporting deficiencies. Ongoing monitoring, as previously described, involves the daily activities of management and may include activities such as reconciliations. Areas to consider for this factor include

- Ensuring personnel obtain evidence to determine if internal controls are functioning.
- Extent to which external parties corroborate internally generated information.
- Periodic comparison between accounting systems and physical assets.
- Responsiveness to auditor recommendations on strengthening controls.
- Feedback provided to management as obtained in various meetings where employees highlight control effectiveness.
- Periodic inquiry regarding employees' understanding of critical control activities.
- Overall effectiveness of internal control activities.

Separate evaluations require a review of the control process directly focusing on its effectiveness. The evaluations vary in scope and frequency based on risk and overall importance to the organization, and they are often performed by external organizations such as audit, consulting, or oversight groups. Some focus items for this factor may be

- Scope and frequency of review
- Appropriateness of the evaluation process
- Adequacy of the methodology for the review
- Proper level of documentation.

The third factor for monitoring is reporting deficiencies. These deficiencies may be highlighted from many sources and should be presented to management. Based on the risk associated with the deficiency, certain issues should be reported to the board. Evaluation of this factor may include

- Existence of a process to capture and report control weaknesses
- Appropriateness of reporting
- Appropriateness of follow-up.

31.8 Control Activities

Control activities represent the component internal audit has historically focused on during evaluations. Control activities do not have additional factors as the activities themselves are the focus of the review. COSO summarizes control activities as the "policies and procedures that help ensure management directives are carried out."

Control activities are broken into three categories: operational, financial reporting, and compliance. These categories may overlap as a particular control activity may meet control objectives of more than one category.

Examination of control activities may include review of policies and procedures and ensuring control procedures are working as intended. Other areas typically reviewed are segregation of duties, reconciliations, performance indicators, top level reviews, and other financial reviews. Within the top level reviews, actual performance compared to budget may be examined, whereas in financial review, trend analysis may occur.

Information processing is a key review area and is largely executed by information technology auditors or specialist trained in information technology (IT) general controls or specified technologies. General controls cover a broad overview of basic operational IT controls such as data center reviews, change control, system development, problem management, maintenance, capacity planning, and access controls. With new technologies, expanding complex systems, large volumes of data transactions, and diverse operating environments specialized testing may be needed for a specific technology or process.

31.9 Risk Assessment

Risk assessment is the identification and analysis of relevant risks to achievement of the objectives, forming a basis for determining how the risks should be managed. This component covers risks from internal and external influences that may prevent the organization from meeting its business objectives. Risk assessment occurs at two levels: one for the overall business and the other within the actual business functions. Four factors should be examined for risk assessment: entity-wide objectives, activity-level objectives, risks, and managing change.

Entity-wide objectives involve review identifying if management has established objectives and if guidance has been provided on what the company desires to achieve. This information should be communicated to employees with appropriate feedback channels. Linkage of the objectives to the overall strategic plan should be evaluated to ensure the strategy supports the objectives and also that proper prioritization and resource allocation has been provided.

Entity-wide objectives set the direction for the activity-level objectives and typically are managed by meeting specific goals with targets and deadlines. Evaluation of an entity's controls should include ensuring adequate linkage between entity-wide and activity-level objectives for all significant activities and also validation of the consistency between the activity-level objections. The objectives should be relevant in that they are established for key activities and are consistent with past performance or with industry practices. These objectives should be measurable and have proper resource allocation. Critical to the success of activity-level objectives is management's involvement at all levels.

The risks factor entails ensuring the company's risk-assessment process identifies and considers implications of relevant risks from external and internal sources. Assessment within this area includes identifying risks from external sources such as suppliers, regulation, technological changes, creditors, competition, natural disasters, and economic and political activities. Internal sources include adequate staffing and talent, financing, competitive labor relations, and controlled information systems. The risk analysis should be comprehensive in order to identify the significance of the risk, the risk's likelihood of occurring, and outcomes.

The final factor to examine for risk assessment is validating how well adapted the organization is for managing change. Each organization needs to have a process to identify conditions that may affect its ability to meet its objectives. External events such as regulatory, economic, or industry change and impact businesses as well, entities activities evolve. Events that require special attention include rapid or declining growth, evolving technology, new product lines, corporate restructurings, and international relations.

Assessing change management first requires the identification of change at all levels. Once identified, the process should include the manner the response to the change. All impacted entities in the change should be brought into the process. Changes that will have long lasting impact to the business should include top management.

31.10 Practical Application of COSO

Since COSO's inception, many variations of COSO implementations have occurred. Two common tools are risk assessment templates and questionnaires. Some components of COSO may be evaluated at the overall entity level; whereas, other components may be evaluated at the operating level. A questionnaire may be useful to assess an organization's control environment; although, a risk assessment with detailed objectives is better suited for a functional area. Regardless of the tool selected, the manner used to assess an organization must be catered to that specific company. Very large companies may work well using survey questionnaires, and small companies may rely on informal interviews.

Supplemental to the COSO report is *Evaluation Tools* that presents examples of how to use COSO for evaluations. These tools are examples and may not work for individual organizations; rather, they should be used solely to gain ideas on what would work within a specific company.

An example of a COSO implementation may include an annual control environment assessment performed by using an informal questionnaire. The questionnaire would contain questions from the points of focus highlighted in the COSO Evaluation Tools. The questionnaire may incorporate entity-wide focus points for monitoring, communication, and risk assessment. Additionally, a risk assessment could be performed in each of the business functions to include monitoring, communication, and risk activities at that level. Finally, the actual traditional audit testing would be used to evaluate control activities. The goal is to gain an overall view of the controls at both the entity and operating level for each of the components and seventeen factors to be able to adequately form an opinion over the overall control environment.

31.11 COSO and Sarbanes Oxley

As previously discussed, COSO came about to address controls because of several financial scandals. COSO was not mandatory; rather, the intent was that organizations would more likely adhere to control frameworks if permitted to implement them as they deemed necessary.

Significant control breakdowns continued to surface with the financial collapses of companies such as Enron, Worldcom, Global Crossing, Tyco Bell, and Parmalat since 2000. Many corporations have restated profits previously reported and fraudulent reporting of financial statements went undetected because of a breakdown in several controls. Factors that led to these events' going undetected include passive actions from the audit committees and independent directors, inadequate control structures, lack of auditor independence, and excessively high fees for audit work. Overall, mandatory regulatory requirements were relaxed and insufficient.

In order to address these issues, the Sarbanes Oxley Act 2002 (named for its originators—Senator Paul Sarbanes and Senator Michael Oxley) was enacted in July 2002 to bolster investor trust and confidence. Key highlights of the act provide new and enhanced standards of responsibility and accountability for accuracy, reliability, and transparency of financial reporting. SOX emphasizes transparent disclosures for meaningful analysis and interpretation. It places a strong emphasis on the use of recognized internal control frameworks for evaluation of internal controls. The act enforces stricter penalties for wrongdoing—intentional or otherwise. The Securities and Exchange Commission (SEC) is responsible for implementation guidance and directives.

The linkage of SOX to COSO comes with the requirement of a control framework. COSO provides the framework that can be used to ensure SOX compliancy. SOX compliancy work is heavily focused on control activities; however, complying with COSO also requires analysis of the other components such as the control environment, risk assessment, and monitoring.

Another control framework focused solely on information technology controls is COBIT. COBIT has been adapted within the information technology areas to ensure controls are in place for SOX-related work. COSO, however, can also be used for IT-related controls. As in this area, the five components are still required, but the evaluation criteria should be catered toward the information technology environment.

31.12 Summary

Committee of Sponsoring Organizations provides a comprehensive framework for evaluating an entity's controls. The framework expands beyond typical control activities into an overall control environment assessment: communication and information, risk assessment, and monitoring. Additionally, the evaluations of these areas provide assurance that an entity maintains operational, financial, and compliance controls.

The Sarbanes Oxley legislative requirements have brought increased awareness to control frameworks. Although COSO has been used since the late 1980s, SOX initiatives have largely driven use and acceptance of COSO. More information on COSO may be found at theiia.org or isaca.org. Many organizations provide guidance and tools for COSO of which careful scrutiny should be applied prior to purchasing as COSO provides the basis these organizations sell.

Toward Enforcing Security Policy: Encouraging Personal Accountability for Corportate Information Security Policy

John O. Wylder

Information security professionals through the years have long sought support in enforcing the information security policies of their companies. The support they have received has usually come from internal or external audit and has had limited success in influencing the individuals who make up the bulk of the user community. Internal and external auditors have their own agendas and do not usually consider themselves prime candidates for the enforcement role.

Other attempts to achieve policy enforcement have included rounding up the usual suspects of senior management and executive management memoranda and security awareness campaigns. In general, none of these programs were felt to be successful, as evidenced by routine tests of information security policy compliance. This chapter discusses a new approach to policy enforcement. The proposal is to encourage the support for these policies by incorporating compliance activities with an individual's annual personnel performance evaluation.

32.1 Background

The successful implementation of an information security program derives from a combination of technical and nontechnical efforts. The process starts with the development of a comprehensive plan that assesses the risks and threats to an individual firm and then moves to the development of a set of policies and strategies to mitigate those risks. These policies are often a mix of technical and nontechnical items that require routine testing or measurement to ensure that the desired level of compliance is maintained over time. In most cases, the technical policies are the initial focus of a security program and are done in cooperation with information technology (IT) staff. This is the traditional home of information security practitioners.

32.2 The Problem

Most security practitioners are aware that the bulk of their problems are internal rather than external. Whatever their level in the organization and regardless of the degree of support they feel they have or do not have within the organization, it has become clear over time that Pareto's law applies here: 80 percent of the problems are caused by 20 percent of the people.

Pentasafe Security Technologies recently conducted a survey among companies and found that nine out of ten employees were likely to open and execute an e-mail attachment without questioning its source or authenticity. This leads, of course, to virus and worm infections on the corporate e-mail server. Why do people do this despite the widespread publicity that such infections have received? Is it the lack of awareness, as some might say, or is it the lack of understanding the consequences of failing to comply with security policy?

Companies have tried a variety of means to ensure that their employees have received at least minimal training in information security policies. Here is a list of some of those approaches:

- Inclusion of security policies in employee handbooks
- Requirement to take a self-study course prior to initial issuance of user credentials
- Annual testing of security awareness
- PR campaigns using posters and Web and e-mail reminders

All of these are valid approaches and should be considered as a part of the security program for any company. Yet despite these types of programs, security practitioners still find that users fail in routine functions of security and still choose passwords, for example, that are easily guessed or even shared. Raising the bar on having complex passwords that must be changed frequently usually results in passwords that are written on notepads and left underneath the keyboard.

When employees are interviewed about their lack of compliance, they often cite the pressure to be productive and that they see the incremental security policy as counter to their productivity. When it comes to complying with security and trying to be productive, most users err on the side of productivity rather than security. This leads to the question of how you make employees personally accountable for their role in compliance with information security policy.

Some security professionals say that the problem starts at the top with a lack of awareness and support by the executive team. There is some truth to that, as the budget and resource allocation starts at the top and if there is no money, there is little chance that the security program will succeed (see Exhibit 32.1).

In some companies, a new approach emerged in the late 1980s, that is, the creation of a "C"-level position for security, that of the Chief Information Security Officer. The thinking was that by elevating the position to a peer with the other "C"-level positions, it would be easier for those people to gain compliance with their policies. By giving them a seat at the table, they would be in a better position to ensure that their policies are ones that have the full support of the management team.

EXHIBIT 32.1 PricewaterhouseCoopers Survey

There was a recent survey by PricewaterhouseCoopers of 1000 companies in the United Kingdom. The survey found the majority of companies spent, on average, less than 1 percent of their total IT budget on information security while an average of 3 to 4 percent was recommended.

Paradoxically, it said that 73 percent of senior managers interviewed believed that IT security was a top priority.

Potter said: "The board of most companies want to do something about security but it does not know how much money it should spend on it." The survey was commissioned by the Department of Trade and Industry.

32.3 The Role of the Chief Information Security Officer (CISO)

Recently, there has been a resurgence in the movement to create the position of Chief Information Security Officer (CISO) that reports to the CIO or at least to the CTO. Another recent innovation is to create a Chief Privacy Officer (CPO), either in addition to or instead of a CISO. All too often, this has been done due to poor results shown in audits of the compliance with the existing policies. The higher-level reporting structure is seen as a way to better ensure that information security receives the proper level of management attention. Creation of the new position alone, however, has not been shown to be the way to ensure policy compliance across the enterprise.

Many companies today have some form of matrix management in place. In one company this author recently worked with, the Chief Security Office had responsibility for security policy from both a creation and an enforcement standpoint, but only had dotted-line responsibility for the tactical side of information security. In that company, the technical policies were done first by and for the IT department and then rolled out into either the employee manual or into the company's corporate-wide compliance manual. It is this set of policies that became the more difficult ones to assess and to ensure compliance, despite its corporate-wide distribution.

This split is not atypical today. The responsibility for administering passwords and user credentials is often part of the technology area. In some cases, these responsibilities may even go to a network help desk for administration. There may be nothing wrong with this approach but the measurement of compliance with policy is often overlooked in this case. The security administrator is measured by things like password resets and log-in failures, but who is measuring why those passwords need to be reset and who is responding to any audits of the strength and quality of the passwords?

32.4 Security Policy and Enforcement

One of the standard descriptions of information security programs is that they are about "people, policies, and procedures." In developing the policies for a company, this is taken to the next level down and the process is then about creating a risk profile and developing the appropriate policies to reduce risk. Once the policies are created, the appropriate implementation mechanisms are put in place and then come the controls that allow the measurement and enforcement of those policies.

32.4.1 Technology-Based Enforcement

For example, the risk profile of a company with product trade secrets will logically be different from the risk profile of a company that is in the services business. The company with the trade secrets has high-risk information that needs to be kept secure and it may have a detailed information classification policy as part of its Information Security Policy manual. Along with information classification, it may also have role-based access controls that allow it to implement the classification policy. This then may lead it to the implementation of certain technologies that allow automated controls and enforcement of the information classification and access control policy. This can then be described as technology-based enforcement. The access control system, once properly implemented, allows or prevents access to information and enforces the policy.

There are many good examples of this approach in the marketplace today. This approach sometimes comes under the title of "Identity Management." It addresses a broad spectrum of controls, including authentication and authorization systems. Included here are such technologies as biometrics, smart cards, and more traditional access control systems. Enforcement is achieved through approval or denial of access and reporting of policy violations through error or audit logs.

32.4.2 Executive Enforcement

Frequently cited in articles on the creation of an effective information security program is the need for support by executive management. This is sometimes seen as the route to enforcement of policy. Comments heard from many information security professionals include, "I need the president of the company to come out in favor of our policies, then I can get people to comply with them." There is a fallacy here because executive management is too far removed from the day-to-day operations of a company to become enmeshed in the enforcement of any given policy or policies. It is unlikely that the president of a large or even a medium-sized company can be brought into the discussion of the virtues of maintaining role-based access controls as opposed to broad-based access. This type of discussion is usually left to the operational areas to work out among them.

It is possible to get the support of the executive team to send the message to all employees about their support for the information security program. That executive support can, in fact, be essential to the information security department as it goes out and spreads its message. It is very difficult, on the other hand, to translate that support into direct action on the enforcement of specific policies.

32.4.3 Audit as Enforcement

The auditing department of a company is often seen as part of the enforcement mechanism and sometimes may be seen as the primary enforcement tool. Most auditors disagree that they should play an operational role and try to keep their "enforcement" role to a minimum. This is often done by auditing the existence of policy, measuring the effectiveness of the policy, and leaving the role of enforcement to others. For example, auditors would look at whether or not there were policies governing the role-based access to classified information. They then may drill down and test the effectiveness of the administration of such policies. Their finding would be one of fact: "We tested the authorization policies of the XYZ department. We found that ZZ members of the department had complete read, write, and update authority to the system. This appears to be inappropriate based on the job description of those people. We recommend that management review the access list and reduce it to the minimum number of people necessary to perform those critical job functions and that access be granted based on the job description on file with the HRMS department."

This type of finding is typical of most auditors' roles and does not lend itself to assisting with the enforcement of policy. For example, in the above case, there is neither a finding that indicates who created the violations, nor is there a finding of what actions should be taken to ensure that that person is admonished for creating the violations.

32.4.4 Traditional Management Enforcement

The remaining place in an organization that most people look to for enforcement of policy is to the individuals managing the various corporate departments. Enforcement of information security policies here comes under the broad heading of enforcement of all corporate-level policies. Managers, like their employees, have to juggle the sometimes-conflicting need to enforce policies while maintaining productivity. Sometimes, employees see the need to have access beyond their normal approved level as a means to improve their job performance. In other cases, there may be conflicting messages sent by management about which company goals have priority. In any case, this model is one of distributed enforcement, which can lead to uneven application of policy and compliance.

All of the above methods have been tried through the years with varying degrees of success. Few people active today in the information security field have great confidence that their enforcement mechanisms are working to their satisfaction.

32.5 Policy Compliance and the Human Resources Department

In asking a security manager if it would make any difference if security compliance were to become part of the employee annual performance assessment process, the response was that "it would make all the difference in the world." During the same engagement, the human resources (HR) manager was asked if his department could help enforce information security policies; his response was, "No way!"

The HR manager explained that policies to them were a zero-sum game; if a new policy were to be added, they needed to consider which policy would be dropped. They understood that compliance could become one of their responsibilities and then said that they already had to measure compliance with policies covering attendance, hiring practices, privacy, pay equity, and a host of others. Which policy should they drop to help with the compliance to security policy?

They had a good point, but I then asked what would happen if we added it as a job-performance criterion. Suddenly there was a change in attitude and an understanding that perhaps a middle ground could be found where compliance could be brought into existing policies and procedures.

The problem then is how to accomplish this and how to maintain the support of the human resources professionals. The remainder of this chapter explores this idea and proposes a possible means to accomplish this through the development of an annual personal information security plan by each employee.

32.6 The Personal Security Plan

The HR people in that engagement gave a glimmer of hope that security could become part of performance appraisals and therefore compliance with policies could not only be measured but could be enforced at some level. Most employees understand the old adage that what is measured gets done. If the company provides a way to report on employee compliance with any policy and links it to performance measurement and compensation, then company employees are more likely to comply with that policy.

32.6.1 Personal Accountability

A new term has popped up recently in the press with respect to IT practices—and that is *accountability*. This has come up with some of the recent legal actions where victims of poor IT practices are filing suits against companies that may not be the perpetrator, but whose own practices may be part of the problem. There was a recent action in which a denial-of-service (DoS) attack occurred and a lawsuit was filed against an Internet service provider (ISP) whose network was used by the perpetrators to launch a zombie DoS attack. This case is still moving through the court system and the outcome at this point is undetermined, but the net effect is to try to shift the burden of blame to people who fail to practice safe computing. This philosophy can then be used in another way to help shift the focus of enforcement of policy from management, audit, or technology to the individual.

This idea recently received a boost with the backing of professionals in the U.S. Government:

> Federal agencies must raise staff accountability for breaches and demand security become standard in all network and computing products. Otherwise, enterprises won't be able to improve cyber attack response and prevention, according to highlights of a recent conference sponsored by the National High Performance Computing and Communications Council.

> Rather than emphasizing technology's role in information security, several speakers urged stronger user awareness programs and more involvement of top management.
>
> You can't hold firewalls and intrusion detection systems accountable. *You can only hold people accountable*, said Daryl White, chief information officer for the U.S. Department of the Interior, in a published report (emphasis added).

32.6.2 The Personal Security Plan: Phase One

Using this approach, the proposal being made here is the creation of a personal security plan and the incorporation of that plan into an employee's annual performance appraisal.

Exhibit 32.2 shows an example of such a plan. This is a simple document that addresses the basic but core issues of security. It is neither highly technical nor does it require the company to invest money in any large-scale implementation of technical solutions such as biometrics, Public Key Infrastructure (PKI), or any other simple or even exotic technologies. The emphasis here is on the routine things an employee does that can create risk to the company.

However, the items to be measured include the need to track compliance at a technical level. It is not practical to just rely on the employee writing a plan and taking a pledge of compliance. It is important that the technical approaches to compliance be used and the results included in the evaluation of the

XXX Company
Personal Information Security Plan

Date:

Plan period — From: ____________ **To:** ____________

Employee Name: ____________

Network user ID: ____________

Home computer profile: ____________

Computer make, type: ____________

Home ISP: AOL ___ WorldNet ___ CompuServe ___ Earth link ___ Other ___

Access type: Dial-up ___ DSL ___ Cable modem ___

Number of times a week used for work:

Home network (if applicable): Ethernet ___ Token ring ___ Wireless ___

Home protection profile (please describe methodologies or technology used at home to protect computers and networks):

Anti-virus software (vendor, version): ____________

Personal firewall (vendor, version): ____________

Other: ____________

____________ ____________
Employee signature Manager's Signature

This section to be completed by supervisor:

From annual security audit describe any security violations or compliance issues:

effectiveness of the plan. These should not come as any surprise to a security professional, and the tools should be part of their arsenal:

- *Password cracking programs*: measuring the strength of the passwords used by the employees.
- *Log-in tracking reports*: recording the number of times the user tried to log in remotely and succeeded or failed.
- *Network security audits*: tracking the use of dial-up lines or DSL access.

All of these would produce data that would then be sent to the employee's supervisor for use in the annual performance appraisal.

The idea here is to broaden the focus on information security policies in the mind of the employee. By making each individual employee accountable for making and executing a Personal Security Plan, each employee then has a stake in the process of practicing safe computing at his or her company. Employees also have to become more knowledgeable about the effects of their actions on the state of security as a whole.

32.6.3 How the Plan Would Work

Prior to his or her annual performance review each year, each employee would be required to complete a Personal Security Plan. The plan would be designed in conjunction with the company's Information Security Policies, which would dictate key items such as remote access policies, password policies, and secure computing standards. The individual's plan would consist of his own usage profile plus his written plans for the year to use corporate computing resources in compliance with the published Information Security Policies.

For example, people who work from home using dial-up lines might be required to use a smart card or other two-factor authentication scheme as part of their access methodology. This may be combined with the use of a personal firewall and installation of anti-virus software. Employees would then use this form to describe their remote access profiles and how they are going to comply with corporate-wide policies. Another aspect of the plan would be for the employees to sign a notice that they understand and comply with the corporate Information Security Plan. This annual certification can become important if the employee is ever investigated for a violation.

Once this form is completed, the employees would give it to their supervisors for approval. The supervisors would be required to review the plan to ensure that it complies with corporate standards. Once approved, a copy of the plan is given back to the employees for their files and the original is kept on file with other vital employee records. The plans would be useful to the Chief Information Security Officer to use to check for overall compliance at the department and division levels.

32.6.4 Enforcement of the Personal Security Plan

Enforcement of the approach would be similar to the managerial approach but much more focused and specific. All employees would have to have a plan, and the effectiveness of both individual plans and the process as a whole could be measured and managed. Employees would know that their job performance and compensation would now be linked to their individual plan. HRMS should be satisfied with this approach because it is not the enforcer of the Information Security Plan, merely of the compliance mechanism. Audit likewise would be satisfied with this approach because it is measurable and has clear lines of accountability that can be measured. Finally, information security professionals should be the happiest of all because they will now have a way to bring the entire organization into the process of Information Security Policy compliance and enforcement.

Each company using this approach is responsible for matching the results to any actions taken with respect to the employee's performance appraisal. The weight that the Personal Security Plan carries for appraisal purposes will vary from company to company. In cases where there is a high-risk profile, the plan will logically carry more weight than in low-risk profile positions. Failure to complete the plan or failure to execute the plan then becomes the negative side of enforcement, requiring disciplinary action to be taken on the part of the responsible manager.

This alone will not end all risk to the company, nor can it be a substitute for technical approaches to solving technology problems. What this can do is move the responsibility to the point closest to compliance—that is, the actual employee required to comply with the policy.

32.7 Support for This Idea

The National Infrastructure Protection Center (NIPC) recently published some simple security tips (see Exhibit 32.3) that fit this strategy.

These tips could become the basis of any company's personal strategy to be used to educate employees on their responsibilities. They then become the core elements to be used in the creation of that company's version of a Personal Security Plan.

These plans would need to be updated on an annual basis and the various items in the plan would be updated as both the employees' usage changes and as technology changes. But once the process begins, the changes become a routine part of the employee's duties.

32.8 The Personal Security Plan: Phase 2

This program could be expanded in a second phase to take into account actual job-performance-related criteria. The first phase concentrates on the employee's personal computer usage and extends to any off-site access of the company network. In the next phase you could add details about the employee's current usage of information and computers while at work.

The following elements could be added to the plan in this phase:

- Access level (public, confidential, private, secret)
- Authorization level (read, write, update)
- System level access, if any (supervisor, operator, analyst)

This would make an excellent tie-in to the company's identity management program, whereby the access rules are provisioned based on job profile. The security plan for the individual would then have components that describe the access rules, authorization levels, and a record of compliance with those rules. This would be much more specific and would require more time on the part of the supervisor.

EXHIBIT 32.3 Seven Simple Computer Security Tips for Small Business and Home Computer Users

Consult www.nipc.gov for more information.

- **Use strong passwords**. Choose passwords that are difficult or impossible to guess. Give different passwords to all accounts.
- **Make regular backups of critical data**. Backups must be made at least once each day. Larger organizations should perform a full backup weekly and incremental backups every day. At least once a month, the backup media should be verified.
- **Use virus protection software**. That means three things: having it on your computer in the first place, checking daily for new virus signature updates, and then actually scanning all the files on your computer periodically.
- **Use a firewall as a gatekeeper between your computer and the Internet**. Firewalls are usually software products. They are essential for those who keep their computers online through the popular DSL and cable modem connections but they are also valuable for those who still dial in.
- **Do not keep computers online when not in use**. Either shut them off or physically disconnect them from Internet connection.
- **Do not open e-mail attachments from strangers**, regardless of how enticing the Subject Line or attachment may be. **Be suspicious of any unexpected e-mail attachment from someone you do know** because it may have been sent without that person's knowledge from an infected machine.
- Regularly download security patches from your software vendors.

The supervisor would be required to review violation and audit logs and track any violations that occurred during the planning period.

The advantage of this approach is that it would bring employees full circle in their understanding of their roles and rights for information access to their actual experiences and performances. This is again aimed at getting individual accountability and making that the key element of the enforcement process.

32.9 Conclusion

The title of this chapter is "Toward Enforcing Information Security Policy." In no way is this approach intended to be the endpoint of the journey to getting full enforcement of an information security policy. This approach gives the security professional a practical way to move enforcement of security policy further along in an organization. It also moves enforcement from a top–down model to a bottom–up model and takes into account individual accountability for policy compliance.

By going beyond awareness and enlisting the assistance of other areas such as Human Resources, security policy becomes a routine part of the job rather than the exception. By making it routine and including it in the measurement of compliance with other more traditional policies, it becomes more feasible to expect that the goal of compliance will be achieved. After all, the goal is compliance, and enforcement is only the mechanism.

33

The Security Policy Life Cycle: Functions and Responsibilities

Patrick D. Howard

Most information security practitioners normally think of security policy development in fairly narrow terms. Use of the term *policy development* usually connotes writing a policy on a particular topic and putting it into effect. If practitioners happen to have recent, hands-on experience in developing information security policies, they may also include in their working definition the staffing and coordination of the policy, security awareness tasks, and perhaps policy compliance oversight. But is this an adequate inventory of the functions that must be performed in the development of an effective security policy? Unfortunately, many security policies are ineffective because of a failure to acknowledge all that is actually required in developing policies. Limiting the way security policy development is defined also limits the effectiveness of policies resulting from this flawed definition.

Security policy development goes beyond simple policy writing and implementation. It is also much more than activities related to staffing a newly created policy, making employees aware of it, and ensuring that they comply with its provisions. A security policy has an entire life cycle that it must pass through during its useful lifetime. This life cycle includes research, getting policies down in writing, getting management buy-in, getting them approved, getting them disseminated across the enterprise, keeping users aware of them, getting them enforced, tracking them and ensuring that they are kept current, getting rid of old policies, and other similar tasks. Unless an organization recognizes the various functions involved in the policy development task, it runs the risk of developing policies that are poorly thought out, incomplete, redundant, not fully supported by users or management, superfluous, or irrelevant.

Use of the *security policy life cycle* approach to policy development can ensure that the process is comprehensive of all functions necessary for effective policies. It leads to a greater understanding of the policy development process through the definition of discrete roles and responsibilities, through enhanced visibility of the steps necessary in developing effective policies, and through the integration of disparate tasks into a cohesive process that aims to generate, implement, and maintain policies.

33.1 Policy Definitions

It is important to be clear on terms at the beginning. What do we mean when we say *policy*, or *standard*, or *baseline*, or *guideline*, or *procedure*? These are terms information security practitioners hear and use every day in the performance of their security duties. Sometimes they are used correctly, and sometimes they are not. For the purpose of this discussion, these terms are defined in Exhibit 33.1.

Exhibit 33.1 provides generally accepted definitions for a security policy hierarchy. A *policy* is defined as a broad statement of principle that presents management's position for a defined control area. A *standard* is defined as a rule that specifies a particular course of action or response to a given situation and is a mandatory directive for carrying out policies. *Baselines* establish how security controls are to be implemented on specific technologies. *Procedures* define specifically how policies and standards will be implemented in a given situation. *Guidelines* provide recommendations on how other requirements are to be met. An example of interrelated security requirements at each level might be an electronic mail security policy for the entire organization at the highest policy level. This would be supported by various standards, including perhaps a requirement that e-mail messages be routinely purged 90 days following their creation. A baseline in this example would relate to how security controls for the e-mail service will be configured on a specific type of system (e.g., ACF2, VAX VMS, UNIX, etc.). Continuing the example, procedures would be specific requirements for how the e-mail security policy and its supporting standards are to be applied in a given business unit. Finally, guidelines in this example would include guidance to users on best practices for securing information sent or received via electronic mail.

EXHIBIT 33.1 Definition of Terms

Policy: A broad statement of principle that presents management's position for a defined control area. Policies are intended to be long-term and guide the development of more specific rules to address specific situations. Policies are interpreted and supported by standards, baselines, procedures, and guidelines. Policies should be relatively few in number, should be approved and supported by executive management, and should provide overall direction to the organization. Policies are mandatory in nature, and an inability to comply with a policy should require approval of an exception.

Standard: A rule that specifies a particular course of action or response to a given situation. Standards are mandatory directives to carry out management's policies and are used to measure compliance with policies. Standards serve as specifications for the implementation of policies. Standards are designed to promote implementation of high-level organization policy rather than to create new policy in themselves.

Baseline: A baseline is a platform-specific security rule that is accepted across the industry as providing the most effective approach to a specific security implementation. Baselines are established to ensure that the security features of commonly used systems are configured and administered uniformly so that a consistent level of security can be achieved throughout the organization.

Procedure: Procedures define specifically how policies, standards, baselines, and guidelines will be implemented in a given situation. Procedures are either technology or process dependent and refer to specific platforms, applications, or processes. They are used to outline steps that must be taken by an organizational element to implement security related to these discrete systems and processes. Procedures are normally developed, implemented, and enforced by the organization owning the process or system. Procedures support organization policies, standards, baselines, and guidelines as closely as possible, while addressing specific technical or procedural requirements within the local organization to which they apply.

Guideline: A guideline is a general statement used to recommend or suggest an approach to implementation of policies, standards, and baselines. Guidelines are essentially recommendations to consider when implementing security. While they are not mandatory in nature, they are to be followed unless there is a documented and approved reason not to.

It should be noted that many times the term *policy* is used in a generic sense to apply to security requirements of all types. When used in this fashion it is meant to comprehensively include policies, standards, baselines, guidelines, and procedures. In this document, the reader is reminded to consider the context of the word's use to determine if it is used in a general way to refer to policies of all types or to specific policies at one level of the hierarchy.

33.2 Policy Functions

There are 11 functions that must be performed throughout the life of security policy documentation, from cradle to grave. These can be categorized in four fairly distinct phases of a policy's life. During its development a policy is created, reviewed, and approved. This is followed by an implementation phase where the policy is communicated and either complied with or given an exception. Then, during the maintenance phase, the policy must be kept up-to-date, awareness of it must be maintained, and compliance with it must be monitored and enforced. Finally, during the disposal phase, the policy is retired when it is no longer required.

Exhibit 33.2 shows all of these security policy development functions by phase and their relationships through the flow of when they are performed chronologically in the life cycle. The following paragraphs expand on each of these policy functions within these four phases.

33.2.1 Creation: Plan, Research, Document, and Coordinate the Policy

The first step in the policy development phase is the planning for, research, and writing of the policy—or, taken together, the *creation* function. The policy creation function includes identifying why there is a need for the policy (for example, the regulatory, legal, contractual, or operational requirement for the policy); determining the scope and applicability of the policy; roles and responsibilities inherent in implementing the policy; and assessing the feasibility of implementing it. This function also includes conducting research to determine organizational requirements for developing policies, (i.e., approval authorities, coordination requirements, and style or formatting standards), and researching

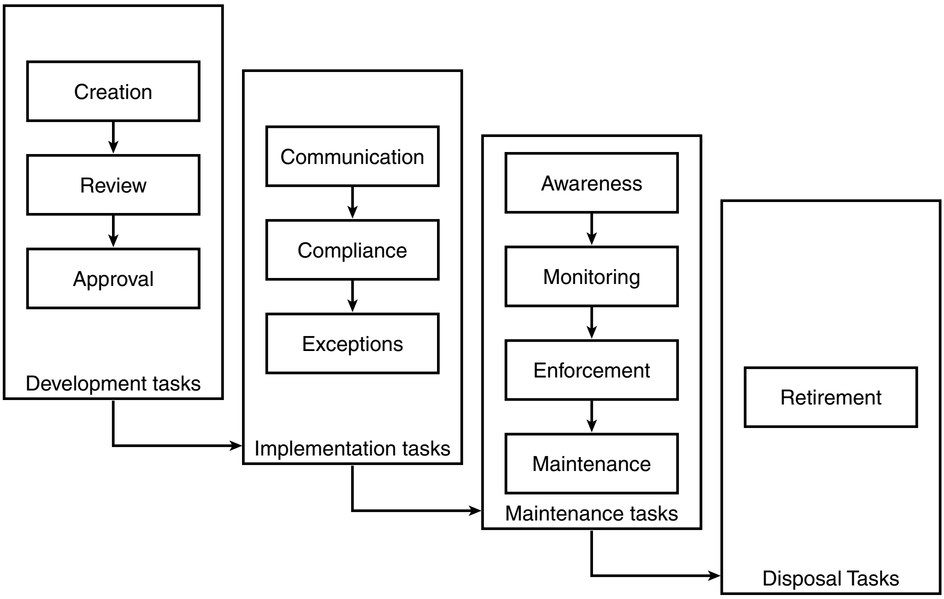

EXHIBIT 33.2 Policy functions.

industry-standard best practices for their applicability to the current organizational policy need. This function results in the documentation of the policy in accordance with organization standards and procedures, as well as coordination as necessary with internal and external organizations that it affects to obtain input and buy-in from these elements. Overall, policy creation is probably the most easily understood function in the policy development life cycle because it is the one that is most often encountered and which normally requires the readily identifiable milestones.

33.2.2 Review: Get an Independent Assessment of the Policy

Policy *review* is the second function in the development phase of the life cycle. Once the policy document has been created and initial coordination has been effected, it must be submitted to an independent individual or group for assessment prior to its final approval. There are several benefits of an independent review: a more viable policy through the scrutiny of individuals who have a different or wider perspective than the writer of the policy; broadened support for the policy through an increase in the number of stakeholders; and increased policy credibility through the input of a variety of specialists on the review team. Inherent to this function is the presentation of the policy to the reviewer(s) either formally or informally; addressing any issues that may arise during the review; explaining the objective, context, and potential benefits of the policy; and providing justification for why the policy is needed. As part of this function, the creator of the policy is expected to address comments and recommendations for changes to the policy, and to make all necessary adjustments and revisions resulting in a final policy ready for management approval.

33.2.3 Approval: Obtain Management Approval of the Policy

The final step in the policy development phase is the *approval* function. The intent of this function is to obtain management support for the policy and endorsement of the policy by a company official in a position of authority through their signature. Approval permits and hopefully launches the implementation of the policy. The approval function requires the policy creator to make a reasoned determination as to the appropriate approval authority; coordination with that official; presentation of the recommendations stemming from the policy review; and then a diligent effort to obtain broader management buy-in to the policy. Also, should the approving authority hesitate to grant full approval of the policy, the policy creator must address issues regarding interim or temporary approval as part of this function.

33.2.4 Communication: Disseminate the Policy

Once the policy has been formally approved, it passes into the implementation phase of the policy life cycle. *Communication* of the policy is the first function to be performed in this phase. The policy must be initially disseminated to organization employees or others who are affected by the policy (e.g., contractors, partners, customers, etc.). This function entails determining the extent and the method of the initial distribution of the policy, addressing issues of geography, language, and culture; prevention of unauthorized disclosure; and the extent to which the supervisory chain will be used in communicating the policy. This is most effectively completed through the development of a policy communication, implementation, or rollout plan, which addresses these issues as well as resources required for implementation, resource dependencies, documenting employee acknowledgment of the policy, and approaches for enhancing visibility of the policy.

33.2.5 Compliance: Implement the Policy

Compliance encompasses activities related to the initial execution of the policy to comply with its requirements. This includes working with organizational personnel and staff to interpret how the policy can best be implemented in various situations and organizational elements; ensuring that the policy is understood by those required to implement, monitor, and enforce the policy; monitoring, tracking, and reporting on the pace, extent, and effectiveness of implementation activities; and measuring the policy's immediate impact on operations. This function also includes keeping management apprised of the status of the policy's implementation.

33.2.6 Exceptions: Manage Situations where Implementation Is Not Possible

Because of timing, personnel shortages, and other operational requirements, not every policy can be complied with as originally intended. Therefore, *exceptions* to the policy will probably need to be granted to organizational elements that cannot fully meet the requirements of the policy. There must be a process in place to ensure that requests for exception are recorded, tracked, evaluated, submitted for approval/disapproval to the appropriate authority, documented, and monitored throughout the approved period of noncompliance. The process must also accommodate permanent exceptions to the policy as well as temporary waivers of requirements based on short-term obstacles.

33.2.7 Awareness: Assure Continued Policy Awareness

Following implementation of the policy, the maintenance phase of the policy development life cycle begins. The *awareness* function of the maintenance phase comprises continuing efforts to ensure that personnel are aware of the policy in order to facilitate their compliance with its requirements. This is done by defining the awareness needs of various audience groups within the organization (executives, line managers, users, etc.); determining the most effective awareness methods for each audience group (i.e., briefings, training, messages); and developing and disseminating awareness materials (presentations, posters, mailings, etc.) regarding the need for adherence to the policy. The awareness function also includes efforts to integrate up-to-date policy compliance and enforcement feedback as well as current threat information to make awareness information as topical and realistic as possible. The final task is measuring the awareness of employees with the policy and adjusting awareness efforts based on the results of measurement activities.

33.2.8 Monitoring: Track and Report Policy Compliance

During the maintenance phase, the *monitoring* function is performed to track and report on the effectiveness of efforts to comply with the policy. This information results from observations of employees and supervisors; from formal audits, assessments, inspections, and reviews; and from violation reports and incident response activities. This function includes continuing activities to monitor compliance or noncompliance with the policy through both formal and informal methods, and the reporting of these deficiencies to appropriate management authorities for action.

33.2.9 Enforcement: Deal with Policy Violations

The compliance muscle behind the policy is effective *enforcement*. The enforcement function comprises management's response to acts or omissions that result in violations of the policy with the purpose of preventing or deterring their recurrence. This means that once a violation is identified, appropriate corrective action must be determined and applied to the people (disciplinary action), processes (revision), and technologies (upgrade) affected by the violation to lessen the likelihood of it happening again. As stated previously, inclusion of information on these corrective actions in the awareness efforts can be highly effective.

33.2.10 Maintenance: Ensure the Policy Is Current

Maintenance addresses the process of ensuring the currency and integrity of the policy. This includes tracking drivers for change (i.e., changes in technology, processes, people, organization, business focus, etc.) that may affect the policy; recommending and coordinating policy modifications resulting from these changes; and documenting policy changes and recording change activities. This function also ensures the continued availability of the policy to all parties affected by it, as well as maintaining the integrity of the policy through effective version control. When changes to the policy are required, several previously performed functions need to be revisited—review, approval, communication, and compliance in particular.

33.2.11 Retirement: Dispense with the Policy when No Longer Needed

After the policy has served its useful purpose (e.g., the company no longer uses the technology for which it applies, or it has been superseded by another policy), then it must be retired. The *retirement* function makes up the disposal phase of the life cycle, and is the final function in the policy development life cycle. This function entails removing a superfluous policy from the inventory of active policies to avoid confusion, archiving it for future reference, and documenting information about the decision to retire the policy (i.e., justification, authority, date, etc.).

These four life-cycle phases comprising 11 distinct functions must be performed in their entirety over the complete life cycle of a given policy. One cannot rule out the possibility of combining certain functions to suit current operational requirements. Nevertheless, regardless of the manner in which they are grouped, or the degree to which they are abbreviated by immediate circumstances, each function needs to be performed. In the development phase, organizations often attempt to develop policy without an independent review, resulting in policies that are not well conceived or well received. Shortsighted managers often fail to appropriately address the exception function from the implementation phase, mistakenly thinking there can be no circumstances for noncompliance. Many organizations fail to continually evaluate the need for their established policies during the maintenance phase, discounting the importance of maintaining the integrity and availability of the policies. One often finds inactive policies on the books of major organizations, indicating that the disposal function is not being applied. Not only do all the functions need to be performed, several of them must be done iteratively. In particular, maintenance, awareness, compliance monitoring, and enforcement must be continually exercised over the full life of the policy.

33.3 Policy Responsibilities

In most cases the organization's information security function—either a group or an individual—performs the vast majority of the functions in the policy life cycle and acts as the proponent for most policy documentation related to the protection of information assets. By design, the information security function exercises both long-term responsibility and day-to-day tasks for securing information resources and, as such, should own and exercise centralized control over security-related policies, standards, baselines, procedures, and guidelines. This is not to say, however, that the information security function and its staff should be the proponent for all security-related policies or perform all policy development functions. For instance, owners of information systems should have responsibility for establishing requirements necessary to implement organization policies for their own systems. While requirements such as these must comport with higher-level policy directives, their proponent should be the organizational element that has the greatest interest in ensuring the effectiveness of the policy.

While the proponent or owner of a policy exercises continuous responsibility for the policy over its entire life cycle, there are several factors that have a significant bearing on deciding what individual or element should have direct responsibility for performing specific policy functions in an organization. These factors include the following:

- The principle of *separation of duties* should be applied in determining responsibility for a particular policy function to ensure that necessary checks and balances are applied. To provide a different or broader perspective, an official or group that is independent of the proponent should review the policy, and an official who is senior to the proponent should be charged with approving the policy. Or, to lessen the potential for conflicts of interest, the audit function as an independent element within an organization should be tasked with monitoring compliance with the policy, while external audit groups or organizations should be relied upon to provide an independent assessment of policy compliance to be consistent with this principle.

- Additionally, for reasons of *efficiency*, organizational elements other than the proponent may need to be assigned responsibility for certain security policy development life-cycle functions. For instance, dissemination and communication of the policy is best carried out by the organizational element normally charged with performing these functions for the entire organization, (i.e., knowledge management, corporate communications, etc.). On the other hand, awareness efforts are often assigned to the organization training function on the basis of efficiency, even though the training staff is not particularly well suited to perform the policy awareness function. While the training department may render valuable support during the initial dissemination of the policy and in measuring the effectiveness of awareness efforts, the organization's information security function is better suited to perform continuing awareness efforts because it is well positioned to monitor policy compliance and enforcement activities and to identify requirements for updating the program, each of which is an essential ingredient in effective employee awareness of the policy.
- Limits on *span of control* that the proponent exercises have an impact on who should be the proponent for a given policy function. Normally, the proponent can play only a limited role in compliance monitoring and enforcement of the policy because the proponent cannot be in all places where the policy has been implemented at all times. Line managers, because of their close proximity to the employees who are affected by security policies, are in a much better position to effectively monitor and enforce them and should therefore assume responsibility for these functions. These managers can provide the policy owner assurance that the policy is being adhered to and can ensure that violations are dealt with effectively.
- Limits on the *authority* that an individual or element exercises may determine the ability to successfully perform a policy function. The effectiveness of a policy may often be judged by its visibility and the emphasis that organizational management places on it. The effectiveness of a policy in many cases depends on the authority on which the policy rests. For a policy to have organization-wide support, the official who approves it must have some recognized degree of authority over a substantial part of the organization. Normally, the organization's information security function does not enjoy that level of recognition across an entire organization and requires the support of upper-level management in accomplishing its mission. Consequently, acceptance of and compliance with information security policies is more likely when based on the authority of executive management.
- The proponent's placement in the organization may cause a lack of *knowledge* of the environment in which the policy will be implemented, thus hindering its effectiveness. Employment of a policy evaluation committee can provide a broader understanding of operations that will be affected by the policy. A body of this type can help ensure that the policy is written so as to promote its acceptance and successful implementation, and it can be used to forecast implementation problems and to effectively assess situations where exceptions to the policy may be warranted.
- Finally, the *applicability* of the policy also affects the responsibility for policy life-cycle functions. What portion of the organization is affected by the policy? Does it apply to a single business unit, all users of a particular technology, or the entire global enterprise? This distinction can be significant. If the applicability of a policy is limited to a single organizational element, then management of that element should own the policy. However, if the policy is applicable to the entire organization, then a higher-level entity should exercise ownership responsibilities for the policy.

33.4 The Policy Life-Cycle Model

To ensure that all functions in the policy life cycle are appropriately performed and that responsibilities for their execution are adequately assigned for each function, organizations should establish a framework that facilitates ready understanding, promotes consistent application, establishes a hierarchical structure of mutually supporting policy levels, and effectively accommodates frequent technological and organizational change. Exhibit 33.3 provides a reference for assigning responsibilities for each policy development function according to policy level.

In general, this model proposes that responsibilities for functions related to security policies, standards, baselines, and guidelines are similar in many respects. As the element charged with managing the organization's overall information security program, the information security function should normally serve as the proponent for most related policies, standards, baselines, and guidelines related to the security of the organization's information resources. In this capacity, the information security function should perform the creation, awareness, maintenance, and retirement functions for security policies at these levels. There are exceptions to this general principle, however. For instance, even though it has a substantial impact on the security of information resources, it is more efficient for the human resources department to serve as the proponent for employee hiring policy and standards.

Responsibilities for functions related to security procedures, on the other hand, are distinctly different than those for policies, standards, baselines, and guidelines. Exhibit 33.3 shows that proponents for procedures rest outside the organization information security function and are decentralized based on the limited applicability by organizational element. Although procedures are created and implemented (among other functions) on a decentralized basis, they must be consistent with higher organization security policy; therefore, they should be reviewed by the organization information security function as well as the next-higher official in the proponent element's management chain. Additionally, the security and audit functions should provide feedback to the proponent on compliance with procedures when conducting reviews and audits.

The specific rationale for the assignment of responsibilities shown in the model is best understood through an exploration of the model according to life-cycle functions as noted below.

- *Creation.* In most organizations the information security function should serve as the proponent for all security-related policies that extend across the entire enterprise; and should be responsible for creating these policies, standards, baselines, and guidelines. However, security procedures necessary to implement higher-level security requirements and guidelines should be created by each proponent element to which they apply because they must be specific to the element's operations and structure.
- *Review.* The establishment of a policy evaluation committee provides a broad-based forum for reviewing and assessing the viability of security policies, standards, baselines, and guidelines that affect the entire organization. The policy evaluation committee should be chartered as a group of policy stakeholders drawn from across the organization who are responsible for ensuring that security policies, standards, baselines, and guidelines are well written and understandable, are fully coordinated, and are feasible in terms of the people, processes, and technologies that they affect. Because of their volume, and the number of organizational elements involved, it will probably not be feasible for the central policy evaluation committee to review all procedures developed by proponent elements. However, security procedures require a similar review, and the proponent should seek to establish a peer review or management review process to accomplish this or request review by the information security function within its capability.
- *Approval.* The most significant differences between the responsibilities for policies vis-à-vis standards, baselines, and guidelines are the level of approval required for each and the extent of the implementation. Security policies affecting the entire organization should be signed by the chief executive officer to provide the necessary level of emphasis and visibility to this most important type of policy. Because information security standards, baselines, and guidelines are

EXHIBIT 33.3 Policy Function-Responsibility Model

	Responsibility			
Function	Policies	Standards and Baselines	Guidelines	Procedures
Creation	Information security function	Information security function	Information security function	Proponent element
Review	Policy evaluation committee	Policy evaluation committee	Policy evaluation committee	Information security function and proponent management
Approval	Chief executive officer	Chief information officer	Chief information officer	Department vice president
Communication	Communications department	Communications department	Communications department	Proponent element
Compliance	Managers and employees organization-wide	Managers and employees organization-wide	Managers and employees organization-wide	Managers and employees of proponent element
Exceptions	Policy evaluation committee	Policy evaluation committee	Not applicable	Department vice president
Awareness	Information security function	Information security function	Information security function	Proponent management
Monitoring	Managers and employees, information security function, and audit function	Managers and employees, information security function, and audit function	Managers and employees, information security function, and audit function	Managers and employees assigned to proponent element, information security function, and audit function
Enforcement	Managers	Managers	Not applicable	Managers assigned to proponent element
Maintenance	Information security function	Information security function	Information security function	Proponent element
Retirement	Information security function	Information security function	Information security function	Proponent element

designed to elaborate on specific policies, this level of policy should be approved with the signature of the executive official subordinate to the CEO who has overall responsibility for the implementation of the policy. The chief information officer will normally be responsible for approving these types of policies. Similarly, security procedures should bear the approval of the official exercising direct management responsibility for the element to which the procedures apply. The department vice president or department chief will normally serve in this capacity.

- *Communication*. Because it has the apparatus to efficiently disseminate information across the entire organization, the communications department should exercise the policy communication responsibility for enterprisewide policies. The proponent should assume the responsibility for communicating security procedures, but as much as possible should seek the assistance of the communications department in executing this function.
- *Compliance*. Managers and employees to whom security policies are applicable play the primary role in implementing and ensuring initial compliance with newly published policies. In the case of organization-wide policies, standards, baselines, and guidelines, this responsibility extends to all managers and employees to whom they apply. As for security procedures, this responsibility will be limited to managers and employees of the organizational element to which the procedures apply.
- *Exceptions*. At all levels of an organization, there is the potential for situations that prevent full compliance with the policy. It is important that the proponent of the policy or an individual or group with equal or higher authority review exceptions. The policy evaluation committee can be effective in screening requests for exceptions received from elements that cannot comply with policies, standards, and baselines. Because guidelines are, by definition, recommendations or suggestions and are not mandatory, formal requests for exceptions to them are not necessary. In the case of security procedures, the lower-level official who approves the procedures should also serve as the authority for approving exceptions to them. The department vice president typically performs this function.
- *Awareness*. For most organizations, the information security function is ideally positioned to manage the security awareness program and should therefore have the responsibility for this function in the case of security policies, standards, baselines, and guidelines that are applicable to the entire organization. However, the information security function should perform this function in coordination with the organization's training department to ensure unity of effort and optimum use of resources. Proponent management should exercise responsibility for employee awareness of security procedures that it owns. Within capability, this can be accomplished with the advice and assistance of the information security function.
- *Monitoring*. The responsibility for monitoring compliance with security policies, standards, baselines, and guidelines that are applicable to the entire organization is shared among employees, managers, the audit function, and the information security function. Every employee who is subject to security requirements should assist in monitoring compliance by reporting deviations that they observe. Although they should not be involved in enforcing security policies, the information security functions and organization audit function can play a significant role in monitoring compliance. This includes monitoring compliance with security procedures owned by lower-level organizational elements by reporting deviations to the proponent for appropriate enforcement action.
- *Enforcement*. The primary responsibility for enforcing security requirements of all types falls on managers of employees affected by the policy. Of course, this does not apply to guidelines, which by design are not enforceable in strict disciplinary terms. Managers assigned to proponent elements to which procedures are applicable must be responsible for their enforcement. The general rule is that the individual granted the authority for supervising employees should be the official who enforces the security policy. Hence, in no case should the information security function or audit function be granted enforcement authority in lieu of or in addition to the

manager. Although the information security function should not be directly involved in enforcement actions, it is important that it be privy to reports of corrective action so that this information can be integrated into ongoing awareness efforts.

- *Maintenance.* With its overall responsibility for the organization's information security program, the information security function is best positioned to maintain security policies, guidelines, standards, and baselines having organization-wide applicability to ensure they remain current and available to those affected by them. At lower levels of the organization, proponent elements as owners of security procedures should perform the maintenance function for procedures that they develop for their organizations.
- *Retirement.* When a policy, standard, baseline, or guideline is no longer necessary and must be retired, the proponent for it should have the responsibility for retiring it. Normally, the organization's information security function will perform this function for organization-wide security policies, standards, baselines, and guidelines, while the proponent element that serves as the owner of security procedures should have responsibility for retiring the procedure under these circumstances.

Although this methodology is presented as an approach for developing information security policies specifically, its potential utility should be fairly obvious to an organization in the development, implementation, maintenance, and disposal of the full range of its policies—both security related and otherwise.

33.5 Conclusion

The life cycle of a security policy is far more complex than simply drafting written requirements to correct a deviation or in response to a newly deployed technology and then posting it on the corporate intranet for employees to read. Employment of a comprehensive policy life cycle as described here will provide a framework to help an organization ensure that these interrelated functions are performed consistently over the life of a policy through the assignment of responsibility for the execution of each policy development function according to policy type. Utilization of the security policy life-cycle model can result in policies that are timely, well written, current, widely supported and endorsed, approved, and enforceable for all levels of the organization to which they apply.

People, Processes, and Technology: A Winning Combination

Felicia M. Nicastro

34.1 Introduction

Security technology is not a silver bullet, as is generally believed, but the growth in security-related technology will continue at a rapid pace as security threats evolve. Firewalls, intrusion detection systems (IDSs), intrusion prevention systems (IPSs), anti-virus software, patch management software, identity management software, asset management tools, and more have been developed to assist organizations in improving their security posture. If all these tools are silver bullets, then why are organizations affected now more than ever by such security threats as malicious hackers, worms, viruses, and other types of vulnerabilities?

The solution to this problem is the subject of some debate among security professionals, but one possible solution is not to throw tools at a security threat or problem but instead improve aspects of the people and processes surrounding the technologies already in place within the organization. This will improve the organization's security posture and reduce their exposure to security threats. The purpose of this chapter is not to minimize the importance of security-related technologies; rather, it is intended to serve as an introduction to the various options available to improve an organization's current security posture—options that include implementing security technologies to supplement what cannot be achieved with people and processes alone. Such a winning combination will result in a more secure organization overall.

Obviously, an organization cannot remove its anti-virus solution or its asset management system; however, with regard to implementing anti-virus protection, the number of overall viruses introduced to the organization can be reduced by providing employees with a few simple security awareness programs.

Employees who are educated on the damage inflicted by viruses will understand why certain security procedures are in place for them to follow, such as for e-mail. They will also understand how viruses can interrupt an organization's e-mail system and the associated remediation costs. Such employee education can be provided by seminars, "Webinars," or postings on the organization's internal Web site. Although these are all good practices, they do not provide employees with the constant stream of information required to reinforce the importance of the existing procedures and the steps they need to follow. To ensure that employees understand the extent to which viruses can affect their work life, a weekly newsletter e-mailed out to all employees can describe how other organizations have been affected by viruses or explain the damage that a recently detected virus could have done to their system. If they have a basic understanding of how a virus is transmitted, what kind of e-mail messages to avoid, and what to do when they get one, they are more likely to handle such situations appropriately, thus saving the organization time and money. This is an example of how people and processes improve the effectiveness of the security technology in place. The security technology provides the anti-virus software, which is updated on a daily basis, but the organization's people, armed with knowledge and documented processes, are key to defending against viruses that threaten the organization. In this example, the combined aspects of technology, people, and processes are a winning combination protecting the organization from the threat of viruses. Of course, security awareness, documented processes, and anti-virus software must be kept current.

34.2 The Silver Bullet

No one tool can be the be-all and end-all for any organization. Granted, this is not the typical attitude of an organization, but organizations do look to tools more today than ever to solve their problems when it comes to security. The combination of a set of tools rather than one can be a more successful solution, although too many flavors of disparate vendor's tools can become an operational nightmare. On the other end of the spectrum, an organization that only has one vendor's software suite in place gives rise to another security risk—having all its eggs in one basket. Not having any tools and relying completely on people and processes is also not a good solution, unless the organization is very small and all of the work can be done manually, even though it is very time consuming to do so. Typically, this occurs in the home office, where complexity is not necessarily the case. The ultimate goal is a balance of required security technologies that complement each other and provide the diversity required to ensure a defense-in-depth approach, in combination with people and processes in such a way as to improve the security posture within the organization.

Consider a firewall. It is a simple security measure that can provide a great deal of security protection if configured and maintained appropriately. A firewall may permit port 80 for HTTP for user Web browsing capabilities; however, some users may find that downloading movies and music at work is faster than via the connection they have at home. No one has told these users that they cannot do this, and the rule set in the firewall permits them to do so. So, every day downloads are started and run in the background for most of the day. At the end of the day, these users burn their music or movies to CDs or DVDs, if available, and take them home for personal use. If these employees do not know that what they are doing is contradictory to the organization's security policy, the employer can do very little when these employees are detected. Also, a firewall that is not configured properly could only be one of several holes in the organization's perimeter. Employees who are not aware that such downloads are against policy will continue to do so unless they are educated on the policy and what it entails. In some cases, these ports have to be accessed through the firewall for business-related tasks, so perhaps the firewall cannot be locked down as it needs to be. Instead, knowledge through education can arm employees with the information they need to know to adhere to company policy. Such education, accompanied by a stringent security policy, which users are required to sign and abide by, gets the point across. Finally, a short session on spyware or safe Internet surfing (or browsing) would be an inexpensive way to accomplish the same task, in addition to further enhancing security. In summary, then, security technology is not the complete and only answer to the problem of security, as it is already in place and still does not provide all of the protection required. Instead, arming employees with the information they need to understand security awareness and the organization's policy ensures that inappropriate activity does not take place.

Today, most viruses, worms, or malicious activities that affect an organization originate with external entities. Although some of the problems are initiated internally, an organization's security problem would be improved if a greater focus was placed on people through awareness and training and through defined and documented policies and procedures than on implementing the latest and greatest security tool or technology.

34.3 People

A current trend for organizations is to place the budget for security awareness and training at the lowest tier of their security priorities and instead put the latest and greatest security products at the top of the list in the hope that these products will solve all of their current security-related threats or problems. If the focus was on the people instead, some security technologies may not even be needed.

A few years ago this was different. Training employees in security and security awareness was more likely to be performed on a yearly basis, in addition to orientation training that all employees receive when they begin employment with the organization. Now, security is included in the orientation training as one topic among many and is the focus of attention for only a short period of time, perhaps an hour or two at the most. Companywide security programs simply do not exist today as they used to. In the January 2005 issue of *CSO Magazine*, a survey was codeveloped by CSOonline and Carnegie Mellon University's Computer Emergency Response Team (CERT). In it, 82% of the respondents stated that they have a process in place to regularly scan for viruses/malware; however, only 40% of the respondents stated that they have a process in place to train employees to identify suspicious physical events or items. The results of this survey showed that security awareness and training are not being performed in organizations as they should be. Companies are conducting fewer security training programs due to budgeting issues. Also, the expense of maintaining the security posture of the organization on a day-to-day basis may not allow the organization to also conduct a training program due to a lack of resources and budget. The problem is that, in most cases, implementation of the security technology has exceeded its allocated budget. As a result monies allocated to security awareness and training are used to complete the technical implementation, and security awareness and training are eliminated altogether.

The key is to get back to basics. The focus has become one of improving security through technology instead of improving security through people. The power of employees is underestimated. Employees obviously want to protect the organization they work for and the internal proprietary information contained therein. If they understand what they need to do to protect themselves and the company's information, they will most likely take the necessary steps to do so. This is why getting back to basics and relying on the employees within the organization to assist in improving the security posture is so important, although many organizations or security groups within the organizations do not look at things this way anymore. The security group may even try to bypass employees to improve security, sometimes using stealth security technology so it does not affect the user; the user may not even know it is there. This is a common requirement set forth by organizations looking to deploy a new security technology. Vendors are asked to ensure that the new software being implemented, such as a personal firewall, anti-virus software, or other desktop-related software, will not impact the employee's ability to work and that it will run quietly in the background. Although employees do not want their ability to work productively to be disrupted, they should be aware that software is on their system that protects them and the organization's proprietary information from security-related threats. This is another level of security awareness. Employees who understand what the software is and how it protects them are less likely to disable it or ignore warnings from this software. Instead, they will choose to follow the policies and procedures that have been outlined for them.

34.4 Processes

Another area that is often overlooked is processes. Maybe not so much overlooked as never gotten around to. Procedures also fall into this category. Before we explore this path, it is important to define process, policy, and procedure using patch management as an example. A *process* would be considered the set of policies, procedures, and guidelines developed to ensure that the patch management policy is adhered to and followed on a regular basis. The patch management *policy* ensures that vulnerable systems within the organization are appropriately patched as needed. The functional policy might state that the organization will utilize a standard third-party tool to accomplish a specific task within patch management, such as inventory management, patch distribution, or reporting. Another section in the policy might define the sanctions to be imposed when an employee does not comply with the policy. A policy is typically a high-level document that defines goals and the high-level requirements that must be implemented to comply with the policy. A policy can exist at more than one level within the organization. Typically, an overall organizational security policy states top management's general goals regarding information security. Lower level policies are created by departments or business units within the organization to support the goals of the overall organizational security policy. For example, a patch management policy would be a functional policy, perhaps created by the security or operations group within the organization. It may state that the department or business unit has established this policy to ensure that all employees are taking the appropriate steps necessary to install appropriate patches on the systems. This policy is supported by procedures and guidelines documented by the system administrator (or other responsible group). It also may state some high-level requirements, such as employees must follow the patch management process.

Procedures are developed to support the policy. In the example of patch management, the procedure would be a patch management procedure. This is a more detailed document that discusses the steps that must be completed to accomplish a task. To continue with the patch management example, the procedure document would include the steps of the procedure, the roles and responsibilities of the individuals involved, and even the method for completing the tasks. The procedures, then, are more detailed step-by-step instructions on how each piece of the process is to be completed. In the patch management example, a procedure would be written directions for how the tool used to deploy the patch will be utilized on a daily basis and would include the steps required to generate the required reports.

This has been a very high-level explanation of a policy and the supporting procedures that make up a process. Actual guidelines have not been included in this example; however, they would be created and compiled with the policy and procedures to make up the patch management process. It takes a great deal of time and dedication initially to develop these documents and make sure that they are not only accurate but also updated on a regular basis. The organization must also train its employees (or at least the responsible individuals) with regard to what has been developed and documented. Many organizations do not have the time or the resources to dedicate to these tasks.

Typically, one organizational security policy establishes the security goals of the organization, and it usually is not regularly updated. The security policy might also contain items that cannot be achieved by the organization due to various constraints. One of the most important items to consider when creating or revising an organizational security policy is to ensure that what is stated as policy is actually achievable by the organization. This is where things can get tricky. Depending on the size and make-up of the organization, some departments may be able to conform to the policy, perhaps because they have to adhere to stringent federal regulations anyway, while other departments may not be able to complete the tasks required as stated in the policy. This is where functional and implementing policies come into play. Departments or business units can create lower level types of policies that apply directly to them. Although individual names should never be included in a policy, the specific actions required of individual departments or business units can be. Such a policy could also call out the functional policies that should be referenced or used for that department depending on the topic.

Federal regulations impose their own set requirements when it comes to policies, procedures, and documentation. Consider the Health Insurance Portability and Accountability Act (HIPAA), passed in 1996. HIPAA regulations require defined and documented policies and procedures to be maintained for all aspects of the organization. The Act also requires that documentation be maintained for a specific amount of time, updated on a regular basis, and made available to all individuals to which it applies. This regulation alone puts a lot of pressure on organizations in the healthcare industry, particularly those considered to be covered entities (CEs). They must complete these tasks to be compliant with the regulation. Over time, the security posture of these organizations will improve because they are taking the necessary steps to educate their employees on their responsibilities and the overall security posture of the organization. This is a roundabout way to ensure that policies and procedures are documented, updated, maintained, and provided to users, but it will prove to be very beneficial to these organizations, even though initially it will require a lot of effort.

This chapter is not intended to go into too much detail surrounding policy and procedure, as many fine publications are dedicated to this topic; instead, the point of including some discussion of policy and procedure was to stress how well-written, formal, and documented policies can improve an organization's security posture without the need for additional security technologies.

34.5 Processes and Security

Processes and related procedures support policies. Processes can be described as an informal combination of policy, standards, procedures, and guidelines that together enable an operation or task to be completed securely. Documenting a process is often a daunting task that no one wants to complete. In a large, complex organization, documenting every process that is followed regularly or is completed on a daily basis can take a great deal of time. In an efficient organization, these processes would be documented as they arise, rather than trying to create them all at one time. Again, this is an area where federal regulations are having an impact on organizations. HIPAA set the requirement that CEs must take reasonable and appropriate steps to ensure that procedures are documented to ensure their compliance with the regulation. Having these procedures in place, not only for the use of system administrators, network operations centers (NOCs), and other operational areas but also for daily use by general employees, ensures that the appropriate procedures are following in all circumstances. In many cases, having these items documented will increase the level of security within the organization without using any security technologies. An employee who knows that a particular policy and procedure must be adhered to when gaining remote access from home or on the road is are less likely to introduce additional risks to the organization by not following a documented process. Again, in a roundabout way, by complying with federal regulations through documented procedures an organization improves its security posture without the need for security technology.

Consider, for example, an employee who accesses the company network remotely through a virtual private network (VPN) from home. This is a common scenario today, one that many organizations provide for their employees. This arrangement can increase productivity, but it could come at the expense of increasing risks to the organization's proprietary information, depending on how educated the employee is. Employees who have a company laptop should be made aware of what they can and cannot do with their company-owned laptop. If an employee connects the laptop at home using broadband, only uses the laptop for work-related purposes, and establishes a VPN connection from home to the corporate network, then risks to the organization will be reduced. If, on the other hand, the employee has a home computer that is shared by all members of their household and is connected over broadband, additional risks could be incurred. The home computer is not likely to have the organization's standard build installed on it or include anti-virus software, a personal firewall, or even spyware protection. In this case, the open computer serves as a bridge between the organization's network over a VPN and the Internet, through the remotely connected user.

In many cases, use of a home computer is not monitored, and viruses, spyware, or other malicious software programs can be downloaded to the home computer without the employee's knowledge. When that employee connects to the organization's VPN, this malicious software can be spread to the organization's network through an otherwise secure connection. If procedures and guidelines have been documented and distributed and education provided to employees, then the employees will understand how they should connect remotely and what precautions they should take on their home computers. Having a simple documented procedure in place can reduce the organization's risk exponentially, depending on the number of employees they have connecting remotely to the network from home but not on a company-issued laptop. Most organizations that offer remote access capabilities to their employees have a remote access policy in place. This is a great start, but providing user education through security awareness or training and procedures for gaining remote access in a secure fashion will improve the security posture of the organization and eliminate the introduction of additional risks into the internal environment.

34.6 Technology

To some, the technology part of people, processes, and technology is irrelevant; for others, implementing a security-related technology would appear to be the only solution. Organizations must determine when a security-related technology should be implemented as an organizational standard to assist in improving the security posture. They must also determine where it is implemented and how it will be managed and maintained on a daily basis. In some instances, the organization will have a NOC or security operations center (SOC) in place. If this is the case, then the implementation, operations, and maintenance of the technology would come from this central group. If no NOC or SOC is in place, then operating procedures must be followed to ensure that the technology meets the requirements of the organization from a daily operational perspective.

In many cases, a security event within the organization, such as the introduction of viruses into the organization's network, will spawn the use of a security technology. Also, if an organization is having a difficult time maintaining systems as patches are released, they may opt for an additional security technology instead of putting a solid patch management process in place. If either of these are strong pain points for an organization, and the current software or processes are not providing the level of support it needs, the organization may opt to go with host-based intrusion detection (or prevention) software. Although this approach gives organizations an additional layer of security on their desktops, they could accomplish the same thing by improving other processes that should be in place. All aspects of implementing such new software on desktops should be completely evaluated prior to implementation to ensure that it will not introduce other issues or risks into the organizations environment.

In other cases, organizations might be experiencing a rapid increase in the unsolicited installation of spyware software on their desktops or laptops. This is a problem that has grown significantly over the past year. Bot networks, which can affect home PCs and unprotected corporate laptops, are systems that have been taken over by a hacker through the use of spyware or other malicious software installed on a system without the user noticing. The system is then controlled by a central system, similar to a centralized management server that sends the commands or actions to the compromised system. When the system is in the control of the hacker, it can be used to perform all types of malicious tasks, including launching distributed denial of service (DDoS) attacks against a target system. In some cases, hackers are waging bot network wars against each other, utilizing numerous systems they control to attack another hacker that has done the same. One way to protect against this is through the use of anti-spyware software that vendors are now making available to users. Such software, combined with personal firewalls, anti-virus software, and the installation of appropriate patches on the desktop, will protect against a bot network takeover. The anti-spyware software prohibits spyware from being installed on a system, thereby protecting the user from the threat that spyware introduces.

Is the best solution to the problem of spyware to go out and buy an anti-spyware software product? As just noted, other steps can be taken to ensure that a PC is protected, and, although adding this software will help, a more comprehensive approach should be taken. This is an area where people and processes can combat against a threat without spending security money on implementing another tool. In all cases, the organization should perform an appropriate analysis of the problem and possible solutions prior to purchasing a new security technology. This will ensure that the company is spending its security budget appropriately and that they are taking reasonable and appropriate steps to improve the overall security posture within the organization. Organizations can determine which security technology is best through various means of analysis. In some cases, organizations will conduct a product "bake-off," or in-house comparison, to test various products to determine which one will fit their needs and integrate easily into the existing network. Organizations should be cautious about adopting new products or using companies fresh on the market; instead, companies should consider going with "baked" solutions, ones that have been around for a reasonable amount of time. In some instances, new products may not have all the features the organization is looking for, but the vendor may make promises to get these new features added to the next release. Often, however, the release of these new versions is delayed. Also, new products may have vulnerabilities directly within the application that have not yet been identified. Going with a proven solution and application will ensure that the organization is implementing a security technology that has gone through rigorous testing and version updates. It is more likely that an established vendor will continue to be in business for a while compared with a new, unproven one. The worst thing for an organization is to implement a complex and costly security technology only to have the vendor disappear in a year's time, leaving the company with not only the costs and technology but also no support or updates in the future. Regardless of the path taken by the organization, due diligence must be taken to ensure that a new security-related technology can be integrated into the current environment and will achieve the results the organization is seeking.

34.7 Achieving Better Security by Leveraging More People and Processes and Less Technology

So, how exactly does an organization improve its security posture by focusing more on people and processes and relying less on technology? This can be accomplished in various ways, such as through instilling security awareness in all employees, providing security-specific training at regular intervals, improving the security culture within the organization, and constantly reinforcing and rewarding employees who promote security.

Security awareness and training are usually lumped together in one category, but they are in fact quite different from one another. They should be approached by two different methods to ensure that the appropriate security-related information is disseminated properly to all employees within the organization. Security awareness is the act of making employees aware of security-related precautions that must be taken and making them more conscious of how security relates to their day-to-day life. This can be in the form of alerting them to new viruses being released, emphasizing the importance of the latest patches, or even discussing new policies, processes, or procedures that relate to them and add to their responsibilities. Security awareness can be disseminated to employees through weekly newsletters, e-mails, posters, or even a booth set up in a common area (*e.g.*, the cafeteria) once a month. Although these are all simple measures, the results can be quite beneficial to the organization as a whole with regard to how employees will react when something happens that they have been made aware of. For example, employees are less likely to get caught up in a phishing scam if a poster in the hallway has warned them about phishing and told them what to do if they get such e-mails, as opposed to employees who are not aware of phishing and take phishing e-mails seriously.

Security-related training (or, simply put, security training) involves getting the employees' direct attention and providing training to them for a specific period of time and only on security. It is very important not to mix orientation training or other training programs with the security training. This should be a time when only security-related topics are discussed with the employees. The training can be provided in the form of seminars, either on or off site or through Web-based seminars so employees can attend the training without even leaving their desks. The latter method is not always as effective as the first, because employees most likely will be distracted and not able to give the training their undivided attention. It is best to separate employees from their duties during training. Giving the employees a quiz after the training is over and asking them to complete a survey regarding its effectiveness are also considered good practices. The quiz and survey indicate whether or not the training was clear and concise and the employees clearly understood everything explained to them. Although security awareness should occur on a regular basis, it is not feasible or cost effective for an organization to provide dedicated security training on a monthly basis. Instead, security awareness may only be conducted once for new hires and then on an annual or semiannual basis. The topics covered in security training can range from the organization's recently updated policies and procedures to new processes that have been put in place (*e.g.*, patch management, incident management) since the last training was conducted. A syllabus that includes the topics covered should be developed well in advance, along with materials to hand out to the participants.

Security awareness and security training can be performed by an internal team of individuals or by a third party. Each approach has its own pros and cons. In some cases the security group within the organization has a clear understanding of how to provide the necessary information to employees. The security group may also have the time to create the training program as well as present it. In other cases, employees may hold the information in higher regard if it comes from a third party. The third party should have a clear understanding of the organization's security posture as well as its policies and procedures. They should be well aware of what the organization is already doing to train its employees in security. The security group may be too deeply involved in day-to-day operational tasks to create the necessary materials and conduct the training. The decision of whether to utilize in-house or third-party personnel depends on the particular organization and should be considered carefully prior to beginning a training program. As an alternative, training can also be divided between internal employees and a third party. Creating a security awareness program that consists of newsletters, flyers, posters, etc. might be done internally, but then a third party could be brought in to conduct the security training. Regardless of the decision, the message should be consistent and performed on a regular basis.

How employees regard the security group differs from one organization to the next, but it rather consistently is perceived as a road block to productivity. In the eyes of regular users, the security group is the cause of a slew of red-tape and bureaucracy, which results in more work when something new is to be deployed within an organization. Over time, the security group can lose respectability, resulting in the security culture of the organization being perceived as more negative than positive. This is an interesting concept, because the security group is there to protect the organization from threats and risks on a daily basis, but the rest of the organization views them as road blocks to productivity. This situation must be changed. The employees and security group should work together, not only to improve the security posture but also to maintain it on a daily basis. If there is no clear communication between them, then an understanding of concerns, needs, and even frustrations is not shared.

For example, when the security group announces that a personal firewall must be installed on all desktops, all the employees may see is a hindrance to their productivity. The NOC may see a Pandora's box of numerous help-desk calls and a loss in productivity because of this new piece of software being installed on the systems. Some enterprising souls may already be thinking of how to disable it so it does not interfere with their job. Without even having the software installed already a negative attitude has formed, not only about the personal firewall software but also about the security group for forcing this new piece of software onto their systems. If unity exists between the employees and the security group such that a common security culture has been created, then the employees would understand and fully support this new addition to their desktops. Improving the security culture within the organization is obviously a big hurdle to overcome. Such hostility is usually a deeply ingrained feeling, one that has been building for a long period of time. To change the way employees think requires a strong plan, a determined security group, and, of course, executive management support.

The purpose of the security awareness program is to provide constant reinforcement on how security is all around us and what we should be conscious of on a daily basis. Without this constant reinforcement, employees are more likely to let their guard down, thereby making the organization more at risk. Implementing a reward system or program is one way to get the employees more involved or more educated in security. For example, if an employee notices an individual who is not an employee propping open the door of the data center and rolling out equipment, would that employee stop to ask that person what he is doing, or would the employee offer to hold the door open? Social engineering tests at various organizations have revealed that typically it is the employees who are the most willing to give away information, whether they think they are being helpful or not. It can be very easy to get through a locked door simply by telling the next person that you forgot your badge or only need to get in for a minute. If employees are regularly trained on what to look for and what to do if something suspicious is happening, they are less likely to give away the keys to the kingdom, even to someone who looks innocent enough. Rewards can be given through multiple avenues. If at the end of the security training a short quiz is given, perhaps the people with the highest scores could get a gift certificate to a local restaurant for lunch or some other type of gift card. Treasure hunts also work well in encouraging security awareness and can be done easily on a company's intranet Web site. The treasure hunt can take employees through numerous policies and procedures by asking questions that have to be answered before moving on to the next part. The first group of employees to complete the treasure hunt can be rewarded in some manner. Although this is a simple gesture, it can go a long way toward improving the security culture and security posture within the organization. Organizations can determine what motivations work best in their environment and put those into place to reward the employees.

One of the most challenging aspects of maintaining security within an organization is accountability. It can be difficult to hold an employee accountable for his or her actions, although doing so depends on the country in which the employee is located. Typically, sanction policies are added to the company's security policy and even to other policies documented by the organization. These sanction policies are becoming less harsh, as they have to be worded in a specific manner as dictated by the human resources and legal departments. Employees cannot simply be fired for downloading a malicious piece of software onto their system which in turn brings down the entire network. Even today, in some cases, employees caught downloading pornographic material to their desktops may be caught doing so three times before being terminated. In Europe, these practices are even more difficult, as organizations cannot associate the name of the employee with any of the data they are collecting; therefore, they cannot hold an employee accountable because they do not have a record of it occurring in the first place. This makes it even more difficult to improve the security posture within the organization, especially if the security culture is not in existence. Employees know they cannot be terminated or reprimanded in any way, regardless of the security breach that occurs because of their actions. This points out again why improving the security culture will inherently improve the security posture, thereby making the level of accountability more irrelevant. In other words, an organization will not need to worry so much about holding employees accountable if it is already taking the necessary steps to ensure that employees are not introducing any new threats or risks to the organization.

34.8 Determining How to Improve the Overall Security Posture

Within most organizations today, a stronger stance is being taken on security and protecting the organization's assets. In most cases, a yearly plan is developed that describes what the organization will do to improve its security posture. This is typically called a security program or security plan. In some cases, a security program office (SPO) may be put in place to make sure that aspects of the program are being completed as documented (and budgeted for). The security program is usually agreed upon by executive management but is developed and carried out by the security manager within the organization. The strategic objectives of the program for the coming year can come from upper management, but, again, they must align with the security manager's needs from the security group's perspective. If executive management recognizes a need to implement a security technology that is going to require a great deal of time and resources, the security manager must be able to communicate that the current headcount and workload will not support such a large undertaking.

In many instances, business consultants work closely with executive management to ensure that the needs of the organization as well as the appropriate security posture are met based on the plan they develop. The business consultant can work with the executive management team as well as the security manager and their team to ensure that the plan aligns with the agendas of both groups.

Another area in security receiving a lot of attention lately is return on security investment (ROSI). Showing a return on investment (ROI) has been a requirement within organizations for years, but now organizations must show that security investments have achieved the intended results. Security is obviously very difficult to measure in terms of dollars, as the threats and risks facing organizations are changing on a daily basis; it is very difficult to measure how each one will impact the organization in terms of cost and how implementing a security mechanism can decrease this cost. This is even truer when it comes to processes. It can be difficult to measure the costs associated with dedicating security personnel to developing a process to reduce the risk to an organization. The only obvious costs associated with this are the employees' time and expenses. If, however, the process reduces the impact of nonpatched systems on the environment, this can yield a high ROSI.

34.9 Conclusion

Organizations can take several steps to ensure that they are using a winning combination of people, processes, and technology. Some are simple steps, yet others require lengthy planning and preparation. The result of this due diligence will be apparent when the organization has improved its security posture and the risks facing the organization decrease. Careful planning and preparation should be taken with regard to security, not only by executive management but also by the security group. When budgets are created is when security groups typically determine what they plan to do for the year. When this time comes, it is best to take all the necessary steps to ensure that what is budgeted for meets the expectations of the executives and the security posture of the organization. One recommendation for preparing for this budget planning is to complete a thorough security assessment of the state of the organization today. Although this should be done on a yearly basis, completing it before the yearly budget is created will ensure that what needs to be addressed is actually going to be addressed over the course of the following year. Many consulting companies perform these assessments today and are the recommended method for completion. Bringing in a third party to assess an organization can provide a more accurate view of the current state of the company. If the security group is performing the assessment, the tendency to be biased can occur, thereby skewing the results of the assessment. The security group may also be so familiar with the organization that they are not able to accurately assess the current state, whereas a third party would gather all the necessary information themselves and accurately assess the current state of security.

The results of the assessment can then be used to plan for the course of action for the next year. Although this assessment should not be the only source of information for creating the yearly security budget, it should be one of the inputs used. Planning is another important step toward creating a winning combination within an organization. Setting achievable goals and expectations during the planning process can result in much success for the security group. If unachievable goals are set, then the security group is doomed to fail or exceed their budget. This can have negative results with regard to perceptions of not only the security group but also the security culture.

The security group, along with executive management, should document the plan and budget expectations for the upcoming year. Having the plan documented and referenced throughout the year can lead to a successful year for the security group. If the plan states that the executive management team will support security-based training sessions, then the executive management team can then be held accountable for ensuring that they take place and they should make themselves available to state their backing of this session, perhaps even through opening comments at the sessions themselves.

The documented plan that has been agreed to by executive management and the security group can also be used to assess and measure the success of the security group and the security posture of the organization. If the plan, when fully executed, resulted in incidents of viruses being down by 70% for that year, indicating that the anti-virus awareness program documented in the plan was a success, then it should be continued for the following year. If a security group can measure the success of the plan on a yearly basis, it will aid them in obtaining additional monies on a yearly basis.

The security assessment, which documents the state of the organization before the plan was built and executed, can also be used to measure the success of the plan. When the next assessment is completed (again, before the new budget is created), it can demonstrate the improvements made during the previous year and set the goals for the next. This is a repeatable process that can be used yearly to ensure that the organization is using the winning combination of people, processes, and technology to improve the security posture of the organization.

35
Building an Effective Privacy Program

Rebecca Herold

35.1 Privacy Governance

Privacy and trust are essential to maintaining good relationships with customers, employees, and business partners. It is also necessary to address privacy issues to comply with a growing number of privacy regulations worldwide. Privacy encompasses how business must be conducted, the communications made with customers and consumers, and the technology that enables business processes. Addressing privacy touches all facets of an organization, including business operations; Web sites and services; back-end systems and databases; communications with third parties, customers, and service providers; and legacy systems. An effective privacy governance program will not only make an enterprise's customers happier, but it will also mitigate its exposure to regulatory noncompliance, lawsuits, bad publicity, and government investigations. This chapter discusses the issues to address when building a privacy governance program.

35.2 Why Is a Privacy Governance Program Necessary?

An increasing number of threats challenge businesses every day to ensure that appropriate safeguards are implemented to preserve business, customer, and employee privacy. These threats include identity theft, new technology weaknesses, disgruntled employees, information thieves, carelessness, lack of training, and criminal activity. Lack of adequate protection against these threats not only puts personal information at risk but also exposes businesses to potential lawsuits, criminal prosecution, and civil actions. Growing numbers of laws and regulations—such as the Health Insurance Portability and Accountability Act (HIPAA), the Gramm–Leach–Bliley Act (GLBA), the Fair Credit Reporting Act (FCRA), the Children's Online Privacy Protection Act (COPPA), and the Telephone Consumer Protection Act (TCPA), as well as various international laws, such as the European Union's Data Protection Directive and Canada's Personal Information Protection and Electronic Documents Act (PIPEDA)—make it a business necessity to establish a privacy governance program in order to effectively protect against threats as well as comply with law and regulatory privacy and security requirements.

35.3 Know What To Protect

An effective privacy governance program will help identify what to protect. The program must identify the personal information an organization handles and processes, determine the risks to that information, and then implement controls to reduce those risks. Very generally, personally identifiable information (PII) is any type of information that can identify or be directly linked to an individual. The most commonly considered PII includes name, address, Social Security number, telephone number, and birth date; however, laws and regulations consider broader ranges of information as being PII if it can be tied to an individual. Some of these include such items as:

- Health information
- Financial information
- Political information
- Internet protocol (IP) addresses
- Serial numbers for network devices
- Organization memberships.

Global generally accepted global Fair Information Practices (FIPs) from the Organization for Economic Cooperation and Development (OECD) recommend that PII be handled in ways that give the person to whom the information applies specific rights over how that information is used. The FIPs generally recommend that organizations:

- Give notice that PII is being collected.
- Provide choice to individuals to opt-in to providing PII, in addition to allowing such information to be shared with others.
- Establish procedures to give individuals access to see the PII that organizations have about them.
- Implement security controls to protect the information.
- Enforce privacy policies and procedures.
- Restrict access to the information to only those people who need it to perform their business activities.
- Limit the use of PII to only those purposes for which it was collected.

35.4 Protect Your Business; Avoid Privacy Mistakes

Implementation of an effective privacy governance program will help to protect a business from experiencing incidents that could have substantial impact on its revenue, brand, and image. As commonly cited examples, the following organizations experienced privacy-related incidents that resulted in significant financial and public relations impacts:

- *Nationwide Mortgage Group GLB violations*. On March 4, 2005, the Federal Trade Commission (FTC) presented Nationwide Mortgage Group, Inc., with a consent order requiring them to retain an independent professional to certify that its security program met the standards listed in the order within 180 days, and then once every other year for 10 years. The November 2004 FTC administrative complaint alleged that Nationwide Mortgage failed to train employees on information security issues; oversee loan holders' handling of customer information; or monitor its computer network for vulnerabilities. The FTC complaint also cited the company for violating the GLB privacy rule by failing to provide required privacy notices to consumers that explain how their personal information may be used or disclosed.
- *Bank of America lost customer information tapes*. On February 25, 2005, Bank of America began informing General Services Administration (GSA) SmartPay charge cardholders of the disappearance of computer tapes during transfer to a backup data center on December 22, 2004. The missing tapes contained customer and account information for around 1.2 million government charge cardholders.
- *ChoicePoint customer privacy breach*. In February, 2005, ChoicePoint sent 145,000 letters to customers notifying them that they detected in October of 2004 that personal information had been accessed through fraudulent means and used for identity theft crimes.
- *Eli Lilly Prozac e-mail incident*. In January 2002, an Eli Lilly employee sent a message to 669 Prozac users who had voluntarily signed up for a prescription reminder service. The message inadvertently contained all the recipients' e-mail addresses. The FTC settlement included annual audits for at least the next 20 years, in addition to state fines.
- *Microsoft Passport*. In August 2002, Microsoft agreed to settle FTC charges regarding the privacy and security of personal information collected from consumers through its Passport Web services. As part of the settlement, Microsoft must implement a comprehensive information security program for Passport and similar services. Each subsequent violation of the order could result in a civil penalty of $11,000.
- *DoubleClick*. A series of class action lawsuits were brought against DoubleClick for violation of privacy relating to the company's cookie tracking practices. In January 2000, DoubleClick's stock was about $135 per share. Following the privacy lawsuits around six months later, DoubleClick's share price had dropped to the mid-$30s. On top of this was the settlement, which included implementing privacy protections, paying all legal fees, and paying up to $1.8 million.
- *Ziff Davis*. Because of how one of their Web pages was designed, a computer file of approximately 12,000 subscription requests could be accessed by anyone on the Internet. As a result, some subscribers incurred fraudulent credit card charges. Under the terms of the August 2002 settlement, Ziff Davis was told to pay $500 to each U.S. consumer who provided credit card information in the online promotion, had to implement multiple security and privacy practices and keep them updated, and was ordered to pay the three states a total of $100,000 to cover investigative costs.
- *Eckerd Drug*. Eckerd had a practice of having customers sign a form that not only acknowledged receipt of a prescription but also authorized the store to release prescription information to Eckerd Corporation for future marketing purposes. The form apparently did not adequately inform customers that they were authorizing the commercial use of their personal medical information. In July 2002, Florida reached a settlement that included requiring Eckerd's to change

their marketing practices, implement privacy protections, and fund a $1 million ethics chair at the Florida A&M School of Pharmacy.

The fact that these companies are widely known and are associated with poor privacy practices, even though they may have subsequently implemented strong privacy governance programs, demonstrates the lasting effect that a privacy incident can have on an organization's reputation. Waiting until after an incident occurs to implement a privacy governance program will have a considerably greater business impact and cause more damage than maintaining due diligence to prevent such incidents from occurring in the first place. Consider the other business impacts and fallout that could happen from privacy and security incidents:

- Dropped stock values
- Lost customers
- Negative press
- Tarnished brand name
- Resources diverted to mitigate impacts
- Paying for ongoing credit reports for impacted customers
- Increased staff necessary
- Costs for mailings, phones calls, news releases
- Mounting opportunity costs
- Marketing, public relations, and other staff taken away from planned projects
- Managers and lawyers spending their time mitigating the impacts

35.5 Building a Privacy Governance Program

35.5.1 Know Your Business

To effectively build a privacy governance program, it is necessary to know your business. The program must support the organization's business processes, goals, and objectives. You must understand the organization's environment and its:

- Consumers and customers
- Businesses, services and products
- Laws and regulations (federal, state, and international)
- Hot topics and trends

The organization must be thoroughly understood, particularly with regard to how the business works now as well as its goals and planned changes for the future. It is necessary to identify the organization's:

- Business model and brand
- Business goals and strategies
- Business partners (who they are and their information handling practices)
- Information handling practices:
  Data collection—What do you collect, from where, from whom, and how often?
  Data sharing—With whom do you share information, and how?
- Handling practices for online *versus* offline information
- Customer and consumer needs
- Opportunities to leverage its brand with its privacy protection efforts
- Practices for using information within communications, technology, and partner initiatives

35.5.2 Perform Privacy Impact Assessments

Most international laws include most, if not all, of the OECD FIP areas. Performing privacy impact assessments (PIAs) around these FIPs will allow an organization to identify gaps in its business privacy practices and will provide much insight for where the organization may be out of compliance with applicable laws and regulations. PIAs should analyze and describe:

- Personal information that is collected by the organization—type and description of each piece of information and the source of the information
- The purpose for which the information was collected, such as to determine program eligibility or collect product registration information
- The intended use of the information collected, such as to verify existing data or keep track of customers who have purchased specific drugs
- How the information is collected, secured, and used within the organization and how it is shared with third parties

An organization should perform a PIA when it establishes a privacy governance program, as well as when other significant organizational milestones occur, such as:

- Required by laws and regulations (such as the E-Government Act)
- When a system change could create privacy risks
- In an acquisition, merger, or divestiture
- When centralizing databases
- When adding pages or capabilities to the Web site
- When changing privacy policies
- When any other significant information handling changes occur

If possible, PIAs should be mandatory. A privacy manager should be designated for each project, and teams and feedback should include information technology (IT), business process, and compliance expertise. The PTA results and resulting mitigation plan must be approved prior to continuing the project.

When reporting the findings, conclusions, and recommendations within the PIA report, these components should be included:

- Data flows, including public access (as well as third-party access) to PII
- Objective review and analysis of data flows
- Plans for integrating PIAs into the project life cycle
- Explanations for why alternative systems were not chosen

35.5.3 Developing a Privacy Program

Build a privacy governance program with:

- *People*—Establish a clear privacy leader who is accountable and has visible executive support. Create a governing or oversight board composed of members throughout your organization to ensure you are effectively incorporating privacy throughout all areas.
- *Policies*—Implement and communicate a clear privacy policy built around the OECD principles and the business environment, and ensure compliance.
- *Processes*—Establish access, authorization, process, and technical controls to support privacy policies.
- *Awareness and training*—Educate all personnel and business partners on privacy requirements.

Use information obtained from the PIA and from speaking with the departmental contacts to build a privacy governance framework:

- Establish a clear privacy leader who is accountable and has visible executive support.
- Implement and communicate a clear privacy policy built around OECD principles, and ensure compliance.
- Educate all personnel and business partners on privacy requirements.
- Establish access, authorization, process, and technical controls to support privacy policies.
- Continuously monitor compliance, new laws and regulations, and update programs as necessary.
- Define and document the PII that the organization handles and map the data flows.
- Establish privacy incident response procedures.
- Report on the privacy environment regularly to board and oversight members.

35.6 Establish Privacy Leadership

35.6.1 The Privacy Official

Establish a privacy officer role, often called the chief privacy officer or corporate privacy officer (CPO), to establish accountability and authority for privacy activities within the organization. Give the CPO responsibility for all aspects of corporate privacy and the authority to implement changes and administer sanctions. Position this role within the company to review and have authority for all operational areas. The CPO position should be filled with a person who understands the “big picture” and has a strategic view of today’s operations and tomorrow’s planning. The privacy activities must be institutionalized as a part of the decision process for any activities involving PII. The position should have its own budget and, very importantly, should have strong, visible backing from the chief executive officer (CEO) and board of directors. The successful CPO will:

- Build a privacy team representing all areas of the organization.
- Understand the organization’s processes and technologies.
- Know that no magic technology solution exists for privacy issues.
- Know that not one, generic, magic privacy policy will comply with all privacy-related laws and regulations.
- Understand that all areas of the organization must participate in establishing a successful privacy protection environment.
- Constantly be on the lookout for new privacy threats and challenges.
- Obtain a budget to adequately support the privacy initiatives.
- Work with vendors and third parties to ensure that they are adequately addressing privacy issues.
- Educate the organization, customers, and third parties about privacy requirements and issues.

35.6.2 The Privacy Team

Identify and involve key people to be on the privacy oversight council. Positions to include, as applicable to each organization, include:

- Chief privacy officer (CPO)
- Chief information security officer
- Chief technology officer
- Director, business development

- Director, advertising and marketing
- Director, Internet services and channels
- Director, customer relationship management (CRM)
- Manager, Internet technology
- Inspector, computer crimes and commerce
- Director, human resources policies and programs
- Legal counsel
- Business unit leaders
- Director, physical security
- Director, call centers
- Director, internal audit
- Director, risk management

35.7 Establish Privacy Policies and Procedures

Post an appropriate Web site privacy policy. Not having a Web site privacy policy can raise red flags. The organization may be subject to specific laws, including broadly interpreted state consumer protection statutes in the United States or elsewhere, that require it to provide notice of its information practices. Develop privacy policies and procedures to support the organization's mission, goals, and activities. Assess current policies and identify gaps and inconsistencies with applicable laws, regulations, and industry standards practices. When establishing privacy policies and procedures, it is important to:

- Draft a unified privacy policy that includes all key business services, products, and operating procedures.
- Identify obstacles to implementation and know where the organization is out of compliance with portions of the policy.
- Prioritize implementation to address the most significant exposures first.
- Limit the scope of the policy to clearly indicate to which of the organization's practices (online only, online and offline, business partners, and so on) the policy applies.
- Identify if and how the organization uses third parties to run banner ads or collect information (those who share information with third parties will be judged by the company they keep).
- Determine if your site uses cookies, Internet tags, Web beacons, or other tracking capabilities; if so, establish procedures for their use and address these within the policies.
- Consider the security promises made within the policy. Are procedures in place to keep those promises?
- Consider whether or not the organization allows customers and consumers to opt-in to additional communications from your organization.
- Determine whether the site and policy address children's privacy rights and legal requirements.
- Include all components necessary to comply with applicable laws.
- Determine if any encryption restrictions exist.
- Determine what use (if any) is made of encryption, steganography, and other types of privacy-enhancing tools within the organization.
- Evaluate whether the privacy policy is too stringent or needlessly constraining.
- Determine whether or not the organization's personnel are aware of their privacy responsibilities for handling information.
- Make the privacy policy easy to find when it is posted to the Web site.

- Communicate and promote the privacy policy internally in employee and partner communications and training sessions. Be sure everyone understands the policy and follows it; otherwise, it will likely fail and could put the organization in legal jeopardy.
- Promote the privacy policy with key stakeholders, including customers, investors, vendors, contributors, and policymakers.
- Update it as necessary to stay current with changes in the organization's business and the law.
- Most importantly, be sure the privacy policy reflects actual practice.

It is also necessary to address privacy within the organizational policies. What should be adopted for internal privacy policies depends on the business and a privacy impact assessment of what is appropriate (and legal) for the situation. It is important to consider all the same issues for the organization's internal policies as listed above for the Web site privacy policy. Typically, the organization's policies should include some statements similar to the following:

- All corporate networks, associated components, and computer systems are for business use only.
- All network activity will be monitored.
- No personal information may be published or disclosed without express permission or information security (or CPO, etc.) authorization.
- All items within corporate facilities are subject to search at any time without advance notice.
- The organization will only collect and store information necessary to fulfill business obligations.
- Only personnel with a business need to know will have access to personnel files.

35.8 Educate All Personnel and Business Partners on Privacy Requirements

Institutionalize your privacy protection measures. Implement a privacy training and awareness program that will instill a culture of privacy throughout the corporation—from the highest positions within the company all the way down to positions that may mistakenly be assumed not to need to know about privacy. A privacy culture starts from the top down. Privacy compliance starts from the bottom up. Effective training and awareness are the keys to success. This is demonstrated by the requirement to implement privacy education within privacy-related lawsuit settlements. Each of the previously discussed privacy actions included education as part of the settlement:

- Microsoft must implement employee and management privacy training.
- Ziff Davis must train personnel in privacy issues.
- DoubleClick must educate its clients in technical and business practices that promote users' privacy.
- Eli Lilly must implement privacy training in each relevant area of its operations.

Document the privacy program. Make it clear that the purpose is to create an executable plan to communicate with employees and other individuals who handle sensitive or confidential customer information. Document your goal, which will likely be something similar to: "The goal of the program is to heighten awareness of privacy issues, change attitudes, influence behavior, help ensure privacy policy and regulatory compliance, and help reduce the probability of privacy incidents being escalated beyond customer call centers." Clearly describe the organization's objectives; for example:

- "Provide an educational architecture framework that supports PII awareness and training."
- "Establish a deployment strategy."
- "Enable personnel with the information necessary to incorporate correct privacy actions within their job functions."

35.8.1 Privacy Education Strategy

Create a privacy education strategy. At a high level, the privacy education roadmap should include the following components:

- Define the privacy message.
- Document the desired tactical outcomes.
- Obtain executive support.
- Identify privacy advocate champions.
- Identify awareness and training groups.
- Design and develop training and awareness materials.
- Establish schedules for privacy training and awareness delivery.
- Launch privacy communications.
- Deliver training.
- Deliver awareness communications and events.
- Evaluate the effectiveness of the education efforts and update appropriately.

The privacy education program must remain current. When policies, laws, and technologies change, employees must be notified and told how these changes affect their handling of customer information. It may be necessary to establish a way to deliver immediate information to specific target groups. The awareness program must make it easy for personnel to get the information necessary for customer privacy issues, and the information must be easy to understand. For a complete detailed resource for managing an education program, see *Managing an Information Security and Privacy Training and Awareness Program* (R. Herold, Auerbach Publications, 2005).

35.9 Establish Access, Authorization, Process, and Technical Controls To Support Privacy Policies

Organizations must build privacy into their business processes and applications. They can use the OECD principles and results of their PIAs as guides to establish privacy standards, guidelines, and processes that are best suited for each particular organization's business environment. Privacy must be a concern every step of the way during the systems development life cycle. Create detailed privacy procedures for developers to follow. Perform a privacy needs assessment for the project to effectively limit the scope. Incorporate a detailed PII design and inventory into the project plan. Test privacy controls during acceptance testing, and ensure they are all working correctly before moving the application or process into business production. Create detailed privacy procedures and guidelines for the organization's process, systems, and applications development team to use. Include within these procedures:

- Privacy policies checklists
- Acceptable purposes for PII collection and sharing
- Code samples and Platform for Privacy Preferences Project (P3P) templates
- Examples of privacy processes
- Lists of related privacy issues
- Terminology definitions (e.g., PII, external, application, third party, and so on)
- Privacy enhancing technologies (PETs) and descriptions for how they should be used

When integrating privacy into the development process:

- Create a plan.
- Create a privacy process flowchart.

- Identify necessary privacy documents.
- Consider multinational issues.
- Document the privacy specifications.
- Perform a privacy review.
- Perform an independent PIA.

35.9.1 Privacy Tools

Use privacy tools appropriately and most effectively for your business processes. A sampling of the tools you can use include the following:

- *Encryption*—Basically, encryption is scrambling information.
- *Steganography*—Otherwise known as "covered writing," it is hiding information within other types of information.
- *Platform for Privacy Preferences Project (P3P)*—This is a project developed by the World Wide Web Consortium that makes Web site privacy policies available in an automated and structured way.
- *Access control systems*—Software is used to control access to files, records, etc.; examples include access control lists (ACLs), rule-based systems, and role-based systems.
- *Privacy seals for Web sites*—This function reassures Web site visitors with regard to their privacy. Visitors to the Web site can find out using the seals what the site will do with personal data obtained and how they will disclose it. Examples of Web seals include those offered by TRUSTe, BBBOnLine, and Privacy Bot.
- *Blind signatures*—Patented by David Chaum and used by his company DigiCash (filed for bankruptcy in November 1998), blind signatures are used in voting and electronic payment systems to allow transactions to be authenticated without revealing the identity of the person behind them; now used by eCash, SureVote, and others.
- *Biometrics*—Biometrics can be used as a person's private encryption key and also in conjunction with access control systems. Biometric tools include such things as fingerprints, retinal scans, hand geometry, facial features, voice verification, signatures, and keystroke characteristics. Besides being used to enhance privacy, they can also be used to invade privacy.
- *Firewalls*—Firewalls keep unauthorized network users away from confidential information, can segment confidential servers and networks from rest of network, and can utilize intrusion detection.
- *Pseudonymous and anonymous systems*—Users can be assigned pseudonym IDs or anonymous IDs to protect their identities. Pseudonyms hide true identities; they can be assigned to customers to use to fill out confidential forms and to ensure that only those authorized to do so fill out the form, but still exclude others. Anonymous systems hide both true and fictional identities (like sending a letter with no return address).
- *Trusted sender stamps*—A cryptographically secure way for consumers, Internet Service Providers (ISPs), spam filters, and e-mail clients to distinguish wanted and trusted e-mail from spam. Currently only offered by Postiva and certified by TRUSTe.
- *Enterprise Privacy Authorization Language (EPAL)*—EPAL is an XML-based programming language that allows developers to build policy enforcement directly into enterprise applications. It builds on current P3P privacy specifications that provide privacy controls for information passed between business applications and consumers with browsers.

- *Anti-spam tools*—This type of software is used to reduce the amount of spam, otherwise known as unsolicited commercial e-mail (UCE). ISPs often provide anti-spam tools. Bayesian filters can be used as a type of spam filter (for example, see http://crm114.sourceforge.net).
- *Pop-up blockers*—Pop-up ads typically open up a separate browser window when a user is visiting or leaving an Internet site. Pop-up blockers try to prevent these ads. Many different and free pop-up blockers are available, such as Stopzilla, PopSwat, AdShield, and Popup BeGone.

35.10 Understand the Impact of Security and Privacy-Related Laws on Business

A good program should continuously monitor compliance and new laws and regulations and update programs as necessary. The number of laws and regulations that govern how personal information must be handled continues to grow worldwide. For example, the EU Data Protection law impacts the activities of any office located outside the European Union that receives, from an entity in the European Union, any information considered as personal information. These restrictions result from the 1995 EU Data Protection Directive, which provides detailed requirements regarding the treatment of personal data, and which requires each of the 25 EU Member States to enact national legislation to conform its law to those requirements. Organizations and the personnel handling the personal information that do business in EU countries must understand and comply with the requirements and laws.

As another example, California SB 1386 became law on July 1, 2003, and requires all companies that do business in California or maintain information about California residents in computerized formats to promptly notify through one of four possible ways each of their California customers in the event a security breach occurs that involves improper access to the resident's unencrypted personally identifiable information. SB 1386 authorizes any person injured by a violation of this statute to institute a civil action to recover damages. The statute also authorizes mandates against businesses that violate or propose to violate the statute, so a court may force a business to disclose a breach and possibly discontinue business until evidence is provided that the breach has been addressed. In addition to legal and monetary penalties, additional impact resulting from a security breach and SB 1386 noncompliance is negative publicity and lost business.

Organizations have been impacted by SB 1386 and have had to use significant human and financial resources to comply with the law following security breaches. For example:

- March 2005—As a result of the customer information fraud incident described earlier, ChoicePoint's common stock dropped from a high of $47.95 per share to $37.65 per share on March 4, 2005. Also on March 4, 2005, ChoicePoint announced it would discontinue sales of consumer information to small businesses, which they indicated will cost them $15 to $20 million in revenue.
- March 2004—Texas-based Web site hosting company Allegiance Telecom, Inc., and two of its subsidiaries reportedly sent letters to more than 4,000 customers in the first 2 weeks of the month to notify them of two computer security breaches that may have involved account or customer information in processing facilities in Boston to comply with SB 1386. Although the law requires notification of California customers only, the company sent the letters to customers both within and outside California.
- February 11, 2004—The California Employment Development Department reportedly sent letters to approximately 55,000 household employees after a hacker accessed a department server containing workers' private information. It appeared the hacker primarily used the server to send spam. The extent of the hacker's access to the private information could not be determined.
- December 30, 2003—A laptop computer, owned by United Blood Services and containing personal information on 38,000 California blood donors, was reportedly stolen from a repair shop in Scottsdale, AZ. Notices were mailed February 9, 2004.

- November 15, 2003—Wells Fargo Bank reportedly sent letters to over 200,000 customers after a laptop containing confidential information including names, addresses, Social Security numbers, and personal line of credit account numbers, was stolen. The bank reportedly has changed account numbers, is monitoring the accounts, and is paying the one-year membership cost of a credit monitoring service for affected customers. In addition to mailing the letters, Wells Fargo also provided a toll-free number to call for additional information and offered a $100,000 reward for information leading to the thief's arrest. Wells Fargo reportedly had notification procedures in place to comply with SB 1386 when the breach occurred.

35.11 Define and Document the PII the Organization Handles and Map the Data Flows

Before an organization can have an effective privacy governance program, it must know what PII it handles and where all the PII comes into the organization, who within the organization touches the PII, and where the PII leaves the organization to be accessed by third parties or to be disposed of. To know this, it is necessary to discover and document the flow of PII within the organization. This task includes establishing and maintaining a PII inventory to:

- Perform an effective PIA.
- Track and organize PII within the organization.
- Analyze the current privacy compliance activities.
- Develop additional privacy compliance procedures as necessary.

Key areas to be addressed, beyond the business units, include information technology, human resources, marketing, customer support, and vendors. When identifying the PII for the inventory, be sure to survey the entire organization. No doubt about it, it will be a large task to initially establish the inventory. If the organization lacks the staff and expertise in-house to do it, it should determine where it can get help from outside the company.

Building the foundation of the PII inventory is based on the following tasks:

- Identify all PII collected.
- Label or describe each type of PII.
- Identify the departments responsible for the PII.
- Identify the primary individuals responsible for custodianship.
- Identify the information source for each piece of data.
- Identify all groups, people, and third parties who have access to each type of PII, and determine the type of access (e.g., view only, update, delete) for each piece of customer information.
- Identify existing policies and procedures for accessing PII.
- Identify profiles created from PII databases.
- Identify third parties who have access to PII.
- Identify third parties who store the organization's PII on their systems.
- Identify existing access capabilities and procedures for PII.
- Identify all servers and systems that store PII.
- Identify all servers and systems that process PII.
- Identify previous PII privacy incidents and outcomes.
- Identify privacy personnel opinions about the use of the PII.
- Identify current administrative controls and capabilities for PII.

- Identify who has administrative capabilities for PII administrative controls.
- Identify how separation of duties with regard to PII access is established and maintained.

The major obstacle to creating a PII inventory and creating a map of the data flow is the volume of work involved in a large organization. Staff resources will be required to help collect the information, to compile the information, and to effectively update the information over time; however, the PII inventory must be as comprehensive as possible or some significant vulnerabilities and risks may not be identified.

35.12 Establish Privacy Incident Response Procedures

The best practice is to prevent a privacy incident from occurring in the first place. Do this by identifying current privacy exposures and prioritize addressing them. When a privacy incident occurs, resolve the issue as quickly as possible following the organization's established policies, and then analyze the incident. Make necessary changes and then institute policies and procedures to prevent recurrences of the same type of incident. Also (and possibly most importantly), train everyone in the organization, as well as anyone else involved with handling the organization's PII, to ensure they understand the importance of privacy.

35.13 Report on the Privacy Environment Regularly to Board and Oversight Members

A privacy or security breach could significantly impact any organization's business as it has impacted the previously discussed organizations. A breach could potentially cost hundreds of thousands to millions of dollars in human resources, communications, and materials expenses in addition to negative publicity, lost business, and legal counsel costs. Examples of breaches, such as the ones discussed here, should be presented to an organization's executives so they have a clear picture of how they could affect their organization financially.

35.13.1 Communicate Leading Practices to Executives

What is the organization doing to address the impact of security and privacy issues? Decision-making executives will want to know so they can determine how much of the budget to assign to information security and privacy efforts. Following are the leading practices that organizations are increasingly following to help ensure an effective information security and privacy program and to help demonstrate due diligence:

- Provide ongoing visible security and privacy support, commitment, and participation from upper management.
- Implement security and privacy policies, objectives, and activities that reflect business goals and the organization's mission.
- Diligently stay aware of new and updated security and privacy-related laws and regulations applicable to the organization.
- Develop and implement procedures addressing security and privacy that are consistent with the organizational culture and support security and privacy policies and legal requirements.
- Make personnel responsible for possessing a good understanding of the security and privacy requirements, risk assessment, and risk management.
- Effectively market and communicate security and privacy issues and requirements to all managers, personnel, and business partners.
- Regularly distribute guidance on security and privacy issues to raise awareness for all personnel and third-party partners.

- Provide ongoing appropriately targeted security and privacy training and education.
- Use a comprehensive and balanced system of measurement to evaluate performance in information security and privacy management and compliance.

The organization, from senior executives down to junior staff, must consider security and privacy to be an integral part of the business, not an afterthought.

35.14 Summary

Taking security and privacy precautions is more than important; it is an essential and inevitable component of business success. Serious consequences to an organization's goals and business success can result from inadequately and not continually addressing these risks. Following a well-thought-out privacy governance program will help an organization successfully and effectively choose the types of security and privacy risks they are willing to reasonably tolerate and decide which others must be effectively addressed. Effectively communicating the program to personnel, with the clearly visible support of executive management, is key to the success of the organization's program.

36

Establishing an E-Mail Retention Policy: Preventing Potential Legal Nightmares

Stephen D. Fried

Author's Note: This chapter discusses the security and privacy aspects concerning the use of electronic mail in the workplace, and is intended to inform the security professional of some of the various issues that need to be addressed when formulating an e-mail retention policy. The information presented in this chapter, including potential policy suggestions, reflects the combined experiences of many organizations and does not reflect the security or legal policy of any one organization in particular. The security professional will need to apply the concepts presented in this chapter to best suit the business, legal, and security needs of his or her own organization. In addition, the chapter discusses legal matters pertaining to e-mail use, but should not be construed as giving legal advice. The security professional should consult with legal counsel skilled in these areas before determining an appropriate course of action. The views expressed are solely those of the author and not of any organization or entity to which the author belongs or by which he is employed.

36.1 Setting the Scene

The scene, circa 1955:

> The young boy sees the old shoebox off to one side of the moldy attic. Unable to contain his curiosity, he picks up the dusty container, unties the loose string knot holding the lid on the box and cautiously peers inside. To his surprise, he sees a large bundle of letters wrapped tightly inside a red lace ribbon. Gently opening the frail envelopes yellowed with age, he reads the hand-written letters adorned with perfect penmanship. He is astonished to find the contents reveal a personal history of his great-grandfather's fortune, as recounted through the exchange of letters between his great-grandfather and his soon-to-be great-grandmother as they courted over the distance. Some of the details are shocking, some loving, but much of it has never been recounted in the oral family history that has been passed down through the generations…

The scene, circa 2004:

> The young technician notes an interesting set of messages hidden deep in a directory tree. Unable to contain his curiosity, he browses to the disk where the files sit, opens the directory containing the messages, and cautiously peers at the contents. To his surprise, he sees a large archive of e-mail wrapped behind nonsensical subject headings and file names. Cautiously opening each message, he reads each piece of e-mail adorned with perfect grammatical clarity. He is astonished to find that the contents reveal a history of the company's rise to market dominance, as recounted through the exchange of e-mail messages between the CEO and the company's senior management as they plotted their rise over the years. Some of the details are shocking, some embarrassing, much of it never recounted in the official version of the company's past that had been told to the subcommittee just a few months ago…

It is not such a far-fetched idea, and it has happened countless times in the recent past. Companies are finding out that the e-mails exchanged between its employees, or between its employees and outsiders, are having an increasing impact on the way they do business and, more importantly, on how much the outside world knows about their internal activities. It is estimated that 31 billion e-mails were sent daily on the Internet in 2002, and that is expected to double by 2006.[1] In addition, more than 95 percent of business documents are now produced, managed, and stored solely in electronic format, never to be printed in physical form. As communication channels grow and expand to fit the way modern businesses interact with each other, it is a natural fit that much of this electronic information will find its way into the e-mail messages companies send and receive every day.

Unfortunately, this explosion of the use of e-mail for critical business communication has also had an unforeseen side effect. The communications medium that many see as a natural extension of verbal communications has, in fact, created a vast repository of critical, sensitive, and, in some cases, damaging evidence that organizations are seeking to limit and control. The production in discovery and use of company e-mail in legal proceedings has become a standard part of the legal process and has led to negative impacts on many legal cases for companies that failed to educate employees on the proper use and retention of internal e-mail.

36.2 Good News and Bad News

The explosive use of e-mail as a primary business communication medium over the past ten years has been widely heralded as a boon to companies needing to communicate quickly and efficiently on a global

[1] Source: International Data Corporation (IDC).

scale. E-mail has many of the benefits of its analog predecessor, standard postal mail. It is fundamentally easy to use. It is a modern-day appliance application with a simplified user interface and an intuitive process:

1. Click “compose message.”
2. Type message.
3. Enter the receiver’s address (or point-and-click it from your “address book”).
4. Click “Send.”

Most everyone from a five-year-old schoolchild to an eighty-year-old grandmother has the ability to easily send a message down the street or around the world. Also contributing to the rise of e-mail popularity has been its nearly universal acceptance in the social and economic fabric of everyday life. There is hardly a business on the planet today that does not have a World Wide Web URL or an e-mail address, and more and more individuals are joining the ranks of online communicators every day.

In a departure from its analog cousin, e-mail is relatively instantaneous. Instead of placing an envelope in a mailbox and waiting days or weeks for it to arrive at its destination, most e-mail messages arrive in seconds or minutes, and a reply can be on its way just as quickly. This immediacy in communications is rivaled only by the telephone, another ubiquitous communications device. Finally, e-mail has become a socially acceptable form of communication between individuals and businesses alike. Many people treat e-mail as another form of “live” communications and carry on lengthy conversations back and forth through the wire. Because people see e-mail as a more informal communications method than written documentation, they will often tend to say things in an e-mail that they would not say in person or in an official company document.

Ironically, despite the social informality associated with e-mail use, many organizations treat e-mail as formal business communication, using it for customer contact, internal approval processes, and command-and-control applications. In many business settings, a message sent by e-mail now has the same social and legal weight as the same message spoken or hand-written on paper. It is often used as documentation and confirmation of the sender’s acts or intent. Setting aside the fact that the security of most modern e-mail systems is insufficient to protect against interception of, or tampering with, e-mail messages, e-mail now has the force of authority that was once reserved only for the hand-written word.

The economics of e-mail have also led to its universal acceptance as a communications medium for modern business. The cost of creating, processing, and delivering e-mail is a fraction of the cost of handling standard paper-based mail. There are no supplies to maintain (no envelopes or stamps, for example) and a user’s management of dozens or hundreds of daily messages is simplistic compared to managing the same volume of physical letters each day. While it is true that the infrastructure required to manage e-mail (such as network connections, servers, and Internet connectivity) can have a substantial cost, most organizations establish and utilize these facilities as part of their general business information processing, with e-mail adding only incrementally to the cost of those facilities.

The cost to store e-mail has fallen dramatically over the past few years. The cost to store 13 million pages of hand-written letters would be prohibitive for all but the largest of corporations, and even then the use of microfiche or other information-miniaturizing technology would be required. However, the cost to store an equivalent amount of e-mail, approximately 40 gigabytes, is well below USD$100.00, well within reach of most consumers. With economics such as this, it is no wonder that many people choose to retain an archive of e-mail often stretching back several years.

And here begins the bad-news side of the e-mail explosion. The benefits of a simple, low-cost, ubiquitous communications medium cannot be without its detracting elements, and e-mail is no exception. One of the largest negative factors is the lack of standardized security mechanisms for protecting the confidentiality and integrity of e-mail content. While a detailed analysis of such issues is beyond the scope of this chapter, they will be revisited briefly later in the discussion surrounding the uses of e-mail in legal proceedings. A second area brought on by the economics of widespread e-mail use is that of management of e-mail information. Because storage is so inexpensive, many users can afford to store their entire e-mail archives locally on their personal (albeit perhaps company-owned) computer. This may be a slight productivity gain for end users of e-mail systems, but it represents a huge loss of centralized control for the management of e-mail systems and the information these systems contain. When the need arises to uniformly search a company's e-mail archives for important information, whether for a disaster recovery exercise or for legal discovery purposes, it becomes difficult to efficiently or uniformly search the private archives of every single user. In a typical medium- to large-scale computing environment, policy and operational issues such as centralized information storage, records retention, and information destruction become much more complicated.

36.3 E-Mail Is Forever

Many people think of e-mail messages in much the same ephemeral way as they regard personal conversations: once the exchange has been completed, the message has passed, never to be heard from again. Unfortunately, e-mail "conversations" are not nearly as ephemeral as their verbal counterparts. An examination of a typical e-mail session reveals just how long-lived an e-mail message can be.

1. The user opens an e-mail program and begins to type a message. If the session takes enough time, the e-mail program may store the message in a local cache or "Drafts" folder as a disaster-recovery method.
2. The user clicks "Send" to send the message. The message is stored on the local machine (typically in a "Sent Messages" folder), then transmitted to the local e-mail server.
3. The local server contacts the recipient's e-mail server and copies the message to that system.
4. The recipient opens an e-mail program and connects to their e-mail server. The message is then copied to the recipient's personal computer where it is read.

Just from this simple scenario, the e-mail message is copied to, and saved on, no fewer than four different systems. This scenario also assumes that the sender's and recipient's e-mail servers are directly connected, which is seldom the case in real life. If there are any intermediate e-mail servers or gateways between the sending and receiving servers, the message will additionally be stored on each of those servers on the way to its final destination. In addition, if the receiver forwards the mail to a PDA or another user, the mail will be copied yet again, perhaps multiple times. This method of transmission is known as *store-and-forward*, and leads to one of the biggest problems when it comes to e-mail retention and destruction: When a company wishes to find all instances of a mail message for use or destruction, or it wishes to find all the messages relating to a particular subject, the messages often reside in multiple locations, and some of those locations may be out of the administrative and security control of the organization. For an organization trying to recover the communications related to a specific event or produce electronic documents in connection with a legal proceeding, this represents a large logistical and legal problem.

36.4 E-Mail Risks Abound

Based on the description of the current e-mail landscape, and given its importance and widespread use, there are clearly risks associated with relying on e-mail as a primary communications method for business. Some of the more prevalent risks include:

- *Breach of confidentiality.* This is a frequent risk of e-mail communications, and can be realized in two ways. First, a malicious actor can deliberately send sensitive and proprietary information in an e-mail to a third party. Although many organizations have policies that allow them to monitor the content of e-mail sent from the organization, most do not have sufficient resources to routinely monitor all e-mail. Thus, it is highly likely that such a maliciously transmitted message will sneak out of the organization undetected. The second method for breaching confidentiality is through the inadvertent misdirection of mail to an unintended recipient. It is a simple matter to mistakenly put the wrong e-mail address in the "To:" section of the message, thus sending confidential information into the wrong hands. A popular reaction to this threat has been an increased use of disclaimers attached to the bottom of all e-mails emanating from an organization. The disclaimer typically identifies the sending organization of the message and requests that if the recipient has received the message in error, the sender should be notified and the recipient should destroy any and all copies of the message. While this may provide some legal protection, these types of disclaimers have been successfully challenged in some courts, so they are not foolproof.

- *Damage to reputation.* As e-mail messages have become recognized as statements of record, their potential to damage the financial stability or reputation of the sender has likewise grown. A poorly worded or offensive message falling into the wrong hands can have grave personal or economic consequences for the sender. A recent case in point comes from a woman in the United Kingdom whose boyfriend worked for Norton and Rose, a U.K. law firm. The woman sent an e-mail to her boyfriend discussing intimate details of their sex life. The message was somehow obtained by friends of the couple and forwarded multiple times to multiple people, eventually reaching millions on the Internet.
- *Legal liability.* As will be discussed in more detail, the widespread use of e-mail as a medium for business communications opens up an organization to legal risks. Many jurisdictions hold the organization, not the individual e-mail user, responsible for the use and content of e-mail messages sent from the organization's network. A 2003 joint study by the ePolicy Institute, the American Management Association, and Clearswift found that 14 percent had been ordered by a court or regulatory body to produce employee e-mail records. That figure is up from only 9 percent in 2001. In addition, 5 percent of companies have battled a workplace lawsuit triggered by e-mail.[2]

36.5 It Can Happen to You: Case Studies and Lessons Learned

To understand the full impact of the business use for e-mail, and the ramifications involved in indefinite retention of e-mail messages, an examination of several real-life cases is in order. These cases show how e-mail messages left on corporate and personal systems have led to damaging evidence in trial court, and sometimes in the "court of public opinion."

One of the most widely publicized cases in recent memory was the U.S. Justice Department's antitrust case against Microsoft.[3] In that case, prosecution lawyers made use of numerous e-mail documents, some of them several years old, to make their case against the software giant. In one particularly damaging message, Microsoft Chairman Bill Gates allegedly describes how he tried to persuade Intuit against distributing Netscape's Internet browser with its financial software. In its defense, Microsoft claimed that the passages used as evidence in the case were taken out of context and were part of a much longer series of messages (commonly known as a *thread*), which altered the underlying meaning of the quote.

Many lessons come from the Microsoft case. The first exemplifies what has already been discussed: e-mail lives inside a company's network far longer than most people imagine. In the Microsoft case, many of the e-mail messages used as evidence were several years old by the time the case came to trial. The second major lesson emanates from the contextual argument used by Microsoft. Public figures whose comments have been quoted accurately yet inappropriately in the media have been subjected to this problem for many years. E-mail threads are often composed of small snippets of commentary sent back and forth by the participants in the communication. While this follows a more conversational style of communication between humans, rarely can a single paragraph or e-mail tell

[2] ePolicy Institute, 2003 Electronic Policies and Practices Survey, http://www.epolicyinstitute.com/survey/index.html.

[3] *United States of America v. Microsoft Corporation*, Civil Action No. 98-1232, http://www.usdoj.gov/atr/cases/f4900/4909.htm.

the whole story of the conversation. The lesson to be learned here is that e-mail users must be made aware that their comments, however incidental or incomplete, can come back to haunt them.

This last point is seen again in the case of *Linnen v. A.H. Robins Co.*[4] In that case, Robins was accused of not warning healthcare providers and consumers about the potential dangers of taking the combination of Pondimin (fenfluramine) and Ionamin (phentermine), which, when prescribed together, were commonly referred to as "fen/phen." The contentious legal battle took a significant turn when computer forensics experts were able to recover an e-mail from one company employee to another pertaining to the side effects of the fen/phen drug. The message read, in part, "Do I have to look forward to spending my waning years writing checks to fat people worried about a silly lung problem?" Partially as a result of that message, the case turned from heated litigation to settlement talks and led to American Home Products paying out billions of dollars in settlement claims. The lesson here is that the internal commentary of your employees, no matter how innocuous or off-the-cuff, can be hiding in your system and, if discovered, used against you.

Surprisingly, although it has received increased attention in the past several years, using e-mail as damaging evidence is nothing new to the legal arena. As far back as the 1980s, Colonel Oliver North tried to delete e-mail messages pertaining to the Iran-Contra affair from his computer system. His mistaken belief that the deletion was permanent, and his lack of understanding of how the White House e-mail system worked, led to damaging evidence against the administration of President Ronald Reagan.

36.6 E-mail Use and the (U.S.) Law

In recent years, the use of e-mail as evidence in criminal and civil proceedings has become commonplace for prosecutors and defense attorneys alike. To be admissible in U.S. courts, evidence must meet certain threshold tests. The evidence must be authenticated; that is, it must be proven to be that which it purports to be.[5] Further, the evidence must be admissible under the rules of evidence. A common objection to documentary evidence is that it is "hearsay," but an equally common exception is that it meets the "business records" exception for the use of hearsay evidence. Most standard business records and communications formally kept and maintained as a normal part of a company's business processes fall under the hearsay exception.[6]

36.6.1 Federal Rules of Civil Procedure

The Federal Rules of Civil Procedure (Fed. R. Civ. P., or FRCP), together with such local practice rules as the district courts may implement, govern the conduct of civil cases in the U.S. federal district courts. While a full analysis of the rules governing any court is beyond the scope of this chapter, some basic information is useful as background. These rules do not, by law, apply to suits brought in state courts, but the rules of many states have been closely modeled after those found in the FRCP. The two rules of the FRCP most germane to a discussion of e-mail as evidence are Rules 26(a) and Rule 34. Rule 26(a) specifically requires the disclosure of, or a description of, certain materials, including "data compilations" relevant to a party's claims or defenses. This rule, or some local rules (which may be more stringent than the federal rules), may require attorneys to locate all sources of such information that their clients might possess, including data stored on individual computers, hard disks, network servers, personal digital assistants, and removable media. Data in the possession of third parties, such as outsourcers, business partners, or Internet service providers may, under some circumstances, also be covered if it is under the party's control.

[5] *Fed. R. Evid.*, 901, Authentication.

[6] *Fed. R. Evid.*, Article VIII, Hearsay.

36.6.2 Discovery

The practice of litigation in U.S. courts involves a process of *discovery* pursuant to which a party may obtain information that can be used at trial in proceedings in advance of the trial, thus reducing the potential for surprise. Because the use of e-mail records in court cases are a common occurrence, lawyers for both sides of cases can expect to receive a request for any and all e-mail records pertaining to a case as part of a discovery request, generally pursuant to FRCP Rule 34, which addresses, in part, the production of documents and things. While this sounds like a simple process, when it comes to the discovery of e-mail records the process of responding can be quite complicated. The organization served with a discovery request may need to locate material responsive to that request, which may be a very broad subject. For many organizations, simply identifying where all the information may be, and who had access to it, can be a daunting task.

If a company stores and processes all its mail in a central location, this can mean extracting relevant records from the central server. If, however, computer users in the company store mail locally on their PCs, the company must gather the relevant information from each of those individual PCs. E-mail records past a certain age can also be stored on backup tapes at alternate locations. To properly respond to a discovery motion, a company may be compelled to retrieve multiple sources of information looking for responsive data in those sources. This can amount to a substantial resource and financial drain on a company during a lengthy litigation.

36.6.3 Spoliation

When a claim is reasonably likely to be asserted, and certainly once asserted, a party must be careful to ensure that relevant information is preserved and not altered, damaged, or destroyed in any way. The result of not following established processes or mishandling information is called *spoliation* and can have serious legal consequences. One of the most prevalent mistakes resulting in spoliation is the failure to discontinue automatic document destruction policies when a company is served with a discovery request. Even if a company's policy states that all documents must be destroyed after seven years (for example), once a company has reason to know it might be involved in litigation, arbitration, or investigation, all information relevant to the claim or issue must be retained until the final outcome (including all possible appeals) is decided. This holds true even if the litigation takes the information well past the seven-year retention cycle. Some complex cases or series of cases can take ten years or more. A company that destroys relevant potential evidence while a case is still underway is risking large penalties, sanctions, or even criminal charges.

Another potential for a spoliation claim might arise from errors made in collection or imaging of electronic data. There are specific procedures for presenting a document in court to ensure its admissibility. If the gathering methodology alters the document such that it is no longer usable, the lost evidence may jeopardize a claim. Security professionals and legal teams are advised to seek out an experienced expert in forensic evidence gathering if they believe this might be an issue with their case.

Legal sanctions for allowing spoliation to occur can be severe. A court could bar evidence, render adverse rulings (for either the case or the specific issue in question), impose monetary sanctions, or instruct the jury that it may infer that the missing material was negative to the party that should have had the information (a so-called "adverse inference instruction"). There is even a risk of criminal prosecution for obstruction of justice through the destruction of evidence.

36.6.4 Authentication and Integrity

An issue that relates to both spoliation and a message's admissibility under the hearsay exception is the authentication of evidence and its integrity throughout the discovery process. To be admissible, evidence must be shown to be authentic and a true representation of the communication in question. At a practical level, this means that a party must show that the message came from an officially recognized source (i.e., the company's corporate e-mail system) and that it was handled in accordance with the company's accepted business practices for such information. This step is required even if the use of the hearsay exception for business records is not at issue.

A company must also prove the integrity of the communication and may need to prove that it has not been altered in any way from the moment it is identified as potential evidence until its production at trial. Altering relevant information (intentionally or inadvertently) can lead to a spoliation claim.

36.7 Planning an E-Mail Retention Policy

Having worked through the issues surrounding the use, risks, and legal circumstances of e-mail use, it should be clear that this is an issue that is best served by a clear policy surrounding the retention of e-mail-based information. By formulating a clear policy, disseminating that policy throughout the organization, and enforcing its application in an efficient and uniform manner, many of the issues previously addressed become easier to manage and the risks associated with e-mail use and retention can be reduced.

The basic principle behind an e-mail retention policy (as is the case with all such information retention policies) is that information should be uniformly and routinely destroyed after a predefined period of time unless exceptions are called for, most notably when the possibility of claims or litigation arise. While this may seem contradictory (calling it a retention policy when it, in fact, advocates the destruction of information), it is completely consistent with current business and legal leading practices. The reasoning behind defining a specific time period for retaining information comes from the need to shelter an organization from long-forgotten "surprise" evidence uncovered during a discovery procedure that could lead to an unfavorable ruling against the company. If an e-mail message is destroyed as a routine, established business practice (and assuming further that the company had no reason not to destroy it, such as a potential or pending claim) it cannot be produced as evidence (because it does not exist). At the same time, the practice protects the company from obstruction charges, because it followed an established procedure and did nothing special in relation to the message or messages in question. It should be noted again, as previously discussed, that such a process only protects a company if the information is destroyed prior to its identification as potential evidence. Once the potential need is known or the facts exist to suggest a potential claim, the information must be preserved despite any policies or procedures the company may have to the contrary.

On a strictly operational level, routine destruction of old information allows the organization to minimize long-term storage costs for outdated information and provides for a more efficient e-mail service for end users.

36.7.1 Management Guidance

As with all effective policies, an e-mail retention policy must start with the support and backing of the senior management of the organization. Management must be consulted to determine its concerns regarding e-mail retention and its tolerance for the varying levels of risk associated with retaining e-mail messages for longer or shorter periods of time. Once management has approved a strategy regarding e-mail retention, including a definition of acceptable risk, work can proceed on developing the company's e-mail retention policy.

36.7.2 Legal and Regulatory Guidance

An organization must take into account the legal and regulatory environment in which it operates when developing an e-mail retention policy. Most regulated industries have strict rules regarding the collection and maintenance of information pertaining to the operation of the business. These rules will include retention requirements and, in some cases, destruction requirements. In other industries, federal, state, or local laws may guide the retention of electronic information for certain periods of time. Additionally, if the company does business in multiple countries, the laws in those jurisdictions may need to be taken into account as well. The organization must be mindful of these requirements so as not to violate any applicable laws or regulatory requirements.

The organization might consider establishing a cross-functional policy planning team. There are hundreds of federal and state record-keeping regulations that govern information retention, as well as many different technology products that attempt to help an organization manage some or all of the records management process. The best way to ensure success of the effort is to combine subject matter experts from the business' key functional areas, including the legal, IT, human resources, finance, and operations teams.

While it is most likely acceptable for an organization to retain records for a longer period of time than the law specifies, it is rarely, if ever, acceptable to destroy records before the time proscribed by law. An organization should always seek the advice of an attorney well versed in this area of the law before creating or amending any retention policy.

36.7.3 Distinguishing Corporate Use from Personal Use

Many organizations today allow the use of company e-mail facilities for limited personal use to send e-mail to friends and family or to conduct personal business during nonproductive business time (before the workday begins or during a lunch break, for example). This may result in a commingling of personal and business e-mails on the user's PC and in the company's e-mail storage facilities. And, as has been previously discussed, those e-mails may be stored in multiple locations throughout the company's e-mail system. Should the company be served with a discovery motion for electronic business records, it may have the additional burden of wading through large amounts of personal mail in an effort to find relevant business messages. By the same token, if a company employee becomes involved in a legal dispute and the opposing counsel learns that the company allows use of its e-mail system for personal reasons, the company may be requested to search through its vast e-mail archive looking for any personal e-mails the employee sent that may be relevant to the case. An e-mail retention policy might need to address such a situation and specify an employee's ability to store personal e-mails on the company's computer system. This also raises many issues concerning employee privacy that are beyond the scope of this chapter.

36.7.4 Records Management

The key to an effective e-mail retention policy is the establishment of clear policies and processes for records management. This affects all business records created and maintained by the company but should particularly stress compliance for e-mail communications.

A good place to start is by creating an inventory of current e-mail information in the organization. Close attention should be paid to historical records stored at off-site facilities, including magnetic tapes, disks, and microfiche. Once these information sources have been identified, they should be cataloged and categorized in as organized a manner as possible. These categories may include the source and destination of the message, the business unit or functional area affected by the message, and the sensitivity of the information contained in the message.

Based on the findings of the inventory, the organization can then begin to develop a strategy for how to deal with future e-mails sent to its employees. It may specify that different categories of e-mail messages must be handled in different ways, or that different categories of information have different retention requirements. Additionally, a policy might specify how employees are to archive mail they receive so as to make later discovery processes easier to manage. Whatever scheme is developed, the planners of the policy should strive to keep it as simple as possible for the average user to understand and implement. If the process is too complicated, users will resist its use.

36.7.5 Responding to Discovery Requests

Because the process of responding to a discovery motion is a complicated one, it should only be undertaken under the direct guidance and supervision of a qualified attorney. Mistakes made during the discovery phase of a trial can have grave consequences for the offending party. For this reason, an e-mail retention policy should clearly define who is responsible for responding to discovery motions and the authority that person or group has to obtain resources and information from other organizations inside the company.

36.8 A Sample E-Mail Retention Policy

To assist organizations in the creation of their own e-mail retention policies, the following sample policy offers some guidance in the areas that should be considered when dealing with e-mail retention issues. This policy is for a fictional publishing company, HISM Enterprises, and contains many of the elements discussed thus far. As with any sample policy, the applicability to a particular organization will vary based on the structure and operating practices of that organization. The security professional can use this sample policy as the basis for establishing an organization's own policy, but should consult with the organization's business and legal representatives to determine the applicability of any particular aspect of the policy to the organization's goals.

36.8.1 Policy Number and Title

6.12: Retention and Destruction of Electronic Mail Records

36.8.2 Policy Background

Electronic mail ("e-mail") is an essential part of the tools that HISM uses to communicate with its customers, suppliers, and business partners. Because it is a primary method of communication, e-mail sent to and from HISM systems contains a great deal of sensitive information about HISM, its employees, and the third parties with which it deals. Unfortunately, some of that information may help HISM's competitors or prove damaging to HISM in the event of a legal dispute over its products, services, or conduct. For that reason, information contained in e-mails must be strictly controlled, processed, and destroyed according to applicable state and federal laws and consistent with internal HISM policies concerning destruction of company information.

36.8.3 Policy Statements

All information stored in HISM e-mail systems must be retained for a period of five years from the date of creation (in the case of e-mail originating from HISM) or the date of first receipt (in the case of e-mail originating from outside HISM).

Once the retention period has passed, the information must be destroyed and further use prevented. For information stored on electronic media (for example, tapes and disks), the information must be erased using a multi-pass overwriting system approved by the HISM Information Security organization. Once the magnetic information has been erased, the physical media must be destroyed. It cannot be reused for HISM information storage or recycled for use by other organizations.

All e-mail will be stored on centralized systems maintained by the HISM Information Technology (IT) organization. The operation of e-mail systems by groups other than IT is prohibited.

Sufficient storage must be made available to allow HISM users to keep e-mail from the past ninety (90) days in online storage. E-mail older than 90 days must be archived to secondary media and stored in a secured location. The use of local e-mail storage (Personal Folders, for example) or the creation of directories on end-user systems for the purpose of creating an e-mail archive is strictly prohibited.

It is HISM policy to allow the limited judicious use of HISM computers and network resources (including e-mail) for personal reasons. A folder named "Personal" will be created in each user's electronic mailbox where users can place e-mail correspondence of a personal nature. This will allow HISM to respond more effectively to legal requests for corporate e-mail evidence without potentially infringing on the privacy rights of HISM employees.

HISM employees are not permitted to respond to court subpoenas or legal discovery requests without first consulting with the HISM Legal Department. All requests for access to e-mail information should be directed to the Legal Department.

In the event that HISM is a party in a legal proceeding that requires the extended retention of e-mail messages past the five-year retention cycle, the HISM IT organization will provide sufficient facilities to store all affected e-mail messages until released from that responsibility by the HISM Legal Department.

36.8.4 Scope

This policy applies to all Company personnel who use HISM systems to create, read, store, or transmit electronic mail. It also pertains to non-employee workers, contractors, consultants, or other personnel performing work for HISM on a permanent or temporary basis.

This policy applies to all HISM business units and corporate functions. Where individual business units are required by law or by contractual obligation to follow e-mail retention policies other than those described in this policy, that business unit is required to seek a policy exception and approval from the Chief Information Officer, the Vice President for Information Security, and the Vice President for Legal Affairs.

36.8.5 Effective Dates, Grandfathering Provisions, and Sunset Provisions

This policy shall be effective immediately upon approval by the HISM Chief Information Officer.

This policy supersedes all previous policies pertaining to retention of e-mail information.

This policy shall continue to remain in effect unless superseded by a subsequent policy approved by the HISM Chief Information Officer.

36.8.6 Roles and Responsibilities

The HISM IT organization is responsible for establishing and maintaining e-mail resources for all HISM employees and associates. It is also responsible for adhering to this policy and developing appropriate procedures for implementing this policy in all HISM e-mail systems.

The Chief Information Officer, the Vice President of Information Security, and the Vice President for Legal Affairs must jointly evaluate and approve any exceptions to this policy. Exceptions will only be granted based on validated business need where compliance with this policy would place HISM in violation of applicable state or federal law.

All HISM sales teams and customer agents are responsible for ensuring that contracts with customers, suppliers, and other business partners do not place HISM in potential violation of this policy. Any potential violation issues should be immediately brought to the attention of the Vice President for Legal Affairs.

The HISM Information Security organization is responsible for specifying appropriate technology for destroying information stored on electronic media.

The HISM Legal Department is responsible for responding to legal inquiries for HISM e-mail information and managing the collection and analysis of that information.

36.8.7 Related Policies

- 5.24: Proper Disposal and Destruction of Sensitive Company Information
- 6.04: Use of Company Computing Resources for Non-Company Functions
- 6.05: Privacy of Personal Information on HISM Systems

36.9 Conclusion

Whether it is dusty old letters stuffed in an attic shoebox or obscure e-mail messages hidden in a long-forgotten directory, there will always be the opportunity to find hidden information among the remnants of long-past communications. Sometimes those remnants provide the catalyst to look back in amused nostalgia. But more and more often, those remnants are providing glimpses into a past best forgotten, information best not shared, or actions best not known. Unless proactive steps are taken to establish a formal e-mail retention policy, followed by an efficient e-mail retention and destruction process, a company is opening itself up to allowing investigators, litigators, and forensics experts to view its most closely held secrets.

37

Ten Steps to Effective Web-Based Security Policy Development and Distribution

Todd Fitzgerald

Paper, Dust, Obsolescence. Affectionately known as shelfware are the magnificent binders filled with reams of outdated policies, procedures, standards, and guidelines. Many times, the only contribution to effective security these binders have is to *increase the security risk* by having more to burn during a fire! Many times, these documents are the proud creations of the security department but have little impact on the end user who is posting a password on his terminal or leaving confidential documents lying on his desk. The documents are typically voluminous, and who will take the time to read them? Simple answer: the same people who read their complete car owner's manual before they put the key into the ignition for the first time—definitely a small segment of the population (not sure we want these individuals driving either!).

So where does this leave us? Granted, documented procedures require a level of specificity to truly become a repeatable process. It is through the process of documentation that consensus is reached on the policies and procedures required for an organization. Without going through this process, many practices may be assumed, with different interpretations between the parties. Organizational members from the different business units—Human Resources, Legal, and Information Technology—need the opportunity to provide input to the documents as well. However, does this mean that the end product must be a dusty set of binders that no one looks at, except on the annual update cycle? This appears to be such a waste of resources and results in limited effectiveness of the deliverable.

37.1 Enter the Electronic Age

Beginning in the mid to late 1990s, large organizations were beginning to realize the efficiencies of the intranet for distributing information internally to employees. External Web presence (the Internet) obtained most of the budget dollars, as this was deemed a competitive and worthwhile investment due to its potential for revenue generation and increased cost efficiencies to those areas such as customer service, order entry, and creating self-service mechanisms. After this functionality was largely in place, the same technology was reviewed for potential savings within the internal environment to support employees. Organizations seem to start and stop these initiatives, causing intranet content to be rich for some areas and nonexistent for others. The level of existing documented procedures as well as their use of technology also contributed to the maturity level of the intranet, Web-based applications. Debates among whom should distribute policies—Compliance? Human Resources? Legal? Information Technology? Individual business units?—can also slow the decision process in selecting the proper tool. At some point, organizations need to "step their toes in the water" and get started versus trying to plan out the entire approach prior to swimming! If there is an existing intranet, security departments would be wise to integrate within the existing process for delivering policies, or influence changing the environment to accommodate the security policy considerations versus creating a new, separate environment.

It is unrealistic to believe that we will ever move completely away from paper; however, the "source of record" can be online, managed, and expected to be the most current version. How many times have you looked at a document that was printed, only to guess whether or not there is a later version? Many times, we print documents without the proper data classification specified (Internal Use, Public, Confidential, or Restricted) and date-time stamped, making it difficult to determine the applicability of the document. Additionally, if the documents are online and housed in personal folders and various network drives, determining the proper version is equally difficult.

37.2 Functionality Provided by Web-Based Deployment

Deploying security policies electronically can provide several advantages, depending on the deployment mechanism. In the simplest form, policies can be placed on the intranet for users to view. This should be regarded as an "entry-level" deployment of security policies. The remaining sections in this chapter discuss the approach and delivery of implementing security policies that are created through a workflow process, deployment to the intranet, notification of new policies, tracking for compliance, limiting distribution to those who need them, informing management of noncompliance, and planning the release of the policies. Placing the policies "on the Web" without managing the process is insufficient in today's regulatory environment of controls with such influences as the Health Insurance Portability and Accountability Act (HIPAA), the Gramm–Leach–Bliley Act (GLBA), the Sarbanes–Oxley Act, California Senate Bill 1386, etc. Verification that users have received the policies and can reference them at a future point is essential for security.

37.3 A Pragmatic Approach to Successful E-Policy Deployment

Deploying policies in a Web-based environment has many similarities to developing paper-based policies; however, there are some additional considerations that must be appropriately planned. The following ten-step approach for the development and distribution of policies will reduce the risk that the electronic policies will become the digitized version of shelfware of the future (in the security profession, we never completely solve problems, but instead reduce risk!).

37.3.1 Step 1: Issue Request for Proposal

Issuing a Request for Proposal (RFP) to multiple vendors serves several purposes. First, it forces the organization to think about what the business requirements are for the product. A list of considerations for selecting a tool is presented in Exhibit 37.1. Second, it causes vendors to move beyond the "sales-pitch" of the product and answer specific questions of functionality. It is very useful to include a statement within the RFP stating that the RFP will become part of the final contract. For example, a vendor might indicate that it "supports e-mail notification of policies" in its glossy brochures, while at the same time omitting the fact that the e-mail address has to conform to its (the vendor's) standard format for an e-mail address, thus requiring an extra step of establishing aliases for all the e-mail accounts. Third, pricing can be compared across multiple vendors prior to entering into pricing negotiations without having to respond to the sales pressure of "end of the sales quarter" deals. Fourth, a team can be formed to review the responses objectively, based on the organizational needs; and finally, more information on the financial stability and existing customer references can be obtained.

There are several players in the policy development and deployment market space, albeit the market is relatively immature and the players change. As of this writing, there are several vendors promoting solutions, such as NetIQ's VigilEnt Policy Center (formerly Pentasafe), Bindview Policy Center, NetVision Policy Resource Center, PricewaterhouseCoopers Enterprise Security Architecture System (ESAS), PoliVec 3 Security Policy Automation System, Symantec, and others. There are also the E-learning companies that overlap this space, such as QuickCompliance, Eduneering, Mindspan, and Plateau systems to name a few. Articulating the pros and cons of each of these products is beyond the scope of this chapter; however, the information provided should enable a reasonable method to start raising knowledgeable questions with the vendors.

To move toward a product that will support the business requirements, an organization could build the product itself. However, there are advantages in purchasing a product to perform these capabilities.

EXHIBIT 37.1 Considerations in Selecting a Policy Tool Vendor

Subscription versus perpetual license pricing
Process for creating security policies
Workflow approval process within the tool
Methods for setting up users (NT Groups, LDAP, individually maintained)
Pass-through authentication with browser
E-mail notification of new policies and capabilities
Construction of e-mail address
Import and export capabilities
Ability to change policy after distribution
Quizzing capability
Role-based administration access (to permit departments other than Security to manage policies in their areas)
Levels of administrative access
Intranet and internet hosting requirements
Vendor customer base using the tool in production
Annual revenues
Application service provider, intranet or Internet-based model
Protection of information if not hosted locally
HIPAA and GLBA policy content included with tool or add-on pricing
Reporting capabilities to track compliance
Policy formats supported (Word, PDF, HTML, XML) and the limitations of using each
Context searching capability
Linkage to external documents from the policy (such as standards, procedures)
Test server instances—additional pricing?
Two- to three-year price protection on maintenance, mergers, or acquisitions
Predeveloped content available
Number of staff dedicated to product development versus committed to sales and administration
Mechanism for distributing policies to different user groups

From a cost perspective, most organizations would spend more in resources developing these tools than they can be purchased for. There is also the issue of time-to-market. The tools are already available and can be deployed within a few months, depending on the match with the technical infrastructure of the organization. Vendors also provide starting policy content that can jump-start the creation of security policies. This content is updated according to the changing requirements of the regulatory bodies.

A cross-functional team composed of representatives from Human Resources, Legal, Information Technology, Compliance, and the key business units should be formed to review the requirements and responses from the proposals. These are the individuals who will have to support the policy tool once it is implemented; therefore, bringing them into the process early on is essential. The tool may be extended beyond the needs of the security department to deliver other organizationwide policies once the basic infrastructure is in place.

Prior to issuing the RFP, a scoring matrix should be prepared that will allow the team to evaluate the vendors independently. The matrix does not have to be complicated and should be driven from the business and technical requirements, the criticality of the requirement, and the level to which the requirement was met (for example, 3 = Exceeds requirements, 2 = Meets requirements, 1 = Does not meet requirements). Once the matrices are scored individually by team members, group discussion focusing on the differences between the products narrows the selection. The duration of the RFP process can be as short as six to eight weeks to select the appropriate product and is time well spent.

It is beneficial to include the company's software purchasing contract within the RFP so that the appropriate terms and conditions can be reviewed by the vendor. This saves time in contract negotiations, as the legal departments will typically review the contract as part of the RFP process. Considerations for the contracting phase include:

- Standard vendor contracts include no-warranty type language—add escape clauses if the product does not function within 90 days of the start of testing.
- Subscription versus perpetual licenses—evaluate the two- to three-year product cost.
- Secure two- to three-year price increase protection, especially on "new to market tools."
- Obtain protection in the event the company or the vendor's merges or is acquired by another company.
- Be aware of future "unbundling" of previously purchased items; ensure functionality is covered in the RFP.
- Establish how a "user" is counted for licensing.

Vendors with different product beginnings are entering the "Security Policy Tool" market. Attempt to understand the company and whether or not this is an "add-on" market for them, or was the product specifically developed for this market space? Add-on products typically have limited investment by the vendor, and functionality enhancements are subject to the direction where the original product started.

The RFP is a critical step, providing focus for the team in clarifying the requirements expected of the product, engaging the stakeholders earlier in the process, and providing the means to compare company and technical product information quickly between the vendors.

37.3.2 Step 2: Establish Security Organization Structure for Policy Review

If a Security Council or committee has not already been established, this is an excellent time to form one. The Security Council becomes the "sounding board" for policies that are introduced into the organization. One of the largest challenges within any information security program is establishing and maintaining support from management for information security practices, many times referred to as "lack of management commitment." The first question is to ask: why is there a lack of commitment? What steps have been taken to **build the management commitment?** Think of an organization being like a large skyscraper. Each successive floor depends on the preceding floor for support. The walls, bricks, concrete, and steel all have to work together to form the needed support to prevent the building from collapsing. It also must be strong enough to withstand high winds, rainstorms, and earthquakes. If we envision organizations as skyscrapers, with senior management occupying the top floors (they seem to always get the best views!), with middle management just below (translating senior management vision into operational actions to accomplish the vision) and the co-workers below that (where the real mission is carried out), we see that the true organizational commitment is built from the bottom up. This occurs brick by brick, wall by wall, floor by floor. The "reality check" occurs by each level in the organization inquiring their subordinates to see if they are in agreement. Obviously, it would take a significant amount of time to engage all users and all management levels in the process of policy development. Granted, someone in the organization below the senior executive leadership must have the security vision to get started, but it is the support of middle management and the co-workers that is essential to maintaining long-term senior management support.

The individual typically having the security vision is the Director, Manager of Information Security, Chief Security Officer, or Chief Information Security Officer. This individual has typically reported through the Information Technology department to the CIO or head of Information Systems. A good indication of success of the security vision being accepted by senior leadership is if positions such as Chief Security Officer, Chief Information Security Officer, or Information Security Officer have been established, with a communication path through the organization's Audit and Compliance committees or Board of Directors. The establishment of these roles and the development of communication lines typically indicate that security has moved out of an operational, data center type function and into a strategic function necessary to carry out the business objectives of the organization. Some organizations are fortunate to have the CEO, CFO, or COO already with a good understanding and strong believers in information security; however, this is the exception. Security has a long history of being viewed as an expense to the organization that was not necessary and that did not contribute to top-line revenues and thus the suggestion to spend more in this area to a C-level management individual should not be immediately expected to be readily embraced. The business case for enabling new products, attaining regulatory compliance, providing cost savings, or creating a competitive advantage must be demonstrated.

The Security Council should consist of representatives from multiple organizational units that will be necessary to support the policies in the long term. Human Resources is essential to providing knowledge of the existing code of conduct, employment and labor relations, and termination and disciplinary action policies and practices that are in place. The Legal department is needed to ensure that the language of the policies is stating what is intended, and that applicable local, state, and federal laws are appropriately followed. The Information Technology department provides technical input and information on current initiatives and the development of procedures and technical implementations to support the policies. Individual business unit representation is essential to understanding how practical the policies can be in carrying out the mission of the business. Compliance department representation provides insight into ethics, contractual obligations, and investigations that may require policy creation. And finally, the Information Security department should be represented by the Security Officer, who typically chairs the council, and members of the security team for specialized technical expertise.

37.3.3 Step 3: Define What Makes a Good Security Policy

Electronically distributed policies must be written differently if they are to be absorbed quickly, as the medium is different. People have different expectations of reading information on a Web site than what would be expected in relaxing in an easy chair to read a novel or review technical documentation. People want the information fast, and seconds feels like hours on a Web site. Therefore, policies should be no longer than two typewritten pages, as a general rule. Any longer than this will lose their attention and should be broken into multiple shorter policies. Hyperlinks were designed to provide immediate access only to the information necessary, making it quick to navigate sites. Individuals may not have time to review a long policy in one sitting, but two pages?—no problem, especially if this is communicated to them ahead of time.

Organizations typically do not have a common understanding of what a "policy" is. It seems like such a simple concept, so why the difficulty? The reason is not the lack of understanding that a policy is meant to govern the behavior within the organization, but rather that in an effort to reduce time, organizations combine policies, procedures, standards, and guidelines into one document and refer to the whole as "the policy." This is not really a time-saver because it introduces inflexibility into the policy each time a procedure or standard has to change. For example, if the password "standards" are written into the password policy for a primarily Windows-based (NT, 2000, XP, 98) environment, what happens when a UNIX server with an Oracle data warehouse project is initiated? Must the password "policy" be updated and distributed to all end users again, although a small percentage of the organization will actually be using the new data warehouse? Consider an alternative approach in which the password standards are placed in standards documents specific to the individual platform and hyperlinked from the high-level password policy. In this case, the high-level policy stating that "passwords appropriate for the platforms are determined by the security department and the Information Technology departments are expected to be adhered to in an effort to maintain the confidentiality, integrity, and availability of information…" will not be required to change with the addition of the new platform. Republishing policies in a Web-based environment is a key concern and should be avoided, especially when they are broken into "many" two-page policies.

At this point, some definitions are in order:

- *Policy*: defines "what" the organization needs to accomplish and serves as management's intentions to control the operation of the organization to meet business objectives. The "why" should also be stated here in the form of a policy summary statement or policy purpose. If end users understand the why, they are more apt to follow the policy. As children, we were told what to do by our parents and we just did it. As we grew older, we challenged those beliefs (as four- and five-year-olds and again as teenagers!) and needed to understand the reasoning. Our organizations are no different; people need to understand the why before they will really commit.
- *Procedure*: defines "how" the policy is to be supported and "who" does what to accomplish this task. Procedures are typically drafted by the departments having the largest operational piece of the procedure. There may be many procedures to support a particular policy. It is important that all departments with a role in executing the procedure have a chance to review the procedure or that it has been reviewed by a designate (possibly a Security Council representative for that business area). Ownership of the procedure is retained within the individual department.
- *Standard*: a cross between the "what" and "how" to implement the policy. It is not worth the effort to debate which one of these applies; the important concept is that the standard is written to support the policy and further define the specifics required to support the policy. In the previous UNIX/Oracle data warehouse example, the standard would be written to include specific services (for example, Telnet, FTP, SNMP, etc.) that would be turned on and off and hardening standards such as methods for remote administration authentication (for example, TACACS, RADIUS, etc.). These do not belong in the policy, as technology changes too frequently and would create an unnecessary approval/review burden (involving extra management levels for detail review) to introduce new standards.
- *Guideline*: similar to standards, but vastly different. A good exercise is to replace the word "guideline" with the word "optional." If by doing so, the statements contained in the "optional" are what is desired to happen at the user's discretion, then it is a great guideline! Anything else, such as required activities, must be contained within the standard. Guidelines are no more than suggestions and have limited enforceability. Guidelines should be extremely rare within a policy architecture, and the presence of many guidelines is usually indicative of a weak security organization and failure to obtain the appropriate management commitment through the processes discussed in Step 2.

These definitions should provide insight into what makes a good policy. Each of the items above (with the exception of guidelines) is necessary to having a good policy. Without procedures, the policy cannot be executed. Without standards, the policy is at too high a level to be effective. Having the policy alone does not support the organization in complying with the policy.

So, the implications for electronic policies include:

- Policies should be written to "live" for two to three years without change.
- Policies are written with "must" "shall" "will" language or they are not a policy, but rather a guideline containing "should" "can" "may" language (exceptions to the policy are best dealt with through an exception process with formal approvals by senior management).
- Technical implementation details belong in standards.
- Policies should be no more than two typewritten (no less than 10 pt font please!) online pages.
- Policies, procedures, standards, and guidelines should be hyperlinked to the policy (the best way to do this is to link one static Web page off the policy and then jump to specific standards, procedures, and guidelines to eliminate the need to change the policy with each addition of a standard).
- Review. Review. Review before publishing.
- Provide online printing capability; however, stress that the current source is *always* on the intranet.

Time spent up front defining a standard format for policies, procedures, standards, and guidelines is time well spent. These formats need not be complex, and simpler is better. For example, a simple online policy approach may be to define four areas: (1) Policy Summary—a brief one-paragraph description of the intent of the policy; (2) Policy Scope—defining to whom the policy applies; (3) Policy Purpose—defines the "why" of the policy; and (4) Policy Statement—a brief reiteration of the policy summary and the actual policy. Definitions and responsibilities can be addressed by creating policies related to these roles and other supporting documents that are linked from the policy. These four areas provide all that is needed for the policy. Judge the policy not on the weight of the printed document, but rather on the clarity of purpose, communication of the benefits to the organization, and clearness of what people are expected to do. With the advantage of electronically posting the policies on the intranet, the ability of users to navigate to the information they need is also a measure of effectiveness of the policy.

37.3.4 Step 4: Establish a Security Policy Review Process

Now that the organization has identified an individual responsible for the development and implementation of security policies the Security Council has created, and an understanding of what makes a good policy has been communicated, there needs to be a process for reviewing the policies. This process can be developed during the creation of the Security Council; what is important is that the policy development process is thought out ahead of time to determine who will (1) create the policy, (2) review and recommend, (3) approve the final policy, (4) publish, (5) read and accept the policies. The time spent in this process, *up front*, will provide many dividends down the road. Many organizations "jump right in" and someone in the Security department or Information Technology department drafts a policy and e-mails it out without taking these steps. Proceeding along that path results in a policy that is not accepted by the organization's management and thus will not be accepted by the organization's end users. Why? Because the necessary discussion, debate, and acceptance of the policies by the leaders of the organization never took place. In the end, the question of management commitment resurfaces, when there was never a process in place to obtain the commitment to begin with.

The process could be depicted in a swim-lane type chart showing the parties responsible, activities, records created through each activity, and decision boxes. Senior management will want this presented at a high level, typically no more than one or two pages of process diagram. The process will vary by organizational structure, geographic location, size, and culture of decision making; however, a successful process for review should contain these steps.

37.3.4.1 Step 4.1: Policy Need Determined

Anyone can request the need for a policy to the Information Security department. Business units may have new situations that are not covered by an existing security policy. If no security policies exist in the organization, the Information Security department needs to take the lead and establish a prioritization of policies that are necessary.

37.3.4.2 Step 4.2: Create, Modify Existing Policy

The Information Security department creates an initial draft for a new policy that can be reacted to. Many Internet sources are available to obtain existing policies (perform a Google search on "Security Policy" as a starting point!), and other model policies are available through organizations such as www.sans.org and vendors such as NetIQ, through the publication of books and CDs such as "Information Security Policies Made Easy." Caution must be taken not to copy and distribute these policies "as-is" because they may not be completely appropriate, enforceable, or supported by procedures within the organization. The level of detail and "grade level" (should not exceed grade level 8) needs to be assessed to determine how acceptable these will be to the organization.

37.3.4.3 Step 4.3: Internal Review by Security Department

People within the Security department will have varying levels of technical expertise, business acumen, and understanding of the organizational culture. By reviewing within the team first, many obvious errors or misunderstandings of the policy can be avoided before engaging management's limited review time. This also increases the credibility of the Information Systems Security department by bringing a quality product for review. It also saves time on minor grammatical reviews and focuses the management review on substantive policy issues.

37.3.4.4 Step 4.4: Security Council Reviews and Recommends Policy

This is arguably the most critical step in the process. This is where the policy begins the *acceptance step* within the organization. The policies are read, line by line, during these meetings and discussed to ensure that everyone understands the intent and rationale for the policy. The management commitment begins here. Why? Because management feels part of the process and has a chance to provide input, as well as thinking about how the policy would impact their own department. Contrast this method with just sending out the policy and saying, "this is it," and the difference becomes readily apparent. These are the same management people who are being counted on to continue to support the policy once it is distributed to the rest of the workforce. Failing in this step will guarantee failure in having a real policy.

Okay, if we buy into the notion that a Security Council is good practice, logical, practical, and appears to get the job done, what is the downside? Some might argue that it is a slow process, especially when senior management may be pushing to "get something out there to address security" to reduce the risks. It is a slower process while the policies are being debated; however, the benefits of (1) having a real policy that the organization can support, (2) buy-in from management on a continuing basis, (3) reduced need to "rework the policies" later, and (4) increased understanding by management of their meaning and why they are important outweigh the benefits of blasting out an e-mail containing policies that were copied from another source, the name of the company changed, and distributed without prior collaboration. Policies created in the latter context rarely become "real" and followed within the organization as they were not developed with thorough analysis of how they would be supported by the business in their creation.

37.3.4.5 Step 4.5: Information Technology Steering Committee Approves Policy

A committee composed of the senior leadership of the organization is typically formed to oversee the strategic investments in information technology. Many times, these committees struggle with balancing decisions on tactical "fire-fighting" one- to three-month concerns versus dealing with strategic issues, and this perspective needs to be understood when addressing this type of committee. The important element in the membership of this committee is that it involves the decision leaders of the organization. These are the individuals who the employees will be watching to see if they support the policies that were initially generated from the Security department. Their review and endorsement of the policies is critical to obtain support in implementing the policies. Also, they may be aware of strategic plans or further operational issues not identified by middle management (through the Security Council) that may make a policy untenable.

Because the time availability of senior leadership is typically limited, these committees meet at most on a monthly basis, and more typically on a quarterly basis. Therefore, sufficient time for planning policy approval is necessary. This may seem to be run counter to the speed at which electronic policies are distributed; however, as in the case with the Security Council review, the time delay is essential in obtaining long-term commitment.

37.3.4.6 Step 4.6: Publish the Policy

Organizations that go directly from Step 2 to this step end up with "shelfware"—or if e-mailed, "electronic dust." By the time the policy gets to this step, the Security department should feel very confident that the policy will be understood by the users and supported by management. They may agree or disagree with the policy, but will understand the need to follow it because it will be clear how the policy was created and reviewed. Care must be taken when publishing policies electronically, as it is not desirable to publish the same policy over and over with minor changes to grammar and terminology. Quality reviews should be performed early in the development process so that the Security Council and Information Technology Steering Committee can devote their time to substantive issues of the policy versus pointing out the typos and correcting spelling. End users should be given the same respect and should expect to be reviewing a document that is error-free. The medium may be electronic but that does not change the way people want to manage their work lives—with the amount of e-mail already in our lives, we should try to limit the amount of "extra work" that is placed upon the readers of the policies.

The Web-based policy management tools provide the facilities to publish the policies very quickly. Because tracking on reading the policies is a key feature of these products, once the policy is published, they typically cannot be changed unless a new policy is created! This has major implications for the distribution of the policy. This means that *any change made* will require the re-publishing of the policy. Imagine thousands of users in the organization who now have to re-read the policy due to a minor change. This situation should be avoided with the review process in place in the preceding steps. The electronic compliance tracking software is usually built this way (and rightly so), so that it is clear which policy version the user actually signed off on.

It should be clear by now that although some of the policy development tools support a workflow process within the tool to facilitate approvals of policies through the various stages (such as draft, interim reviews, and final publishing), there is no substitute for oral collaboration on the policies. Electronic communications are very "flat" and do not provide expression of the meaning behind the words. Through discussions within the various committees, the documented text becomes more clear beyond just those with technical skills. The purpose is more apt to be appropriately represented in the final policies through the collaborative process.

37.3.5 Step 5: Installation and Configuration of Web-Based Policy Distribution Application

While this is noted as Step 5 in the process, the actual installation may occur earlier and in parallel with the prior steps. There are usually technical issues that are specific to the company's own operating environment and previous implementation decisions that were made. Vendor products must be written to adapt to a majority of the environments, and there may be one technical "gottcha" that takes up 90 percent of the implementation time to work through that particular issue. Some vendors offer a training class or consulting to get the product up and running, each lasting on average two or three days. These are worth taking advantage of and can save time in understanding the product.

Some configuration options made during this step in the process are not easily changed in the future, so attention should be paid to the impact of each option, asking questions about the impact of the decisions. While the following list will vary product by product, these are some considerations to probe beyond the vendors' glossy brochures and sales claims to understand the specific technical answers to the questions.

37.3.5.1 How Are the Individual Users Set Up with the Product?

The users could be set up within the tool itself, which means that every new employee added, terminated, or changing job roles (if policies are published to different groups based on job function) would have to manually be updated within the tool. This could result in many hours of maintenance just keeping up with the changes. As an alternative, the product may offer, using the existing NT groups or using Lightweight Directory Access Protocol (LDAP), to retrieve the previously established members. Using the NT group approach, accounts are assigned to an NT group outside the policy tool (within NT), and these groups are then referenced to ensure that the appropriate departments have access to the policies (i.e., a management group, all users, information technology, remote users, temporary employees, contractors, etc.). Organizations usually do not have these groups predefined by department areas, and they thus need to be constructed and maintained with the implementation and ongoing support of the product. The question then becomes: who is going to take on this "extra" administrative task? If the Information Security department takes on this role, there needs to be extra communication with the Human Resources and Information Technology departments to ensure that changes in membership between these groups is kept current. These added processes are usually not communicated by the vendors of the policy products, but rather the inference that "policies can be published using your existing NT groups!" In practice, there will be additional NT groups that will need to be defined with this approach.

If LDAP is used, this simplifies the process because the existing distribution groups set up on a Microsoft Exchange Server can be utilized as the groups. Maintenance processes should already be in place with distribution list update owners specified, making adoption of the process easier. There can still be "gottchas" here, depending on the product. In the installation of NetIQ's product, delays were experienced because a special character (comma) in the distinguished name on the exchange server caused the vendor's software to crash. After working with the vendor, they indicated that the implementation had to be changed to use NT groups to function within our environment. Subsequently, the vendor product was fixed, but not until we had to change directions, implement the product, and spend the resources investigating and trying to resolve the issue. Other vendor products will have their own "gottchas" in different areas. The lesson here? Always build test cases utilizing your environment early in the process to uncover the major "gottchas." The product needs to work in your installation, and whether or not it works in 100 percent of other implementations becomes irrelevant.

37.3.5.2 Is E-Mail Supported?

Users are very busy individuals, and the last thing they need to be instructed to do is check a Web site daily to see if there are any new policies. In support of this, e-mail notification of new policies is essential so that the policies can be "pushed" to the individual. How the e-mail address is constructed becomes an important integration issue. Is there flexibility in the construction of the e-mail address, or is it always composed of first name followed by last name? If this is the case, aliases may need to be created and maintained, adding to the administrative burden. Additionally, if NT groups are used, do all the users across all domains defined have unique NT IDs? If not, this will cause problems when the product constructs the e-mail address according to the predefined methods, as different individuals in different domains will equate to one e-mail address. Again, the products are written to be generic and ignore any company standards that are in use. A thorough examination of the IDs and e-mail addresses will lead to a discussion of what changes need to be made to support the implementation, either through workarounds (adding aliases) or changing the existing setups (eliminating duplicates). Some implementations may support Simple Mail Transfer Protocol (SMTP) e-mail addresses and do not support the creation of Messaging Application Programming Interface (MAPI). If there are users who do not have external (Internet, SMTP) e-mail addresses due to business restrictions, then e-mail addresses with a different SMTP domain name that is nonroutable to the Internet would need to be established to support the internal notification by e-mail. This would permit the users to receive the "new policies are available" notifications while at the same time continuing to support the business restrictions preventing their ability to send and receive Internet e-mail.

37.3.5.3 How Easy Is It to Produce Accurate Compliance Reports?

Running compliance reports against domains containing large numbers of users can be very time consuming and may time-out before the reports complete. What is the threshold, or number of users who can be reported on? Do these reports have to be run on each policy and each domain separately? For example, if six policies are published with users in ten NT domains, do sixty separate reports have to be run, or just one? If there are users with multiple accounts in different domains, are they viewed as different users by the tool? Can the policy reports be run only for a specific NT group (i.e., management, all users, Information Technology)? If NT groups are used, how does the product handle disabled versus deleted accounts; in other words, will these show up in the reports as users? If exporting to Microsoft Excel or Word, are there any "gottchas" with the export, such as the handling of double-quotes within the results? Compliance reporting can be a very time-consuming process and may not be the "click of a button" action that is typically reported.

37.3.5.4 How Do Users Authenticate to the Tool?

If Microsoft NT Network IDs are utilized, the policy product may provide for pass-through authentication integrated with IIS. Using this method, the user would be automatically logged into the policy deployment tool after selecting the URL for the site in the Web browser. Alternatively, IDs could be set up within the tool, with log-ins and passwords to control access. Because the average corporate user today has at least eight userID/password combinations to keep track of, this approach should be avoided.

37.3.6 Step 6: Pilot Test Policy Deployment Tool with Users

Once the infrastructure has been established, and some test cases have been run through it, the product is ready for pilot testing. A few "draft policies" with the new format should be created and distributed through the tool to a small set of users. It is important to recruit users from different departments, levels of experience, education, and familiarity with computer technology. Selecting a sample made up only of information technology individuals may not surface common user questions. The purpose of pilot testing is to collect feedback on the ease of use of the product, establish a base of individuals who will support (get behind) the product during the rollout phase, and most importantly, to anticipate the questions that need to be addressed to formulate the appropriate training materials.

The process should be scripted to have the users perform different functions, such as reading a policy, providing comments to a policy, accepting the policy, locating the policy documents after they have been accepted, taking a quiz, searching policies for terms, reporting an incident, and so forth according to the functionality provided within the tool.

37.3.7 Step 7: Provide Training on the Tool

Why would training be important? After all, this is a Web-based application and should be intuitive, right? Surely, much of the workforce will be able to navigate the tool correctly, provided the tool was designed with use-ability in mind. The key reason for providing training is to gain ongoing support for using the tool in the future! Just as individuals need to understand the "why" of a policy, they also need to understand "why" they should take time to read the policies presented in the tool! This is a great opportunity to get middle management and line management involved in supporting the security program—use the opportunity to train-the-trainer by training management on the use of the tool. By doing so, management will be paying more attention to the training themselves, knowing that they will, in turn, have to train their staff (who wants to look foolish in front of their staff members?).

Recognizing that management personnel are also very busy and information security is one more thing on their list, there needs to be (1) structure around the training, (2) expected due dates, and (3) provided training materials. Some management personnel may feel comfortable creating their own training materials to shape their own message, but most will prefer to have something canned to which they can add specifics. Using this approach allows them to cover the material in a staff meeting without much preparation. The managers are also in the best position to tailor the "why this is important to us" message to their specific departmental needs. It also demonstrates their support for security versus having it always come from the Information Security Officer.

There are several training materials that should be constructed in advance of the training session by the Information Security department. These materials should be posted to the intranet and made available for management personnel to download themselves, thus reducing the time required by the Information Security department to distribute the information and making it available to management when they need it. It is also more efficient for the Information Security department to create one set of materials than to have each individual manager spend time creating his or her own. The essential training materials to roll out the policy deployment tool include:

- *PowerPoint presentation*: slides showing how policies are created, who is involved, and screen shots of the policy tool showing specific functionality, due dates for reading and accepting the policies, and future plans for deployment of policies.
- *Pamphlet*: a trifold pamphlet as a handy reference for using the tool. This is also useful for showing contact information of the Security department(s) to call for information security questions, password resets, and policy tool questions.
- *Acknowledgement form*: form stating that the training was received and also that they acknowledge that clicking on an acceptance button within the tool has the same effect as if they were to affix their written signature to the policy. These forms should be filed with Human Resources in their personnel file in the event that there is subsequent disciplinary action or termination resulting from violation of a security policy.
- *Training roster*: a sheet that the manager can have each employee sign to confirm that they have received the training. This information should be captured centrally within Human Resources to keep track of the security awareness training that the individual has received.
- *Give-aways*: what would security awareness training be without chocolate and give-aways? Mousepads, pens, monitor mirrors, mugs, and other tokens can be very useful, especially if the intranet Web address of the policy tool is imprinted on the token.
- *Notes*: a separate PowerPoint presentation set up to print the notes pages can be provided to help managers fill in the graphics and words on the slides.

By providing these tools, individual users have the benefit of receiving a consistent message and having it communicated from their own manager. Although the medium is electronic, training is still essential for the first rollout of the policies. This may very well be the first application with the organization that is distributed to all users and, as such, will represent change that needs to be appropriately managed.

37.3.8 Step 8: Rollout Policies in Phases

The first-phase rollout of policies to the end users will be the policies used in the pilot phase. A limited number of policies should be rolled out at this time, such as a password policy and policies indicating the roles of the various departments involved in creating the policies. For example, there could be a separate policy indicating the responsibility and authority of the overall security program and the executive sponsorship behind the policies. The roles of the Information Security department, Security Council, Information Technology Steering Committee, management, and the end users could be spelled out in separate policies. By having these as the first set of policies, it sets up the organizational and control structure for issuing future policies. It also sends the message that management is involved and behind the policies, and they are not solely products of the Information Security department.

The primary goal of the first phase is to lay this foundation for future policy rollouts and also to provide users with the opportunity to use the new tool. Users will have many questions using the technology itself during this phase, questions that should not be underestimated. They may be unable to get to the Web site due to problems with their log-in setup; they may have read the policy but not clicked the appropriate checkbox to accept the policy; or they may not understand a specific policy. Hopefully, these questions can be reduced through the train-the-trainer approach; however, there will still be questions on use-ability. By keeping the policy content "simple" at this stage, more attention can be given to helping users become familiar with the tool.

A six- to nine-month plan for the rollout of policies should be established so that they are not receiving all the policies at once. There is much information to be absorbed in the information security policies due to the breadth of organizational impact. Delivering these in bite-size pieces is more conducive to really having them understood within the organization. Sometimes, this is unavoidable, especially if they are the result of a focused-policy project. Policies should be grouped into these "phases" so that users are not receiving a policy too frequently (remember: they do have other work to do). Users will appreciate the grouping and, after a few phases, will come to understand that this is a normal, ongoing process.

When the policies are issued, an e-mail containing a link to the Web site and, if possible, directly to the specific policy should be included. Expectations of "compliance" of the policy should be stated, with a 30- to 45-day period to read, understand, and provide acceptance of the policy through the policy deployment tool. At least 30 days is necessary, as people may be on vacation, traveling, involved in some key time-sensitive projects, etc. As security professionals, we need to be sensitive to the fact that we think about security all the time, but end users have other jobs to perform. The timeframes depend on the culture of each organization.

37.3.9 Step 9: Track Compliance

This is arguably the key difference between utilizing a Web-based policy development tool versus placing the policies on a Web site with hyperlinks to each policy. The vendors of the products promote this capability as a key feature, and rightly so. When policies are simply placed on a Web site, e-mailed to new users, or distributed in paper binders, it becomes a very difficult job to ascertain who has read the policies, let alone received them. If the distributions are sent out by e-mail, many organizations still require that a signed document confirming that the documents have been read and accepted be sent back to the policy originator.

Policy deployment tools provide a much better way of tracking compliance by tracking the acceptance of the users in a database. Users are provided with assignments, provided a timeframe to complete, and then the tracking is housed within one integrated system. Additionally, because the information is being captured in a database, the tools also provide functionality to report on the current status of policy acceptance. This is useful after a rollout to see how fast the adoption rate is; that is, are people reviewing the policies right away, or is there a large number waiting until the last few days of the period? This can assist in future training to educate users that waiting until the final days of the period may cause unavailability problems of the Web site.

The compliance tracking process is not completely automatic, as there will be differences between the vendor product (generic) and the organizational structure (specific). For example, if there are multiple geographic locations within the company, an extra step may be needed to produce reports by geographic location and manager responsible, by relating the ID used in the policy tool to the human resources system (which contains the department/manager information). Alternatively, if the tool supports a data feed from the human resources system, and was set up with the department and a user role (supporting distribution of policies to only those users within that role), it may be necessary to relate the department to a manager outside the tool to produce the reports by manager. Depending upon the management reporting needs the out-of-the-box tool may not provide all the compliance reporting functionality needed. Fortunately, many of the products have an export option to pull the information in another product like Microsoft Access or Excel to manipulate the information.

There are other considerations in compliance tracking as well, such as disabled accounts showing up in the user reporting lists, system accounts, and if distribution lists were used to distribute the policies, how accurate are they and how are they maintained? Completeness of the user population being reported on must receive periodic verification to ensure that the policies are reaching everyone. If there are users within the organization who do not have access to computers, then kiosks where they can log into the system must be made available or their manager must take on the responsibility of printing the policies for their signature as a workaround. For compliance tracking to be complete, it would need to be known which users fall under the paper-based exception.

After the 30- to 45-day "acceptance period" has been completed for the policies, the initial compliance reports are run. It is a good practice to provide the compliance reports within one week of the end of the period to the management responsible. Management can then follow up with its employees on the lack of compliance. Reports can be run again after providing management a one-week turnaround to correct the situation. At this point, a second set of compliance reports is run, and organizational escalation procedures should take place by elevating the issue to senior management.

Some users may object to the policies as published, so the tool should provide the capability of providing these comments. Provided that the previous steps of management approval were followed prior to publishing the policy, it should be clear that the distributed policies are expected to be adhered to and complied with. Therefore, compliance tracking should expect 100 percent acceptance by the users of the policy (hence again stressing the importance of the management review before publishing). Compliance tracking should not have to be concerned with disagreements with the policy.

Once a few phases of policy rollouts have been completed, the process becomes a very effective and efficient way to track compliance to policies.

37.3.10 Step 10: Manage Ongoing Process for Policy Violations

The Web-based tool should support a mechanism for users to report security incidents so that as they become aware of violations of the policy, they have the capability to report the incident. This process can be very helpful in understanding where the exceptions to the policy are occurring, gaps in training, or missing procedures to support the policy. New procedures or changes to the policies can occur as a result of receiving information directly from those required to implement the policy. Although rigorous reviews may be done by management prior to publication, there still may be unanticipated circumstances that, upon further analysis, may require revision and republication of the policy.

Tracking numbers should be assigned within the tool to each reported incident with follow-ups occurring within a reasonable period of time (24–48 hours for first response). It may be necessary to supplement the Web-based tool with external tracking spreadsheets; however, if a tracking number is assigned, these items can be manageable. To some extent, this process could be considered a "security effectiveness monitoring" process for the policies themselves. The reporting of incidents provides a means to monitor whether or not people are following the policies.

37.4 Whew! … Ten Steps and We Are Done, Right?

One thing is that is very clear in policy development is that it is never done. However, once an organization has moved from "no policies" to a base set of security policies, procedures, standards, and guidelines and has executed the ten steps above, with multiple phased rollouts, the organization is 90 percent there in terms of policy development. In the paper-based policy world, policies can suffer from dust and obsolescence if they are not maintained, refreshed, and communicated properly. The same holds true for the "digital" world where policies exist electronically on the company intranet. Policies can get stale and may come out of sync with reality. Organizations go through many changes, such as mergers and acquisitions, connections with third-party business partners, outsourced services, adoption of new technologies, upgrades to existing technologies, new methods of security awareness training, new regulations that must be addressed, etc. Policies should be reviewed, at a minimum, annually to ensure that they are still appropriate for the organization. Upon each major organizational or technological change, policies that could be impacted should be identified and reviewed.

37.5 Final Thoughts

Paper will not be going away anytime soon. Dust is optional, and obsolescence can be replaced by a mechanism that provides current, relevant, updated information upon which the organization can rely. The key word here is "can," as moving the paper to an electronic format takes care of the dust problem but does little to change the obsolescence problem if policy creation is seen as a one-time thing to "get them out there quickly."

The Web-based policy deployment tools of the past few years have done a great job of providing an infrastructure for the communication and management of policies. If we think of the tool as a hammer, we need to remember that the hammer itself performs no work and makes no progress in building things unless there is a person using it to pound nails. People utilizing the review and approval processes are critical in the development of policy, whether the policies are paper based or electronically deployed. Using these tools does provide great benefit in the deployment of policies as discussed in the prior sections, such as providing support to large user bases, keeping the policies fresh, enabling periodic quizzing of the content, tracking compliance, controlling the timing of the review, and ensuring that users are seeing policies as appropriate to their job functions. The tools also provide great benefit to the end users by providing a mechanism for them to view up-to-date policies, submit security incidents, perform context searches, and follow the linkage to procedures, standards, and guidelines through navigating the Web site.

So, it is time to enter the dust-free environment, build the infrastructure, and never return to the binders with the nice tabs that few people see. Start small, start somewhere, just start. It is well worth the effort.

38

Roles and Responsibilities of the Information Systems Security Officer

Carl Burney

Information is a major asset of an organization. As with any major asset, its loss can have a negative impact on the organization's competitive advantage in the marketplace, a loss of market share, and become a potential liability to shareholders or business partners. Protecting information is as critical as protecting other organizational assets, such as plant assets (i.e., equipment and physical structures) and intangible assets (i.e., copyrights or intellectual property). It is the information systems security officer (ISSO) who establishes a program of information security to help ensure the protection of the organization's information.

The information systems security officer is the main focal point for all matters involving information security. Accordingly, the ISSO will:

- Establish an information security program including:
  - Information security plans, policies, standards, guidelines, and training
- Advise management on all information security issues
- Provide advice and assistance on all matters involving information security

38.1 The Role of The Information Systems Security Officer

There can be many different security roles in an organization in addition to the information system security officer, such as:

- Network security specialist
- Database security specialist
- Internet security specialist
- E-business security specialist
- Public key infrastructure specialist
- Forensic specialist
- Risk manager

Each of these roles is in a unique, specialized area of the information security arena and has specific but limited responsibilities. However, it is the role of the ISSO to be responsible for the entire information security effort in the organization. As such, the ISSO has many broad responsibilities, crossing all organizational lines, to ensure the protection of the organization's information.

38.2 Responsibilities of The Information Systems Security Officer

As the individual with the primary responsibility for information security in the organization, the ISSO will interact with other members of the organization in all matters involving information security, to include:

- Develop, implement, and manage an information security program.
- Ensure that there are adequate resources to implement and maintain a cost-effective information security program.
- Work closely with different departments on information security issues, such as:
  - The physical security department on physical access, security incidents, security violations, etc.
  - The personnel department on background checks, terminations due to security violations, etc.
  - The audit department on audit reports involving information security and any resulting corrective actions
- Provide advice and assistance concerning the security of sensitive information and the processing of that information.
- Provide advice and assistance to the business groups to ensure that information security is addressed early in all projects and programs.
- Establish an information security coordinating committee to address organization-wide issues involving information security matters and concerns.
- Serve as a member of technical advisory committees.
- Consult with and advise senior management on all major information security-related incidents or violations.
- Provide senior management with an annual state of information security report.

Developing, implementing, and managing an information security program is the ISSO's primary responsibility. The Information Security Program will cross all organizational lines and encompass many different areas to ensure the protection of the organization's information. Exhibit 38.1 contains a noninclusive list of the different areas covered by an information security program.

EXHIBIT 38.1 An Information Security Program Will Cover a Broad Spectrum

Policies, Standards, Guidelines, and Rules	Reports
Access controls	Risk management
Audits and reviews	Security software/hardware
Configuration management	Testing
Contingency planning	Training
Copyright	Systems acquisition
Incident response	Systems development
Personnel security	Certification/accreditation
Physical security	Exceptions

38.2.1 Policies, Standards, Guidelines, and Rules

- Develop and issue security policies, standards, guidelines, and rules.
- Ensure that the security policies, standards, guidelines, and rules appropriately protect all information that is collected, processed, transmitted, stored, or disseminated.
- Review (and revise if necessary) the security policies, standards, guidelines, and rules on a periodic basis.
- Specify the consequences for violations of established policies, standards, guidelines, and rules.
- Ensure that all contracts with vendors, contractors, etc. include a clause that the vendor or contractor must adhere to the organization's security policies, standards, guidelines, and rules, and be liable for any loss due to violation of these policies, standards, guidelines, and rules.

38.2.2 Access Controls

- Ensure that access to all information systems is controlled.
- Ensure that the access controls for each information system are commensurate with the level of risk, determined by a risk assessment.
- Ensure that access controls cover access by workers at home, dial-in access, connection from the Internet, and public access.
- Ensure that additional access controls are added for information systems that permit public access.

38.2.3 Audits and Reviews

- Establish a program for conducting periodic reviews and evaluations of the security controls in each system, both periodically and when systems undergo significant modifications.
- Ensure audit logs are reviewed periodically and all audit records are archived for future reference.
- Work closely with the audit teams in required audits involving information systems.
- Ensure the extent of audits and reviews involving information systems is commensurate with the level of risk, determined by a risk assessment.

38.2.4 Configuration Management

- Ensure that configuration management controls monitor all changes to information systems software, firmware, hardware, and documentation.
- Monitor the configuration management records to ensure that implemented changes do not compromise or degrade security and do not violate existing security policies.

38.2.5 Contingency Planning

- Ensure that contingency plans are developed, maintained in an up-to-date status, and tested at least annually.
- Ensure that contingency plans provide for enough service to meet the minimal needs of users of the system and provide for adequate continuity of operations.
- Ensure that information is backed up and stored off-site.

38.2.6 Copyright

- Establish a policy against the illegal duplication of copyrighted software.
- Ensure inventories are maintained for each information system's authorized/legal software.
- Ensure that all systems are periodically audited for illegal software.

38.2.7 Incident Response

- Establish a central point of contact for all information security-related incidents or violations.
- Disseminate information concerning common vulnerabilities and threats.
- Establish and disseminate a point of contact for reporting information security-related incidents or violations.
- Respond to and investigate all information security-related incidents or violations, maintain records, and prepare reports.
- Report all major information security-related incidents or violations to senior management.
- Notify and work closely with the legal department when incidents are suspected of involving criminal or fraudulent activities.
- Ensure guidelines are provided for those incidents that are suspected of involving criminal or fraudulent activities, to include:
  - Collection and identification of evidence
  - Chain of custody of evidence
  - Storage of evidence

38.2.8 Personnel Security

- Implement personnel security policies covering all individuals with access to information systems or having access to data from such systems. Clearly delineate responsibilities and expectations for all individuals.
- Ensure all information systems personnel and users have the proper security clearances, authorizations, and need-to-know, if required.

- Ensure each information system has an individual, knowledgeable about information security, assigned the responsibility for the security of that system.
- Ensure all critical processes employ separation of duties to ensure one person cannot subvert a critical process.
- Implement periodic job rotation for selected positions to ensure that present job holders have not subverted the system.
- Ensure users are given only those access rights necessary to perform their assigned duties (i.e., least privilege).

38.2.9 Physical Security

- Ensure adequate physical security is provided for all information systems and all components.
- Ensure all computer rooms and network/communications equipment rooms are kept physically secure, with access by authorized personnel only.

38.2.10 Reports

- Implement a reporting system, to include:
  - Informing senior management of all major information security related incidents or violations
  - An annual State of Information Security Report
  - Other reports as required (i.e., for federal organizations: OMB CIRCULAR NO. A-130, Management of Federal Information Resources)

38.2.11 Risk Management

- Establish a risk management program to identify and quantify all risks, threats, and vulnerabilities to the organization's information systems and data.
- Ensure that risk assessments are conducted to establish the appropriate levels of protection for all information systems.
- Conduct periodic risk analyses to maintain proper protection of information.
- Ensure that all security safeguards are cost-effective and commensurate with the identifiable risk and the resulting damage if the information was lost, improperly accessed, or improperly modified.

38.2.12 Security Software/Hardware

- Ensure security software and hardware (i.e., anti-virus software, intrusion detection software, firewalls, etc.) are operated by trained personnel, properly maintained, and kept updated.

38.2.13 Testing

- Ensure that all security features, functions, and controls are periodically tested, and the test results are documented and maintained.
- Ensure new information systems (hardware and software) are tested to verify that the systems meet the documented security specifications and do not violate existing security policies.

38.2.14 Training

- Ensure that all personnel receive mandatory, periodic training in information security awareness and accepted information security practices.
- Ensure that all new employees receive an information security briefing as part of the new employee indoctrination process.
- Ensure that all information systems personnel are provided appropriate information security training for the systems with which they work.
- Ensure that all information security training is tailored to what users need to know about the specific information systems with which they work.
- Ensure that information security training stays current by periodically evaluating and updating the training.

38.2.15 Systems Acquisition

- Ensure that appropriate security requirements are included in specifications for the acquisition of information systems.
- Ensure that all security features, functions, and controls of a newly acquired information system are tested to verify that the system meets the documented security specifications and does not violate existing security policies, prior to system implementation.
- Ensure that all default passwords are changed when installing new systems.

38.2.16 Systems Development

- Ensure information security is part of the design phase.
- Ensure that a design review of all security features is conducted.
- Ensure that all information systems security specifications are defined and approved prior to programming.
- Ensure that all security features, functions, and controls are tested to verify that the system meets the documented security specifications and does not violate existing security policies, prior to system implementation.

38.2.17 Certification/Accreditation

- Ensure that all information systems are certified/accredited, as required.
- Act as the central point of contact for all information systems that are being certified/accredited.
- Ensure that all certification requirements have been met prior to accreditation.
- Ensure that all accreditation documentation is properly prepared before submission for final approval.

38.2.18 Exceptions

- If an information system is not in compliance with established security policies or procedures, and cannot or will not be corrected:
  - Document:
- The violation of the policy or procedure

- The resulting vulnerability
- Any necessary corrective action that would correct the violation
- A risk assessment of the vulnerability.
  - Have the manager of the information system that is not in compliance document and sign the reasons for noncompliance.
  - Send these documents to the CIO for signature.

38.3 The Nontechnical Role of the Information Systems Security Officer

As mentioned, the ISSO is the main focal point for all matters involving information security in the organization, and the ISSO will:

- Establish an information security program.
- Advise management on all information security issues.
- Provide advice and assistance on all matters involving information security.

Although information security may be considered technical in nature, a successful ISSO is much more than a "techie." The ISSO must be a businessman, a communicator, a salesman, and a politician.

The ISSO (the businessman) needs to understand the organization's business, its mission, its goals, and its objectives. With this understanding, the ISSO can demonstrate to the rest of the management team how information security supports the business of the organization. The ISSO must be able to balance the needs of the business with the needs of information security.

At those times when there is a conflict between the needs of the business and the needs of information security, the ISSO (the businessman, the politician, and the communicator) will be able to translate the technical side of information security into terms that business managers will be better able to understand and appreciate, thus building consensus and support. Without this management support, the ISSO will not be able to implement an effective information security program.

Unfortunately, information security is sometimes viewed as unnecessary, as something that gets in the way of "real work," and as an obstacle most workers try to circumvent. Perhaps the biggest challenge is to implement information security into the working culture of an organization. Anybody can stand up in front of a group of employees and talk about information security, but the ISSO (the communicator and the salesman) must "reach" the employees and instill in them the value and importance of information security. Otherwise, the information security program will be ineffective.

38.4 Conclusion

It is readily understood that information is a major asset of an organization. Protection of this asset is the daily responsibility of all members of the organization, from top-level management to the most junior workers. However, it is the ISSO who carries out the long list of responsibilities, implementing good information security practices, providing the proper guidance and direction to the organization, and establishing a successful information security program that leads to the successful protection of the organization's information.

39

Organizing for Success: Some Human Resources Issues in Information Security

Jeffrey H. Fenton
James M. Wolfe

In a holistic view, information security is a triad of people, process, and technology. Appropriate technology must be combined with management support, understood requirements, clear policies, trained and aware users, and plans and processes for its use. While the perimeter is traditionally emphasized, threats from inside have received less attention. Insider threats are potentially more serious because an insider already has knowledge of the target systems. When dealing with insider threats, people and process issues are paramount. Also, too often, security measures are viewed as a box to install (technology) or a one-time review. Security is an ongoing process, never finished.

This chapter focuses on roles and responsibilities for performing the job of information security. Roles and responsibilities are part of an operationally excellent environment, in which people and processes, along with technology, are integrated to sustain security on a consistent basis. *Separation of responsibilities*, requiring at least two persons with separate job duties to complete a transaction or process end-to-end, or avoiding a conflict of interest, is also introduced as part of organizing for success. This concept originated in accounting and financial management; for example, not having the same person who approves a purchase also able to write a check. The principle is applied to several roles in information technology (IT) development and operations, as well as the IT system development life cycle. All these principles support the overall management goal to protect and leverage the organization's information assets.

39.1 Information Security Roles and Responsibilities

This section introduces the functional components of information security, from a role and responsibility perspective, along with several other IT and business functional roles. Information security is much more than a specialized function; it is everyone's responsibility in any organization.

39.1.1 The Business Process Owner, Information Custodian, and End User

The *business process owner* is the manager responsible for a business process such as supply-chain management or payroll. This manager would be the focal point for one or more IT applications and data supporting the processes. The process owner understands the business needs and the value of information assets to support them. The International Standard ISO 17799, Information Security Management, defines the role of the information asset owner responsible for maintaining the security of that asset.[1]

The *information custodian* is an organization, usually the internal IT function or an outsourced provider, responsible for operating and managing the IT systems and processes for a business owner on an ongoing basis. The business process owner is responsible for specifying the requirements for that operation, usually in the form of a service level agreement (SLA). While information security policy vests ultimate responsibility in business owners for risk management and compliance, the day-to-day operation of the compliance and risk mitigation measures is the responsibility of information custodians and end users.

End users interact with IT systems while executing business functional responsibilities. End users may be internal to the organization, or business partners, or end customers of an online business. End users are responsible for complying with information security policy, whether general, issue-specific, or specific to the applications they use. Educating end users on application usage, security policies, and best practices is essential to achieving compliance and quality.

In an era of budget challenges for the information security functions, the educated and committed end user is an information security force multiplier for defense-in-depth. John Weaver, in a recent essay, "Zen and Information Security,"[2] recommends turning people into assets. For training and awareness, this includes going beyond rules and alerts to make security "as second nature as being polite to customers," as Neal O'Farrell noted in his recent paper, "Employees: Your Best Defense, or Your Greatest Vulnerability?"[3] All users should be trained to recognize potential social engineering. Users should also watch the end results of the business processes they use. Accounting irregularities, sustained quality problems in manufacturing, or incorrect operation of critical automated temperature-control equipment could be due to many causes, including security breaches. When alert end users notice these problems and solve them in a results-oriented manner, they could identify signs of sabotage, fraud, or an internal hacker that technical information security tools might miss. End users who follow proper practices and alert management of suspicious conditions are as important as anti-virus software, intrusion detection, and log monitoring. Users who learn this holistic view of security can also apply the concepts to their homes and families.[4]

In today's environment, users include an increasing proportion of *non-employee* users, including temporary or contract workers, consultants, outsourced provider personnel, and business-partner representatives. Two main issues with non-employee users are non-disclosure agreements (NDAs) and the process for issuing and deleting computer accounts. Non-employee users should be treated as business partners, or representatives of business partners, if they are given access to systems on the internal network. This should include a written, signed NDA describing their obligations to protect sensitive information. In contrast with employees, who go through a formal human resources (HR) hiring and separation process, non-employee users are often brought in by a purchasing group (for temporary labor or consulting services), or they are brought in by the program manager for a project or outsourced activity. While a formal HR information system (HRIS) can alert system administrators to delete computer accounts when *employees* leave or transfer, *non-employees* who do not go through the

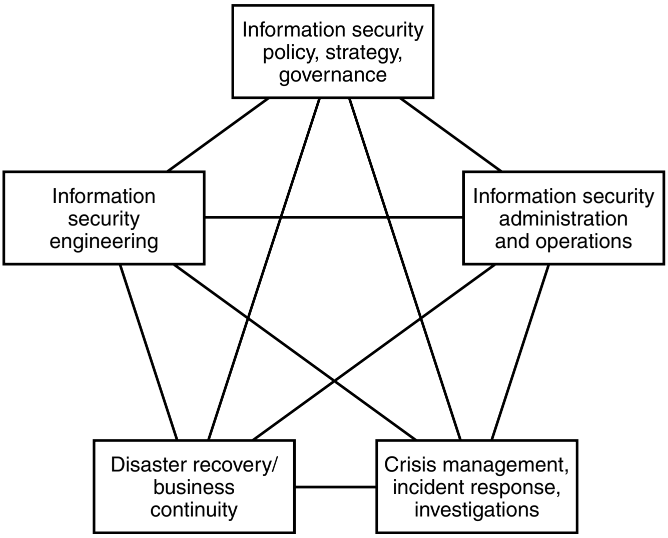
HRIS would not generate this alert. Removing computer accounts for departed non-employees is an weak operational link in many organizations.

39.1.2 Information Security Functions

Information security functions fall into five main categories—policy/strategy/governance, engineering, disaster recovery/business continuity (DR/BC), crisis management and incident response/investigation, and administrative/operational (see Exhibit 39.1). In addition, information security functions have many interfaces with other business functions as well as with outsource providers, business partners, and other outside organizations.

Information security policy, strategy, and governance functions should be organized in an information security department or directorate, headed by an information security manager or director who may also be known as the chief information security officer (CISO). This individual directs, coordinates, plans, and organizes information security activities throughout the organization, as noted by Charles Cresson Wood.[5] The information security function must work with many other groups within and outside the organization, including physical security, risk management (usually an insurance-related group in larger companies), internal audit, legal, internal and external customers, industry peers, research groups, and law enforcement and regulatory agencies.

Within the information security function, policy and governance include the development and interpretation of written information security policies for the organization, an education and awareness program for all users, and a formal approval and waiver process. Any deviation from policy represents a risk above the acceptable level represented by compliance with policy. Such deviations should be documented with a formal waiver approval, including the added risk and additional risk mitigation measures applied, a limited term, and a plan to achieve compliance. Ideally, all connections between the internal network and any outside entity should be consolidated as much as possible through one or a few gateways and demilitarized zones (DMZs), with a standard architecture and continuous monitoring. In very large organizations with decentralized business units, this might not be possible. When business units have unique requirements for external connectivity, those should be formally reviewed and approved by the information security group before implementation.



Information security policy, strategy, governance
Information security engineering
Information security administration and operations
Disaster recovery/ business continuity
Crisis management, incident response, investigations

EXHIBIT 39.1 Five information security roles.

The security strategy role, also in the central information security group, includes the identification of long-term technology and risk trends driving the evolution of the organization's security architecture. The information security group should develop a security technology roadmap, planning for the next five years the organization's need for security technologies driven by risk management and business needs. Once the roadmap is identified, the security group would be responsible for identifying and integrating the products to support those capabilities. Evaluating new products is another part of this activity, and a formal test laboratory should be provided. In larger IT organizations, the security strategy function would work closely with an overall IT strategy function. The information security group should have project responsibility to execute all security initiatives that affect the entire organization.

Information security engineering is the function of identifying security requirements and bringing them to realization when a specific network or application environment is newly developed. While the information security group would set the policies as part of the policy and governance function, security engineers would assess the risks associated with a particular program (such as implementing a new enterprise resource planning [ERP] system), identify the applicable policies, and develop a system policy for the system or application environment. Working through the system development life cycle, engineers would identify requirements and specifications, develop the designs, and participate in the integration and testing of the final product. Engineering also includes developing the operational and change-control procedures needed to maintain security once the system is fielded. Information security engineering may be added to the central information security group, or it may be organized as a separate group (as part of an IT systems engineering function).

Disaster recovery/business continuity (*DR/BC*) includes responding to and recovering from disruptive incidents. While DR involves the recovery of IT assets, BC is broader and includes recovery of the business functions (such as alternative office space or manufacturing facilities). While DR and BC began by focusing on physical risks to availability, especially natural disasters, both disciplines have broadened to consider typically non-physical events such as breaches of information confidentiality or integrity. Much of the planning component of DR/BC can utilize the same risk assessment methods as for information security risk assessments. In large organizations, the DR/BC group is often separate from the central information security group, and included in an operational IT function, because of DR's close relationship to computer operations and backup procedures. Because of the convergence of DR/BC applicability and methods with other information security disciplines, including DR/BC in the central information security group is a worthwhile option.

Crisis management is the overall discipline of planning for and responding to emergencies. Crisis management in IT began as a component of DR. With the broadening of the DR/BC viewpoint, crisis management needs to cover incident types beyond the traditional physical or natural disasters. For all types of incidents, similar principles can be applied to build a team, develop a plan, assess the incident at the onset and identify its severity, and match the response to the incident. In many organizations, the physical security and facilities functions have developed emergency plans, usually focusing on physical incidents or natural disasters, separate from the DR plans in IT. For this reason, an IT crisis management expert should ensure that IT emergency plans are integrated with other emergency plans in the organization. With the broadening of *crisis* to embrace non-physical information security incidents, the integrative role must also include coordinating the separate DR plans for various IT resources. During certain emergencies, while the emergency team is in action, it may be necessary to weigh information security risks along with other considerations (such as rapidly returning IT systems or networks to service). For this reason, as well as for coordinating the plans, the integrative crisis management role should be placed in the central information security group. Information security crisis management can also include working with the public relations, human resources, physical security, and legal functions as well as with suppliers, customers, and outside law enforcement agencies.

Incident response has already been noted as part of crisis management. Many information security incidents require special response procedures different from responding to a physical disaster. These procedures are closely tied to monitoring and notification, described in the next two paragraphs. An organization needs to plan for responding to various types of information security attacks and breaches, depending on their nature and severity. Investigation is closely related to incident response, because the response team must identify when an incident might require further investigation after service is restored. Investigation is fundamentally different in that it takes place after the immediate emergency is resolved, and it requires evidence collection and custody procedures that can withstand subsequent legal scrutiny. Along with this, however, the incident response must include the processes and technology to collect and preserve logs, alerts, and data for subsequent investigation. These provisions must be in place and operational before an incident happens. The investigation role may be centralized in the information security group, or decentralized in large organizations provided that common procedures are followed. If first-line investigation is decentralized to business units in a large corporation, there should be a central information security group specialist to set technical and process direction on incident response planning and investigation techniques. For all incidents and crises, the lessons learned must be documented—not to place blame but to prevent future incidents, improve the response, and help the central information security group update its risk assessment and strategy.

Information security administration and operations include account management, privilege management, security configuration management (on client systems, servers, and network devices), monitoring and notification, and malicious code and vulnerability management. These administrative and operational functions are diverse, not only in their content but also in who performs them, how they are performed, and where they reside organizationally. Account and privilege management include setting up and removing user accounts for all resources requiring access control, and defining and granting levels of privilege on those systems. These functions should be performed by a central security operations group, where possible, to leverage common processes and tools as well as to ensure that accounts are deleted promptly when users leave or transfer. In many organizations, however, individual system administrators perform these tasks. Security configuration management includes configuring computer operating systems and application software, and network devices such as routers and firewalls, with security functions and access rules. This activity actually implements much of the organization's security policy. While the central information security group owns the policy, configuration management is typically distributed among system administrators and telecommunication network administrators. This is consistent with enabling the central information security group to focus on its strategic, policy, and governance roles.

Monitoring and notification should also be part of a central security operations function, with the ability to "roll up" alerts and capture logs from systems and network devices across the enterprise. Intrusion detection systems (IDSs) would also be the responsibility of this group. In many large organizations, monitoring and notification are not well integrated, with some locally administered systems depending on their own system administrators who are often overworked with other duties. As noted earlier, monitoring and notification processes and tools must meet the needs of incident response. The additional challenges of providing 24/7 coverage are also noted below.

Malicious code and vulnerability management includes deploying and maintaining anti-virus software, isolating and remediating infected systems, and identifying and correcting security vulnerabilities (in operating systems, software applications, and network devices). These activities require centrally driven technical and process disciplines. It is not enough only to expect individual desktop users to keep anti-virus software updated and individual system administrators to apply patches. A central group should test and push anti-virus updates. The central group should also test patches on representative systems in a laboratory and provide a central repository of alerts and patches for system and network administrators to deploy. Malicious code management is also closely tied to incident response. With the advent of multifunctional worms, and exploits appearing quickly after vulnerabilities become known, an infection could easily occur before patches or anti-virus signatures become available. In some cases, anomaly-based IDSs can detect unusual behavior before patches and signatures are deployed, bringing malicious code and vulnerability management into a closer relationship with monitoring. These central activities cross several functional boundaries in larger IT organizations, including e-mail/messaging operations, enterprise server operations, and telecommunications, as well as security operations. One approach is establishing a cross-functional team to coordinate these activities, with technical leadership in the central information security organization.

39.1.3 Distributed Information Security Support in Larger Organizations

Some of the challenges of providing security support in a large organization, especially a large corporation with multiple business units, have already been noted. Whether IT functions in general are centralized or distributed reflects the culture of the organization as well as its business needs and technology choices. In any organization, presenting the business value of the information security functions is challenging. Beyond simply preventing bad things from happening, security is an enabler for E-business. To make this case, the central information security group needs to partner with the business as its internal customer. Building a formal relationship with the business units in a large enterprise is strongly recommended.

This relationship can take the shape of a formal information protection council, with a representative from each division or business unit. The representative's role, which must be supported by business unit management, would include bringing the unique technical, process, and people concerns of security, as viewed by that business unit, to the information security group through two-way communication. The representatives can also assist in security training and awareness, helping to push the program to the user community. Representatives can also serve in a first-line role to assist their business units with the approval and waiver requests described earlier.

39.1.4 Information Security Options for Smaller Organizations

The most important information security problem in many smaller organizations is the lack of an information security function and program. Information security must have an individual (a manager, director, or CISO) with overall responsibility. Leaving it to individual system administrators, without policy and direction, will ensure failure. Once this need is met, the next challenge is to scale the function appropriately to the size and needs of the business. Some of the functions, which might be separate groups in a large enterprise, can be combined in a smaller organization. Security engineering and parts of security operations (account and privilege management, monitoring and notification, incident response, crisis management, and DR) could be combined with the policy, governance, and user awareness roles into the central information security group. The hands-on security configuration management of desktops, servers, and network devices should still be the separate responsibility of system and network administrators. In the earlier discussion, the role of an in-house test laboratory, especially for patches, was noted. Even in a smaller organization, it is strongly recommended that representative test systems be set aside and patches be tested by a system administrator before deployment.

For smaller organizations, there are special challenges in security strategy. In a smaller enterprise, the security technology roadmap is set by technology suppliers, as the enterprise depends on commercial off-the-shelf (COTS) vendors to supply all its products. Whatever the COTS vendors supply becomes the *de facto* security strategy for the enterprise. To a great extent, this is still true in large enterprises unless they have a business case to, and have or engage the expertise to, develop some of their own solutions. While a large enterprise can exert some influence over its suppliers, and should develop a formal technology strategy, smaller enterprises should not overlook this need. If a smaller enterprise cannot justify a strategy role on a full-time basis, it could consider engaging external consultants to assist with this function initially and on a periodic review basis. Consultants can also support DR plan development. As with any activity in information security, doing it once is not enough. The strategy or the DR plan must be maintained.

39.1.5 Internal and External Audit

The role of auditors is to provide an independent review of controls and compliance. The central information security group, and security operational roles, should not audit their own work. To do so would be a conflict of interest. Instead, auditors provide a crucial service because of their independence. The central information security group should partner with the internal audit organization to develop priorities for audit reviews based on risk, exchange views on the important risks to the enterprise, and develop corrective action plans based on the results of past audits. The audit organization can recognize risks based on what it sees in audit results. External auditors may be engaged to provide a second kind of independent review. For external engagements, it is very important to specify the scope of work, including the systems to be reviewed, attributes to be reviewed and tested, and processes and procedures for the review. These ground rules are especially important where vulnerability scanning or penetration testing is involved.

39.1.6 Outsourcing Providers

Outsourcing providers offer services for a variety of information security tasks, including firewall management and security monitoring. Some Internet service providers (ISPs) offer firewall and VPN management. Outsourcing firewall management can be considered if the organization's environment is relatively stable, with infrequent changes. If changes are frequent, an outsourcing provider's ability to respond quickly can be a limiting factor. In contrast, 24/7 monitoring of system logs and IDSs can be more promising as an outsource task. Staffing one seat 24/7 requires several people. This is out of reach for smaller organizations and a challenge in even the largest enterprises. An outsourcing provider for monitoring can leverage a staff across its customer base. Also, in contrast with the firewall, where the organization would trust the provider to have privileged access to firewalls, monitoring can be done with the provider having no interactive access to any of the customer's systems or network devices. In all consulting and outsourcing relationships, it is essential to have a written, signed NDA to protect the organization's sensitive information. Also, the contract must specify the obligations of the provider when the customer has an emergency. If an emergency affects many of the same provider's customers, how would priority be determined?

39.1.7 To Whom Should the Information Security Function Report?

Tom Peltier, in a report for the Computer Security Institute,[6] recommends that the central information security group report as high as possible in the organization, at least to the chief information officer (CIO). The group definitely should *not* be part of internal audit (due to the potential for conflict of interest) or part of an operational group in IT. If it were part of an operational group, conflict of interest could also result. Peltier noted that operational groups' top priority is maintaining maximum system uptime and production schedules. This emphasis can work against implementing and maintaining needed security controls. The central information security group should also never be part of an IT system development group because security controls are often viewed as an impediment or an extra cost add-on to development projects. A security engineer should be assigned from the security engineering group to support each development project.

There are several issues around having the central information security group as part of the physical security organization. This can help with investigations and crisis management. The drawbacks are technology incompatibility (physical security generally has little understanding of IT), being perceived *only* as preventing bad things from happening (contrast with the business enabler viewpoint noted earlier), and being part of a group that often suffers budget cuts during difficult times. Tracy Mayor[7] presented a successful experience with a single organization combining physical security and information security. Such an organization could be headed by a chief security officer (CSO), reporting to the chief executive officer (CEO), placing the combined group at the highest level. The combined group could also include the risk management function in large enterprises, an activity usually focused on insurance risks. This would recognize the emerging role of insurance for information security risks. The model can work but would require cultural compatibility, cross-training, management commitment, and a proactive partnership posture with customers. Another alternative, keeping information security and physical security separate, is to form a working partnership to address shared issues, with crisis management as a promising place to begin. Similarly, the CISO can partner with the risk management function.

Although the DR/BC function, as noted earlier, might be part of an operational group, DR/BC issues should be represented to upper management at a comparable level to the CISO. The CISO could consider making DR/BC a component of risk management in security strategy, and partnering with the head of the DR/BC group to ensure that issues are considered and presented at the highest level. Ed Devlin has recommended[8] that a BC officer, equal to the CISO, reports at the same high level.

39.2 Filling the Roles: Remarks on Hiring Information Security Professionals

One of the most difficult aspects of information security management is finding the right people for the job. What should the job description say? Does someone necessarily need specific information security experience? What are the key points for choosing the best candidate? Answering these questions will provide a clearer picture of how to fill the role effectively.

Note: This section outlines several procedures for identifying and hiring job candidates. It is strongly recommended to review these procedures with your human resources team and legal advisors before implementing them in your environment.

39.2.1 Job Descriptions

A description of the position is the starting point in the process. This job description should contain the following:[9]

- The position title and functional reporting relationship
- The length of time the candidate search will be open
- A general statement about the position
- An explicit description of responsibilities, including any specific subject matter expertise required (such as a particular operating system or software application)
- The qualifications needed, including education
- The desired attributes wanted
- Job location (or telecommuting if allowed) and anticipated frequency of travel
- Start date
- A statement on required national security clearances (if any)
- A statement on requirements for U.S. citizenship or resident alien status, if the position is associated with a U.S. Government contract requiring such status
- A statement on the requirements for a background investigation and the organization's drug-free workplace policy.

Other position attributes that could be included are:

- Salary range
- Supervisor name
- Etc.

The general statement should be two to three sentences, giving the applicant some insight into what the position is. It should be an outline of sorts for the responsibilities section. For example:

General: The information security specialist (ISS) uses current computer science technologies to assist in the design, development, evaluation, and integration of computer systems and networks to maintain system security. Using various tools, the ISS will perform penetration and vulnerability analyses of corporate networks and will prepare reports that may be submitted to government regulatory agencies.

The most difficult part of the position description is the responsibilities section. To capture what is expected from the new employee, managers are encouraged to engage their current employees for input on the day-to-day activities of the position. This accomplishes two goals. First, it gives the manager a realistic view of what knowledge, skills, and abilities will be needed. Second, it involves the employees who will be working with the new candidate in the process. This can prevent some of the difficulties current employees encounter when trying to accept new employees. More importantly, it makes them feel a valued part of the process. Finally, this is more accurate than reusing a previous job description or a standard job description provided by HR. HR groups often have difficulty describing highly technical jobs. An old job description may no longer match the needs of a changing environment. Most current employees are doing tasks not enumerated in the job descriptions when they were hired.

Using the above general statement, an example of responsibilities might be:

- Evaluate new information security products using a standard image of the corporate network and prepare reports for management.
- Represent information security in the design, development, and implementation of new customer secured networks.
- Assist in customer support issues.
- Using intrusion detection tools; test the corporation's network for vulnerabilities.
- Assist government auditors in regulatory compliance audits.

39.2.2 Relevant Experience

When hiring a new security professional, it is important to ensure that the person has the necessary experience to perform the job well. There are few professional training courses for information security professionals. Some certification programs, such as the Certified Information System Security Professional (CISSP),[10] require experience that would not be relevant for an entry-level position. In addition, Lee Kushner noted, "… while certification is indeed beneficial, it should be looked on as a valuable enhancement or add-on, as opposed to a prerequisite for hiring."[11] Several more considerations can help:

- Current information security professionals on the staff can describe the skills they feel are important and which might be overlooked.
- Some other backgrounds can help a person transition into an information security career:
  - Auditors are already trained in looking for minute inconsistencies.
  - Computer sales people are trained to know the features of computers and software. They also have good people skills and can help market the information security function.
  - Military experience can include thorough process discipline and hands-on expertise in a variety of system and network environments. Whether enlisted or officer grade, military personnel are often given much greater responsibility (in numbers supervised, value of assets, and criticality of missions) than civilians with comparable years of experience.
  - A candidate might meet all qualifications except for having comparable experience on a different operating system, another software application in the same market space, or a different hardware platform. In many cases, the skills are easily transferable with some training for an eager candidate.
- A new employee might have gained years of relevant experience in college (or even in high school) in part-time work. An employee with experience on legacy systems may have critical skills difficult to find in the marketplace. Even if an employee with a legacy system background needs retraining, such an employee is often more likely to want to stay and grow with an organization. For a new

college graduate, extracurricular activities that demonstrate leadership and discipline, such as competing in intercollegiate athletics while maintaining a good scholastic record, should also be considered.

39.2.3 The Selection Process

Selecting the best candidate is often difficult. Current employees should help with interviewing the candidates. The potential candidates should speak to several, if not all, of the current employees. Most firms use interviews, yet the interview process is far from perfect. HR professionals, who have to interview candidates for many kinds of jobs, are not able to focus on the unique technical needs of information security. Any interview process can suffer from stereotypes, personal biases, and even the order in which the candidates are interviewed. Having current employees perform at least part of the interview can increase its validity.[12] Current employees can assess the candidate's knowledge with questions in their individual areas of expertise. Two additional recommendations are:

1. Making sure the interviews are structured with the same list of general questions for each candidate.
2. Using a candidate score sheet for interviewers to quantify their opinions about a candidate.

A good place to start is the required skills section and desired skills section of the position description. The required skills should be weighted about 70 percent of the score sheet, while the desired skills should be about 30 percent.

Filling an open position in information security can be difficult. Using tools like the position description[13] and the candidate score sheet (see Exhibit 39.2 and Exhibit 39.3) can make selecting a new employee much easier. Having current employees involved throughout the hiring process is strongly recommended and will make choosing the right person even easier.

Because information security personnel play a critical and trusted role in the organization, criminal and financial background checks are essential. Eric Shaw et al.[14] note that candidates should also be asked about past misuse of information resources. Resumes and references should be checked carefully. The same clearance procedures should apply to consultants, contractors, and temporary workers, depending on the access privileges they have. ISO 17799[15] also emphasizes the importance of these measures. Shaw and co-authors recommend working with HR to identify and intervene effectively when any employee (regardless of whether in information security) exhibits at-risk conduct. Schlossberg and Sarris[16] recommend repeating background checks annually for existing employees. HR and legal advisors must participate in developing and applying the background check procedures.

39.2.4 When Employees and Non-Employees Leave

The issue of deleting accounts promptly when users leave has already been emphasized. Several additional considerations apply, especially if employees are being laid off or any departure is on less than amicable terms. Anne Saita[17] recommends moving critical data to a separate database, to which the user(s) leaving does(do) not have access. Users leaving must be reminded of their NDA obligations. Saita further notes that the users' desktop computers could also contain backdoors and should be disconnected. Identifying at-risk behavior, as noted earlier, is even more important for the employees still working after a layoff who could be overworked or resentful.

39.3 Separation of Responsibilities

Separation of responsibilities, or segregation of duties, originated in financial internal control. The basic concept is that no single individual has complete control over a sequence of related transactions.[18] A 1977 U.S. federal law, the Foreign Corrupt Practices Act,[19] requires all corporations registering with the

EXHIBIT 39.2 Sample Position Description

Job Title: Information Security Specialist Associate
Pay Range: $40,000–$50,000 per year
Application Date: 01/25/03–02/25/03
Business Unit: Data Security Assurance
Division: Computing Services
Location: Orlando, FL
Supervisor: John Smith

General:

The Information Security Specialist Associate uses current computer science technologies to assist in the design, development, evaluation, and integration of computer systems and networks to maintain system security. Using various tools, the information security specialist associate will perform penetration and vulnerability analyses of corporate networks and will prepare reports that may be submitted to government regulatory agencies

Responsibilities:

- Evaluate new information security products using a standard image of the corporate network and prepare reports for management.
- Represent information security in the design, develop.ment, and implementation of new customer secured network.
- Assist in day-to-day customer support issues.
- Using intrusion detection tools, test the corporation's network for vulnerabilities.
- Provide security and integration services to internal and commercial customers.
- Build and maintain user data groups in the Win NT environment.
- Add and remove user Win NT accounts.
- Assist government auditors in regulatory compliance audits.

Required Education/Skills:

- Knowledge of Windows, UNIX, and Macintosh operating systems
- Understanding of current networking technologies, including TCP/IP and Banyan Vines
- Microsoft Certified Systems Engineer certification
- Bachelor's degree in computer science or relevant discipline

Desired Education/Skills:

- Two years of information security experience
- MBA
- CISSP certification

EXHIBIT 39.3 Candidate Score Sheet

Candidate Name:	**Fred Jones**
Date:	**1/30/2003**
Position:	**Information Security Specialist Associate**

Required Skill	Knowledge Level[a]	Multiplier	Score
OS knowledge	2	0.2	0.4
Networking knowledge	2	0.2	0.4
Bachelor's degree	3	0.2	0.6
MCSE	2	0.1	0.2
Desired skill			
InfoSec experience	0	0.1	0
MBA	2	0.1	0.2
CISSP	0	0.1	0
Total			1.8

Note: It is strongly recommended to review your procedures with your human resources team and legal advisors. Knowledge level × Multiplier = Score.

[a] Knowledge level: 0, Does not meet requirement; 1, Partially meets requirement; 2, Meets requirement; 3, Exceeds requirement.

Securities and Exchange Commission to have effective internal accounting controls. Despite its name, this law applies even if an organization does no business outside the United States.[20] When separation of duties is enforced, it is more difficult to defraud the organization because two or more individuals must be involved and it is more likely that the conduct will be noticed.

In the IT environment, separation of duties applies to many tasks. Vallabhaneni[21] noted that computer operations should be separated from application programming, job scheduling, the tape library, the help desk, systems programming, database programming, information security, data entry, and users. Information security should be separate from database and application development and maintenance, system programming, telecommunications, data management or administration, and users. System programmers should never have access to application code, and application programmers should not have access to live production data. Kabay[22] noted that separation of duties should be applied throughout the development life cycle so that the person who codes a program would not also test it, test systems and production systems are separate, and operators cannot modify production programs. ISO 17799 emphasizes[23] that a program developer or tester with access to the production system could make unauthorized changes to the code or to production data. Conversely, compilers and other system utilities should also not be accessible from production systems. The earlier discussion of system administration and security operations noted that account and privilege management should be part of a central security operations group separate from local system administrators. In a small organization where the same person might perform both these functions, procedures should be in place (such as logging off and logging on with different privileges) to provide some separation.[24]

Several related administrative controls go along with separation of duties. One control is requiring mandatory vacations each year for certain job functions. When another person has to perform a job temporarily, a fraud perpetrated by the regular employee might be noticed. Job rotation has a similar effect.[25] Another approach is dual control, requiring two or more persons to perform an operation simultaneously, such as accessing emergency passwords.[26]

Separation of duties helps to implement the principle of least privilege.[27] Each user is given only the minimum access needed to perform the job, whether the access is logical or physical. Beyond IT positions, every position that has any access to sensitive information should be analyzed for sensitivity. Then the security requirements of each position can be specified, and appropriately controlled access to information can be provided. When each position at every level is specified in this fashion, HR can focus background checks and other safeguards on the positions that truly need them. Every worker with access to sensitive information has security responsibilities. Those responsibilities should be made part of the job description[28] and briefed to the user annually with written sign-off.

39.4 Summary

This chapter has presented several concepts on the human side of information security, including:

- Information security roles and responsibilities, including user responsibilities
- Information security relationships to other groups in the organization
- Options for organizing the information security functions
- Staffing the information security functions
- Separation of duties, job sensitivity, and least privilege.

Security is a triad of people, process, and technology. This chapter has emphasized the people issues, the importance of good processes, and the need to maintain security continuously. The information security function has unique human resources needs. Attention to the people issues throughout the enterprise helps to avoid or detect many potential security problems. Building processes based on separation of duties and least privilege helps build in controls organic to the organization, making security part of the culture while facilitating the business. Secure processes, when understood and made part of each person's business, are a powerful complement to technology. When the organization thinks and acts securely, the job of the information security professional becomes easier.

Information Security Policies from the Ground Up

Brian Shorten

Security is people-based. As Bruce Schneier says in *Secrets & Lies*, "If you think technology can solve your security problems, then you don't understand the problems and you don't understand the technology." The first step in a coordinated security process is a security policy.

40.1 Reasons for a Policy

It cannot be stated too strongly that the security policy is the foundation on which all security is based. Ironically, when trying to introduce a policy, a security practitioner may encounter resistance from a senior management structure, which sees the one-off purchase of an anti-virus application as the solution to all security problems. In such circumstances, it follows that the security practitioner must explain to senior management the purpose of a policy.

A formal security policy, signed by the CEO, defines how the company intends to handle security and states that the company is not only concerned about security, but intends to take it seriously. Note the phrase "signed by the CEO." This is an important part of the overall process. It is vital that staff can see that there is management buy-in right from the top. Although sign-off from the security manager or director is good, it does not convey the same message. After all, as some staff members see it, the security manager or director is expected, and paid, to care about security.

So, what meaning does the policy put into words? The information security policy tells staff members what they CAN do, what they CANNOT do, what they MUST do, and what their RESPONSIBILITIES are.

40.2 What Should Be in a Policy

There are many books written on what should be contained in a policy. Some say that the policy should be short, a series of bulleted points covering only one side of a sheet of paper. Some even give examples, which can be adopted and modified for the practitioner's own company.

Although a short document may have more chance of being read by its intended audience, most of these samples are basically mission statements, which must still be supported by a more detailed policy. The author suggests that the mission statement be used as a personal foreword, signed by the CEO, to the policy.

40.3 Policy versus Procedures

A policy states what should be done. Procedures define how to implement the policy. For example, if the policy says, "All applications must have a password," the procedure would detail exactly how the password for each application is to be created and maintained.

40.4 Contents of the Policy

The following issues should be addressed by the policy.

40.4.1 Access Control Standards

Users should have access to the information and applications they require to perform their job functions, and no more. A discretionary access control policy must be implemented to provide users with that level of access. Users are responsible for managing the necessary changes to their passwords. Where possible, users will be automatically prompted to change their passwords every 30 days.

40.4.2 Accountability

It is important that users are held accountable for all actions carried out under their user IDs. Users must ensure that when they are away from their desks, their computer is in a secure state (i.e., the screen saver is activated with password protection, or in "lock workstation" mode).

40.4.3 Audit Trails

The actions carried out by users must be recorded and logged. Specifically, the following actions should be logged:

- A minimum of 30 days of user sign-on and sign-off details.
- All unauthorized attempts to read, write, and delete data and execute programs.
- Applications must provide detailed audit trails of data changes, when required by the business.

It is the data owner's responsibility to identify such audit trail requirements.

40.4.4 Backups

All software and user data will be backed up to alternative media on a regular basis and kept in a secure area. The frequency of the backups, which must be specified in the policy, will be appropriate to the importance of the system and the data that would need to be recovered in the event of a failure.

40.4.5 Business Continuity Plans

The tendency is to concentrate on information security systems when considering a business continuity plan (BCP). There should be a contingency plan for all computer services that support critical systems, and that plan should have been designed, implemented, and tested. The BCP should identify those services that are critical to the operation of the business, and ensure that contingency plans are in place. These contingency plans need to take into account a variety of disaster recovery scenarios.

40.4.6 Disposal of Media

The manner in which hardware and storage media—such as disk drives, floppy disks, and CD-ROMs that contain confidential data—are destroyed when no longer required must be carefully considered. An unauthorized person can retrieve data from media if it has not been obliterated correctly. Use of the ERASE, DELETE, and FORMAT functions is not sufficient. There are many freely available applications that can easily reverse these functions. Therefore, methods should be used that can overwrite media so data cannot be retrieved, or products should be used that degauss the media so data is obliterated and cannot be read. For confidential data, the media may require physical measures to render it unreadable—destroying hard drives with a hammer, shredding floppy disks, cutting CD-ROMs. The policy should lay down the agreed-to method for this disposal, depending on media type and the data in question.

40.4.7 Disposal of Printed Matter

Despite this being the age of the paperless office, many people prefer to print documents and write their comments. In such circumstances, it is easy to forget that the confidentiality of the printed data is unchanged by being printed—confidential data remains confidential. Once printed, these sheets containing confidential data must be disposed of carefully, and not in the nearest waste bin. All staff must have convenient access to a shredder. The shredder used must be cross-cut to reduce the chances that an unauthorized person, using sticky tape, could reconstruct the sheet.

40.4.8 Downloading from the Internet

Most businesses currently give their staff members access to the Internet. Although such access is usually intended for business use only, the security practitioner must ensure that the policy advises staff clearly on how that access is to be used, both to maximize the use of bandwidth and to prevent illegal acts from being carried out. The policy must state very clearly that Internet access is provided for business use only. Employees who have doubts as to what is correct business use should be advised to consult their line management for approval prior to accessing Internet information. Staff should be expressly forbidden to access, load, view, print, copy, or in any way handle obscene material from any source using company facilities.

40.4.9 Information Ownership

It is important that all data be assigned an owner who can make a decision as to who should be able to access that data. Because this decision is a business decision, the owner should be from the business and possess a good knowledge of business processes and the data.

40.4.10 Management Responsibilities

Managers, at all levels, have responsibilities for information security. These responsibilities may be mainly to ensure that all their staff members understand and comply with the policy, but such responsibilities need to be laid out in the policy itself to remove any misunderstanding. Each person holding a management or supervisory position is responsible for noting and reporting any deviations from the policy.

40.4.11 Modems and Analog Lines

Modems allow the use of an analog line, which circumvents the firewall and exchange gateway. Therefore, it follows that there is no anti-virus check on any data to and from the modem. Analog lines are now used by faxes, conference phones, and video phones. Some desk phones also require analog lines for the facilities they provide to users, such as voicemail. For these reasons, the security practitioner must ensure that the installation of analog lines for any use is prohibited unless prior authorization is given after the requestor has provided a business case for the line as full justification. It also follows that when a modem is in use, there must be no simultaneous connection to the company network, to prevent any computer virus from being “imported” to the network.

40.4.12 Off-Site Repairs to Equipment

Although most companies have an internal department to repair equipment, there are occasions when those repairs will need to either be sent off-site, or for a third party to come to the company to make repairs. It is vital to be sure who has access to company equipment and company data. If the data could be classified as confidential, it should be removed from any media before any non-company member of staff is allowed to work on the equipment.

40.4.13 Physical Security

Security is multi-layered; physical may be considered the first level of security. Although authorization and authentication processes control logical access, physical access security measures are required to protect against the threats of loss and damage to the computing-based equipment and information. All assets and materials are required to be protected from unauthorized use or removal, or damage, whether accidental or deliberate. The physical security policy of the company ensures that information systems, their peripherals, removable storage media, electrical services, and communications services are protected from unauthorized access and from damage as far as possible, consistent with a cost-efficient operation.

40.4.14 Portable Devices

The days are long gone when a PC was so heavy it could not easily be moved from a desk. Laptop computers are now as powerful as desktops, and create new problems because portability makes laptops easy to take out of the office, and easy to steal. Users must be made aware that such equipment issued to them is their responsibility, both in and out of the office. Not only can the laptop be stolen and therefore lost to the company, but any information on the laptop will also be lost or compromised if not encrypted. The security practitioner should always consider that the information may well have a higher value than the replacement cost of the laptop. For example, consider the information on the merger or takeover of one global company by another.

The security practitioner should also think about the growing use of various personal digital assistants (PDAs) such as PalmPilots, Psion organizers, etc. These are extremely vulnerable because they have a high value and are extremely portable. In addition, users often download documents from the company systems to a personal PDA for convenience; such equipment often does not have more than rudimentary security.

Users must be made aware that care of PDAs must be taken when traveling to avoid their loss or compromise, and that they must not be left unattended in public areas. When left in cars, houses, or hotel rooms, users must take all possible measures to ensure their security. As a method to persuade users to take care of laptops, a process should be used to request that laptop users confirm that they still have the laptop in their possession when they return to the office.

40.4.15 Staff Responsibilities

Just as managers have specific responsibilities by virtue of their positions, staff members also have responsibilities for security, the most fundamental of which is the protection of the company's information assets. For employees to carry out these responsibilities, they are required to:

- Understand and comply with the company's security policies.
- Know and follow all instructions for controlling access to, and use of, the company's computer equipment.
- Know and follow all instructions governing the secure handling of the company's information assets.
- Keep all passwords secret and be aware that they must never be given to anyone.
- Be aware that some actions are expressly forbidden for staff. Forbidden actions could include:
  - — Installing, executing, downloading, uploading, or in any other way introducing third-party software onto company computer equipment, or in any way changing, deleting, or reconfiguring the standard desktop without written authority (prior to the installation) from both the IT security department and the IT department.
  - — Abuse of any special account privileges that may have been granted to that staff member.
- Understand that each employee is responsible for noting and reporting any deviations from the company's security policy.

The security practitioner must ensure that all staff members realize that the computer equipment, software, and services provided by the company are for authorized business use only, and that staff members must not use the equipment for any other purpose unless authorized in writing to do so by their line manager. At this stage, staff members must be warned that violation of the security policy is deemed a serious offense and may result in disciplinary action.

40.4.16 Use of E-Mail

With so much of modern business dependent on e-mail, the security policy must ensure that the company's attitude toward staff members' use of e-mail is well-known. It should also be considered that, legally, an e-mail carries the same weight as a letter on company letterhead. In the recent past in the United Kingdom, an e-mail with a derogatory comment about a rival company was legally held to be the responsibility of the original company. In this case, the rival company sued the original company, despite the fact that the e-mail was initially between two employees, and not "official." The aggrieved company sued the original company, which had money for costs, rather than the employees, who had none.

Staff members must be made aware that the company provides internal mail and e-mail facilities for business use only. Many companies currently allow staff members to send and receive personal e-mails using the company system. In these circumstances, staff members must know that this is a concession that must not be abused, either by the number of e-mails sent or the time taken from the business day to deal with personal e-mails.

Such personal use must be at the discretion of the user's line manager.

As described, personal use of the company e-mail system may be permitted. However, provision should be made for monitoring or reviewing all e-mails into and out of the company. There are reasons why this may be necessary—the authorities may present a warrant to view e-mails as part of an investigation or the company itself may have the need to follow up on a fraud involving company systems and finances.

The security practitioner should also be aware of the decisions of recent legal findings on personal e-mail. If the policy says, "No personal e-mails sent or received," but the practice is that staff members do send and receive e-mails without any comment or censure from managers, the courts will be guided by the practice, rather than the policy, and find accordingly.

The policy should contain a clear warning to staff that no employee or user of the company e-mail system should have any expectation of privacy with respect to any electronic mail sent or received. The company may, at any time and without prior notification, monitor, review, audit, or control any aspect of the mail system, including individual accounts. It follows that this process should have built-in internal control processes that are subject to audit, to ensure that the ability to review e-mail is not abused.

The policy should address the contents of e-mails, and include reference to attachments to e-mails, which themselves may pose a risk to company systems. Such a reference could be:

- No computer software, files, data, or document that may give rise to violation of any policy, law, license agreement, or copyright law should be attached to or sent with any e-mail communication.
- Inappropriate use of the e-mail system(s) may result in disciplinary action. "Inappropriate use" is the dissemination of any text, software (or part thereof), or graphics (including moving graphics) that violate any company policy.
- In addition, any mail, the content of which is considered profane, sexist, racist, sexual, or in any way discriminatory to any minority, is also "inappropriate use."
- Employees are responsible for checking files received via e-mail for viruses and content.
- Any mail received by employees that breaches policy must be reported to the Security Department immediately.

40.4.17 Viruses

Despite the best efforts of the anti-virus industry, and IT and security professionals, computer viruses continue to be distributed globally. Staff members should be aware that they have a part to play in the anti-virus process, and that it is essential that any data files that come into the company are virus checked before being loaded to the data network. Any questions regarding virus checking should be directed to the Help Desk. Staff members should not be discouraged from reporting to management or the IT department if they believe they have detected a virus.

40.4.18 Workstation Security

There is a real threat to the security of systems when a user leaves a terminal logged in to a system and the terminal is left unattended; this terminal can then be used by an unauthorized person. In such a circumstance, the unauthorized person can use the terminal and access the system, just as if the authorized user were present, without having to know or guess the authorized user's sign-on or password. For this reason, users must be advised not to leave a terminal logged in, without use of a password-protected screen saver. Some systems may themselves have a process whereby inactivity of the keyboard or mouse will automatically prevent use of the terminal unless the authorized user enters a password. If such a process exists, the policy should be written to require its use. For a similar reason, users should not be allowed to be signed on to the same system at multiple terminals simultaneously.

40.4.19 Privacy

Although most companies do not have the resources, or the reason, to monitor e-mails on a regular basis, there will be occasions when it will be necessary to check the e-mail of a particular staff member. The security practitioner should prepare for that occasion by ensuring that the policy spells out the company's stance on privacy. An example of such a statement might be:

> No employee or user of the company mail system(s) should have any expectation of privacy with respect to any electronic mail sent or received. The company may, at any time without prior notification, monitor, review, audit or control any aspect of the mail systems, including individual accounts. This process has internal control processes and is subject to audit.

By using such a statement, staff members will then be aware that the facility to monitor e-mail exists, but that is bound by checks and balances.

40.4.20 Noncompliance

Having written a policy that specifies what behavior is expected of staff members, it is necessary for the security practitioner to ensure that the policy also contains a reference to the consequences of noncompliance. Such stated consequences may simply be that *non-compliance may result in disciplinary action*, which should suffice. Note the use of the word "may." This leaves management with various options for disciplinary action, which can run from a verbal warning to dismissal.

40.4.21 Legislation

With the increase in global trading, it is vital that security practitioners become conversant with the various legislation relevant to the different aspects of information security. This is becoming more and more vital as more and more companies operate on an international basis, having offices, staff, and customers in many countries. In this case, the policy must make reference to all relevant legislation, and include the relevant legislation for every location where the company has staff members who are expected to comply with the policy. For a company with offices throughout the world, this would be a separate appendix.

40.4.22 Other Issues

It is important to make the policy a document that can be utilized by staff members. To this end, the security practitioner must include separate appendices for choosing secure passwords and advice on good security practice. The security practitioner should consider that the overall security policy is an umbrella document that forms the basis of separate implementing security policies, while standards and baselines, which form the next level, can be application-specific.

The overall policy should not be too specific. Specifying "must have a password that meets current standards" is better than stating the exact size, format, and make-up of the password. After all, the company will have several applications requiring a password, and it is certain that different rules will apply in each case.

In addition, there are others in the company who have input to the process of creating the policy. The Legal department should be involved to ensure that the wording of the policy is correct; it is particularly important that the human rights legislation is taken into account, particularly in the sections covering staff responsibilities. The Human Resources department needs to confirm that the company disciplinary process is adequate for the task. If the policy specifies a disciplinary action for staff members who do not comply with the policy, there must be willingness on the part of the company, and the Human Resources department, to take that action—otherwise, the policy is useless.

The company's Data Protection Officer must be involved to ensure that the policy complies with the data protection legislation in all relevant countries.

40.5 The First Steps in Writing a Security Policy

In starting the process of creating a security policy, the security practitioner has several resources. The international standard ISO I7799, created by a group of international companies to form the basis of a security policy, started life as a guideline issued by the Department of Trade and Industry in the United Kingdom, then became a British Standard, BS 7799, before being adopted as ISO 17799. Professional peers, such as other security practitioners with the CISSP designation, can also offer advice and support. Books are also available for the security practitioner to consult.

The security practitioner has other considerations that are more allied with the culture and environment of the company concerned, particularly if this is the first policy for that company. This is where you need to consider the culture of the company.

The following gives a real-life example:

> The company, with 300 staff members, had one floor in a shared building and there had been problems with outsiders coming in and property being stolen. The first draft policy said, "all staff must wear the identity badge issued to them," and "all staff are to challenge anyone not known to them." This is not too excessive. However, because the CEO did not like all staff to wear an identity badge, because he himself felt self-conscious doing so, the policy was changed to "all staff must have an identity badge." Senior managers balked at challenging strangers because they said they would take forever to get to the bathroom in the morning. This section of the policy became, "if you see someone in your area who you don't recognize, you should query this with departmental managers or HR." In such cases, the security practitioner has to accept the culture, amend the first policy, and review it again in a few months. No surprise: the thefts of property continued.

The lesson for the security practitioner to learn here is that the policy must cover all staff members: if the policy says, "wear a badge," it sends the wrong signal if senior management and higher take the view that "everyone knows me" and leave their identity cards in their wallets.

Once the policy is drafted, the security practitioner must ensure that all interested parties are involved and invited to make comments. These parties are Legal, Audit, Human Resources, and Data Protection as previously mentioned, plus the IT department. Any member of the board who has shown an interest should also be included. After comments are invited, and any necessary changes made to the policy, the security practitioner should submit the policy to the board for acceptance and sign-off by the CEO.

It is important to cover all issues before submitting the draft. It should only be submitted to the board once for acceptance; having to make changes and return will only weaken the security practitioner's credentials as the company security guru.

40.6 The Next Steps

Once the policy is written, accepted by the board, and signed by the CEO, the security practitioner must ensure that the policy is read and accepted by staff members. There are various methods for this, all of which should be considered by the security practitioner; these include:

- Print enough copies for all staff members, and distribute them throughout the company.
- Have the Human Resources department send a copy to all new staff members with the new joiner details.
- E-mail a copy to all staff members.

- Place a copy on a server that all staff members can access, and e-mail the shortcut to all staff members.
- Place a copy on the company intranet and e-mail the shortcut to all staff members.
- Place posters advising staff members of the policy in staff refreshment areas.
- Issue mouse pads with security hints to all staff members.
- Use log-on banners for various applications that contain security advice.

However, having considered the several ways to communicate the policy to staff, security practitioners must be selective in their application to avoid having staff get so many copies that they switch off and ignore the message.

It is important to have staff agreements that they have read, and will comply with, the policy. These agreements will provide useful evidence should any staff members dispute the fact that they have read and understood the policy after having committed some act that contravenes the policy.

Whichever method the security practitioner selects to send the policy to staff, it is vital to receive back a signed document of agreement or a specific e-mail acknowledging acceptance of the policy. Either method of acceptance can be utilized. However, for the security practitioner, a form that the user can read, sign, and return is preferable. The form can then be kept by HR and constitute part of the staff member's file.

40.7 Reviewing the Policy

The security practitioner must remember that a security policy is a "living document" that must be reviewed regularly and updated as necessary. This should occur at least every six months. There are several issues to be addressed as part of the review, including:

- The policy must continue to be relevant. References to outdated equipment must be removed. The policy may refer to floppy disks although there are no PCs with floppy disk drives in the company.
- Processes may have changed. If the policy on computer viruses refers only to virus scanning floppy disks, although the company has moved to virus scanning on all servers and terminals, the policy needs to be updated.
- New technology may have been introduced since the policy was written.
- Senior managers may now be issued personal digital assistants (PDAs).

Once the policy has been reviewed and updated, it must be resubmitted to the board for acceptance and signed again by the CEO.

40.8 Staff Awareness

The security practitioner must be aware that although it is the responsibility of the security department to produce and maintain the security policy, security is a process that should involve all staff members. If staff members see security as something that is an obstacle to their work, they will not take on their proper responsibility, and worse, will go out of their way to find a work-around to any security measure they do not consider necessary.

The security practitioner needs staff members to understand why security is important, and that they themselves are being protected. A staff awareness process will follow the process discussed earlier. Again, care should be taken to be selective in their application to avoid reaching such overload that staff members switch off and ignore the message.

The security practitioner should remember that it is not possible to be everywhere at once; an educated staff can go a long way toward acting on the behalf of the practitioner.

Educated users are more likely to pick a good password, challenge a stranger, or lock the PC when going for coffee, if they are aware of the consequences of not doing so.

40.9 Conclusion

The security policy is the mainstay of security, and the security practitioner must remain aware of the different issues to be addressed—legal, physical, systems, staff education. The security practitioner must not only be aware of the issues, but must also become a master of them.

41
Policy Development

Chris Hare

This chapter introduces the reason why organizations write security policy. Aside from discussing the structure and format of policies, procedures, standards, and guidelines, this chapter discusses why policies are needed, formal and informal security policies, security models, and a history of security policy.

41.1 The Impact of Organizational Culture

The culture of an organization is very important when considering the development of policy. The workplace is more than just a place where people work. It is a place where people congregate to not only perform their assigned work, but to socialize and freely exchange ideas about their jobs and their lives.

It is important to consider this culture when developing policies. The more open an organization is, the less likely that policies with heavy sanctions will be accepted by the employees. If the culture is more closed, meaning that there is less communication between the employees about their concerns, policies may require a higher degree of sanctions. In addition, the tone, or focus, of the policy will vary from softer to harder.

Regardless of the level of communication, few organizations have their day-to-day operations precisely documented. This highly volatile environment poses challenges to the definition of policy, but it is even more essential to good security operations.

41.2 The History of Security Policy

Security policy is defined as the set of practices that regulate how an organization manages, protects, and assigns resources to achieve its security objectives. These security objectives must be tempered with the organization's goals and situation, and determine how the organization will apply its security objectives. This combination of the organization's goals and security objectives underlie the management controls that are applied in nearly all business practices to reduce the risks associated with fraud and human error.

Security polices have evolved gradually and are based on a set of security principles. While these principles themselves are not necessarily technical, they do have implications for the technologies that are used to translate the policy into automated systems.

41.2.1 Security Models

Security policy is a decision made by management. In some situations, that security policy is based on a security model. A security model defines a method for implementing policy and technology. The model is typically a mathematical model that has been validated over time. From this mathematical model, a policy is developed. When a model is created, it is called an informal security model. When the model has been mathematically validated, it becomes a formal model. The mathematics associated with the validation of the model is beyond the scope of this chapter, and will not be discussed. Three such formal security models are the Bell–LaPadula, Biba, and Clark–Wilson security models.

41.2.1.1 The Bell–LaPadula Model

The Bell–LaPadula, or BLP, model is a confidentiality-based model for information security. It is an abstract model that has been the basis for some implementations, most notably the U.S. Department of Defense (DoD) *Orange Book*. The model defines the notion of a secure state, with a specific transition function that moves the system from one security state to another. The model defines a fundamental mode of access with regard to read and write, and how subjects are given access to objects.

The secure state is where only permitted access modes, subject to object are available, in accordance with a set security policy. In this state, there is the notion of preserving security. This means that if the system is in a secure state, then the application of new rules will move the system to another secure state. This is important, as the system will move from one secure state to another.

The BLP model identifies access to an object based on the clearance level associated with both the subject and the object, and then only for read-only, read-write, or write-only access. The model bases access on two main properties. The *simple security property*, or *ss-property*, is for read access. It states that an object cannot read material that is classified higher than the subject. This is called "no read up." The second property is called the *star property*, or **-property*, and relates to write access. The subject can only write information to an object that is at the same or higher classification. This is called "no-write-down" or the "confinement property." In this way, a subject can be prevented from copying information from one classification to a lower classification.

While this is a good thing, it is also very restrictive. There is no discernment made of the entire object or some portion of it. Neither is it possible in the model itself to change the classification (read as downgrade) of an object.

The BLP model is a discretionary security model as the subject defines what the particular mode of access is for a given object.

41.2.1.2 The Biba Model

Biba was the first attempt at an integrity model. Integrity models are generally in conflict with the confidentiality models because it is not easy to balance the two. The Biba model has not been used very much because it does not directly relate to a real-world security policy.

The Biba model is based on a hierarchical lattice of integrity levels, the elements of which are a set of subjects (which are active information processing) and a set of passive information repository objects. The purpose of the Biba model is to address the first goal of integrity: to prevent unauthorized users from making modifications to the information.

The Biba model is the mathematical dual of BLP. Just as reading a lower level can result in the loss of confidentiality for the information, reading a lower level in the integrity model can result in the integrity of the higher level being reduced.

Similar to the BLP model, Biba makes use of the *ss-property* and the **-property*, and adds a third one. The *ss-property* states that a subject cannot access/observe/read an object of lesser integrity. The **-property* states that a subject cannot modify/write-to an object with higher integrity. The third property is the *invocation property*. This property states that a subject cannot send messages (i.e., logical requests for service) to an object of higher integrity.

41.2.1.3 The Clark–Wilson Model

Unlike Biba, the Clark–Wilson model addresses all three integrity goals:

1. Preventing unauthorized users from making modifications
2. Maintaining internal and external consistency
3. Preventing authorized users from making improper modifications

Note: Internal consistency means that the program operates exactly as expected every time it is executed. External consistency means that the program data is consistent with the real-world data.

The Clark–Wilson model relies on the well-formed transaction. This is a transaction that has been sufficiently structured and constrained as to be able to preserve the internal and external consistency requirements. It also requires that there be a separation of duty to address the third integrity goal and external consistency. To accomplish this, the operation is divided into sub-parts, and a different person or process has responsibility for a single sub-part. Doing so makes it possible to ensure that the data entered is consistent with that information which is available outside the system. This also prevents people from being able to make unauthorized changes.

Exhibit 41.1 compares the properties in the BLP and Biba models.

These formal security models have all been mathematically validated to demonstrate that they can implement the objectives of each. These security models are only part of the equation; the other part is the security principles.

EXHIBIT 41.1 BLP and Biba Model Properties

Property	BLP Model	Biba Model
ss-property	A subject cannot read/access an object of a higher classification (no-read-up)	A subject cannot observe an object of a lower integrity level
*-property	A subject can only save an object at the same or higher classification (no-write-down)	A subject cannot modify an object of a higher integrity level
Invocation property	Not used	A subject cannot send logical service requests to an object of higher integrity

41.2.2 Security Principles

In 1992, the Organization for Economic Cooperation and Development (OECD) issued a series of guidelines intended for the development of laws, policies, technical and administrative measures, and education. These guidelines include:

1. *Accountability*. Everyone who is involved with the security of information must have specific accountability for their actions.
2. *Awareness*. Everyone must be able to gain the knowledge essential in security measures, practices, and procedures. The major impetus for this is to increase confidence in information systems.
3. *Ethics*. The method in which information systems and their associated security mechanisms are used must be able to respect the privacy, rights, and legitimate interests of others.
4. *Multidisciplinary principle*. All aspects of opinion must be considered in the development of policies and techniques. These must include legal, technical, administrative, organizational, operational, commercial, and educational aspects.
5. *Proportionality*. Security measures must be based on the value of the information and the level of risk involved.
6. *Integration*. Security measures should be integrated to work together and establish defensive depth in the security system.
7. *Timeliness*. Everyone should act together in a coordinated and timely fashion when a security breach occurs.
8. *Reassessment*. Security mechanisms and needs must be reassessed periodically to ensure that the organization's needs are being meet.
9. *Democracy*. The security of the information and the systems where it is stored must be in line with the legitimate use and information transfer of that information.

In addition to the OECD security principles, some addition principles are important to bear in mind when defining policies. These include:

10. *Individual accountability*. Individuals are uniquely identified to the security systems, and users are held accountable for their actions.
11. *Authorization*. The security mechanisms must be able to grant authorizations for access to specific information or systems based on the identification and authentication of the user.
12. *Least privilege*. Individuals must only be able to access the information that they need for the completion of their job responsibilities, and only for as long as they do that job.
13. *Separation of duty*. Functions must be divided between people to ensure that no single person can a commit a fraud undetected.
14. *Auditing*. The work being done and the associated results must be monitored to ensure compliance with established procedures and the correctness of the work being performed.
15. *Redundancy*. This addresses the need to ensure that information is accessible when required; for example, keeping multiple copies on different systems to address the need for continued access when one system is unavailable.

16. *Risk reduction*. It is impractical to say that one can completely eliminate risk. Consequently, the objective is to reduce the risk as much as possible.

There are also a series of roles in real-world security policy that are important to consider when developing and implementing policy. These roles are important because they provide distinctions between the requirements in satisfying different components of the policy. These roles are:

1. *Originator*: the person who creates the information
2. *Authorizer*: the person who manages access to the information
3. *Owner*: may or may not be a combination of the two previous roles
4. *Custodian*: the user who manages access to the information and carries out the authorizer's wishes with regard to access
5. *User*: the person who ultimately wants access to the information to complete a job responsibility

When looking at the primary security goals—confidentiality, integrity, and availability—security policies are generally designed around the first two goals, confidentiality and integrity. Confidentiality is concerned with the privacy of, and access to, information. It also works to address the issues of unauthorized access, modification, and destruction of protected information. Integrity is concerned with preventing the modification of information and ensuring that it arrives correctly when the recipient asks for it.

Often, these two goals are in conflict due to their different objectives. As discussed earlier, the Bell–LaPadula model addresses confidentiality, which, incidentally, is the objective of the Trusted Computing Standards Evaluation Criteria developed by the U.S. Department of Defense.

The goal of integrity is defined in two formal security models: Biba and Clark–Wilson. There is no real-world security policy based on the Biba model; however, the objectives of the European ITSEC criteria are focused around integrity.

Availability is a different matter because it is focused on ensuring that the information is always available when needed. While security can influence this goal, there are several other factors that can positively and negatively influence the availability of the information.

The Chinese Wall policy, while not a formal security model per se, is worth being aware of. This policy sees that information is grouped according to information classes, often around conflicts of interest. People frequently need to have access to information regarding a client's inside operations to perform their job functions. In doing so, advising other clients in the same business would expose them to a conflict of interest. By grouping the information according to information classes, the provider cannot see other information about its client. The Chinese Wall is often used in the legal and accounting professions.

However, the scope of security policy is quite broad. To be successful, the security policy must be faithfully and accurately translated into a working technical implementation. It must be documented and specified unambiguously; otherwise, when it is interpreted by human beings, the resulting automated system may not be correct. Henceforth, it is absolutely essential that the definition of the policy be as specific as possible. Only in this manner is it possible for the translation of security policy to an automated implementation to be successful.

In addition, several policy choices must be made regarding the computing situation itself. These include the security of the computing equipment and how users identify themselves. It is essential to remember that confidentiality and integrity are difficult to combine in a successful security policy. This can cause implementation problems when translating from the written policy to an automated system. The organization's real-world security policy must reflect the organization's goals.

The policy itself must be practical and usable. It must be cost-effective, meaning that the cost of implementing the policy must not be higher than the value of the assets being protected. The policy must define concrete standards for enforcing security and describe the response for misuse. It must be clear and free of jargon, in order to be understood by the users. Above all, the policy must have the support of the highest levels of senior management. Without this, even the best security policy will fail.

It is also very important that the policy seek the right balance between security and ease of use. If one makes it too difficult for the users to get their jobs done, then one negatively impacts business and forces the users to find ways around the security implementation. On the other hand, if one leans too much to ease of use, one may impact the organization's security posture by reducing the level of available security.

41.3 Why Does One Need Policy?

People have understood the need for security for a long time. Ever since an individual has had something of value that someone else wanted, they associated security with the need for the protection of that asset. Most people are familiar with the way that banks take care of our money and important documents by using vaults and safety deposit boxes. If the banks did not have policies that demonstrated how they implement appropriate protection mechanisms, the pubic would lose faith in them.

Security itself has a long history, and computers have only recently entered that history. People have installed locks on their doors to make it more difficult for thieves to enter, and people use banks and other technologies to protect their valuables, homes, and families. The military has long understood the need to protect its information from the enemy. This has resulted in the development of cryptography to encode messages so that the enemy cannot read them.

Many security techniques and policies are designed to prevent a single individual from committing fraud alone. They are also used to ensure supervisory control in appropriate situations.

41.3.1 The Need for Controls

Policy is essential for the people in the organization to know what they are to do. There are a number of different reasons for it, including legislative compliance, maintaining shareholder confidence, and demonstrating to the employee that the organization is capable of establishing and maintaining objectives.

There are a number of legal requirements that require the development of policies and procedures. These requirements include the duty of loyalty and the duty of care. The duty of loyalty is evident in certain legal concepts, including the duty of fairness, conflict of interest, corporate opportunity, and confidentiality. To avoid a conflict of interest situation, individuals must declare any outside relationships that might interfere with the enterprise's interests. In the duty of fairness, when presented with a conflict of interest situation, the individual has an obligation to act in the best interest of all affected parties.

When presented with material inside information such as advance notices on mergers, acquisitions, patents, etc., the individual will not use it for personal gain. Failing to do so results in a breach of corporate opportunity.

These elements have an impact should there be an incident that calls the operation into question. In fact, in the United States, there are federal sentencing guidelines for criminal convictions at the senior executive level, where the sentence can be reduced if there are policies and procedures that demonstrate due diligence. That means that having an effective compliance program in place to ensure that the corporation's policies, procedures, and standards are in place can have a positive effect in the event of a criminal investigation into the company.

For example, the basic functions inherent in most compliance programs

- Establish policies, procedures, and standards to guide the workforce.
- Appoint a high-level manager to oversee compliance with the policies, procedures, and standards.
- Exercise due care when granting discretionary authority to employees.
- Ensure that compliance policies are being carried out.
- Communicate the standards and procedures to all employees.

- Enforce the policies, standards, and procedures consistently through appropriate disciplinary measures.
- Implement procedures for corrections and modification in case of violations.

The third element from a legal perspective is the Economic Espionage Act of 1996 in the United States. The EEA, for the first time, makes the theft of trade secret information a federal crime, and subjects criminals to penalties including fines, imprisonment, and forfeiture. However, the EEA also expects that the organization who owns the information is making reasonable efforts to protect that information.

In addition to the legal requirements, there are also good business reasons for establishing policies and procedures. It is a well-accepted fact that it is important to protect the information that is essential to an organization, just like it is essential to protect the financial assets.

This means that there is a need for controls placed on the employees, vendors, customers, and other authorized network users. With growing requirements to be able to access information from any location on the globe, it is necessary to have organizationwide set of information security policies, procedures, and standards in place.

With the changes in the computing environment from host-based to client/server-based systems, the intricacies of protecting the environment have increased dramatically. The bottom line then is that good controls make good business sense. Failing to implement good policies and procedures can lead to a loss in shareholder and market confidence in the company should there be an incident that becomes public.

In writing the policies and procedures, it is necessary to have a solid understanding of the corporation's mission, values, and business operations. Remember that policies and procedures exist to define and establish the controls required to protect the organization, and that security for security's sake is of little value to the corporation, its employees, or the shareholders.

41.3.2 Searching for Best Practices

As changes take place and business develops, it becomes necessary to review the policy and ensure that it continues to address the business need. However, it is also advisable for the organization to seek out relationships with other organizations and exchange information regarding their best practices. Continuous improvement should be a major goal for any organization. The review of best industry practices is an essential part of that industry improvement, as is benchmarking one organization against several others.

One organization may choose to implement particular policies in one way, while another does it in a completely different fashion. By sharing information, security organizations can improve upon their developed methods and maintain currency with industry.

There are a number of membership organizations where one can seek opinions and advice from other companies. These include the Computer Security Institute Public Working forums and the International Information Integrity Institute (I-4). There are other special-interest groups hosted by engineering organizations, such as the Association for Computing Machinery (ACM).

As in any situation, getting to that best practice, whether it be the manufacturing of a component or the implementation of a security policy, takes time.

41.4 Management Responsibilities

In the development and implementation of policy, management has specific responsibilities. These include a clear articulation of the policy, being able to live up to it themselves, communicating policy, and providing the resources needed to develop and implement it. However, management is ultimately responsible to the legislative bodies, employees, and shareholders to protect the organization's physical and information assets. In doing so, management has certain legal principles that it must uphold in the operation of the organization and the development of the policies that will govern how the organization works.

41.4.1 Duty of Loyalty

Employees owe to their employers a legal duty of honesty, loyalty, and utmost good faith, which includes the avoidance of conflict of interest and self-interest. In carrying out the performance of their day-to-day responsibilities, employees are expected to act at all times in their employers' best interest unless the responsibility is unlawful. Any deviation from this duty that places an employee's interest above the employer's can be considered a breach of the employee's duty of care, loyalty, or utmost good faith. Fiduciary employees will owe a higher standard of care than ordinary employees.

If a manager knows that an employee may be putting his or her own interest above that of the employer's, it is incumbent upon the manager to warn the employee, preferably in writing, of the obligation to the employer. The manager should also advise the employer of the situation to prevent her or him from also being held accountable for the actions of the employee.

41.4.2 Conflict of Interest

Conflict of interest can be defined as an individual who makes a decision with the full knowledge that it will benefit some, including himself, and harm others. For example, the lawyer who knowingly acts on behalf of two parties who are in conflict with each other, is a conflict of interest.

41.4.3 Duty of Care

The duty of care is where the officers owe a duty to act carefully in fulfilling the important tasks assigned to them. For example, a director shall discharge his or her duties with the care and prudence an ordinary person would exercise in similar circumstances, and in a manner that he or she believe is in the best interests of the enterprise.

Furthermore, managers and their subordinates have a responsibility to provide for systems security and the protection of any electronic information stored therein, even if they are not aware of this responsibility. This comes from the issue of negligence, as described in the Common Law of many countries.

Even if the organization does cause a problem, it may not be held fully responsible or liable. Should the organization be able to demonstrate that it:

- Took the appropriate precautions,
- Employed controls and practices that are generally used,
- Meets the commonly desired security control objectives,
- Uses methods that are considered for use in well-run computing facilities
- Used common sense and prudent management practices,

then the organization will be said to have operated with due care, as any other informed person would.

41.4.4 Least Privilege

Similar to its counterpart in the function role, the concept of least privilege means that a process has no more privilege than what it really needs in order to perform its functions. Any modules that require "supervisor" or "root" access (i.e., complete system privileges) are embedded in the kernel. The kernel handles all requests for system resources and permits external modules to call privileged modules when required.

41.4.5 Separation of Duties/Privilege

Separation of duties is the term applied to people, while separation of privilege is the systems equivalent. Separation of privilege is the term used to indicate that two or more mechanisms must agree to unlock a process, data, or system component. In this way, there must be agreement between two system processes to gain access.

41.4.6 Accountability

Accountability is being able to hold a specific individual responsible for his or her actions. To hold a person accountable, it must be possible to uniquely and effectively identify and authenticate that person. This means that an organization cannot hold an individual responsible for his or her actions if that organization does not implement a way to uniquely identify each individual. There are two major themes: (1) the identification and authentication of that individual when the user accesses the system; and (2) the validation that the individual initiated or requested a particular transaction.

41.4.7 Management Support for Policy

Management support is critical to the success of any initiative, be it the development of a new product or service, or the development of a policy. If senior management does not approve the intent behind the activity, then it will not be successful. This is not restricted to the development of the organization's security policy, but any activity. However, security policy can both raise and address significant issues in any organization. Obtaining management support is often the most difficult part of the planning process.

41.5 Planning for Policy

Planning and preparation are integral parts of policy, standards, and procedure development, but are often neglected. Included in the preparation process is all of the work that must be done. Policy lays out the general requirements to take; the standards define the tools that are to be used; and the procedures provide employees with the step-by-step instructions to accomplish it.

Well-written procedures never take the place of supervision, but they can take some of the more mundane tasks and move them out to the employees. Employees use policy to provide information and guidance in making decisions when their managers are not available. The policy should identify who is responsible for which activity.

An effective set of policies can actually help the organization achieve two key security requirements: separation of duties and rotation of assignments. No single individual should have complete control over a complete process from inception to completion. This is an element in protecting the organization from fraud.

Planning during policy development must include attention to security principles. For example, individuals who are involved in sensitive duties should be rotated through other assignments on a periodic basis. This removes them from sensitive activities, thereby reducing their attractiveness as a target. Rotation of duties can also provide other efficiencies, including job efficiency and improvement. The improvement aspect is achieved as the result of moving people through jobs so that they do not develop short-cuts, errors creeping into the work, or a decrease in quality.

Once the policies are established, it is necessary to define the standards that will be used to support those policies. These standards can include hardware, software, and communications protocols to who is responsible for approving them.

There is no point in progressing through these steps unless there is a communication plan developed to get the information out to the employees and others as appropriate. This is particularly important because management does not have the luxury of sitting down with every employee and discussing his or her responsibility. However, management does have a responsibility to communicate to every user in an ongoing fashion about the contents of the policy and the employee's responsibilities in satisfying it.

The ability to provide the information to the employees is an essential part of the development of the policies, standards, and procedures. Through these vehicles, the employees will understand how they should perform their tasks in accordance with the policies.

Part of the planning process involves establishing who will write the policies and related documents, who will review them, and how agreement on the information contained is reached. For example, there are a number of experts who are consulted when establishing how management's decision will be written to allow for subsequent implementation. These same experts work with writers, management, and members from the community of interest to ensure that the goals of the policy are realistic and achievable. In addition to these people who effectively write the policy, additional resources are required to ensure that the policies are reasonable. For example, Human Resources and Legal are among the other specialists who review the policy.

41.6 The Policy Management Hierarchy

There are essentially five layers in the policy management hierarchy. These are illustrated in Exhibit 41.2.

Legislation has an impact on the organization regardless of its size. The impact ranges from revenue and taxation, to handling export-controlled material. Legislation is established by government, which in turn often creates policy that may or may not be enacted in legislation.

The second layer—policy—references the policy that is developed by the organization and approved by senior management and describes its importance to the organization. Standards are derived from the policy. The standard defines specific, measurable statements that can be used to subsequently verify compliance.

The fourth layer—procedures—consists of step-by-step instructions that explain what the user must do to implement the policy and standards. The final layer—guidelines—identifies things that the organization would like to see its members do. These are generally recommendations; and while the standards are mandatory, guidelines are optional.

There may be one additional layer, which is inserted between the standards and the procedures. This layer addresses practices, which can be likened to a process. The standard defines what must be done; the practice defines why and how; while the procedures provide specific step-by-step instructions on the implementation. These documents are discussed later in this chapter, including their format and how to go about writing them.

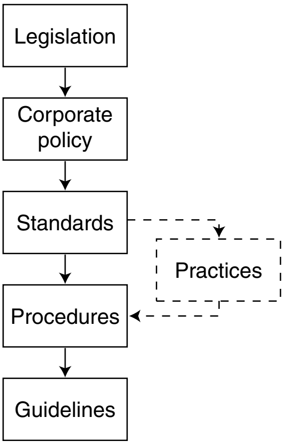

EXHIBIT 41.2 Policy management hierarchy.

41.7 The Types of Policy

There are three major classifications of policy, one of which has been discussed: regulatory, advisory, and informative. It is also important to note that an organization can define specific policies applicable to the entire organization, while individual departments may provide policy for themselves.

41.7.1 Regulatory

Regulatory policy is not often something that an organization can work around. Rather, they must work with them. Governments and regulatory and governing bodies that regulate certain professions, such as medicine and law, typically create this type of policy. In general, organizations that operate in the public interest, such as safety or the management of public assets, or that are frequently held accountable to the public for their actions, are users of regulatory policy.

This type of policy consists of a series of legal statements that describe in detail what must be done, when it must be done, who does it, and can provide insight as to why it is important to do it. Because large numbers of groups use these policies, they share the use and interpretation of these policies for their organizations. In addition to the common objectives of confidentiality, integrity, and availability (CIA), there are two premises used to establish regulatory policy.

The first is to establish a clearly consistent process. This is especially true for organizations involved with the general public, and they must show the uniformity with how regulations are applied without prejudice. Second, the policy establishes the opportunity for individuals who are not technically knowledgeable in the area to be sure that the individuals who are responsible are technically able to perform the task.

Regulatory policies often have exclusions or restrictions regarding their application. Frequently, regulatory policies are not effective when people must make immediate decisions based on the facts before them. This is because many situations present many different outcomes. Establishing a policy that is capable of addressing all possible outcomes results in a policy that is highly complex, difficult to apply, and very difficult to enforce.

41.7.2 Advisory

An advisory policy provides recommendations often written in very strong terms about the action to be taken in a certain situation or a method to be used. While this appears to be a contradiction of the definition of policy, advisory policy provides recommendations. It is aimed at knowledgeable individuals with information to allow them to make decisions regarding the situation and how to act.

Because it is an advisory policy, the enforcement of this policy is not applied with much effort. However, the policy will state the impact for not following the advice that is provided within the policy. While the specific impacts may be stated, the policy provides informed individuals with the ability to determine what the impacts will be should they choose an alternate course of action.

The impacts associated with not following the policy can include:

- Omission of information that is required to make an informed decision
- Failure to notify the correct people who are involved in making the decision or complete the process
- Missing important deadlines
- Lost time in evaluating and discussing the alternatives with auditors and management

It is important to consider that the risks associated with not following the advisory policy can be significant to the organization. The cost of lost productive time due to the evaluation of alternatives and discussions alone can have a significant impact on the organization, and on determining the validity and accuracy of the process.

Advisory policies often have specific restrictions and exclusions. For example, the advisory policy may set out that latitude in determining the course of action can only be extended to experienced individuals, while less-experienced persons must follow the policy as defined, with little opportunity for individual decision making. It is also important that any exceptions to the policy be documented and what is to be done when those situations are encountered.

41.7.3 Informative

The third type of policy is informative in nature, the purpose of which is to communicate information to a specific audience. That audience is generally any individual who has the opportunity or cause to read the policy. This policy implies no actions or responsibilities on the part of the reader and no penalty is imposed for not following the policy.

Although informative policies typically carry less importance than regulatory or advisory policies, they can carry strong messages about specific situations to the audience. Due to the wide audience intended for informational policies, references to other, more specific policies are made to provide even more information. This means that the distribution of the informative policies can be conducted with little risk to the organization, keeping policies that contain more sensitive information for a limited distribution.

41.7.4 Corporate versus Departmental

The only difference between corporate and departmental policy is the scope. For example, the organization may specify policy regarding how customer interactions will be handled. Specific organizations may choose to define policy about how to handle customer interactions specific to that department. There is no other difference other than the corporate or organizational policy applies to the entire organization, while departmental policy is specific to only that department. With the scope being narrowed, the process of reviewing and approving the policy can be much shorter due to the reduced number of people that must review it and express their opinions about it.

41.7.5 Program versus Topic Policy

Aside from these major policy types, it is important to make the distinction between program and topic policy. Program policy is used to create an organization’s overall security vision, while topic-specific policies are used to address specific topics of concern. In addition to the topic policies are application-specific policies that are used to protect specific applications or systems.

41.8 Writing Policy

Having examined the different types of policy, the importance of management support and communication of the new policy, and why policy is needed in an organization, we now turn to the process of writing policy for the organization.

41.8.1 Topics

Every organization must develop a basic set of policies. These can normally be found as a document prepared by the organization and can be used by an information security professional to reinforce the message as needed. Policy is the result of a senior management decision regarding an issue. Consequently, there is a wide range of topics available. These include:

1. Shared beliefs
2. Standards of conduct

3. Conflict of interest
4. Communication
5. Electronic communication systems
6. Internet security
7. Electronic communication policy
8. General security policy
9. Information protection policy
10. Information classification

This is not an all-inclusive list, but is intended to identify those areas that are frequently targeted as issues. It is not necessary to identify all of the policy topic areas before getting started on the development. It is highly likely that one policy may make reference to another organizational policy, or other related document.

There is a specific format that should be used in any policy, but it is important that if there are already policies developed in an organization, one must make the new policies resemble the existing ones. This is important to ensure that when people read them, they see them as policy. If a different style is used, then it is possible that the reader might not associate them with policy, despite the fact that it is identified as a policy.

41.8.1.1 The Impact of Security Principles on Policy Development

The organization should select some quantity of security principles that are important to it. When developing policies and related documents, the chosen principles should be reconsidered from time to time, and a review of the correlation of the policy (or standard, procedure, and guidelines) to the chosen principles should be performed. This can easily be done through the implementation of a matrix as shown in Exhibit 41.3.

In the matrix, the desired principles are listed across the top of the matrix, and the policy statements are listed down the left-hand column. An “X” is marked in the appropriate columns to illustrate the relationship between the principle and the policy statement. By correlating the principles to the policy (or policy components), the policy writer can evaluate their success. This is because the principles should be part of the objectives or mission of the organization. If there is a policy or component that does not address any principles, then that policy or component should be reviewed to see if it is really necessary, or if there is a principle that was not identified as required. By performing this comparison, the policy writer can make changes to the policy while it is under development, or make recommendations to senior management regarding the underlying principles.

41.8.2 Policy Writing Techniques

When writing the policy, it is essential that the writer consider the intended audience. This is important because a policy that is written using techniques that are not understood by the intended audience will result in confusion and misinterpretation by that audience.

41.8.2.1 Language

Using language that is appropriate to the intended audience is essential. The language must be free of jargon and as easy to understand as possible. The ability of the user community to understand the policy

EXHIBIT 41.3 Reviewing Principles while Developing Policies

Policy Statement	Principle 1	Principle 2
Entire policy statement	If this principle applies, then put an X in this column	If this principle applies, then put an X in this column

allows them to determine what their responsibilities are and what they are required to do to follow the policy. When the policy is written using unfamiliar language, misinterpretations regarding the policy result.

41.8.2.2 Focus

Stay focused on the topic that is being addressed in the policy. By bringing in additional topics and issues, the policy will become confusing and difficult to interpret. An easy rule of thumb is that for each major topic, there should be one policy. If a single policy will be too large (i.e., greater than four pages), then the topic area should be broken down into sub-topics to ensure that it focuses on and covers the areas intended by management.

41.8.3 Format

Policy is the cornerstone of the development of an effective information security architecture. The policy statement defines what the policy is, and is often considered the most effective part of the policy. The goal of an information security policy is to maintain the integrity, confidentiality, and availability of information resources. The basic threats that can prevent an organization from reaching this goal include theft, modification, destruction, or disclosure, whether deliberate or accidental.

The term "policy" means different things to different people. Policy is management's decision regarding an issue. Policy often includes statements of enterprise beliefs, goals, and objectives, and the general means for their attainment in a specified subject area.

A policy statement itself is brief and set at a high level. Because policies are written at a high level, supporting documentation must be developed to establish how employees will implement that policy. Standards are mandatory activities, actions, rules, or regulations that must be performed in order for the policy to be effective.

Guidelines, while separate documents and not included in the policy, are more general statements that provide a framework on which procedures are based. While standards are mandatory, guidelines are recommendations. For example, an organization could create a policy that states that multi-factor authentication must be used, and in what situations. The standard defines that the acceptable multi-factor authentication tools include specific statements regarding the accepted and approved technologies.

Remember that policies should:

1. Be easy to understand
2. Be applicable
3. Be do-able
4. Be enforceable
5. Be phased in
6. Be proactive
7. Avoid absolutes
8. Meet business objectives

Writing policy can be both easy and difficult at the same time. However, aside from working with a common policy format, the policy writer should remember the attributes that many journalists and writers adhere to:

- *What*. What is the intent of the policy?
- *Who*. Who is affected? What are the employee and management responsibilities and obligations?
- *Where*. Where does the policy apply? What is the scope of the policy?
- *How*. What are the compliance factors, and how will compliance be measured?
- *When*. When does the policy take effect?
- *Why*. Why is it necessary to implement this policy?

In considering the policy attributes, it is easier for the policy writer to perform a self-evaluation of the policy before seeking reviews from others. Upfront self-assessment of the policy is critical. By performing the self-assessment, communication and presentation of the policy to senior management will be more successful. Self-assessment can be performed in a number of ways, but an effective method is to compare the policy against the desired security principles.

It is important for the policy writer to ascertain if there are existing policies in the organization. If so, then any new policies should be written to resemble the existing policies. By writing new policies in the existing format, organization members will recognize them as policies and not be confused or question them because they are written in a different format.

A recommended policy format includes the following headings:

- *Background*: why the policy exists
- *Scope*: who the policy affects and where the policy is required
- *Definitions*: explanations of terminology
- *References*: where people can look for additional information
- *Coordinator/Policy Author*: who sponsored the policy, and where do people go to ask questions
- *Authorizing Officer*: who authorized the policy
- *Effective Date*: when the policy takes effect
- *Review Date*: when the policy gets reviewed
- *Policy Statements*: what must be done
- *Exceptions*: how exceptions are handled
- *Sanctions*: what actions are available to management when a violation is detected

While organizations will design and write their policies in a manner that is appropriate to them, this format establishes the major headings and topic areas within the policy document. The contents of these sections are described later in this chapter in the section entitled “Establishing a Common Format.”

41.9 Defining Standards

Recall that a standard defines what the rules are to perform a task and evaluate its success. For example, there is a standard that defines what an electrical outlet will look like and how it will be constructed within North America. As long as manufacturers follow the standard, they will be able to sell their outlets; and consumers will know that if they buy them, their appliances will fit in the outlet.

The definition of a standard is not easy because implementation of a standard must be validated regularly to ensure that compliance is maintained. Consider the example of an electrical outlet. If the manufacturing line made a change that affected the finished product, consumers would not be able to use the outlet, resulting in lost sales, increased costs, and a confused management, until the process was evaluated against the standards.

Consequently, few organizations actually create standards unless specifically required, due to their high implementation and maintenance costs.

A recommended format for standards documents includes the following headings:

- *Background*: why the standard exists
- *Scope*: who requires the standard and where is it required
- *Definitions*: explanations of terminology
- *References*: where people can look for additional information
- *Coordinator/Standards Author*: who sponsored the standard, and where do people go to ask questions

- *Authorizing Officer*: who authorized the standard
- *Effective Date*: when the standard takes effect
- *Review Date*: when the standard gets reviewed
- *Standards Statements*: what the measures and requirements are

While organizations will design and write their standards in a manner that is appropriate to them, this format establishes the major headings and topic areas within the policy document.

It is important to emphasize that while the standard is important to complete, its high cost of implementation maintenance generally means that the lifetime, or review date, is at least five years into the future.

41.10 Defining Procedures

Procedures are as unique as the organization. There is no generally accepted approach to writing a procedure. What will determine how the procedures look in the organization is either the standard that has been developed previously or an examination of what will work best for the target audience. It can be said that writing the procedure(s) is often the most difficult part, due to the amount of detail involved.

Due to the very high level of detail involved, writing a procedure often requires more people than writing the corresponding documents. Consequently, the manager responsible for the development of the procedure must establish a team of experts, such as those people who are doing the job now, to document the steps involved. This documentation must include the actual commands to be given, any arguments for those commands, and what the expected outcomes are.

There are also several styles that can be used when writing the procedure. While the other documents are written to convey management's desire to have people behave in a particular fashion, the procedure describes how to actually get the work done. As such, the writer has narrative, flowchart, and play script styles from which to choose.

The narrative style presents information in paragraph format. It is conversational and flows nicely, but it does not present the user with easy-to-follow steps. The flowchart format provides the information in a pictorial format. This allows the writer to present the information in logical steps. The play script style, which is probably used more than any other, presents step-by-step instructions for the user to follow.

It is important to remember that the language of the procedure should be written at a level that the target audience will be able to understand. The key procedure elements as discussed in this chapter are identifying the procedure needs, determining the target audience, establishing the scope of the procedure, and describing the intent of the procedure.

A recommended format for procedure documents includes the following headings:

- *Background*: why the procedure exists, and what policy and standard documents it is related to
- *Scope*: who requires the procedure and where is it required
- *Definitions*: explanations of terminology
- *References*: where people can look for additional information
- *Coordinator/Procedure Author*: who sponsored the procedure, and where do people go to ask questions
- *Effective Date*: when the procedure takes effect
- *Review Date*: when the standard gets reviewed
- *Procedure Statements*: what the measures and requirements are

While organizations will design and write their procedures in a manner that is appropriate to them, this format establishes the major headings and topic areas within the policy document.

41.11 Defining Guidelines

Guidelines, by their very nature, are easier to write and implement. Recall that a guideline is a set of nonbinding recommendations regarding how management would like its employees to behave. Unlike the other documents that describe how employees must perform their responsibilities, employees have the freedom to choose what guidelines, if any, they will follow. Compliance with any guideline is totally optional.

Policy writers often write the guidelines as part of the entire process. This is because as they move through the documents, there will be desired behaviors that cannot be enforced, but are still desired nonetheless. These statements of desired behavior form the basis for the guidelines.

Similar to the other documents, a recommended format for guideline documents includes the following headings:

- *Background*: why the guideline exists, and what policy and standard documents it is related to
- *Scope*: who requires guidelines and where are they required
- *Definitions*: explanations of terminology
- *References*: where people can look for additional information
- *Coordinator/Guidelines Author*: who sponsored the guidelines, and where do people go to ask questions
- *Effective Date*: when the standard guidelines take effect
- *Review Date*: when the standard guidelines get reviewed
- *Standards Statements*: what the measures and requirements are

Unlike the other documents, it is not necessary to have an approver for a guideline. As it is typically written as part of a larger package, and due to its nonbinding nature, there is no approving signature required.

41.12 Publishing the Policy

With the documents completed, they must be communicated to the employees or members of the organization. This is done through an employee policy manual, departmental brochures, and online electronic publishing. The success of any given policy is based on the level of knowledge that the employees have about it. This means that employees must be aware of the policy. For this to happen, the organization must have a method of communicating the policy to the employees, and keeping them aware of changes to the policy in the future.

41.12.1 Policy Manual

Organizations have typically chosen to create policy manuals and provide a copy to each individual. This has been effective over time because the policies were immediately available to those who needed to refer to them. However, other problems, such as maintenance of the manuals, became a problem over time. As new updates were created, employees were expected to keep their manuals updated. Employees would receive the updated manual, but due to other priorities would not keep their manuals up-to-date. This resulted in confusion when an issue arose that required an examination of policy.

Even worse, organizations started to see that the high cost of providing a document for each member of the organization was having a negative effect on their profit lines. They began to see that they were getting little value from their employees for the cost of the manuals. Consequently, organizations began to use electronic publishing of their policies as their communication method.

41.12.2 Departmental Brochures

Not all policies are created for the entire organization. Individual department also had to create policies that affected their individual areas. While it was possible to create a policy manual for the department, it was not practical from an expense perspective. Consequently, departments would create a brochure with the policies that pertained only to their area.

41.12.3 Putting the Policy Online

With the growth of the personal computer and the available access to the information online, more and more organizations have turned to putting the policies online. This has allowed for increased speed in regard to getting new policies and updates communicated to employees.

With the advent of the World Wide Web as a communication medium, organizations are using it *as the* method of making policies available. With hyperlinks, they can link to other related documents and references.

41.12.4 Awareness

However, regardless of the medium used to get the information and policies to the employees, they must be made aware of the importance of remaining up-to-date with the policies that affect them. And even the medium must be carefully selected. If all employees do not have access to a computer, then one must provide the policies in printed form as well. An ongoing awareness program is required to maintain the employee's level of knowledge regarding corporate policies and how they affect the employee.

41.13 Establishing a Common Format

A common format makes it easier for readers to understand the intent of the policy and its supporting documents. If there have been no previous written policies or related documents, creating a common format will be simple. If there is an existing format used within an organization, it becomes more difficult. However, it is essential that the writer adapt the layout of written documents to match that, which is already in use. Doing so will ensure that the reader recognizes the document for what it is, and understands that its contents are sanctioned by the organization. The format and order of the different sections was presented earlier in the chapter, but is repeated here for conciseness:

- *Background* (all)
- *Scope* (all)
- *Definitions* (all)
- *References* (all)
- *Coordinator/Document Author* (all)
- *Authorizing Officer* (policy, standard, procedure)
- *Effective Date* (all)
- *Review Date* (all)
- *Disposal* (all)
- *Document Statements* (all)
- *Exceptions* (policy)
- *Sanctions* (policy)

Each of these sections should appear in the document unless otherwise noted. There are sections that can be considered as part of one document, while not part of another. To retain consistency, it is recommended that they appear in the order listed throughout all the documents.

In the following chapter sections, the term "document" is used to mean either a policy, standard, procedure, or guideline.

41.13.1 Background

It is important that the document include a statement providing some information on what has prompted the creation of the document. In the case of a new policy, what prompted management's decision, as new policy is generally created as a reaction to some particular event. The other documents would indicate that it references the new policy and why that document is required to support the new policy. By including the background on the situation in the document, one provides a frame of reference for the reader.

41.13.2 Scope

In some situations, the document is created for the benefit of the entire corporation, while others are applicable to a smaller number of people. It is important that the scope define where the document is applicable to allow people to be able to determine if the policy is applicable to them.

41.13.3 Definitions

It is essential that the documents, with the exception of the procedure, be as free as possible from technical jargon. Within documents other than the procedure, technical jargon tends to confuse the reader. However, in some situations, it is not possible to prevent the use of this terminology. In those situations, the effectiveness of the document is improved by providing explanations and definitions of the terminology.

41.13.4 Reference

Any other corporate documentation, including other policies, standards, procedures, and guidelines, that provides important references to the document being developed should be included. This establishes a link between the policy and other relevant documents that may support this policy, or that this policy may support.

If creating the document as an HTML file for publishing on the Web, then it is wise to include hyperlinks to the other related documentation.

41.13.5 Coordinator/Author

The coordinator or author is the sponsor who developed and sought approval for the document. The sponsor is identified in the policy document to allow any questions and concerns to be addressed to the sponsor. However, it is also feasible that the policy author is not the coordinator identified in the policy. This can occur when the policy has been written by a group of people and is to be implemented by a senior manager.

41.13.6 Authorizing Officer

Because senior management is ultimately responsible for the implementation of policy, it is important that a member of that senior management authorize the policy. Often, the senior executive who accepts responsibility is also responsible for the area concerned. For example, the Chief Information Officer will assume responsibility for information systems policies, while the Chief Financial Officer assumes responsibility for financial policies.

If the standard is to be defined as a corporate standard, then the appropriate member of senior management should authorize the standard. If the standard is for one department's use, then the senior manager of that department approves it. Procedures are generally only for a department and require a senior manager's approval. Guidelines do not need approval unless they are for implementation within the company. In such situations, the senior manager responsible for the function should approve them.

41.13.7 Effective Date

This is the date when the document takes effect. When developing policy, it is essential that support be obtained for the policy, and sufficient time for user education be allowed before the policy takes effect. The same is true for the supporting documents, because people will want access to them when the policy is published.

41.13.8 Review Date

The review date establishes when the document is to be reviewed in the future. It is essential that a review period be established because all things change with time. Ideally, the document should make a statement that establishes a time period and whenever circumstances or events warrant a review. By establishing a review date, the accuracy and appropriateness of the document can be verified.

41.13.9 Disposal

In the event that the document is classified or controlled in some manner within the organization, then specific instructions regarding the disposal are to be indicated in this section. If there are no specific instructions, the section can be omitted, or included with a statement indicating that there are no special instructions.

41.13.10 Document Statement(s)

The policy statement typically consists of several text lines that describe what management's decision was. It is not long, and should be no more than a single paragraph. Any more than that, and the policy writer runs the risk of injecting ambiguity into the policy. However, the policy statements are to be clear enough to allow employees to determine what the required action is.

Statements within a standard must be of sufficient length to provide the detail required to convey the standard. This means that the standard can be quite lengthy in some situations.

Procedure statements are also quite detailed as they provide the exact command to be executed, or the task to be performed. Again, these can be quite lengthy due to the level of detail involved.

41.13.11 Exceptions

This section is generally included only in policy documents. It is advisable to include in the policy document a statement about how exceptions will be handled. One method, for example, is to establish a process where the exception is documented, an explanation provided about why an exception is the most practical way to handle the situation. With this done, the appropriate management is identified and agreement is sought, where those managers sign the exception. Exceptions should have a specific lifetime; for example, they should be reviewed and extended on an annual basis.

41.13.12 Violations and Sanctions

This section is generally included only in policy documents. The tendency is for organizations to sacrifice clarity in the policy for sanctions. The sanctions must be broad enough to provide management with some flexibility when determining what sanction is applied. For example, an organization would not dismiss an employee for a minor infraction. It is necessary that Human Resources and Legal review and approve the proposed sanctions.

41.14 Using a Common Development Process

A common process can be used in the creation of all these documents. The process of creating them is often managed through a project management approach if the individual writing them requires a number of other people to be involved and must coordinate their time with other projects. While it is not necessary, using this process in conjunction with a project management approach can ensure that management properly supports the document writing effort. One example of a process to use in defining and developing these documents consists of several phases as seen in Exhibit 41.4. Each of these development phases consists of discrete tasks that must be completed before moving on to the next one.

41.14.1 Phase One: Initial and Evaluation Phase

A written proposal to management is submitted that states the objectives of the particular document (policy, standard, etc.) and the need it is supposed to address. Management will then evaluate this request to satisfy itself that the expected benefit to the organization justifies the expected cost. If it does, then a team is assembled to develop and research the document as described in Phase Two. Otherwise, the submitter is advised that no further action will take place.

41.14.2 Phase Two: Development Phase

In the development phase, funding is sought from the organization for the project. The organization can choose to assemble a new team, or use one that was previously used for another project. The team must work with management to determine who will be responsible for approving the finished document.

The structure of the team must be such that all interested parties (stakeholders) are represented and the required competency exists. The team should include a representative from management, the operations organization responsible for implementation (if appropriate), the development team, a technical writer, and a member of the user community that will ultimately be a recipient of the service or product.

By including a representative from management, they can perform liaison duties with the rest of the organization's management, legal, and other internal organizations as required. The development team is

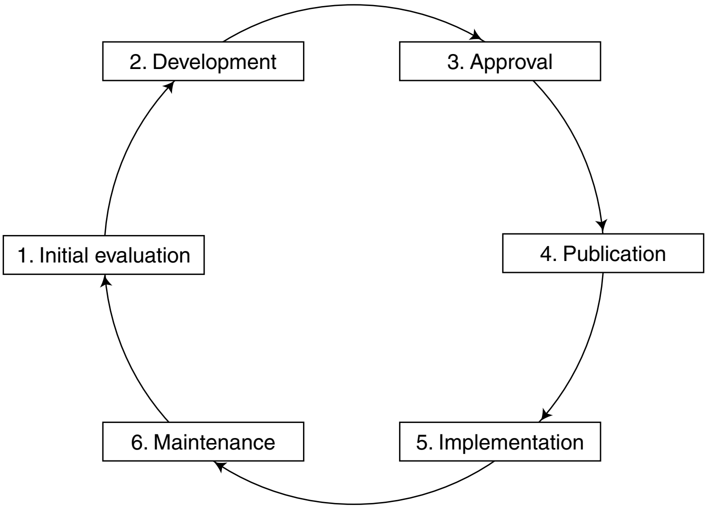

EXHIBIT 41.4 Defining and developing documents.

essential to provide input on the requirements that are needed when the product or service is being developed or assembled into the finished product. Operations personnel provide the needed input to ensure that the document can actually be put into practice once it is completed. The user community cannot be ignored during the development phase. If they cannot accept the terms of the document, having their input upfront rather than later can shorten the development process. Finally, the technical writer assists in the creation of the actual language used in the document. While most people feel they can write well, the technical writer has been trained in the use of language.

Remember that unless the members of this team have these roles as their primary responsibility, they are all volunteers. Their reward is the knowledge that they have contributed to the content of the standard and the recognition of their expertise by virtue of having their names published in the document.

This team is the heart of the development process. The technical requirements are put forward, designed, and worded by the experts on the team. These people discuss and debate the issues until final wording is agreed upon. Consensus is the key, as unanimity is not often achieved.

As the draft is developed through a number of iterations and approaches the original design objectives, it is made available to the general population within the organization for review and comment. The review period generally lasts 30 days and allows for input from those outside the team.

During this review period, the document should be tested in a simulated exercise. For example, if the document being developed is a procedure, then a less-experienced person should be able to successfully perform the tasks based on the information within the procedure. If they cannot, then there is a deficiency that must be addressed prior to approval.

After the comments have been deliberated by the team and it feels that the document is technically complete, it moves on to Phase Three.

41.14.3 Phase Three: Approval Phase

When the team has completed the design phase, the document is presented to the appropriate body within the organization. Some organizations will have formalized methods for approving policy, while others will not. It is necessary during the development phase to establish who the approving body or person is.

The document is presented to the approving body and a discussion of the development process ensues, highlighting any reasons that the team felt were important considerations during development. The document is “balloted” by the approving body, and any negative issues should be addressed prior to approval of the document.

41.14.4 Phase Four: Publication Phase

Finally, the document is translated (if required) and published within the organization. At this point, the document is ready for implementation as of the effective date. In some situations, the effective date may be the date of publication.

41.14.5 Phase Five: Implementation

During implementation, the various groups affected by the new document commence its implementation. This implementation will be different, depending on where it is being placed into use. For example, a user’s perspective will be different from that of an operational team. While the document is being used, people should be encouraged to send their comments and questions to the coordinator. These comments will be important during the review or maintenance phase.

41.14.6 Phase Six: Maintenance Phase

As decided during the development phase, the document is reviewed on the review date. During this review, the continuing viability of the document is decided. If the document is no longer required, then it is withdrawn or cancelled. If viability is determined and changes are needed, the team jumps into the development cycle at Phase Two and the cycle begins again.

41.15 Summary

This chapter has examined why policy is important to information security and some issues and areas concerning the development of that policy. Information Security Policy establishes what management wants done to protect the organization's intellectual property or other information assets. Standards are used to establish a common and accepted measurement that people will use to implement this policy. Procedures provide the details—the how of the implementation—while guidelines identify the things that management would like to see implemented.

Policy is an essential and important part of any organization because it identifies how the members of that organization must conduct themselves. To the information security manager, policy establishes what is important to the organization and what defines the shape of the work that follows.

Training Your Employees to Identify Potential Fraud and How to Encourage Them to Come Forward

Rebecca Herold

42.1 Introduction

Information security and privacy training and awareness are challenges in every organization. Most people do not like to participate in training; however, ensuring that employees understand their responsibilities for protecting information is vital to an organization's success and is required by law for many industries and jurisdictions. Helping employees understand how to identify and report fraud is especially important in today's business climate. A fraud awareness and training program must support an organization's business environment, be integrated within the information security program and policies, and meet applicable regulatory requirements. Personnel must be motivated to learn how to identify and report fraud by tangible and specific rewards and penalties to support an organization's fraud prevention efforts. Fraud prevention training must become part of the job appraisal process to build a truly effective fraud prevention education program. Corporate leaders must not only ensure compliance with regulatory issues but also effectively communicate fraud prevention policy and regulatory issues to the organization. Organizations cannot have a successful awareness and training program if personnel do not understand the impacts and consequences of noncompliance.

42.2 The Fraud Landscape

On February 1, 2005, the Federal Trade Commission (FTC) released its annual fraud report[1] detailing consumer complaints and listing the top ten fraud complaint categories reported by consumers in 2004. Identity theft was the number one complaint for the fifth consecutive year. Consumers filed over 635,000 complaints to the FTC in 2004, which was up from 542,378 in 2003. Of the complaints received in 2004, 61 percent were complaints about fraud and 39 percent were identity theft reports. The top eight categories of consumer fraud complaints within the FTC 2004 fraud report included the following:

- Internet auctions—16 percent
- Shop-at-home/catalog sales—8 percent
- Internet services and computer complaints—6 percent
- Foreign money offers—6 percent
- Prizes, sweepstakes, and lotteries—5 percent
- Advance fee loans and credit protection—3 percent
- Telephone services—2 percent
- Business opportunities and work-at-home plans—2 percent

The increase of fraud is indeed a concern and has caught the attention of the Executive Branch. President Bush's fiscal year 2006 budget[2] allots $212 million for the FTC, an $8 million increase over the appropriation for fiscal year 2005. If passed, the higher budget will provide the FTC with more resources to handle anti-fraud and privacy legislation, such as the Controlling the Assault of Non-Solicitated Pornography and Marketing (CAN-SPAM) Act and the Fair and Accurate Credit Transactions (FACT) Act, which establish identity theft and consumer credit protection responsibilities with the FTC.

Fraud concerns are not just at the federal level. Many states are also taking legislative moves in an effort to turn the tide of fraud activity levels. The following are just a few examples of proposed bills covering just identity theft:

- *Texas*—H.B. 1527 would require companies to alert their customers if a breach of security puts them at risk of identity theft.
- *New York*—A.4254 and S.2161 would require businesses and state agencies to notify consumers of any security breach of their data. Two other bills, A.5487 and S.3000, would only cover "business entities," not state agencies.
- *Washington*—S.B. 6043 would require companies that own and license computerized data containing personal information to inform Washington consumers of any breach of data security.
- *Minnesota*—H.F. 1410 and S.F. 1307 would require systems that own or license computerized data that includes personal information to notify Minnesota residents if there is reason to believe that the information was taken by an unauthorized person.
- *Georgia*—S.B. 251 would require certain businesses to give notice to consumers of security breaches.
- *Illinois*—Governor Rod Blagojevich (D-Ill.) proposed legislation in February that would require consumer notification in Illinois in cases where corporate security systems have been breached and consumer information has been compromised.
- *Rhode Island*—2005-S-0880 would require any business experiencing a security breach to immediately notify all Rhode Island residents in an affected database that their identities or financial documents may have been compromised.

[1] http://www.consumer.gov/sentinel/pubs/Top10Fraud2004.pdf.

[2] http://a255.g.akamaitech.net/7/255/2422/07feb20051415/www.gpoaccess.gov/usbudget/fy06/pdf/budget/other.pdf.

- *Florida*—An amendment was proposed to pending legislation (S.B. 284 and H.B. 129 CS) that would require immediate disclosure any time an individual's private personal financial information or Social Security number is stolen from a data-collection agency.
- *California*—S.B. 852 would require organizations to notify individuals for breach of personal information in any format, not just electronic.

Government leaders recognize the importance of businesses in fraud prevention efforts. In some instances, they legally require businesses to take active anti-fraud steps and to implement ongoing fraud prevention awareness and training programs. This trend is likely to continue. It is important that corporate leaders know and understand their obligations not only for anti-fraud activities but also for the anti-fraud training and awareness requirements for management, personnel, business partners, and customers.

42.3 Regulatory and Legal Requirements for Training

42.3.1 Why Is Regulatory Education Important?

Privacy and security awareness and training are important activities and key components of an effective fraud prevention and security program. In fact, many regulations require awareness and training as part of compliance, a few specifically for fraud prevention but many for information security, which encompasses fraud prevention activities. The most commonly discussed right now are the Health Insurance Portability and Accountability Act (HIPAA), the Sarbanes–Oxley (SOX) Act, and the Gramm–Leach–Bliley (GLB) Act. However, personnel education has been a requirement under other guidelines and regulations for several years. An increasing number of laws and regulations require some form of training and awareness activities to occur within the organizations over which they have jurisdiction. For example, the Federal Sentencing Guidelines,[3] enacted in 1991, updated to create more corporate management responsibility in 2004, and often used to determine fines and restitution for convictions, have seven requirements, one of which is for executive management to educate and effectively communicate to their employees the proper business practices with which personnel must comply. Issues that impact the severity of the judgments include consideration of the following:

- How frequently and how well does the organization communicate its policies to personnel?
- Are personnel effectively getting trained and receiving awareness?
- What methods does the organization use for such communications?
- Does the organization verify the desired results from training that has occurred?
- Does the organization update the education program to improve communications and to get the appropriate message out to personnel?
- Does the training cover ethical work practices?
- Is there ongoing compliance and ethics dialog between staff and management?
- Is management getting the same educational messages as the staff?

Implementing an effective, ongoing awareness and training program will:

- Establish accountability.
- Comply with regulatory requirements for education.
- Help ensure compliance with published policies.
- Demonstrate due diligence.

[3] http://www.ussc.gov/2003guid/2003guid.pdf; pp. 456–457.

Sentences under the guidelines can be as high as $290 million plus jail time, or even higher in some circumstances, but are these guidelines really ever applied? The U.S. Sentencing Commission documents that, in 1995,[4] 111 organizational defendants were sentenced according to the guidelines, with 83 cases receiving associated fines. By 2001,[5] the number of organizational defendants sentenced rose to 238, with 137 getting fines and 49 getting both fines and restitution. The average fine was $2.2 million, and the average amount of restitution awarded was $3.3 million. Of those sentenced, 90 had no compliance program, which was a documented culpability factor in the sentencing. Having a poor compliance program was also a documented factor in other decisions.

It is likely that the numbers of fines and penalties will increase with implementation of the updated guidelines.[6] Recent amendments include establishing an effective compliance program and exercising due diligence in the prevention and detection of criminal conduct. Any organizations with some type of compliance requirements or plans (basically all public entities, given the Sarbanes–Oxley Act of 2002) are directly impacted by the new guidelines. One way such due diligence is demonstrated is through an effective, executive-supported information security and privacy awareness program.

The organizational sentencing guidelines motivate organizations to create a program to reduce and, ultimately, eliminate criminal conduct by implementing an effective ethics and compliance program that includes compliance with all applicable laws. The updates to the sentencing criteria incorporate leading practices that have been referenced and identified in such regulations as the Sarbanes–Oxley Act, HIPAA, GLBA, and other internationally recognized standards. The 2004 updates are contained within new guidelines at §8B2.1 and elaborate upon the need for organizations to more rigorously demonstrate responsibility and demonstrate executive leadership.

To have a program that is effectively described by the guidelines, an organization must demonstrate that it exercises due diligence in meeting compliance requirements and also promotes "an organizational culture that encourages ethical conduct and a commitment to compliance with the law." It is important to note that the guidelines describe functional requirements, and it does not matter if an organization calls the program a compliance program, ethics program, or some other description. The actions and activities will be what are reviewed if a due diligence and sentencing situation arises. At a high level, the following are the organizational requirements described in the updated guidelines:

- Develop and implement standards and procedures designed to prevent and detect criminal conduct.
- Assign responsibility at all levels and provide adequate resources and authority for the compliance or ethics program.
- Perform personnel screening as applicable (in accordance with laws, regulations, and labor union requirements) and as related to program goals and the responsibilities of the staff involved.
- Provide adequate and effective awareness and training throughout all levels of the organization.
- Ensure that auditing, monitoring, and evaluating activities occur to verify program effectiveness.
- Implement internal reporting systems that eliminate retaliatory reactions.
- Provide incentives and enforce discipline to promote compliance.
- Consistently take reasonable steps to respond to violations and prevent similar violations from occurring.

According to wide discussion, the motivation behind these updated guidelines seems to be to ensure that, if an organization is convicted of a federal offense, the leader will face stiff sentences and civil penalties unless they have proof of having a stringent, well-communicated compliance program. This

[4] http://www.ussc.gov/ANNRPT/1995/ANNUAL95.htm.

[5] http://www.ussc.gov/ANNRPT/2001/SBtoc01.htm.

[6] http://www.ussc.gov/2004guid/gl2004.pdf.

should drive organizations to make ongoing, continuously communicated, compliance programs, including awareness and training components, a priority. The new 2004 U.S. Federal Sentencing Guidelines[7] state:

§8B2.1. Effective Compliance and Ethics Program

(a) To have an effective compliance and ethics program, for purposes of subsection (f) of §8C2.5 (Culpability Score) and subsection (c)(1) of §8D1.4 (Recommended Conditions of Probation—Organizations), an organization shall—

(1) exercise due diligence to prevent and detect criminal conduct; and

(2) otherwise promote an organizational culture that encourages ethical conduct and a commitment to compliance with the law.

Such compliance and ethics program shall be reasonably designed, implemented, and enforced so that the program is generally effective in preventing and detecting criminal conduct. The failure to prevent or detect the instant offense does not necessarily mean that the program is not generally effective in preventing and detecting criminal conduct.

(b) Due diligence and the promotion of an organizational culture that encourages ethical conduct and a commitment to compliance with the law within the meaning of subsection (a) minimally require the following:

(1) The organization shall establish standards and procedures to prevent and detect criminal conduct.

(2) (A) The organization's governing authority shall be knowledgeable about the content and operation of the compliance and ethics program and shall exercise reasonable oversight with respect to the implementation and effectiveness of the compliance and ethics program.

(B) High-level personnel of the organization shall ensure that the organization has an effective compliance and ethics program, as described in this guideline. Specific individual(s) within high-level personnel shall be assigned overall responsibility for the compliance and ethics program.

(C) Specific individual(s) within the organization shall be delegated day-to-day operational responsibility for the compliance and ethics program. Individual(s) with operational responsibility shall report periodically to high-level personnel and, as appropriate, to the governing authority, or an appropriate subgroup of the governing authority, on the effectiveness of the compliance and ethics program. To carry out such operational responsibility, such individual(s) shall be given adequate resources, appropriate authority, and direct access to the governing authority or an appropriate subgroup of the governing authority.

(3) The organization shall use reasonable efforts not to include within the substantial authority personnel of the organization any individual whom the organization knew, or should have known through the exercise of due diligence, has engaged in illegal activities or other conduct inconsistent with an effective compliance and ethics program.

(4) (A) The organization shall take reasonable steps to communicate periodically and in a practical manner its standards and procedures, and other aspects of the compliance and ethics program, to the individuals referred to in subdivision (B) by conducting effective training programs and otherwise disseminating information appropriate to such individuals' respective roles and responsibilities.

(B) The individuals referred to in subdivision (A) are the members of the governing authority, high-level personnel, substantial authority personnel, the organization's employees, and, as appropriate, the organization's agents.

[7] U.S. Sentencing Commission, Sentencing Guidelines for United States Courts, http://www.ussc.gov/FEDREG/05_04_notice.pdf.

(5) The organization shall take reasonable steps—
  (A) to ensure that the organization's compliance and ethics program is followed, including monitoring and auditing to detect criminal conduct;
  (B) to evaluate periodically the effectiveness of the organization's compliance and ethics program; and
  (C) to have and publicize a system, which may include mechanisms that allow for anonymity or confidentiality, whereby the organization's employees and agents may report or seek guidance regarding potential or actual criminal conduct without fear of retaliation.

(6) The organization's compliance and ethics program shall be promoted and enforced consistently throughout the organization through—
  (A) appropriate incentives to perform in accordance with the compliance and ethics program; and
  (B) appropriate disciplinary measures for engaging in criminal conduct and for failing to take reasonable steps to prevent or detect criminal conduct.

(7) After criminal conduct has been detected, the organization shall take reasonable steps to respond appropriately to the criminal conduct and to prevent further similar criminal conduct, including making any necessary modifications to the organization's compliance and ethics program.

(c) In implementing subsection (b), the organization shall periodically assess the risk of criminal conduct and shall take appropriate steps to design, implement, or modify each requirement set forth in subsection (b) to reduce the risk of criminal conduct identified through this process.

It is no longer enough simply to write and publish information security and privacy policies and procedures. Organizational leaders must now have a good understanding of the program, support the program, and provide oversight of the program as reasonable for the organization. This reflects a significant shift in the responsibilities of compliance and ethics programs from positions such as the compliance officer or committee to the highest levels of management. The guidelines require that executive leaders support and participate in implementing the program. To accomplish this, an effective ongoing information privacy, security, and compliance education program must be in place.

Every compliance plan, including information security and privacy, must include continuing involvement of the highest level of organizational management in its design and implementation. Compliance will then, as a result, become part of upper management daily responsibilities. Requirements for effective training and awareness now extend not only to personnel and business partners and associates but also to the highest levels of management and must be ongoing.

When considering due diligence, it follows that a standard of due care must be observed. Quite simply, this means that organizational leaders have a duty to ensure the implementation of information security and privacy even if they are not aware of the specific legal requirements. If leaders do not ensure actions are taken to reasonably secure information and ensure privacy, and as a result others experience damages, it is possible that both the organization and the leaders could face legal action for negligence. This certainly should motivate leaders to invest time, resources, and personnel in establishing an ongoing, effective, well-documented information security and privacy awareness and training program.

42.4 Laws and Regulations Requiring Education

Many existing laws and regulations include requirements for information security training and making personnel, management, or customers aware of certain aspects of the laws, such as the need to identify and prevent potentially fraudulent activities. Exhibit 42.1 provides excerpts from the actual regulatory text that are applicable to information security awareness and training activities for just a few of the existing U.S. laws and regulations. Organizations should review this list and discuss it with their legal departments to determine which ones apply to their particular businesses. This list does not include state laws and regulatory requirements, many of which also contain personnel training and awareness

EXHIBIT 42.1 Laws and Regulations

The following lists some of the U.S. laws and regulations that have requirements for information security, sometimes specifically indicating fraud prevention, awareness, and training within various organizations and industries. This is not an exhaustive list but will serve as a good starting point for researching an organization's regulatory training and awareness requirements. The actual regulatory text that applies specifically to awareness or training is indicated in italics. Read the full regulation or law to learn all the requirements for meeting compliance.

Health Insurance Portability and Accountability Act (HIPAA)[a]

Privacy Rule — Sec. 164.530(b)(1)[b] Standard:

> Training. A covered entity must train all members of its workforce on the policies and procedures with respect to protected health information required by this subpart, as necessary and appropriate for the members of the workforce to carry out their function within the covered entity.

Security Rule — Sec. 164.308(a)(5)(i)[c] Standard:

> Security awareness and training. Implement a security awareness and training program for all members of its workforce (including management).

21 CFR Part 11: Electronic Records; Electronic Signatures

Sec. 11.10(i).[d] Controls for Closed Systems:

> Determination that persons who develop, maintain, or use electronic record/electronic signature systems have the education, training, and experience to perform their assigned tasks.

Computer Security Act of 1987

Sec. 5. Federal Computer System Security Training:[e]

> (a) IN GENERAL. Each Federal agency shall provide for the mandatory periodic training in computer security awareness and accepted computer security practice of all employees who are involved with the management, use, or oration of each Federal computer system within or under the supervision of that agency. Such training shall be —
>
> > (1) provided in accordance with the guidelines developed pursuant to section 20(a)(5) of the National Bureau of Standards Act (as added by section 3 of this Act), and in accordance with the regulations issued under subsection (c) of this section for Federal civilian employees; or
> >
> > (2) provided by an alternative training program approved by the head of that agency on the basis of a determination that the alternative training program is at least as effective in accomplishing the objectives of such guidelines and regulations.
>
> (b) TRAINING OBJECTIVES. Training under this section shall be started within 60 days after the issuance of the regulations described in subsection (c). Such training shall be designed —
>
> > (1) to enhance employees' awareness of the threats to and vulnerability of computer systems;
> >
> > (2) to encourage the use of improved computer security practices; and
> >
> > *(3) to include emphasis on protecting sensitive information in federal databases and federal computer sites that are accessible through public networks.*
>
> (c) REGULATIONS. Within six months after the date of enactment of this Act, the Director of the Office of Personnel Management shall issue regulations prescribing the procedures and scope of the training to be provided Federal civilian employees under subsection (a) and the manner in which such training is to be carried out.

Computer Security Enhancement Act[f]

10/13/1998 — Senate preparation for floor; status — placed on Senate Legislative Calendar under General Orders (Calendar No. 718):

> *Section 9. Federal computer system security training*
>
> > This section amends section 5(b) of the Computer Security Act of 1987 by adding an emphasis on protecting sensitive information in Federal databases and Federal computer sites that are accessible through public networks.

Computer Fraud and Abuse Act (CFAA)[g]

Sec. 1030. Fraud and related activity in connection with computers:

> One court has interpreted the CFAA as providing an additional cause of action in favor of employers who may suffer the loss of trade secret information, or other negative impact, at the hands of disloyal employees.[h] It has been widely discussed and debated that, to enforce, employees must have communicated related policies.

Privacy Act[i] **(Applies to U.S. Government Agencies)**

5 U.S.C. Sec. 552a(01/16/96)(e). Agency requirements:

> Each agency that maintains a system of records shall —

EXHIBIT 42.1 (continued)

(9) establish rules of conduct for persons involved in the design, development, operation, or maintenance of any system of records, or in maintaining any record, and instruct each such person with respect to such rules and the requirements of this section, including any other rules and procedures adopted pursuant to this section and the penalties for noncompliance

Freedom of Information Act (FOIA)[j]

5 U.S.C. Sec. 552:

(a)(4)(A)(i) In order to carry out the provisions of this section, each agency shall promulgate regulations, pursuant to notice and receipt of public comment, specifying the schedule of fees applicable to the processing of requests under this section and establishing procedures and guidelines for determining when such fees should be waived or reduced. Such schedule shall conform to the guidelines which shall be promulgated, pursuant to notice and receipt of public comment, by the Director of the Office of Management and Budget and which shall provide for a uniform schedule of fees for all agencies.

(a)(6)(B)(iv) Each agency may promulgate regulations, pursuant to notice and receipt of public comment, providing for the aggregation of certain requests by the same requestor, or by a group of requestors acting in concert, if the agency reasonably believes that such requests actually constitute a single request, which would otherwise satisfy the unusual circumstances specified in this subparagraph, and the requests involve clearly related matters. Multiple requests involving unrelated matters shall not be aggregated.

(a)(6)(D)(i) Each agency may promulgate regulations, pursuant to notice and receipt of public comment, providing for multitrack processing of requests for records based on the amount of work or time (or both) involved in processing requests.

(a)(6)(E)(i) Each agency shall promulgate regulations, pursuant to notice and receipt of public comment, providing for expedited processing of requests for records

Federal Information Security Management Act (FISMA)[k]

Sec. 3544. Federal Agency Responsibilities:

(a) IN GENERAL. The head of each agency shall —

(4) ensure that the agency has trained personnel sufficient to assist the agency in complying with the requirements of this subchapter and related policies, procedures, standards, and guidelines.

(b) AGENCY PROGRAM. Each agency shall develop, document, and implement an agency wide information security program, approved by the Director under section 3543(a)(5), to provide information security for the information and information systems that support the operations and assets of the agency, including those provided or managed by another agency, contractor, or other source, that includes —

(4) security awareness training to inform personnel, including contractors and other users of information systems that support the operations and assets of the agency, of —

(A) information security risks associated with their activities; and

(B) their responsibilities in complying with agency policies and procedures designed to reduce these risks.

Digital Millennium Copyright Act (DMCA)[l]

Sec. 512(h). Conditions for Eligibility:

(1) Accommodation of Technology. The limitations on liability established by this section shall apply only if the service provider —

(A) has adopted and reasonably implemented, and informs subscribers of the service of, a policy for the termination of subscribers of the service who are repeat infringers

Gramm–Leach–Bliley (GLB) Act

Sec. 314.4. Safeguards Rule:[m]

(b) Identify reasonably foreseeable internal and external risks to the security, confidentiality, and integrity of customer information that could result in the unauthorized disclosure, misuse, alteration, destruction or other compromise of such information, and assess the sufficiency of any safeguards in place to control these risks. At a minimum, such a risk assessment should include consideration of risks in each relevant area of your operations, including —

(1) employee training and management;

(2) information systems, including network and software design, as well as information processing, storage, transmission and disposal; and

(3) detecting, preventing and responding to attacks, intrusions, or other systems failures.

EXHIBIT 42.1 (continued)

Sarbanes–Oxley (SOX) Act[n]

Title III Sec. 302(a)(4):

(4) the signing officers —

(A) are responsible for establishing and maintaining internal controls;

(B) have designed such internal controls to ensure that material information relating to the issuer and its consolidated subsidiaries is made known to such officers by others within those entities, particularly during the period in which the periodic reports are being prepared.

SEC Guidance That Emphasizes Training and Awareness[o]

III. Components of Objectives-Oriented Standard Setting

I. Behavioral Changes. i. Exercise of Professional Judgment

Second, there is the long-run consequence. Since the application of an objectives-oriented regime relies on preparers and auditors' ability to identify the objectives of the standard (as well as the specific guidance) and match that to the underlying transaction or event, there is a need to train preparers and auditors in understanding the substance of the class of transactions. Additionally, it appears likely that in moving to a more objectives-oriented regime, the FASB will issue more standards that rely on fair value as the measurement attribute. If so, it would be imperative that accounting professionals be trained in valuation theory and techniques.

IV. Implementation Issues

I. Transition Costs

We believe that the transition costs would be relatively small, as the transition to an objectives-oriented approach already is underway, at least in part, and should continue on a gradual basis. We believe that the accounting profession itself would incur only *de minimis* transitional costs in the immediate term, since we expect the FASB to continue to implement these recommendations on a gradual basis through its continuing standard-setting efforts. Going forward, however, as objectives-oriented accounting standards are adopted, to the extent that a different type of professional judgment is called for on the part of practitioners, accounting firms will find that they may have to further strengthen their training, quality control and oversight mechanisms for all accounting personnel within the firm. Moreover, there may be additional efforts needed internally on training and education to accommodate the heightened professional and intellectual demands that will be placed on practitioners. On the other hand, this extra cost may be offset by the reduction in training associated with the elimination of excessively detailed standards associated with a rules-based approach.

Bank Protection Act (12 CFR Chapter V, Sec. 568)[p]

Sec. 568.3. Security Program:

(a) Contents of security program. The security program shall —

(3) provide for initial and periodic training of officers and employees in their responsibilities under the security program and in proper employee conduct during and after a burglary, robbery, or larceny.

Sec. 568.4. Report:

The security officer for each savings association shall report at least annually to the association's board of directors on the implementation, administration, and effectiveness of the security program.

U.S. Patriot Act[q]

Sec. 352. Anti-Money Laundering Programs:

(a) IN GENERAL. Section 5318(h) of Title 31, U.S.C., is amended to read as follows:

(h) ANTI-MONEY LAUNDERING PROGRAMS.

(1) IN GENERAL. In order to guard against money laundering through financial institutions, each financial institution shall establish anti-money laundering programs, including, at a minimum —

(A) the development of internal policies, procedures, and controls;

(B) the designation of a compliance officer;

(C) an ongoing employee training program.

Sec. 908. Training of Government Officials Regarding Identification and Use of Foreign Intelligence:

(a) PROGRAM REQUIRED. The Attorney General shall, in consultation with the Director of Central Intelligence, carry out a program to provide appropriate training to officials described in subsection (b) in order to assist such officials in —

(1) identifying foreign intelligence information in the course of their duties; and

(2) utilizing foreign intelligence information in the course of their duties, to the extent that the utilization of such information is appropriate for such duties.

EXHIBIT 42.1 (continued)

Sec. 1005. First Responders Assistance Act:

(c) ANTITERRORISM TRAINING GRANTS. Antiterrorism training grants under this subsection may be used for programs, projects, and other activities to address —

(1) intelligence gathering and analysis techniques;
(2) community engagement and outreach;
(3) critical incident management for all forms of terrorist attack;
(4) threat assessment capabilities;
(5) conducting follow up investigations; and
(6) stabilizing a community after a terrorist incident.

FFEIC Customer Identification Program[r]

Customer Identification Programs for Banks, Savings Associations, and Credit Unions:[s]

A. Regulations Implementing Sec. 326:

Under the proposed regulation, the CIP must be incorporated into the bank's anti-money laundering (BSA) program. A bank's BSA program must include (1) internal policies, procedures, and controls to ensure ongoing compliance; (2) designation of a compliance officer; (3) an ongoing employee training program; and (4) an independent audit function to test programs. Each of these requirements also applies to a bank's CIP.

requirements. Be sure to research the state and local regulations and laws that are applicable to the organization's facilities and customer locations.

42.5 Training Motivators

Information security and fraud prevention must be integrated with job performance and the appraisal process. Personnel become motivated to actively support anti-fraud initiatives when they know that their job advancement, compensation, and benefits will be impacted. Studies about employee motivation in general have been demonstrating this since the 1920s.[8] When personnel do not have this motivation, then an organization is destined to ultimately depend only on technology for information security assurance and fraud prevention. Organizations must understand the importance of implementing these motivators

[8] Mayo, Roethlisberger and Dixon, and Landsberger, to name a few.

to validate due diligence and to be in compliance with laws and regulations such as those previously discussed. Much research has been done about job motivators, and many theories abound. Good managers want to know how to be more effective with their business efforts, and the human resources department is usually willing to try a motivator if it is well presented and explained. Legal compliance, revenue support, and due diligence are enhanced by training and implementing motivation for training.

Organizational motives for information security and fraud prevention must support primary business objectives and meet regulatory compliance; they cannot be an afterthought or superfluous. For example, fraud prevention and information security activities are necessary to:

- Comply with applicable laws and regulations.
- Demonstrate due diligence.
- Help prevent loss and thus increase profit.
- Protect the organization from liabilities related to security negligence.
- Enhance and/or support customer and public reputation.

So, what are personnel information security and fraud prevention activity motivators? The details will vary from organization to organization; however, high-level personnel motivators include at least the following, in no particular order:

- Complying with laws and regulations
- Getting a good report following a regulator's compliance review
- Meeting security requirements during internal compliance reviews
- Getting the respect and admiration of coworkers
- Having good relationships and interactions with coworkers
- Doing work that is interesting and fulfilling
- Following personal, ethical, and social principles
- Reducing information security risks
- Personally experiencing a security incident or loss
- Learning the loss experiences of others
- Showing dedication and faithfulness to the employer
- Making the boss happy
- Protecting personal and employer reputation
- Competing to succeed beyond peers
- Doing something that is fun and interesting
- Creating good working conditions
- Feeling achievement and satisfaction from a job well done
- Obtaining power and affiliation with others in power
- Getting good press for the employer for demonstrated effective security and anti-fraud practices
- Avoiding bad press for the employer because security was ineffective or a fraud was instigated
- Preventing a fraud or security incident from happening again after experiencing one
- Implementing automated security and anti-fraud mechanisms that are transparent to the end user and do not degrade systems performance or slow business processing
- Making security more convenient than alternative (non-secure) methods
- Creating an anticipation for receipt of rewards for security and fraud prevention activities relative to corresponding job responsibilities

- Creating fear and reminding of experiences of penalties for inadequate security and fraud prevention activities relative to corresponding job responsibilities

The last two items on this list are the most powerful motivators to individuals. They relate directly to the human need for safety and security as demonstrated in such models as Maslow's Hierarchy of Needs.[9] They are also the two items from this long list that organizations can most effectively control. Rewards and penalties are not new ideas; they have been traditional job performance motivators in business since business began and should be used for motivating personnel to be secure and help to prevent fraud as well. Rewards for participating in training and taking anti-fraud precautions and actions can include one or more of the following, in addition to other rewards not listed:

- Job promotion and advancement
- New privileges and benefits
- Additional vacation
- Gifts, prizes, and awards
- Praise and recognition
- Financial rewards, such as bonuses or raises

Penalties for not engaging in anti-fraud activities, on the other hand, can include one or more of the following, in addition to other penalties not listed:

- Loss of employment
- Demotion
- Loss of benefits, privileges, or perks
- Salary reduction
- Unpaid leave
- Legal action
- Internal publication of noncompliant personnel

Some of the above may work very well in some environments but may be completely unacceptable, or possibly illegal, in other organizational environments. Always discuss any of the motivators, prizes, penalties, and sanctions with the human resources and legal departments prior to implementation. It is important to ensure that the plans are in compliance with existing laws, contracts, and policies and to ensure that the information security and fraud prevention departments have the support of the legal and human resources areas.

42.6 Implementing Information Security Motivation

Donn Parker covers the previously described topics of motivation factors, in addition to creating a framework to integrate security into job responsibilities, in his book *Fighting Computer Crime: A New Framework for Protecting Information*.[10] The following is the essence of his sage advice as it applies to building a fraud prevention education program.

- *Make demonstrated due diligence the objective of security and fraud prevention activities.* Risk reduction and fraud prevention are the ultimate desired outcomes, but they really have little inherent motivational value. Personnel demonstrate due diligence by being in compliance with

[9] One source out of many is http://web.utk.edu/~gwynne/maslow.HTM.

[10] Parker, D. 1998. *Fighting Computer Crime: A New Framework for Protecting Information*, pp. 462–473. John Wiley & Sons, New York.

security standards (such as ISO 17799 or NIST), laws and regulations (such as HIPAA or GLBA), organizational policies, and accepted industry best practices and by taking proactive anti-fraud actions.

- *Update organizational policies and standards to include documentation of rewards, motivation, and penalties.* An organization's information security policy must be current, be accepted and supported by stakeholders (such as executive management and business unit leaders), and be practical to achieve. It should also document motivators for personnel compliance.
- *Include fraud prevention and information security as specific objectives in job descriptions.* Work with management to develop the objectives in each area of the organization. Do what applicable labor unions and laws allow. Job descriptions should include specific security and fraud prevention assignments that will comply with regulations and policies and provide accountability for the organization's assets.
- *Require all personnel to regularly sign an information security agreement.* State in the contract that the individual will support organizational information security and fraud prevention policies and standards, will actively work to prevent fraudulent activities, and will promptly report fraudulent activities and security incidents. Require employees to sign the agreement upon initial employment and on an annual basis. This ensures that personnel have reviewed the policies and provides accountability for compliance.
- *Establish fraud prevention and reporting activities as a specific objective in performance appraisals.* It is important to have the support of management and unions. This motivator is particularly effective for employees whose job descriptions explicitly state anti-fraud activities.
- *Engage top management to explicitly review the information security performance of all managers.* Managers with poor security and anti-fraud practices also have direct reports with poor security and anti-fraud practices. Managers who model good security practices have direct reports with good security practices. Top–down motivation of managers is necessary to achieve security and anti-fraud support through all levels of an organization.
- *Implement rewards and penalties that are supported and carried out consistently by management.* When penalties and rewards are documented, they must be consistently applied to make them effective motivators. When establishing rewards and penalties, do not require more security and anti-fraud activities than are necessary for the organization's business circumstances. When an organization tries to "overdo" security with no justification behind the requirements it will not get support from management; the security and anti-fraud efforts will be negatively impacted and possibly fail.

Motivators are effective when they are consistently applied. Do a little research and observe. Determine the motivators that will work best for the organization and environment. These answers will not come neatly packaged from anywhere else other than from understanding the organization's personnel and organization.

42.7 Anti-Fraud Awareness and Training Information

Employees can perform many different activities that will help to identify potential fraudulent activities. It is the responsibility of the organization's board of directors to support a written security program and training designed to help employees identify potential fraud and report potentially fraudulent activities to appropriate management. Personnel must be made aware of actions they need to take to help prevent fraud and what to do when they suspect or identify fraudulent activities. The following anti-fraud information and activities should be incorporated into the organization's fraud prevention awareness materials and training curriculum as is applicable and appropriate for the particular business and organization:

- Regularly communicate, via awareness messages and through formal training, the organization's security procedures to discourage robberies, burglaries, larcenies, and fraudulent activities. This will help employees to assist in the identification and prosecution of persons who commit such acts.
- Train personnel on the appropriate administrative, technical, and physical safeguards to protect the security, confidentiality, and integrity of customer information.
- Designate a security officer with the authority to develop and administer a written security and prevention program for each business unit and office. Communicate to personnel who the officer is, the responsibilities of the officer, and when the officer should be contacted.
- Establish procedures for opening and closing business facilities and for safekeeping all currency, negotiable securities, and similar valuables at all times. Communicate these procedures to all personnel.
- Establish procedures to assist in identifying persons committing crimes against the organization. These procedures should preserve evidence that may aid in their identification and prosecution. Appropriate personnel need to be made aware of the procedures. Such procedures and actions to consider include, but are not limited to, the following:
  - Use a hidden or closed circuit camera to record all office activities.
  - Use identification devices, such as prerecorded serial-numbered bills or chemical and electronic devices.
  - Retain a record of all robberies, burglaries, larcenies, and frauds committed against the organization.
- Provide initial and regularly scheduled ongoing officer and employee training and awareness that explains personnel and management responsibilities under the security program and proper employee conduct during and after a burglary, robbery, larceny, or fraudulent activity.
- Train appropriate personnel with related job responsibilities in how to select, test, operate, and maintain security, fraud prevention, and fraud detection devices. Such devices may include the following:
  - Mechanisms to protect cash and other liquid assets, such as a vault, safe, or other secure spaces
  - A lighting system for illuminating the area around the vault, if the vault is visible from outside the facilities
  - Tamper-resistant locks on publicly accessible doors and windows
  - Alarm systems or devices to immediately notify the nearest law enforcement officers of an attempted or perpetrated robbery or burglary
  - Automated network tools to detection discrepancies within data that indicate potential fraudulent transactions
  - Other devices as appropriate, taking into consideration:
    - The incidence of crimes against financial institutions in the area
    - The amount of currency and other valuables exposed to robbery, burglary, or larceny
    - The distance of the facilities from the nearest law enforcement office
    - The cost of the security devices
    - Other security measures used within the facilities
    - The physical characteristics of facility structures and surrounding environment
- Train personnel who service customers how to verify the identity of each person seeking to open an account following the organization's approved identity verification procedures.

- Train personnel how to determine if individuals appear on any lists of known or suspected terrorists or terrorist organizations provided to the financial institution by any government agency.
- Communicate regularly to personnel the organization's beliefs and values that fraud is unacceptable and will not be tolerated. This applies social pressure on fraudsters not to attempt the crime in the first place and on others to report suspicion of fraud.
- Communicate to personnel the organization's sanctions for committing or assisting with fraud. Let personnel know that the organization regularly reviews activities and systems to detect fraud and that it is the responsibility of personnel to assist with fraud prevention.
- Communicate information security policies and procedures to personnel. Fraud prevention begins with good security.
- Teach personnel the appropriate procedures to report fraud as quickly as they suspect or detect such activities. Be sure to include examples of suspicious activities and case studies to be most effective.
- Establish ways to confirm that suspected fraud is a fraud and not a "false positive." Be sure appropriate personnel understand how to appropriately gather evidence related to such crimes.
- Implement appropriate sanctions for fraudulent activities. Such sanctions can include disciplinary, civil, and criminal actions. Combinations of sanctions can often occur simultaneously, such as dismissing an employee and pressing charges.
- When fraud has been proven, make every effort to recover the losses. Make employees aware of the efforts that must be made.
- Establish fraud activity "red flags" and communicate them to employees.
- Instruct employees to conduct checks for identity theft before issuing loans or other forms of credit to individuals.
- Instruct employees how to obtain sufficient information to verify a customer's identity to reduce the risk that the organization will be used as a conduit for money laundering and terrorist financing.
- Teach employees the procedures for responding to circumstances when they cannot confirm the true identity of a customer.

Credit card fraud prevention activities for employees should include the following:

- Teach employees to ask to see the customer's credit card for all in-person purchases.
- For credit card purchases, teach employees to swipe the card for electronic data. If the card will not swipe, an imprint should be secured and the embossed information examined.
- Teach employees to always compare the account number on the receipt with the number on both the front and back of the card.
- Teach employees to always compare the name on the store receipt with the name on the front of the card. If the card is not signed, consider implementing a procedure to have the employee ask the customer to sign the card, ask for another form of identification, and compare the signatures. If the customer refuses, the transaction should not be completed, and the employee should advise the customer to contact the credit card company at the number on the back of the card.
- Teach employees to always get a signature on the printed receipt for all face-to-face transactions. The employee should not complete the transaction if the signature on the receipt does not match the name on the front of the card and the signature on the back of the card.
- Teach employees not to accept a fax or photocopy of a credit card to complete a transaction.
- Establish procedures to ensure that personnel and the credit card processor are submitting all the magnetic stripe information required by the credit card companies. Be sure to train appropriate personnel to follow these procedures.

- Instruct employees to obtain the expiration date for all methods (electronic, keyed, or manual) of credit card authorization requests.
- Instruct employees to follow steps similar to the following when processing credit cards manually or when the magnetic stripes on credit cards are unreadable:

  If your business authorizes payment electronically and the magnetic stripe is unreadable, instruct employees to key the transaction and expiration date into the terminal for authorization approval. When processing charge requests manually, always get a voice authorization from the applicable credit card company.

  Obtain an imprint of the credit card on a paper sales draft that conforms with the applicable credit card company requirements.

  Require the customer to sign the paper receipt and compare the signature.

42.8 Training and Awareness Methods

Much has been written about the need for security and privacy education through effective awareness and training activities. A regulatory and fraud prevention education program should address the organization's interpretation of applicable privacy and security laws and regulations as well as support activities of the organization to mitigate fraud risk. It is vital for organizations to evaluate, and continue to reevaluate, the effectiveness of these education programs. Too many organizations spend considerable time and money to launch awareness and training programs only to let them then wane, wither, and die on the vine because they did nothing beyond the big implementation; they failed to put forth the effort and activities necessary to evaluate, update, and modify their programs as necessary to be truly effective.

42.8.1 Evaluation Areas

The methods you use for evaluation and measurements are diverse. The following objects of evaluation identified by Verduin and Clark[11] are useful. Tailor them to facilitate an evaluation of the organization's fraud prevention education programs by considering the questions listed with each object:

- *Access*. What groups are you reaching? Are any groups missing? Is everyone in the target group participating? Are you providing appropriate delivery methods for your target audiences? Can all of your target audience access your training and awareness materials and participate in your delivery methods?
- *Relevancy*. Is your fraud prevention education program relevant to your organization's business goals and expectations? Are your training and awareness messages and information relevant to job responsibilities? Will your education program have a noticeable impact on business practices? Was your training content appropriate for your target participants? Did your training cover regulatory and policy requirements?
- *Quality*. Is the quality of your awareness materials adequate to get attention and effectively deliver the intended message? Does the quality of your training materials contribute to your students' success? Do your trainers and teachers deliver quality education? Do they know how to interactively adjust to the abilities and experiences of their students? Were the conditions right for learning and for each learner's subjective satisfaction?
- *Learning outcomes*. Is the amount of time allowed for learning appropriate for successfully understanding the message? What do your participants say about the usefulness and effectiveness of your training and awareness activities? Do you tell the participants the expected outcomes of your education activities? What did the participants actually learn? Did your participants indicate they had a satisfactory learning experience?

[11] Verduin, Jr. J. R. and Clark, T. A. 1991. *Distance Learning*. Jossey-Bass, San Francisco, CA.

- *Impact*. What is the impact of your education program on your organization as a whole? Were activities and habits changed appropriately following training and awareness activities? What are the long-term impacts? Did the training methods promote the desired skills? Did job performance improve? What is the pattern of student outcomes following each training session? Did you assist managers with determining their own workforce performance? Did you create return on investment statistics to support training and awareness funds?
- *Cost effectiveness*. What time requirements are involved? What are the costs for the materials? How many people are in your targeted groups? How is training being delivered? Are you using inside or outside training and awareness resources? What is the value of the method of awareness activity or training session you used compared to other awareness and training options?
- *Knowledge generation*. Do you understand what is important for your personnel and managers to know? Do you understand what works and what does not work in your education program? Are you utilizing your evaluation results? Did you assist employees in determining their own performance success? Did you compile trend data to assist instructors in improving both learning and teaching?
- *General to specific*. Do your instructors give students enough information to allow them to self-evaluate their own success in implementing what they learn? Are students told overall goals and the specific actions necessary to achieve them? Are goals and actions realistic and relevant? What is the necessary, prerequisite general and specific knowledge?

42.8.2 Evaluation Methods

Consider using a combination of the following methods for determining the effectiveness of fraud prevention education within the organization, but be sure to discuss the methods with the legal department prior to implementation to make sure the program is not violating any applicable laws, labor union requirements, or employee policies:

- Videotape your training sessions. Review and critique to identify where it might be necessary to improve delivery, content, organization, and so on.
- Give quizzes immediately following training to measure comprehension.
- Distribute a fraud-prevention awareness survey to some or all personnel. Do this prior to training to establish a baseline then after training to help determine training effectiveness.
- Send follow-up questionnaires to people who have attended formal training approximately four to six months after the training to determine how well they have retained the information presented.
- Monitor the number of compliance infractions for each issue for which training is provided. Is this number decreasing or increasing?
- Measure fraud prevention knowledge as part of yearly job performance appraisals.
- Place feedback and suggestion forms on an appropriate intranet Web site, preferably one devoted to fraud prevention information.
- Track the number and type of fraud and security incidents that occur before and after the training and awareness activities.
- Conduct spot checks of personnel behavior; for example, walk through work areas and note if workstations are logged in while unattended or if negotiable check stock or customer information printouts are not adequately protected.
- Record user IDs and completion status for Web- and network-based training. Send a targeted questionnaire to those who have completed the online training.
- Ask training participants to fill out evaluation forms at the end of the class.
- Identify the percentage of the target groups that participate in training.

- Determine if the number of instructors is adequate and if they have the necessary level of expertise for the corresponding training topics.
- Determine if the training materials address all the organization's goals and objectives. Identify the gaps and make a plan to fill them.
- Review training logs to see trends in attendance.
- Tape or film participants performing their work after training to determine if they are utilizing the skills taught.
- Administer occasional tests to personnel. Use multiple choice, short answer, essay tests, or a combination. Avoid using true or false tests.
- Perform interviews with past training participants as well as personnel who have not yet been trained. Use structured and unstructured interview sessions.

42.9 Training Design and Development

Design the training curriculum based on the learning objectives for the associated target groups. The training delivery method should be based on the best way to achieve the organization's objectives. In choosing a delivery method, select the best method for the learning objectives, the number of students, and the organization's ability to efficiently deliver the material.

42.9.1 Training Materials

A curriculum must be created for the following if it does not already exist:

- Computer-based training (CBT)
- Briefings
- Web-based training
- Videos
- Telephone conferences
- Quarterly meetings
- Classroom

42.9.2 Design and Development

During the design and development phase, keep these things in mind:

- Outline the class content.
- Divide the training into instructional units or lessons.
- Determine time requirements for each unit and lesson.
- Create content based on what personnel need to know to perform their job responsibilities.
- Include interactive activities that can be taken back to their jobs and used right away.
- Be clear about the behaviors, actions, and activities expected of the students when performing their jobs.
- Describe how personnel would demonstrate successfully meeting the objectives being taught.
- Build upon existing capabilities and experiences within the group.
- Sequence topics to build new or complex skills onto existing ones and to encourage and enhance the student's motivation for learning the material.
- Use multiple learning methods.

When determining the best instructional method for your target groups, keep the following in mind:

- *Consider the people within the target group audience.* Consider the audience size and location. Consider experience levels. Consider time constraints. If the audience is large and geographically dispersed, a technology-based solution, such as Web-based, CD, or satellite learning, may work best.
- *Consider the business needs.* If the budget is limited, then a technology-based delivery or bringing in an outside instructor with already prepared materials may be appropriate.
- *Consider the course content.* Some topics are better suited for instructor-led, video, Web-based, or CBT delivery. There are many opinions about what type of method is best. Much depends on the organization. It will be helpful to get the advice of training professionals who can assess materials and make recommendations.
- *Consider what kind of student-teacher interaction is necessary.* Is the course content best presented as self-paced individual instruction or as group instruction? Some topics are best covered with face-to-face and group interaction, and other topics are best suited for individualized instruction. For example, if the goal is just to communicate policies and procedures, a technology-based solution may be most appropriate; however, if students need to perform problem-solving activities in a group to reinforce understanding or demonstrate appropriate actions, then a classroom setting would be better.
- *Consider the type of presentations and activities necessary.* If the course content requires students to fill out forms, to use a specialized software program, or to participate in role playing, a classroom setting would be best.
- *Consider the stability of the class content.* The stability of content is a cost issue. If content will change frequently (e.g., procedures are expected to change as a result of mergers, acquisitions, or divestitures) or if new software systems are planned, the expense of changing the materials needs to be estimated by considering difficulty, time, and money. Some instructional methods can be changed more easily and cost-efficiently than others.
- *Consider the technology available for training delivery.* This is a critical factor in deciding the instructional strategy. Will all students have access to the technologies required? For Web-based training, will all students have access to the intranet or Internet? Do students have the necessary bandwidth for certain types of multimedia?

The content for each target group should be based on the organization's information security policy, fraud prevention guidelines, and appropriate business unit practices and guidelines. Additionally, content must support applicable security and privacy laws, regulations, and accepted standards. Following is a list of the content topics generally common to all target groups (core content) and the content that will have to be specialized for each target group (targeted content):

- *Core content*

  Background fraud information

  Corporate fraud prevention policy

  Business impact of fraudulent activities

  Fraud-related terms and definitions

  Legal requirements for fraud prevention and reporting

  The organization's fraud prevention procedures

- *Targeted content*

  The fraud and risk implications for the targeted group based on their business responsibilities

  Actions for the target group related to their job responsibilities, interactions with customers, interactions with third-party business partners, and so on

The organization's fraud prevention fundamentals, rules, policies, standards, procedures, and guidelines applicable to the target group
Case studies designed specifically for the target group
Review of key points
Tools and checklists specific to the target group to meet fraud prevention goals
Resources
Summary
Questions

42.9.3 Content Based on Fraud Prevention Goals

Fraud prevention and detection training content must include information that supports the organization's security and fraud prevention goals and principles. When creating training curriculum, the following can be used to guide content development. These are the methods of training delivery most commonly used, and indicated with each method are the benefits and drawbacks for the corresponding method.

42.9.3.1 Instructor-Led Classroom Training

Instructor-led classroom training is recommended for target groups that have the most decision-making responsibilities and procedures.

- *Benefits*

  Is typically the most high-quality and interactive method.

  Is comparatively easy to update and can most easily be tailored to the audience compared to other methods.

  Allows for the most interaction compared to other methods.

  Gets participants away from distracting environments.

  Can gauge and measure participant understanding.

- *Disadvantages*

  May be costly with regard to time and resources necessary.
  Can train only a relatively small number of participants at a time.
  Often requires a large time investment for participants.
  Takes participants away from their work area.

42.9.3.2 Computer-Based Training or CD-ROM Training

This type of training is recommended for general audiences and training remote participants.

- *Benefits*

  Allows participants to remain in their work areas.

  Costs less overall than most other methods.

  Can be taken in modules.

  Allows participants to be widely dispersed geographically.

  Allows a large number of participants to undergo training in a short amount of time.

- *Disadvantages*

  Does not allow instructor interaction.
  Is a type of static training that may quickly become outdated.
  Is difficult to gauge participant understanding.

42.9.3.3 Web-Based Live Training ("Webinars," Net Meetings)

- *Benefits*
  Can reach a large number of participants in a short amount of time.
  Accommodates participants in many different locations.
  Can be recorded and subsequently viewed anywhere, anytime, anyplace.
  Offers the option of on-line support.
  Is cost effective.
- *Disadvantages*
  Could require a large amount of network resources.
  Provides for only limited interaction.

42.9.3.4 Videos

- *Benefits*
  Can be shown anywhere, anytime, anyplace.
  Typically does not require any instructor-student interaction.
  Can be viewed by a large number of participants in a short period of time.
- *Disadvantages*
  Is not interactive.
  May be expensive.

42.9.3.5 Satellite Presentations

- *Benefits*
  Allows for live interactions.
  Is more timely and up-to-date than videos and computer-based training.
  Is interactive.
  Reaches a large number of participants.
- *Disadvantages*
  May be costly to establish if infrastructure is not already in place.
  Can be difficult to coordinating times to accommodate wide range of geographic locations.

Many instructional elements will be consistent from course to course, regardless of the instructional methods used. Most courses will involve delivery with voice, text, and graphics. To make instruction more effective, consider incorporating pictures or graphics, video, demonstrations, role playing, simulations, case studies, and interactive exercises. Several of these presentation methods will be used in most courses. Remember that it is generally considered most effective for student understanding to deliver the same message or information multiple times using multiple methods. The students (employees and other applicable personnel) all have their own unique learning styles, and what works well for one person will not necessarily be effective for others. Develop instructional methods based on instructional objectives, course content, delivery options, implementation options, technological capabilities, and available resources. Web-based training is often a good alternative for large audiences and can provide an overview of the topic and communicate policies and facts; however, this type of instruction method is often not appropriate for audiences that are learning procedures or how to act in specific types of situations in which role playing is necessary.

43

Change That Attitude: The ABCs of a Persuasive Security Awareness Program

Samuel W. Chun

43.1 Social Science, Psychology, and Security Awareness: Why?

In any book, guide, or article on information security, it is impossible to avoid a discussion on the role of people in an information security program. Information security, like everything else, is a human enterprise and is influenced by factors that impact the individual. It is well recognized that the greatest information security danger to any organization is not a particular process, technology, or equipment; rather, it is the people who work within the “system” that hide the inherent danger.

One of the technology industry's responses to this danger has been the ever-important information security awareness program. A well-designed, effective awareness program reminds everyone—IT staff, management, and end users—of the dangers that are out there and things that can be done to defend the organization against them. The intent of this chapter is not to be a "how-to" on writing a security awareness program. There are numerous authors and specialists who have offered expertise in this field, as well as a plethora of reference materials that are available to everyone on the mechanics of writing an awareness program.

Rather, the main goal of this chapter is to explore and exploit the scientific body of knowledge around the psychology of how humans behave and make decisions. Using psychological principles that social scientists and psychologists have discovered over the past 50 years, we can produce security awareness programs that are more personal, relevant, and persuasive. Ultimately, knowing, understanding, and applying what we know about the engines of personal behavior will allow us to write more effective awareness programs.

43.2 Attitudes and Social Science in Everyday Life: Love Those Commercials!

Scientists have been studying the factors that drive and influence decision making and behavior for hundreds of years. There are scientists who specialize in these factors, such as environment (e.g., heat, cold, pain) and biology (e.g., genetics, neuroscience). Because information security practitioners cannot really manipulate these factors for benefit in awareness programs (although infliction of pain has probably been discussed in many organizations), this chapter focuses on the works of a group of scientists called *social psychologists*, who have collected a wonderful body of knowledge that we can directly apply.

Some individuals often doubt scientific knowledge and bemoan the lack of applicability in real life. Basically, is what social psychologists know of value (especially to information security practitioners)? The good news is that the social psychologists' findings have been widely known, accepted, and applied for years by a variety of different groups and people to great effect. Examples include political campaigns, activists, and sales people. However, social psychologists' knowledge of human behavior has been most effectively exploited in the field of advertising to persuade people to buy goods (that, in many cases, people do not need). There is no reason why these same principles cannot be used to make security awareness programs more effective. After all, if people can be persuaded to buy a plastic singing fish for $29.95, they should be even more receptive to information that can actually benefit them (such as keeping their passwords secret).

43.3 Attitudes: The Basics

Before delving into a discussion of the various techniques for influence and persuasion, readers need to understand the basics of what we are trying to change. What structure or object in our minds are we trying to change to positively or negatively impact behavior? The answer to this question is our attitudes. Attitudes are defined as our positive or negative response to something. For example, if I have a negative attitude toward privacy, I am more willing to give out network passwords and usernames to random, unauthorized people. If I have a positive attitude toward a new corporate security awareness program, I am more likely to abide by it as well as be a proponent. As you can clearly see, attitudes not only define our "feeling" toward something, but also play a role in our behavior. We, as information security professionals, need to be aware of attitudes (their structure and function) for three reasons:

1. *Predictor of behavior.* Attitudes are a good predictor of behavior. That is why surveys are an invaluable tool in an overall security program. If you can determine the target population's attitudes toward information security issues such as privacy and confidentially, you can use that information to predict how secure your environment will be. For example, if you have a large call

center population with a measured negative attitude toward privacy, you can reasonably predict that the employees are not employing good work clean-up habits (i.e., shredding trash, logging out of workstations).

2. *Targets of change.* Attitudes can be targeted for change. If you can subtly or directly change someone's attitude, you can consequently change behavior. It is often easier to change behavior through an attitude shift than to change behavior directly. For example, a learned, repeated behavior such as leaving a workstation logged in while away is difficult to change directly. However, a strong emotional appeal toward the individual's attitude about confidentiality might have a better effect.
3. *Source of risk.* Attitudes are a source of risk for an information security professional. Extreme attitudes toward someone or something can lead to irrational cognitive function and behavior. This is one of the most feared situations for an information security manager, because it cannot be rationally predicted. Although an individual might "know" and "feel" that what he is doing is wrong, he might still be blinded by rage, love, or obsession into destructive behavior such as stealing, inappropriate access, confidentiality violations, etc.

43.4 Attitude Structure and Function: The ABC's of the Tripartite Model

For 30 to 40 years, the immense practical value of studying attitudes has encouraged social psychologists' research. During that time, they have learned a lot about attitudes through experimentation, population studies, and statistical analysis. One of the results of their labor has been a mathematical modeling of attitudes called the Tripartite Model (see Exhibit 43.1). The Tripartite Model, also known as the ABC Model, presents attitude as an amalgam of three separate measurable components: affect, behavior, and cognition.

1. *Affect.* The affective component is the emotional aspect of our attitudes. Our feelings toward an object or subject play an important role in determining our attitudes. We are more likely to participate and do things that make us feel happy or good. Our aversion to things that elicit feelings of guilt, pain, fear, or grief can be used to change attitudes and, eventually, behavior. The affective appeal to our attitudes is common in TV commercials that make us laugh (e.g., beer commercials) or make us afraid (e.g., an alarm system), thus changing our attitudes toward a certain product. A security awareness program can easily be written to appeal to these emotional responses. An excellent example of this phenomenon is the series of identity theft commercials that depicts the results of someone stealing someone else's credit card number.
2. *Behavior.* The behavior component is derived from the fact that our behavior serves as a feedback mechanism for our attitudes. In short, "doing" leads to "liking." In an ingenious experiment, two randomly selected groups of subjects were asked to rate how much they liked a cartoon they were watching. The two groups watched the same cartoon, with only one group biting a pencil to simulate the facial muscles of a smile. It was found that the group that had to bite on a pencil rated the cartoon as being much more amusing and likeable than the group that did not. Other similar experiments with a variety of different tasks found that forcing yourself to do something you may not like (e.g., changing network passwords) may change your attitude toward it (privacy).
3. *Cognition.* The cognitive component is the thoughtful, thinking aspect of our attitudes. Opinions toward an object or subject can be developed based solely on insightful, process-based thinking. It is no wonder

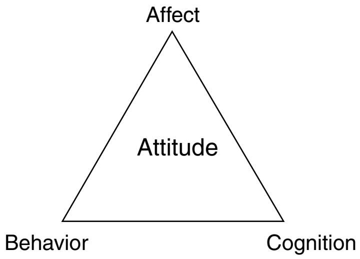

EXHIBIT 43.1 Tripartite model.

that the nature of TV commercials during news programs is radically different than that aired on Saturday mornings. During news programs, people are more likely to be processing information and "thinking." Therefore, advertisers, with the help of social psychologists, have been attacking the cognitive component of our attitudes toward cars, cell phones, and other products, listing features and benefits (for cognitive processing) rather than using imagery.

43.5 Examples: The Tripartite Model and Customizing Security Awareness

A better understanding of the structure of attitudes allows us to more effectively customize our awareness program toward the target audience. Consider the following business environments and their security awareness requirements. Think about what component of the ABC Model of Attitudes is the most likely to result in changes in behavior through a security awareness program.

- *The law firm*. This law firm is based in Washington, D.C., and has 500 attorneys and more than 1000 associated staff. Each of the firm's attorneys is issued laptops and travel often to trial sites with sensitive information. The biggest concern is laptop security, with the firm having "lost" several laptops with client information.
- *The call center*. This call center, located in Dallas, Texas, has 400 call takers of low skill level processing credit card purchases of refurbished printers in a large, open area. The call center has recently had a series of incidents in which customers' credit numbers have been stolen by employees and used illegally.
- *The hospital*. This hospital, in Miami, Florida, has one of the largest and busiest emergency rooms in the country. Medical information is processed by doctors and nurses in open work areas that allow easy access to PC workstations. Due to recent HIPAA regulations, the hospital must change the behavior of its healthcare providers in better safeguarding patient information.

If you thought about cognitive (listing consequences of lost laptop to clients), affective (provide visual reminders of consequences of criminal behavior), and behavior (change desktop locations) appeals for the environments above, you were correct. If you thought of other components for the environments above, you were also correct. It is important to note that there is no right or wrong answer, just possibilities. In each of these cases, one aspect of the Tripartite Model may have produced better results than another. But more importantly, these examples demonstrate that by understanding what attitudes are and how they are structured, we can glean invaluable clues into how to tailor our information security awareness programs to have more impact on specific groups of users.

43.6 Science of Persuasion and Influence: Now the Good Part! Time to Change Your Mind!

The previous sections of this chapter established a foundation for understanding what our attitudes are; how they are constructed; and how they can be influenced to predict, motivate, and change behavior. We have applied our understanding of attitudes into methods that can be used to create more influential security awareness programs. This section shifts the focus toward what scientists have found in the phenomenon of influence. This area of social psychology dealing specifically with the changing of attitudes and behavior is known as *persuasion*. Due to the immense practical value of knowledge about the mechanisms of persuasion, over 50 years of research has been accumulated by many psychologists at numerous universities. With this vast knowledge of the science and art of influence, we as information security practitioners should incorporate it as part of our repertoire in information security programs.

The following sections describe some of the most well-known phenomena in the science of influence. Each phenomenon will be described, along with some of the scientific evidence that has been performed on it. A discussion of the application of this phenomenon in an information security awareness context is also provided.

43.6.1 Reciprocity: Eliciting Uninvited and Unequal Debts

43.6.1.1 Phenomenon

The obligation to reciprocate on debt has been observed by scientists in every culture on this planet. Sociologists, who study populations and cultures, believe that the need to reciprocate favors or debt is so pervasive that modern civilization could not have been built without it. Debt obligation allows for division of labor, exchange of goods and services, systems of gift and aid, and trade. However, social psychologists have discovered that people's innate sense of reciprocation can be manipulated. In fact, our innate sense of indebtedness can be subtly exploited so that uneasy feelings of debt can be obtained without invitation. What is worse is that a small favor can produce a sense of obligation that can be used to return a much bigger favor.

43.6.1.2 Science

Our innate need to reciprocate (and sometimes reciprocate with more than what we need to) has been demonstrated in a variety of different experiments. A classic experiment involved two groups of subjects who were asked to purchase raffle tickets. The only difference between the two groups was that the first group was provided a free soda before being asked to purchase raffle tickets. It was found that the group that was given a soda, on average, purchased more than double the amount of raffle tickets than the group that was not given free soda. Considering that at the time of the study, a raffle ticket was 500 times the price of a soda, the return on investment (ROI) was high indeed. This unequal, reciprocating phenomenon has been demonstrated in countless experiments and can be seen in daily life in places such as airports with Hari Krishnas and their flowers (for donations) and at supermarkets with their free samples (ever buy a block of cheese after eating a sample?).

43.6.1.3 Application

Information security professionals can use our natural need to reciprocate by offering inexpensive "favors" or "gifts" as part of the security awareness program. Trinkets such as "awareness program" pencils, magnets, and mouse pads can be cheaply procured and easily distributed to elicit indebtedness in the user population. Although there may not be conscious or direct evidence of indebtedness, it does exist and may play a role in an individual deciding to take the security awareness program seriously. The investment in these favors is generally very low and the ROI, even if it has a subtle role in preventing a security incident, is so high that it makes good sense to provide these free "samples" to your organization's "shoppers."

43.6.2 Cognitive Dissonance: Win Their Body, and Their Hearts and Minds Will Follow

43.6.2.1 Phenomenon

Cognitive dissonance occurs when an individual performs an action that is contrary to his belief or attitude. It is the subconscious "tension" that is created when action is contrary to belief. An individual will alleviate this cognitive dissonance by changing his belief structure (i.e., change his attitudes). In anecdotal terms, this is an example of the heart and mind following the body when forced to perform distasteful tasks.

43.6.2.2 Science

The best evidence for cognitive dissonance was discovered by psychophysiologists specializing in measuring physiological response from psychological stimuli. Dissonance experimentalists have been able to directly measure dissonance through physiological tests such as heart rate, blood pressure, and galvanic skin response. When subjects were asked to perform tasks that were contrary to their attitudes, an immediate physiological response was measured. When continually pressed to repeat the contrary task, alleviation of dissonance was measured over time, along with changes in attitudes.

43.6.2.3 Application

Security practitioners can use cognitive dissonance to their advantage when introducing new security policy procedures that are not popular with the user community. Unpopular policies such as mandatory password changes, proper disposal of sensitive material, and adherence to physical security practices may initially be met with resistance. When introduced, these policies might be perceived as nothing more than a nuisance. However, *consistency is the key*. By making these security requirements mandatory and consistent, the practitioner will find that over the long-term, user dissatisfaction will wane and positive attitude change toward the program may occur as a result of cognitive dissonance.

43.6.3 Diffusion of Responsibility: InfoSec Is Not My Problem!

43.6.3.1 Phenomenon

People behave differently based on the perception of being part of a group as opposed to being an individual. It has been commonly observed that people tend to work less in a group than as individuals when only group output is measured. People, in addition, tend to feel less responsibility in a group than as a single individual. The bigger the group, the lower the felt sense of personal responsibility. Social psychologists call this diffusion of responsibility and the phenomenon is commonly observed across all cultures.

An extreme example includes an event in which a woman senselessly was beaten, stabbed, and murdered in an alleyway in New York while 38 neighbors watched from their windows. When interviewed, these neighbors referred to the presence of others as the source of their inaction. Another extreme example of diffusion of responsibility is suicide-baiting, when an individual in a group yells "jump" while observing a person on the ledge of a building. Suicide-baiting almost never occurs during the day with one or two people, but is much more common at night when mobs of people are gathered.

43.6.3.2 Science

Diffusion of responsibility has been demonstrated in numerous scientific experiments. However, the most interesting and insightful one occurred in a basement at Ohio State University where various students were brought into a room and told to scream as loud as they could into a microphone. Each student was shown other rooms and told that there were anywhere from one to ten other students screaming with them (in other rooms), and that only group output would be measured. In reality, there were no other students, only a perception of such. It was reliably found that people tended to scream incrementally less, depending on the number they thought were screaming with them. Diffusion of responsibility has been reliably found in a variety of different tasks and cultures.

43.6.3.3 Application

Diffusion of responsibility is most likely to occur in anonymous group environments. Recall the example in the previous section of this chapter of the large call center where credit card numbers are being processed. Although a security awareness program may exist and apply to the workers of the call center, diffusion of responsibility is likely to be playing a role in how seriously the workers are taking security precautions.

Environments such as data processing centers, helpdesks, and call centers, with their generic cubicle office structures, promote de-individualization and diffusion of responsibility. Not only is productivity lessened but also more importantly, workers are less likely to take programs like information security seriously, because they could incorrectly perceive having no personal responsibility for network security. So what can practitioners do to lessen the impact of diffusion of responsibility? What can organizations do to minimize the negative attitude of "InfoSec IS NOT my problem" in a group setting?

43.6.4 Individualization: InfoSec Is My Problem!

43.6.4.1 Phenomenon

The absolute antithesis of diffusion of responsibility is the effect of individualization on behavior. When people are reminded of themselves, for example, via visual stimuli or personal introspection, they tend to behave completely opposite than in an anonymous group. When individualization is perceived, people tend to be more honest, work harder, eat less, and take more responsibility. This is the reason why mirrors are common in retail stores (prevent theft by individualization) while they are never found in restaurant dining rooms (promote diffusion). In the case of the murder of Catherine Genovese in front of 38 neighbors in New York, individualization (pointing to a single person and screaming for help) could have resulted in action rather than the tragedy that occurred.

43.6.4.2 Science

Much like diffusion of responsibility, there have been countless studies performed on the effects of de-individualization and individualization in groups. In the infamous Stanford "prison" study, students were randomly selected and separated into two groups: "prisoners" and "guards." These two student groups were introduced into a mock prison created for the experiment. Shockingly, over six days, the two groups experienced so much de-individualization within the experiment that the study had to be stopped. The "guards" had lost so much individual identity that they began to torment and abuse the "prisoners" beyond the requirement of the study. The "prisoners" who were deprived of individual identities began to experience psychosomatic disorders such as rashes, depression, and random moaning. The scientists concluded that so much de-individualization took place that students lost regard for human life and well-being.

43.6.4.3 Application

Although the examples and studies provided in this section appear extreme, they are documented events. The effects of de-individualization and individualization are real and play a role in how users perceive their role in an information security awareness program. In the credit card processing call center example, de-individualization can encourage theft, carelessness, and loss of productivity. By making small, inexpensive investments and encouraging individuality, organizations can enhance their security program's effectiveness. Examples of such investments include mirrors, name plates, name tags, customized workspaces, and avoidance of uniforms.

43.6.5 Group Polarization: Group Dynamics in Security Awareness

43.6.5.1 Phenomenon

Group interaction tends to polarize attitudes on a given subject rather than moderate it. This phenomenon of group polarization, also known as *risky shift*, has been a surprise finding by social psychologists in their study of group dynamics. Individuals in a group tend to shift and adopt more extreme attitudes toward a given topic over time. Scientists surmise that several factors are at work in this phenomenon, including diffusion of responsibility and a natural gravitation toward the creation of a group authority figure with the most extreme view of the group.

43.6.5.2 Science

Group dynamics scientists have found that individuals think and behave quite differently when exposed to the attitudes of a group. Studies have found that test subjects of similar attitudes toward a subject (for example, a group of students who all feel moderately for capital punishment) once introduced to group discussions and activities, almost always come out individually more polarized toward the subject. In many cases, attitude "ring leaders" with the most extreme views arise to take group authority roles.

43.6.5.3 Application

Group polarization could be both an asset and a liability for the information security practitioner. In an organization that may already have an inclination toward having a safe, secure environment (military, intelligence, and government), group dynamics and polarization may serve an enhancing role in the security awareness program. Unfortunately, the opposite effect may be experienced in environments where decentralization and personal freedom have been the norm. Educational and nonprofit organizations have a difficult time implementing strong security programs due to the communal, trust-based relationships that are fostered in them. It is important for the security practitioner to remember that user populations that may be predisposed to a specific opinion about information security will end up having enough stronger feelings about it after group interaction.

43.6.6 Social Proof: We Have Found the Information Security Enemy and It Is Us!

43.6.6.1 Phenomenon

People determine what behavior is correct in a given situation to the degree that they see others performing it. Whether it is figuring out which utensil to use at a dinner party or deciding whether to let a stranger follow you into an office building, we use the actions of others as important guidelines in our own behavior. We do this because early in life we learn that doing as “others do” is more likely than not the right behavior.

43.6.6.2 Science

Social proof has been repeatedly demonstrated in very simple, yet classic experiments. In one study, psychologists took a group of toddlers who were extremely fearful of dogs and showed them a child playing with dogs for 20 minutes a day. The scientists found that after only four days, more than 65 percent of the toddlers were willing to step into a pen alone with a dog. Even more remarkable was that the experiment produced similar results when it was repeated with video footage rather than a live child and dog.

43.6.6.3 Application

Social proof in an information security environment can be both a blessing and curse. When others are able to observe positive attitudes and action toward aspects of a security awareness program, social proof can serve as a multiplier in encouraging positive behavior. However, examples of negative attitude and action toward security awareness policies (disregard, indifference, or denigration) can quickly spread, especially in confined environments such as processing centers, help desks, and call centers. It is up to information security managers and senior management of an organization to swiftly deal with those who set bad examples, and to encourage, promote, and foster those who take corporate security policies seriously.

43.6.7 Obedience to Authority: The High-Ups Say So!

43.6.7.1 Phenomenon

Sociologists have observed that the inherent drive to obey authority figures is omnipresent across all cultures. They surmise that a hierarchical organization of individuals offers immense advantages to a society. It allows for the ability to manage resources, create trade, organize defense, and have social control over the population. The proclivity to obey authority figures may have a biological foundation with the same behavior being observed in a variety of different animals.

43.6.7.2 Science

Deference to authority has been a well-researched field within social psychology. After World War II, social scientists wanted to understand how ordinary people were motivated to commit horrible atrocities. The common answer they found was that they were just following orders. In a well-known series of experiments at Yale University, Stanley Milgram found that randomly selected subjects were willing to deliver horrendous electrical shocks to a screaming participant on the orders of a researcher wearing a labcoat. This study found that as long as the researcher continued to prompt the test subject, the vast majority of subjects would continue to inflict pain, even after the victim had apparently lost consciousness.

Milgram performed a series of these experiments (with a variety of wrinkles thrown in) and found that individuals would almost always defer to the researcher for orders. When asked by a researcher to stop, 100 percent of the people stopped delivering shocks. When two white lab-coated researchers were included in the experiment that gave contradictory shock orders, it was found that test subjects always attempted to determine who was the higher ranking of the two researchers (rank). Factors such as proximity (standing next to the subject versus on a phone), sex (male versus female researchers), appearance (lab coat versus not), size (short versus tall) were all determined to play a role in people's willingness to obey authority. These studies were also performed in Europe and Asia, and no discernable differences were observed across cultures.

43.6.7.3 Application

It is universally agreed that management buy-in and approval of an information security program is considered an essential requirement for success. However, approval and sponsorship is only a small fraction of the potential role management can play in an awareness program. Because people are predisposed to authority, management's active participation (being the lab-coated researcher) in the awareness program can only serve to magnify the impact of the program. Information security practitioners should look to leverage authority figures and determinants such as proximity (personal announcements instead of e-mails) and rank (having active participation from the highest-ranking manager possible) to maximize the power of the message as much as possible.

43.6.8 Familiarity and Repeated Exposure: The Price of Security Is Eternal Vigilance

43.6.8.1 Phenomenon

Does familiarity breed contempt? Or does repeated exposure lead to liking? Scientists have found overwhelming evidence that repeated exposure to stimuli almost always results in positive attitude change. Radio stations repeatedly play the same songs, and for good reason—because we enjoy the song more when it is constantly repeated.

43.6.8.2 Science

Pioneering scientists at the University of Michigan (and consequently other universities) have been studying repeated exposure versus liking for more than 30 years. They have found strong, consistent evidence of repeated exposure and familiarity leading to liking in a vast array of experiments. Bob Zajonc, in his classic experiment, found that students rated nonsense syllables as having positive connotations in direct proportion to the amount of times they were exposed to them. This phenomenon has been repeated with a variety of different stimuli, including objects, pictures, symbols, sounds, and faces.

43.6.8.3 Application

As mentioned previously, consistency is one of the keys to a more persuasive security awareness program. Even in the face of end-user dissatisfaction, repeated exposure to the various components and policies and rationales for the program is essential for changing end-user attitudes. The most common mistake that is observed with a security awareness program is its inconsistency. Often, there is great activity and enthusiasm during the introduction of a security program; but after months have passed, there is little semblance of the initial fanfare. A trickle of e-mails and periodic postings on corporate newsgroups are all that is left to remind the users of the program. A program that is designed with consistency and longevity in mind (regular status communications, weekly workshops, daily E-reminders, and management announcements) will have a better chance of changing the attitudes of the user community to adopt the various parts of the security awareness program.

43.7 Summary

Information security awareness programs serve a critical role in keeping an organization safe by keeping the user community vigilant against the dangers of intruders. This chapter enlisted the help of social scientists—experimental psychologists, sociologists, and psychophysiologists—who have worked to further our knowledge about how we think and behave, making our security awareness programs more relevant, powerful, and effective. Through their research, we have found that at the core of our action are our attitudes. Knowing the subtle, unconscious ways to influence and nudge these attitudes can be a useful asset in implementing a more persuasive and effective security awareness program.

44

Maintaining Management's Commitment

William Tompkins

After many information security and recovery/contingency practitioners have enjoyed the success of getting their programs off the planning board and into reality, they are then faced with another, possibly more difficult challenge … keeping their organization's program "alive and kicking." More accurately, they seem to be struggling to keep either or both of these programs (business continuity and information security) active and effective.

In many instances, it is getting the initial buy-in from management that is difficult. However, if practitioners "pass the course" (i.e., Management Buy-in 101), they could be faced with a more difficult long-term task: maintaining management's commitment. That "course" could be called Management Buy-in 201. This chapter addresses what can be done beyond initial buy-in, but it will also expand on some of those same initial buy-in principles.

This chapter discusses methods to keep management's attention, keep them involved, and keep all staff members aware of management's buy-in and endorsement. One of the primary requirements to continuing the success of these programs is keeping management aware and committed. When management does not visibly support the program or if they think it is not important, then other employees will not participate.

44.1 "What Have You Done for Me Lately?!"

Up to this point in time, most practitioners have not had a manager say this to them, although there have been a few practitioners who have actually heard it from their managers. But, in many instances, the truth is that many managers think of these programs only as a project; that is, the manager thinks "… when this is completed, I can move on to other, more important …." With this in mind, InfoSec and disaster recovery planners always seem to be under this "sword of Damocles." A key item the practitioner must continually stress is that this is a journey, not a destination.

What does this journey include? This chapter concentrates on four categories:

1. *Communication*. What are we trying to communicate? Who are we communicating with? What message do we want them to hear?
2. *Meetings*. The practitioner will always be meeting with management; so, what should be said to the *different* levels of management we meet with?
3. *Education*. Educating anyone, including management, is a continuous process. What information is it that management should learn?
4. *Motivation*. What one can (or should) use to encourage and inspire management and to keep their support.

44.2 Communication

Why is it difficult to communicate with management? "Management does not understand what the practitioner does." "Management is only worried about costs." Or, "Management never listens." These are familiar thoughts with which a practitioner struggles.

The message must be kept fresh in management's mind. However, the underlying issues here are that the practitioner (1) must keep up-to-date, (2) must speak in terms managers can associate with the business, and (3) is obligated to come up with cost-saving ideas (this idea itself may need some work). One more consideration: do managers only pay attention to those who make them look good? Well, yes, but it is not always the same people who appear to make them look good. The practitioner must continuously work at being "the one to make them look good."

44.2.1 Assumptions versus Reality

What to communicate or what to avoid communicating? Both are important, but it is critical in both the security and business continuity professions to avoid assumptions. Many examples can probably be imagined of management and security/BCP (business continuity planning) practitioners suffering from the after-effects of incorrect assumptions.

In the area of disaster recovery planning, it is of paramount importance to ensure that upper management is aware of the actual recovery capabilities of the organization. Management can easily assume that the organization could recover quickly from a crisis—possibly in terms of hours rather than the reality, at a minimum, of days to recover. Management may be assuming that all organizational units have coordinated their recovery plans through the Disaster Recovery Coordinator rather than the reality that business units have been purchasing and installing their own little networks and sub-nets with no thought for organization-wide recovery. Management may be assuming that, regardless of the severity of the disaster, all information would be recovered up to the point of failure when the reality is that the organization might be able to recover using last night's backups but more probable is that the recovery may only be to a point several days previous.

Then there is the flip-side of mistaken assumptions. At a security conference in March 2000, Dr. Eugene Schulz, of Global Integrity Corp., related a story about the peers of a well-respected information security practitioner who believed that this person had a very good security program.

Unfortunately, the reality was that senior management in the company was very dissatisfied with the program because the security practitioner had developed it without becoming familiar with the organization's real business processes. This type of dissatisfaction will precipitate the loss of management as stakeholders in the program and loss of budgetary support or, at the least, management will no longer view themselves as a partner in the program development process.

44.2.2 Differing Management Levels … Different Approach

Who a practitioner works with in any organization or, more accurately, who is communicated with should dictate what will be discussed and whatever is said must be in terms that is certain to be understood by any manager. Avoid techno-babble; that is, do not try to teach somebody something they probably will not remember and, typically, not even care to know.

The references used by a practitioner to increase understanding in any topic area must be interpreted into management's terms, that is, terms that management will understand. When possible, stick to basic business principles: cost-benefit and cost-avoidance considerations and business enablers that can be part of an organization's project planning and project management. Unless contingency planning services or information security consulting is the organization's business, it is difficult to show how that company can make a revenue profit from BCP or InfoSec. But, always be prepared to discuss the benefits to be gained and what excessive costs could be avoided if BCP and InfoSec are included in any MIS project plan from the beginning of the project.

Exhibit 44.1 provides some simple examples of cost benefits and cost avoidance (versus return on investment) that most companies can recognize.

44.2.3 The Practitioner(s) … A Business Enabler?

Hopefully, the organization is not in what might be the "typical" recovery posture; that is, information technology (IT) recovery is planned, but not business process recovery. Whatever the requirements for an IT project, the practitioner must continually strive to be perceived as a value-added member of the team and to ensure significant factors (that might keep the business process going) are considered early in development stages of a project. Practitioners will be recognized as business enablers when they do not rely on management's assumptions and they clearly communicate (and document) explicit recovery service level agreements, such as time to recovery (maximum acceptable outage duration), system failure monitoring, uptime guarantees (internal and external), performance metrics, and level-of-service price models.

EXHIBIT 44.1 Cost Benefits and Cost Avoidance

	BCP	InfoSecurity
Benefits		
Protect the organization	X	X
Maintain the company's reputation	X	X
Assurance of availability	X	
Minimize careless breach of security		X
Maximize effort for intentional breaches		X
Avoidance		
Increase cost for unplanned recovery	X	
Possibly up to four times (or more) of an increase in total project costs to add InfoSec (or BCP) to an application or system that has already been completed	X	X
The cost of being out of business is …?	X	X

In today's business world, it is generally accepted that almost all businesses will have some dependence on the Internet. It has become a critical requirement to communicate that the success of the business processes will depend significantly on how quickly the company can recover and restore the automated business process in real-time. Successfully communicating this should increase the comfort level the organization's customers and partners have in the company because it demonstrates how effectively the company controls its online business processes.

Get involved early with "new" system development. It is imperative to do whatever is reasonable to get policy-based requirements for info security and contingency planning considered in the earliest phases of developing a business process. Emphasize that these are part of infrastructure costs—not add-on costs.

Avoid the current trend (organization pitfall, really) of trying to drive the development of a new business process from the IT perspective rather than the reverse. That is, automated business processes should be structured from the perspective of the business needs.

44.3 Meetings

As stated, where the practitioner is located within the organizational structure of the company will determine whom to start working with, but first, (1) know the business, (2) know what management desires, and (3) know the technical requirements. Practitioners must have some kind of advance understanding of what their administration will "move" on or they will probably do more harm than good if they try to push an idea that is certain to die on the drawing board (see Exhibit 44.2).

Some of the most important things that should be on the practitioner's mind include:

- What are management's concerns?
- What are the organizational accomplishments?
- How can I help? Go into any meeting prepared to discuss a long-term strategic plan. Be prepared to discuss short-term tactical efforts. Always be ready to discuss probable budget requirements.

Restating one of the "planks" in the practitioner's management commitment platform, practitioners must keep themselves up-to-date regarding changes in technology. Be prepared to discuss information technology impacts on the organization. Exhibit 44.3 lists just a few of the items with which the practitioner should be familiar.

On the administrative side, the practitioner should always be comfortable discussing policy. Creating or modifying policy is probably one of the most sensitive areas in which one is involved. Typically, it is not within the practitioner's appropriate scope of authority to set policy, but one is expected to make recommendations for and draft policies in one's area of expertise. Here again, the practitioner can be viewed as a value-added part of the team in making recommendations for setting policy; specifically, does the company perform a periodic review of policy (making timely changes as appropriate)? Also, to what level does the organization's policy address those pesky details; for example, does the policy say who is

EXHIBIT 44.2 Introductory Meetings

One of the most important tasks I assign myself when starting at a new organization is to schedule a one-on-one "Introductory Meeting" with as many managers as is possible. The stated objective of this meeting is to get to know the business. I tell each manager that I am not there to discuss my role in the organization, typically because my role is still in its formative stages. I tell them up front that I need to know about *this* section's business processes to become better able to perform my role. Sometimes, I have to remind them that I am really interested in learning about the business process and not necessarily about the IT uses in the section. Next, I ask them if they would suggest someone else in the organization that they feel would be helpful for me to meet to get a more complete "picture" of the organization (a meeting is subsequently scheduled based on this recommendation). Finally, if it seems appropriate, I ask them if they have any security concerns. I try to keep this initial meeting around half an hour long and not more than 45 minutes at the outside. You will find that many times higher level managers will only be able to "squeeze" in 15 minutes or so … take what you can get!

EXHIBIT 44.3 Topics for Discussion

Be prepared to discuss:

- Total cost of recovery
- Moving from EDI on VANs to VPNs
- Total cost of operations
- Voice-over-IP
- Voice recognition systems
- Wireless networking
- Self-healing networks
- IT risk insurance
- Data warehousing impacts
- Charge-back accounting
- BCP and InfoSec at conception
- Virtual Router Redundancy Protocol

responsible/accountable? Does the policy address compliance; that is, is there a "hammer?" How is the policy enforced? The practitioner should be able to distinguish different levels of policy; for example, at a high level (protect information resources) and at a more detailed level (a policy for use of the WWW or a procedure for recovering a Web site).

44.3.1 Meetings with Executive and Senior Management

When (and if) practitioners get onto the executive committee agenda, they must be prepared! Only you can make yourself look good (or bad) when these opportunities arise. Typically, a status update should be simple and to-the-point: what has been accomplished, what is now happening, and what is in the works. Again, it cannot be over-emphasized that it is important to keep the information relevant to the organization's industry segment and keep the (planned) presentation brief. Remember: do not try to teach management something they probably are not interested in learning and probably will not remember anyway.

44.3.2 Meeting Mid-level Managers

Try to concentrate on how things have changed since the last meeting with them. For management, what has changed in their business area; for the practitioner, what has changed in continuity and security activities. Ensure that any changes in their recovery or security priorities, due to the changes that have been experienced, are discussed.

It will probably be productive to develop a friendly relationship with the folks in the organization's human resources section. One obvious reason is to promote the inclusion of an information security introduction within the company's new employee orientation program. Another benefit is to try to become informed of "new" managers in the organization. It is also significant to try to find out when a current employee is promoted to a management position and, probably more important, to learn when someone from outside the organization fills an open management position.

44.4 Education

A continuing education program is another good example that this is a journey and not a destination. Because one is confronted with almost continual changes in business processes and the technology that supports them, one knows how important it is to continually educate everyone within the organization. Although it may seem to be an uphill battle, it must be emphasized, once again, that one must keep one's company and oneself up-to-date on the vulnerabilities and exposures brought about by new technology.

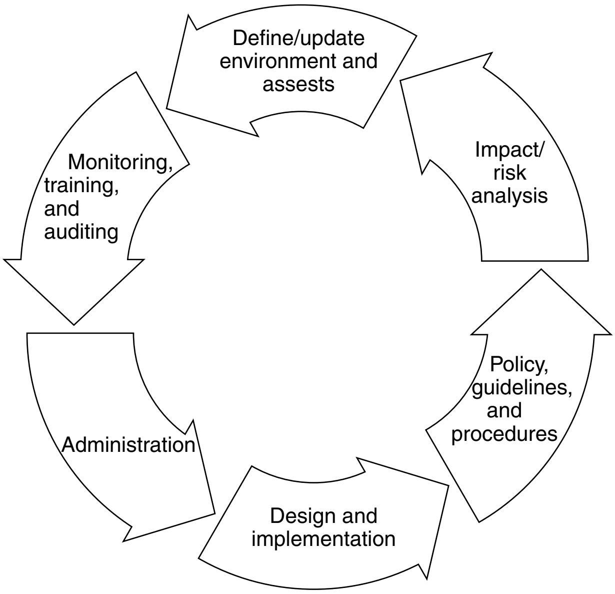
The practitioner must read the current industry magazines, not only business continuity and information security magazines, but also industry magazines that are relevant to the organization's industry. Articles to support the education efforts must always be close at hand, ready to be provided to management. Also, the practitioner is obligated to inform management of changes in technology as it directly relates to recovery or security. But here, it is necessary to urge caution that these articles will be primarily used with mid-level managers. It is most effective to provide supporting documents (articles, etc.,) to senior management only after the executive manager has broached a topic and a clear interest on their part for additional information is perceived.

Another form of "education" can be provided through the use of routine e-mails. Simply "cc": appropriate managers when sending e-mail within the organization relating to InfoSec/BCP planning tasks.

Be prepared for an opportunity to discuss (or review) the risk management cycle (see Exhibit 44.4). That is, there will be a time when the practitioner is confronted with a "this project is complete" attitude. The practitioner should be ready, at any time, to provide a quick summary of the risk management cycle.

Step 1 Define/update the organization's environment/assets.
Step 2 Perform business impact/risk analyses.
Step 3 Develop/update policies, guidelines, standards, and procedures based on the current organization operations and impacts to the assets.
Step 4 Design and implement systems/processes to reinforce policies, etc. that support the company's mission and goals.
Step 5 Administer and maintain the systems.
Step 6 Monitor the systems and business processes by testing and auditing them to ensure they meet the desired objectives … and as time goes on, the cycle must repeat itself when it is determined (through monitoring, testing and auditing) that things have changed and the company needs to reassess the environment and its assets.

Most companies have regularly scheduled/occurring employee meetings, whether at the lowest levels (e.g., a section meeting) or at the annual/semi-annual employee meetings. The practitioner should



Define/update environment and assests
Impact/ risk analysis
Policy, guidelines, and procedures
Design and implementation
Administration
Monitoring, training, and auditing

EXHIBIT 44.4 Risk management cycle.

attempt to get items of importance added to the agenda of these meetings. Preferably, these presentations will be given by the practitioner to increase recognition within organization. Or, at a minimum, ask management to reinforce these items when they get up to the podium to speak to the employees.

44.4.1 Management Responsibilities

The practitioner must carefully choose the timing for providing some of the following information (education) to managers; but, here again, be ready to emphasize that the success of the continuity/security program is dependent on management's understanding and their support. Management responsibilities include:

- Ensuring that all employees are familiar with IT user responsibilities before accessing any organizational resource
- Leading by example: active, visual support of BCP/InfoSec initiatives
- Praise and reward for those who protect information and improve policies (*Note*: if management is reluctant to do this, then at least try to convince them to allow it to be done, preferably by the practitioner personally.)

Do not overlook the influence that employee involvement can have on management's education. Employee involvement in the program should be encouraged. The employees who recognize that their involvement is a significant factor to the success of an information security or recovery program will enhance a strong self-image. The employee will realize an increased importance to the organization; but most important is that this effort will reinforce the success of the program from the bottom up. When management begins hearing about recovery or security issues from the employees, management will remain (or become more) interested in what is being done for the company.

44.5 Motivators

This chapter section reviews the issues that typically stimulate management to action, or at least what will motivate management to support continued recovery and information security planning and the recurring program activities.

There is little argument that the primary management motivator is money. If something increases revenue for the organization, then management is usually happy. Conversely, if doing something costs the organization money and there is no foreseeable return on investment, then management will be much more critical of and less motivated to evaluate and approve the activity. Beyond the issue of finances there are a number of items that will motivate management to support the business continuity and information security program(s). Unfortunately, the most used (and abused) method is FUD—Fear, Uncertainty, and Doubt. A subset of FUD could include the aspects of a higher-authority mandate, for example, an edict from the company's Board of Directors or its stockholders. Additionally, the requirements to comply with statutory, regulatory, and contractual obligations are more likely to make an impression on management. A positive motivation factor in management's view is the realization of productivity — if not increased productivity, then at least the assurance that InfoSec and business contingency planning will help ensure that productivity levels remain stable. Fortunately, many practitioners have begun to successfully use due-care motivation. The following chapter subsections review each of these areas of motivation along with some of their details.

44.5.1 FUD = Fear, Uncertainty, and Doubt

One of the fastest things that will get management's attention is an adverse happening; for example, a fire in a nearby office building or an occurrence of a new virus. Exhibit 44.5 identifies only a few of the significant events that occurred in the year 2000.

EXHIBIT 44.5 Real-World FUD Examples

Tornado	Downtown Ft. Worth, Texas; 6:00 p.m., March 28; downtown area closed until emergency crews investigated buildings and determined structural damage
Hurricane	Gordon; Tampa Bay, Florida; in p.m., September 17, tornadoes and flooding
Fire	Los Alamos, New Mexico; May 12; fires were started by Forest Service officials — intentional brush clearing fires … 11,000 citizens were evacuated (from AP, 5/10/00)
Terrorism	Numerous occurrences: (1) Arab hackers launched numerous attacks in the U.S. and in Israel against Jewish Web sites, (2) Pakistani groups periodically target Web sites in India, etc.
Espionage	QUALCOMM Inc.'s CEO had his laptop stolen from the hotel conference room while at a national meeting; it is suspected the reason for the theft was to obtain the sensitive QUALCOMM info on the laptop (from AP, 9/18/00)
Public image	(embarrassment) In September, during repairs to the Web site, hackers electronically copied over 15,000 credit and debit card numbers belonging to people who used the Western Union Web site (from AP, 9/11/00)

44.5.2 It Is Easier to Attract Flies with Honey than with Vinegar

Although there are innumerable examples of FUD, the practitioner should be wary of using FUD as a lever to attempt to pry management's support. Maintaining management's commitment is more likely to happen if the practitioner is recognized as an enabler, a person who can be turned to and relied upon as a facilitator, one who provides solutions instead of being the person who makes the proverbial cry, "Wolf!" Granted, there may be an appropriate time to use FUD to advantage, and a case can be made in many organizations that if there was not a real example of FUD to present to management then, subsequently, there would not be any management support for the InfoSec or business contingency program in the first place.

To management, probably the most worrying aspect of FUD is public embarrassment. The specter of bad press or having the company's name appear in newspaper headlines in an unfavorable way is high on management's list of things to avoid. Another example of the practitioner being a facilitator, hopefully to assist in avoiding the possibility of public embarrassment or exposure of a critical portion of the company's vital records, is to be recognized as a mandatory participant in all major information technology projects. Planning must include reliable access management controls and the capability for quick, efficient recovery of the automated business process. During the development of or when making significant changes to an information technology-supported business process within the organization, access controls and recovery planning should be mandatory milestones to be addressed in all projects. Within various organizations, there are differing criteria to determine vital records. A recurring question for management to consider: Does the company want its vital records to become public? In today's rapidly advancing technology environment, the reality is that incomplete planning in a project development life cycle can easily lead to the company's vital records becoming public records.

44.5.3 Due Care

Today's business world is thoroughly (almost totally) dependent on the support information resources provided to its business processes. The practitioner is confronted with the task of protecting and controlling the use of those supporting resources as well as ensuring the organization that these resources will be available when needed. It presents a practitioner with the responsibility to effectively balance protection versus ease of use and the risk of loss versus the cost of security controls. Many practitioners have determined that it is more productive to apply due care analysis in determining the reasonable (and acceptable) balance of these organizational desires, as opposed to trying to convince management of protection and recoverability "minimum" requirements that are based on the inconsistencies that plague a (subjective) risk analysis process.

To summarize due care considerations for any company: Can management demonstrate that (1) security controls and recovery plans have been deployed that are comparable to those found in similar organizations, and (2) they have also made a comparable investment in business continuity/information security? … or else, has the organization documented a good business reason for *not* doing so?

44.5.4 Mandates: Statutory, Regulatory, and Contractual

All organizations are accountable to some type of oversight body, whether it is regulatory (Securities and Exchange Commission, Federal Financial Institutions Examination Council, or Health Care Financial Administration); statutory (Healthcare Insurance Portability and Accountability Act of 1996, IRS Records Retention, and various state and federal computer security and crime acts); an order from the company Board of Directors; or of course, recommendations based on findings in an auditor's report. The practitioner should reasonably expect management to be aware of those rules and regulations that affect their business, but it can only benefit the practitioner to become and remain familiar with these same business influences. Within each company an opportunity will present itself for the practitioner to demonstrate management's understanding of these rules and regulations and to provide management with an interpretation, particularly in relation to how it impacts implementation of information technology-supported business processes.

> …the hallmark of an effective program to prevent and detect violations of law is that the organization exercised due diligence in seeking to prevent and detect criminal conduct by its employees and other agents…
>
> —U.S. Sentencing Guidelines, §8A1.2

Every practitioner should also try to be included, or at least provide input, in the contract specifications phase of any large information technology project. Organizations have begun anticipating that E-commerce is a routine part of doing business. In that regard the company is more likely to be confronted with a contractual requirement to allow its external business partners to actually perform a security or disaster recovery assessment of all business partners' security and contingency readiness. Is the practitioner ready to detail the acceptable level of intrusive review into their company's networks? The practitioner can be management's facilitator in this process by expecting the business partners to continue expanding requirements for determining the actual extent of protection in place in the operating environment and then being prepared to provide detailed contractual specifics that are acceptable within their own organization.

44.5.5 Productivity

Automated access management controls … Controlling access is essential if the organization wants to charge for services or provide different levels of service for premier customers and partners. Ensuring a system is properly developed, implemented, and maintained will ensure that only appropriate users access the system and that it is available when the users want to work.

In today's technological work environment, most managers will insist that the information technology section unfailingly install and keep up-to-date, real-time technology solutions. Without automated virus detection and eradication, there is little doubt that the organizational use of information resources might be nonexistent. With virus protection in place and kept up-to-date, employee productivity is, at the least, going to be stable.

There are varying opinions as to whether encryption enhances productivity, but there are few managers who will dispute that it is a business enabler. Encryption enables added confidence in privacy and confidentiality of information transmitted over shared networks, whether these are extranet, intranets, or the Internet. There is and will continue to be a business need for the confidentiality assurances of encryption. Increasing use of PGP and digital signature advances provides a greater assurance that sensitive or proprietary corporate information can be transmitted over open networks with confidence that the intended recipient will be the only one to view the information.

A basic part of the technology foundation in any organization is being prepared to respond to any computer incident. Having an active and trained response team will minimize downtime and, conversely, lend assurance to increased productivity.

44.5.6 Team-up to Motivate Management

Practitioners typically feel that the auditor is an ally in obtaining management's buy-in, but remember to look at any situation from the auditor's perspective. It is their responsibility to verify that business processes (including continuity and security processes) are performed in a verifiable manner with integrity of the process ensured. This basic premise sets up a conflict of interest when it comes to attempting to involve the auditor in recommendations for developing controls in a business process. But at the same time, it is a very good idea for the practitioner to develop a modified "teaming" relationship with the company's internal audit staff. One of the most likely places to obtain useful organizational information regarding what is successful within the organization and what might stand to be improved is in working in concert with internal audit.

Similarly, the practitioner can be an ally to the legal staff, and vice versa. This "motivator" is not addressed in this chapter as it has been well-documented in earlier editions of this handbook.

44.6 Summary

Management says:	You can do this yourself; aren't you the expert?
The practitioners' response:	This will always be a team effort; as much as I know the business, I will never understand the level of detail known by the people who actually do the work

Practitioners should try to make their own priorities become management's priorities, but more important for the practitioner is to ensure that management's priorities are their own priorities. If the practitioner knows management's concerns and what items management will "move" on, they will be more successful than if they try to make managers accept "requirements" that the managers do not view as important to the success of the business.

The practitioner must strive to be recognized as a facilitator within the organization. The successful practitioner will be the one who can be depended upon to be an effective part of a project team and is relied upon to bring about satisfactory resolution of conflicts, for example, between users' desires (ease of use) and an effective automated business process that contains efficient, programmed controls that ensure appropriate segregation of duties.

It is an old euphemism but with all things considered it should hold a special significance to the practitioner: "The customer is always right." It is a rare situation where the practitioner can force a decision or action that management will not support. If the practitioner makes the effort to know the business and keeps up-to-date with industry changes that impact the organization's business processes, then the practitioner will know what the customer wants. That practitioner will be successful in maintaining management's commitment.

45

Making Security Awareness Happen

Susan D. Hansche

Information technology (IT) is apparent in every aspect of our daily life—so much so that in many instances, it seems completely natural. Imagine conducting business without e-mail or voice mail. How about handwriting a report that is later typed using an electric typewriter? Computer technology and open-connected networks are the core components of all organizations, regardless of the industry or the specific business needs.

Information technology has enabled organizations in the government and private sectors to create, process, store, and transmit an unprecedented amount of information. The IT infrastructure created to handle this information flow has become an integral part of how business is conducted. In fact, most organizations consider themselves dependent on their information systems. This dependency on information systems has created the need to ensure that the physical assets, such as the hardware and software, and the information they process are protected from actions that could jeopardize the ability of the organization to effectively perform official duties.

> Several IT security reports estimate that if a business does not have access to its data for more than ten days, it cannot financially recover from the economic loss.

While advances in IT have increased exponentially, very little has been done to inform users of the vulnerabilities and threats of the new technologies. In March 1999, Patrice Rapalus, Director of the

Computer Security Institute, noted that "corporations and government agencies that want to survive in the Information Age will have to dedicate more resources to staffing and training of information system security professionals." To take this a step further, not only must information system security professionals receive training, but every employee who has access to the information system must be made aware of the vulnerabilities and threats to the IT system they use and what they can do to help protect their information.

Employees, especially end users of the IT system, are typically not aware of the security consequences caused by certain actions. For most employees, the IT system is a tool to perform their job responsibilities as quickly and efficiently as possible—security is viewed as a hindrance rather than a necessity. Thus, it is imperative for every organization to provide employees with IT-related security information that points out the threats and ramifications of not actively participating in the protection of their information. In fact, federal agencies are required by law (Computer Security Act of 1987) to provide security awareness information to all end users of information systems.

Employees are one of the most important factors in ensuring the security of IT systems and the information they process. In many instances, IT security incidents are the result of employee actions that originate from inattention and not being aware of IT security policies and procedures. Therefore, informed and trained employees can be a crucial factor in the effective functioning and protection of the information system. If employees are aware of IT security issues, they can be the first line of defense in the prevention and early detection of problems. In addition, when everyone is concerned and focused on IT security, the protection of assets and information can be much easier and more efficient.

To protect the confidentiality, integrity, and availability of information, organizations must ensure that all individuals involved understand their responsibilities. To achieve this, employees must be adequately informed of the policies and procedures necessary to protect the IT system. As such, all end users of the information system must understand the basics of IT security and be able to apply good security habits in their daily work environment. After receiving commitment from senior management, one of the initial steps is to clearly define the objective of the security awareness program. Once the goal has been established, the content must be decided, including the type of implementation (delivery) options available. During this process, key factors to consider are how to overcome obstacles and face resistance. The final step is evaluating success. This chapter focuses on these steps of developing an IT security awareness program.

> The first step in any IT security awareness program is to obtain a commitment from executive management.

45.1 Setting the Goal

Before beginning to develop the content of a security awareness program, it is essential to establish the objective or goal. It may be as simple as "all employees must understand their basic security responsibilities" or "develop in each employee an awareness of the IT security threats the organization faces and motivate the employees to develop the necessary habits to counteract the threats and protect the IT system." Some may find it necessary to develop something more detailed, as shown here:

Employees must be aware of:

- Threats to physical assets and stored information
- How to identify and protect sensitive (or classified) information
- Threats to open network environments
- How to store, label, and transport information
- Federal laws they are required to follow, such as copyright violations or privacy act information

- Who they should report security incidents to, regardless of whether it is just a suspected or actual incident
- Specific organization or department policies they are required to follow
- E-mail/Internet policies and procedures

When establishing the goals for the security awareness program, keep in mind that they should reflect and support the overall mission and goals of the organization. At this point in the process, it may be the right (or necessary) time to provide a status report to the Chief Information Officer (CIO) or other executive/senior management members.

45.2 Deciding on the Content

An IT security awareness program should create sensitivity to the threats and vulnerabilities of IT systems and also remind employees of the need to protect the information they create, process, transmit, and store. Basically, the focus of an IT security awareness program is to raise the security consciousness of all employees.

The level and type of content are dependent on the needs of an organization. Essentially, one must tell employees what they need to protect, how they should protect it, and how important IT system security is to the organization.

45.3 Implementation (Delivery) Options

The methods and options available for delivering security awareness information are very similar to those used for delivering other employee awareness information, such as sexual harassment or business ethics. Although this is true, it may be time to break with tradition and step out of the box—in other words, it may be time to try something new.

Think of positive, fun, exciting, and motivating methods that will give employees the message and encourage them to practice good computer security habits.

Keep in mind that the success of an awareness program is its ability to reach a large audience through several attractive and engaging materials and techniques. Examples of IT security awareness materials and techniques include:

- Posters
- Posting motivational and catchy slogans
- Videotapes
- Classroom instruction
- Computer-based delivery, such as CD-ROM or intranet access
- Brochures/flyers
- Pens/pencils/keychains (any type of trinket) with motivational slogans
- Post-It notes with a message on protecting the IT system
- Stickers for doors and bulletin boards
- Cartoons/articles published monthly or quarterly in in-house newsletter or specific department notices
- Special topical bulletins (security alerts in this instance)
- Monthly e-mail notices related to security issues or e-mail broadcasts of security advisories
- A security banner or pre-logon message that appears on the computer monitor
- Distribution of food items as an incentive. For example, distribute packages of the gummy-bear type candy that is shaped into little snakes. Attach a card to the package, with the heading

"Gummy Virus Attack at XYZ." Add a clever message such as: "Destroy all viruses wiggling through the network—make sure your anti-virus software is turned on."

The Web site http://awarenessmaterials.homestead.com/ lists the following options:

- First aid kit with slogan "It's healthy to protect our patient's information; it's healthy to protect our information."
- Mirror with slogan: "Look who is responsible for protecting our information."
- Toothbrush with slogan: "Your password is like this toothbrush; use it regularly, change it often, and do not share it with anyone else."
- Badge holder retractable with slogan: "Think Security"
- Key-shaped magnet with slogan: "You are the key to good security!"
- Flashlight with slogan: "Keep the spotlight on information protection."

Another key success factor in an awareness program is remembering that it never ends—the awareness campaign must repeat its message. If the message is very important, then it should be repeated more often—and in a different manner each time. Because IT security awareness must be an ongoing activity, it requires creativity and enthusiasm to maintain the interest of all audience members. The awareness materials should create an atmosphere that IT security is important not only to the organization, but also to each employee. It should ignite an interest in following the IT security policies and rules of behavior.

An awareness program must remain current. If IT security policies are changing, the employees must be notified. It may be necessary and helpful to set up a technical means to deliver immediate information. For example, if the next "lovebug" virus has been circulating overnight, the system manager could post a pre-logon message to all workstations. In this manner, the first item the users see when turning on the machine is information on how to protect the system, such as what to look for and what not to open.

Finally, the security awareness campaign should be simple. For most organizations, the awareness campaign does not need to be expensive, complicated, or overly technical in its delivery. Make it easy for employees to get the information and make it easy to understand.

Security awareness programs should (be):

- Supported and led by example from management
- Simple and straightforward
- Positive and motivating
- A continuous effort
- Repeat the most important messages
- Entertaining
- Humor, where appropriate; make slogans easy to remember
- Tell employees what the threats are and their responsibilities for protecting the system

In some organizations, it may be a necessary (or viable) option to outsource the design and development of the awareness program to a qualified vendor. To find the best vendor to meet an organization's needs, one can review products and services on the Internet, contact others and discuss their experiences, and seek proposals from vendors that list previous experiences and outline their solutions to the stated goals.

45.4 Overcoming Obstacles

As with any employee-wide program, the security awareness campaign must have support from senior management. This includes the financial means to develop the program. For example, each year management must allocate dollars that will support the awareness materials and efforts. Create a project plan that includes the objectives, cost estimates for labor and other materials, time schedules, and outline any specific deliverables (i.e., 15-min video, pens, pencils, etc.). Have management approve the plan and set aside specific funds to create and develop the security awareness materials.

Keep in mind that some employees will display passive resistance. These are the employees who will not attend briefings and create a negative atmosphere by ignoring procedures and violating security policies. There is also active resistance where an employee may purposefully object to security protections and fights with management over policies. For example, many organizations disable the floppy drive in workstations to reduce the potential of viruses entering the network. If an employee responds very negatively, management may stop disabling the floppy drives. For this reason, management support is important to obtain before beginning any type of security procedures associated with the awareness campaign.

Although one will have resistance, most employees (the author is convinced it is 98 percent) want to perform well in their job, do the right thing, and abide by the rules. Do not let the naysayers affect your efforts—computer security is too important to let a few negative people disrupt achieving good security practices for the organization.

What should one do if frustrated? It is common for companies to agree to an awareness program, but not allocate any human or financial resources. Again, do not be deterred. Plan big, but start small. Something as simple as sending e-mail messages or putting notices in the newsletter can be a cost-effective first step. When management begins to see the effect of the awareness material (of course, they will notice; you will be pointing them out) then the resources needed may be allocated. The important thing is to keep trying and doing all that one can with one's current resources (or lack of them).

Employees are the single most important asset in protecting the IT system. Users who are aware of good security practices can ensure that information remains safe and available.

> Check out the awareness tip from Mike Lambert, CISSP, on his Web page: http://www.frontiernet.net/~mlambert/awareness/. Step-by-step directions and information is provided on how to develop "pop-up announcements." It is a great idea!

45.5 Evaluation

All management programs, including the security awareness program, must be periodically reviewed and evaluated. In most organizations, there will be no need to conduct a formal quantitative or qualitative analysis. It should be sufficient to informally review and monitor whether behaviors or attitudes have changed. The following provides a few simple options to consider:

1. Distribute a survey or questionnaire seeking input from employees. If an awareness briefing is conducted during the new-employee orientation, follow up with the employee (after a specified time period of three to six months) and ask how the briefing was perceived (i.e., what do they remember, what would they have liked more information on, etc.).
2. While getting a cup of coffee in the morning, ask others in the room about the awareness campaign. How did they like the new poster? How about the cake and ice cream during the meeting? Remember that the objective is to heighten the employee's awareness and responsibilities of computer security. Thus, even if the response is "that poster is silly," do not fret; it was noticed and that is what is important.
3. Track the number and type of security incidents that occur before and after the awareness campaign. Most likely, it is a positive sign if one has an increase in the number of reported incidents. This is an indication that users know what to do and who to contact if they suspect a computer security breach or incident.
4. Conduct "spot checks" of user behavior. This may include walking through the office checking if workstations are logged in while unattended or if sensitive media are not adequately protected.

5. If delivering awareness material via computer-based delivery, such as loading it on the organization's intranet, record student names and completion status. On a periodic basis, check to see who has reviewed the material. One could also send a targeted questionnaire to those who have completed the online material.
6. Have the system manager run a password-cracking program against the employee's passwords. If this is done, consider running the program on a stand-alone computer and not installing it on the network. Usually, it is not necessary or desirable to install this type of software on one's network server. Beware of some free password-cracking programs available from the Internet because they may contain malicious code that will export one's password list to a waiting hacker.

Keep in mind that the evaluation process should reflect and answer whether or not the original objectives/goals of the security awareness program have been achieved. Sometimes, evaluations focus on the wrong item. For example, when evaluating an awareness program, it would not be appropriate to ask each employee how many incidents have occurred over the last year. However, it would be appropriate to ask each employee if they know who to contact if they suspect a security incident.

45.6 Summary

> Employees are the single most important aspect of an information system security program, and management support is the key to ensuring a successful awareness program.

The security awareness program needs to be a line item in the information system security plan of any organization. In addition to the operational and technical countermeasures that are needed to protect the system, awareness (and training) must be an essential item. Various computer crime statistics show that the threat from insiders ranges from 65 to 90 percent. This is not an indication that 65 percent of the employees in an organization are trying to hack into the system; it does mean employees, whether intentionally or accidentally, may allow some form of harm into the system. This includes loading illegal copies of screensaver software, downloading shareware from the Internet, creating weak passwords, or sharing their passwords with others. Thus, employees need to be made aware of the IT system "rules of behavior" and how to practice good computer security skills. Further, in federal organizations, it is a law (Computer Security Act of 1987) that every federal employee must receive security awareness training on an annual basis.

The security awareness program should be structured to meet the organization's specific needs. The first step is deciding on the goals of the program—what it should achieve—and then developing a program plan. This plan should then be professionally presented to management. Hopefully, the program will receive the necessary resources for success, such as personnel, monetary, and moral support. In the beginning, even if there are insufficient resources available, start with the simple and no-cost methods of distributing information. Keep in mind that it is important just to begin, and along the way, seek more resources and ask for assistance from key IT team members.

The benefit of beginning with an awareness campaign is to set the stage for the next level of IT security information distribution, which is IT security training. Following the awareness program, all employees should receive site-specific training on the basics of IT security. Remember that awareness does not end when training begins; it is a continuous and important feature of the information system security awareness and training program.

45.7 Training

Training is more formal and interactive than an awareness program. It is directed toward building knowledge, skills, and abilities that facilitate job capabilities and performance. The days of long, and dare one say, boring lectures have been replaced with interactive and meaningful training. The days when instructors were chosen for their specific knowledge, regardless of whether they knew how to communicate that knowledge, have disappeared. Instructional design (i.e., training) is now an industry that requires professionals to know instructional theories, procedures, and techniques. Its focus is on ensuring that students develop skills and practices that, once they leave the training environment, will be applicable to their job. In addition, training needs to be a motivator; thus, it should spark the student's curiosity to learn more.

During the past decade, the information systems security training field has strived to stay current with the rapid advances of information technologies. One example of this is the U.S. National Institute of Standards and Technology (NIST) document, SP800-16 "IT Security Training Requirements: A Role- and Performance-based Model." This document, developed in 1998, provides a guideline for federal agencies developing IT security training programs. Even if an organization is in the private sector, NIST SP800-16 may be helpful in outlining a baseline of what type and level of information should be offered. For this reason, a brief overview of the NIST document is included in this chapter. Following this overview, the chapter follows the five phases of the traditional instructional systems design (ISD) model for training: needs analysis and goal formation, design, development, implementation, and evaluation. The ISD model provides a systematic approach to instructional design and highlights the important relationship and linkage between each phase. When following the ISD model, a key significant aspect is matching the training objectives with the subsequent design and development of the content material. The ISD model begins by focusing on what the student is to know or be able to do after the training. Without this beginning, the remaining phases can be inefficient and ineffective. Thus, the first step is to establish the training needs and outline the program goals. In the design and development phase, the content, instructional strategies, and training delivery methods are decided. The implementation phase includes the actual delivery of the material. Although the evaluation of the instructional material is usually considered something that occurs after completing the implementation, it should be considered an ongoing element of the entire process. The final section of the article provides a suggested IT security course curriculum. It lists several courses that may be needed to meet the different job duties and roles required to protect the IT system. Keep in mind that course curriculum for an organization should match its identified training needs.

45.7.1 NIST SP800-16 "IT Security Training Requirements: A Role- and Performance-Based Model" (Available from the NIST Web site http://csrc.nist.gov/nistpubs/)

The NIST SP800-16 IT Security Learning Continuum provides a framework for establishing an information systems security training program. It states that after beginning an awareness program, the transitional stage to training is "Security Basics and Literacy." The instructional goal of "Security Basics and Literacy" is to provide a foundation of IT security knowledge by providing key security terms and concepts. This basic information is the basis for all additional training courses.

Although there is a tendency to recognize employees by specific job titles, the goal of the NIST SP800-16 IT Security Learning Continuum is to focus on IT-related job functions and not job titles. The NIST IT Security Learning Continuum is designed for the changing workforce: as an employee's role changes or as the organization changes, the need for IT security training also changes. Think of the responsibilities and daily duties required of a system manager ten years ago versus today. Over the course of time, employees will acquire different roles in relationship to the IT system. Thus, instead of saying the system manager needs a specific course, SP800-16 states that the person responsible for a specific IT system function will need a specific type of training.

Essentially, it is the job function and related responsibilities that will determine what IT system security course is needed. This approach recognizes that an employee may have several job requirements and thus may need several different IT security training classes to meet the variety of duties. It can be a challenge to recognize this new approach and try to fit the standard job categories into this framework. In some organizations, this may not be possible. However, irrespective of the job function or organization, there are several IT security topics that should be part of an IT system security curriculum. Always keep in mind that the training courses that are offered must be selected and prioritized based on the organization's immediate needs.

In an ideal world, each organization would have financial resources to immediately fund all aspects of an IT security training program. However, the reality is that resource constraints will force an evaluation of training needs against what is possible and feasible. In some cases, an immediate training need will dictate the beginning or first set of training courses.

> If one is struggling with how to implement a training program to meet one's needs, training professionals can help to determine immediate needs and provide guidance based on previous experiences and best practices.

45.7.2 Management Buy-In

Before the design and development of course content, one of the first challenges of a training program is receiving support from all levels of the organization, especially senior management. Within any organization are the "training believers" and the "on-the-job-learning believers." In other words, some managers believe that training is very important and will financially support training efforts, while others believe that money should not be spent on training and employees should learn the necessary skills while performing their job duties. Thus, it is an important first step to convince senior managers that company-provided training is valuable and essential.

> Senior management needs to understand that training belongs on the top of everyone's list. When employees are expected to perform new skills, the value of training must be carefully considered and evaluated.

To help persuade senior management of the importance of sponsoring training, consider these points:

1. *Training helps provide employee retention*. To those who instantly thought that, "No, that is not right; we spend money to train our employees and then they leave and take those skills to another company," there is another side. Those employees will leave anyway; but, on average, employees who are challenged by their job duties (and … satisfied with their pay) and believe that the company will provide professional growth and opportunities will stay with the company.
2. *Find an ally in senior management who can be an advocate*. When senior managers are discussing business plans, it is important to have someone speak positively about training programs during those meetings.
3. *Make sure the training program reflects the organizational need*. In many instances, one will need to persuade management of the benefits of the training program. This implies that one knows the weaknesses of the current program and that one can express how the training program will overcome the unmet requirements.
4. *Market the training program to all employees*. Some employees believe they can easily learn skills and do not need to take time for training. Thus, it is important to emphasize how the training will meet the employee's business needs.
5. *Start small and create a success*. Management is more likely to dedicate resources to training if an initial program has been successful.
6. *Discover management's objections*. Find out the issues and problems that may be presented. Also, try to find out what they like or do not like in training programs; then make sure the training program used will overcome these challenges. Include management's ideas in the program; although one may not be able to please everyone, it is a worthy goal to meet most everyone's needs.

Be an enthusiastic proponent. If one does not believe in the training program and its benefits, neither will anyone else.

45.8 Establishing the Information System Security Training Need

After receiving management approval, the next step in the development of a training program is to establish and define the training need. Basically, a training need exists when an employee lacks the knowledge or skill to perform an assigned task. This implies that a set of performance standards for the task must also exist. The creation of performance standards is accomplished by defining the task and the knowledge, skills, abilities, and experiences (KSA&Es) needed to perform the task. Then compare what KSA&Es the employees currently possess with those that are needed to successfully perform the task. The differences between the two are the training needs.

In the information systems security arena, several U.S. Government agencies have defined a set of standards for job functions or tasks. In addition to the NIST SP800-16, the National Security Telecommunications and Information Systems Security Committee (NSTISSC) has developed a set of INFOSEC training standards. For example, the NSTISSC has developed national training standards for four specific IT security job functions: Information Systems Security Professionals (NSTISSC #4011); the Designated Approving Authority (NSTISSIC #4012); System Administrator in Information System Security (NSTISSC #4013); and Information System Security Officer (NSTISSC #4014). The NIST and NSTISSC documents can be helpful in determining the standards necessary to accomplish the information system security tasks or responsibilities.

Once the needs analysis has been completed, the next step is to prioritize the training needs. When making this decision, several factors should be considered: legal requirements; cost-effectiveness; management pressure; the organization's vulnerabilities, threats, information sensitivity, and risks; and who is the student population. For some organizations (i.e., federal agencies, banking, health care), the legal requirements will dictate some of the decisions about what training to offer. To determine cost-effectiveness, think about the costs associated with an untrained staff. For example, the costs associated with a network failure are high. If an information system is shut down and the organization's IT operations cease to exist for an extended period of time, the loss of money and wasted time would be enormous. Thus, training system administrators would be a high priority. Executive pressures will come from within, usually the Chief Information Officer (CIO) or IT Security Officer. If an organization has conducted a risk assessment, executive-level management may prioritize training based on what it perceives as the greatest risks. Finally, and what is usually the most typical determining factor, training is prioritized based on the student population that has the most problems or the most immediate need.

Due to the exponential technological advances, information system security is continually evolving. As technology changes, so do the vulnerabilities and threats to the system. Taking it one step further, new threats require new countermeasures. All of these factors necessitate the continual training of IT system professionals. As such, the IT Security Training Program must also evolve and expand with the technological innovations.

In conducting the needs analysis, defining the standards, prioritizing the training needs, and finalizing the goals and objectives, keep in mind that when beginning an information system security training program, it is necessary to convince management and employees of its importance. Also, as with all programs, the training program's success will be its ability to meet the organization's overall IT security goals, and these goals must be clearly defined in the beginning of the program.

45.8.1 Developing the Program Plan

Once the training needs are known, the plan for the training program can be developed. The program plan outlines the specific equipment, material, tasks, schedule, and personnel and financial resources needed to produce the training program. The program plan provides a sequence and definition of the activities to be performed, such as deliverables for specific projects. One of the most common mistakes that training managers make is thinking they do not need a plan.

> Remember this common saying: If you do not plan your work, you cannot work your plan.

Another mistake is not seeking approval from senior management for the program plan. An integral part of program planning is ensuring that the plan will work. Thus, before moving to the next step, review the plan with senior managers. In addition, seeking consensus and agreement at this stage allows others to be involved and feel a part of the process—an essential component of success.

45.9 Instructional Strategy (Training Design and Development)

The design of the training program is based on the learning objectives. The learning objectives are based on the training needs. Thus, the instructional strategy (training delivery method) is based on the best method of achieving the learning objectives.

In choosing an instructional strategy, the focus should be on selecting the best method for the learning objectives, the number of students, and the organization's ability to efficiently deliver the instructional material. The key is to understand the learning objectives, the students, and the organization.

During the design and development phase, the content material is outlined and developed into instructional units or lessons. Remember that content should be based on what employees need to know and do to perform their job duties. During the needs analysis, one may have established the tasks and duties for specific job functions. If the content is not task-driven, the focus is on what type of behaviors or attitudes are expected. This involves defining what performance employees would exhibit when demonstrating the objective and what is needed to accomplish the goal. The idea is to describe what someone would do or display to be considered competent in the behavior or attitude.

> The course topics must be sequenced to build new or complex skills onto existing ones and to encourage and enhance the student's motivation for learning the material.

A well-rounded information system security training program will involve multiple learning methods. When making a decision about the instructional strategy, one of the underlying principles should be to choose a strategy that is as simple as possible while still achieving the objectives. Another factor is the instructional material itself; not all content fits neatly into one type of instructional strategy. That is, for training effectiveness, look at the learning objectives and content to determine what would be the best method for students to learn the material. One of the current philosophies for instructional material is that it should be "edutainment," which is the combination of education and entertainment. Because this is a hotly debated issue, the author's advice is not to get cornered into taking a side. Look at who the audience will be, what the content is, and then make a decision that best fits the learning objective.

When deciding on the method, here are a few tips:

- *Who is the audience?* It is important to consider the audience size and location. If the audience is large and geographically dispersed, a technology-based solution (i.e., computer-based [CD-ROM] or Web-based training [delivery over the Internet]) may be more efficient.
- *What are the business needs?* For example, if a limited amount of travel money is available for students, then a technology-based delivery may be applicable. Technology-based delivery can reduce travel costs. However, technology-based training usually incurs more initial costs to design and develop; thus, some of the travel costs will be spent in developing the technology-based solution.
- *What is the course content?* Some topics are better suited for instructor-led, video, Web, or CD-ROM delivery. Although there are many debates as to the best delivery method

(and everyone will have an opinion), seek out the advice of training professionals who can assess the material and make recommendations.

- *What type of learner interaction is necessary?* Is the course content best presented as self-paced individual instruction or as group instruction? Some instructional materials are better suited for face-to-face and group interaction, while other content is best suited for creative, interactive, individualized instruction. For example, if students are simply receiving information, a technology-based solution may be more appropriate. If students are required to perform problem-solving activities in a group, then a classroom setting would be better.
- *What types of presentations or classroom activities need to be used?* If the course content requires students to install or configure an operating system, a classroom lab might be best.
- *How stable is the instructional material?* The stability of content can be a cost issue. If content will change frequently, the expense of changing the material must be estimated in difficulty, time, and money. Some instructional strategies can be revised more easily and cost-efficiently than others.
- *What type of technology is available for training delivery?* This is a critical factor in deciding the instructional strategy. The latest trend is to deliver training via the Internet or an intranet. For this to be successful, students must have the technological capability to access the information. For example, in instances where bandwidth could limit the amount of multimedia (e.g., audio, video, and graphic animations) that can be delivered, a CD-ROM solution may be more effective.

Regardless of the instructional strategy, there are several consistent elements that will be used to present information. This includes voice, text, still or animated pictures/graphics, video, demonstrations, simulations, case studies, and some form of interactive exercises. In most courses, several presentation methods are combined. This allows for greater flexibility in reaching all students and also for choosing the best method to deliver the instructional content. If unfamiliar with the instructional strategies available, refer to the appendices in Chapter 85 for a detailed definition of instructor-led and technology-based training delivery methods.

While deciding on what type of instructional strategy is best suited for the training needs, it is necessary to explore multiple avenues of information. Individuals should ask business colleagues and training professionals about previous training experiences and then evaluate the responses. Keep in mind that the instructional strategy decision must be based on the instructional objectives, course content, delivery options, implementation options, technological capabilities, and available resources, such as time and money.

45.9.1 Possible Course Curriculum

Appendix B in Chapter 84 contains a general list of IT security topics that can be offered as IT system security training courses. The list is intended to be flexible; remember that as technologies change, so will the types of courses. It merely represents the type of training courses that an organization might consider. Additionally, the course content should be combined and relabeled based on the organization's particular training needs.

The appendices in Chapter 84 contain more detailed information for each course, including the title, brief description, intended audience, high-level list of topics, and other information as appropriate. The courses listed in Appendix B are based on some of the skills necessary to meet the requirements of an information system security plan. It is expected that each organization will prioritize its training needs and then define what type of courses to offer. Because several of these topics (and many more) are available from third-party training companies, it is not necessary to develop custom courses for an organization. However, the content within these outside courses is general in nature. Thus, for an organization to receive the most effective results, the instructional material should be customized by adding one's own policies and procedures. The use of outside sources in this customization can be both beneficial and cost-effective for the organization.

45.10 Evaluating the Information System Security Training Plan

Evaluating training effectiveness is an important element of an information system security training plan. It is an ongoing process that starts at the beginning of the training program. During all remaining phases of the training program, whether it is during the analysis, design, development, or implementation stage, evaluation must be built into the plan.

Referring back to NIST SP800-16, the document states that evaluating training effectiveness has four distinct but interrelated purposes to measure:

1. The extent that conditions were right for learning and the learner's subjective satisfaction
2. What a given student has learned from a specific course
3. A pattern of student outcomes following a specified course
4. The value of the class compared to other options in the context of an organization's overall IT security training program

Further, the evaluation process should produce four types of measurement, each related to one of the evaluation's four purposes. Evaluation should:

1. Yield information to assist the employees themselves in assessing their subsequent on-the-job performance
2. Yield information to assist the employee's supervisors in assessing individual students' subsequent on-the-job performance
3. Produce trend data to assist trainers in improving both learning and teaching
4. Produce return-on-investment statistics to enable responsible officials to allocate limited resources in a thoughtful, strategic manner among the spectrum of IT security awareness, security literacy, training, and education options for optimal results among the workforce as a whole

To obtain optimal results, it is necessary to plan for the collection and organization of data, and then plan for the time an analyst will need to evaluate the information (data) and extrapolate its meaning to the organization's goals.

One of the most important elements of effective measurement and evaluation is selecting the proper item to measure. Thus, regardless of the type of evaluation or where it occurs, the organization must agree on what it should be evaluating, such as perceptions, knowledge, or a specific set of skills.

> Because resources, such as labor hours and monies, are at a premium for demand, the evaluation of the training program must become an integral part of the training plan.

Keep in mind that evaluation has costs. The costs involve thought, time, energy, and money. Therefore, evaluation must be thought of as an ongoing, integral aspect of the training program and both time and money must be budgeted appropriately.

45.11 Summary

IT system security is a rapidly evolving, high-risk area that touches every aspect of an organization's operations. Both companies and federal agencies face the challenge of providing employees with the appropriate awareness, training, and education that will enable employees to fulfill their responsibilities effectively and to protect the IT system assets and information.

> Employees are an organization's greatest asset, and trained employees are crucial to the effective functioning and protection of the information system.

This chapter has outlined the various facets of developing an information system (IS) security training program. The first step is to create an awareness program. The awareness program helps to set the stage by alerting employees to the issues of IT security. It also prepares users of the IT system for the next step of the security training program—providing the basic concepts of IT security to all employees. From this initial training effort, various specialized and detailed training courses should be offered to employees. These specific training courses must be related to the various job functions that occur within an organization's IT system security arena.

Critical to the success of a training program is having senior management's support and approval. During each step of the program's life cycle, it is important to distribute status reports to keep all team members and executive-level managers apprised of progress. In some instances, it may be important (or necessary) to receive direct approval from senior management before proceeding to the next phase.

The five steps of the instructional process are relevant to all IS security training programs. The first step is to analyze the training needs and define the goals and objectives for the training program. Once the needs have been outlined, the next step is to start designing the course. It is important to document this process into some type of design document or blueprint for the program. Because the design document provides the direction for the course development, all parties involved should review and approve the design document before proceeding.

The development phase involves putting all the course elements together, such as the instructor material, student material, classroom activities, or if technology-based, storyboarding and programming of media elements. Once course development has been completed, the first goal of the implementation phase is to begin with a pilot or testing of the materials. This allows the instructional design team to evaluate the material for learner effectiveness and rework any issues prior to full-scale implementation. Throughout the IS security training program, the inclusion of an evaluation program is critical to the program's success. Resources, such as time and money, must be dedicated to evaluate the instructional material in terms of effectiveness and meeting the learning and company's needs. Keep in mind that the key factor in an evaluation program is its inclusion throughout the design, development, and implementation of the IT security training program.

Several examples of training courses have been suggested for an IS security training program. Remember that as technology changes, the course offerings required to meet the evolving IT security challenges must also change. These changes will necessitate modifications and enhancements to current courses. In addition, new courses will be needed to meet the ever-changing IT system advances and enhancements. Thus, the IS security training program and course offerings must be flexible to meet the new demands.

Each organization must also plan for the growth of the IT professional. IT security functions have become technologically and managerially complex. Companies are seeking educated IT security professionals who can solve IT security challenges and keep up with the changing technology issues. Currently, there is a lack of IT security professionals in the U.S. workforce; thus, organizations will need to identify and designate appropriate individuals as IT security specialists and train them to become IT security professionals capable of problem-solving and creating vision.

As one faces the challenges of developing an information system security training program, it is important to remember that the process cannot be accomplished by one person working alone. It requires a broad, cross-organizational effort that includes the executive level bringing together various divisions to work on projects. By involving everyone in the process, the additional benefit of creating ownership and accountability is established. Also, the expertise of both training personnel (i.e., training managers, instructional designers, and trainers) and IT security specialists are needed to achieve the training goals.

> Always remember the end result: "A successful IT security training program can help ensure the integrity, availability, and confidentiality of the IT system assets and its information—the first and foremost goal of IT security."

46

Beyond Information Security Awareness Training: It Is Time To Change the Culture

Stan Stahl

46.1 Introduction

The effectiveness of an information security program ultimately depends upon the behavior of people. Behavior, in turn, depends upon what people know, how they feel, and what their instincts tell them to do. Although an awareness training program can impart information security knowledge, it rarely has a significant impact on people's feelings about their responsibility for securing information or their deeper security instincts. The result is often a gap between the dictates of information security policy and the behaviors of our people.

One sees this phenomenon every time an employee opens an unexpected e-mail attachment from a friend. The employee may not really care about the potential that the attachment is a virus, or they may care but their instincts are not finely enough honed to intuitively recognize the threat.

It is the same issue every time an employee falls victim to social engineering. People's instincts are to be helpful. We amplify this instinct every time we tell employees about the importance of customer service, and then we wonder why, in that moment of truth, after the social engineer has sounded so friendly and seemed so honest, the employee disregards the awareness training program and gives up his password.

Sometimes it is management who, in a weak moment, falters. What of the operations manager who needs to share information with a vendor? Yes. He knows he is supposed to arrange this through the chief information security officer, but time is of the essence. He has known the vendor for 20 years, and the vendor would never do any harm. Before you know it, he has connected the corporate crown jewels to an untrusted third party.

The root cause of the recent rash of thefts of bank account and Social Security numbers at companies such as ChoicePoint and Lexis-Nexis is the failure on the part of people to recognize an information risk and, having recognized it, to act on it. Phishing schemes succeed only because people are not sensitive to the potential for information harm. Identity theft has become the fastest growing white-collar crime in the United States because society has not yet evolved a strong sensitivity to information risk. Information risk has not yet become something we feel in our gut. Yet until and unless we affect how people feel about the need to secure information, until and unless our people develop good information security instincts, the gap between the dictates of information security policy and the behaviors of our people will persist. It is the role of culture to close this gap.

46.2 Organizational Culture

The culture of an organization can be defined as:

> A pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems.[1]

What this means is simply that, as an organization evolves, it discovers ways to adapt to market, competitive, regulatory, and other changes in its external environment. It also figures out ways to organize itself internally—formally, as represented by the organization chart, and, more importantly, informally—the way the work actually gets done. These ways are never perfect, but they are satisfactory for achieving the organization's goals and objectives. These ways of being and of adapting then become the norm for the organization, and they characterize the organization's culture.

Cultures have subcultures; thus, one finds marketing and subculture and a sales subculture. These two subcultures emphasize building relationships with one's markets and customers. That is why a lot of golf is played by people in these subcultures. We all know the penuriousness of those in the financial subculture; they are not called "bean counters" without good reason. Operations people have their own subculture, as they are focused on managing the supply chain and transforming streams of orders and raw materials into the delivery of products and invoices. The information technology (IT) organization, too, has its own subculture, very distinct from other organizational subcultures. It even speaks a language of its own. If the organization is big enough, it will even have its own security subculture, typically populated by former law enforcement personnel expert at guarding people and things.

One of the things to observe is that the marketing, sales, operations, and financial subculture form the core of an organization and, consequently, dominate in setting the culture of the entire organization. A second thing to observe is that a great deal of interaction occurs between people in these core subcultures. They work together to accomplish the mission of the organization. As a result, there is a

[1] Schein, E. H. 1992. In *Organizational Culture and Leadership, 2nd Ed.*, Jossey-Bass, San Francisco, CA.

mixing of subcultures, and people throughout these parts of the organization evolve a somewhat similar way to perceive, think, and feel about problems and challenges.

One of the major challenges in strategically integrating the IT organization into the senior management team is that the cultural barriers are often difficult to break through. As IT has become more readily acknowledged as being strategically critical to the success of the organization, more leadership energy is being put into breaking down the cultural barriers between IT and the core organization.

Note, finally, that in the typical organization the entire protection function is externally located in the security function, with little if any mixing between the security culture and the rest of the organization. Responsibility for protection lies with the security organization; everyone else gets to go about their business without worrying about security because the guards are presumed to have it all covered.

46.3 The Information Security Cultural Challenge

Given the cultural context in which the information security organization finds itself, the cultural realities of the situation are, to be honest, somewhat bleak:

- Information security is a new kid on the block. In most organizations, the information security function is at most a few years old. The field itself dates back to only 1970.[2]
- Information security is nowhere near core to the organization. Even when a regulatory requirement for information security controls exists, it is pushed by senior management only because it is legally required. Top-level support for information security could dry up in an instant if the legal and regulatory landscape were to change.
- Even more challenging, the information security organization manages a set of concerns seemingly disconnected from those of the marketing, sales, operations, and financial organizations, with the result that the information security subculture is dramatically disconnected from these other, mush more dominant subcultures.
- Because the term “information security” contains the word “security,” the cultural expectation is that the information security group will take care of security just like the guards do, with no need for “me” to get involved.
- Except for the annual awareness training, the only time the information security culture touches the rest of the organization is when employees forget their passwords or when system apparently will not let employees “do their job.” Consequently, natural opportunities for cultural blending are few, with the result that the information security subculture will tend to evolve in isolation from the dominant culture.

It is against this backdrop that the information security organization must embed its culture into the culture of the larger organization, for this is the only way to transfer to the larger organization the correct way to perceive, think, and feel in relation to information security problems.

46.4 The Chief Information Security Officer’s New Job

The energy for the required cultural change must come from the information security organization, ultimately from the chief information security officer (CISO). Without the CISO’s commitment, organizational change will not occur. With adequate commitment, with enough time and energy put into the challenge of embedding information security into the very sinews of the organization, and with this commitment applied wisely, success can be a nice easy marathon. Any CISO who takes the CISSP

[2] I date the origin of the field as the publication date of *Security Controls for Computer Systems: Report of Defense Science Board Task Force on Computer Security*, edited by Willis H. Ware. A classified version was published in 1970 for the Office of the Secretary of Defense. The Rand Corporation published an unclassified version in 1979.

Security Management Practice Domain seriously and thinks logically about it can come to no other conclusion than that cultural change is and must be a part of his or her job description. The alternative, frankly, is a copout, and it results in more crisis work cleaning up after user messes; consequently, all CISOs should add the following to their job descriptions: Embed information security subculture itself as quickly as feasible into the larger culture, so the larger culture perceives, thinks, and feels correctly in relation to information security problems.

46.5 Leadership: The Force for Cultural Evolution

Cultures are never static. Left to their own devices, they continuously evolve in reaction to the internal and external pressures faced by the organization. The challenge of leadership is to optimally affect the ongoing course of organizational evolution, to be the change agent directing this evolution, keeping in mind that:[3]

> Culture and leadership are two sides of the same coin. …If cultures become dysfunctional, it is the unique function of leadership to perceive the functional and dysfunctional elements of the existing culture and to manage cultural evolution and change in such a way that the group can survive in a changing environment.
>
> Leadership … is the ability to step outside the culture … and to start evolutionary change processes that are … adaptive. This ability to perceive the limitations of one's own culture and to develop the culture adaptively is the essence and ultimate challenge of leadership.

This aspect of leadership—changing the larger culture in the direction of information security—must be part of any CISO's job description. Until and unless the information security way of seeing the world becomes a part of the organization's culture, the organization is dysfunctional. Every time a security breach occurs (even if it fell in the forest and no one was there to hear it), every time an information security breach occurs whose root cause is human, that is evidence of the dysfunctionality. So, the CISO must step outside the culture and look at it from the outside, molding and shaping its evolution so over time people are doing the right thing. They are being careful, they are paying attention, and they are even training each other, all because an information security mindset has become embedded in the larger culture.

46.6 Strategic Imperative: Evolve an Information Security Learning Organization

Real security lies not just in firewalls, passwords, and awareness training but also in a culture that perceives, thinks, and feels correctly with regard to information security problems. This can only happen gradually as the culture evolves into an information security learning organization. David Garvin, in an article in the *Harvard Business Review*, defines a learning organization as follows:[4]

> A learning organization is an organization skilled at creating, acquiring and transferring knowledge, and at modifying its behavior to reflect new knowledge and insights.

An information security learning organization is an organization skilled at creating, acquiring, and transferring knowledge about information security and at modifying its behavior to reflect new information security knowledge and insights. In *The Fifth Discipline*, Peter Senge, one of the pioneers

[3] Schein, E. H. 1992. In *Organizational Culture and Leadership, 2nd Ed.*, Jossey-Bass, San Francisco, CA.

[4] Garvin, D. 1993. Building a learning organization. *Harvard Business Rev.*, 71, 4, 78–91.

of learning organizations, identified five key disciplines that are prerequisites to establishing a learning organization.[5] These five disciplines are as follows.

46.6.1 Personal Mastery

Personal mastery refers to approaching one's life as a creative work, living life from a creative as opposed to a reactive viewpoint. This requires that we continually clarify what is important to us and continually learn how to see reality more clearly. We can only learn when we are unafraid; consequently, the CISO has to create a trusting environment in which people are willing to open up to their information security inadequacies without fear of feeling stupid or otherwise inadequate. Implementing this discipline gives the CISO a great opportunity to help people recognize the significant risks that their behavior subjects information to. As people's defenses fall, the CISO will have more opportunities to help people gain greater clarity about their information security responsibilities. In this way, the CISO can lead the culture to become ever more conscious of information risk and the things we must all do to counter it.

46.6.2 Mental Models

Continually managing our mental models—surfacing them, testing them, and improving them—brings our mental models of how we think things are into greater and greater alignment with how things really are. This requires providing people with the intellectual tools necessary to understand information security so its principles come to be applied in every situation where people might put information at risk. The CISO must define the very language by which the organization can talk about the security of information.

46.6.3 Shared Vision

Developing and nurturing a shared vision of the future is a powerful force for aligning the organization; out of a shared vision can come transcendental powers of accomplishment. The information security leader needs to connect information security to the very success or failure of the organization, helping people understand, for example, how an information breach could close the company and put people out of work. With the heightened concern about identity theft, the CISO has the opportunity to connect information security to the ethics of the Golden Rule: Everyone's information, including our own, is at risk. We must protect other people's information just as we rely on others to protect ours.

46.6.4 Team Learning

Team learning is aligned learning, based on dialog and discussion and having the power to efficiently move an organization toward its shared vision. The CISO must help people understand the reasons behind all the security rules. People do not like to follow rules, but they willingly embrace behavior when they have discovered its necessity for themselves. Thus, the CISO must work with people so they come to train each other. A goal should be to make information security a common theme in discussions around the water cooler.

46.6.5 Systems Thinking

Systems thinking is the ability to fully understand the cause-and-effect relationships that exist between events, that everything we do can simultaneously be both cause and effect. The CISO must understand the forces on the organization's culture and the myriad of causes and effects that impact the culture's evolution. And, having understood them, the CISO must create and implement a strategy for information security cultural change that aligns with these forces. To be effective, the change strategy must amplify those cultural forces, such as increased compliance and the organization's need for information availability, that demand greater cultural change. Conversely, an effective strategy must

[5] Senge, P. 1990. *The Fifth Discipline*, Doubleday Currency, New York.

overcome systemic realities, such as information security usually being relatively inconsequential to the core of the organization.

46.7 Real Power: The Force for Evolving the Information Security Culture

The greatest challenge that CISOs face as they go out into the world of culture change is a lack of any of the trappings of power. The typical power of the CISO is negative: "It's the information security group that makes me change my password." "Well I don't see why I can't have wireless in my office. Who made *them* God?" "Sorry, Bill. We can't go over end-of-month reports until Thursday. I have to take my information security awareness training. Boring!" And, although it may be possible to convince a chief information officer (CIO) or chief executive officer (CEO) to support you as the CISO, you know their attention will be diverted by the next crisis, and then they will kind of forget about you again … until the next disaster, when, unless you are lucky, you will be blamed for a human error the root cause of which is firmly embedded in the culture. Even if a CISO has the power to impose an information security perspective on the larger culture, the reality of organizational change programs—upwards of 75 percent of them fail—suggests that the CISO is not likely to succeed.

Fortunately, there is a better way, one that does work. It involves changing the culture imperceptibly, one moment of truth at a time, but doing so with strategic insight. Like the butterfly effect in complexity science, the CISO's objective is to achieve large outcomes from small inputs.[6] The strategic guide for accomplishing this was written in China 2500 years ago. According to legend, the *Tao Te Ching*, eastern philosophy in the Buddhist tradition, was written by a monk named Lao-tzu.

In their book *Real Power*, management consultant James Autry along with the noted religious scholar Stephen Mitchell, apply the *Tao Te Ching* to the modern business organization. Mitchell describes the *Tao* as follows:[7]

> *Tao* means literally *the way*. … The *Tao* has been called the wisest book ever written. It is also the most practical book ever written. In eighty-one brief chapters, the *Tao Te Ching* looks at the basic predicament of being human and gives advice that imparts balance and perspective … the classic manual on the art of living.

The authors describe the essence of the Tao's applicability to work as follows:

> The most important understanding we can have about work is not that we are there to cultivate ideas, but that we are there to cultivate the space that holds ideas.

Think about it. When the CISO is talking to the purchasing department about information security, the purpose is not to tell people the results of our thinking about information security. The purpose is to create opportunities for people to think about information security for themselves. Autry and Mitchell write the following as an analogy:

> We use materials and techniques to make a wheel or a pot or a house—yet what makes them useful is not their form but the space that their form defines and creates. A room is what is inside its four walls; the walls make the room possible but they aren't the room. Even what is inside the room—its furniture, lighting, floor coverings, and so on—only accommodates how people live within the room; they are not the living itself.

[6] The butterfly effect suggests that a butterfly flapping its wings in Los Angeles can cause a storm in Singapore 14 days later.

[7] Autry, J., Mitchell, S., 1998. *Real Power: Business Lessons from the Tao Te Ching*. Riverhead Books, New York.

It is not the passwords and the anti-virus software and the policies and the awareness training that are the information security culture. From the perspective of real power, these are merely the trappings of security. Real security lies in the culture perceiving, thinking, and feeling correctly in relation to information security problems. The culture does this by becoming an information security learning organization, and this happens, little by little, as those who know more about information security create opportunities for others to learn. It all starts with the CISO taking every opportunity to create an opportunity to cultivate the organizations ideas about securing information.

What gets in the way of opportunities for people to learn about information security? Autry and Mitchell tell us:

> *There's just one thing that collapses that space: expectations*. When people are talking with the boss, they are always aware of hierarchy, so they measure their words and actions, assuming that they are constantly being judged. This is, in fact, most often the case, and the added self-consciousness can stifle someone's best ideas. But if people feel that they can be themselves, that they aren't being judged against the boss's preconceptions, then they can become liberated to do their best work. When you act in this way to support people and ideas, you will be creating an atmosphere that gives birth to high morale and productivity.

Even though the CISO is not the boss, when he talks to people about information security he is the authority, acting in the role of judge. When people think they are being judge they become fearful. When they become fearful, they become defensive. When they become defensive, learning shuts down … and the CISO loses an opportunity to impact the culture. To be successful at creating culture change, then, the CISO must not judge. This is reflected in the very first of Deming's highly influential 14 points of quality improvement: "Drive out fear."[8]

With the above as prelude, the following are some verses from the *Tao* that are particularly germane to the challenge of embedding information security into the organizational culture:

> The ancient Masters
> Didn't try to educate the people,
> But kindly taught them to not-know.
>
> When they think that they know the answers,
> People are difficult to guide.
> When they know that they don't-know,
> People can find their own way.
>
> The Master doesn't talk, he acts.
> When his work is done,
> The People say, "Amazing:
> We did it, all by ourselves!"
>
> Intelligent control appears as uncontrol or freedom.
> And for that reason it is genuinely intelligent control.
> Unintelligent control appears as external domination.
>
> And for that reason it is really unintelligent control.
> Intelligent control exerts influence without appearing to do so.
> Unintelligent control tries to influence by making a show of force.

[8] Deming, W. E. 1986. *Out of the Crisis.* MIT Center for Advanced Educational Studies, Boston.

> If you want to shrink something,
> You must first allow it to expand.
> If you want to get rid of something,
> You must first allow it to flourish.
>
> Giving birth and nourishing,
> Having without possessing,
> Acting with no expectations,
> Leading and not trying to control:
> This is the supreme virtue

46.8 Ethical Persuasion: Changing Culture Means Building Relationships

> If you would win a man to your cause, first convince him that you are his sincere friend. Therein is a drop of honey that catches his heart, which is the high road to his reason, and which, when once gained, you will find but little trouble in convincing his judgment of the justice of your cause, if indeed that cause be a just one. —*Abraham Lincoln, 16th U.S. President*

Changing a culture requires changing people—changing how people perceive, think, and feel about information security problems. In effecting cultural change, the CISO must win everyone to the cause of information security, and to do that, as Lincoln reminds us, requires the CISO to be a sincere friend. If the CISO is to change people, the CISO must engage in what is known as *ethical persuasion*, the honest attempt to induce people, to change their behavior. To persuade ethically—to catch the heart, which is the high road to reason—the mode of persuasion must be direct and honest, respectful of people, and without manipulation. Recent work in the behavioral sciences has discovered six specific persuasion triggers that the CISO can use to influence the extent to which people will open themselves up to being persuaded.[9]

46.8.1 Trigger 1. Reciprocity

People feel obliged to give to people who have given to them

This trigger is, perhaps, at the core of human interaction and relationship building. It appears to be invariant across all human cultures. Besides instilling obligations, the reciprocity trigger is an inducement to build relationships. The trigger is activated by gifts and concessions. The key is to provide a gift or a concession as a way of getting a relationship started. The reciprocity trigger is a testament to the power of the Golden Rule: Give unto others as you would have them give unto you. First you give, then you get. The most important gifts a CISO can give are the gifts of friendship and respect, the gift of recognizing that coworkers have needs and challenges and responsibilities of their own, and the gift of accepting that these can get in the way of people's information security obligations. This does not mean abandoning information security standards, but it does mean giving people flexibility in meeting the standards. The CISO should also seek out opportunities to apply information security standards to helping people do their jobs. To most employees, information availability is more important than information confidentiality. The CISO who gives employees the gift of information availability can reciprocally trigger employees to better protect information confidentiality and integrity.

[9] Cialdini, R. 2001. Harnessing the science of persuasion. *Harvard Business Rev.*, 79, 71–79.

46.8.2 Trigger 2. Social Proof

People follow the lead of similar others

An information security bandwagon is forming as society increasingly recognizes the need to secure sensitive information. Laws are being passed requiring whole industries to implement information security safeguards. Legal duties of due care are being established in the courts, by the Federal Trade Commission, and by several Attorneys General. Business organizations, including the influential *Business Roundtable*, are recommending that information security become a matter for attention by a company's board of directors. Joining the bandwagon are all those employees who see their productivity suffer from spam, viruses, and the other digital detritus that finds its way into their information systems. An effective CISO can use this emerging bandwagon to trigger social proof. By gently demonstrating how this bandwagon is growing, by sharing with personnel how others are coming to think, feel, and act differently about information security issues, the CISO can influence people to join the bandwagon. To amplify this trigger the CISO can demonstrate how ubiquitous information security concerns are becoming and how the entire society is becoming concerned about information security matters. Building a bandwagon inside the company adds additional amplification as people tend to be more strongly influenced by people who are like them. People are particularly prone to doing what others do when they find themselves in unfamiliar situations where they are not quite sure what they should do. As information security requires employees to act differently, the effective CISO will always be on the lookout for opportunities to share information that illustrate effective security practices.

46.8.3 Trigger 3. Authority

People defer to experts who provide shortcuts to decisions requiring specialized information

As general rule, people tend to rely on those with superior knowledge, expertise, or wisdom for guidance on how to behave. This trigger illustrates the difference in influence between begin *an* authority and begin *in* authority. CISOs can naturally tap into this trigger as people typically respond to the trappings of authority. A CISO's title, CISSP certification, diplomas on the wall, books on the shelf, even the ability to speak geek are the trappings that establish the CISO's authority. Where the CISO sits in the organizational hierarchy can add or detract from the CISO's trappings of authority, which is a big reason why it is important for the CISO to have a seat at the management table. Although people will generally respond to the trappings of authority, research has shown that the most effective authority is the authority who is perceived as *credible*. Two factors dictate the extent to which people will deem the CISO as a credible authority: the CISO's expertise and trustworthiness. This is one reason why the CISSP certification is so valuable. Not only is it a trapping of authority, but it also serves to demonstrate expertise. It serves notice that the CISO is not just an empty suit. Trustworthiness is the second amplifier of the authority trigger. Trustworthiness means being honest with people about the realities of information security. It means not trying to frighten senior management into budget increases or employees into meek compliance with horror scenarios having a 0.00001 percent chance of occurrence. Trustworthiness means being brutally honest about the strength and robustness of one's information security controls, making them out to be neither stronger nor weaker than they really are.

46.8.4 Trigger 4. Consistency

People fulfill written, public, and voluntary commitments

Consistency is a very powerful trigger for the CISO who knows how to use it, but it also has the capacity to seriously backfire if misused. For this trigger to succeed, it is important that the commitment be voluntary. An involuntary commitment is at best neutral toward inducing behavioral change. At its worst it is downright dangerous, often acting to produce exactly the opposite effect from what is desired. So, although an organization may be obligated for legal reasons to require every employee to sign a statement agreeing to abide by the organization's information security policies, this involuntary commitment is unlikely to serve to change people's behaviors. Far more effective is for the CISO to understand people's values and behaviors and to link desired information security behaviors to behaviors to which the employee has already committed. If, for example, the organization values a strong chain of command, the CISO can link desired information security behavior into this chain of command. In this circumstance, employees will secure information as a way of fulfilling their commitment to respect the organization's chain of command. Alternatively, if the organization publicly values a looser, less restrictive, more autonomous environment, then it is important for the CISO to link information security behaviors to people's personal responsibility to do the right things for the organization.

46.8.5 Trigger 5. Scarcity

People value what is scarce

Because information security is about protecting the organization from loss, this trigger is a natural tool for the CISO. To understand the value of this trigger, it is important to recognize that several psychological studies have shown that people are more likely to expend money and energy to avoid loss than to achieve gain.[10] Consequently, by discussing information security in the language of loss, the CISO is far more able to induce people to take action to limit the potential for loss. CISOs can increase their effectiveness even more by making a point to couch the loss in terms that are meaningful to the listener. Consider, as an example, the impact of an open honest discussion about how an information security breach can result in lower revenues and how lower revenues translate into fewer jobs. (ChoicePoint provides a good starting point for the discussion.) This kind of discussion provides an opportunity for employees to link their jobs to the security of information. Because people are typically very risk averse with regard to losing their jobs, this well-positioned link to scarcity can serve to induce people to pay more attention to their information security actions.

46.8.6 Trigger 6. Liking

People prefer to say "yes" to people who they perceive like them

We have been taught how important it is that people like us, that our success depends in part on how well we are liked. To some extent this is true, but, like all great truths, there is another, deeper, perspective. It turns out that even more important than people liking us is us liking them. People like, and are inclined to follow, leaders who they perceive as liking them. If people perceive that the CISO likes them, they are more inclined to say "yes" to the CISO. What a golden opportunity for the CISO! CISOs must go out of their way to find legitimate opportunities to demonstrate to the people they work with that they really, truly like them. Add the liking trigger to the other five persuasion trigger, and the CISO has a sure-fire winning strategy for changing the organization's culture; for changing how the organization perceives, thinks, and feels in relation to information security problems; and for supporting the organization's becoming skilled at creating, acquiring, and transferring knowledge about information security and modifying its behavior to reflect new information security knowledge and insights. A thoughtful CISO can use the liking trigger in so many different ways. Rather than the CISO imposing information security requirements on people—a clear signal that the CISO does not respect them enough to solicit their input—a better strategy is to ask their opinion about how best they can secure information, thereby clearly demonstrating that the CISO values their opinion and likes them.

[10] Kahneman, D., Slovic, P., and Tversky, A. eds. 1982. *Judgment Under Uncertainty: Heuristics and Biases.* Cambridge University Press, Cambridge, U.K.

To influence people, win friends. An effective CISO will always be on the lookout for opportunities to establish goodwill and trustworthiness, to give praise, and to practice cooperation. To the extent CISOs show they like the people in their organizations and to the extent that CISOs show that they share their concerns and problems, to this extent will people provide the CISOs with opportunities to change the culture.

46.9 A Warning: Ignore at Your Own Peril

Integrity and honesty are absolutely vital in the application of these persuasion triggers. The six triggers have been shown to work in persuading people to act in ways desired by the persuader. Obviously, this power can be used for both good objectives and cynical ones. To be effective as a change agent, however, CISOs must take pains to use their powers of persuasion ethically. If people perceive a lack of moral or intellectual integrity on the part of their CISOs, not only will they not follow them, but they will also become even more cynical about the attempt of the information security organization to force changes upon them. Instead of embedding information security concerns in the larger culture, the larger culture will reject the embedding attempt.

46.10 Summary

The effectiveness of an information security program ultimately depends on the behavior of people. Behavior, in turn, depends on what people know, how they feel, and what their instincts tell them to do. Although an awareness training program can impart information security knowledge, it rarely has significant impact on people's feelings about their responsibility for securing information or their deeper security instincts. The result is often a gap between the dictates of information security policy and the behaviors of our people. It is the role of culture to close this gap. It is the CISO's responsibility to provide the organizational leadership required to change how the organization perceives, thinks, and feels in relation to information security problems and to embed the information security subculture into the dominant culture of the organization. Meeting this responsibility requires the CISO to create an information security learning organization, one skilled at creating, acquiring, and transferring knowledge about information security and modifying its behavior to reflect new information security knowledge and insights. At a deep strategic level, the CISO can only do this in harmony with the basic principles of real power, seeking to create the spaces in which information security learning can take place. Tactically, the CISO has available six specific persuasion triggers that taken together open up the spaces in which information security learning can take place. By ethically applying these persuasion triggers over and over and over again, day in and day out, the CISO has the opportunity to win the hearts and minds of the people, making information security information security come alive so everyone in the organization, from the CEO to the receptionist, can evolve an information security mindset.

47

Overview of an IT Corporate Security Organization

Jeffrey Davis

47.1 Introduction

An IT corporate security organization is composed of many different functions. These functions include architecture, policy management, risk assessment, awareness/training, governance, and security operations including incident response and threat and vulnerability management. Each of these functions will rely on information from the other functions, as well as information from the enterprise itself in order to manage the security risks inherent in business operations. These functions work together to comprise an organization that implements the basic tenants of confidentiality, integrity, and availability.

47.2 Security Architecture

The security architecture group provides both the road map for risk management and the security controls utilized by an organization. Its function is important in providing risk management for the institution and for coordinating the controls that reduce that risk. The security architecture is created from data incorporated from other security functions. These sources include functional security policy, metrics of past incidents, and evaluations of new threats that could be detected from the security operations function or the risk assessment function. Security policy input is used to illustrate the amount of risk the business is willing to accept and this information is used to define the security standards used throughout the entity for specific technologies. The policy assists in defining the functions and requirements required by the architecture. An example of this would be the security policy requiring that certain data be encrypted. The security architecture would need to define the way that requirement would be accomplished in the various areas of the enterprise. Additionally, the security architecture needs to address past incidents that have caused damage to the company. These incidents indicate areas that may require improved or revised security controls. New threats may require alterations in the security architecture and additional controls. The security architecture must also integrate with the existing technology infrastructure and provide guidance in establishing the proper risk controls necessary for the enterprise to perform its business securely, both in the present and in the future (Exhibit 47.1).

After taking into account those different inputs, the architecture should define the requirements for the individual tools and technologies that are needed to make up the architecture and ensure that, when integrated, they provide the appropriate level of risk mitigation. One example of this is virus protection. Most security architectures define multiple levels of antivirus protection at different areas of the infrastructure to cover the different vectors that malware might take to get into the company. This may include antivirus software at Internet gateways, internal email servers, file servers, and clients. The architecture should take into account the protection that each one of these controls affords and ensure that it integrates with the other layers and provides the appropriate amount of redundancy.

One way for the architecture function to begin is to define a security strategy. This strategy can then be used to align the actions of the security functions to ensure that the overall risk to the corporation is being addressed. The strategy should contain an overall framework that defines how security should be addressed in each area of the IT infrastructure, including networks, servers, and clients. Once a strategy is formed, then the group can put together an architecture description to implement that strategy. The architecture will reflect the different types of tools and configurations that will be used to realize the strategy. An example of this is a network segmentation strategy that would define a network architecture which would be used to limit access to certain servers and data. Some tools that could be used to implement this would be firewalls and routers that only allow certain traffic and servers to reach specific

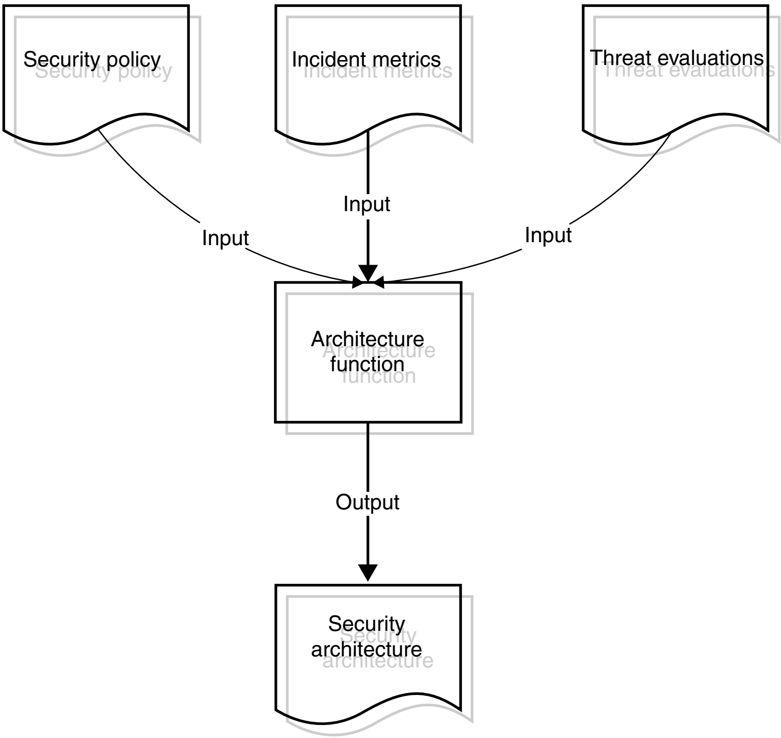


EXHIBIT 47.1 Inputs and outputs of the architecture function.

parts of the network. Other security controls, like antivirus protection, access controls, and identity management tools would also be defined as part of the architecture. Describing these tools and where they are implemented in the enterprise is the main function of the security architecture group.

47.3 Security Policy Management

Security policy ensures that risks are being addressed and controlled in a consistent manner across the enterprise. The security policy management function ensures that the enterprise's policy reflects the necessary guidelines to provide the appropriate amount of risk protection for the enterprise. In order to provide this risk protection, the policies must be reviewed and updated periodically in order to address new threats, new technologies being introduced inside the corporation, incidents that have occurred, and changes that administration wants to make to the level of risk acceptance (Exhibit 47.2).

New threats to an environment will sometimes require new policies. This is usually a result of a new threat or vulnerability changing the risk associated with a technology. An example of this would be the compromising of an encryption algorithm that is used to protect data. The policy that requires the use of encryption would need to be amended to ensure that this algorithm is no longer used, as it no longer provides its previous level of protection. Newer technologies that are introduced into the environment may also require new policies to ensure they do not introduce new risks. An example of this would be the use of wireless network technologies. These technologies introduce different threats into the environment then those that existed previously. Policies for these technologies need to be developed to ensure that those risks are consistently minimized. Security incidents may also highlight areas that require new policies. One example of this would be an incident involving the stealing of a laptop. This may prompt a new policy requiring that all data on a laptop be encrypted to reduce the risk of the loss a laptop.

Output
Security policies

EXHIBIT 47.2 Inputs and outputs of the policy management function.

Encrypting the data would reduce the risk of the data being accessible to third parties in the event the laptop was stolen.

The last item that may prompt a policy modification is a change in the level of risk that an enterprise is willing to endure. This can be triggered by two different factors. The first is that it becomes too expensive to implement the controls needed to satisfy the existing policy. The second is that the technology required to perform the function does not provide the security controls that the policy requires. For either of these situations, exceptions to policies can be documented and the risk accepted based on the business need. However, if these exceptions become numerous or more needed over the long term then it may be appropriate to modify the policies to reflect the acceptance of the risk rather than continue to manage the acceptance of the risk through an exception to policy.

The policy management function is usually performed by a team composed of security subject matter experts, members of the architecture team, representatives from the different technologies areas, and business representatives. The team works together to develop a policy that balances the risks associated with the technologies used within the enterprise with the functional needs of the business. This results in a policy document that is typically composed of general guidelines, as well as configuration requirements for specific technologies. This document is then used by other teams within the enterprise to ensure that the technology is being implemented in a way that is policy-compliant. This ensures that the risk is being managed consistently across the corporation.

47.4 Security Operations

The security operations function includes a number of different activities. These are performed to support the security protections for the enterprise. These functions include security incident response, compliance or vulnerability management, and threat assessment. Security operations may also include the operating of security controls, such as firewalls or Web-filtering software. These functions are performed to support the security policies, controls, and processes that are described by the security architecture and are used to reduce the risk to the enterprise (Exhibit 47.3).

The first function is incident response. This provides for a response to incidents that require security expertise or special skills, such as evidence gathering or specialized forensics. These may be incidents that require law enforcement involvement, responses on a large scale that require an unusual amount of resources, or mitigation of security vulnerabilities that require unique subject matter expertise. Large scale incidents may be managed by a computer security incident response team. This team may be made up of security specialists, system administrators, management, and others, as needed. Another function performed is compliance management. This is carried out to ensure with compliance security policy. This may include inspecting server configurations for secure settings, checking to ensure that machines are being patched and other actions to ensure that they are in compliance with security policy. Scanning and configuration management tools may be used to assist with these activities. The function may also partner with an audit function to ensure compliance with any legal regulations, such as Sarbanes Oxley. A third function would be to perform threat assessment. This is done to evaluate new threats to the environment. This would encompass new vulnerabilities discovered by the security community, as well as alerts from vendors. This team would gauge the risk associated with the new threats and then suggest appropriate actions and timeframes in which to take those actions to mitigate the threats. In the case of most vendor alerts, this will involve applying a patch to a piece of software. In other cases, it may require the changing of a security control, such as a firewall to block the traffic that would produce the threat. Other functions that security operations may perform may include the operating of other security controls such as firewalls, Web filtering software, intrusion detection systems, or antivirus filters. The operation by a security team of these controls ensures that they are monitored by appropriately-trained personnel familiar with the security threats that are being mitigated by these controls.

The security operations team relies heavily on the security policy, security architecture, and security controls to perform their jobs. The policies and architecture define what the business has accepted as the

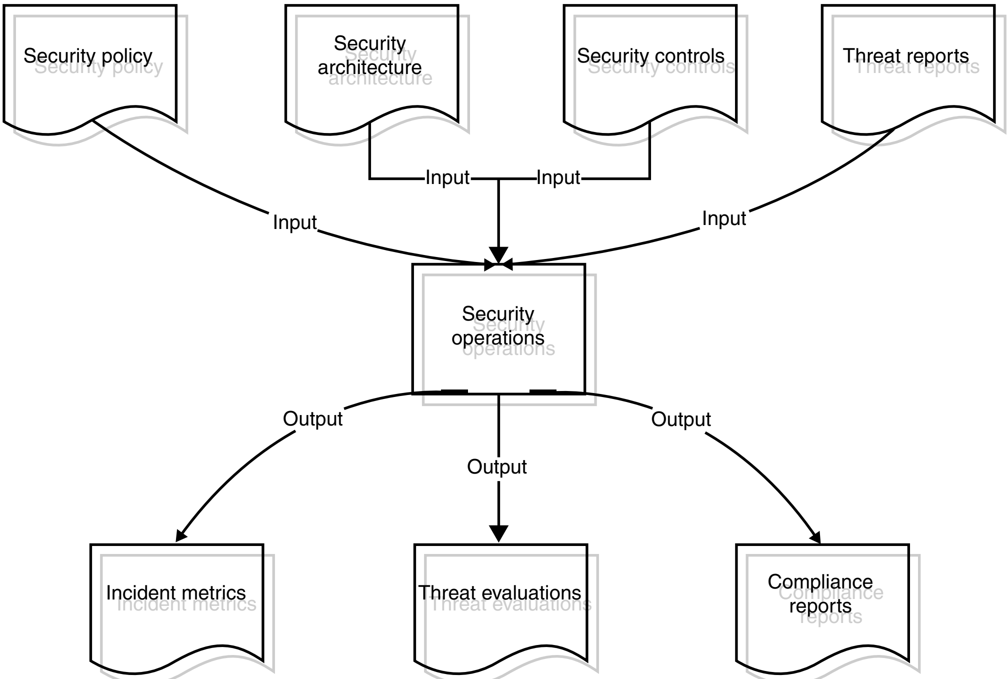

EXHIBIT 47.3 Inputs and outputs of the security operations function.

controls required to provide the appropriate level of risk protection. It is the job of the security operations department to apply those policies and ensure that they are providing the level of risk mitigation with which they are entrusted. One way to measure the effectiveness of the policies and security controls is to track the number and type of security incidents and threats that are being responded to. Compliance reports and metrics are also useful in understanding how the enterprise is doing in meeting the requirements of the security policies. These metrics can indicate whether the policies and controls in place are effective. They also provide feedback to other security functions such as architecture and policy management so that they can assess if the strategies and controls they are proposing are providing the level of risk control that the enterprise needs.

The security operation function applies and operates the policies and architecture that the other security functions form so that they alleviate the threats to the greatest possible degree. It also provides feedback to those other functions as to the effectiveness of those policies and architectures.

47.5 Risk Assessment

The risk assessment function provides a process by which to measure the risks of changes made to the existing technology of the enterprise. It will also assess the risks of introducing new technologies and the risk of not being compliant to existing policy if the business need requires it. This function provides a way to consistently judge and understand the risks associated with these actions (Exhibit 47.4).

Measuring the risks of changes is an important part of risk management within the company. As changes are implemented, they must be checked to ensure they are not changing the security threats and that they are compliant with the current policy. This is especially important when changes are made to infrastructure components that affect security controls. Changes can open up gaps in the security control architecture that may increase the security risk for the enterprise. These changes need to be examined for compliance with policy and introduction of new vulnerabilities or threats into the environment. Risk

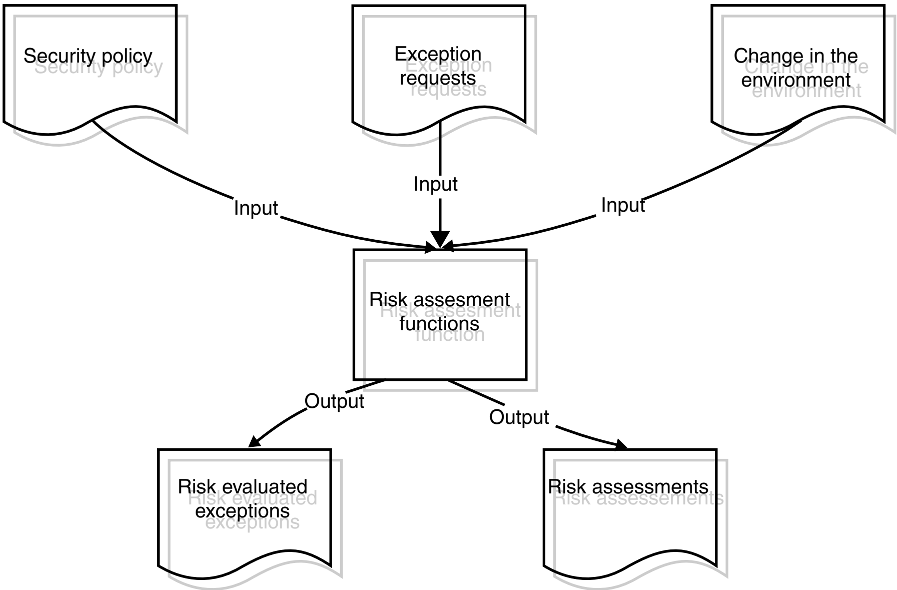

EXHIBIT 47.4 Inputs and outputs of the risk assessment function.

assessment should also address changes that involve the introduction or use of new technologies to understand the impact to the security of the enterprise. This is especially important if these new technologies are not addressed by existing policy. In these cases, the policy management function may need to craft new policy. The last function performed is the assessment of exceptions to existing security policy. Exceptions are usually requested when the existing security policy can not be met. An example of this may be that a technology being utilized may not be capable of providing the controls as outlined in the policy. An illustration of this is a policy that requires passwords to be a certain length and complexity. Some operating systems and applications, especially legacy systems, will not have the functionality to accomplish this and so, therefore, will not be able to comply with the policy. In these cases, it will be necessary to have an exception to the policy to acknowledge the risk and seek approval from the appropriate management to accept it. Another case may be when the cost or resources to implement the control are too high. An example of this would be a policy requiring a daily antivirus scan. In some cases, especially on older machines, this is not resource- or time-efficient and may prevent the machine from accomplishing its business function. It may also not be cost-effective to move the application to a larger machine capable of handling the daily scanning. It may prove advisable to the business to accept the risk of not running the scan on a daily basis and run it during a weekly maintenance window instead. They may also want to implement other mitigating controls like more frequent backups to reduce the risk of lost data. For either of these cases, an exception to the existing policy would need to be considered and assessed. The results of the assessment would then be evaluated to understand if the business is willing to accept the risk or would need to implement a different technology.

The exceptions and assessments that are created by this function are used by the other security functions to evaluate existing policies and to ensure that risk is being controlled consistently. Exceptions to this policy may indicate that the business is willing take on additional risk in certain areas and that a change in the security policy is needed to align this with the risk that is being accepted. Risk assessments of new technologies should also be reflected in changes to the security policies and should be incorporated as part of the policy management function. The main function of the risk assessment function is to ensure a consistent judgment of risk within the enterprise and that risk management is being addressed whenever changes are made.

47.6 Awareness/Training

The awareness and training function is needed to inform the enterprise of the security policies that are in place and to set the understanding of the end users and administrators as to what actions are expected from them. It also informs them of threats that can affect them and of actions that they can take to reduce the risk of incidents occurring from those threats. The awareness and training function may provide this information via classroom training, Web-based courses, emails to address specific threats, posters, and other ways of sharing and communicating information to the enterprise (Exhibit 47.5).

Making end users aware of the policies is another control in managing risk. In some areas, policies will depend on people performing (or not performing) certain actions. An example of this may be the encryption of specific types of data. The user of the data may need to identify which data needs to be encrypted so that it is protected as the policy requires. Another example would be a policy that requires IDs to only be used by the individuals to whom they were assigned. This policy is not easily enforced by a setting or program and must rely on the actions of the people who use the IDs. Another reason for appropriate awareness of policies is in the compliance area. If the enterprise is not aware of the policy, then they cannot be held accountable for adherence to it. This is important not only to the end users of the enterprise, but also to the system administrators that operate the systems so that they understand what is expected of them. Updates to policies must be communicated promptly so that anyone implementing new systems is aware of how that system should be securely configured.

The awareness function will use not only inputs from the policy function but also information from the security operations functions on incidents to use in generating training material. This information is used by the awareness function to create and present the appropriate materials to different groups within the enterprise. Different groups may require different levels of awareness. For example, system administrators may require more awareness on detecting and responding to security incidents that happen on the servers that they administer while end users will need more awareness of things aspects they encounter such as email and Web surfing. It is the main function of the awareness and training function to ensure that the appropriate material is shared and feedback gathered during the training to be shared with the other security groups to help improve their processes. All in all, the awareness and

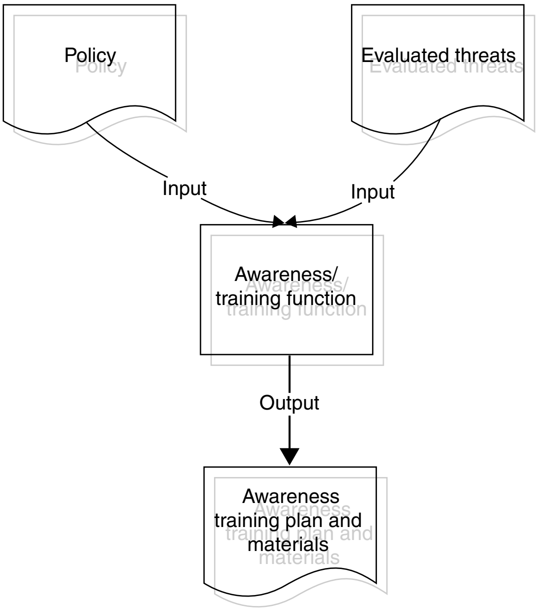

EXHIBIT 47.5 Inputs and outputs of the awareness/training function.

training function will need to communicate the security policies and threats to the enterprise in order to assist in mitigating the security risks.

47.7 Security Governance

The governance function provides for the integration of the different security functions and ensures that they operate together to provide the correct level of risk management that the business requires. To determine the correct level of risk, the governance function interfaces with business personnel and upper management to ensure that they are getting the protection that they require. The governance function also uses metrics such as incident reports, exception requests, and risk assessments to understand the risks present in the environment. The governance group needs to organize and gather the metrics from the other groups and provide direction and priorities in the security areas. The function also needs to consider the cost of providing the security controls. The amount of risk that is being mitigated will need to be acceptable to the business (Exhibit 47.6).

To ensure that the appropriate amount of risk is being mitigated, the governance function will require guidance from the business. One way to get this feedback is to have them assist in the creation and modification of the policies that are being used to protect the services. This can be done by having them review the policies or participate directly on the team that manages them. They should also review reports of new threats and security incidents that affect the enterprise and ensure that the risks are being addressed appropriately and incidents are being responded to in the correct manner. One thing that may be done is to categorize the data and services in the enterprise to identify the areas that are more critical to the business. This will allow the governance group to increase the amount of protection for those services by specifying different policies. These policies may provide more controls and monitoring for those critical services. For less critical systems, it may provide for a relaxing of controls, which may result in a cost savings to the enterprise.

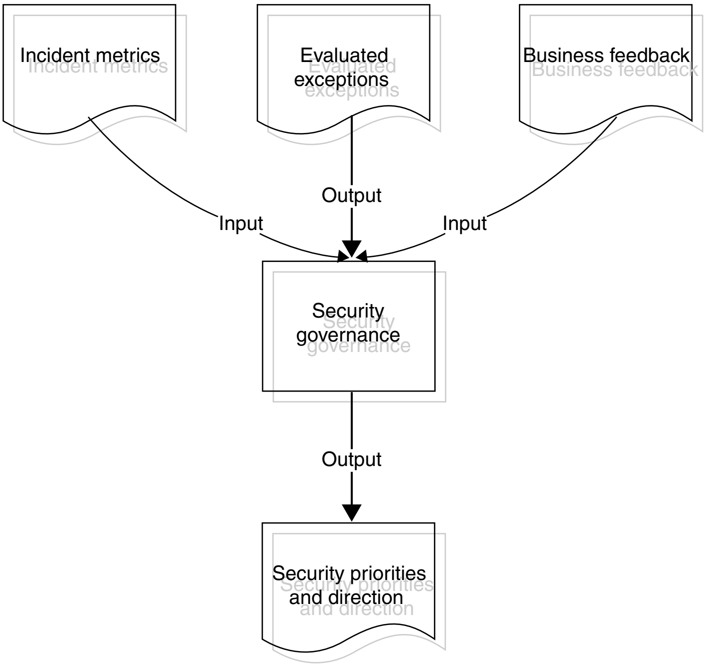

EXHIBIT 47.6 Inputs and outputs of the security governance function.

Metrics play an important part in managing the risks in the environment and the function of the governance team. Metrics, such as the number of incidents and risk assessments, provide information on what is at risk in the environment. This is important information that needs to be shared with the business members and managers to help them understand the risks that are being mitigated by the security team and it helps to focus the business on the current problems within the environment. Metrics produced over time will also indicate any trends in risk areas that may prompt a change, not only in the security controls but also in the underlying strategy and architecture as well. An example of this would be a metric that measures the number of machines that are being detected as being infected with a virus because they do not have current anti-virus definitions. This may indicate that there is a need for an adjustment of the anti-virus controls to obtain updates more frequently or consistently. This may point towards a new architecture using a centralized updating mechanism. One of the functions of the governance organization is to make sure these metrics are gathered and evaluated. The governance function should also lead the discussion on addressing the trends that the metrics indicate and make recommendations on actions to prevent any increased risk to the enterprise.

Another measurement that the governance functions will need to track is the cost of providing the security functions and controls. While it is important to mitigate the risks to the enterprise, it is also important to make sure that these risks are mitigated at the appropriate level of costs. If a system is worth about $1000 a day to the business, and it costs more than that to protect, then the business may want to rethink the amount of protection being provided and possibly take on more risk, if they want to continue to operate cost-effectively. This is where using some formulas such as the annual loss expectency (ALE) can be useful. The ALE is a function of the annual probability of an occurrence, annualized rate of occurrence (ARO), and the cost to the business of each single occurrence, single loss expectancy (SLE). The single loss expectance can usually be calculated by using information from the business as well as the cost to restore the system, if needed. The difficult part of the function is calculating the rate of occurrence. This is a probability that can depend on many factors, some of which are known and some of which are not. The known factors include hardware measurements, such as mean time between failures and historical data on outages or incidents which have occurred in the past on similar systems. One unknown factor that is difficult to estimate is the disclosure of previously unknown vulnerabilities. When these are made public, they increase the likelihood that the vulnerability would be exploited because the knowledge is more widespread. Another unknown factor is the availability of toolkits or scripts for vulnerabilities. Some vulnerabilities require specialized knowledge in order to be exploited and this knowledge may not be widespread. If a toolkit or script is made available via the Internet to a large number of people, this will increase the number of people who have the ability to exploit vulnerability by decreasing the knowledge needed to exploit it. This will increase the probability of an incident exploiting that vulnerability. These unknown factors are difficult to quantify. One of the best methods for understanding these probabilities has been relying on past experiences with similar characteristics as well as relying on consensus information from security experts. Using these pieces of information can help the governance group in determining the probability of an incident and providing guidance on the appropriate amount of controls needed to mitigate the risk.

The main function of the governance group is to coordinate the activities of the other groups to ensure they are performing their required functions and effectively managing the risks in the environment. The governance group will need to set priorities and resolve conflicts between the groups in order for them to operate effectively. It will also need to take guidance from management to ensure that the proper areas of the enterprise are being addressed.

47.8 Organizational Models—Distributed vs Centralized

The security functions can be organized in different ways. One is a centralized model that combines all of the functions into one management group that reports via a single executive. The second model is a distributed model that places the security functions out into the individual IT organization functions. Each one of these models has strengths and weaknesses in different areas.

The centralized model is one in which all of the functions in a security group report up through the same management chain. One of the strengths of this model is that this aligns all of the functions to the team, which ensures a consistent view of risk throughout the enterprise. This reduces the conflict within the organization that may occur when different opinions are expressed on the degree of threat and risk to the enterprise. This also centralizes the responsibilities of security to one organization. Centralizing the responsibility for security can introduce both strength and weakness. The company is strengthenend in that it can ensure that issues are heard at the appropriate level within the organization, but it is also weakened as other organizations will assume that security is being handled by the centralized security organization. This may lead to an avoidance of responsibility in ensuring that security risks are being addressed within their organization. However, another strength is that, from a management point of view, it is easier to quantify the resources needed to implement the security functions if they are centralized with the same organization. This makes it easier to quantify the resources needed to implement security within the enterprise.

A second management model is a decentralized model that pushes the security functions out to different groups within the IT organization. This distributes the security functions across the enterprise and embeds them within the various groups that provide IT services. One of the strengths of this model is that it moves the responsibility of implementing security closer to the owners of the applications and infrastructures that require it. It also gives the security functions that are embedded within those organizations more information and experience regarding what is happening in those areas. This gives the security functions more feedback and enables them to react more quickly to the needs of the enterprise. One of the weaknesses of this model is that it can create a disjointed security strategy. Because each security function may report to a different management chain, a conflict in priorities between security functions may arise. Risk management will also become more challenging as it will be more difficult to reach a consensus between the different security functions as to the level of risk that the enterprise should accept. The most difficult function to perform would be the coordination of the groups through the governance function. It will be difficult to ensure the coordination of the security functions as they may have different priorities based on the IT services in which they are embedded. It will require a conflict resolution process or upper management intervention to resolve disagreements.

In comparing the two models, it seems that they both have some advantages and some disadvantages. The centralized model is more traditional and easier for organizations that are looking for a standard and consistent approach to security risk. The distributed model spreads security throughout the enterprise, raising awareness and local responsibility, but may result in an inconsistent approach to risk management.

47.9 Conclusion

Each of the security functions relies on each other to provide information and feedback to the others to ensure that the system performs properly. Each area performs a specific function:

- The policy function provides the requirements for risk mitigation
- The architecture function describes how to meet those requirements
- The security operations function attempts to implement and operate the architecture that is described
- The awareness/training function communicates the policies and threats
- The risk assessment function assesses changes, new technologies, and exceptions
- The governance team will coordinate and measure the effectiveness of the different functions.

These functions may be centralized as part of one team or may be distributed by embedding them within the other IT management teams. The functions each perform tasks that use information either from other security functions or from the business itself. Together these functions help to manage the risk to the enterprise to reduce the likelihood of incidents and keep its information and assets available and secure.

Make Security Part of Your Company's DNA

Ken M. Shaurette

48.1 Introduction

The Sarbanes–Oxley Act of 2002 (SOX) is one of the most important and sweeping regulatory changes of the past century. Enacted in response to the accounting scandals of 2001 and 2002, SOX is intended to protect investors from insiders who misuse their access to financial and accounting information in order to commit fraud within an organization. Sarbanes–Oxley Act contains a variety of provisions, but the one most applicable to corporate information technology (IT) personnel is the Section 404 requirement that mandates corporations must annually disclose, audit, and report on their assessment of internal controls that are in place to prevent misuse of financial data.

Sarbanes–Oxley Act is not the first legislation of its kind. Security and legislation specifically targeted to the health care (Health Insurance Portability and Accountability Act—HIPAA) and financial industries (Gramm, Leach, Bliley Act—GLBA) have received recent attention. Although each of these as well as others of their kind have predated the SOX act, the SOX legislation seems to be the first to make a widespread impact on corporate management.

Modern business is intensely reliant on IT. Internal audits for SOX compliance aim to certify that an organization's IT infrastructure cannot be used as a vehicle to evade regulatory requirements. Most of the other legislations such as GLBA and HIPAA have been much more focused on protecting employees' and customers' privacy. This fact coupled with the criminal liability SOX places on executives who fail to take it serious and comply with the requirements add extreme pressure on IT network and security personnel already challenged with securing their internal networks.

48.2 Auditors' Guidelines

Auditors use a variety of methodologies and guidelines to design, verify, and document IT compliance and maintain good practice for internal controls, including ISO17799 (eventually to be renamed ISO27001), Committee Of Sponsoring Organizations (COSO), and Control Objectives for IT (CobiT). This chapter focuses on CobiT, one of the most popular and straightforward frameworks to control objectives for information and related technologies. The CobiT standard provides a reference framework for management, users, and IT audit, control, and security practitioners.

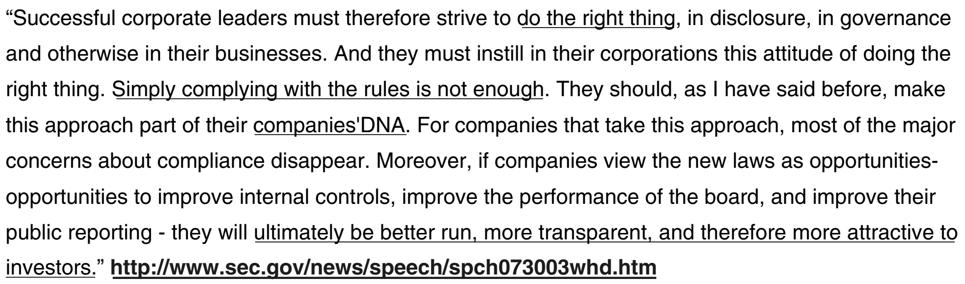
48.2.1 Disclaimer

Only a lawyer can fully appreciate today's legislation. Lawyers are on one of two sides. Either they are in support of an organization to help ensure that the organization reduces liability and puts in place reasonable and proper controls, or they are on the consumer side looking to find an organization at fault for not having done enough. I'm not a lawyer and I do not play one on TV; the information contained in this chapter has been formed from years of experience and represent my professional opinion. I believe every organization should trust but verify; regulations will change, and new ones are being passed almost daily. Security is like a young child; it requires continuous nurturing and like our parents did for us, we have an opportunity to make security better than what we had during our lifetime.

48.3 Making Security Part of the Company's DNA

On July 30, 2003, SEC Chairman William H. Donaldson pointed out that compliance is not enough (see Exhibit 48.1 for full text). Chairman Donaldson expressed the importance of doing the right thing, the importance of making security and compliance part of any organization's DNA. Organizations that make security and compliance part of their structure will be better run, are an overall better organization, and are more attractive to investors and the community.

As the SEC Chair noted, simply doing just enough to get by is not adequate. Security professionals are often asked what the minimum requirements are for any given company's security structure. Management often looks for the minimum measures it needs to take in order to be compliant with regulations like HIPAA and GLBA. Companies only want to spend just enough and do no more than the regulations require. The regulations sometimes state "provide adequate security over transmission of customer data." The challenge, at that point, is explaining to management that less is not always better and that *adequate* changes as technology improves and organizations advance their protection strategies.



"Successful corporate leaders must therefore strive to do the right thing, in disclosure, in governance and otherwise in their businesses. And they must instill in their corporations this attitude of doing the right thing. Simply complying with the rules is not enough. They should, as I have said before, make this approach part of their companies'DNA. For companies that take this approach, most of the major concerns about compliance disappear. Moreover, if companies view the new laws as opportunities-opportunities to improve internal controls, improve the performance of the board, and improve their public reporting - they will ultimately be better run, more transparent, and therefore more attractive to investors." **http://www.sec.gov/news/speech/spch073003whd.htm**

EXHIBIT 48.1 From Speech by Chairman William H. Donaldson, U.S. Securities and Exchange Commission to the National Press Club, July 30, 2003.

48.4 Minimalist Attitude

The minimalist approach is the wrong attitude for an executive. Such an attitude gets propagated throughout an organization. It establishes a "tone at the top." The tone at the top is what many regulatory agencies and auditors look for when performing an overall assessment of an organization. When doing compliance and security reviews, security professionals look for vulnerabilities and levels of risk, but they also talk to people throughout the organization in order to gauge their feelings, their attitudes about security, and their awareness of their personal responsibility to protect the confidentiality, integrity, and availability (CIA) of the data with which they work. When an auditor or examiner gets the sense that an organization does not appear to be prepared, he or she is going to be taking a closer look. When the attitude at the top is that security is unimportant, it will permeate into other areas of the organization and be recognizable during an assessment performed by experienced security or audit professionals. An auditor or examiner is likely to dig much deeper, request more documentation, or perform more tests when the organization seems unready. Security professionals doing an assessment should scrutinize an organization more thoroughly, because, if the attitude is lax, then the risk is probably not adequately managed.

What are organizations up against? The number of regulations creates requirements that organizations must balance. For organizations dealing on a global level, these regulations can sometimes be conflicting between countries. These include everything from the well known, mostly U.S.-based, commercial regulations that impact security such as HIPAA, GLBA, and SOX to state regulations such as California SB1386 or HR1950 that address the handling of customer information. The bottom line is about providing adequate due diligence to manage risk in order to reduce liability. These regulations came about in the first place because industry was doing a poor job of protecting privacy, and it was not improving its protections on information assets. Until some of the regulations gained significant publicity, many of the industry organizations they impacted simply ignored, or took for granted, security. They were more inclined to add to the bottom line than they were to add measures to protect the CIA of the information that made the bottom line possible.

48.5 Cost of Non-Compliance

Compliance spending has become, without a doubt, a significant portion of every organization's IT budget. AMR Research identified that IT compliance budgets were expected to rise 10% in 2005. It was also noted that as a result, more time, resources, and budget dollars are needed by CIOs in their planning process.

The cost of reaching and maintaining compliance can be significantly less than non-compliance in the long run. Consider the ramifications as illustrated in Exhibit 48.2.

48.6 How Much Security is Enough?

To make security part of an organization's DNA means integration. It means planning and documentation. It means establishing the definition of *reasonable security* for an organization. Adequate security from an operational standpoint means more than simply complying with regulations or implementing accepted practices. Establishing the concept of adequate security helps to establish an actual business benefit, forming an actual return on investment (ROI) as illustrated in Exhibit 48.2. This is an ideal outcome for the security investment, but in order for this to be successful, it must balance security risks to an organization with the business mission and objectives. That is where security risk management comes into play. It is not adequate for business decisions to always win over reasonable security or security to be implemented in spite of business needs. There must be a balance between them.

Costs of non-compliance	*Costs of compliance*
Financial and legal penalties, including fines Regulations such as SOX Criminal penalties resulting in prison time.	The due diligence to establish and maintain controls that meet compliance requirements
Consumer mistrust of a company impacts purchase habits, resulting in potential lost business (revenues, stock price, consumer confidence, etc.) For example, Enron and MCI WorldCom, also impacted audit firm Arthur Anderson.	Due diligence will produce quality, improvement efficiencies, increased revenues, higher stock price, along with customer and consumer confidence, etc.
Poorly run operations cause increased costs because of poorly automated systems, ineffective systems,and a lack of controls that result in greater potential for outsiders and insiders getting away with inappropriate activity.	Better system automation. Systems and staff are more effective. Improvements that are often automated. Controls can eliminate manual overhead and operating expenses.

EXHIBIT 48.2 In the long run, the cost of reaching and maintaining compliance can be significantly less than non-compliance.

Security risk management is the establishment of what is reasonable in an organization: not only for today, but also for tomorrow. How much is enough? How can a company forecast how much it will spend on compliance next year or five years? What solutions are available to help companies meet compliance needs? The issue of compliance is not going away. Even if an organization does not need to specifically meet a compliance regulation today, there will be some regulation if it does not already exist that will impact the company in the near future. Organization executives must do their best in order to prepare to meet these requirements. Because an organization is not required to meet a compliance requirement today is not a good reason to not take advantage of the current accepted practices.

The term *reasonable* is found throughout many of the regulations' descriptions. Determing how much is enough and what is reasonable will be defined in the court systems, and the bar by which security will be measured will continue to rise. Case law will establish levels of reasonableness based on the accepted practices of organizations of similar size and industry to any given company. Tort law in the United States requires four fundamental components as illustrated in Exhibit 48.3.

Currently, four character passwords for authentication are not reasonable, but neither are retina scanners at every workstation. Maybe some form of strong controlled password or multiple factor authentication such as smart cards or biometrics will be reasonable. What is reasonable to one organization may be different than for another even within the same industry.

1. *Duty*: Do I have a responsibility to protect information?
   - Policies assign management's understanding of duty.
2. *Negligence*: Defines a breach of duty.
   - Can evidence be produced showing unfilled duty of due care?
3. *Damage*: Quantifiable harm.
   - Commercial System Hacked from School Computers
4. *Cause*: Duty + Negligence + Damage

EXHIBIT 48.3 Four fundamental components required by United States tort law.

48.7 Security's Golden Rule

If workplace data are treated as though they were personal data, "employees will be more apt to use reasonable measures to protect them and ensure they are handled in a manner providing adequate security."

Security is about common sense. About 75 percent of what every organization must do is the same, regardless of the industry or the regulations it must comply with. Every organization's Information Security Risk Management Program must still include an information security policy, firewalls, basic access controls, user activity logs to provide monitoring or auditing, change and patch management, and other basic security components. Fifteen to twenty percent of security requirements that will be unique will be dictated by the regulations (state, federal, local, or industry specific) that each organization is required to comply with, whereas the remaining 5–10 percent of what each organization needs for security requirements is determined by the uniqueness of the organization, its unique business culture, and social attitudes.

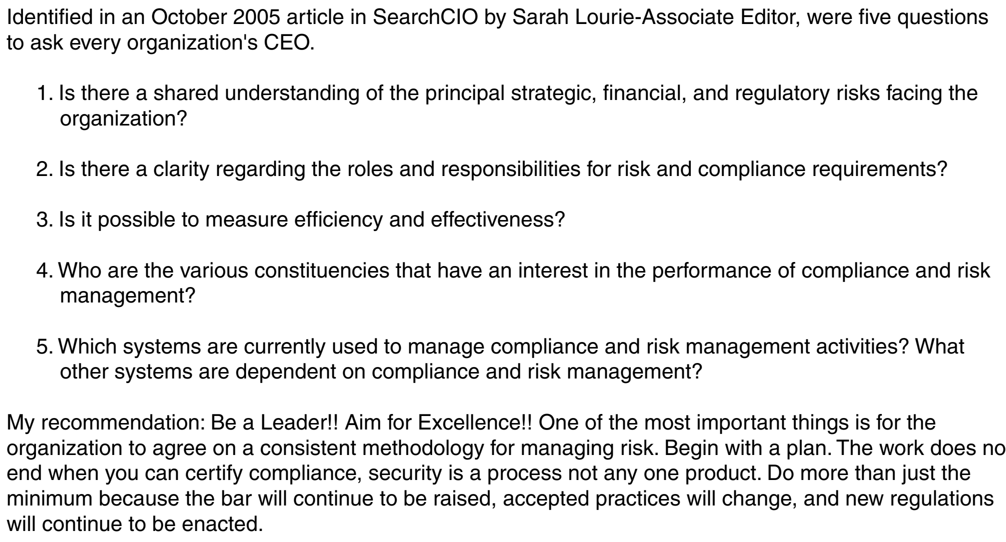
Using best practices, some experts say, is not enough. Many CIOs are looking for the standardized approach. They want to take a set of minimum best practices or guidelines and adopt and implement them so management can simply announce that its job is complete. Management feels that by doing this, it can then state that the company is certified as compliant. This trend is evidenced by the popularity of guidelines such as National Institute of Standards and Technology (NIST) SP800 guidelines and the ISO code of information security management. As outlined by the SEC Chair's speech illustrated in Exhibit 48.1, the minimalist attitude is the wrong approach. Making another organization's accepted solution its own, an organization copied the security policies of another, including the spelling errors.

This approach of looking for the standard approach, as evident by the popularity that security standards such as ISO17799 have gained over the past few years, is flawed. In the end, it all comes back to due diligence, using simple concepts such as the basic security principle of least privilege or minimum necessary. Information access in an organization should be set up to allow people to see only what they are authorized to see; hear only what they are authorized to hear; and share only with those authorized to receive the information the individual is authorized to share.

Some of the confusion for organizations stems from the need to understand compliance monitoring and risk management. These terms, although similar, can be confusing. Compliance monitoring, for example, provides the ongoing validation that ensures proactive controls are in place and working. Confusing to organizations is that they must also have a monitoring process to identify or recognize incidents or inappropriate behavior along with a process to react to such incidents. This is not compliance monitoring; rather, it is a part of incident monitoring that is a component of a security or risk management program. For example, the President checks into a hospital. Who should be authorized to review information pertaining to the President's treatment? Can the organization monitor that activity as outlined by the HIPAA Security regulation? Can it react quickly should an incident occur to minimize the impact? This is all part of managing security risk. Both elements must be addressed—compliance monitoring and risk management (a component of which is monitoring for incidents so a reaction can take place). A couple of key tools for security are a well-written information security policy and an information security operations plan.

As previously noted, Sarbanes–Oxley, also known as SOX, has established the bar by which compliance will be measured, and it put the burden on executives. It is no longer just a financial burden. It has a much broader reaching impact. Penalties in many regulations do not seem all that severe. Health Insurance Portability and Accountability Act, for example, identified a base penalty of $100 per incident with a maximum annual penalty. However, the regulation also describes that, in addition to the penalty, reasonable and customary legal fees can also be recovered, so not only might the company pay for its own attorney, but it may also be responsible for the other side's attorney's fees as well. Thomas N. Shorter, an attorney with Godfrey and Kahn in Madison, Wisconsin, explained that what an attorney considers to be reasonable legal fees might be very different than what a company considers them to be. The indirect effects can be severe, even as simple as customers' losing faith in a company's business practices. As a result, even being found innocent of an incident has a price.

48.8 Five Compliance Questions to Ask the CEO



Identified in an October 2005 article in SearchCIO by Sarah Lourie-Associate Editor, were five questions to ask every organization's CEO.

1. Is there a shared understanding of the principal strategic, financial, and regulatory risks facing the organization?
2. Is there a clarity regarding the roles and responsibilities for risk and compliance requirements?
3. Is it possible to measure efficiency and effectiveness?
4. Who are the various constituencies that have an interest in the performance of compliance and risk management?
5. Which systems are currently used to manage compliance and risk management activities? What other systems are dependent on compliance and risk management?

My recommendation: Be a Leader!! Aim for Excellence!! One of the most important things is for the organization to agree on a consistent methodology for managing risk. Begin with a plan. The work does not end when you can certify compliance, security is a process not any one product. Do more than just the minimum because the bar will continue to be raised, accepted practices will change, and new regulations will continue to be enacted.

48.9 Top Challenges

There are several challenges to address in any compliance effort. Most important in all compliance regulations is documentation. The challenge is determining the appropriate level of documentation that is needed. Some companies do not have adequate documentation of their legacy applications. As an example, consider ageless mainframe CICS applications. Many of these transactions are often poorly documented, and few people understand the full workings of each transaction id or the detail access control rights. Any associated documentation is inadequate to determine the appropriate levels of separation of duty necessary.

A recommendation would be to establish a coordinator function for IT compliance whose functions include being a liaison between business process owners, data owners, and IT. A critical responsibility for this position is quality control, verifying adequacy of controls, and controls testing along with ensuring that documentation is handled by owners and, where possible, a documentation standard is followed. Integrating the importance of documentation and properly following established processes should be incorporated in the Information Security Awareness Program. An interesting consideration is whether the organization can obtain an automated tool that will support the documentation standard to help ease the overall maintenance and management burden associated with documentation.

The challenge associated with outsourced processes requires that companies inventory and identify all third-party organizations and interfaces. Secondly, there must be appropriate planning for how, when, and where to test the controls related to outsourced processes. Third party organizations must notify the company of changes to their processes and associated controls. An important question to ask is if third party contracts contain provisions for audits such as SAS70 (including types of SAS70) or if the implications of any regulations have been considered.

Another challenge that many organizations are faced with is testing strategy. Now that many of the compliance dates have passed or organizations have reached levels of compliance, it is necessary to identify how frequently tests of controls should be done by process, application, or sub-process. Determining material weaknesses, according to Stephen Gauthier's *An Elected Official's Guide to Auditing* identifies that some reportable conditions are more serious than others and are of such magnitude that they could potentially result in a material misstatement of the financial statements. These are known as material weaknesses. One example would be an organization's failure to reconcile monthly bank statements to the customer account balances.

By definition, all material weaknesses are reportable conditions. Not all reportable conditions, however, are material weaknesses. Auditors generally distinguish reportable conditions that are material weaknesses from those that are not. As such, a clearly documented testing strategy is needed, including sampling sizes and the extent of testing for areas where an audit may identify a reportable condition.

Using this definition is popular in identifying applications where testing is needed for compliance with SOX 404. Expanding on it, it is possible to use this definition for all regulations to help in determining the extent of testing and sampling sizes. Also, it can help to ensure that just the right amount of documentation is generated for any controls that need to be in place for reportable conditions that might impact overall CIA. This becomes especially critical when considering areas of weakness for privacy concerns that are addressed by HIPAA and GLBA. A good question to ask before the audit is if a consistent testing approach and adequate test samplings have been chosen and communicated to IT's test team.

Determining testing frequency is also a challenge for organizations. Setting how often controls are tested is a challenge because not all controls need to be tested at the same frequency. This can be dictated by several factors related to the testing as well as taking into account the level of material weakness in the tested system. For example, if a system has a very high dollar value for potential impact to the organization, it is recommended that testing be more frequent, maybe monthly, whereas if the potential for impact is much less, then tests can be performed less often—quarterly, semi-annually, or annually. Another factor to consider determining the frequency is how complete and efficient each control test is and how well the control documentation is maintained.

One of the last challenges covers identifying what an organization does if exceptions are found. Many organizations have created a central location where the identified issues are maintained in order to facilitate communication of these exceptions across the organization, especially to management and process owners. This way, exceptions can be corrected immediately rather than waiting for an audit or the next test. It is suggested that IT establish a regular meeting with the audit committee, internal audit, and when available, any external audit representatives. This can be another important role for the IT Compliance Coordinator.

Here is an example of a place where the information security policy should include clear definitions of roles and responsibilities in the organization. Especially important is defining the term *owner* and his or her responsibility when managing risk. Owners become the decision makers when it comes to access rights and signing off on effectiveness tests to measure the efficiency and effectiveness of controls. Owners have significant input into identifying material weakness and frequency or effectiveness of testing. Most owners come from the business arena. All areas of management need to consider their interest in compliance in order to understand how the compliance regulations impact their responsibilities. This will also help them determine how the documentation needs to be represented.

One of the key issues organizations are facing is as simple as needing to change the company's attitude. Every organization can tolerate risk at differing levels. For example, a K-12 school district's risk profile is very different than that of higher education, yet they are both in the business of education. A 50 bed hospital or small clinic's tolerance for risk is very different than a 500 bed hospital or a large pharmaceutical company. Each of these organizations must do their due diligence, especially to understand their risk in order to adequately manage it. Their available resources, budget, and talent pools will be very different. Taking steps to assess their current security posture, identify, evaluate, and test controls as well as continually comparing all that to compliance requirements, accepted practices, and, of course, the question of reasonability. Although resources differ, appropriate security is still required and determining reasonability still applies.

48.10 Organizational Changes—Technology Assistance

In a 2005 presentation by Michael Rasmussen, Senior Research Analyst with Forrester, Inc., he identified that organizations are beginning to create positions to deal with risk management such as a Chief Risk Officer (CRO). It is true there are new positions in executive management to deal with security risk. Positions such as Chief Information Security Officer (CISO), Chief or Corporate Security Officer (CSO), Corporate Privacy Officer, and Corporate Compliance Officer were virtually unheard of five years ago. Today, regulations specifically state the need to appoint someone or a group who perform the function of a Security or Privacy Officer. Health Insurance Portability and Accountability Act, for example, requires both. Integration and the importance of bringing together multiple disparate areas for the good of the business are not always that easy in an organization. Physical and information security are good examples. Historically, these two have reported to different management chains in the organization. More and more there is becoming a synergy among these responsibilities. Much of the reason this has happens leads back to technology's becoming prevalent in physical security controls.

The challenge becomes coordinating all the appropriate areas. Organizations must consider more than just the technical aspects of information security. For years, technology was used by IT management as the answer to protecting data. It is not that simple, and technology cannot resolve the issues posed by people and process. Monitoring employee activity to identify inappropriate activity and policy compliance even to the extent of determining criminal activity is becoming an accepted practice.

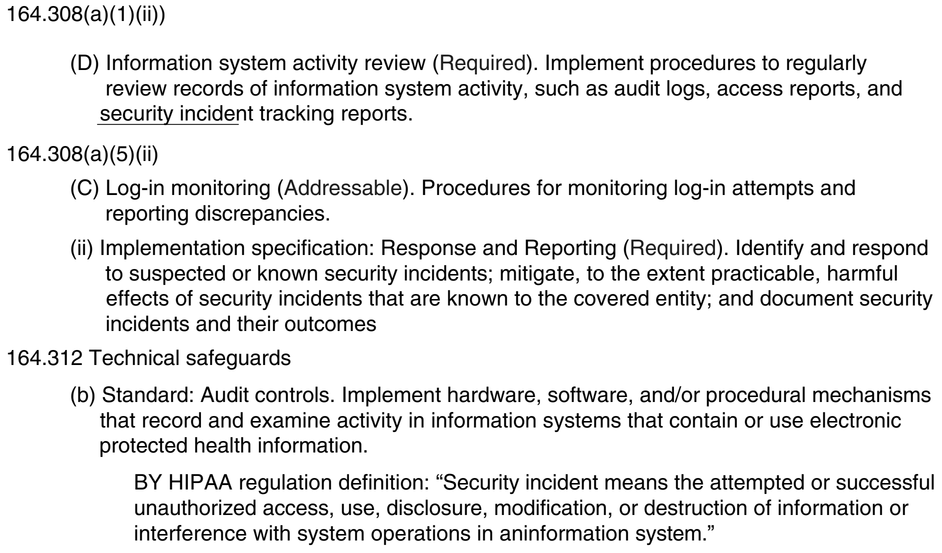
In 2005, the American Management Association (AMA) and ePolicy Institute conducted an Electronic Monitoring and Surveillance Survey that illustrates how organizations are motivating employee compliance. The survey showed that organizations are putting teeth in their computer policies by using technology to manage productivity and protect resources. The main technology and process consists of monitoring employees' use of computer resources in support of acceptable use policies. Regardless of whether or not companies have crafted computer, e-mail, or Internet use policies, the implementation of technology to monitor proper use is becoming prevalent. The survey illustrated that 26 percent of organizations have fired workers for misusing the Internet, 25 percent have terminated employees for e-mail misuse, and another 6 percent have fired employees for misusing office phones.

When it comes to workplace computer use, companies are showing a very strong focus on Internet surfing with 76 percent monitoring workers' website connections. Blocking access has become a very acceptable method for increasing productivity, and meeting policy compliance shows a 27 percent increase since 2001 when the last such survey was completed.

An especially rapidly growing area is focused around identification of employee use of computer systems and access to corporate data. Computer monitoring takes various forms with 36 percent of employers tracking content, keystrokes, and time spent at the keyboard, whereas an additional 50 percent identified that they store and review employees' computer files. Many companies have begun to keep a closer eye on e-mail with 55 percent retaining and reviewing messages.

Most employers are notifying employees that they are being monitored with 80 percent identifying that they inform employees that the company is monitoring e-mail use to ensure appropriate business use of computer resources and compliance with policies. Including monitoring in corporate information security policy is especially important, but how to enforce the policy can be quite time consuming and have varying degrees of effectiveness.

In the financial industry, the FFIEC IT Examination Handbook identifies that "Financial institutions can achieve effective employee awareness and understanding through security training, employee



164.308(a)(1)(ii))

(D) Information system activity review (Required). Implement procedures to regularly review records of information system activity, such as audit logs, access reports, and security incident tracking reports.

164.308(a)(5)(ii)

(C) Log-in monitoring (Addressable). Procedures for monitoring log-in attempts and reporting discrepancies.

(ii) Implementation specification: Response and Reporting (Required). Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity; and document security incidents and their outcomes

164.312 Technical safeguards

(b) Standard: Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information.

BY HIPAA regulation definition: "Security incident means the attempted or successful unauthorized access, use, disclosure, modification, or destruction of information or interference with system operations in aninformation system."

EXHIBIT 48.4 Specific requirements from the HIPAA Security Rule.

certifications of compliance, self-assessments, audits, and *monitoring*." Every effective information security program includes an ongoing awareness program that goes beyond just new employee orientation.

Organizations need the ability to detect an incident and identify non-compliance before it becomes a significant loss to the organization. This is becoming a routine part of incident management programs and necessary to prevent fraud or other illegal activity on a proactive basis.

Health care organizations are another industry that must meet detailed regulatory requirements around monitoring access to client data as spelled out in the HIPAA Security Rule. Specific requirements from the HIPAA Security Rule are illustrated in Exhibit 48.4.

It has become necessary to track all activity at a source closest to the user in order to have a window into the network and the activity that is happening in the organization. This way, compliance with acceptable use policy and proper performance of accepted controls can be quickly identified. Software of this type has quickly identified events such as an HR Director's downloading and accessing child pornography, exposing the material weakness in HR procedures protecting privacy, or determining that the teller was not completing her daily closing processes in the banking industry. As a result, the teller was going around the business controls in place, and money was mysteriously disappearing.

Policy is a very important control still being taken for granted in some organizations. In a complaint in 2003 against Guess.com, Guess had its Privacy and Security Policy posted on its web site, but its applications and website were vulnerable. The vulnerability existed from October of 2000 to the time of an attack in 2002. In February 2002, a visitor using the SQL injection attack was able to read customer credit card numbers in clear text.

Guess.com stated in its policy posted on the website that data gathered were unreadable and encrypted at all times. The finding by the FTC was that the policy was false or misleading and constituted unfair and deceptive business practices.

I'm not a lawyer, but assume that if the policy had been more carefully crafted to some extent for it to be vague, using some of the same terminology as regulations, such as saying, "We take *reasonable* measures to protect data gathered by our company." The liability may have been different if Guess could show it used reasonable measures to protect the data. I think lawyers would probably cause using this kind of language, "wiggle words." At least I think lawyers would have more fun defending a general statement such as that.

48.11 Summary

There are guidelines available to help companies understand the things that will be reviewed by regulators or auditors. For example, the Federal Financial Institution Examination Council (FFIEC) provides an Information Technology Examination Handbook. It assists financial institutions' understanding of what security controls are important. Another reference for the financial industry is the Financial Institution Shared Assessment Program (FISAP) documents that were released in February 2006. These documented released by BITS (BITS is a nonprofit, CEO-driven industry consortium, consisting of members from 100 of the largest financial organizations.) include a process for financial institutions to evaluate IT service providers. These documents can be found at www.bitsinfo.org/fisap/. National Institute of Standards and Technology has published several guidelines for information security and as previously mentioned, the ISO17799 Information Security Standard that provides a place to start. Companies should not rely on any single guide to be the answer.

Technology is beginning to play a critical part in policy compliance and in monitoring employee access to resources. The need to have forensic evidence for litigation will continue to grow. Tools such as the appliance solution, Aristotle™, from Sergeant Laboratories in Lacrosse, Wisconsin, are making it feasible to manage computer access without unnecessary overhead or significant application changes.

In order to make compliance part of a company's DNA, a company must allow it to adapt to grow. Like a child, it needs nurturing, proper care, and feeding. By understanding vulnerabilities and risk in an organization, a security program can be implemented that includes planning and policy as the roadmap. The program will include change, configuration, and patch management along with numerous technologies to close gaps in security. Maintaining secure systems will become normal activity. It will not be necessary to build a secure network; every network architected will be securely designed and configured. Proactive monitoring of internal controls and reactive monitoring for compliance with policy will make security dynamic, help foster an understanding of the environment's requirements, and further close unreasonable gaps.

Documentation is crucial. Every organization is continually accepting risk; it is a factor of doing business. When accepting risk, it is still critical that the risk or vulnerability be understood, the decision to accept it is documented, and a justification is included. A company must ensure that it is doing its due diligence. Along with simply accepting the risk, overall risk management methods include transferring the risk. This is taking out insurance and putting the burden of the financial portion of the risk on another company. There are not many insurance companies yet stepping into this area because there is insufficient data to predict the potential of an event or the per incident dollar loss in order to establish reasonable premiums. The more common method for dealing with most technical risk is the mitigation of the risk or at least minimizing it through properly implemented technology or business process controls.

This chapter has outlined current regulations and business needs; legal council has provided input; and companies know how to anticipate what its business partners expect. This information provides a company with the input it needs to solidify its requirements. Compliance framework and the control structure will have a foundation based on the company's policy, operational, and technical control components. Management vision and organizational alignment provide for a secure architecture. Governance is going to provide the oversight, the accountability, and the risk management.

Establishing a framework of controls is the first step. Build on established frameworks, but a company should not make them its only gauge. Now a company must bring them all together—the reasonable steps. A company must start with policy as it is a company's roadmap and defines its tone at the top. Next, a company must work toward protection by identifying the technologies that will be implemented to support policy. The next step must be detection or how will a company monitor compliance and identify incidents? Companies often boast that has never or it very rarely experiences any type of incident. If there are not adequate detection procedures in place, how does the organization even know? Lastly, what will the company's reaction be to an incident? Does it intend to submit incidents to law

1) Compliance standards and procedures;

2) High-level oversight;

3) Due care in delegation of authority;

4) Training;

5) Monitoring and auditing;

6) Enforcement and discipline; and

7) Response and prevention.

EXHIBIT 48.5 Seven components for an effective compliance program.

enforcement? Will it have the documentation and evidence necessary to support its case or to protect the organization?

In late 2004, the U.S. Sentencing Commission (United States Sentencing Commission, Guidelines Manual, §8A1.2, comment (n.3(k)) (2000)) updated the sentencing guidelines to better align with technologies. In a Wake Forest Law Review article by Paul Fiorelli, seven components for an effective compliance program are identified for a successful compliance program as illustrated in Exhibit 48.5. Notice that these are what have been discussed throughout this chapter .

When it comes to the Federal Sentencing Guidelines, it is pretty clear that doing nothing increases risk and liability. Doing only the minimum will lead to inadequacy. Documentation and having an information security operational plan will make a big difference.

Security and compliance is a process; it must become part of every organization's DNA. Assessments, testing, and monitoring for compliance will be ongoing. Planning is the prescription for compliance. Documentation is the remedy. A company must be ready to do due diligence and better manage risk by making security part of its DNA.

Building an Effective and Winning Security Team

Lynda L. McGhie

49.1 Introduction

In general, a heightened appreciation for security in today's post 9/11 environment has occurred. It is increasingly obvious that not only foreign enemies but also others driven by financial gain or even just plain malice have become an increasing threat. These evildoers have the propensity to inflict grief onto an organization as well as cause burgeoning costs to repair the damage. The threat stems from both physical and technological sources and, therefore, requires both of these security disciplines to be revisited and enhanced in response.

In response to this growing awareness, an organization may be building a security team from scratch or enhancing and reworking an existing team. Perhaps the security organization that has existed for years simply needs to be enhanced or elevated within the organization structure. Nevertheless, it is clear that in today's environment an ad hoc security function simply will not be sufficient. Organizations with this goal in mind should develop and execute an approved and well-thought out and orderly plan.

Having a well-defined security function is the most important reaction to today's threats, and for the most part, where it sits in the organization is a secondary consideration. It has proven to be easier to administer a security team if the team reports high up in the organization's structure. Additionally, if the person accountable and charged with the responsibility reports high up in the organization and has ready access to executive management, there is a higher probability of success. Ultimately, the head of the organization and the organization itself need to be accountable and well-supported.

Today's business and IT environment is increasingly more diverse and dynamic. Most organizations find themselves in a constant state of flux. Because security touches all business, IT functions, and processes, these changes result in the need for adjustments and modifications to the supporting security organization. IT organizations have struggled with their ability to do long range planning, and the typical five year or three year plan has fallen by the wayside with most organizations pragmatically favoring an annual plan. Organizations driven by quarterly financials and other closely tracked metrics also revisit their planning on a quarterly basis and take the opportunity to measure and right size efforts based on their findings. To manage dynamic risk and perpetual change, the security organization should also follow this process.

Whether an organization is building a security team from scratch or it is assessing the strength and success of its current team toward adding resources or functionality, a common set of principles and process steps apply. The first preliminary process is the gathering of information. For a new security program or organization, this could be an extensive effort. Information can be gathered by existing staff or a consulting service. A business analyst or project manager could potentially lead this effort or a security practitioner or professional may do so. There may already be an information library or website where information is documented on policies, procedures, guidelines, business, and technical goals and plans, etc. Another set of information can be gathered through discussion, group meetings, questionnaires, and interviews. The key is to identify key stakeholders and subject area experts. Industry research and benchmarking can also be helpful to help an organization define its outcome and action and to support its decisions and recommendations.

Once an organization understands its IT and business goals and supporting plans and schedules, it is ready to assess the effectiveness of the policies, procedures, guidelines, etc., in facilitating achievement of the goals and gaining an understanding of how information security and risk management can contribute to the overall bottom line of the organization. Although the highest level corporate policies' defining who does what should stay fairly stable and consistent, they should always be in review as business directions, laws and regulations, technology, and risk are constantly changing. A review and updated policy process needs to be incorporated into the functionality of the security program and process.

The next step in the process is to conduct a gap analysis between what the security program is currently doing versus what the policies and the business imperative dictate. If the identified gaps are threatening or actually inhibiting the achievement of corporate goals, this becomes the basis and critical input for corrective actions and the definition of the new or improved security function. The next step is to develop a recommendation and action plan. The amount of data collected and the extent of the process will vary based on the existence or the maturity of the information security organization and team.

The process noted above can be done on a one-time-only basis or driven by an audit finding or a compromised data or other security breach or incident as well as any number of other management dictates or risk mitigation actions. The task can be completed with internal personnel or by outsourcing to security vendors, security consultants, and service providers or contracting with IT consultants. Drivers include project scope, available funding, and timeframe for the recommendation and implementation. As a note of caution, outsourcing can be very pricey and needs close oversight and management. An outside evaluation could cost upward of $500k.

Because successful security organizations are governed by risk and protection models as well as quantitative and qualitative risk assessments, the results of this analysis and measuring will dictate a certain amount of ongoing change and adjustment to the overall security environment and its supporting security program. With that said, the dark and gloomy reality is that today's organizations are so cost driven, budget constrained, and success oriented that business trade-offs will often win favor given decisions to accept the risk, remediate the risk, or avoid the risk's going forward.

49.2 Senior Executive Support is Crucial

For most organizations, a key success factor is having executive management's support. This needs to be more than an all-hands memo or an annual corporate goal. It must be visible to all employees, part of everyone's performance appraisal and the management incentive program, and embedded in the corporate culture. Such high-level interest helps ensure that information security is taken seriously at lower organizational levels and that security specialists have the resources needed to implement an effective security program. Along with this critical level of management, support will follow the need for allocation of budgets commensurate with security requirements, risk mitigation, and annual goals. Although the emphasis on security should generally emanate from top officials, it is the security specialists at lower levels that will nurture and contribute to a repeatable and sustainable process.

According to the results of the second annual Global Information Security Workforce Study conducted by global analyst firm IDC and sponsored by ISC2, the security profession continued to mature in 2005. The study also found that ultimate responsibility for information security moved up the management hierarchy with more respondents identifying the board of directors and Chief Executive Officer (CEO) or Chief Information Security Officer (CISO) and Chief Security Officer (CSO) as being accountable for their company's information security.

> Nearly 21% of respondents, up from 12% in 2004, say their CEO is now ultimately responsible for security, while those saying that the board of directors is now ultimately responsible for security rose nearly 6% from 2.5% in 2004. For the Chief Information Officer (CIO) security accountability dropped to about 30.5%, from approximately 38% in 2004 and rose to 24% from 21% in 2004 for CISO/CSOs.

Plan ahead. Do not be in a position of simply reacting to evolving and dynamic situations or new threats and vulnerabilities. In order to do this effectively, the security team needs to be plugged into strategic and tactical planning at the highest level within the organization. At a minimum, structured "what if" sessions with functional organizations and business process owners with the purpose of synching up future company strategies with future developments in the external environment can help level set security strategies and tactical plans. Constantly monitor the industry, and measure and monitor the internal IT and business process environment.

The ultimate goal is flexibility and agility. Be ready for anything, and anticipate change as it is unavoidably a constant. Minimally, have a plan in place and tested for operational readiness with the goal of prevention at the highest level, ongoing protection at all levels, and a recovery process if the previous are not achieved. Predefine how the organization might modify the plan given change to the organizational structure, business imperative, new threats, and vulnerabilities or tweaks to the enterprise risk management plan.

Information technology as well as information resources and assets are integral ingredients of a successful organization. Organizations that actually understand this recognize that information and information systems are critical assets essential to supporting their operations that must be protected. As a result, they view information protection as an integral part of their business operations and of their strategic planning. Not only is executive management support necessary to be successful, but organizations must also identify key stakeholders in the process who can receive the recommendation and action plan and approve and allocate funding to follow through.

The second step in the critical path is the identification and formation of the right team comprised of executive sponsors, key business and technology stakeholders, subject area experts, and a solid project manager. Whenever possible, the project should not be lengthy, and resources should be dedicated for the core team.

49.3 Distinguishing Roles: CISO versus CSO

The CISO should be designated by the CIO, the CEO, or the Chief Financial Officer (CFO). In some organizations, the CISO must also be approved by the board of directors. The CISO is responsible for establishing and ensuring compliance to corporate policy and procedure. Other primary roles and responsibilities include security training and awareness, incident management, security governance, compliance, and risk management. In some cases, the CISO will also be responsible for security operations. This security governance pertains to all corporate information and IT assets.

The CSO, on the other hand, is also a high level executive position appointed and approved by the same high level corporate officers as the CISO. This role is responsible for maximum coordination and integration of security protocols, procedures, and policies within the corporate structure. Other roles include ensuring the safety and security of employees; protecting and maintaining corporate facilities, physical assets, and property; and ensuring the security and continued preservation of all corporate information, research, and proprietary data and the technology that supports it.

Both roles should be supported by seasoned security professionals and those with senior level leadership experience. The CSO role tends more toward physical security, but it currently incorporates IT security. The CISO role does not usually incorporate physical security, personnel, and safety. However, as discussed below, with the recent move to convergence, these lines are blurring and getting redefined.

As explained in a recent CSO article, “a converged organization is positioned to make security a functional strategy and possibly a business opportunity. Expanding the view and scope of security is a necessary part of integrating security risk management into an organization. In a converged security organization with functional alignment, the definition of security is broadened to include physical security, information security, risk management and business continuity. A CSO with this functional breadth provides more value to the organization and to the overall leadership team.

The overall goal is to embed security into business processes and executive decision-making. This is the convergence recipe. The only ingredients that the CSO can not provide are forward-thinking senior executives who are willing to do more than pay lip service to ensuring the company’s sustained secure performance—even if this support stems only from the realization that security will protect their lucrative jobs and incentive plans.”

49.4 Centralized versus Decentralized Security Organizations and Partnering with the Business

Overall, the central security group serves as a catalyst for ensuring that information security risks are considered in both planned and ongoing operations. The group provides a consultative role for advice and expertise to decentralized business and security groups throughout the organization. The central team is also a conduit for keeping top management informed about security-related issues and activities affecting the organization. In addition, the central group is able to achieve efficiencies and increase consistency in the implementation of the organization’s security program by centrally performing tasks that might otherwise be performed by multiple individual business units. By developing and adjusting organization-wide policies and guidance, the central team is able to reduce redundant policy-related activities across the organization.

Generally, the activities provided by the central group considerably differ from the decentralized security teams. The central team provides content, and the decentralized teams generally provide execution. This will vary from organization to organization as well. The central group provides governance and oversight, and it educates employees and other users about current information security risks and helps to ensure consistent understanding and administration of policies through help-line telephone numbers, presentations to business units, and written information communicated electronically or by paper memo.

Another critical role for the centralized security team is ongoing partnerships with the decentralized security team and the organization's business and functional organizations. The role has both formalized aspects such as periodically meeting with senior management to discuss business and security requirements, new and evolving risks and vulnerabilities, and new security solutions and technology. Informal and ongoing ad hoc discussions can also include updates to risk assessments and policies and procedures.

The central group has an ongoing role to research potential threats, vulnerabilities, and control mechanisms and to communicate optional security and control capabilities. The central team should also poll the entire organization for best practices and share those out to the decentralized teams and businesses. The central group should also be engaged in ongoing outreach to professional organizations, educational and research groups, and vendors and government agencies. This information should be communicated to the business units in regular structured and unstructured ways. Newsletters, memos, websites, computer-based training, and security training checklists should all be used in the annual security training and awareness program.

Organization managers are expected to know corporate policies and procedures and to comply. To do so, the centralized security team can provide tools and processes for the distributed organizations to use to comply with policy and to ensure consistent approaches. Also, the organization managers will be more likely to actually do it. Managers of decentralized teams and businesses should know what their security problems are and have plans in place to resolve them. To help ensure that managers fulfill this responsibility, they are provided with self-assessment tools that they can use to evaluate the information security aspects of their operations. When weaknesses are discovered, the business managers are expected to either improve compliance with existing policies or to consult with the corporation's security experts regarding the feasibility of implementing new policies or control techniques.

49.5 Critical Roles and Responsibilities

A primary function of the security team and the CISO or CSO is to promote senior executive awareness of information security issues and to provide information they can use to establish a management framework for more effective information security programs. Most senior executives are just beginning to recognize the significance of these risks and to fully appreciate the importance of protecting their information resources. Assigning accountability is of the utmost importance to ensure success and allocating personnel, functional areas of responsibility, and risk management.

It is necessary for the security and executive teams to recognize that information resources are essential organizational assets. Together, these two teams should develop practical risk assessment procedures that link security to business needs. As previously mentioned, whether the security organization is centralized or decentralized, it is imperative to hold program and business managers accountable for risk management and information protection. This is not just a one shot effort, but risk must be continually managed on an ongoing basis. Results of risk assessments, gap analysis, and vulnerability studies will ensure that the security program keeps pace with the risk and ensures the business imperatives of the organization are being met.

It is imperative that the centralized security team be empowered to govern the overall enterprise security program. The team should have ongoing and easy access to executive management both for formalized briefings and for ad hoc discussions. The security function and the team must be adequately staffed and funded for success and commiserate with the organization's risk, threat, and vulnerability models. The security team should be dynamic and evolving as risk management temperance or acceptability changes. It is important to evolve and enhance the security team's skill base and expertise.

The enterprise security policies must also continue to evolve and keep pace with the business imperatives. Security policies should decompose and succinctly explain the procedures, guidelines, frameworks, and baselines of the organization. Security must be viewed as an enabler and a contributor to the bottom line. Business, technology, and process risks must be in locked step throughout the security program. Communication and education and awareness are primary functions that the security team should address within annual goals and ongoing process.

A critical contributor to success is ongoing monitoring and ensuring that the security goals and objectives are on course, and risk is being managed as expected and defined. Accountability and expectations must be driven through all levels of the organization from executive management to individual contributors. Finally, the security program must not lose sight of the organization's principle goals and readily adjust in headcount, team functionality, skill base, tasks, etc.

49.6 Where Should the Centralized Security Group Report?

Security professionals and practitioners learn early on that the best bet is to swim up stream with the ever-aspiring goal of reporting as high up in the organization as possible. That would place the CISO or the CSO directly reporting to the corporation's CEO or COO. For the CISO, more often than not, the highest reporting structure would be to the CIO. The CIO should directly report to the CEO or the COO. At many companies, however, the CISO reports into the CFO, the Chief Risk and Compliance Officer, or the Chief Counsel. More often than not, however, it is more common to find the CISO and the CSO reporting two or even three levels below the "C" levels. Security organizations placed too low in the corporate organizational structure are at risk of being ineffective and uninformed and often have little or no opportunity to discuss information security issues with their CIOs and other senior agency officials.

Who "owns" the security problem? Ultimately, it is the board of directors and the owners of the company who are culpable. However, the day-to-day accountability can be delegated to the CISO, the CSO, the Chief Privacy Officer (CPO), the Chief Compliance Officer (CCO), the Chief Risk Officer (CRO), or the VP of Security. These roles have not been critical positions within a company for very long. Previously, all of these options and these roles or functions were not recognized as solid professions or necessary support functions for organizations. Again, it is not as important where the security function reports or who has the red letter "X" as it is that someone does and that his or her accountability and roles and responsibilities are clearly defined.

Regardless of where the CISO or CSO and their respective organizations report within the structure, successful organizations will establish senior executive level business and technical governance councils to ensure that information technology issues, including information security, receive appropriate attention.

It makes sense to follow the corporation's organizational model. If IT is centralized, it makes sense to centralize IT governance and security administration as well. If IT is decentralized, distributed security teams should have a dotted line relationship to the CISO. Corporate Lines of Business (LOBs) and functional organizations are responsible to have appropriately supervised professional technical support staffing sufficient to maintain information security. The staffing level should be appropriate to the environment considering the amount and type of information for which they are responsible as well as the level of risk.

At the onset, there is high value in involving more, rather than less, of the enterprise in the requirements' generation and the planning process. Of course, it is commonly acknowledged that large planning teams do not work. Perhaps a central project with an executive steering committee is best. Membership on working teams as well as the executive steering committee should come from functional and business areas. It is important to get everyone involved in the process for buy-in and success. Again, look for structured and streamlined ways of doing this such as disciplined requirements gathering, surveys and questionnaires, and feedback loops.

Business functional areas must be very involved in the planning and execution process and also committed to the overall success of the security organization. There is a need to communicate up and down the organization throughout the process. The decentralized business group must be given clear policies, procedures, and guidelines to follow as well as technical tools and processes. The central team should be its ongoing lifeline, and it should provide a level of oversight, guidance, and ongoing control monitoring.

49.7 Developing a Staffing Plan

Since 9/11, true security professionals are hard to come by and are often very expensive to acquire. There are many would-be applicants who have gained professional and technical security certifications and more or less do not have practical experience. It takes a keen eye during the resume screening process and a keen ear during the interview process to filter out the true security professional and practitioner. Ideally, an organization will want to find candidates who are strong in both areas. If an organization must choose between a security practitioner with hands-on experience in security operations and implementations versus a security professional who may be certified but has only had consulting and risk assessment background, it will be best served to go with the security practitioner and mentor and train him or her toward the higher goal of solid security professional skills and experience. Ideally, the organization will need both when building and maintaining its security team.

Because of the ongoing barrage of legal and regulatory requirements, many business, IT, and auditors are adding regulatory and legal compliance such as GLBA, SOX, and HIPAA to their resumes in hopes of snagging a well-paying role in compliance and audit organizations or in IT shops for risk assessment, mitigation, and technical implementations.

Most organizations have a staffing strategy to include preferences and policies for hiring permanent full-time employees versus using contractors. Once an organization determines the vision and mission of the security team, has well-defined expectations from executive management, clear definitions of roles and responsibilities, and has developed supporting goals and objectives, it is ready to build the security team. If an organization is starting from scratch, it must define the roles and responsibilities of the team and map out the skills needed for it to be successful. If it is enhancing or modifying an existing team, it must follow the same steps but conduct a gap assessment between the existing skill set and the desired skills necessary to be successful and build its winning team.

In today's environment, an ongoing assumption is that budgets are tight, and staffing justifications will be required for any budget, resource, and staffing increase. Although some reports are encouraging and attest to a more favorable outlook in the future, it is still wise to be prepared for shrinking budgets and ups and downs in the financial arena. According to the ISC2 research, "Organizations spend on average more than 43% of their IT security budgets on personnel, education and training. Overall, respondents are anticipating their level of education and training to increase by 22% over the coming year.

A solid business case and justification, resulting in quickly gained approvals and management support will occur as long as an organization has fully researched and managed its plan. With a disciplined and repeatable process in place, it will gain credibility and success for ongoing and future staffing requirements. Do not forget that critical discovery preliminary effort you began this project with in information gathering and learning the organization. Of particular value in staffing the organization is ensuring the requirements incorporate the culture and maturity of the organization as well as its goals and objectives.

49.8 How Large Should the Security Team Be?

The Robert Frances Group (RFG) published an article on calculating staffing requirements, and it makes the point that although having a baseline is merely a source of comparison and a starting place, having it in the organization's arsenal is still a good and worthwhile idea. Referencing any industry statistics and benchmarks will also help it to build a case and justification for staffing and budgets. Per RFG, "Calculating security staffing requirements is a methodical process that requires significant planning documentation. Even if no staffing changes are planned, these calculations can provide valuable insight into the security needs of the organization." RFG also stresses the importance of understanding roles and responsibilities for the security function and recommend detailing this by functional roles.

As previously stated, the security team does not have to own or perform all related security functions, but rather, it must ensure that a defined program is being followed, that all the pieces come together to manage risk and secure the enterprise, and that there is accountability within the process and execution. Ideally, the more the entire enterprise is involved in some aspect of information protection or security, the more solid and successful the team will be.

A 2003 Deloitte Touche Tohmatsu (DTT) survey found that "one information security professional for every 1,000 users was a good standard to aspire towards. Previous Computer Security Institute (CSI) studies have cited security headcount benchmarks as rather a percentage of IT budget or overall IT annual spending. In recent years with the growing awareness of increased risk and the emphasis on security, these percentages have moved upwards of 3%–5%. Other variables in the equation or in deriving the appropriate staffing levels for your organization include; numbers of employees, numbers of computing devices, numbers of applications and systems, and the complexity of the IT environment.

Defining, acquiring, implementing, and maintaining the right number of security personnel with the right skills and implementing the right program can sometimes be seen as a mysterious and magical feat. It takes talented and experienced security leaders to pull this off with executive management's understanding and support. As always, the budget realities must factor in. It is also important for the entire team to work together to establish common goals and derive a balance between a minimalist approach and getting the job done.

Because of the varying mix of applications and support levels required in different organizations, ratios of staff to the number of systems maintained can (and does) vary widely. There are several factors affecting this ratio and the related productivity of the security staff. As a first step of developing a resource and staffing strategy and plan, the following can serve as a guideline to get an organization started.

If a company is regulated and governed by a lot of laws and regulations, dictating the protection of the company's and its customer's private data, higher levels of staffing may be required to develop policies and procedures for protecting sensitive and private information and to execute on those policies. The company must also evaluate and implement technical products to govern and manage access controls, identity management, audit, and content monitoring. This is also a different skill set to include risk management, audit expertise, security administration, security engineering, and legal compliance and regulatory expertise.

If the organizational model is decentralization and the business areas manage access control and have delegated security responsibilities such as information security officers (ISO), the central team can be smaller, having more of a governance role to include communication, training, and awareness. Again, the maturity of the overall organization and its culture plays into the equation. As the business model and the IT pendulum continually swings from centralization and back to decentralization, the company's model should adjust accordingly as well as its staffing size.

These decentralized teams need ongoing oversight and monitoring. They also need help interpreting security policies and defining and managing risk. They should not be able to accept and manage risk that impacts the entire enterprise, only enclaves within the enterprise network. Decentralized risk management and security teams can unwittingly add significant additional risk to the environment through susceptibility to various security vulnerabilities by mis-configuration and a lack of awareness and knowledge.

For more centralized security teams, the team must be of sufficient size to allow continuous support during absences such as vacations and sick leave as well as training time away from the workplace for the technical staff. If there is a requirement for any systems to operate or be monitored during non-work hours, a capability to provide such support must be included in the staffing levels. A staff size of one person cannot, in most cases, provide this capability, especially if private data are involved.

The support method or model can also have a significant impact and effect on staffing and response time. For example, a department with 100 desktop computers that are centrally managed requires a lower staffing level (and can be much more easily secured) than one that requires a visit to every computer to perform maintenance. Explicit unit decisions should be made regarding the appropriate model after review of the alternatives.

Also consider the company's acquisition model. The equipment and software acquisition model can have a significant effect on staffing, response time, and security. A department with a smorgasbord of ages and models of equipment and software requires greater expertise and more staffing than one with more limited options. Vendors do not issue security patches for older versions of software and operating systems. Explicit unit decisions should be made regarding the appropriate hardware and software replacement model after review of the alternatives.

Other factors to consider are the diversity and complexity of the organization's business model, its supporting business processes, and its information technology. The more complexity within the overall organization, the greater the challenge for the security team and greater risk for its success. Additionally, if the organization is growing or shrinking, the complexity of integrating new acquisitions and mergers from a security and risk management perspective can tax an existing security organization and require additional resources. If the organization is acquiring or developing new software and IT systems, there is also a greater need for security staffing as opposed to a mature and stable organization that is maintaining operational systems. Therefore, the number and complexity of IT systems and applications play into the equation to determine staffing levels. Remember that contractors, by nature, are meant to handle these blips in staffing requirements.

As the previously mentioned RFG model illustrates, organizations should develop minimal baseline staffing calculations and models. This information can be used to determine areas where the enterprise is understaffed, but it should avoid premature termination of employees in areas that appear overstaffed. RFG also acknowledges the need to understand the organization's application and systems environment and the necessary security individuals to manage access control and risk. "In many ways, enterprise security requirements continue to place IT executives between a "rock" and a "hard place." Business partners, customers, and government regulators expect enterprises to prove their abilities to conduct business without compromising security. At the same time, budget constraints often prevent IT executives from applying every resource available to addressing those same security concerns. This quandary leads to a balancing act to ensure that serious negative consequences do not apply."

Hiring a group of security professionals with varying levels of expertise will not only round out a team, but it will ensure career enhancement, coaching and mentoring, and upward mobility for junior and less experienced personnel. If an organization is building a larger team, it may want a combination of technical breadth and technical depth. If it has a smaller team, it will have to look for more breadth in the skill set mix to include other skills such as systems engineering, business analyst, project management, business process engineering, etc.

In addition to highly technical and subject area expertise in security, security team members need to have excellent customer service and communication skills. They should also be able to talk upward and downward within the organization. They should be able to talk technical-speak as well as understand and articulate business issues. Security team members should be active listeners and effective negotiators. In today's environment with heightened attention to legal and regulatory requirements, team members should also be honest and ethical. Many organizations require higher level background checks for security personnel.

A successful staffing strategy will supplement the team in times of unplanned resource requirements or for projects of shorter duration by hiring external contractors. Another benefit of using contractors is that budgets can be tightened when they are thin without depleting a full-time employee base. Contractors are also a good way to bring in state-of-the-art expertise to the existing team, both for projects and for enhancing the core competence of the team.

49.9 Hiring Security Consultants to Augment a Company's Staff

When the needed skill set or resources are not internally available either through the centralized and decentralized security team or within another internal functional group, staff augmentation through external consulting services should be considered. Sometimes, using a consultant is beneficial in providing a non-biased recommendation or to ensure that a conflict of interest does not exist.

When looking externally for a consultant, an organization should seek out its normal recruiting organizations internally and externally. Reach out to professional organizations and networking contacts. Many organizations are currently requiring that contractors be a blend of professional and practitioner. Another growing trend is professional certifications to include Certified Information Systems Security Professionals (CISSP). Consider security individuals formerly residing in the Department of Defense (DoD), ex-military personnel, or local law enforcement personnel.
