- All appropriate security disciplines must be included in the scope of the certification. Although a system may have very strong controls in one area, weak controls in another area may undermine the system's overall security posture.
- Management's political and financial support is vital to the acceptance and implementation of the C&A process. Management should be briefed on the C&A program, its objectives, and its processes.
- Information systems to undertake a C&A must be identified and put in a priority order to ensure that the most important systems are addressed first.
- Security requirements must be established (if not already available); and the requirements must be accurate, complete, and understandable.
- Technical evaluators must be capable of performing their assigned tasks and be able to remain objective in their evaluation. They should have no vested interest in the outcome of the evaluation.
- Access to the personnel and documentation associated with an information system is vital to the completion of required documentation and analyses.
- A comprehensive basic evaluation should be performed. A detailed evaluation should be completed where necessary.

189.13.2 Industry Implementation

Where do you stand?

- If your organization's security department is not sufficiently staffed, what type of individuals (and who) can be tasked to support C&As on a part-time basis?
- C&A process steps and associated documentation will be necessary. Use the references presented in this chapter as a starting point for creating the applicable documentation for your organization.
- Systems for which a C&A will be conducted must be identified. Consider sensitivity and criticality when you are creating your list. Identify those systems with the highest risks and most impact if threats are realized. Your organization has more to lose if those systems are not adequately protected.
- The level of C&A to be conducted will depend on the available resources. You may suggest that your organization starts with minimal C&A levels and move up as time and funding permit. The level of effort required will help you determine the associated costs and the perceived benefits (and return on investment) for conducting the C&As.

189.13.3 Take that Step and Keep Stepping

You may have to start at a lower level of C&A than you would like to conduct for your organization, but you are taking a step. Check with your colleagues in other organizations on their experiences. Small, successful C&As will serve as a marketing tool for future efforts. Although the completion of a C&A is no guarantee that there will not be a loss of information confidentiality, integrity, or availability, the acceptance of risk is based on increased performance of security controls, user awareness, and increased management understanding and control. Remember: take that step. A false sense of security is worse than no security at all.

System Development Security Methodology

Ian Lim
Ioana V. Bazavan

Many organizations have a System or Software Development Lifecycle (SDLC) to ensure that a carefully planned and repeatable process is used to develop systems. The SDLC typically includes stages that guide the project team in proposing, obtaining approval for, generating requirements for, designing, building and testing, deploying, and maintaining a system. However, many SDLCs do not take security into consideration adequately, resulting in the productionalization of insecure systems. Even in cases where there are security components in the SDLC, security is oftentimes the sacrificial lamb in a compressed project delivery timeframe. This neglect brings risk to the organization, and creates an operational burden on the IT staff, resulting in the need for costly, difficult, and time-consuming security retrofitting. In a climate where the protection of information is increasingly tied to an organization's integrity, security needs to be strongly coupled with the system development process to ensure that new systems maintain or improve the current security level of the organization.

This chapter describes a System Development Security Methodology (SDSM), which is a *modus operandi* for incorporating security into the system development process. The SDSM is designed to be an extension, not a replacement, of an organization's preexisting SDLC. This pairing and differentiation is meant both to complement and draw attention to the importance of security in the SDLC. The SDSM is especially useful for organizations that have SDLCs that lack security considerations. Whereas the overall SDLC addresses all aspects and stages of the system, the SDSM focuses primarily on the system's security needs and is limited to the Requirements, Analyze, Design, Build and Test, and Deploy stages.

The SDSM's primary audience is the project team that will be developing a new system in-house, or evaluating a third-party system for purchase. The project team should incorporate the concepts from each phase of the SDSM into the corresponding phases of the organization's existing SDLC to ensure that security is appropriately considered and built into the system from the beginning stages. Inclusion of security in this way will result in a robust end system that is more secure, easier to maintain, and less costly to own.

190.1 System Development Security Framework

Exhibit 190.1 provides a framework for the System Development Security Methodology. Each step is described in detail later in this chapter.

190.1.1 System Development Security Methodology

The following sections describe in detail what the System Development Security Framework (Exhibit 190.1) depicts visually. Sections are numbered as in Exhibit 190.1.

190.1.1.1 Stage 1: Requirements

The high-level objectives of the requirements stage are to:

- Extrapolate information security requirements from business requirements
- Capture applicable security policies, standards, and guidelines from within the organization
- Capture applicable regulatory and audit requirements, such as GLBA, HIPAA, Common Criteria, etc.
- Create a detailed security requirements deliverable.

EXHIBIT 190.1 System Development Security Framework

	Stage				
Software Development Lifecycle	**1. Requirements**	**2. Analyze**	**3. Design**	**4. Build and Test**	**5. Deploy**
System development security	1.1 Identify information protection requirements	2.1 Identify risks and costs	3.1 Design system security components	4.1 Build secure environments	5.1 Secure code migration
	1.2 Identify corporatewide and regulatory security requirements	2.2 Conduct risk vs. cost analysis	3.2 Determine and establish development security needs	4.2 Enforce secure coding practices; build security components	5.2 Sanitize obsolete environments; secure production environment
	1.3 Identify user base and high-level access requirements	2.3 Determine security scope and finalize security requirements	3.3 Security procurement	4.3 Conduct code review	5.3 Secure deployment process
	1.4 Identify security audit requirements	2.4 Evaluate resource needs (time, budget, people)	3.4 Develop security testing approach	4.4 Conduct security testing	5.4 User awareness and training
Security deliverable/endproduct	1.5 Detailed security requirements	2.5 Security project plan 2.6 Initial risk mitigation document	3.5 Security design 3.6 Security test plan	4.5 The prepilot environment	5.5 Completed risk mitigation document
Information security certification	Initial certification review		Certification checkpoint	Vulnerability assessment	Certification issuance

190.1.1.1.1 Step 1.1: Identify Information Protection Requirements.

The typical SDLC tends to focus on business capabilities in the Requirements stage. The SDSM seeks to anchor the project team on the confidentiality, availability, and integrity of information early in the development process. Different industries and systems have dissimilar information protection requirements. For example, healthcare organizations might stress the confidentiality of patient records, whereas banking might be more concerned about the integrity of monetary transactions.

The project team needs to understand and capture what adequate protection of information means in their specific context. Organizations with an information or data classification policy(ies) are at an advantage here because the team could more conveniently identify the type of information that is processed as well as the organization's requirements as to how the information is to be protected. Once the types of information are identified, protection requirements should be organized further into areas such as storage and exchange, authentication, and access control. Requirements should be based, not only on the classification of the data (e.g., internal use, highly confidential), but also on the way in which data is accessed (e.g., via the Internet, remotely via leased lines, or from inside the organization), and the type of user (e.g., educated employees, public users, etc.), as well as the way in which access is managed (e.g., rule-based, role-based).

190.1.1.1.2 Step 1.2: Identify Organization and Regulatory Security Requirements.

Of key importance is that the project team verifies and captures all applicable information security policies and standards pertaining to the system to be developed to ensure that the organization's security requirements are being met. Equally important is for the project team to be aware of current as well as pending federal, state, and local regulatory standards. Project teams should be aware that different states have begun implementing bills specific to information security. For example, the California Senate Bill 1386, which became effective on July 1, 2003, requires a business to notify individuals if their personal information may have been compromised because of a security breach. Finally, the organization should document any requirements from the organization's audit and compliance group.

190.1.1.1.3 Step 1.3: Identify User Base and Access Control Requirements.

The largest impact to a system's security is caused by users. It is important to know the user communities that will require access to the system, and how the system will identify, authenticate, and authorize the users in each community. As part of the access control mechanism, the project team should also consider the service requirement. If the team is evaluating or developing a system of critical importance that may be subject to service attacks, it is important that access be controlled to ensure that the most important users have priority when they need it. In most organizations, loss of service is an annoyance or results in loss of revenue. In the military, loss of service could result in loss of life.

190.1.1.1.4 Step 1.4: Identify Security Audit Requirements.

Depending on the sensitivity or criticality of the information stored on the system, the organization may need to hold individual users highly accountable for their actions on the system. The SDLC tends to focus on error reporting and system events. It is not uncommon for systems to be built with little or no consideration for security auditing requirements. This neglect affects the accuracy and granularity of security-related event tracking, which in turn makes auditing and incident handling activities more complex. The project team should consider the following when identifying security audit requirements:

- Determine the alignment with organizationwide security auditing strategy
- Determine the audit approach: subject-oriented (uses, roles, groups) vs. object-oriented (files, transactions) vs. a hybrid approach
- Determine the level of granularity needed to provide a sufficient audit trail
- Determine the administration and protection of the audit logs

- Determine the life cycle of the audit logs (align with the organization's retention policies)
- Determine the interoperability of the auditing capability (operability with other repositories)

190.1.1.1.5 Step 1.5: Detailed Security Requirements Deliverable.

The detailed security requirements deliverable should be a subset of the requirements document(s) produced in the SDLC process. Exhibit 190.2 provides a sample of sub-headings that should be included in this deliverable.

The detailed security requirements deliverable is a living document that may need updating in later stages. This document will be used in the Design stage to create a one-to-one mapping of functionality to requirements to ensure that all requirements have been addressed.

190.1.1.2 Stage 2: Analyze

The objective of the Analyze stage in the SDSM is to provide a dose of reality in the ideal world of the Requirements stage. The project team must determine the viability of designing and implementing the security requirements and adjust appropriately according to budget, resource, and timeline constraints. Subsequently, the final scope should be defined; the project deliverables, timelines, checkpoints, budget, and resources should be identified; and a security project plan should be created for incorporation into the overall SDLC project plan. A high-level information security risk document should also be prepared for presentation at the initial certification review (discussed later in the chapter).

It is critical that a thorough security analysis is done to ensure that the proper security elements are considered in the Design stage. An incomplete analysis could lead to a faulty design, which at best will lead to costly rework, and at worst will result in an insecure end product.

EXHIBIT 190.2 Sample of Content that Should Be Included in the Detailed Security Requirements Deliverable

Subheadings	Content	Example
Information storage and exchange	Information classification Encryption requirements (if applicable) Information exchange control points (entry/exit)	Customer insurance policy information is classified as Confidential, and must be encrypted when transmitted over the Internet Customer insurance policy being transmitted to business partner must pass through a single entry/exit point
Identification/ authentication	User communities specification (external end users, internal end users, business partners, support, administrators, vendors, etc.) Authentication strength (password, strong passwords, two-factor, biometrics) Warning banner requirements Credential management requirements	Public end users must be uniquely identified and authenticated to the system using strong passwords
Authorization	Mode of access control (role-based, rule-based) Levels of access rights Access move, add, delete requirements	Role-based authorization must be used Users can have multiple roles
Reliability of service	High availability and redundancy requirements Fail-safe requirements Error and security notification requirements	Failure of the log-on mechanism must exit safely and not grant access to the requestor
Accountability	Security-related activities to be logged	Log-on failures must be timestamped and the user ID and number of attempts logged
Audit	Audit reporting functionality	Report of failed log-ons over the past 30 days

190.1.1.2.1 Step 2.1: Identify Risks and Costs.

The project team should understand how the addition of a new system will impact the organization's existing IT architecture, and what new security risks the system could introduce into the environment. This exercise should identify the appropriate network location of the new system, and the security touchpoints between the system and the preexisting IT infrastructure.

Once the new system has been "placed" into the environment, the project team should identify all possible security threats to the system, including technical hazards (e.g., power outages, security vulnerabilities), man-made hazards (e.g., fire, sabotage), and natural hazards (e.g., floods, tornadoes). The team should then identify the likelihood that each threat will occur, and estimate the cost of the potential damage. Next, the project team should estimate the cost to mitigate the risk, and determine the business impact if a risk is not addressed. Finally, the project team should highlight the most costly and complex security requirements, and document the risk and cost findings at a high level in the information security risk document. Exhibit 190.3 summarizes the process of identifying risks and costs.

190.1.1.2.2 Step 2.2: Risk vs Cost Analysis.

It is possible that the costs of implementing security outweigh the risks, in which case the requirements should be modified or an exception to the security requirement obtained. For example, a project team in the healthcare industry is building a capability that requires external e-mail exchange of personal health information (PHI). Encryption of PHI transmitted over public e-mail is a regulatory requirement. If the cost of deploying a secure interorganizational e-mail solution is beyond the budget of the project, an alternative may be to use "snail mail" or secure faxes. Another option is to propose a shared infrastructure for an enterprisewide secure e-mail solution and obtain an exception until this capability is built out.

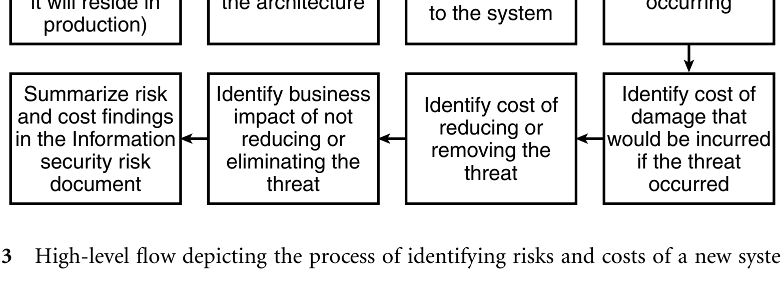
190.1.1.2.3 Step 2.3: Determine Security Scope and Finalize Security Requirements.

Once risks, costs, and impact have been analyzed, the project team should determine the system requirements to include or exclude based on cost, risk, complexity, timing, impact, etc. This determination should take into consideration the impact of security on end users, the potential damage that the end user could do to the system, other threats to the system (i.e., natural, technical, or man-made hazards), and business needs. The risk analysis should be consolidated, and the project team should formulate risk mitigation activities and prepare exception requests (discussed later).

The project team should also make a determination around building, buying, reusing, or outsourcing security components. In this decision, the cost of security vs. the value it adds should be considered, as well as the complexity and robustness of the solution options. Lastly, the requirements should be finalized.

190.1.1.2.4 Step 2.4: Evaluate Resource Needs.

Once the final requirements have been established, the project team can identify timelines and checkpoints to build or configure the required functionality. The project team should also identify the project budget, and resources that will be conducting the design, build, test, and implement work, along



"Place" the new system in its environment (as it will reside in production)
Identify security touchpoints in the architecture
Identify technical, man-made, and natural threats to the system
Identify likelihood of each threat occurring
Identify cost of damage that would be incurred if the threat occurred
Identify cost of reducing or removing the threat
Identify business impact of not reducing or eliminating the threat
Summarize risk and cost findings in the Information security risk document

EXHIBIT 190.3 High-level flow depicting the process of identifying risks and costs of a new system.

with their roles and responsibilities. Resources performing security tasks should have a security background or should be supervised by someone who does. This may necessitate budgeting for internal or external security subject matter experts (SMEs) if security expertise is not available on the project team. Finally, the project team should plan time, effort, and resources for the certification process (discussed later).

190.1.1.2.5 Step 2.5: Security Project Plan.

The security project plan deliverable should be a subset of the overall project plan produced in the SDLC process. The security project plan should include the subheadings listed in Exhibit 190.4.

190.1.1.2.6 Step 2.6: Initial Risk Mitigation Document.

The risk mitigation document is a living document that is created in the Analyze stage and updated throughout the SDLC process to track information security risk. This document is completed at the end of the certification process in the Deployment stage. The risk mitigation document should identify assets that are affected by the new system; the threats to and vulnerabilities within those assets, including likelihood of occurrence; the business impact if a vulnerability is exploited; a prioritization of the risks in accordance with the likelihood of occurrence and impact to the business; and a mitigation plan for each risk.

190.1.1.3 Stage 3: Design

The high-level objectives of the SDSM Design stage are to:

- Formulate how security components are to be built and incorporated into the overall system design
- Define the environments for secure development
- Conduct vendor or capability selection
- Prototype designs and finalize procurement decisions
- Formulate security testing plans (component, integration, product)
- Pass the certification checkpoint (discussed later).

190.1.1.3.1 Step 3.1: Design System Security Components.

At this point, the project team should define the design of security components that will meet the documented security requirements. These components include security functions within the system, such as access role definitions, or separate yet complementary security components, such as a single sign-on architecture. The objective here is to flesh out the various security components of the system to meet

EXHIBIT 190.4 Subheadings that Should Appear in the Security Project Plan Deliverable, and Their Suggested Content

Subheadings	Content
Timelines and checkpoints	Convert security requirements into tasks and assign duration and FTE to tasks Identify tasks for security certification Establish checkpoints to monitor progress
Budget	Identify FTE cost Identify material cost (software, hardware, support, services) Identify project management cost Identify miscellaneous cost
Roles and responsibilities	Define organizational structure Define roles to complete security tasks Define responsibilities for each role

stated requirements. Success criteria should also be defined for each security component (to be used in security testing). Here are some security design principles to keep in mind:

- *Avoid security for security's sake:* Focus on the overall capability and the associated risk factors.
- *Address the key security areas:* Identification, authentication, authorization, confidentiality, integrity, availability, accountability, and where applicable, non-repudiation.
- *Forge multiple layers of controls:* Be wary of single-points-of-failure and the location of the weakest link.
- *Strive for transparent security:* It is an end user's best friend.
- *Keep security simple:* Complex designs have many secrets.
- *Consider the life cycle of the security component:* Start with secure defaults and end with fail-safe stance.
- *Favor mature and proven security technologies:* New is not always best, and organic is not always healthiest.
- *It is ready when you can take it to an expert:* Engage information security subject matter experts to review the soundness of the design.

Perform Prototype Testing to Validate the Capability. Prototype testing validates that the combined elements of a proposed design meet the security requirements. This should occur before the detailed design is complete. The prototype testing is also considered a precursor to the application testing. This may occur in a prototype or test-bed environment. Designers should choose the basic components that will constitute the system based on the assumption that the components possess the capabilities called for in the requirements.

Before time and effort is devoted to a detailed design, these assumptions must be verified and the risks must be evaluated. How this analysis is done (empirically, by developing a prototype of the proposed system, or less formally) will depend on the familiarity of the design team with the proposed architecture. In short, a gray area exists where the differences between verification and actual testing are ill defined. The project team should seek a level of rigor appropriate for the complexity of the system.

190.1.1.3.2 Step 3.2: Determine and Establish Development Security Needs.

It is critical that the project team has an appropriate environment (or environments) in which to conduct the Build and Test stage. This environment should be documented as part of the Design stage. The project team should make arrangements to acquire development, testing, staging, and production environments that meet their needs. These environments should be physically or logically separate and properly secured. The project team should also define mechanisms to maintain the integrity, confidentiality, and availability of the source code by version control, checksums, access rights, logging, etc.

Access privileges should be defined according to roles and responsibilities. Access to source code, system utilities, developer privileges, and developer manuals should be restricted. Media should be protected and software properly licensed.

To ensure secure and smooth migration from one environment to the next, the project team should define change control and risk mitigation processes, including a secure code migration strategy.

190.1.1.3.3 Step 3.3: Security Procurement.

To reduce costs and ensure interoperability with other systems in the organization, the project team should identify and procure any reusable security components, such as token or smart card technologies. If a third-party system is to be purchased, the project team should undergo a vendor selection process in which preexisting vendor relationships, industry recognition, company stability, support offering, product features, etc., are considered.

Once candidate components are procured, the project team should prototype potential solutions to verify capability, performance, interoperability, etc. When a vendor is selected, the project team should work with applicable legal or procurement representatives to establish contracts and agreements (Service Level Agreements, Operational Level Agreements, Nondisclosure Agreements, etc.).

190.1.1.3.4 Step 3.4: Develop Security Testing Approach.

Security testing in the SDSM differs from functional testing in the SDLC. Security testing focuses, not only on those functions that invoke security mechanisms, but also on the least-used aspects of the mechanisms, primarily because the least-used functions often contain flaws that can be exploited. As such, security testing usually includes a high number of negative tests whose expected outcomes demonstrate unsuccessful attempts to circumvent system security. By contrast, functional testing focuses on those functions that are most commonly used.

Develop a List of Assertions. A reasonable approach to testing is to begin by developing a list of assertions. Security test assertions are created by identifying the security-relevant interfaces of a component, reviewing the security requirements and design documentation, and identifying conditions that are security relevant and testable. A few examples of security-relevant interfaces include the password-changing module available to a user, the user administration module available to a security administrator, the application programming interface (API) available to an application programmer, and the console interface available to a network administrator.

Examine such interfaces and the documentation associated with them for testable assertions. For example, the statement “A user should be able to change his own password” is an assertion that might be found in design documentation; a test can be built around this assertion.

Distinguish between Different Types of Tests. Security test procedures will be needed for several types of tests:

- Prototype testing to validate the security capability
- Component testing to validate package, reuse, and custom security component tests
- Integration testing to validate security functionality in integration testing and product testing
- Volume testing to ensure that the system will process data across physical and logical boundaries
- Stress testing to ensure effective transaction processing immediately after system downtime, after network downtime, or during peak periods (denial-of-service conditions)
- Data recovery testing to investigate both data recovery capabilities and system restart capabilities for fail-over and redundancy
- Database security testing to ensure that access is not provided outside the system environment

190.1.1.3.5 Step 3.5: Security Design Deliverable.

The security design deliverable should be a subset of the overall system design deliverable produced in the SDLC process. The format and subheadings of the security design deliverable should follow that of the overall system design deliverable.

Exhibit 190.5 provides a recommended listing of security subheadings for this document.

190.1.1.3.6 Step 3.6: Security Test Plan.

The security test plan should be a subset of the overall test plan deliverable produced in the SDLC process. The format and subheadings of the security test plan should follow that of the overall test plan deliverable, as summarized in Exhibit 190.6.

190.1.1.4 Stage 4: Build and Test

The high-level objectives of the Build and Test stage are to:

- Build secure environments to foster system development integrity and protect preexisting infrastructure
- Promote secure coding practices to ensure the security quality of the finished product

EXHIBIT 190.5 Recommended Subheadings for the Security Design Deliverable, and Their Suggested Content

Subheadings	Content
Introduction	Purpose Context Scope References
Security requirements to design mapping	List security requirements List matching security components to meet each requirement
High-level description	Describe each security component design at a high level Describe interaction among security components, system architecture, and network infrastructure Describe information flow Describe environments Include diagrams and flow charts
Detailed design	Describe each security component in detail Describe software, hardware, service specifications
Environment design	Describe details of development, testing, staging, and production environments Describe code maintenance process Describe secure code migration strategy Describe media protection and licensing protocols Describe change control and risk mitigation processes Describe physical security of development servers and workstations

- Enforce formal code review procedures to inculcate checks and balances into the code-development process
- Thoroughly test all security components to validate the design; build a pilot capability
- Resolve issues within the certification process and pass the vulnerability assessment (discussed later).

190.1.1.4.1 Step 4.1: Build Secure Environments.

Due to the laxness that typically exists in nonproduction environments, preexisting and future production environments should be appropriately demarcated from development, testing, and training

EXHIBIT 190.6 Recommended Subheadings for the Security Test Plan Deliverable, and Their Suggested Content

Subheadings	Content
Introduction	Purpose Context Scope References
Security design to test mapping	List security design List matching testing components to validate each design
High-level description	Describe test approach or process and documentation procedures (should be similar to SDLC) Describe each testing stage: component, integration, product Characterize test environments Specify entry/exit criteria Describe dependencies
Detailed design	Develop list of assertions Specify test input requirements Describe test cases Define each testing phase; provide entry/exit criteria for each phase Describe test procedures; specify “testware” to use Describe regression test approach and criteria Describe code fix criteria Describe testing deliverables

segments. The project team should also configure (or arrange for the configuration with the network support team) network control points (such as firewalls, routers, etc.) to meet development, administrative, and operational objectives. Furthermore, the development environment should mirror the production environment as closely as possible for system build because the system will ultimately have to function properly in the more rigorously controlled production environment.

A key activity in the SDSM's Build stage is server hardening. Hardening is the process of removing or disabling unneeded services, reconfiguring insecure default settings, and updating systems to secure patch levels. A common fallacy in the SDLC process is that systems are developed on unhardened servers and server hardening takes place in the production build-out phase. This predicament makes deploying applications on hardened servers a crapshoot, often resulting in system anomalies, finger-pointing, delayed timelines, and worst of all, a permissive hardening stance to accommodate the application. A better approach is to ensure that development is done on hardened servers and that documentation of necessary services, protocols, system settings, and OS dependencies is captured through the development process.

Finally, to ensure availability, the project team should build or make arrangements for appropriate backup and availability capabilities.

190.1.1.4.2 Step 4.2: Enforce Secure Coding Practices and Build Security Components.

Software developers must be educated in secure coding practices to ensure that the end product has the required security functionality. This is a challenge in most organizations because, historically, security techniques have not been taught in programming classes. Where possible, the organization should arrange for formal secure coding training for its developers.

The following paragraphs describe some high-impact recommendations for improving information security within an organization's application(s).

Encryption and Random Number Generators. The developer should use well-established cryptographic algorithms as opposed to implementing proprietary or obscure cryptographic algorithms. An example of published encryption standards and mechanisms recognized by the cryptographic community are those listed in the Federal Information Processing Standards (FIPS) publication.

Another fallacy related to cryptographic functions is the use of pseudorandom number generators (PSNG). Developers should evaluate their PSNG against the criteria set by RSA:[1]

- Random enough to hide patterns and correlations (i.e., distribution of 1s and 0s will have no noticeable pattern)
- Have a large period (i.e., it will repeat itself only after a large number of bits)
- Generate on average as many 1s as 0s
- Not produce preferred strings such as "01010101"
- Is a simple algorithm with good performance
- Knowledge of some outputs will not help predict past or future outputs
- The internal state of the PRNG will be sufficiently large and unpredictable to avoid exhaustive searches

Input Validation and Exception Checking. Always validate (user and application) input. Most of the exploits seen in recent years were a direct result of poor or incorrect input validation and mishandled exceptions. Independent of the platform, applications have been regularly broken by using attacks such as buffer overflows, format string vulnerabilities, utilization of shell escape codes, etc. Never trust input when designing an application and always perform proper exception checking in the code.

Authentication. Authentication strength is paramount to the security of the application or system, because other security controls, such as authorization, encryption, and auditing, are predicated on the

[1] http://www.rsasecurity.com/solutions/developers/whitepapers/Aricle4-PRNG-pdf

authenticity of the user's identity. However, authentication strength must always be weighed against usability. Enforcing a 10-character password will only lead users to write passwords on Post-It notes and stick them next to the terminal.

Do not hardcode credentials into applications and do not store them in clear-text. Hardcoded passwords are difficult to change and sometimes even result in a clearly visible password in compiled application executables. A simple "string application_name" command on a UNIX host can reveal a password that is not encrypted. A good practice is always to encrypt authentication credentials. This is especially important in a Web application that uses cookies to store session and authentication information.

Favor centralized authentication where possible. Centralized authentication repositories allow for a standardized authentication policy across the enterprise, consistency in authentication data, and a single point of administration.

Authorization. The authorization control is only as strong as its link to the identity it is authorizing (this link is the main target of impersonation attacks). In building out the authorization model, it is critical to form a strong link to the identity through the life cycle of the authenticated session. This is of particular importance in Web applications or multi-layered systems where the identity is often propagated to other contexts.

Logging and Auditing. Logging and auditing can provide evidence of illegal or unauthorized access to an application and its data. It can become legal material if law enforcement authorities get involved. For this reason, logging and auditing should be designed to offer configurable logging and auditing capabilities, which allow the capturing of detailed information if necessary.

Code Dependencies. Code development, especially object-oriented programming, often depends on the use of third-party libraries. Only acquire and use libraries from established vendors to minimize the risk of unknown vulnerabilities. Also, validate return code or values from libraries where possible. Similar precautions should be taken when relying on external subsystems for processing and input.

Error Messages and Code Comments. Error messages should not divulge system information. Attackers usually gather information before they try to break into an application or a network. For this reason, information given out to a user always should be evaluated under the aspect of what a user needs to know. For example, an error message telling the user that a database table is not available already contains too much information. Exception handling should log such an error and provide the user with a standard message, saying that the database is not available.

In the same vein, do not include comments in public viewable code that could reveal valuable information about the inner workings of the system. This is strictly targeted at Web applications where code (and its associated comments) resides on the browser.

Online Coding Resources. The following Web pages provide detailed practical assistance for programmers:

- Java: http://java.sun.com/products/jaas; http://java.sun.com/security/seccodeguide.html; http://dwheeler.com/javasec/
- UNIX: http://dwheeler.com/secure-programs;http://www.sans.org/
- ASP: http://msdn.microsoft.com/library/default.asp?url=/library/en-us/iisref/html/psdk/asp/aspguide.asp

190.1.1.4.3 Step 4.3: Conduct Code Review.

Code review from the SDSM perspective has the objectives of checking for good security coding practices as well as auditing for possible backdoors in the code. It is a well-known fact that insiders conduct the majority of security exploits. Code developers are no exception to that rule.

190.1.1.4.4 Step 4.4: Conduct Security Testing.

Security testing provides assurance that security was implemented to meet the security requirements and to mitigate the risks identified in the security design plan. Security testing ascertains that the proposed components actually perform as expected and that security requirements are met throughout the integrated solution.

The key aim of security testing is to search for exposures that might result in unauthorized access to the underlying operating system, application resources, audit or authentication data, network resources, or that could lead to denial-of-service attacks. Security testing also aims to identify and address the risk of noncompliant components. The risk and proposed mitigation plans should be captured in the project's risk mitigation document (which was created in the Analyze stage).

There are as many different breakdowns for testing phases as there are SDLCs. In the interest of simplicity, the SDSM has three broad test phases: component testing, integration testing, and product testing, as described in the following paragraphs.

Perform Component Testing. Many components combine to form a security infrastructure. In general this includes firewalls, authentication servers, encryption products, certificate servers, access control mechanisms, and routers. Configuration management is often the weak link that creates new exposures. Perform testing for these components individually to test the functionality and to identify any weaknesses in the configuration. The component testing should cover security functionality, performance, failure-proof or fail-safe ability (in case the individual component is compromised), logging and monitoring capability, and manageability.

Security testing should include stress testing. Stress testing and worst-case-scenario testing will help in exposing how well the component behaves under overloaded conditions. These types of testing will also indicate the capability's exposure to denial-of-service attacks.

Perform Integration Testing. The next phase of the testing should focus on integration testing. This phase focuses on how well each component integrates with the other components in the architecture. The objective is to ensure that security requirements are met throughout the environment. Migrations to new environments and integration of custom and packaged components should be thoroughly tested.

Perform Product Testing. Product test execution will occur only after all package, custom, and reuse components have completed integration testing. The product test execution may not end until the entire product test model has been executed completely and without discrepancies.

All pieces of the security solution are to be installed and configured in a test environment to mimic a production environment as closely as possible. For the best results, product testing should occur in a production-readiness (staging) environment. This environment should include all packaged software and all hardware chosen for production.

When a new capability is introduced into an existing networked environment, the new capability inherits all the risks associated with that environment. Therefore it is extremely important to test how well the capability meets its security requirements within the production environment.

General Tips on Security Testing. The following list provides some general tips on testing for security:

- Discourage the use of production data in the test environment
- Do not use production passwords in the test environment
- Use strong passwords (minimum seven characters, alphanumeric, with mixed case and special characters) in the development environment to emulate production
- Educate the testing team on specific security concerns, such as buffer overruns in C, TCP/IP vulnerabilities, operating system bugs, and ActiveX, Java, and CGI code problems
- Purge test data appropriately so that residual data is not available in the operating environment after it is used
- Disable test accounts when they are no longer necessary
- Document, evaluate, and address security risks of a noncompliant component at each testing phase

190.1.1.4.5 Step 4.5: The Prepilot Environment.

The prepilot environment should have full system functionality and have gone through and passed all testing stages. This environment should be part of the SDLC process. The additional security requirement here is getting the environment through the security certification process. This involves coordinating with the certification team to conduct a vulnerability assessment on the prepilot environment.

190.1.1.5 Stage 5: Deploy

The high-level objectives of the Deploy stage are to migrate systems safely from development through to production; systematically cleanse obsolete environments of security-sensitive information; ensure and preserve the confidentiality, integrity, and availability of the production environment(s); implement secure deployment of systems, user information and credentials, post-configuration information, etc.; employ secure code enhancement, software updates, and bug-fixes procedures; secure deliverables produced during the SDLC; and complete the risk mitigation document and obtain certification sign-off.

190.1.1.5.1 Step 5.1: Secure System Migration.

A secure system migration process contributes to the goal of keeping the production environment as pristine as possible. To ensure that security is maintained throughout the migration process, the project team should assign migration owners and appropriate approval processes to ensure accountability and control during migration. Furthermore, least privilege should be used when granting access to personnel involved in the migration process.

The migration should be conducted using secure protocols and mechanisms across environments. Once the system has been migrated, integrity verifiers (e.g., checksums, message digests) should be used to verify the system's integrity. The project team should also identify and enforce security maintenance as part of regularly scheduled maintenance windows to ensure the continued integrity of the new system in production. Security regression testing should be incorporated in the maintenance cycle to validate the integrity of the system after scheduled changes.

190.1.1.5.2 Step 5.2: Sanitize Obsolete Environments and Secure Production Environment(s).

The project team should implement a process to identify and sanitize development, test, and staging computing resources or environments that are no longer needed. Passwords (root, system, administrative, default, etc.) used in predeployment activities should be changed in all environments, especially production. The project team should also conduct a formalized transition of relevant credentials, system information, processes, documentation, licenses, etc., to the permanent operations or production team.

During the SDLC process, a number of deliverables were produced that contain sensitive information, such as architecture specifics and risk analyses. Such deliverables must be kept for auditing and historical purposes, but they must be controlled to avoid improper disclosure of the information they contain.

Finally, the project team should ensure that the new system has adequate physical security when placed in production.

190.1.1.5.3 Step 5.3: Secure Deployment.

In the rush of making production deadlines, it is not uncommon for user password lists and other sensitive material to be mass distributed. These types of information could be used at a later time to gain unauthorized access into the system. The SDSM seeks to raise awareness of this issue. During deployment, the collection, setup, and distribution of credentials (passwords, tokens, etc.), and post-configuration information (gateway, required ports, environment variables, etc.) should be appropriately controlled, monitored, and accounted for. When granting access to personnel involved in deployment activities, and to permanent system users, least privilege should be used. All user access should be documented.

190.1.1.5.4 Step 5.4: User Awareness and Training.

It is difficult to maintain the security of a system without properly educating the users of that system. It is important that the project team raise user awareness on how to create good passwords, protect credentials, and promote understanding of other security-specific features, such as timeout mechanisms, account lockout, etc.

The project team should identify user support activities and set up caller authentication procedures to verify the identities of users calling the help desk for assistance, and users should be made aware of help desk authentication practices to avoid social engineering attacks.

190.1.1.5.5 Step 5.5: Completed Risk Mitigation Document.

The risk mitigation document is a living document that was created in the Analyze stage and updated throughout the SDLC process to track information security risk. The project team should confirm that all open risk items have been adequately mitigated or have appropriate exception approvals. The completed risk mitigation document should be signed-off as part of the certification issuance process.

190.2 Certification Framework

Throughout this chapter the concept of certification has been alluded to. A certification framework is critical to ensuring the sustenance and improvement of the organization's information security baseline. The objectives of certification are to:

- Ensure correct interpretation of security policies and standards
- Assess and manage risk throughout the capability development life cycle
- Formalize the confirmation of compliance to security policies and standards
- Formalize the acknowledgment and acceptance of information security risks
- Facilitate resolutions, suggest alternatives, and authorize waivers to achieve compliance
- Authorize and track waivers and postponements

It is highly recommended that the organization develop an internal certification process in conjunction with the internal audit and compliance group. An internal certification process can be implemented instead of or in preparation for a formal, external certification such as SAS 70 or ISO 17799, or for a government certification and accreditation. The following paragraphs describe the certification components that have been referenced throughout this chapter.

190.2.1 Initial Certification Review

The initial certification review takes place after the Requirements and Analyze stages and before the Design stage. The objectives of this review can be seen from two sides—the certification team and the project team. For the certification team, this review is an introduction to the project and allows the team to get acquainted with the project's key players as well as the overall capability that is being proposed. For the project team, the objectives of the review are to familiarize them with the certification process, raise exceptions issues, and glean security subject matter expertise from the certification team. The benefits of the initial certification review are early identification of noncompliant issues, facilitation of exceptions requests, and knowledge sharing.

In the initial certification review, the certification team will conduct requirements review and interview sessions with relevant individuals, collect and document the project's alignment with security policies and standards, and provide project teams with resources (e.g., templates, information from similar projects) to facilitate the certification process. The certification team will also review any exception requests that have already been documented, and facilitate the approval or denial of those requests. It should be noted that although the certification team is comprised of security professionals, the individual that certifies the system or approves an exception is a functional owner, who is in a position to accept the risk for the organization.

Prior to entering the initial certification review, the project team must have obtained and reviewed all pertinent information security policies and standards, business requirements, and external regulatory requirements, and produced a detailed security requirements document, a security project plan, an initial risk mitigation document, and any initial exception requests.

Upon completion of the initial certification review, the project team will be provided with approvals or denials of all initial exception requests, and they will have all the information necessary to create the risk analysis document for the Requirements and Analyze stages, which capture risk issues, policies, standards, and regulations that are violated, business impact, likelihood of risk, the discovery timeframe, and the cost to fix. The document also contains a listing of risks that are ranked, an outline of mitigations, and timeframes for compliance.

190.2.2 Certification Checkpoint

The certification checkpoint takes place after the Design stage and before the Build and Test stage. The purpose of this checkpoint is to keep the channels of communication and feedback open between the certification team and the project during the Design stage.

At this time the certification team validates the project team's security design against stated security requirements. The certification team also reviews the security designs to identify noncompliant issues and potential security implications with the enterprisewide security posture. Handling exceptions should also be a common activity during the certification checkpoint. Finally, the certification team should also provide cross-enterprise resources to the project team. For example, the certification team would know of previously certified projects that have a secure file transfer design similar to the needs of the current project.

Prior to entering the certification checkpoint, the project team must have a completed security design document. After the checkpoint, the project team will receive approvals and denials on any new exception requests, based upon which they will need to update the risk analysis document.

190.2.3 Vulnerability Assessment

The goal of the certification team during the vulnerability assessment is to test and identify noncompliant areas prior to deployment. In so doing, the certification team should exercise best effort to minimize disruption to project productivity. As a result of the vulnerability assessment, the certification team will provide empirical data to the project team, so they can update the risk mitigation document. The certification team also facilitates discussions with project teams to establish detailed activities for certification issuance at this point.

The certification team's activities during a vulnerability assessment are to:

- Understand and analyze the environment by conducting interview sessions with relevant parties
- Obtain and review environment documentation
- Assess threat factors and identify application, system, infrastructure, and process vulner-abilities
- Perform a vulnerability assessment with automated scanning tools and selected manual exploits
- Present security analysis findings to the project team
- Discuss security implications and project mitigation activities
- Establish and gain consensus for the completion of the risk mitigation document
- Establish a timeline and checkpoints for certification issuance

Prior to entering the vulnerability assessment, the project team must have an updated risk mitigation document, as well as completed build and test deliverables.

Once the vulnerability assessment has been completed, the certification team provides the project team with a security assessment report, which contains the findings from the assessment. At this time, the project team can update the risk analysis document for the Build and Test stage, as well as the risk mitigation document.

190.2.4 Certification Issuance

The purpose of certification issuance is to formalize the confirmation of compliance to security policies and standards, as well as the acknowledgment and acceptance of information security risks.

Prior to certification issuance, the certification team must validate the completion of the risk mitigation document; ensure that all design, build, and test deliverables have been finalized; and that all exceptions have been approved or that risks for denied exceptions have been mitigated. At this time, the certification team makes a recommendation to the certification issuer about whether or not the system should be certified.

Upon completion of this phase, the project team has completed risk mitigation and risk analysis documents, and a certification issuance decision.

190.3 Summary

To those unfamiliar with the SDLC and SDSM processes, the information presented in this chapter may seem daunting and unrealistic. Implementing such a methodology is in fact mostly a cultural issue, because it requires that project and development teams be more disciplined. It can also extend the project timeline a bit longer than management would like. However, the additional time and due diligence exercised prior to implementation has proven time and again to pay dividends in the long run, by producing systems that are robust, secure, and that do not require costly redesign. Those organizations that have undergone the growing pains have found that it was well worth the effort.

For the implementation of an SDSM or the larger SDLC to be successful, full management support and attention are needed. Also, a complete methodology must be developed by each organization with much more detail than was provided here, in terms that are specific to the needs of the individual organization. Furthermore, such a methodology must be maintained over time to ensure relevance. The technology focus at the writing of this chapter includes things like application servers and CGI scripts, but by the time this text is published, the hot technology will be Web services. Although the base methodology of Requirements-Analyze-Design-Build and Test-Deploy and certification will stand the test of time, the technical details will change frequently, and project teams and developers must keep up.

191

Methods of Auditing Applications

David C. Rice

Graham Bucholz

191.1 Introduction: Ubiquitous Insecurity

The microprocessor—the computer—is the seventh simple machine. Like its predecessors, the wheel, the incline plane, and the lever, the microprocessor performs simple tasks, and therefore makes it easier to accomplish more. Moreover, as production costs and the size of the processors shrink, the silicon chip is becoming inexpensive and tiny enough to slip into every object we manufacture.

As the number of devices containing microprocessors increases, so too will the impact on daily life. Personal computers, the most popular and well known of devices containing a microprocessor, are only one example, but there are many, many others as well. Microprocessors are embedded in everything: cell phones, watches, microwave ovens, automobiles, stereos, and even rice cookers. These "noncomputer" chips already number in the billions. Devices are getting smarter and smaller, but there is more to the story: a single microprocessor can only do so much. Sure it may be fast, and the microprocessor may be smart, but the technological revolution occurs when microprocessors start talking to one another. In other words, the microprocessor by itself is an impressive invention, but interconnected microprocessors, well, that is momentous. Whether personal computer, BlackBerry, PalmPilot, AutoPC, or refrigerator, we are attempting to connect everything to everything else through copper, radio, infrared, and fiber.

Of course, distributed and decentralized computing is nothing new, but it is the scope and scale of microprocessor technology and communication protocols over the last three decades that has allowed decentralized computing to attain new heights. Microprocessors are talking on more devices than ever before, but more importantly these microprocessors are *listening* on more devices than ever before. This grand network of proto-consciousnesses is creating an environment of ubiquitous computing and pervasive connectivity that surrounds and infuses the everyday life of humanity. Underlying this marvelous development of universal computing, however, is something completely transparent to the everyday user: software.

"Connecting all to all" becomes possible only because software, or code, *makes* it possible. Paralleling the rapid expansion of microprocessors into virtually all areas of our business and private lives is the expansion—and dependency—on code. Wherever microprocessors can be found, so must software.

Most computer users probably have not heard of languages like C, C++, Java, and COBOL. If they have, they most likely shun the very mention of them, warily avoiding such cryptic lexicons. Yet these languages and many, many others shape the function—and ultimately the devices—that serve humanity.

If microprocessors are finding their way into our traffic lights, medical devices, airplanes, homes, business supply chains, enterprise management systems, transportation systems, and household appliances, then so too is software. Ubiquitous computing *means* ubiquitous software. Code therefore is quickly becoming the foundation of civilization.

As reliance on software grows, so do the consequences of software failure. If code is becoming the foundation of civilization, then civilization is only as durable as the code.

A majority of consumers would never settle—let alone pay for—homes, automobiles, or buildings constructed as poorly as many software applications are today. Software bugs seem to be an accepted part of the computing environment. However, if the software is buggy, what does that say about the software's security? Bugs are indicative of a greater problem, yet they are often eschewed as "the cost of doing business."

The heavier the reliance on software in our everyday existence, the higher the exposure to risk if that software should fail or be leveraged for malicious intent. Couple this risk to a highly networked, distributed environment—an environment that almost insists on pervasive communications—and the potential for havoc becomes highly feasible. If ubiquitous computing means ubiquitous software, then ubiquitous software means ubiquitous insecurity.

Perhaps the reader's first inclination is to state the effectiveness of firewalls, intrusion detection systems, and virus detectors against insecurity. Ironically, many of these security applications are no better designed or implemented than the applications they are attempting to protect. If the software on security systems is flawed, so is the security the device provides. However, too much faith in security systems or encryption masks the real problem. Firewalls and intrusion detection systems are really just a network response to a software-engineering problem, and for the most part, do not and cannot protect from ZeroDay[1] events. This is not to say security systems are entirely useless. Security systems can be a valuable addition to a network's defense, but do nothing to solve the problem of insecurity, only delay it.

Ubiquitous insecurity stems from our unwillingness and inability to unravel the software-engineering predicament at its root: code. The pronoun "our" in the previous sentence is left purposely nebulous because the software-engineering problem belongs to everyone—government, industry, consumer, and developer. As long as insecure code is developed and purchased, whether by private consumer, corporate entity, or government institution, ubiquitous insecurity will imperil the foundations of the civilization being built today. This is not to say that the future is unequivocally doomed; every civilization has faced a foreboding, dark shadow threatening its very survival, but few civilizations have willingly created and installed a nemesis within their fledgling critical infrastructure.

Although the seventh simple machine can be a great servant to humanity, it can also be an appalling master if not supervised appropriately. The inventor of the wheel could never imagine to what ends the wheel would be used, no more than the future utilization of the microprocessor can be foreseen at this moment in time. We must create software worthy of the title "foundation."

[1] ZeroDay events refer to a newly released exploit into the public domain for which no signature is available to identify it. Because security devices are in large part knowledge-based, the security device must have knowledge of the exploit to protect against it. If the security device is not aware of the exploit, it cannot protect against it until a signature is made available. For those exploits that are not made public, most security devices are unable to protect their respective networks from exploitation.

191.2 Scope of Discussion

This chapter is intended to inform technical managers and developers about the mistakes and bad coding practices that make ubiquitous insecurity a reality. What follows in this chapter is a description of vulnerability discovery methods or attack techniques used to audit and evaluate applications for insecurities. These same techniques can also be used to subvert applications for gain, curiosity, or otherwise. In no way do the authors encourage illegal behavior.

The methods discussed in this chapter apply mainly to binary applications, and do not address Web applications or Web services directly, though some techniques may be leveraged to do so. Web applications are avoided as a topic of discussion mainly because they are site-specific and techniques are not easily generalized.

Every section deserves to be its own book, but by necessity only a subset of relevant topics can be discussed within the limits of a single chapter. Therefore, exhaustive technical depth must give way to brevity in a majority of this discussion; the reader will not be able to put down this book and immediately begin subverting applications. However, the authors have made every attempt to keep this chapter meaningful and informative.

191.3 Setting the Stage

Meaningful vulnerability discovery requires a nontrivial skill set, one that requires an extraordinary amount of patience, time, resources, and exhaustive technical knowledge to acquire. The world of vulnerability discovery is not for the indolent or the faint of heart, nor is that world abundantly populated. To some extent, the difficulty in acquiring the necessary skills to discover unique and original vulnerabilities should comfort those who use the digital world on a daily basis. In laymen's terms, vulnerability discovery is not an amateur endeavor. However, these skills are not impossible to learn, and even a rank amateur can attain some modicum of success. As code infiltrates and delineates our critical infrastructure, more individuals will be enticed to acquire these skills.

In this section, we summarize the required knowledge base for a software/application auditor to understand binary applications, the tools required, and the crucial mindset for executing successful vulnerability discovery. There always will be exceptions to this list, and also unfortunate omissions, but what follows is a good starting point.

191.3.1 Mindset: "There Is No Box"

> The world is seamless, with no boundaries or dividing walls…
>
> **—Ikkyu, Abbot, Buddhist Daitokuji Monastery, Kyoto, Japan**

The foundation for continued, successful vulnerability discovery is the right mindset. Although it seems most of corporate culture, political leadership, and mid-level managers spend time striving to "think-outside-the-box," great hackers[2]—truly great hackers—know *there is no box.*

This apparently esoteric point is absolutely necessary to understand why great hackers are so good at discovering vulnerabilities or subverting applications, networks, and just about anything else they get their hands on. It is also absolutely necessary to understand the concept of "no box" to comprehend why corporate leadership feels hoodwinked when their intranet gets compromised despite liberal firewall placement.

[2] The authors purposely avoid distinguishing "hackers" from "crackers," mostly due to the amount of paper wasted explaining the difference between the two. The Dark Side of the Force can seduce great hackers; get over it.

191.3.2 "No Box"

The "box" is simply the identification of "what is possible or acceptable," based on a given body of knowledge or assumptions. What is considered possible articulates the boundaries of the box. The paradox of "thinking outside the box" is the box immediately expands to include that which escapes it; that is, original thought is quickly burdened with the onus of formulization and imitation.

Boundaries, or boxes, are created by the human mind for the benefit of perception; the mind *must* classify, it must distinguish between good and bad strategies, between "this" and "that" for a matter of survival, but reality is by no means ruled by the mind's perceptions.

Great hackers comprehend the digital world, like the real world, as "seamless, with no boundaries or dividing walls." The digital world is not cordoned off by firewalls nor defined by applications. The digital world is not illuminated by intrusion detection systems nor bounded by user interfaces. The digital world is influenced by these abstractions, no doubt; but the digital world is not beholden to any authority save one—code. Code determines how bits, the 1s and 0s, are created, stored, and transformed into usable information humans can digest. Code is law in the digital world, but it is not absolute. In other words, boxes are a manifestation of code, but code transcends the nature of boxes. Unlike in the real world, where the gravitational constant in one part of the universe is the same as in another, code determines which rules are applied in the digital world and to what extent.[3] Changing the code changes the rules. In a sense, there are those individuals who are impressed with their ability to "think outside the box," and then there are those who create the boxes in the first place.

Often, in the authors' evaluation of software applications, the comments "that's not what the application was designed to do" or "you shouldn't be able to do that," have been heard regularly. From the client's perspective, this is certainly true, but only from that singular perspective. A developer looks at an application as a collection of well-behaved components. A user sees applications as a collection of desktops, windows, and icons. A network administrator sees the network as an amalgam of switches, routers, and proxies.

However, the digital world is by no means ruled by these perceptions. Great hackers see the digital world without the assumptions placed on it by developers, users, and marketing divisions; great hackers see through convenient distinctions as the illusory boxes they are. Hackers see bits only[4] as perhaps scientists see only matter or energy.

Great hackers, however, are not all-powerful deities roaming the digital landscape, changing the rules at whim. For the most part, such a description is inappropriate, but not wholly inaccurate. Code can be a great servant of mankind, but it can also be an appalling master, even to those who know its nuances. Acknowledging "no box" is an important realization, but one that does not confer magical powers upon the enlightened. What is essential after this relatively inexpensive epiphany is a strong, practical foundation in the skills software developers possess.

191.3.3 Knowledge Set

Knowledge of the intended target is vital. In large part, the required knowledge set is target dependent, and increases in importance the deeper into the technical architecture one travels. While the "no box" mindset may permit the application attacker to view the digital world in an entirely different way, the current rules (i.e., code) in place must first be understood before they can be altered.

[3] This point is especially meaningful with the introduction of XML. XML can describe all the information about Mozart's Symphony No. 40. A user might want to listen to the file or print out the sheet music, but depending on what the user wants, data is transformed appropriately to meet the request.

[4] In the physical world, manipulating atoms is not practical for the average human being. We see a cup, move it, drink from it, break it, but we are handicapped about altering how the atoms form the cup. If the cup were made out of bits, however, we could alter each bit, perhaps changing the color of the cup, or even making the cup into a song or picture. In the digital world, you can do anything you want with bits; shape, form, even behavior are not immutable.

The first requirement is to identify the target's platform. A platform is defined by a combination of a microprocessor architecture (Intel, Motorola, AMD, etc.) and an operating system (Windows, Linux, MacOS, etc.). It is not necessary to understand the target platform in its entirety—a task that is almost impossible for any single person–but it is essential to understand a majority of the platform's functional aspects, including input/output, security implementation (if any), file access, memory management, and process creation.

The second requirement is knowledge of a programming language. Languages such as C/C++ are most common, but knowledge of other languages such as Java, COBOL, and Ada may be required; which language is necessary will depend on the target application. Also, knowledge of the assembly language the microprocessor architecture executes can be extremely helpful.

Programming languages are the prime vehicles for exploring a target in-depth. Knowledge of how applications are designed and written assists in analysis. The public interface conceals much of the underlying operations an application performs. The more adept an auditor is at programming, the more portions of an application unexposed by the public interface may be examined. Additionally, programming skills may accelerate the vulnerability discovery processes by automating many common testing procedures and, if a flaw is discovered, to verify the flaw's potential as a vulnerability. Without a doubt, programming skills will augment the auditor's tool set.

The third requirement is knowledge of communication protocols, both network and host-based. TCP/IP is the most common network communication protocol and any application capable of internetworking will usually employ it, but knowledge of other network protocols, such as NetBIOS and IPX/SPX, may be required. The requisite network protocol will depend on the target application.

Host-based communication protocols are those that involve intra-computer communication such as inter-process communication (IPC) or serial/parallel ports. This is one area where developers often devise their own proprietary protocols; however, understanding standard protocol implementations, such as TCP/IP, along with their respective strengths and weaknesses, will help in deciphering and analyzing these proprietary protocols.

The fourth and final requirement is a willingness to learn. It takes time and effort to acquire this body of knowledge and apply it accordingly. Although a computer science degree would be helpful in learning the above-mentioned requirements, it is not mandatory. Knowledge can be acquired by anyone. Every individual has the potential to become a proficient vulnerability researcher with work and practice; a degree is not necessary, it just lowers the learning curve.

191.3.4 Tools of the Trade

Possessing the basic knowledge described previously is often not enough; having the proper tools is also important. Tools of the trade not only include specialized software applications, but also the people you know and the books you read.

There is a number of specialized software applications available free from the Internet or for purchase on the open market. These tools allow auditors to increase their understanding of a particular system. A number of the tools application developers utilize to debug their applications are similarly useful for the auditor in analyzing the same application. Two such tools for software auditing come to the forefront: Numega's SoftICE and DataRescue's IDAPro.

SoftICE is a dynamic debugger for Intel's x86 architecture, capable of interrupting an application while it is executing, permitting the examination of the application's current internal state. This is especially useful for examining current operations that the application is performing that are not observable through the public interface.

IDAPro is an interactive static disassembler capable of displaying the operations for more than 30 different microprocessor architectures on which an application may execute. Much like SoftICE, IDAPro allows the auditor to view operations not observable through the public interface; however, unlike SoftICE, IDAPro examines the entire application without execution. By loading an executable into IDAPro, the auditor may view all possible instructions an application may perform in an easily readable document-like format. However, IDAPro does not support run-time evaluation so the auditor cannot view which instructions are actually executed.

Other tools frequently needed are binary editors, network protocol analyzers, and various forensic programs and devices to display the current state of the system. Binary editors are frequently used to modify programs or files that reside on disk. Forensic programs provide a window into the system's current state without altering data or interrupting program execution. Network protocol analyzers allow an auditor to capture and view inter-application network traffic. Whichever tools the auditor selects is usually dependent on the target environment, economic factors (some tools are more expensive than others, and usually a similar freeware program can be found), and personal preferences.

The expertise of others is one tool most often overlooked. As stated earlier, most modern applications and operating systems are too complicated for any one person to know everything in detail. However, there are experts on facets of every platform, willing to share their insight. This sharing usually manifests in newsgroups, mailing lists, lectures, application documentation, and books, books, books. Usually a good starting point to answer any question may be found in one of the aforementioned forums.

191.4 Attack Methodology

191.4.1 An Art Built on a Science

Currently, auditing programs is still more of an art than a science. There is no "right way" to go about probing an application for security vulnerabilities. Although the methodology for attacking applications mirrors the scientific method, it also has a lot to do with intuition, viewpoint (i.e., "no box"), previous experience, and innovation. These four traits make successful auditors. However, without the patience of a scientist and the critical mindset, most auditors would simply yield to frustration.

191.4.2 Information Gathering

The first step in any process in auditing an application is gathering as much information as possible. Without defining and describing the target, it is difficult to see the full picture, and obvious flaws might be missed. The first place to look is product documentation. Documentation is a great way to see how developers presume their product is supposed to work, and is usually available for applications in varying forms and degrees. Usually, documentation regarding the internal structure of an application is unavailable, but information on a majority of the public interfaces and functionality is included for the benefit of the average user.

After the basics of the application are understood, other information should be gathered to flesh out the picture and focus the search. Most modern applications for personal computers are so large that trying to examine the entire package at once is not feasible, especially if there is a deadline. Good places to look for more information are newsgroups and mailing lists for any mention of the product. Reading other users' experiences can lead to insight into how the product is actually being used (or misused) in the real world. Also, any mention of difficulties or problems using the application should be noted, as this might be indicative of a flaw in the application.

As well as looking for information on the specific product, looking for information on similar products and on different products by the same vendor/developer also can lead to insights. Certain types of applications have specific concerns, regardless of the vendor who created the application, so difficulties in a different application might lead to ideas as to what to explore in the evaluated application. The same concept can be used with different programs from the same vendor. Often applications from a vendor are created by the same developers, or by developers that program with the same corporate mindset. So flaws found in other, unrelated products by the same vendor might also lead to thoughts as to where to focus attention in the targeted application.

Mainly, the purpose of this step is to gain a thorough understanding of the application, and uncover as many potential problems as possible. All this information is then fed into the next step: analysis.

191.4.3 Analysis

Once the raw information is gathered from the preceding step, it must be collated and whittled down into a number of specific areas that might be vulnerable to attack. How this narrowing of possibilities is done is most often based on the past experiences of the person performing the application audit. There really is no right or wrong way to complete this step. Often, the information from previously discovered vulnerabilities is reused against the current application, such as testing user inputs for buffer overflows. Truly unique vulnerabilities are discovered most often by understanding the application as specified in the documentation and then observing the application acting in an inconsistent way. By definition, these types of vulnerabilities are the hardest to find because there is no historical precedent for them. They must be discovered by understanding how the system works, how the application is actually working (as opposed to how the documentation says it works), and often by a good dose of luck.

Once the list of possible vulnerable areas is sorted based on probability of success and resources available, the list is then used in the next step: hypothesis.

191.4.4 Hypothesis

From the last step, a list of possible vulnerabilities was produced. For each of these, a hypothesis should be generated. A hypothesis allows the parameters for each vulnerability to be specified, making it easier to both develop a test for the vulnerability and to more easily see what assumptions may have caused the test to fail. Also, having a semiformal statement of what is being considered is good for documenting the actual testing. Nothing is worse than coming back a few months after an audit, or being handed someone else's work, and not knowing what was done. Usually a hypothesis takes the form, "If we do X, then Y will (or will not) occur." In the application-testing arena, an example may be, "if a large string is entered into a specific field, then an access violation will occur." A true hypothesis would be more specific than that example, but that is the idea. These hypotheses can then be developed into actual tests to be run against the application.

There are a number of common classes of vulnerabilities that should be looked for. Following is our list of them. It is by no means a complete list.

191.4.4.1 Input Validation

Previously highlighted as an example, input validation tests whether an application properly handles input from an external source. In this context, an external source could be the user, another program, operating system, or anything outside the application destined for internal processing. The most common types of input validation errors result in buffer overflow, format string, or denial-of-service exploits. Because developers can accidentally overlook input validation, this type of error occurs frequently.

Most often this form of testing is accomplished by sending varying amounts of data—both properly and improperly formatted—into an application and viewing the results. Application response will help determine if this application is potentially vulnerable to the aforementioned exploits.

191.4.4.2 Angry Monkey

In this method, an automated program randomly performs input validation against the target. Angry Monkey, as any other input validation test, focuses on the application's ability to handle input; however, no criteria are established for external interfaces of the application. Any component of the application may be tested with randomly generated data, in no particular order or for any particular reason.

191.4.4.3 Session Management Validation

Network applications need to manage multiple conversions with numerous communication partners often at the same time. State variables such as session IDs, cookies, and secret keys uniquely identify these sessions. These variables are often randomly generated values that are assigned to a particular communications channel for a limited period of time.

Testing an application for session management vulnerabilities consists of attempting to guess, capture, and modify any of these state variables to elicit undesirable results from the application. By altering these variables, access may be gained to other communication channels that could lead to privilege escalation, loss of privacy or data confidentiality, or unauthorized access to resources.

191.4.4.4 Race Condition Analysis

Applications perform numerous operations in the course of completing any function, including security-related functions. In general, a race condition exists when there is a window of time between a security operation and the general function it applies to. This window of opportunity can allow security measures to be circumvented. An example of this is an application first creating a new file and then applying security to that file. Racing the application attempts to access the file between the time the application creates it and when it actually applies the security. Identifying and testing for race conditions can be difficult due to very short windows of opportunity.

191.4.4.5 Cryptographic Analysis

Applications may handle sensitive data, such as passwords, credit card information, company trade secrets or intellectual property, or private personal information. This data is frequently protected by cryptographic methods. There are a lot of different cryptographic algorithms available for applications to use, both public and private. Experts have created and extensively examined some of them, and the vendors themselves have developed others. Those subjected to public scrutiny by experts are believed to be much stronger and more resilient to attack than private algorithms created by vendors. Determining what algorithm an application uses may lead to knowledge of its strengths and weaknesses. However, regardless of the strength of the algorithm used by the application, if the vendor uses it incorrectly, the data may not be protected as advertised. Errors could include improper creation, handling, or storage of the cryptographic keys. Examination, then, needs to include both the algorithm itself and the key management mechanism.

191.4.4.6 Code Coverage Analysis

Applications need to make numerous decisions in the course of performing their tasks. Each end result of these decisions should be secure. Code coverage analysis usually employs source code (or disassembled code) to ensure that proper security measures are taken on all possible paths of execution. There may exist execution paths through the application that allow for security to be bypassed, leaving the system in a vulnerable state. This analysis can take an extremely large amount of resources, both in people and time, depending on the size and complexity of the application. If at all possible, this type of analysis should be done in stages during the development of an application before it is ever considered ready for production.

191.5 Testing

The final step is taking the first hypothesis and actually testing it. How this is exactly accomplished all depends on both the application and the hypothesis. Sometimes it can be as simple as changing a setting and observing the effect. Other times a complex set of interactions between the application, the system, and possibly some custom-designed code must be choreographed.

Additionally, because applications today are such complex pieces of code, the results of testing a hypothesis can as varied as all the possible tests. However, if the hypothesis was sufficiently developed before testing, success or failure should be fairly easy to determine.

The most difficult part of testing is not finding vulnerability, though. It is proving (at least to whatever level of satisfaction required) that the application is not vulnerable to a specific test. If the test failed to prove the hypothesis, then the next step is to decide whether it failed because the parameters and assumptions being operated under were invalid, or because the hypothesis is wrong. In the previous example, if a long string is entered and does not cause an access violation, is it because the input was correctly handled, or was the string not long enough? Questions like this must be considered, and the hypothesis must be restated to correct any faults, or the results must be accepted and the next hypothesis on the list can be addressed. How concerns like this are handled are more often a matter of policy than of a technical nature.

191.6 Conclusion

Software development is an error-prone process; flaws inevitably creep into any product despite quality control efforts. The prevalence of software in nearly every aspect of modern life leads to reliance on software and as that reliance grows, so do the consequences of software failure or exploitation. No one can say when or why an application will be attacked, so finding and preventing these failures before they occur becomes an important endeavor.

Remember, application auditing is a nontrivial task that requires a special set of knowledge, skills, and resources. While it does not take a genius to succeed, it does require focused effort, patience, and a little bit of luck. The information and methodology described herein are good first steps toward learning what is required. However, it needs to be said that there is not, nor will there ever be, a last step when it comes to application auditing. There is no single solution to solving the problem of insecure applications. Even by auditing an application, there may remain undiscovered weaknesses that will surface months, years, or even decades later. Every weakness found and fixed, however, is one less that threatens the stability of modern life.

192

Hacking Methods

Georges J. Jahchan

192.1 Introduction

Using ever more sophisticated technologies, administrators have been closing the gaps in their network periphery defenses, making it more difficult and expensive for hackers to target weaknesses in the network layer. This fact, coupled with the proliferation of Web-based applications relying on dynamically generated content, has resulted in a distinct shift by hackers: they are increasingly targeting vulnerabilities in Web applications. Successful exploitation of these vulnerabilities could compromise the availability, integrity, and confidentiality of information, with the potential to cause substantial financial loss to victim organizations.

The Symantec Internet Security Threat Reports VI, VII, and VIII covering the periods from January 2004 to June 2005 confirm the trend. So do the SANS Top 20 Reports: Web server and add-on vulnerabilities lead the list of Windows systems vulnerabilities and are second in Unix systems after the Internet name daemon.

Another less obvious trend is the shift in hackers' motives. In the early days, hackers were after fame and recognition; currently, financial gain is a driver. It is not uncommon for a hacker to obtain unauthorized access to valuable confidential information, then turn around and blackmail the victim, offer the data for sale, make use of it (rack CC charges), or post the data on the Internet.

The common denominators in Web application hacks are dynamic (script-generated) Web pages and insufficient checking of Web server input and output. This combination results in susceptibility of web applications to SQL injection (for applications with SQL back-ends), cross-site scripting (XSS), and parameter manipulation.

A search through the Securia Web site reveals over 750 advisories, most of them recent, for applications that are vulnerable to SQL injection, more than 150 for XSS, and more than 50 for parameter manipulation, with some applications vulnerable to more than one class. Digging deeper reveals that the login pages of some high-profile sites are vulnerable to XSS.

In the following section, we will look in more detail into each of these classes of Web application vulnerabilities, how to test susceptibility to them, and how to effectively mitigate the resulting risk.

192.2 Cross-Site Scripting

Cross-site scripting is an attack technique that forces a Web site to echo attacker-supplied executable code that loads in a user's browser. The code itself is usually written in HTML/JavaScript, but may also be in VBScript, ActiveX, Java, Flash, or any other browser-supported technology.

There are two types of classical XSS attacks: nonpersistent and persistent. DOM-based XSS attacks are also seen.

192.2.1 Persistent Attacks

Typically, Web bulletin boards track users who are logged in through a session-ID cookie. In a persistent attack, the attacker posts an html message containing malicious code. Victims viewing the message could have their cookie stolen and their account compromised.

Alternately, the malicious code could be embedded in an e-mail message sent to the victim. When the unaware victim views the e-mail or clicks on the malicious link included in the e-mail, the code executes, performing actions preprogrammed by the hacker.

192.2.2 Nonpersistent Attacks

Many Web portals offer a personalized view of the Web site. The data referencing the logged-in user is stored within the query string of a URL and echoed to the screen. If an attacker were to modify the user name field in the URL, embedding cookie-stealing code, it is possible to gain control of the user's account.

192.2.3 DOM-Based Cross-Site Scripting

The prerequisite is for the vulnerable site to have an HTML page that uses data from the document.location or document.URL or document.referrer (or any of the various other objects that the attacker can influence) in an insecure manner.

192.3 Protection Methods: The Server-Side Theory According to CERT

Web developers must evaluate whether their sites will send untrusted data as part of an output stream. Untrusted input can come from, but is not limited to:

- URL parameters
- Form elements
- Cookies
- Databases queries

A combination of steps must be taken to mitigate this vulnerability. These steps include:

- Explicitly setting the character set encoding for each page generated by the Web server
- Identifying special characters

- Encoding dynamic output elements
- Filtering specific characters in dynamic elements
- Examining cookies

These steps may sound simple, but in practice the implementation of some of these steps can be fairly complex in proportion to the complexity of the legitimate content served by the Web application.

192.3.1 Explicitly Setting the Character Set Encoding

Web servers should set the character set, and then make sure that the data they insert is free from byte sequences that are special in the specified encoding. For example:

```
<HTML>
<HEAD>
<META http-equiv=“Content-Type”
content=“text/html; charset=ISO-8859-1”>
<TITLE>HTML SAMPLE</TITLE>
</HEAD>
<BODY>
<P>This is a sample HTML page</P>
</BODY>
</HTML>
```

192.3.2 Identifying the Special Characters

The next two steps, encoding and filtering, first require an understanding of “special characters.” The HTML specification determines the characters that are “special” because they have an effect on how the page is displayed. However, many Web browsers try to correct common errors in HTML. As a result, they sometimes treat characters as special when, according to the specification, they are not. In addition, the set of special characters depends on the context:

- In the content of a block-level element (in the middle of a paragraph of text):
  - “<” is special because it introduces a tag.
  - “&” is special because it introduces a character entity.
  - “>” is special because some browsers treat it as special, on the assumption that the author of the page really meant to put in an opening “<” but omitted it in error.
- Attribute values:
  - In attribute values enclosed with double quotes, the double quotes are special because they mark the end of the attribute value.
  - In attribute values enclosed with single quote, the single quotes are special because they mark the end of the attribute value.
  - Attribute values without any quotes make the white-space characters such as space and tab special.
  - “&” is special when used in conjunction with some attributes because it introduces a character entity.
- In URLs, for example, a search engine might provide a link within the results page that the user can click to re-run the search. This can be implemented by encoding the search query inside the URL. When this is done, it introduces additional special characters:
  - Space, tab, and new line are special because they mark the end of the URL.
  - “&” is special because it introduces a character entity or separates CGI parameters.
  - Non-ASCII characters (that is, everything above 128 in the ISO-8859-1 encoding) are not allowed in URLs, so they are all special here.

  - The “%” must be filtered from input anywhere parameters encoded with HTTP escape sequences are decoded by server-side code. The percent must be filtered if input such as “%68%65%6C%6C%6F” becomes “hello” when it appears on the Web page in question.
- Within the body of a <SCRIPT> </SCRIPT>:
  - Each of the semicolon, parenthesis, curly braces, and new line characters should be filtered in situations where text could be inserted directly into a preexisting script tag.
- Server-side scripts:
  - Server-side scripts that convert any exclamation points (!) in input to double-quote characters (“) on output might require additional filtering.
- Other possibilities
  - No current exploits rely on the ampersand. This character may be useful in future exploits. Conservative Web page authors should filter this character out if possible.

192.3.3 Encoding Dynamic Output Elements

Each character in the ISO-8859-1 specification can be encoded using its numeric entry value. A complete description of the ISO-8859-1 specification is beyond the scope of this document.

Encoding untrusted data has benefits over filtering untrusted data, including that it preserves visual appearance in the browser. This is important when special characters are considered acceptable.

Unfortunately, encoding all untrusted data can be resource intensive. Web developers must select a balance between encoding and data filtering.

192.3.4 Filtering Dynamic Content

A default deny filter is the best approach in filtering dynamic content: allow characters that are known to be safe and filter all else. Regular expressions enable fine-grained control over allowable dynamic content, and are supported to varying degrees in various programming languages.

For example, the following regex filters e-mail addresses, restricting them to known safe values: ame1.name2, name1_name2 or name1_name2 before the @ (name must be all characters or numbers), which is followed by domain.xxx or domain.xxx.yy with no more than one dash or underscore allowed in the string between the @ and the first dot in the FQDN. The only additional restriction is a limitation on the total number of characters to be accepted in the e-mail address field.

```
^[a-zA-Z0-9] + ([-_\.][a-zA-Z0-9] + ?@[a-zA-Z0-9]
+ ([-_\.][a-zA-Z0-9]+)?([\.][a-zA-Z0-9]+) + $
```

The filtering process can be done as part of the data input process, the data output process, or both. Filtering the data during the output process, just before it is rendered as part of the dynamic page, is recommended. Done correctly, this approach ensures that all dynamic content is filtered. Filtering on the input side is less effective because dynamic content can be entered into a Web site’s database(s) via methods other than HTTP. In that case, the Web server may never see the data as part of the input process. Unless the filtering is implemented in all places where dynamic data is entered, the data elements may still remain tainted.

192.3.5 Examine Cookies

One method to exploit this vulnerability involves inserting malicious content into a cookie. Web developers should carefully examine the cookies they accept and use the filtering techniques described above to verify that they are not storing malicious content.

192.4 Determining If You are Vulnerable

192.4.1 Web Applications

- Keep the application current with vendor patches and hotfixes.
- Subscribe to vendor and third-party security advisories.
- Anonymously subscribe to application-specific mailing lists.
- Download XSS exploit code from the Internet and test your application.
- Follow proven system development life cycle methodologies for applications developed in-house, and design from the ground up with security in mind.

192.4.2 Web Browsers

- All browsers are vulnerable to one form or another of XSS in their default configuration. Research will reveal details of individual browser/version vulnerabilities.

192.5 Protection Methods

Because successful execution of cross-site scripts requires a vulnerable web server and a vulnerable client, the defense-in-depth principle requires that both clients and Web site developers address XSS issues independently.

Defense-in-depth implies using a combination of preventive, detective, and corrective controls on the server and on the client to effectively mitigate XSS vulnerabilities.

192.5.1 Server Side

192.5.1.1 Microsoft Internet Information Server (IIS)/ASP

- Specify the codepage, and use URLEncode and HTMLEncode in active server pages.
- Filter input parameters for special characters using regular expressions.
- Filter untrusted output: any data previously passed by a user and not sanitized should be filtered.

192.5.1.2 Apache/Perl

- Filter input parameters for special characters using regular expressions.
- Encode HTML using HTML::Entities::encode() or Apache::Util::escape_html(); the latter is a faster-performing function.
- Use Apache Taint module to determine if output is tainted, and if tainted, escape it using the Apache::Util::escape_html() function.

192.5.1.3 Third-Party Add-Ons

- Use an HTML payload filter such as Third Brigade Deep Security Agent to sanitize and filter HTML content from/to the Web server. It is to be stressed that DSA is not a substitute for the above server-side steps, but a welcome addition in a multilayered server-side defense strategy.

192.5.2 Client Side

192.5.2.1 General

- Users should apply the least-privilege principle by not enabling unneeded browser functionality; they should also use an account with the least-operating-system privilege. We will look below at practical steps to implement in two popular browsers, Microsoft Internet Explorer (MSIE) and Mozilla Foundation Firefox.

192.5.2.2 Microsoft Internet Explorer 6.0 SP1

- Disabling active scripting is the safest approach, but by disabling active scripting, a significant number of sites will not display correctly, if at all. A more usable (and less secure) approach is to set the Internet zone security active scripting option to "Prompt". Using this setting, IE will prompt the user before executing scripts. The downside is that there will be many prompts when browsing script-rich web sites.

192.5.2.3 Mozilla Foundation Firefox

- Download and install the free script-filtering plug-in. Because a large number of Web sites rely on scripts to display any content, much like IE, a default "deny policy" secures the client, but at an unacceptable cost in lost functionality. The script-filtering plug-in selectively allows the user to change script settings on-the-fly, temporarily, or permanently remembering the new settings per domain or per FQDN.
- Enable DOM inspector (under Tools menu or by pressing Ctrl-Shift-I) and review the content of questionable pages.

192.5.2.4 MSIE and Firefox

- Safe browser settings require constant user interaction. Indiscriminately allowing scripts to run whenever prompted by IE, or whenever Firefox reports blocked scripts, defeats the purpose of the above measures. Allow scripts to run only when absolutely necessary.
- Set both browsers to prompt on redirection.

192.5.2.5 Outlook and Outlook Express

- Both e-mail client applications should run in the Restricted Zone, where default settings do not allow active scripting.
- Do not follow links included in e-mails before ensuring where they lead.

192.5.2.6 WebMail Services

We will cover two popular free Web mail services and outline the approach to use with each service to effectively mitigate the threat of XSS on the server side.

- Yahoo! Mail remains functional with scripting disabled. The server will recognize that scripting is disabled and present the old (script-free) user interface (UI). The UI is not as attractive as the script-driven one, but it does not allow scripts to run, effectively eliminating the threat.
- HotMail does not work if scripting is disabled, but gives the user the option to force plain-text display of messages, eliminating the possibility of executing code embedded in HTML messages.

- In other Web mail services, users should explore the available server-side options and opt for the safest method of access, using either of the above-mentioned approaches.
- For all Web mail services, users should make use of junk mail filtering if available. The engines are reasonably effective at catching junk mail. Unless the user is specifically targeted by a malicious e-mail, a mass mailing stands a good chance of being classified as such. As always, users should not view or open e-mails from unknown sources, or from known sources with strange subjects.

192.5.2.7 Instant Messengers

- Do not click on any link included in messages and do not accept file transfers. IM worms may present links to malicious pages that seem to come from IM buddies.

192.5.2.8 Other Services

- Users should be especially wary of unmoderated public bulletin boards that display posted messages in HTML format, and do not adequately sanitize user postings. It is difficult for a user to determine how safe the content is on the server side, so users should assume that content is not checked and act accordingly.

192.5.3 SQL Injection

SQL Injection occurs when an attacker manages to embed a series of SQL statements into a query by manipulating the data input into an application. Such attacks are made possible when the server application does not adequately check for and filter or sanitize user input from embedded SQL statements. Such statements—when submitted in input fields and not adequately checked—may lead to a compromise of the back-end database or server. Depending on the capabilities, motivation and determination of the attacker, such compromises may result in unauthorized access to information, unauthorized information disclosure (breaches of confidentiality), unauthorized modification (breaches of integrity), or worse, may lead to the attacker gaining administrative access to the server's operating system (breaches of A/I/C).

Unlike XSS attacks that require a vulnerable server and a vulnerable client, SQL injection and parameter manipulation are exclusively server-side vulnerabilities. Attackers typically submit a query to the application that would elicit SQL error messages, and use the server response from each query to further refine the next query.

For example, if normal user input in a web application results in the following URL: http://www.website.com/script.asp?docID = 10, the attacker would append to it a condition that is always true and submit it to the web server: http://www.website.com/script.asp?docID = 10 AND 1 = 1.

If the second user input returns the same output as the first one, then the attacker has confirmed that the front-end (in this example, a Web application) is vulnerable to SQL injection.

By then submitting successive "targeted" SQL injections, the attacker aims at gaining additional information with each new injection; for example:

http://www.website.com/script.asp?docID = 10 AND USER_NAME() = 'dbo' [in MSSQL user dbo is the database owner and has full privilege over the database]. If the application is connecting to the back-end database with "dbo" privilege, then docID 10 is returned, otherwise it should return an SQL error message.

Complex SQL queries can be injected into a vulnerable SQL database front end. The examples provided above only serve to illustrate the point, and are not meant as a reference. The intricacies of SQL injection into the different applications/databases are beyond the scope of this document.

Typically, when security is not adequately addressed, it is weak at multiple levels. It is not uncommon for a vulnerable application to run on a back-end database that has not been adequately secured, and is itself running on a server platform with lax security that is installed on a network that is too permeable. Couple the preceding with inadequate application/database/server/network monitoring, and it would not take long for a skilled attacker to “own” such a server before anyone in the victim organization realizes what has happened.

192.5.4 Parameter Manipulation

Parameter manipulation occurs when an attacker successfully manages to pass to the Web application user-specified parameters in URLs, form fields, cookies, hidden fields, or headers. By manipulating any of the preceding data to his advantage, an attacker could gain unauthorized access to confidential information, compromise the integrity of information, and negatively affect information availability.

192.5.4.1 Cookie Manipulation

Cookies are used to maintain state information in the stateless HTTP protocol. In addition, web developers use cookies to store user preferences and session tokens. Because cookies are stored on the hard disk of the client, they can be easily modified. The impact depends on what the cookie is used for. Cookies are usually Base64 encoded, and this protocol provides no cryptographic protection.

192.5.4.2 HTTP Header Manipulation

HTTP headers are control information passed between the client and the web server. The referer header sent by most browsers normally contains the URL of the Web page from which the request originated. The accept-language header tells an internationalized application the language preference of the client. Malicious manipulation of an accept-language header that is looked up in a database could result in successful SQL injection.

192.5.4.3 HTML Form Manipulation

A browser typically sends form field values to the application as an HTTP GET or POST. These could be hidden from view in the browser but are nevertheless sent along when the client submits the completed page. By locally modifying the HTML code of the page and reloading it, an attacker can easily bypass any client-side user input validation checks.

192.5.4.4 URL Manipulation

It is not uncommon for an application to allow an authenticated user to make selections from pre-filled drop-down boxes and initiate transactions when submitted to the application. The following HTTP request:
http://www.hacked.com/script.asp?userid=johndoe&amount=25 could easily be modified to:
http://www.hacked.com/script.asp?userid=victim&amount=2000
and submitted to a vulnerable application, which would process them accordingly.

The properties of hyperlinks in Web pages could be easily viewed and modified in the browser’s address bar.

Free tools such as Fiddler (https://www.fiddler.com/fiddler) permit HTTP traffic manipulation between the browser and the Web application.

192.5.5 Determining if Your Application is Vulnerable

Administrators of Web applications should test their applications’ weaknesses by using automated testing tools and manual methods. SPI Dynamics Web Inspect and Watchfire AppScan (among others) automate Web application security testing.

An application developer should conduct Internet searches and find application exploits or “how-tos” that are specific to his environment to supplement automated tools with manual tests.

Application developers should also be aware of any vulnerability in the tools they use to develop their applications that, if ignored, may result in applications with security flaws.

192.5.6 Protection Methods Against SQL Injection and Parameter Manipulation

Traditional network periphery security measures (firewalls, IDS, IPS, etc.) are really not geared towards protecting Web applications. For maximum effectiveness, protection measures need to be built into applications themselves.

192.5.6.1 Primary Protection Methods Against SQL Injection

- Follow proven system development life cycle methods for building applications, with security integrated into every step of the development process. Tools are available to continuously detect/correct security flaws throughout the system development lifecycle.
- Filter or sanitize all input so only known safe content is accepted by the application. This approach requires determination of what constitutes safe content and development, implementation and testing of appropriate content filters (regular expressions).

192.5.6.2 Primary Protection Methods Against Parameter Manipulation

192.5.6.2.1 Cookie Manipulation

- Do not trust user input for known parameters. Instead, use a session token to reference properties stored in a server-side cache.
- Before accepting cookies, verify cookie content for correctness.
- Encrypt cookies or generate an MD5 hash and verify that the hash matches. This may not be effective if the web server is compromised.

192.5.6.2.2 Header Manipulation

- Do not rely on header content for any security decisions.

192.5.6.2.3 Hidden Form Fields

- Avoid putting parameters in a query string or hidden form fields.
- If parameters must be passed, use session tokens in a secure manner.
- Parameters should never be accepted unless the application can independently validate that they were bound for and are authorized to be acted upon.
- If a parameter cannot be removed from the form fields, it (or better, the entire query string) should be encrypted to prevent unauthorized disclosure or modification. Alternately, it is possible to append an additional parameter consisting of an MD5 hash of the entire query string. The second method ensures query string integrity, but not its confidentiality.

192.5.6.3 Supplemental Protection Methods

- webSecurity webApp.secure PE. If it performs as advertised, webApp.secure PE provides comprehensive Web content protection + SSL encryption/decryption between clients and the Web application server (which receives clear text, irrespective of whether the client connection is encrypted or not).
- Third Brigade Deep Security Agent. This application provides comprehensive http content filtering, firewall, and host-based network IPS (with generic and exploit-specific rules).

193

Enabling Safer Deployment of Internet Mobile Code Technologies

Ron Moritz

Highly functional applications—isn't this the Holy Grail that information systems managers have been searching for since the 1960s? Historically, we could go back more than a decade to the client-server platform whose technologies included third- and fourth-generation development tools and, later, Visual Basic and C++, and whose infrastructure included relational database servers in a distributed UNIX environment communicating over TCP/IP. More recent history is built around the Web platform where we find development technologies that include HTML and multimedia authoring tools, Java for developing program objects, and a variety of scripting languages used to glue various systems together.

New network computing initiatives require technologies that push both data and code between remote servers and local clients. Since mid-1996, mobile code technology, also referred to as active or downloadable content, has received considerable attention. Mobile code changes the model of client-server computing. Mobile code allows us to deliver both data and program code to the desktop without user intervention. By removing user participation in the download, installation, and execution of software, mobile code helps advance the reality of network computing. Mobile code is contributing to the maturing infrastructure of Web servers and browsers and is being assimilated with existing technologies and information system investments, often referred to as legacy applications and systems. The next generation of client-server services is emerging using the Web architecture to develop and deploy application servers.

Application servers have enhanced the performance and scalability of Web-based applications. Connecting such servers to the Internet, an open network connected to hundreds and thousands of other networks, results in new threats. Despite the growing threats, most organizations have done little to protect themselves against mobile code moving between Web servers and browsers. Security has taken a back seat. Corporate security policies that block mobile code adversely affect the evolution of the Internet, intranet, and extranet. The benefits of distributed subprograms and routines are lost if Java applets, ActiveX controls, scripts, and other mobile code are diverted or prevented from reaching the browser. While no security implementation is absolute, functionality is not achieved by disconnecting users from the network and preventing access to programs. In this chapter we will:

- Explore the problems associated with and alternatives available for allowing untrusted code to execute on the corporate network.
- Examine both the current and historical security issues associated with mobile code.
- Outline the risks of executable content within the context of new client-server computing.
- Describe Java security and author and capability signing models.
- Provide guidance for using mobile code on the corporate network.
- Provide a roadmap for mobile code deployment.
- Review mobile code security solutions available today.

193.1 Highly Mobile Code

Imagine no longer having to jump into the car and drive to the local computer superstore to buy software. Imagine not having to wait for your favorite mail-order house to ship software to your home or office. Imagine not having space-consuming software boxes lining your shelves. Imagine not having to spend hours installing software. Imagine loading software only when you need it.

Mobile code technologies allow Web users to automatically download and run platform-independent code from all over the world on their own machines without technical skills. This “breakthrough” is actually not a new theory; several languages have been introduced with this same goal. What is important today is that we recognize that the underlying computer communications infrastructure has provided the vehicle for a legitimate paradigm shift in computing: real programs that make the Web dynamic by delivering animation, computation, user interaction, and other functions to the desktop.

The emergence of mobile code as a Web-based client-server tool has been made possible by the:

- Positioning of Sun Microsystem’s Java™ as a platform-independent language and standard
- Acceptance of Microsoft’s Internet Explorer™ browser supporting ActiveX™ controls
- Ability to plug-in or add services to Netscape Communication’s Communicator™ browser

The desire to create applications that install without the user’s participation in the download, setup, and execution processes is logically equivalent to the concept of just-in-time inventory management systems deployed in the manufacturing sector. This is the premise on which the next generation of computing has been planned: locally run programs, dynamically loaded over the network, taking advantage of distributed computing horsepower, allowing “fresh” software to be distributed “as needed.”

Java and ActiveX are being used today to create new business applications. Scripting languages, such as JavaScript™ and Visual Basic Script™, are used to create interfaces between new Web services and older, back-end data servers. In large enterprises you will find even the most lightweight application developer deploying programs on department servers. Such code follows no formal software development methodology, seldom undergoes a third-party quality assurance process, and frequently lacks the support services normally available with applications developed by the information services group. The desire for just-in-time software along with the infrastructure that facilities the transport and delivery of the code has resulted in a large and growing base of uncontrolled software.

193.2 Java

"The Java programming language and platform is a tsunami that will sweep through the economy. In the face of this tide of change, Microsoft and Apple are both forces from the past."[1] Ironically, this statement was issued on the same day that Microsoft infused Apple with $150 million. Nevertheless, it is important to understand the impact Java has had on the Internet and specifically with respect to next-generation, client-server computing. A 1997 research study of 279 corporations that had deployed or were planning to deploy Java lent support to the Java story.[2] The report claimed that a major shift had taken place in the way corporations viewed the Internet, intranet, and extranet: 52 percent of the companies surveyed were already using Java applications, the balance were in the testing or planning phase. The report predicted that 92 percent of the corporations surveyed would be using Java as an enterprise-wide solution for mission-critical applications by 1999.

Mobile code technology is a critical part of any online business model. For information publishers mobile code provides ways to customize information delivery and consumer interactivity. For users, it translates into more productive use of the network. In organizations surveyed, Java is being used for serious computing applications such as information sharing, resource scheduling, and project and workgroup management. Simultaneously, there are emerging dangers associated with the deployment of Java. These threats, while not yet materialized, could potentially threaten system integrity at least as extensively as viruses do today. Fundamental shifts in the uses of the Java programming language may weaken the overall security of Java. A new wave of more powerful Java attacks are expected to appear in coming years. Java attacks consist of Java code which contains malicious instructions, embedded in Web pages and e-mail with HTML attachments. In the past, these Java attacks have had rather minor effects, such as freezing the browser or consuming desktop resources, and at worst required a reboot of the workstation. The current threat has escalated dramatically. New Java applications could open the computer to attacks on the hardware itself. Such attacks could affect data on the hard drive, interfere with CPU operations, or corrupt other hardware-based services.

193.2.1 Java Technology

Unlike other languages, the Java compiler does not translate from the program language written by programmers directly to machine code. This may be obvious in that machine code is processed (hence, machine dependent), while Java is marketed as machine independent. Java code is compiled into "bytecodes" (called applets) that are interpreted by the Java run-time system on the target computer. This run-time system is called the Java Virtual Machine (JVM), and an operating system-dependent version of this interpreter is required.

193.2.2 How Applets Execute Locally Without User Participation

HyperText Markup Language (HTML) pages can contain pointers or references to graphic images, tables, Java applets, and other "objects." Like the image, the applet bytecode is contained in another file on the Web server. When the Java-enabled browser encounters an applet "tag," it sends a request to the remote server to fetch the file containing the applet bytecode; the file is passed to the browser's JVM where it begins to execute. The JVM is multithreaded, which means that several applets can run simultaneously. Browser vendors Java-enable their applications by integrating the JVM into the browser. The specification for the JVM is available from JavaSoft, the Sun Microsystems subsidiary. Vendors are free to determine the level of security in their implementations.

[1] Gilder, G. 1997. *The Wall Street Journal*, p. A12. August 8.

[2] Zona Research Industry Report. 1997 (July). *The Java Enterprise.*

193.3 Scripting Languages

"Scripting languages get to the point of a problem more concisely than do C++ or Java [object-oriented programming languages]. Programmers can create [some] solutions quickly and succinctly [using scripting languages]."[3] A script is a much higher language that allows the programmer or, as in most cases, a nonprogrammer to focus on the business problem and not the language. The downside is that the computer is forced to do more work during execution of the script and, consequently, system performance limitations are reached more quickly.

Scripts are best applied when applications must be set up and deployed quickly, require frequent changes, or are used to glue together existing components such as Web access to legacy systems and services. Scripts are not used for performance-intensive applications. Scripts tend to be safer than object-oriented programming languages because most scripting languages, having recognized that programmers who understand how to allocate and use memory correctly are rare, minimize errors by automating memory management and related functions. Of course, Java is supposed to do that but we know better.

JavaScript is a light programming language created by Netscape Communications that is used to develop code that is embedded in HTML documents and executed in the browser. Text between the JavaScript tags in the HTML file is passed to the JavaScript interpreter; browsers that do not support JavaScript simply ignore the JavaScript tags and code. JavaScript does not run in the Java Virtual Machine and is, therefore, not sandboxed by the same security models developed for securing Java applets.[4]

JavaScript is used in a variety of applications. Most commonly it can be found opening windows for user input in order to verify that input parameters, such as date fields, are correct or fall within a prescribed range. Prior to the introduction of mobile code, this level of data validation of form input was performed through CGI scripts on the host Web server or on programs developed for back-office servers. JavaScript enables programs to take advantage of the local processor and computing services to perform such checks.

JavaScript also introduces security problems. Most JavaScript security violations require only minor user interaction, such as a mouse click, to activate the malicious code. By simply creating a pop-up window that asks the user to click "OK" to continue, JavaScript attack code can be executed. Based on the risks associated with known JavaScript security violations, many have advocated turning JavaScript off.

Today, blocking JavaScript is less common. One reason is that corporate users find it necessary to run JavaScript to enable required services. Consider an application that enables browsers to be used as clients of legacy systems through custom Web pages that link to various host applications. To improve services to users the application relies on JavaScript to automate tasks such as log-in sequences and menu navigation. In the travel industry, several sites have emerged that deliver services only when JavaScript is enabled. There is little doubt that blocking JavaScript or other scripting languages will not be an option for long.

193.4 Plug-In Services

Today's browser technology supports the ability to automatically download and install plug-in applications that support user interaction with multimedia data. Although independent software vendors are traditionally responsible sources of such plug-in products, it is possible for well-known plug-ins to be maliciously modified. Because the browser gives users a window to collect plug-in applications, the result is an environment in which uncontrolled software is freely distributed and used, often in contradiction with an established computer security policy.

[3] Laird, C. and K. Soraiz. 1998. Get a grip on scripts. *Byte* June: 88–96.

[4] See section titled "The Java Sandbox" for a discussion of the Java security model.

193.5 ActiveX

An example of ActiveX is the embedding of a Microsoft Excel spreadsheet (object) into a Microsoft Word document. The object contains information that tells the document how the object should behave, what operations it can perform, how it looks, and so forth. The document is the Object Linking & Embedding (oh-lay) container and the spreadsheet is the OLE control. OLE is the interface through which they communicate.

In the Web world, a browser that supports ActiveX acts as an ActiveX container by allowing ActiveX controls to run inside of it. When you open an HTML page, the browser runs out and downloads the graphics then displays them. With an ActiveX browser, the browser can also download ActiveX objects (including viruses) and run them in the same way that Word runs the Excel spreadsheet. ActiveX is the interface through which the browser communicates with the downloaded program or control. That is, an ActiveX control is a program that implements an ActiveX interface.

ActiveX controls are native programs and have the capabilities of native programs including access to the hard disk, system memory, and other local system and network resources. They differ from Java applets in three significant ways: they are much less secure, they are not cross-platform in that they require the Windows 32-bit operating system, and they are very large. ActiveX controls were birthed from the OLE technology and OLE was never intended to be used across bandwidth-constrained networks. The OLE object or ActiveX control must contain a lot of extra information to let the container, either the Word document or Web browser, know how it works. In contrast, Java applets were designed from the start to be used across wide-area, limited-bandwidth networks.

There is nothing native to the ActiveX environment that protects the user. An ActiveX control can perform any action on the desktop, making it the perfect vehicle for the delivery of a Trojan horse. For example, an ActiveX game could, on the side, scan your hard drive for documents and send them to an attacker's Web server using a series of encrypted HTTP commands. It is so dangerous that *Wired Magazine* wrote:

> Microsoft's ActiveX technology is the single greatest technological threat to the future of the World Wide Web. Microsoft's ActiveX promoters are either so blinded by their own rhetoric that they don't see the danger of this new technology, or else they are so cynical that they would destroy the very essence of the Internet rather than compromise their market dominance.[5]

193.6 Buggy Code

Programs, by their nature, are inherently buggy and untrustworthy. Mobile code technology enables these buggy and untrustworthy programs to move to and execute on user workstations. The Web acts to increase the mobility of code without differentiating among program quality, integrity, or reliability. Consider multimedia documents such as Web pages. Such files, regularly created and distributed by nontechnical employees, are containers for textual content, graphic images, sound files, and programs. Using available tools, it is quite simple to "drag and drop" code into documents which are subsequently placed on Web servers and made available to employees throughout the organization or individuals across the Internet. If this code is maliciously designed, poorly programmed, or improperly tested, it can cause great distress. Although the effect of running such code cannot be anticipated, its delivery and execution are the default. In the new world of network computing, employees have a greater opportunity to create and deploy serious threats with fewer skills. How can managers be sure that programs delivered

[5] Garfinkel, S. 1996. Will ActiveX threaten national security? *Wired News* (http://www.wired.com/news/story/451.html?/news/96/47/4/top_stories4a.html).

over the network through interaction with remote application servers are bug-free, crash-free, virus-free code? Are we certain that the code is noninvasive? Can we guarantee the proper operation of code?

193.7 Mobile Code and Security

We frequently hear that the only way to ensure 100 percent security for an organization's computer assets is to "disconnect them from the Net, turn them off, and lock them away in a safe." While worthy of an academic thesis, business realities do not afford managers such luxuries. The ability to gain control over mobile code that reaches into and executes on the workstation connected to the corporate network is a business requirement. Security is evolutionary. Four security concepts that can be applied to mobile code today can be summarized as follows:

- Java is reasonably secure and is becoming more so all the time.
- The Java language provides features that assist in the development of secure applications.
- The Java Virtual Machine deploys a "sandbox" concept designed to control access to local resources and to reduce the probability of introducing programs with undesirable effects.
- Security extensions, such as Java Archive (JAR) signing and Microsoft's Authenticode™, provide for encryption keys and digital certificates used by software publishers to sign code.

Sun Microsystems, Java's creator, knew that it would be essential that Java provide both software developers and users a secure development and run-time environment. To a large extent, they were successful: Java has made and continues to make a significant impact on the world of computing. But is it riskless? Clearly, the answer is no. The idea that untrusted executable content in the form of data is distributed across the network and is automatically executed on a local host wherever it goes gives rise to serious security concerns.

Additional strategies, optimized for mobile code security, are required to realize the full potential of the new client-server code exchange. These are accomplished through a powerful, cooperative set of technologies. A security infrastructure optimized for the mobile code is one that provides both client and server facilities that do not exist in the Web browsing environment. For example, a signing system to address the issue of how software publishers provide downstream assurance *vis-à-vis* their mobile code enables an entire class of applications that are not practical on the Web today due to the untrusted nature of software.

Basic differences between the Java and ActiveX approach to security include:

1. Java provides users with a security manager. The security manager acts according to his design to enforce preprogrammed security policies. Error recovery enables high-risk functions to be stopped while allowing the code to continue running.
2. Microsoft's Authenticode is simply a technology designed to identify the publisher of the code. One of the true values of code signing is its ability to assure end users that the code has not been tampered with or altered before or during the download process.
3. When Java applets are found to create insecurities, it is usually a bug in the specification of the JVM or its implementation. Because Java applets (by language specification) are designed to be safe, an insecure applet is exploiting a previously undiscovered weakness in the security scheme Java uses.
4. ActiveX controls do not contain security bugs because ActiveX technology was not designed with security in mind. ActiveX controls have total and complete control of your system.

Let's examine the two security models in more detail.

193.7.1 Digital Certificates

Authenticode is Microsoft's code signing strategy in conjunction with digital certificate vendor VeriSign. Signed code contains the author's digitally encrypted signature so recipients of the code can, based upon the publisher, determine whether the program is permitted to go outside the secure partition where it would normally run. Applets whose authors are trusted are granted full access to network and file resources.

From the attacker's perspective, Microsoft's Authenticode or code signing strategy is equivalent to asking mail bombers to include a return address on bombs sent through postal mail. As a recipient of a package, aware of the threat from letter bombs, am I more concerned with knowing whom a letter is from or what is inside. Clearly, given the choice, knowing what the contents are is more critical to security than knowing who sent the letter. Besides, how often do you reject packages simply because they have no return receipt? So it is with code coming from the network, regardless of whether that network is internal or external, regardless of the source, trusted or untrusted.

Even within the enterprise we are at risk. Between 60 and 80 percent of attacks, hacks, and computer crime come from within the corporation. What makes us so confident that we can trust our own software and application developers? Do applets and controls pass through a quality assurance process that gives us confidence that the code is free of bugs or malicious behavior?

Users are already weary of the "possible threat" warning box every time they download a non-HTML object. These warnings are simply not understood, ignored, or disabled. Given that it is straightforward to write an ActiveX control that scans the hard drive, sends all your files to a remote server, writes a virus to your boot sector, shouts obscenities at you, and formats your hard drive, it is reasonable for managers to be alarmed. It should be clear that a certificate attached to the code will not, in and of itself, keep you out of harm's way. By digitally signing the code using a stolen digital signature, or one registered under a false name, the unsuspecting accidental tourist to whom the control was pushed is lulled into a false sense of security: "It's signed; therefore it is safe." Besides, whom would you prosecute when it is found that the digital certificate owner does not exist, or lives in a country that is not concerned with computer crime, or with whom your country does not maintain criminal reciprocity?

We conclude that Authenticode, based on who and not what, does not deliver authorization and does not provide control over the execution of the signed mobile code. More important, code signing, whether applied to applets or controls, does not ensure bug-free, virus-free, noninvasive, or safe code. On the other hand, code signing does provide assurance that the code was not altered when moving from point A to point B; if it was malicious at A, it will be malicious at B.

193.8 The Java Sandbox

JavaSoft's security theory, often referred to as the "sandbox model," is based upon a protected area in the computer memory where Java applications are allowed to "play" without risking damage to the system that hosts them. This security model, built into the Java Virtual Machine or applet run-time environment, was designed to restrict or control malicious applet behavior. There are a number of documented examples that show that the model, in its current form, is susceptible to attack. For example, applets with hostile intent could access system files or extract data without the user's knowledge or interaction.

Some of the Java security we hear about is inherent in the Java language itself. For example, Java attempts to provide only one way to program a particular task. But the real security advantages can be found in the Java run-time environment. The Java run-time performs several safety checks before a downloaded applet can execute. The model is based on three components that work together like legs of a three-legged chair to create a fence around each applet. The model works as follows.[6]

- Byte code downloaded from a Web page undergoes format and static-type checking courtesy of the *byte code verifier*. The verifier is the system component that inspects untrusted, foreign, and potentially malicious code performing dataflow analysis to determine if the code adheres to the virtual machine's safety constraints. The verifier checks code for typesafety, the key security

[6] McGraw, G. and Felten, E. eds. 1996. *Java Security: Hostile Applets, Holes and Antidotes*. John Wiley & Sons, New York.

property on which Java depends.[7] Any failure of the verifier to reject code that does not conform to the Java bytecode specification is a flaw as it can result in a circumvention of typesafety and can lead to security violations.

- The *class loader* instantiates the applet and the classes referenced in namespace. It also determines when and how an applet can add classes to a running Java environment. For example, the class loader prevents applets from installing code that could replace components of the Java run-time.
- When an applet executes in the Java Virtual Machine there may be many active class loaders or applets, each with its own namespace. If the applet attempts a dangerous method or function, the *security manager* is consulted before the method runs. It is the security manager that implements browser-level security policies, as specified by the browser software vendor, by performing runtime checks on certain methods.

The Java security manager implemented in today's popular Web browsers provides only an initial layer of protection and is available only at the Java Virtual Machine level. The "sandbox" idea is problematic if you want to do something useful with applets. Another issue is that all applets that run on the browser get the same privileges, no matter where they come from. This doesn't make sense for real applications.

In an effort to make new applications based on Java more powerful, browser developers enabled code that arrived with a publisher signature or digital certificate to operate beyond the confines of the sandbox. Such efforts to enhance Java by getting the code "out of the sandbox" and deeper into the local system weaken the security model built into the Java run-time. Newer initiatives, including JavaSoft's Java Development Kit (JDK) 1.2, provide access beyond the sandbox based on capabilities requested by developers. For example, a developer with a need to write data to a temporary directory may announce his intention and allow the user to decide whether this request is legitimate. Problems with such initiatives are grounded by the inherent lack of confidence we have in our end users. Leaving an access or capability request decision to the user is functionally equivalent to eliminating all security controls. We cannot expect the user to answer "no" when presented with a grant request by an enticing site.

193.9 Security Solutions for Mobile Code

Remember Computer Security 101? The most important penetrations of computer systems have not exploited bugs; rather, they used some feature that had been carefully designed into the system in a way that the designer did not anticipate. Dr. Bill Wulf, a leading security researcher from the University of Virginia, suggests that the Java sandbox model suffers from the same problems as the Maginot Line, a strong line of defense that prevented the Germans from invading France directly.[8] The Maginot Line had engendered a false sense of security in France, and Wulf claims that however strong a sandbox model may be to a frontal attack "once it is breached the battle is lost completely and irrevocably."[9] As the Germans demonstrated, the way to defeat the Java sandbox is to use an attack other than the ones anticipated. Wulf concludes that as long as a sandbox or single line of defense is the dominant model of computer security, there will be no security against a determined attacker.

Current solutions include disabling mobile code at the browser or at a gateway server. But disabling Java at the browser is like giving your teenager the car without any wheels. Distributing preconfigured Java-disabled browsers does not prevent users from downloading functionally equivalent software without such restrictions. Even blocking mobile code at the firewall does not prevent users from pulling applets on board through other protocols such as FTP or SMTP (e-mail).

[7] A language is type safe if the only operations that can be performed on the data in the language are those sanctioned by the type of the data; see *Java Is Not Type-Safe* by Vijay Saraswat, AT&T Research, 1997 (http://www.research.att.com/~vj/bug.html).

[8] Germany ultimately succeeded in invading France through the back door—Belgium. For more information, refer to http://www.grolier.com/docs/wwii/wwii_4.html.

[9] JavaSoft Forum 1.1, http://java.sun.com/forum/securityForum.html.

The original code signing solution was binary. The code was either blocked or allowed through and granted full system access. An alternative to signing is to grant specific permissions to each Java program. For example, applet "alpha" may request and be granted permission to read from the TEMP directory and access the FTP service in order to send a specific file to a remote server. Applet "beta" may request the same access and be granted only the read operation.

This approach, called capability signing, was introduced by Sun's JavaSoft but implemented uniquely by Microsoft and Netscape. It is still not well defined nor effectively implemented by any vendor. Specifically, asking each Java application to ask for the specific privileges it needs when it starts up or during execution would require a rewriting of the Java security manager to examine each request and decide whether to grant or deny it based on the user's security policy.

An alternative is to consider solutions that deploy heuristics. Heuristics is a method of analyzing outcome through comparison to previously recognized patterns. Using heuristics, it is possible to inspect and profile applets and controls to determine the program's intentions. After all, we are more interested in what a program will do than who wrote it. This approach, sometimes referred to as content inspection, offers a way to add another layer of security around the sandbox.

193.10 Mobile Code Security Architecture Overview

There are several approaches to the design of mobile code security solutions. As with any security strategy, maximum protection and risk reduction is achieved through a layered solution approach. The philosophy is rather straightforward: use different technologies deployed at several levels in order to push the risk away from the resources being protected.

The first, and simplest, approach is a client-only solution where the security is built into the client Web browser. This approach can be classified as "internal protection" as the technology that enables mobile code to be pulled from the Web and executed automatically on the client machine is also charged with protecting the desktop. Examples of this type of solution include the security manager or sandbox built into the Java Virtual Machine and the identification of the code publisher as the criteria for allowing code to execute.

The second approach is also client-based, but involves installation of a security service outside the Web browser. In this solution both the Web browser and the operating system on which the browser application operates are protected. The approach at this level is analogous to creating a demilitarized zone (DMZ) between the Web browser and the operating system; the mobile code is executed inside or through this DMZ. In this way, operations requested by mobile code delivered by the Web browser can be monitored, in real time, and risk level evaluated. Moreover, the user is able to set access control policy to suit his security needs. Operations that fall outside acceptable tolerance levels can be automatically rejected. There is no theoretical limit to the number of different policies that can be configured. However, like all reasonable security solutions, implementation of a DMZ requires isolation of a finite set of policies that can be clearly and rapidly understood by the desktop user.

The third approach is the next generation of the second approach. This solution still places the security service—real-time monitoring—at the desktop where applets can be watched as they execute and shut down before doing damage. But, it moves policy management, logging services, and a data repository to a central location for administration, control, and enterprise-wide information sharing.

The fourth approach is server based: Dedicated content inspection servers check incoming code. In this approach a gateway machine is used to intercept mobile code moving from a Web server (host) to a Web browser (client). Risk level and delivery decisions are assessed through the static evaluation of that code. The resultant applet security profile is used as a basis for policy application to control and manage which applets are allowed into the corporate network.

The fifth approach is a derivative of the third and fourth approaches. This solution combines the effectiveness of real-time monitoring (dynamic code testing) with security policy management services (static code testing) available through a gateway server. Moreover, because client traffic must pass through the gateway server, policies can be established that require clients to have the desktop mobile code security software installed and operational prior to being allowed access to a Web server or mobile code host.

The sixth approach is the identification of mobile code features and characteristics even before the code is placed and made public on a Web server. This solution requires the attachment of a nonmodifiable digital profile to the code. The profile can later be read and evaluated by downstream gateways, servers, and clients. Go and no-go decisions can be issued on the fly, with a high confidence level and little or no performance overhead.

193.11 Conclusion

Java is an interesting programming language that has been designed to support the safe execution of applets on Web pages, but execution of remotely loaded code is a new phenomenon and "Java and ActiveX pose serious security risks" to firms that are doing little to protect themselves from malicious code.[10] Using advanced Java programming techniques, computer security research teams have developed stronger, more damaging Java code that could be easily modified for use in a major Java attack. Applets that allow the security of the Java Virtual Machine or run-time environment to be compromised have been created to demonstrate service denial, show the ease with which passwords can be stolen and cracked, and simulate theft of corporate data. Reports of attacks resulting in stolen digital certificates have been verified—all of them able to take advantage of reduced security services available when Java runs "outside the sandbox." It is only a matter of time until more serious Java attacks are widely reported.[11] Although vendors have done a good job responding to the findings and research, it is believed that additional flaws will continue to be found. A new Java vulnerability was announced even as this chapter was being finalized.[12]

What is known is that when the theoretical possibility of threats are discussed among academicians, theory usually turns into practice as irresponsible members of the technical community try their hand at the new game. As Java moves into its new phase, threats from downloaded Web pages will continue to pose a serious threat. Given the explosive growth of the Internet, such threats could become far more dangerous than any posed by viruses.

Attacks using Java code may become more severe as incoming Java code is allowed to interact more with computer hardware. Because of the limited nature of Java attacks in the past—crashing a user's browser, playing unwanted sound files on the user's computer, and so forth—Java security has been largely dismissed as a minor issue by the technical community. Today's defenses of blocking Java and ActiveX at the firewall are analogous to holding a finger in the breach of the dam: the floodgates are opening as corporations begin to rely on services provided by mobile code. With major applications written in Java being deployed, Java security should return to the focus of Internet security practitioners.

We are entering a window of opportunity for malicious Java code writers. New, advanced Java code is now being developed in laboratories. This means that it could emerge in malicious form unexpectedly. With viruses, little if anything was done to preempt an attack and action was seldom taken until an infection was noticed. Inaction against the dangers posed by applets is not an option. Fortunately, despite their surreptitious movement onto the user desktop, there are solutions to the mobile code threat. Several computer software companies have developed Java security solutions that work to capture and eliminate

[10] Julian, T. et al. 1998. Securing Java and ActiveX. *Forrester Res.* 12(7) (http://www.forrester.com/cgibin/cgi.pl?displayOP&URL=/network/1998/reports/jun98nsr.htm#focus).

[11] Some analyst reports suggest that these applets will be in widespread use within two years.

[12] Another Java security flaw was announced on July 15, 1998. The vulnerability allows a malicious applet to disable all security controls in Netscape Navigator 4.0x browser. After disabling the security controls, the applet can do whatever it likes on the victim's machine, including arbitrarily reading, modifying, or deleting files. A demonstration applet that deletes a file was developed by the Princeton University Security Internet Programming Team (http://www.cs.princeton.edu/sip/History.html).

bad Java applets before they can affect a computer. Expect other solutions to emerge. It is important to be on the lookout for Java security solutions as they mature and to plan to use these defensive systems as faithfully as antivirus and firewall software.

Glossary

Administrator The person charged with defining and implementing the enterprise security policy.

Applet In this chapter, it is used as a generic name for a mobile code unit. May refer to Java applets, ActiveX controls, JavaScript scripts, VisualBasic scripts, plug-in modules, and so forth. Applets may also be referred to as *downloadables* or *executable* content.

Mobile code Any code that is implicitly delivered and automatically executed on a desktop host during network access. Users may not be aware of mobile code activity. Mobile code is typically driven by HTML (Web) documents. It may be delivered by various tools and protocols.

"Sandbox" policy The default security policy that is assigned by the Java security manager to applets. The sandbox denies any access to the file system, allows network access only to the local host computer and to the applet's server, and allows very limited access to properties of the local host and of the local JVM.

Security policy The operations that are allowed to be performed on the resources of desktop computers.

User An individual browser client user. A user is typically identified by his user name, domain or group name, and the IP address of his computer.

Security Considerations in Distributed Computing: A Grid Security Overview

Sasan Hamidi

Regardless of how inexpensive hardware becomes, building a high-powered cluster computing environment is out of the reach of many organizations and individuals. Analyzing large chunks of data may require more CPU cycles and memory than an organization has in its arsenal. Enter grid computing: for a reasonable fee, and depending on the type and quantity of resources needed, a company can "rent" grid time from IBM and Sun Micro Systems. It is a beautiful concept: the power of a Big Blue for the price of a middle-tier server. The concept of grid computing has evolved in the past 30 years. In this short time, the idea of utilizing unused processing cycles across a network for purposes other than what they were originally intended for has gone from a beautiful thought to reality. This paper discusses the evolution of grid computing, emphasizing security issues and standards that have risen as the direct result of its popularity. It reviews major developments in standardizing grid access and authentication, their strength and weaknesses, current vulnerabilities, and paths to the future.

194.1 Introduction

The idea of distributed computing has existed for a long time—since the days when man realized the limitations of processing cycles and memory. Even Gordon Moore's bold prediction 40 years ago has not reduced the need for more power and speed. In essence, distributed computing grew from the need to know more information faster. Its central idea is to use "parallel" processing instead of a first-in, first-out, single-processor scheme. From there, the concept grew from the "parallel" mode to the use of various computers across a network to accomplish a task. Grid computing is a form of distributed computing where computers across a vast network, and perhaps geographically dispersed, work together to form a "super computer." It was originally intended for the academic and research world, where obtaining fast computers was not economically feasible. Many universities started developing their own grids to support some very advanced research. Later on, as the concept began to take hold and many earlier issues were resolved, commercial uses of this environment became a reality. An example of an early grid is the Internet: a series of computers working together to allow millions of people to communicate and disseminate information through its many resources.

194.2 A Brief History of Search for Extraterrestrial Intelligence (SETI)

Any discussion of grid computing without mention of the SETI project would be incomplete. SETI stands for Search for Extraterrestrial Intelligence. What are the possibilities that in amongst the billions of stars within our galaxy and billions of other galaxies there are life forms? What if these living entities have been searching for us as well? It seems that the most reasonable method of inter-galactic communication would be through some type of signal that can travel well beyond its source; signals such as microwave radio and optical waves could accomplish such a task.

In the early 1960s, astronomer Frank Drake conducted the very first search for microwave radio signals from our solar system by pointing an 85-foot antenna in the direction of two sun-like stars for a period of two months. Although Drake did not detect any signals of extraterrestrial origin, his research sparked the interest of many in the astronomical community, specifically Russian scientists. The Russians expanded Drake's search by utilizing multidirectional antennas. This search method allowed them to listen to a wider range of signals, and not just from nearby solar systems. The problem, however, was the enormous number of signals that they had to process. The resulting signal processing issues proved to be more than just merely backlogging work; chunks of data were being discarded to save time.

Interest in SETI gained momentum once again in the early 1970s; NASA's Ames Research Center in Mountain View, California began reviewing all the issues that were stumbling blocks to an effective search. A group of scientists put together a comprehensive report detailing existing issues and technologies, code-named *Cyclops*, which forms the foundation on which much of the future work by the SETI project would be based. One of the most important issues highlighted in Cyclops was the need for "super computers" capable of processing billions of instructions per second, and parallel computing. Although much progress was made in advancing technologies required for this tremendous project, NASA lost its funding in 1992, and as of the publication of this paper, has not received funding to continue this research. Project Phoenix, spun from NASA's SETI project, fueled by private funding, promises to utilize the world's largest antennas and resources to answer perhaps one of the most profound questions ever raised.

May 17, 1999, marked the launch of the University of California at Berkley SETI@Home project, the very first open-grid computing system. SETI@Home takes advantage of millions of computers spread around the globe by allowing users to download a small program that acts similar to a screen saver. The concept is fairly simple: the program launches when the computer is idle and begins the task of searching signals collected from various sources. Once the analysis is complete, a connection to the Internet is established, the result of analysis is submitted and a new chunk of raw data is downloaded. The computing power harnessed by utilizing the cycles of individual PCs participating in the SETI@Home project comprises the biggest supercomputer in the world. This is a bold statement considering that the majority of this grid consists of home-based PCs with average CPU speed and memory.

194.3 Introduction to Grid Architecture

How are grids built? Is there an underlying architecture upon which they are designed? Are there any standards? These are questions that must be answered before any security discussion can take place.

There are three basic types of grids:

- *Cluster grids*: a group of computers clustered together in a network form a cluster grid. Normally, cluster grids are used by individual departments and designed for specific projects. For example, the Sun N1Grid consists of thousands of machines running Linux and Sun OS operating systems that are clustered together.
- *Enterprise grids*: a collection of cluster grids forms an enterprise grid. In many cases, as the need for more processing power arises, additional clusters can be added to an existing grid cluster. These additional resources allow multiple departments to share the computing cycles necessary to accomplish their projects.
- *Global grids*: when multiple enterprise grids are connected, they form a global grid. In this scheme, multiple organizations are sharing the resources of the grid and performing multiple tasks, each with their own policies and procedures.

194.4 Benefits of Grid Computing

A grid can often provide the following:

- *Cost benefits*. It is much cheaper for an organization needing computing power to utilize a commercial grid instead of purchasing and building an in-house solution. In many cases, the time-to-market is shortened tremendously while hardware, software, and development costs are simultaneously reduced.
- *Scalability*. The grids' modular design allows for additions, integration and upgrades. These can expand as the needs of its users grow.
- *Flexibility*. As organizational needs change, so can the computing power of the grid. The power of the grid can adjust to consumption in almost real-time.

These following are some of the overall challenges of grid computing:

- Specialized middleware—the software glue that connects an application to the "plumbing" to make it run—is needed.
- This "glue" does not yet exist in a robust form.
- Mechanisms are needed for determining what computer and database resources are available.
- Methods for organizing them into a functioning system are needed.
- Perhaps the biggest challenge is security.

194.5 Grid Security Considerations

In the beginning, the idea of assembling tremendous computing power was the single driving force behind the invention of the grid. There was not much talk of security because grid use was limited to academic and high-level research; neither of these environments was at that time concerned about possible compromise or loss of their data. However, as commercial use of these grids began to grow, designers realized that users demanded a much more secure environment. There was a definite need for standardizing security measures across all grids because that is the basic premise behind their existence: they are able to communicate with one another, seamlessly and unbeknownst to the user.

194.5.1 General Grid Security Issues

Grid security must:

- Allow access to trusted resources
- Trust in a dynamic environment (thousands of computers) that is hard to define

- Utilize commercial grid middleware, most of which are designed for “intra-grids” and not suitable for open grids
- Make use of virtual organization (VO). VOs are a set of individuals or institutions with some common purpose or interest that need to share their interests to further their goals; and one of the central issues with VOs is that they do not scale well.

194.5.2 Specific Security Challenges

- Application protection: all applications on the grid must be protected from unauthorized access
- Authentication (X.509, proxy credentials): how, what, and where?
- Authorization (SAML)
- Access control (XACML)
- Accounting: auditing and monitoring
- Node-to-node communication: intercommunication amongst the grid computers
- Protection against malicious code, viruses, worms, etc.

One of the most widely used and implemented security standards was designed by the Globus Project in 1998. (Microsoft has since integrated Globus Security Infrastructure (GSI) into Passport.). The Globus Toolkit includes software for security, information infrastructure, resource management, data management, communication, fault detection, and portability. It is packaged as a set of components that can be used either independently or in concert to develop applications. Every organization has unique modes of operation, and collaboration between multiple organizations is hindered by incompatibility of such resources as data archives, computers, and networks. The Globus Toolkit was conceived to remove obstacles that prevent seamless collaboration. Its core services, interfaces and protocols allow users to access remote resources as if they were located within their own machine room while simultaneously preserving local control over who can use resources and when.

The GSI, part of the Globus Toolkit, addresses many security issues that stood in the way of utilizing grids in a commercial environment. The issues that prompted the design of GSI include:

- Users must be able to authenticate securely to the grid: authentication schemes, policies and procedures must be developed that implement standards across the grid.
- Elements within the grid must be able to communicate securely: hosts or clusters must be able to authenticate one another in a robust manner.
- Implementing security across organizational boundaries: in other words, there should not be a “centrally managed” security environment. Each organization could potentially apply its policies to the grid.
- A “single sign-on” solution must be in place for users so that they would not have to log in multiple times to various systems and applications.

The architecture of GSI is based on the freely available SSLeay security package. At the heart of the authentication scheme is the use of X.509 authentication certificates (based on PKI) which can be signed by multiple certificate authorities (CAs). A GSI certificate includes four primary pieces of information:

- A subject name, which identifies the person or object that the certificate represents.
- The public key belonging to the subject.
- The identity of a CA that has signed the certificate to certify that the public key and the identity both belong to the subject.
- The digital signature of the named CA.

One of the features of these certificates is the addition of an expiry date. These certificates are referred to as *proxy certificates*—a temporary binding of a new key pair to an existing user identity. The use of proxy certificates allows an entity to temporarily delegate its rights to remote processes or resources on the Internet. Each certificate has a time expiry allowing for additional security. Once a certificate has been authenticated, the holder will no longer be required to present these credentials again, thus allowing a "single sign-on" scheme.

If two parties have certificates, and if both parties trust the CAs that signed each other's certificates, then the two parties can prove to each other that they are who they say they are. The GSI uses the secure socket layer (SSL) for the mutual authentication protocol. Each party involved in this mutual authentication must have a copy of the other's trusted CA certificate, which contains the public key for that party.

Because the communication between parties includes public key information, it is not secured, meaning that there are no encryptions at this stage. However, GSI can be configured so that shared key information can be used. In this scheme, all authentications can be performed using encryption (today GSI supports many different encryption schemes, including AES).

One of the issues at the center of every key-based encryption is how to safeguard the private key. In the GSI scheme, the private key is stored on the local user's computer. As in other encryption algorithms, such as PGP, to use the GSI, the user must enter the passphrase for the private key. This is the "password" through which the key was originally encrypted. Without this passphrase, the user will not be able to authenticate within GSI's infrastructure to use the grid services.

194.5.3 A Bit About the Proxy Certificate

As mentioned earlier, the term *proxy certificate* is used to define a short-term restricted credential that can be created from a normal, long-term, X.509 credential.

One of the issues in using proxy certificate is how to restrict rights of a delegated proxy to a subset of those associated with the issuer. In other words, how can we ensure that only the issuer of the certificate is actually the one using the rights granted to it? The answer is through the use of a "restriction policy" embedded in the proxy certificate. The policy reduces the rights available to the proxy certificate to a subset of those held by the user. This, however, raises another concern, and that is the possibility of "policy language" wars. The GSI has been able to resolve this issue by including only the policy specification, without actually defining the language. The idea is that the language can evolve over time.

194.6 Summary

Over the past decade, there has been tremendous progress in not only standardizing grid infrastructure, but as the use of commercial grids increases, so have security protections. Currently, Sun Microsystems, IBM, AT&T and hundreds of other organizations offer grid services for commercial use. Many smaller organizations in need of computing power are taking advantage of these services. It is clear that many of the challenges that grid security architects face are those confronting normal computing environments.

Managing Unmanaged Systems

Bill Stackpole
Man Nguyen

Do you know what is connected to your LAN? Self-propagating worms such as Slammer and MSBlaster make the presence of unmanaged or rogue systems a major security threat. Many organizations hit by Slammer and Blaster were infected by external systems that were brought in and attached to their internal network, and the intensity of the attack was amplified by unmanaged (and unpatched) systems on internal local area networks (LANs). This chapter provides guidance for operations, support, and security personnel on how to managing common types of unmanaged systems, including systems that are known to the organization and those that are not. The text assumes the reader already has a standard process (and associated technology) for managing the majority of their systems and is looking for guidance with systems that are not or cannot be subject to the standard process. This chapter is a collection of both process and technology practices from the authors' experiences and is, to the best extent possible, vendor and industry neutral.

Where do unmanaged or rogue systems come from? Vendors and contractors are a common source. They are often allowed to attach their laptops to company LANs for product demonstrations, testing, and project work. A second source is company developers and engineers, who often build systems for testing and prototyping purposes outside the standard build and patch processes. Another common source is third-party products or systems with an embedded operating system (OS). Other sources include home PCs used for virtual private network (VPN) access and personally owned portable systems (i.e., laptops) that get infected outside the organization and are brought in and connected to the corporate LAN.

Unmanaged systems fall into two basic categories. First are the systems that operations and support are aware of but do not actively manage. Examples of these systems include lab, development, and test devices; systems owned or managed by third parties; and special-purpose (i.e., one-off) machines. One-off systems are often too critical to endure automated management procedures; examples include medical devices, broadcast video systems, and machine controllers. The second type of unmanaged machines is systems attached to the network that are unknown to the operations or support group. This chapter refers to these systems as rogue devices. Examples of rogue systems include non-company-owned systems (e.g., vendor or contractor laptops), non-domain-joined systems built for temporary or test purposes and possibly external systems attaching to an unsecured wireless access point. Rogue systems are particularly troublesome because they are not part of a standard build or patch rotation; consequently, they are usually missing key security updates making them subject to compromise.

A network with unmanaged systems represents an uncontrolled environment with significant security risks. Unmanaged systems and particularly rogue systems usually do not comply with company security policies and standards and consequently are ripe for compromise. When compromised, they can be used as a launching point for additional internal or external attacks. Rogue systems, especially portable ones, can easily introduce worms and viruses from a previous infection onto the internal network. Security breaches not only are expensive to recover from but may also include regulatory fines or other downstream liabilities.

It simply is not possible to secure (or manage) systems that the operations and support groups are not aware of, so along with better compliance the next biggest advantage to actively managing unmanaged systems is greater visibility into the actual environment being managed. Another advantage is a reduction in network attack surface from rogue systems being detected and remediated. This is equally true when other unmanaged systems are monitored to ensure they are compliant with security policies, standards, and procedures. A smaller attack surface, in turn, reduces the impact of virus and worm outbreaks by keeping potential targets (i.e., unpatched systems) to a minimum. Finally, the process helps keep essential management and inventory data up to date on these systems.

195.1 System Management Essentials

Before going into management specifics for unmanaged systems we will cover some of the foundational elements involved in system management. These are the common elements necessary for the operation and support of managed as well as unmanaged systems.

195.1.1 Policies, Standards, and Procedures

First, it is necessary to have a good set of policies, standards, and procedures governing system management processes. These include naming conventions, classification standards, patching/update timelines, and auditing requirements. It is not possible to have an effective system management process unless the personnel involved have a clear understanding of what is required of them and the timelines they have to accomplish the work. While policies and procedures are outside the scope of this chapter, the importance of having well-defined system management requirements, roles, and responsibilities cannot be overemphasized. Do not leave this essential element out of the system management strategy.

195.1.2 Asset Determination

The second essential element is asset determination. As mentioned above, it is not possible to manage what you do not know about or, perhaps more accurately, what you do not know enough about to determine the management or security requirements of the device. A complete and accurate inventory of the devices attached to the network is the most essential element of system management after policies, standards, and procedures. Most organizations have some type of asset inventory system, and several system management tools have hardware and software inventory capabilities but these systems may not cover all the devices connected to the network. Building an accurate asset inventory requires discovery, inventory, and classification. Discovery is a proactive process intended to find all the active devices connected to the network and to gather some of the information necessary to manage that device. Discovery methods are discussed in more detail later in this chapter.

When a system has been discovered it can be entered into inventory. The inventory operation captures the key system attributes required for proper operations and support and stores them to an inventory database. The database is sometimes referred to as the configuration management database (CMDB) because it contains key system configuration elements such as manufacture, model, OS version, and installed applications. But, it also contains other pieces of information necessary for security and maintenance operations, including the criticality of the system, its location and ownership contacts.

Exhibit 195.1 shows the basic CMDB data elements. These are considered the minimum elements; other device attributes may have to be captured to meet the specific organizational requirements. If an information technology (IT) inventory system is already in place, it probably contains several of these data elements. Rather than duplicate the existing data, it may be easier to modify the inventory database schema or link the two databases to cover all the required data elements. The SystemID is the record key. It is generated when the system record is created and is used to associate this system with other data records. This allows the system name to be changed without losing these associations. SystemName, NetworkAddress, and NICAddress are the primary system identifiers. OSVersion, SystemType, Role/Application, AppVersion, and CriticalityClass are used to determine system baselines. The ExemptFlag is used to designate systems that are not subject to standard operations and support procedures (i.e., unmanaged systems). Owner/Contact and Location are used for remediation, and the LastUpdate elements are used to track discovery, monitoring, and other record updates.

One of the key things to consider when building an IT inventory is the database management system (DBMS) itself. The DBMS should have good reporting capabilities and integrate well with the other system management tools. Structure Query Language (SQL)-based systems with store procedure capabilities are best. Another key thing to consider is inventory maintenance, keeping the inventory up to date. Automated tools are great for this, but procedures should also be in place that hook the system build and support functions so inventory records are updated when systems are built, rebuilt, or retired.

Classifying system criticality is the final asset determination activity. Understanding the criticality of the system to the business is crucial to proper system management especially in large environments. It provides for the proper prioritization and scheduling of security and maintenance tasks, as well as the establishment of appropriate timelines for their completion. For example, the timeline between a patch release and its installation will be shorter for higher criticality systems. System criticality can be based on

EXHIBIT 195.1 Example of Data Elements for Configuration Database

Data Field	Description	Type	Size
SystemID	Sequentially generated system identifier	Integer	—
SystemName	Unique device name	Char	41
NetworkAddress	System TCP/IP address	Char	12
NICAddress	Media access control (MAC) address of network interface card	Long integer	—
OSVersion	Type of operating system and major and minor version numbers	Char	128
SystemType	System classification (e.g., desktop, laptop, server)	Char	41
Role/Application	Primary usage (e.g., file and print, Web, SQL, DC)	Char	128
AppVersion	Name and version of primary application	Char	128
CriticalityClass	High, medium, or low rating of system criticality	Char	8
ExemptFlag	Exempt from standard operations flag	Boolean	—
Owner/Contact	Primary user, system owner/administrator, or support group	Char	128
Location	Physical location of device	Char	128
LastUpdateTime	Last date and time the record was updated	Date/time	—
LastUpdateID	UserID of person who last updated the record	Char	61

a number of risk factors, including the susceptibility of the system to attack, impact to business operations, and potential financial liabilities. High, medium, and low are the criticality classifications used in this chapter.

195.1.3 Baseline Determination

The third element is baseline determination. A baseline is the minimum acceptable configuration for a system. It is not possible to determine the compliance level or remediation requirements of systems without first understanding the baseline requirements. Common sources for baseline requirements include system build and hardening standards, security policies and standards, and industry and vendor best practices, as well as experience (i.e., recurring issues the organization has had to deal with). Some baselines are common to all systems (e.g., password requirements), and others are specific to the system type or role or the applications it runs. For example, a Web server would have Apache- or IIS-specific baselines in addition to the common baselines. Exhibit 195.2 is an example of some common system baselines. Baselines establish the metrics necessary for monitoring systems for compliance with established requirements and determining what remediation actions should be taken.

195.1.4 Discovery, Monitoring, and Reporting Infrastructure

An effective and efficient system discovery, monitoring, and reporting capability is essential to good system management. It is considered *infrastructure* because it encompasses and impacts the entire corporate network; therefore, it must be carefully planned to ensure proper coverage, performance, and integration.

A good network segmentation scheme can substantially aid system discovery and monitoring; for example, a network that assigns end-user systems to specific segments reduces the number of segments that must be monitored. Systems with guest network segments facilitate quarantine and system remediation. A network with dedicated management segments helps ensure the reliable delivery of system alerts and notifications. Other elements, such as directory services, can also enhance monitoring by allowing systems with common attributes to be grouped together so scans can be targeted to system-specific requirements.

Coverage incorporates the ability to work across the entire network and all the targeted devices. For example, the ability to discover or monitor systems should not be hampered by network controls (e.g., routers, firewalls, switches), hardware type, OS versions, etc. Performance includes the efficient use of network bandwidth, effective turn-around times, and accuracy. Discovery tools must be able to work

EXHIBIT 195.2 Example of Common System Baselines

Category	Description
Operating system	Operating system is an approved version.
Antivirus	Antivirus is installed, active, and up to date.
Domain	System is joined to the domain.
Policy	Local and domain policies are set properly.
File System	File, directory, and share access control lists (ACLs) and audit settings are correct.
Accounts	Required accounts and groups are present. Accounts are configured properly.
Services	Required services are installed and operational. Prohibited services are not installed.
Protocols	Required network protocols are installed. Prohibited protocols are not installed.
Software	Required software is installed and configured properly. Prohibited software is not installed.
Updates	All critical and high risk patches are installed.
Processes	Prohibited processes are not running.

efficiently across the entire network and gather at a minimum the system name, operating system, and MAC and IP addresses. This is equally true for monitoring techniques; they must be able to efficiently and accurately measure the baseline compliance of all targeted systems. Remote monitoring tools come in two varieties:

- *Agent-based tools*—Tools that install software on the system to gather baseline information and report it to a central console (e.g., Symantec ESM).
- *Read-only tools*—Tools that do not install software on the system but use remote system calls instead to gather and report baseline information (e.g., Pedestal's Security Expressions).

Finally, discovery and monitoring tasks must be completed within a reasonable timeframe to be effective. For example, desktop systems must be scanned at least once during normal working hours or they will likely be powered off. A monitoring or discovery infrastructure that cannot sweep the network within this timeframe will not work effectively for desktop systems. In large environments and on networks with low bandwidth links, agent-based tools and tools using distributed scanning devices usually prove to be more effective.

It is often necessary to deploy multiple tools to achieve the discovery and monitoring coverage required so integration becomes a major factor. Ideally, the outputs for these processes should have a common format so they can be easily written to a common database for consolidation and reporting purposes; examples include tools that write comma delimited files or use Open Database Connectivity (ODBC). For tools that use proprietary formats the stored procedure capabilities of the DBMS can be used to filter and import results.

Accurate reporting is the principle purpose for collecting and consolidating discovery and monitoring data. For example, discovery data can be compared to existing inventory data to report on new (rogue) devices or devices that have been renamed since the last inventory (same MAC address, different system name). Monitoring data can be used to report on overall compliance to specific baselines (e.g., critical patch compliance) or to report systems that require remediation (i.e., noncompliant systems). Ideally, the reporting system should provide for predefines (canned) reports as well as *ad hoc* queries.

195.1.5 Remediation Infrastructure

The final element of good system management is remediation. Good discovery and monitoring capabilities are meaningless if system risks cannot be remediated in an effective and timely manner. Having a good remediation strategy is essential to successful system management. Remediation is usually a combination of manual and automated processes. For example, when a system is first discovered someone will have to determine what type of device it is, what role or application it has, who owns the device, etc. When the basic CDBM information is known, the system can be subject to automated management processes such as software updates, patch deployments, and policy settings. One key point to remember is that manual remediation is the most time-consuming and costly way to update systems. Manual remediation procedures should always be in place (these are necessary for one-off systems), but every effort should be made to automate as much of the remediation process as possible.

A large number of remediation tools is available (some are covered later in the chapter). When selecting a tool consider how versatile the tool is, how well it covers the target devices, and how well it integrates with the configuration management database. Remember that this is an *infrastructure* tool (it encompasses the entire network), so network performance and impact must also be considered.

It is unlikely that any one tool is going to cover all the required remediation tasks, but choosing a versatile tool that covers multiple system management functions helps reduce integration headaches. For example, tools such as SMS, Alteris, and Tivoli combine inventory, discovery, and software distribution and update capabilities into a single tool using a single database. Having a primary and secondary remediation capability is also a smart idea. Automated tools such as SMS and Alteris rely on system agents to perform system management tasks; if the agent was not installed or becomes disabled, remediation will fail. Having a secondary methodology such as an Active Directory software installation Group Policy Object (GPO) or log-in script process catches these systems and reduces the number of systems that must be remediated manually.

195.2 Known Unmanaged System Procedures

Known unmanaged systems are systems that are tracked in the configuration management database but for one reason or another are exempt from standard operations and support procedures. Examples of known unmanaged systems include:

- Third-party production systems such as Voice over IP (VoIP) servers, voicemail systems, etc. that are not maintained by the operations team
- Lab, development, staging, and other non-production test systems
- One-off systems such as production controls, medical devices, broadcast video systems, etc.

Known unmanaged systems are usually added to the CMDB as part of the build process. Systems may also be added as part of an automated system management process—for example, when they are joined to the domain or added to the directory service. Often these systems do not have standard system management or monitoring software installed because they are located on network segments with restricted access (e.g., lab or demilitarized zone [DMZ]), the agents are not compatible with installed applications, or the management or monitoring agents adversely impact system performance. In these instances, a manual registration process must be used. Although known but unmanaged systems do not follow standard management procedures, they are not exempt from baseline requirements. Instead, special procedures must be developed to ensure that these systems remain compliant.

195.2.1 Dealing with Third-Party Systems

Third-party system configuration and maintenance are typically controlled by contract so it is important that third-party contracts include baseline compliance requirements and timelines. When this is not possible, third-party systems must be subject to other controls to remediate noncompliance risks; for example, they may have to be firewalled or placed on segments that are isolated from other internal resources. Whenever possible, provisions for monitoring and reporting compliance should also be included. For example, contracts should require third-party systems to install monitoring agents or provide the credentials necessary for read-only monitoring. This provision provides a way to monitor not only baseline compliance but also contract service level agreement (SLA) compliance. When remote monitoring is not possible, then contracts should clearly spell out compliance reporting requirements and timelines for third-party personnel.

195.2.2 Dealing with Non-Production Systems

Lab, development, and other test systems are not critical to the business operations, but they cannot be overlooked or neglected. Non-production systems are subject to frequent OS, configuration, or software changes and often have limited access (e.g., not domain joined, attached to isolated segments). Despite these challenges, provisions still must be made to ensure that these systems meet baseline requirements and can be monitored for compliance.

Non-production systems should be, at a minimum, subject to all security baselines; other baselines can be kept to a minimum. Build procedures should include the installation of required security software, updates, and settings (e.g., anti-virus, patches, password complexity) as well as monitoring agents or the accounts or credentials necessary for read-only monitoring.

Because the onus for compliance is on the system owners, it is importance to have clearly defined requirements and expectations as well as a good communications plan. Owners must understand exactly what is required of them and the timeframes for completing the work. The communication of new compliance requirements (e.g., a new security patch) must be effective and timely. It is best to have multiple system contacts for known unmanaged systems so new baseline requirements and remediation actions can be escalated if necessary.

Because these systems are subject to frequent changes, they should be closely monitored. This may require some special firewall or router configurations when these systems are located on isolated segments. When remote monitoring is not possible, then policies and procedures must clearly spell out compliance reporting requirements and timelines for system support personnel.

195.2.3 Dealing with One-Off Systems

Due to their production criticality (e.g., a medical device tied to patient health or safety), one-off systems have unusual management requirements. Despite the challenges, one-off systems still must meet baseline requirements and be monitored for compliance. For the most part, one-off systems use manual processes (carried out by the system owner or support personnel) to maintain system baseline compliance. When a one-off system cannot meet the baselines, it must be subject to other controls to remediate noncompliance risks. One such control would be placing the device on a firewall-protected or isolated network segment. Build procedures for one-off systems should include the installation of required security software, updates and settings (e.g., anti-virus, patches, password complexity) as well as monitoring agents or the accounts or credentials necessary for read-only monitoring. Like non-production systems, the onus for compliance is on the system owner, so it is important to have clearly defined requirements and expectations as well as good communications. Owners must understand exactly what is required of them and the timeframes for completing the work. The communication of new compliance requirements (e.g., a new security patch) must be effective and timely. It is best to have multiple system contacts for one-off systems so new baseline requirements and remediation actions can be escalated when needed. One-off systems are production boxes and should be monitored at the same interval as other production systems. When remote monitoring is not possible, then policies and procedures must clearly spell out compliance reporting requirements and timelines for system support personnel.

195.3 Unknown System Procedures

Unknown systems are often called rogues because they are systems that have been attached to the network without the knowledge of the operations or support groups. Unknown systems do not appear in the configuration management database or other IT inventories so they are not activity managed to ensure that all critical security settings and updates are installed. Because the overall security state of these systems is not known, rogue systems pose a huge security risk to the computing environment.

Portable computers brought in and attached to a network by vendors, partners, contractors, and employees are a common source of rogue systems. Other common sources include home computers used for remote network access and systems built outside the lab environment for testing, experimentation, or backup. Unauthorized wireless access points (APs) are also becoming an issue. Because of their low cost, employees will unwittingly purchase and attach these devices to the internal network without understanding the security implications. External entities (e.g., hackers) can then use these APs to attach rogue devices to the network.

Perhaps the best approach for dealing with rogue systems is to prohibit them entirely. Many organizations have policies prohibiting the attachment of any non-company-owned system to their networks and most ban the use of unauthorized wireless APs entirely. Instead, they provide company-owned and managed systems to their vendors. Others require vendors' systems to be joined to the domain or otherwise subject to baseline security checks before being attached to the internal network; however, these options are not always practical, in which case the use of restricted segments is a good alternative. A restricted segment (e.g., a DMZ or extranet) provides limited access to internal resources while providing unrestricted external connectivity so vendors can reach their home offices for mail, data entry, etc. Another strategy for mixed environments such as conference rooms is to provide restricted access for vendor systems through the wired connections while giving company-owned systems unrestricted access through secured wireless connections. Unfortunately, policies and restricted segments will not keep rogue systems off the network; as noted earlier, many of these systems are company owned or authorized devices.

Dealing with rogue systems requires two distinct processes: discovery and remediation. First, there must be an effective way to identify rogue systems attached to the network and, second, there must be a very specific methodology for bringing these systems into the known system space or removing them from the network.

195.4 Discovering Unknown Systems

Several different approaches can be used to find rogue devices, but they all fall into two basic categories: passive and active. Active methods provide real-time or near real-time detection of new devices; passive discovery methods periodically scan the network to detect new devices.

195.4.1 Passive Discovery Methods

195.4.1.1 IP Scanning

Internet Protocol (IP) scanning is one of the most commonly used discovery methods. An IP scanner is an application that attempts to access and identify systems connected to the network based on a range of IP addresses. The scanner attempts to communicate with the target IP address by initiating Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) handshakes to common service ports; depending on the services or software that is running, the target machine will generate a response. Based on these responses, the scanner can deduce the presence of the device and, potentially, the system name, OS version, and system role (e.g., router, Webserver, DBMS). These results can then be compared to CMDB records to determine whether or not this is a known or rogue device.

Fairly simple to use, IP scanners are reasonably accurate and have good performance attributes. Also, quite a few IP scanners are available so it should not be difficult to find one that suits an organization's particular needs. Because IP scanners generate relatively small amounts of network traffic, they can be used effectively on low-bandwidth connections, including dial-up. This efficiency also makes it possible to scan a large number of addresses in a relatively short period of time. This improves their effectiveness by permitting them to be run more often. IP scanners also have their limitations. Scans are only conducted on a periodic basis so only those systems that are online when the scan is conducted will be detected. Remote or portable systems that only access the network for short periods may never be detected. Periodic scanning also means a rogue device could be on the network distributing worms or other malware for a significant period of time before being detected. The greater the interval between scans the more significant these issues become. IP scanners are not selective, so they will report on every device that responds within the specified address range; therefore, it may be necessary to filter the results to eliminate some devices before comparing them to CMDB records.

Network devices such as firewalls and routers using IP filters as well as similar host-based security measures can significantly reduce the effectiveness of IP scanners by masking or limiting the responses needed to properly identify a device. Network services such as proxy PING, Dynamic Host Control Protocol (DHCP), and dynamic Domain Name System (DNS) can also skew results by reporting nonexistent systems or making systems appear under multiple IP or name records. For specific information about IP scanning tools and techniques, see the tools section.

195.4.1.2 SNMP Scanning

Simple Network Management Protocol (SNMP) scanners are similar to IP scanners, and they can be configured to scan a range of IP address or specific targets. All the devices attached to the network are configured to respond to a standard SNMP System Group query. This read-only query is mandatory for all SNMP implementations and should return the following information:

- *System name*—The administratively assigned name of this device; usually the fully-qualified domain name.
- *System description*—A textual description of the device including the type of hardware, software operating system, and networking software for the system.
- *System contact*—A textual description of the person or group responsible for managing this device including information on how to contact this person (e.g., telephone number, e-mail).
- *System location*—The physical location of this device (e.g., telephone closet, third floor, Bldg. 4).
- *System up time*—Amount of time in hundreds of seconds since the last system restart.

Among its several advantages, SNMP queries have very little impact on network bandwidth or targeted systems so they can be used to scan a large number of systems across all types of connections. Network devices such as firewalls and routers can be easily configured to allow SNMP operations across network segments without significantly increasing risk. The queries are read only and return most of the key management data required. Queries can also be tuned to specific types of systems using different community strings, eliminating the need to filter results to remove unwanted responses.

On the down side, SNMP queries cannot distinguish between a nonexistent node and an active node that does not have SNMP enabled; both will fail to respond. This means that SNMP scans must incorporate other methods such as PING or reverse DNS lookup to validate results. Because SNMP uses UDP, results can be adversely impacted by network bandwidth availability. The usefulness of the returned data may also vary. The text fields have no specific format so it may be difficult to accurately parse the data Elements (e.g., OS type, version), and the amount of contact and location information returned depends entirely on what was entered in those fields when the SNMP agent was configured.

195.4.1.3 Network Service Query

Network services that dynamically register systems can also be used for discovery purposes. For example, the database of a DHCP service contains system names and MAC and IP addresses. Periodically querying the DHCP service for a list of active devices and comparing the results to the CMDB will reveal rogue systems. This is equally true of naming systems such as dynamic DNS and the MEWindows Internet Naming Service (WINS). Periodically comparing registered system names to CMDB entries should expose unknown devices. Systems also dynamically register their MAC and IP addresses in router Address Resolution Protocol (ARP) tables, so comparing ARP data to CMDB entries is also an effective way to find rogues.

A big advantage to using this method is that it requires no new or custom tools. These services are already present on the network, and systems will automatically register with them. The key to the effectiveness of this method is to set the query interval low enough to capture the data before the service ages out (drops) the information. A good rule of thumb is to set the interval to one half the aging value. A DHCP system that expires leases every 24 hours can be queried as little as twice a day, but an ARP service that drops inactive nodes in 40 minutes must be queried at least three times an hour.

Several issues arise with regard to using network services data for discovery purposes. The data is only collected on a periodic basis so only those systems that are registered when the data is collected will be found. If the interval between queries is too long, records will age out and some systems will not be detected. Periodic scanning also means a rogue device can be on the network for some period of time before being detected. Depending on the service, the results may have to be filtered because they contain all types of devices (e.g., ARP) or augmented because they only contain a subset of devices (e.g., WINS).

Another thing to realize is that systems do not have to use these services (e.g., systems with static IPs do not register with DHCP), and this also affects the accuracy of the results.

Finally, it is important to understand that these services are not designed for this kind of usage. Extracting data can be difficult and could potentially cause the service to malfunction. ARP is probably the exception; it can be queried using SNMP but ARP is not a centralized database. It is necessary to query all the distribution routers to collect all the required data.

195.4.1.4 Network Probe

The final passive discovery method uses network probes to collect node information. A probe is a device that monitors network traffic and gathers data about the devices sending or receiving packets. Remote Monitoring (RMON) is an Internet Engineering Task Force (IETF) standard monitoring specification designed to provide network administrators with diagnostic, planning, and performance tuning information. Several commercial and freeware probes have been designed to specifically address security issues such as unauthorized network devices for wired and wireless environments (e.g., NDG Software's Etherboy, AirMagnet Products' AirMagnet Distributed). Probes are very efficient. They use minimal network bandwidth, as they only generate traffic in response to report queries. Probes gather information about systems over time and can usually determine the system name, OS, and version with reasonable accuracy. Depending on the implementation, probes can filter and consolidate data and automatically forward it to a central collection console; however, probes have limited effectiveness because they can only see systems that generate traffic on the segment they are connected to. It is not practical to place a probe on every segment, but placing them on commonly used segments such as the Internet feed or network backbone will improve their effectiveness. Nonetheless, a rogue system that never generates traffic on these segments could remain on the network and never be detected. The accuracy of a probe can also be reduced if high-traffic volumes exceed the processing capabilities of the probe, causing it to drop packets.

195.4.1.5 Summary

Passive discovery methods can be reasonable effective at finding unknown or rogue systems. They are fairly simple to use, reasonably accurate, and very efficient. Many passive scanners are available, so it is not difficult to find one suited to an organization's particular requirements, and they will work in most environments without any infrastructure changes. However, scans conducted on a periodic basis can only detect devices that are online during the scanning period; consequently, systems that access the network for short periods may not be detected. Periodic scanning makes it possible for infected devices to be connected to the network for a significant period of time before being detected. Finally, scanning applications are not particularly selective; they will report on every device that responds within the specified address range, making it necessary to filter the results to eliminate uninteresting systems.

195.4.2 Active Discovery Methods

Active discovery methods have the advantage of providing real-time or near real-time detection of new devices. Active discovery can use network devices or services to identify devices connected to the network.

195.4.2.1 Network Service Monitoring

The network service query technique described above can provide proactive real-time notifications by setting up a process to monitor changes to the service data files. For example, if changes to the DHCP database are monitored, as soon as a device registers with the DHCP the management system is notified of the change and can take action to identify the new system. For systems that are unknown, further actions can be taken to gather additional inventory information. Network service monitoring has the same advantages as the network service query method with the added advantage of providing near realtime detection of new or rogue devices; however, an infected system still may have sufficient active access to the network to spread the infection. It is also important to remember that, like the query method, the results may have to be filtered to specific devices, and the accuracy of the results depends on the systems using the services being monitored. The fact that this is a custom solution is also a disadvantage from a maintenance and service perspective. The volume of changes can also influence the effectiveness of results if it overwhelms the processor.

195.4.2.2 Network Probe SNMP Traps

Some network probes can be configured to generate SNMP traps when they detect a new node. This is a standard capability on RMON probes. When the trap is received, the network management system can initiate a process to identify the system, gather additional inventory information, or take remediation action. This method has the advantage of supplying near real-time detection, but an infected system will still have active access to the network and could spread the infection. This method, however, has the same drawback as the passive network probe solution; it can only monitor for new nodes on a single segment. If a rogue system is not connected to a monitored segment, it will never be detected. The accuracy of a probe can also be reduced by high traffic volumes that exceed the processing capabilities of the probe or interfere with SNMP trap deliveries.

195.4.2.3 IEEE 802.1x

The IEEE 802.1x standard defines port-based, network access control for Ethernet networks. This portbased network access control uses the physical characteristics of the switched LAN infrastructure to authenticate devices attached to a LAN port. Access to the port can be denied if the authentication process fails. Although this standard is primarily used for wireless (802.11) networks, many vendors also support it on wired Ethernet LANs. The IEEE 802.1x standard defines four major components: the port access entity, the supplicant, the authenticator, and the authentication server. A port access entity (PAE) is a LAN port that supports the IEEE 802.1x protocol. A PAE can adopt the role of the authenticator or the supplicant, or both. A supplicant is a PAE that is attempting to access services on the network, typically an end-user device such as a laptop, workstation, or PDA. An authenticator is a PAE that enforces authentication before granting the supplicant network access. For wireless connections, the authenticator, is the logical LAN port on a wireless access point; on a wired network, it is a physical port on an Ethernet switch. The authentication server is used to verify the credentials of the supplicant. The authenticator collects credentials from the supplicant and passes them to the authentication server for verification. The authentication server can be a component of the authenticator device but more often it is a separate device such as a Remote Dial-In User Service (RADIUS) server. Exhibit 195.3 shows these components for a wireless LAN network.

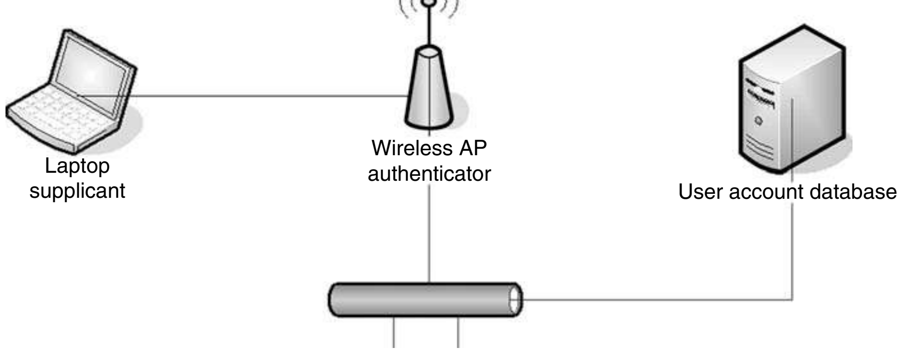

EXHIBIT 195.3 Components for a wireless LAN network.

An authenticator has two types of ports. It uses an uncontrolled port to communicate with LAN devices and exchange data with the authentication server. It uses a controlled port to communicate with supplicants. Before authentication, no network traffic is forwarded between the supplicant (client) and the network. This has the advantage of preventing an infected device from spreading that infection on the network. Exhibit 195.4 shows the two types of ports in a wireless configuration. When the client is authenticated, the controlled port is switched so the client can send Ethernet frames to the network. In a wireless network, multiple clients can be connected to the logical ports on an AP; on a wired network, only one client is connected to a physical port on the Ethernet switch.

The 802.1x mechanism supports multiple authentication methods via the Extensible Authentication Protocol (EAP). These include PEAP-MSCHAPv2, digital certificates (EAP-TLS), and two-factor authentication using tokens. For each of these authentication methods, a RADIUS server is used to verify credentials and provide the "EAP Successful" message to the authenticator.

The major advantages of 802.1x are that it works in real time and will keep unauthorized/rogue systems off the network entirely. This prevents the spread of worms or viruses from infected unknown systems. Some of the major drawbacks include the necessity of having an infrastructure that supports 802.1x, including compatible switches, wireless access points, and clients. Also, 802.1x does not prevent a known system with an infection or vulnerability from attaching to the network and posing a threat to the entire computing base, and 802.1x does not provide notification or inventory information for unknown systems. Systems that fail to authenticate are simply not allowed on the network. Monitoring RADIUS accounting and EAP message logs can provide some information regarding these devices, but this is not real time and may not be sufficient to effectively identify and remediate unmanaged systems.

195.4.2.4 IPSec

Internet Protocol Security (IPSec) provides the logical equivalent of 802.1x. Instead of preventing the physical connection of a device to the network, it prevents logical connections between systems. Where 802.1x relies on switches and access points to apply physical controls, IPSec makes the systems themselves the control points. IPSec has two protection mechanisms: the Authentication Header (AH) and the Encapsulating Security Protocol (ESP). The AH header is used for authentication and the ESP header for encryption and integrity. IPSec uses security associations (SAs) to establish connections between systems. Two systems with a common SA can authenticate one another and set up a data connection. SAs can also be setup dynamically using the Internet Key Exchange (IKE) protocol which includes node authentication with mechanisms such as X.509 certificates or Kerberos.

Because unknown or rogue systems do not have the required SAs or access to the required authentication mechanism, they cannot connect to systems requiring IPSec connections. IPSec does not prevent unmanaged systems from being physically connected to the network but it does deny them logical access to other systems, which prevents the exploitation of vulnerabilities or the spreading of malicious code. IPSec is supported on most operating systems; unlike 802.1x, no

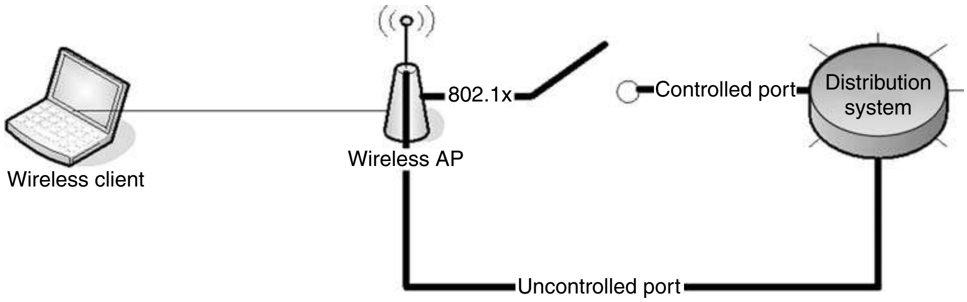

EXHIBIT 195.4 Controlled and uncontrolled ports for IEEE 802.1X.

major infrastructure upgrades are required. IP is also supported on many network control devices such as routers, switches, and VPN servers, which allows for expanded control scenarios, such as the use of VPN-style connections on internal segments; however, configuring an infrastructure to use IPSec is not a trivial task.

A big disadvantage of IPSec is the lack of tools for managing IPSec connections across vendor platforms. This means many connections must be manually configured and maintained. Manual configurations usually require fixed IP addresses rather than dynamically allocated IPs (e.g., DHCP). Systems with common operating systems fair better; for example, Windows-based systems can use GPOs to centrally manage IPSec settings and Kerberos to perform dynamic authentications, making the practical deployment of IPSec fairly straightforward. Coverage is another issue. Although most host devices (e.g., servers) can be configured to accept only IPSec connections, end-user systems (e.g., workstations and laptops) must allow non-IPSec connections to systems such as Web sites or identity management (IM) servers. This can make them susceptible to compromise from infected rogue devices. Finally, IPSec does not provide notification or inventory information for unknown systems; systems that fail authentication are simply not allowed to connect to an IPSec-protected resource. Monitoring IPSec and system authentication logs can provide some information regarding unknown devices, but this is not real time and may not be sufficient to effectively identify and remediate an unmanaged system.

195.4.2.5 Health-Check Mechanisms

Several companies are producing health-check mechanisms that help administrators enforce compliance with security and configuration policies before granting network access. They were first introduced on remote access connections; after connecting, systems are denied network access while the VPN or connection agent performs the necessary health checks. This capability has been expanded to include wired and wireless connections. Health-check mechanisms are not security controls *per se* but can help prevent the introduction of malicious code and unmanaged systems to the network. Health-check mechanisms consist of three components: client agent, policy service, and enforcement agent. When a system is first connected to the network, the enforcement agent requests the health status of the device from the client agent. Any system without the agent will obviously fail; otherwise, the enforcement agent will compare the status to the appropriate policy on the policy service. If the system passes the health check, it is granted access to the network; if not, network access is blocked or the device is referred to a remediation process.

Remediation referral is a major advantage on two fronts. First, it allows system issues to be proactively addressed and automatically resolved, and, second, it allows (depending on the capabilities of the mechanism) remediation to perform just about any action. Developers and administrators can create solutions for validating any number of requirements and provide the required remediation, including system identification and inventory, staff notification, update deployment, or system quarantine. These mechanisms work in real time, so malicious activity is proactively prevented.

Health-check mechanisms do have their disadvantages. They are not designed to secure a network from malicious users; they are designed to help administrators maintain the health of the computers on the network, which in turn helps maintain the overall integrity of the network. Just because a system complies with all the defined health policies does not mean it is not infected with malicious code, only that the infection is not covered by existing policies. The ability of a system to gain network access also depends on the enforcement mechanism; for example, if the enforcement mechanism uses DHCP, it is relatively easy to bypass enforcement using a fixed IP address. On the other hand, if 802.1x is used for enforcement, it would be difficult to bypass.

195.4.2.6 Summary

Active discovery methods can accurately identify unknown or rogue systems in real or near real time. They are more complex to operate but produce better overall results. Fewer active discovery tools are available, but they tend to be more selective so results do not require extensive filtering; however, active tools may require customization to effectively address particular requirements. Also, some active methods such as 802.1x can require substantial infrastructure changes. Nonetheless, active discovery methods do prevent infected devices from accessing the network for any substantial period of time.

195.5 Unknown System Remediation

Finding unknown systems is only half the process. When detected, these systems must be identified, located, and integrated into the management process or removed from the network. The IP address is usually sufficient to narrow the location of an unknown system to a specific area and to notify the support or security personnel responsible for that area. The area personnel must take the steps necessary to mitigate the risks these systems represent. These steps can include joining the system to the domain, installing required software and updates, configuring required system policies, and disabling generic user accounts. To be effective, this remediation process must be well defined and have established timelines. Exhibit 195.5 provides an example of how this process might work for a system requiring remediation for high-risk vulnerabilities. The timeframe for system remediation is based on two factors: the risks associated with the system and company policies and standards governing risk remediation. For example, a system running a worm executable (e.g., MSBLASTER.EXE) would require immediate remediation, whereas a system missing a medium-risk security patch might have a two-week timeframe. The actually remediation actions will vary depending on the requirements and the system (or systems) the company uses for remediation. For example, some possible remediation action could include:

- Join the system to the domain, which allows security GPOs to be applied and the system management services to install required software and updates.
- Inform system management services, which allows management systems to apply appropriate updates and settings.
- Move the system to a restricted/controlled network segment.
- Manually apply updates and settings.

195.6 Tool Reviews and Examples

This section contains information on several tools that can be used to facilitate or automate discovery, inventory, and monitoring practices.

EXHIBIT 195.5 Remediation Schedule

	Action	Timeframe
1	Establish system owner/administrator.	Within 4 business hours of discovery
2	Determine management requirements (third-party, lab/test, one-off, unmanageable).	Within 1 business day
3a	If unmanageable, remove from network.	ASAP
3b	Enter system into configuration management database (CMDB).	Within 1 business day
4	Determine remediation requirements.	Within 1 business day
5	Develop remediation plan.	Within 1 business day
6	Test remediation solutions for system compatibility.	Within 5 business days
7	Deploy remediation solutions.	Within 7 business days
8	Verify system compliance.	ASAP

195.6.1 Nmap

Nmap ("Network Mapper") is a free open source utility for network exploration and security auditing. It was designed to rapidly scan large networks, although it will work equally well for single systems. Nmap uses raw IP packets in novel ways to determine what hosts are available on the network and their operating system (including version), the services they are running, the packet filters or firewalls in use, and dozens of other characteristics. Nmap runs on most vendor platforms and is available in both console and graphical versions. Nmap is distributed under the terms and conditions of the GNU's General Public License (GPL).

195.6.1.1 Examples

The following example displays the OS, OS version, and services running on a single system named *Madell*:

```
./nmap -A -T4 Madell.company.com
Starting nmap 3.40PVT16 (http://www.insecure.org/nmap/) at
   2004-01-03 02:56 PDT
Interesting ports on Madell (127.0.0.1):
(The 1640 ports scanned but not shown below are in state: closed)
PORT        STATE     SERVICE     VERSION
22/tcp      open      ssh         OpenSSH 3.1p1 (protocol 1.99)
53/tcp      open      domain      ISC Bind 9.2.1
443/tcp     open      ssl/http    Apache httpd 2.0.39 ((Unix)
   mod_perl/1.99_04-dev [cut])
5001/tcp    open      ssl/ssh     OpenSSH 3.1p1 (protocol 1.99)
6000/tcp    open      X11         (access denied)
8080/tcp    open      http        Apache httpd 2.0.39 ((Unix)
   mod_perl/1.99_04-dev [cut])
Device type: general purpose
Running: Linux 2.4.X|2.5.X
OS details: Linux Kernel 2.4.0 - 2.5.20
Uptime 3.45 days (since Fri Jan 03 1:32:40 2004)
Nmap run completed -- 1 IP address (1 host up) scanned in 51.24 seconds
```

The scan can be expanded to all systems on the network segment by adding a range parameter to the command:

```
./nmap -A -T4 Madell.company.com/24
```

By adding the /24 class C network mask, Nmap will scan all the systems on the segment Madell is attached to.

195.6.2 Nbtstat

Nbtstat is a Windows tool that displays NetBIOS over TCP/IP protocol statistics including the NetBIOS name tables and the NetBIOS name cache. The target can be the local computer or a remote host, but Nbtstat does not support scanning a range of IP addresses. This requires some minor scripting efforts. For example, the following command line will feed a list of IP addresses from a text file into the Nbtstat command.

```
FOR /F %a IN (IPAddresses.txt) DO Nbtstat -A %a
```

195.6.2.1 Example

This example returns the system name table and MAC address for a system name *Products*.

```
C:\ >nbtstat -an Products
```

```
Local Area Connection:
Node IpAddress: [192.168. 0.98] Scope Id: [ ]
NetBIOS Remote Machine Name

      Name                    Type                Status
PRODUCTS              <20> UNIQUE            Registered
PRODUCTS              <00> UNIQUE            Registered
MAC Address=00-08-02-B2-AD-C9
```

195.6.3 SuperScan

SuperScan is a free utility from Foundstone that can be used to collect information about systems connected to the network. SuperScan is a graphical user interface (GUI)-based utility with a large number of discovery and scanning options as well as a set of compatible tools for gathering additional information about a device or network. For example, it has a DNS zone transfer tool, a Whois tool, and a configurable Windows Enumeration tool. SuperScan can be configured to use the Internet Control Messaging Protocol (ICMP), TCP, and UDP to discover systems. The tool is preconfigured with the most commonly used ports but other ports can be added. The Windows Enumeration tool has an interesting option that allows users to enumerate a number of registry keys. The keys are specified in a flat text file so it is possible to use the option to check for installed software and patches. SuperScan is extraordinarily fast and accurate, but the report mechanism is weak; only HTML reports are supported. SuperScan version 4 is available from http://www.foundstone.com/resources/scanning.htm.

195.6.4 SNMP Sweep

SNMP Sweep is part of the SolarWinds Network Management Suite. The suite contains a number of utilities for network discovery and performance management designed with an emphasis on speed, accuracy, and ease of use. SNMP Sweep can scan a range of IP addresses and show which IP addresses are in use and their DNS lookup names. If the systems have SNMP enabled and the proper community string configured in SNMP Sweep, the system name, location, contact, last reboot, and system description are also returned. SNMP Sweep can print results or export them into plain text, http, or comma-delimited files for reporting or consolidation. Additional information on SNMP Sweep and the SolarWinds tools can be found at: http://www.solarwinds.net.

195.6.5 Systems Management Server

On the enterprise end of tools is Systems Management Server (SMS) 2003. It provides a comprehensive solution for change and configuration management for the Microsoft platform, enabling organizations to provide relevant software and updates to users quickly and cost effectively. SMS 2003 SP1 provides a number of system management functions, but the primary ones we are interested in for this article are the discovery and asset management capabilities of the product. SMS has three primary discovery methods: Heartbeat, Network, and Active Directory. Heartbeat discovery is used to refresh discovery data in the SMS database; it is primarily used to update system discovery data for systems that would be missed by the other discovery methods. Network discovery is used to find devices with IP addresses; network discovery can be configured to search specific subnets, domains, SNMP devices, or Windows DHCP databases. Active Directory discovery identifies computers by polling an AD domain controller; AD discovery can be configured to search specific containers such as domains, sites, organizational units, or groups for new systems. All three discovery methods are passive; the administrator must schedule their periodic execution. SMS also supports the execution of scripts so it is possible to implement other discovery methods to meet specific reporting needs. For example, a script can be used to discover clients during a network log-on. Scripts also provide administrators with greater flexibility and control, including the ability to send alerts and notifications or to process non-Windows devices. When a node has been discovered, it is possible to use other features of SMS to gather additional information about the node. For example, the SMS automatic deployment option can be used to install the SMS client on the system, and the agent can then perform a full hardware and software inventory of the system.

195.6.6 Hardware and Software Inventory

Utilizing the Windows Management Instrumentation (WMI), SMS 2003 can accumulate a richer set of inventory data during an inventory scan including BIOS and chassis enclosure information. This function can be used to compare hardware attributes against an asset inventory to discover unfamiliar hardware attributes. These hardware attributes may point to a foreign or illegal system that was joined to the domain or newly acquired hardware models that may require the establishment of new security baselines. SMS 2003 can provide a comprehensive inventory of executables on a system but also has granularity controls that permit administrators to focus on a core set of applications and files of particular importance or interest. SMS 2003 also supports wildcard file searches and searches for specific file properties or environment variables. These functions can be used to discover missing files, malicious content, and spyware. SMS stores result in an extensible SQL database that can serve as the configuration management database. It also provides for robust, flexible, and fully extensible Web reporting with over 120 pre-built reports. Importing and exporting capabilities are also available for consolidating information from other sources or transferring SMS results to other environments.

195.7 Conclusion

Unmanaged or rogue systems present a major security threat to networks. Worm and virus infections can often be traced to external systems brought into the company and attached to the internal network. Unmanaged systems can facilitate and intensify attacks and create downstream liabilities. Turning unmanaged systems into managed systems or removing them from the network is crucial to maintaining network security. This chapter has identified a number of methods that can be used to identify and remediate unmanaged or rogue systems on network systems. You cannot secure what you do not know about; start managing your unmanaged systems now.

196

Storage Area Networks Security Protocols and Mechanisms

Franjo Majstor

196.1 Introduction and Scope

Storage devices were, up to fairly recently, locked in a glass room and hence the data stored on them was enjoying the privileges of the physical data center security and protection mechanisms. With the development of storage area network (SAN) technology, hard drives and tape drives are not necessarily directly attached to a host anymore but could be rather physically distant—up to several hundred kilometers or even around the globe. Such a flexibility of logically instead of physically attached storage devices to a host made them remotely accessible and highly available; however, it brought into consideration all security elements of the modern network environment, such as privacy, integrity of the data in transit, and authentication of the remotely connected devices. From the data perspective, one can distinguish between storage network security, which refers to protection of the data while it is in transit, versus storage data security, which refers to when the data is stored on tapes or hard drives. This chapter focuses on making information security professionals aware of the new communication protocols and mechanisms for storage network security, explaining threats and their security exposures, as well as describing guidelines for their solutions.

196.2 SAN (Storage Area Network) Technology and Protocols Overview

196.2.1 DAS versus NAS versus SAN

Historically, storage devices, such as disk drives and backup tapes, were directly attached to a host—hence the name "direct attached storage" (DAS). This was typically performed via a SCSI (Small Computer Systems Interface) parallel bus interface with a speed of up to 320 MBps (megabytes per second). This approach of attaching storage devices emanates from the internal computer architecture, which has obviously reached its limits in several ways. The number of devices that could be attached to one bus is limited even in the latest version of the SCSI protocol to only 16 devices, while the distances are no greater than 15 meters. Sharing disk or tape drives among multiple hosts were, due to the architecture of DAS, impossible or required specialized and typically expensive software or controllers for device sharing. On the other side, utilization of the storage spread across the multiple servers was typically lower than on one single pool. Necessary expansions of storage volumes and replacement of the failed hard drives have, in DAS architecture, frequently generated system downtime. The DAS architecture is illustrated in Exhibit 196.1. The effort to get better usage out of storage devices by multiple hosts has generated specialized devices for shared storage access on the file level. This architecture is commonly referred as Network Attached Storage, abbreviated as NAS. NAS architecture consists of a dedicated device called Filer, which is actually a stripped-down and optimized host for very fast network file sharing. Two of the most typically supported file systems on Filers are NFS (Network File System) for the UNIX world and CIFS (Common Internet File System) for the Microsoft world. While the NAS solution has its simplicity in maintenance and installation as its main advantage, its main drawback is limited file and operating system support or support of future new file systems. The NAS architecture is illustrated in Exhibit 196.2. The latest mechanism for attaching storage remotely with block-level access is commonly referred to as a storage area network (or SAN). A SAN consists of hosts, switches, and storage devices. Hosts equipped with host bus adapters (HBAs) are attached via optical cable to storage switches, which act as a fabric between the hosts and the storage devices. SAN architecture is illustrated in Exhibit 196.3. The invention of Fibre Channel (FC) has opened up a completely new era in terms of the way the storage devices are connected to each other and to hosts. The first advantage was the greater distance (up to ten kilometers), while the different topologies also opened up a much bigger number of storage devices that could get connected and be shared among the multiple hosts.

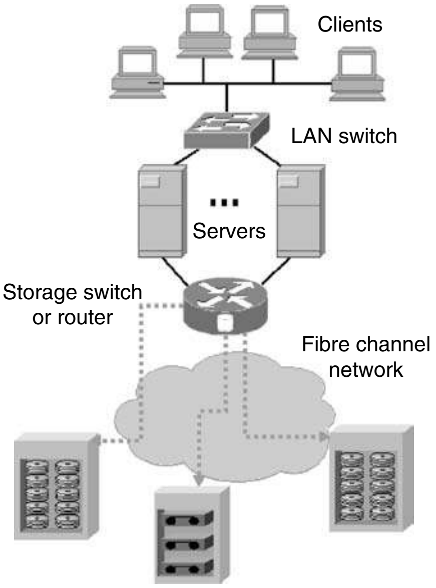

EXHIBIT 196.3 SAN architecture.

196.2.2 Small Computer Systems Interface (SCSI)

In the long history of adaptations and improvements, the line sometimes blurs between where one Small Computer System Interface (SCSI) ends and another begins. The original SCSI standard approved in 1986 by the American National Standards Institute (ANSI) supported transfer rates of up to 5 MBps which is, measured by today's standards, slow. Worse yet, it supported a very short bus length. When the original SCSI was introduced, however, it represented a significant improvement over what was available at that time, but the problem was that of compatibility—as many vendors offered their own unique SCSI options. The next generation of the SCSI standard, SCSI-2, incorporated SCSI-1 as its subset. In development since 1986, SCSI-2 gained final approval in 1994 and resolved many of the compatibility issues faced by the original SCSI-1. With SCSI-2, it was possible to construct more complex configurations using a mix of peripherals. The most noticeable benefit of SCSI-2 over SCSI-1 was its speed. Also called Fast SCSI, SCSI-2 typically supported bus speeds up to 10 MBps, but could go up to 20 MBps when combined with fast and wide SCSI connectors. Fast SCSI enabled faster timing on the bus (from 5 to 10 MHz), thereby providing for higher speed. Wide SCSI used an extra cable to send data that

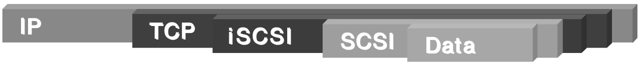

EXHIBIT 196.4 iSCSI encapsulation.

was 16 or 32 bits wide, which allowed for double or quadruple the speed over the bus versus standard, narrow SCSI interfaces that were only 8 bits wide. The latest specification of the SCSI protocol, SCSI-3, was, among other improvements, the first one that provided for a separation of the higher-level SCSI protocol from the physical layer. This was the prerequisite of giving alternatives to run SCSI commands on top of different physical layers than the parallel bus. Hence, the SCSI-3 specification was the basis of porting the SCSI protocol to different media carriers such as Fibre Channel, or even other transport protocols such as TCP/IP.

196.2.3 Internet SCSI

The SCSI-3 protocol has been mapped over various transports, such as parallel SCSI, IEEE-1394 (firewire), and Fibre Channel. All these transports have their specifics but also have limited distance capabilities. The Internet SCSI (iSCSI) protocol is the IETF draft standard protocol that describes the means of transporting SCSI packets over TCP/IP. The iSCSI interoperable solution can take advantage of existing IP network infrastructures, which have virtually no distance limitations. Encapsulation of SCSI frames in the TCP/IP protocol is illustrated in Exhibit 196.4. The primary market driver for the development of the iSCSI protocol was to enable broader access of the large installed base of DAS over IP network infrastructures. By allowing greater access to DAS devices over IP networks, storage resources can be maximized by any number of users or utilized by a variety of applications such as remote backup, disaster recovery, or storage virtualization. A secondary driver of iSCSI is to allow other SAN architectures such as Fibre Channel to be accessed from a wide variety of hosts across IP networks. iSCSI enables block-level storage to be accessed from Fibre Channel SANs using IP storage routers or switches, thereby furthering its applicability as an IP-based storage transport protocol.

iSCSI defines the rules and processes to transmit and receive block storage applications over TCP/IP networks. Although iSCSI can be supported over any physical media that support TCP/IP as a transport, most iSCSI implementations run on Gigabit Ethernet. The iSCSI protocol can run in software over a standard Gigabit Ethernet network interface card (NIC) or can be optimized in hardware for better performance on an iSCSI host bus adapter (HBA).

iSCSI enables the encapsulation of SCSI-3 commands in TCP/IP packets as well as reliable delivery over IP networks. Because it sits above the physical and data-link layers, iSCSI interfaces to the operating system's standard SCSI access method command set to enable the access of block-level storage that resides on Fibre Channel SANs over an IP network via iSCSI-to-Fibre Channel gateways, such as storage routers and switches. The iSCSI protocol stack building blocks are illustrated in Exhibit 196.5.

Initial iSCSI deployments were targeted at small to medium-sized businesses and departments or branch offices of larger enterprises that had not yet deployed Fibre Channel SANs. However, iSCSI is also an affordable way to create IP SANs from a number of local or remote DAS devices. If Fibre Channel is present, as it typically is in a data center, it could be also accessed by the iSCSI SANs via iSCSI-to-Fibre Channel storage routers and switches.

196.2.4 Fibre Channel

Fibre Channel (FC) is an open, industry standard, serial interface for high-speed systems. FC, a protocol for transferring the data over fiber cable, consists of multiple layers covering different functions. As a protocol between the host and a storage device, FC was really outside the scope of an average information technology professional for the simple reason that it was a point-to-point connection between the host

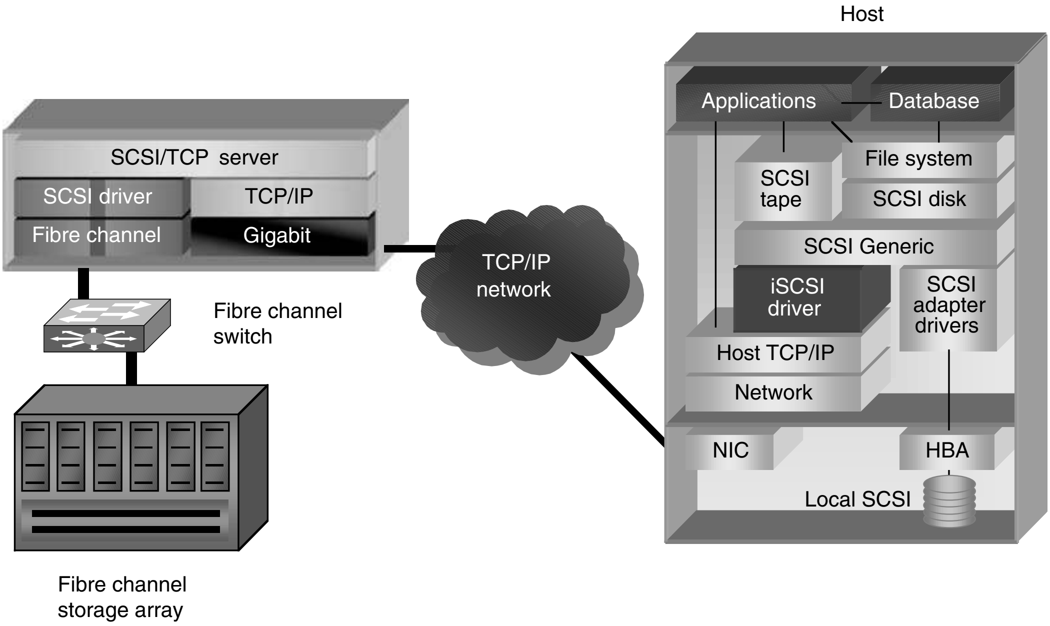

EXHIBIT 196.5 iSCSI solution architecture.

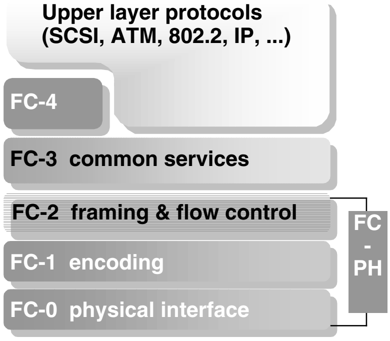
with an HBA and a storage device of typically the same vendor, which did not require any knowledge or understanding except maybe during the installation process. From a speed perspective, FC is already available in flavors of 1 GBps and 2 GBps, while specifications for 4 GBps as well as 10 GBps are being worked on and are not that far away.

The FC protocol stack is defined in a standard specification of a Technical Committee T11.3 of an INCITS (InterNational Committee for Information Technology Standards) and is illustrated in Exhibit 196.6.

The lowest level (FC-0) defines the physical link in the system, including the fiber, connectors, optical, and electrical parameters for a variety of data rates. FC-1 defines the transmission protocol, including serial encoding and decoding rules, special characters, and error control.

The signaling protocol (FC-2) level serves as the transport mechanism of Fibre Channel. It defines the framing rules of the data to be transferred between ports, the mechanisms for controlling the different service classes, and the means of managing the sequence of a data transfer.



Upper layer protocols (SCSI, ATM, 802.2, IP, ...)
FC-4
FC-3 common services
FC-2 framing & flow control

FC-0 physical interface
FC - PH

EXHIBIT 196. 6 Fibre Channel protocol stack.

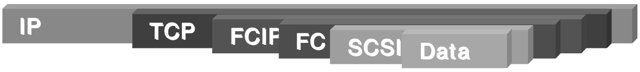

EXHIBIT 196.7 FCIP encapsulation.

The FC-3 level of the FC standard is intended to provide the common services required for advanced features, such as:

- *Striping*: to multiply bandwidth using multiple ports in parallel to transmit a single information unit across multiple links.
- *Hunt groups*: the ability for more than one port to respond to the same alias address. This improves efficiency by decreasing the chance of reaching a busy port.
- *Multicast*: Packet or message sent across a network by a single host to multiple clients or devices.

The FC-3 level was initially thought to also be used for encryption or compression services. However, the latest development has put these services into the level 2 of the FC architecture, as will be described later.

FC-4, the highest level in the FC structure, defines the application interfaces that can execute over Fibre Channel. It specifies the mapping rules of upper layer protocols such as SCSI, ATM, 802.2, or IP using the FC levels below.

196.2.5 Fibre Channel-over-TCP/IP

The Fibre Channel-over TCP/IP (FCIP) protocol is described in the IETF draft standard as the mechanisms that allow the interconnection of islands of Fibre Channel storage area networks over IP-based networks to form a unified storage area network in a single Fibre Channel fabric. Encapsulation of the FC frames that are carrying SCSI frames on top of the TCP is illustrated in Exhibit 196.7. FCIP transports Fibre Channel data by creating a tunnel between two endpoints in an IP network. Frames are encapsulated into TCP/IP at the sending end. At the receiving end, the IP wrapper is removed, and native Fibre Channel frames are delivered to the destination fabric. This technique is commonly referred to as tunneling, and has historically been used with non-IP protocols such as AppleTalk and SNA. Usage of the FCIP as well as iSCSI protocols is illustrated in Exhibit 196.8. The technology is implemented using FCIP gateways, which typically attach to each local SAN through an expansion-port connection to a Fibre

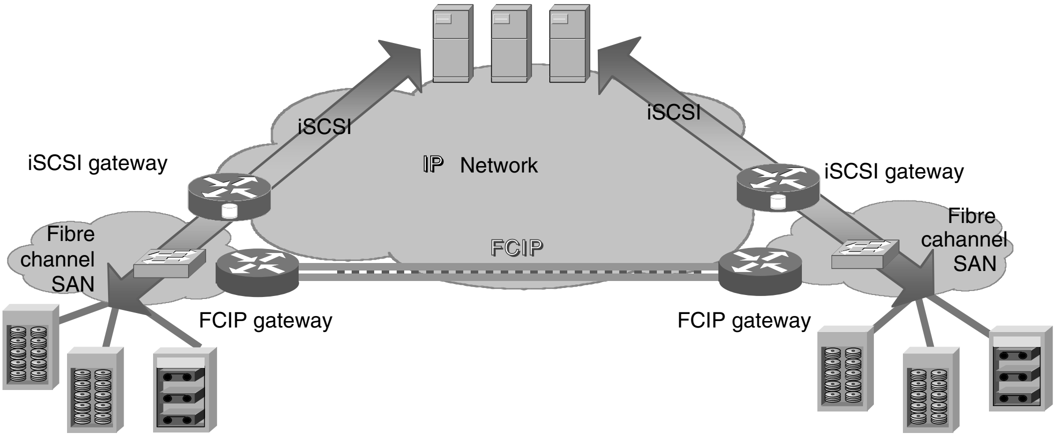

EXHIBIT 196. 8 FCIP and iSCSI solution architecture.

Channel switch. All storage traffic destined for the remote site goes through the common tunnel. The Fibre Channel switch at the receiving end is responsible for directing each frame to its appropriate Fibre Channel end device.

Multiple storage conversations can concurrently travel through the FCIP tunnel, although there is no differentiation between conversations in the tunnel. An IP network management tool can view the gateways on either side of the tunnel, but cannot look in on the individual Fibre Channel transactions moving within the tunnel. The tools would thus view two FCIP gateways on either side of the tunnel, but the traffic between them would appear to be between a single source and destination—not between multiple storage hosts and targets.

Connecting Fibre Channel switches creates a single Fibre Channel fabric analogous to bridged LANs or other layer 2 networks. This means that connecting two remote sites with FCIP gateways creates one Fibre Channel fabric that can extend over miles. This preserves Fibre Channel fabric behavior between remote locations but could leave the bridged fabric vulnerable to fabric reconfigurations or excessive fabric-based broadcasts.

196.2.6 Other SAN Protocols

There are several other SAN protocols in IETF draft proposal stage or development, including Internet Fibre Channel Protocol (iFCP) and Internet Storage Name Services (iSNS). iFCP is also a gateway-to-gateway approach in which FC frames are encapsulated directly into IP packets, and IP addresses are mapped to FC devices. iFCP is a more iP-oriented scheme than the FCIP tunneled SCSI frames but is a more complex protocol that was designed to overcome the potential vulnerabilities of stretched fabrics, enable multi-point deployments, and provide native IP addressing to individual Fibre Channel transactions.

The iSNS protocol is used for interaction between iSNS servers and iSNS clients to facilitate automated discovery, management, and configuration of iSCSI and FC devices on a TCP/IP network. iSNS provides intelligent storage discovery and management services comparable to those found in FC networks, allowing a commodity IP network to function in a similar capacity to a storage area network. iSNS also facilitates seamless integration of IP and FC networks, due to its ability to emulate FC fabric services, and manage both iSCSI and Fibre Channel devices. iSNS thereby provides value in any storage network comprised of iSCSI devices, Fibre Channel devices (using iFCP gateways), or any combination thereof. iFCP requires iSNS for discovery and management, while iSCSI may use iSNS for discovery, and FCIP does not use iSNS.

196.3 SAN Security Threats Analysis

Security is a key issue for wide acceptance when it comes to SAN technologies. According to numerous market surveys, the main reason why most enterprises have not yet deployed SANs is due to security concerns. When SAN technology was introduced, security was routinely ignored. This was partly because the largely unknown Fibre Channel protocol used for communication was not a big target for attackers, and also mainly because security simply was not a priority. Today, when SANs are starting to reach across the country and even around the globe, storing and transferring terabytes of sensitive and confidential data may quickly draw the attention of potential attackers. When the underlying protocol carrying the data over long distances and out of the glass room does not provide the essential data protection mechanism, data in transit is exposed to the threat of being stolen, seen by an unintended party, modified, or simply not being available when it is needed. Logical instead of physical attachment of the storage devices also opens issues of access control and authentication of the remote nodes exchanging the data. Moving SAN communications to IP-based networks makes it even more exposed and vulnerable to many of the attacks made on corporate networks.

196.3.1 Availability

With a SAN technology, storage devices could be reached through several possible redundant paths, as well as easily shared between multiple hosts and simultaneously accessed by multiple clients. It is no longer necessary to bring critical hosts down to be able to replace broken storage devices or expand their capacity. With such features, one might say that SAN technology has, by decoupling the storage from hosts, achieved the greatest level of storage availability. However, one must also keep in mind that by moving storage communication protocols to run on top of TCP/IP, one has also inherited the threats and exposures of the TCP/IP environment. One can look at the threats and exposures from two perspectives: (1) exposures to data running on top of TCP, as well as (2) exposure to SAN infrastructure devices. It is important to look at the mechanisms that are available—or not available—within each of the SAN carrier protocols for protecting the storage devices against the availability attacks. With the introduction of storage switches and routers as new infrastructure devices also managed via TCP/IP protocol, it is vital to have proper availability protection mechanisms in place on their management channels as well as to have access control mechanisms and different role levels for their configuration control management.

196.3.2 Confidentiality and Integrity

IP networks are easy to monitor but are also easy to attack. One of the major issues introduced by running SANs over IP networks is the opportunity to sniff the network traffic. All IP-based storage protocols just encapsulate the SCSI frames on top of TCP but do not provide any confidentiality or integrity protection. The same can be said for Fibre Channel communication. Although it is much more difficult than sniffing an IP-based network, it is also possible to sniff a Fibre Channel network. Hence, both IP- as well as FC-based SANs require additional traffic protection mechanisms regarding the confidentiality as well as integrity of the data.

196.3.3 Access Control and Authentication

Another critical aspect of SAN security is authorization and authentication—controlling who has access to what within the SAN. Currently, the level of authentication and authorization for SANs is not as detailed and granular as it should be. Most security relies on measures implemented at the application level of the program requesting the data, not at the storage device, which leaves the physical device vulnerable.

Moving SAN communications to IP-based networks makes them even more exposed and vulnerable to attacks made on corporate networks, such as device identity spoofing. Each of the technologies, such as iSCSI as well as FC or FCIP, has its own mechanisms of how to address the remote node authentication requirements or it relies on other protocols such as IP Security (IPSec) protocol.

196.4 Storage Area Network Security Mechanisms

The basic rules of security also apply to SANs. Just because the technology is relatively new, the security principles are not. First, SAN devices should be physically secured. This was relatively simple to accomplish when SANs existed mainly in well-protected data centers. But as SANs grow more distributed and their devices sit in branch office closets, physical security is tougher to guarantee. On top of that, each of the protocols mentioned thus far has its own subset of security mechanisms.

196.5 Securing FC Fabric

By itself, Fibre Channel is not a secure protocol. Without implementing certain security measures within a Fibre Channel SAN, hosts will be able to see all devices on the SAN and could even write to the same physical disk. The two most common methods of providing logical segmentation on a Fibre Channel SAN are zoning and LUN (logical unit number) masking.

196.5.1 Zoning

Zoning is a function provided by fabric switches that allows segregation of a node in general by physical port, name, or address. Zoning is similar to network VLANs (virtual LANs), segmenting networks and controlling which storage devices can be accessed by which hosts. With zoning, a storage switch can be configured, for example, to allow host H1 to talk only with storage device D1, while host H2 could talk only to storage device D2 and D3, as illustrated in Exhibit 196.9. Single host or storage device could also belong to multiple zones, as for example in the same figure, device D1 belonging to Zone A as well as to Zone B. Zoning can be implemented using either hardware or software; hence one can distinguish two main types of zoning within FC: "soft" zoning and "hard" zoning.

Soft zoning refers to software-based zoning; that is, zoning is enforced through control-plane software on the FC switches themselves—in the FC Name Server service. The FC Name Server service on a Fibre Channel switch does mapping between the 64-bit World Wide Name (WWN) addresses and Fibre Channel IDs (FC_ID). When devices connect to an FC fabric, they use the name server to find which FC_ID belongs to a requested device WWN. With soft zoning, an FC switch responding to a name server query from a device will only respond with a list of those devices registered in the name server that are in the same zone(s) as that of the querying device. Soft zoning is, from a security perspective, only limiting visibility of the devices based on the response from the name server and does not in any other way restrict access to the storage device from an intentional intruder. This is the job of *hard zoning*, which refers to hardware-based zoning.

Hard zoning is enforced through switch hardware access ports or Access Control Lists (ACLs) that are applied to every FC frame that is switched through the port on the storage switch. Hardware zoning therefore has a mechanism that not only limits the visibility of FC devices, but also controls access and restricts the FC fabric connectivity to an intentional intruder.

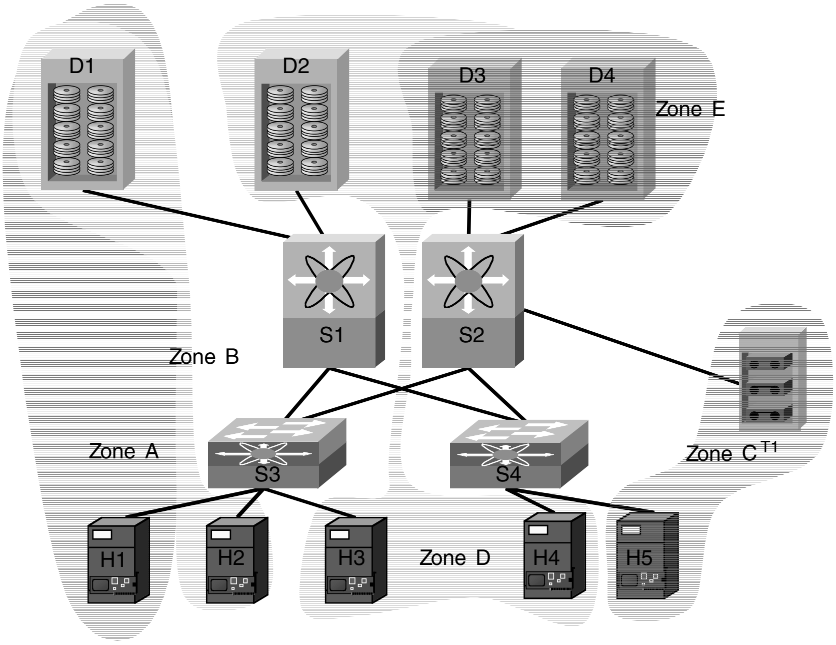

EXHIBIT 196.9 FC zoning example.

FC zoning should always be deployed in FC fabric—if not from a node isolation perspective, then for the purpose of minimizing the loss of data. In general, it is also recommended that as many zones are used as there are hosts communicating with storage devices. For example, if there are two hosts each communicating with three storage devices, it is recommended that two zones be used.

196.5.2 LUN Masking

To further protect the SAN, LUN (logical unit number) masking can be used to limit access to storage devices. LUN masking is an authorization process that makes a LUN available to some hosts and unavailable to other hosts. LUN masking is important because Microsoft Windows-based hosts attempt to write volume labels to all available LUNs. This can render the LUNs unusable by other operating systems and can result in data loss. LUN masking goes one step beyond zoning by filtering access to certain storage resources on the SAN and can also be provided through hardware (i.e., intelligent bridges, routers, or storage controllers) or through software, utilizing a piece of code residing on each computer connected to the SAN. For each host connected to the SAN, LUN masking effectively masks off the LUNs that are not assigned to the host, allowing only the assigned LUNs to appear to the host's operating system. The hardware connections to other LUNs still exist but the LUN masking makes those LUNs invisible. Managing paths by LUN masking is a reasonable solution for small SANs; however, due to the extensive amount of configuration and maintenance involved, it is cumbersome for larger SANs.

Although zoning and LUN masking provide one layer of SAN device separation, they are not exclusive security mechanisms but rather isolation mechanisms, and as such they do not give any granular control over data access. Overall SAN security depends on the security of the hosts accessing the storage devices, especially if specific controls are not in place to protect the data. Consider the following zoning example. If host H1 can access storage device D1, an unauthorized user or an attacker who compromises host H1 will be able to access any data on storage device D1. For SANs to be secure, there must be control that requires proper authorization and authentication to access any data on the storage device, regardless of where the request is originating. It is also needed to limit access to a SAN so that only authenticated and authorized nodes could join the FC fabric as well as protect the confidentiality and integrity of the data in transport through the fabric. These security mechanisms are addressed in "Work in Progress" in the Fibre Channel Security Protocol (FC-SP) specification.

196.5.3 Fibre Channel Security Protocols

To address additional security concerns of FC fabric, top SAN industry players have developed the Fibre Channel Security Protocol (FC-SP) specification, which is the effort of a working group of the International Committee for Information Technology Standards (INCITS) T11.3 Committee. The result is the draft of the future FC-SP standard that extends the Fibre Channel architecture with:

- Switch-to-switch, switch-to-device, and device-to-device authentication
- Frame-by-frame FC-2 level encryption that provides origin authentication, integrity, anti-replay, and privacy protection to each frame sent over the wire
- Consistent and secure policy distribution across the fabric

With implementing FC-SP, switches, storage devices, and hosts will be able to prove their identity through a reliable and manageable authentication mechanism. FC-SP can protect against impersonation attacks from rogue hosts, disks, or fabric switches, as well as provide protection from common misconfigurations when cabling devices in a fabric. With FC-SP, Fibre Channel traffic can be secured on a frame-by-frame basis to prevent snooping and hijacking, even over nontrusted links. A consistent set of policies and management actions are propagated through the fabric to provide a uniform level of security across the entire fabric. FC-SP includes support for data integrity, authentication for both switch-to-switch and host-to-switch communication, as well as optional confidentiality.

196.5.3.1 FC-SP Authentication and Key Management Protocols

Authentication is the process by which an entity is able to verify the identity of another entity. As such, authentication is the foundation of security. A Fibre Channel device can authenticate the entity trying to access resources by verifying its identity. Different authentication protocols can be used to validate an entity on the basis of different parameters. Each Fibre Channel entity is identified by a name. The purpose of an authentication protocol for Fibre Channel is to verify, using some form of digital credentials, that a claimed name is associated with the claiming entity. FC-SP specifies three optional authentication mechanisms, the first role of which is to address the threat of identity spoofing within or when accessing the FC fabric.

196.5.3.2 Diffie–Hellman Challenge Handshake Authentication Protocol (DH-CHAP)

The Diffie–Hellman Challenge Handshake Authentication Protocol (DH-CHAP) is a password-based authentication and key management protocol that uses the CHAP algorithm (RFC 1994) augmented with an optional Diffie–Hellman algorithm. DH-CHAP provides bi-directional, and optionally uni-directional, authentication between an authentication initiator and an authentication responder. To authenticate with DH-CHAP, each entity, identified by a unique name, is provided with a secret. Each other entity that wants to verify that entity will know the secret associated with that name or defer the verification to a third party, such as a RADIUS or TACACS+ server that knows that secret. When the Diffie–Hellmann part of the protocol is not performed, DH-CHAP reduces its operations to those of CHAP, and it is referred to as DH-CHAP with a null DH algorithm. DH-CHAP with a null DH algorithm is the authentication protocol that is mandatory to implement in each FC-SP-compliant implementation, for interoperability reasons. DH-CHAP has other parameters that are possible to negotiate such as the list of hash functions (e.g., SHA1, MD5) and the list of the usable Diffie–Hellman Group Identifiers. Possible Diffie–Hellman Group Identifiers include 1, 2, 3, or 4, with group bit sizes of 1024, 1280, 1536, and 2048, respectively.

196.5.3.3 Fibre Channel Authentication Protocol

Fibre Channel Authentication Protocol (FCAP) is an optional authentication and key management protocol based on digital certificates that occurs between two Fibre Channel endpoints. When the FCAP successfully completes, the two Fibre Channel endpoints are mutually authenticated and may share a secret key.

To authenticate with the FCAP, each entity, identified by a unique name, is provided with a digital certificate associated with its name, and with the certificate of the signing Certification Authority (CA). Each other entity that wants to participate in FCAP is also provided with its own certificate, as well as the certificate of the involved Certification Authority for the purpose of the other entity certificate verification. At this time in FC-SP specification, the only supported format of the digital certificate is X.509v3. FCAP is, for the purpose of the shared secret derivation, also using the Diffie–Hellman algorithm. For hashing purposes, FCAP uses the RSA-SHA1 algorithm.

196.5.3.4 Fibre Channel Password Authentication Protocol (FCPAP)

The Fibre Channel Password Authentication Protocol (FCPAP) is an optional password-based authentication and key management protocol that uses the Secure Remote Password (SRP) algorithm as defined in RFC 2945. FCPAP provides bi-directional authentication between an authentication initiator and an authentication responder. For hashing purposes, FCPAP relies on the SHA-1 algorithm. When the FCPAP successfully completes, the authentication initiator and responder are authenticated and, using the Diffie–Hellman algorithm, have obtained a shared secret key. Parameters for authentication in the SRP algorithm are a password, a salt, and a verifier. To authenticate with FCPAP, each entity, identified by a unique name, is provided with a password. Each other entity that wants to verify that entity is provided with a random salt, and a verifier derived from the salt and the password.

EXHIBIT 196.10 FC-SP Authentication and Key Management Protocols

FC-SP Authentication Protocol	Authentication Mechanism	Hashing Mechanism	Key Exchange Mechanism
DH-CHAP	RFC 1994, CHAP	MD5, SHA-1	DH
FCAP	x509v3 certificates	RSA-SHA1	DH
FCPAP	RFC 2945, SRP	SHA-1	DH

196.5.3.5 FC-SP Authentication Protocols Comparison

As listed, each of the authentication protocols have their similarities and differences, depending on what mechanism they use for the authentication as well as hashing. These are illustrated in Exhibit 196.10.

As also seen, by using a Diffie–Hellman algorithm, all three authentication protocols are capable of performing not only initial mutual entity authentication, but are also capable of doing key exchange and deriving the shared secret that can be used for a different purpose, such as per-frame integrity and confidentiality.

196.5.3.6 FC-SP per-Frame Confidentiality and Integrity

Recognizing the need for per-message protection that would secure each FC frame individually, top storage vendors such as Cisco Systems, EMC, QLogic, and Veritas proposed an extension to the FC-2 frame format that allows for frame-by-frame encryption. The frame format has been called the ESP Header, because it is very similar to the Encapsulating Security Payload (ESP) used to secure IP packets in IPSec. Given that the overall security architecture is similar to IPSec, this aspect of the security architecture for FC is often referred to as FCSec.

The goals of the FCSec architecture are to provide a framework to protect against both active and passive attacks using the following security services:

- Data origin authentication to ensure that the originator of each frame is authentic
- Data integrity and anti-replay protection, which provide integrity and protects each frame transmitted over a SAN
- Optional encryption for data and control traffic, which protects each frame from eavesdropping

The goal of FCSec is also to converge the storage industry on a single set of security mechanisms, regardless of whether the storage transport is based on iSCSI, FCIP, or FC, so that FCSec could be layered onto existing applications with minimal or no changes to the underlying applications.

One of the main benefits of using ESP to secure an FC network is its great flexibility; it can be used to authenticate single control messages exchanged between two devices, to authenticate all control traffic between two nodes, or to authenticate the entire data traffic exchanged between two nodes. Optional encryption can be added to any of the steps above to provide confidentiality.

A per-entity authentication and key exchange protocol also provides a set of other services, including the negotiation of the use of ESP for encapsulation of FC-2 frames, the exchange of security parameters to be used with the ESP encapsulation protocol, and the capability to update keys used by the two entities without any disruption to the underlying traffic flow.

ESP is used as a generic security protocol. Independently from the upper layers, ESP can provide the following:

- *Per-message integrity, authentication, and anti-replay.* When used with a null encryption algorithm and an HMAC authentication algorithm, it guarantees that the frames have not been altered in transit, are authenticated for the originating entity, and belong to the same sequence exchange.
- *Traffic encryption.* When used with a non-null encryption algorithm such as AES, Triple DES, or RC5, it allows the encryption of the frame content.

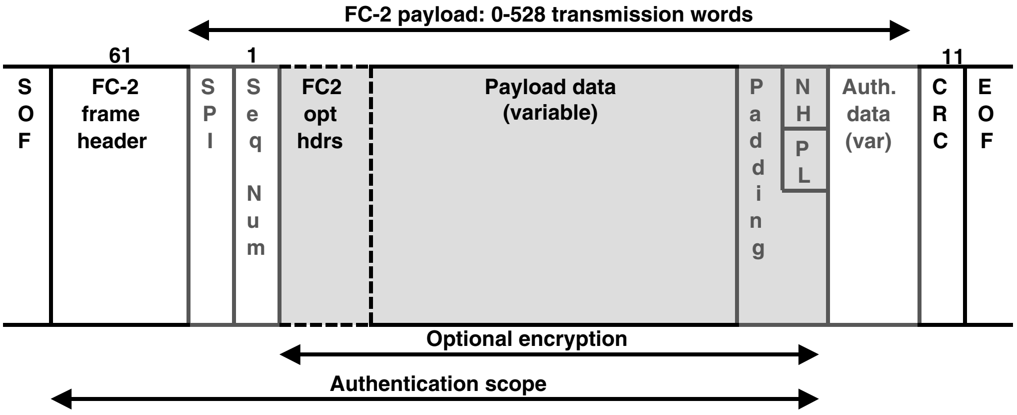

EXHIBIT 196. 11 Fibre Channel Security Protocol frame.

The specific fields covered by authentication, as well as fields that can optionally be encrypted within the FC-SP frame, are illustrated in Exhibit 196.11. While IPSec is briefly discussed later, it is important to note here the major differences between the IPSec ESP and FCSec in the role of authentication and confidentiality. FCSec frame format gives authentication the complete frame, including the header of the frame, and has mandatory authentication, while encryption is optional. On the other side, IPSec ESP header does not offer the authentication of the packet header. For that purpose, IPSec uses the Authentication Header (AH); and while ESP mandates encryption, it has an optional authentication for the rest of the packet payload.

196.5.4 Securing Storage over IP Protocols

With the exception of initial session log-in authentication, none of the other IP-based SAN protocols—iSCSI, iFCP, FCIP, or iSNS—defines its own per-packet authentication, integrity, confidentiality, or anti-replay protection mechanisms. They all rely on the IPSec protocol suite to provide per-packet data confidentiality, integrity, authentication, and anti-replay services, together with Internet Key Exchange (IKE) as the key management protocol.

The IP Storage Working Group within the Internet Engineering Task Force (IETF) has developed a framework for securing IP-based storage communications in a draft proposal entitled “Securing Block Storage Protocols over IP.” This proposal covers the use of the IPSec protocol suite for protecting block storage protocols over IP networks (including iSCSI, iFCP, and FCIP), as well as storage discovery protocols (iSNS).

196.5.5 IP Security Protocol Overview

This chapter is by no means an extensive IP Security (IPSec) protocol description but rather an overview of the elements that are necessary to understand its usage for storage over IP protocols protection. IPSec is applied at the network layer, protecting the IP packets between participating IPSec peers by providing the following:

- *Data confidentiality.* The IPSec sender can encrypt packets before transmitting them across a network.
- *Data integrity.* The IPSec receiver can authenticate packets sent by the IPSec sender to ensure that the data has not been altered during transmission.
- *Data origin authentication.* The IPSec receiver can authenticate the source of the IPSec packets sent.
- *Anti-replay.* The IPSec receiver can detect and reject replayed packets.

To achieve the listed functions, the IPSec protocol uses:

- Diffie–Hellman key exchange for deriving key material between two peers on a public network
- Public key cryptography or preshared secret for signing the Diffie–Hellman exchanges to guarantee the identities of the two parties and avoid man-in-the-middle attacks
- Bulk encryption algorithms, such as DES (Data Encryption Standard), 3DES (Triple DES), or AES (Advance Encryption Standard) for encrypting data
- Keyed hash algorithms, such as HMAC (Hashed Message Authentication Code), combined with traditional hash algorithms such as MD5 (Message Digest 5) or SHA1 (Secure Hashing Algorithm 1) for providing packet integrity and authentication

The IPSec framework consists of two major parts:

1. Internet Key Exchange (IKE), which negotiates the security policies between two entities and manages the key material
2. IP Security Protocol suite, which defines the information to add to an IP packet to enable confidentiality, integrity, anti-replay, and authenticity controls of the packet data

IKE is a two-phase negotiation protocol based on the modular exchange of messages defined in RFC 2409. It has two phases and accomplishes the following three functions in its Phase 1 and the fourth one in Phase 2:

1. *Protected cipher suite and options negotiation*: using keyed MACs, encryption, and anti-replay mechanisms.
2. *Master key generation*: via Diffie–Hellman calculations.
3. *Authentication of endpoints*: using preshared secret or public key cryptography.
4. *IPSec Security Association (SA) management* (traffic selector negotiation, options negotiation plus key creation, and deletion).

IPSec is adding two new headers to the IP packet:

1. AH (Authentication header)
2. ESP (Encapsulation Security Payload) header

The **AH header** provides authentication, integrity, and replay protection for the IP header as well as for all the upper-layer protocols of an IP packet. However, it does not provide any confidentiality to them. Confidentiality is the task of the **ESP header**, in addition to providing authentication, integrity, and replay protection for the packet payload. Both headers can be used in two modes: Transport and Tunnel Modes. The **Transport Mode** is used when both the communicating peers are hosts. It can also be applied when one peer is a host and the other is a gateway, if that gateway is acting as a host or ending point of the communication traffic. The Transport Mode has the advantage of adding only a few bytes to the header of each packet. With this choice, however, the original IP packet header can only be authenticated but not encrypted. The **Tunnel Mode** is used between two gateway devices, or between a host and a gateway if that gateway is the conduit to the actual source or destination. In Tunnel Mode, the entire original IP packet is encrypted and becomes the payload of a new IP packet. The new IP header has the destination address of its IPSec peer. All information from the original packet, including the headers, is protected. The Tunnel Mode protects against attacks on the endpoints due to the fact that, although the IPSec tunnel endpoints can be determined, the true source and destination endpoints cannot be determined because the information in the original IP header has been encrypted. This is illustrated in Exhibit 196.12.

With IPSec, data can be transmitted across a public network without fear of observation, modification, or spoofing. This enables applications such as virtual private networks (VPNs), including intranets, extranets, remote user access, and remote transport of storage over IP.

The IETF draft RFC is dictating that IPSec and IKE be used with the IP-based storage protocols to provide secure private exchanges at the IP layer. To be compliant, an IP storage network element must

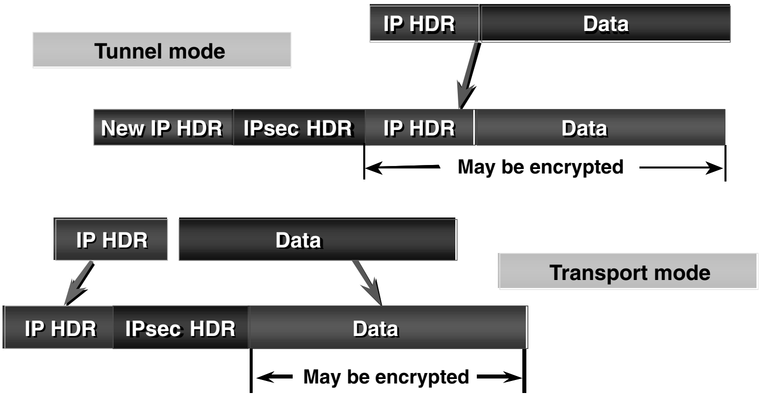

EXHIBIT 196.12 IPSec Transport and Tunnel Mode.

follow the specifications and implement IPSec Tunnel Mode with the ESP where confidentiality is obtained by encrypting the IPSec tunnel using 3DES or, optionally, AES in Cipher Block Chaining (CBC) Mode; integrity checking is done using SHA-1; and node authentication is done via IKE using a preshared key or digital certificates.

196.5.6 iSCSI Security Mechanisms

The iSCSI Internet draft specifies that although technically possible, iSCSI should not be used without security mechanisms, except only in closed environments without any security risk. Security mechanisms defined in the draft standard include the following:

- In-band authentication between the initiator and the target at the iSCSI connection level
- Per-packet protection (integrity, authentication, and confidentiality) by IPSec at the IP level

The iSCSI protocol specification defines that during log-in, the target must authenticate the initiator and the initiator may authenticate the target, which means that mutual authentication is optional but not mandatory. The authentication is performed on every new iSCSI connection during the log-in process with a chosen authentication method. The authentication method cannot assume any underlying IPSec protection, because the use of IPSec is optional and an attacker should gain as little advantage as possible by inspecting the authentication process. Due to listed requirements, the chosen authentication method for the iSCSI protocol is Challenge Handshake Authentication Protocol (CHAP). The authentication mechanism protects against an unauthorized log-in to storage resources using a false identity (spoofing). Once the authentication phase is complete, if the underlying IPSec is not used, all subsequent messages are sent and received in clear text. The authentication mechanism alone, without underlying IPSec, should only be used when there is no risk of eavesdropping, message insertion, deletion, modification, or replaying.

An iSCSI node must also support the Internet Key Exchange (IKE) protocol to provide per-packet authentication, security association negotiation, and key management where a separate IKE phase 2 security association protects each TCP connection within an iSCSI session.

196.5.7 iFCP, FCIP, and iSNS Security Mechanisms

iFCP and FCIP are peer-to-peer transport protocols that encapsulate SCSI and Fibre Channel frames over IP. Therefore, Fibre Channel, the operating system, and user identities are transparent to the iFCP and FCIP protocols. iFCP and FCIP sessions can be initiated by either or both peer gateways. Consequently, bi-directional authentication of peer gateways must be provided. There is no requirement that the identities used in authentication be kept confidential. Both iFCP and FCIP, as well as the iSNS protocol, heavily rely on IPSec and IKE to provide security mechanisms for them. To be compliant with security specifications in their draft RFCs, storage nodes using any of the three IP storage protocols must implement IPSec ESP in Tunnel Mode for providing data integrity and confidentiality. They can implement IPSec ESP in Transport Mode if deployment considerations require the use of Transport Mode. When ESP is utilized, per-packet data origin authentication, integrity, and replay protection also must be used. For message authentication, they must implement HMAC with SHA-1, and should implement AES in CBC MAC mode. For ESP confidentiality, they must implement 3DES in CBC mode and should implement AES in CTR mode. For key management, entities must support IKE with peer authentication using preshared key and may support peer authentication using digital certificates.

196.6 Storage Security Standard Organizations and Forums

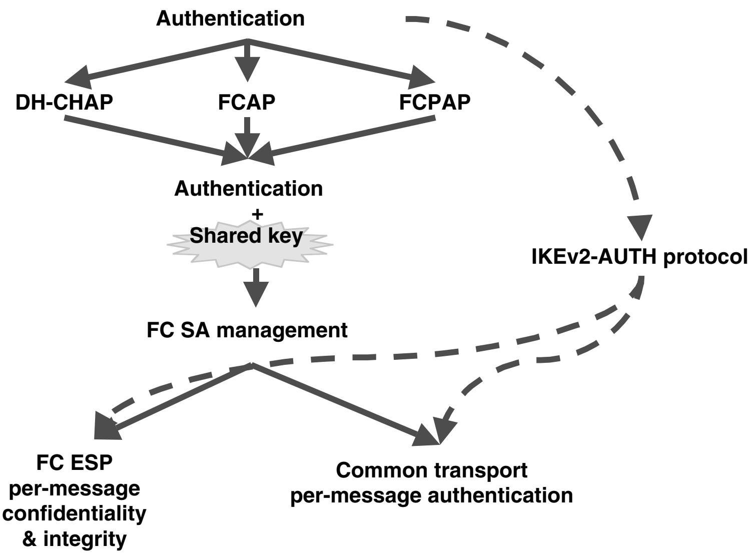
All IP-related protocols are under development within the Internet Engineering Task Force (IETF) working groups. This includes iSCSI, FCIP, and iFCP protocols, as well as IPSec and interaction of IP storage protocols with IPSec and IKE. On the other hand, FC, FC-SP, and SCSI specifications are developed within the American InterNational Committee for Information Technology Standards (INCITS) technical committees. The INCITS is the forum of choice for information technology developers, producers, and users for the creation and maintenance of formal *de jure* IT standards. INCITS is accredited by, and operates under rules approved by, the American National Standards Institute (ANSI) and is ensuring that voluntary standards are developed by the consensus of directly and materially affected interests.

Multiple specifications in different standard bodies as well as numerous vendor implementations obviously require standards to drive the interoperability of the products. The lack of interoperability among storage devices also creates security problems. Each vendor designs its own technology and architecture, which makes communication between devices difficult, if not impossible.

Forums and vendor associations are luckily smoothing things. The Storage Networking Industry Association (SNIA) is a nonprofit trade association established in 1997 that is working on ensuring that storage networks become complete and trusted solutions across the IT community, by delivering materials and educational and information services to its members. The SNIA Storage Security Industry Forum (SSIF) is a vendor consortium dedicated to increasing the availability of robust storage security solutions. The forum tries to fulfill its mission by identifying best practices on how to build secure storage networks and promoting standards-based solutions to improve the interoperability and security of storage networks.

196.7 Future Directions

Storage security is still an evolving topic and security mechanisms defined in the draft standards are yet to be implemented, as well as their interoperability being tested and approved by storage security forums. We have also seen that most IP-based storage network protocols rely on IPSec for protection. While IPSec is currently a well-defined and accepted set of standards, it is also developing further with a new key management specification, IKEv2. FC-SP is following the example set by IPSec by allowing in its latest specification the use of IKEv2 as its security policy distribution and key management protocol. All the FC-SP options are illustrated in Exhibit 196.13. An FC Security Association (SA) management protocol is actually a simplified version of the Internet Key Exchange protocol version 2 (IKEv2) that builds on the results of the FC authentication and key management protocol. The SA management protocol uses an obtained shared secret key as the authentication principle to set up the Security Associations. There are situations where it is acceptable to use IKEv2 to perform both functions: authentication and SA



Authentication

Common transport per-message authentication

EXHIBIT 196. 13 FC SP policy distribution and key management options.

management. This is referred to as a protocol called IKEv2-AUTH. On a side of SAN security protocols development, it is also necessary that hardware implementations follow up the software ones, because only when the security mechanisms are built-in in silicon will the SAN technology leverage the full benefit of them. Most of the future development in the SAN security area lies on the side of protecting the data while it is stored on disk, which requires further research of the group key management protocols and their implementation on SAN technology.

196.8 Summary

Although SAN technologies and protocols are relatively new, the security threats they are exposed to are not so new. This, in particular, is true once the storage data leaves the protection space of the data center's glass room and traverses the external, most of the time security-wise uncontrolled and unprotected network segments. The good news is that SAN technologies and protocols are already fairly well equipped with proper security mechanisms in most aspects. Although all of the security mechanisms, such as node authentication, data integrity, and confidently, are not built-in in all storage protocols themselves, especially when they are carried on top of IP, there are pretty mature specifications coming from international standardization organizations such as the IETF and INCITS that well define how they should be extended or be used in conjunction with IPSec and IKE protocols as their protection mechanisms. Native SAN fabric protocol FC is, on the other hand, either already leveraging the development of IPSec in a form of FCSec protocol or closely following the development in the key management and policy distribution area with the next-generation Internet Key Management protocol, IKEv2. This all promises a unified level of storage data protection traveling over different media carriers and encapsulation protocols. It is now up to industry forums such as the SNIA and SSIF to evangelize the security best practices and guidelines to use when designing, deploying, or maintaining SANs. Information security professionals must be aware that the data stored or traversing the SAN technologies is exposed to security threats and understand and use all possible tools, protocols, and mechanisms for their protection.

Operations: The Center of Support and Control

Kevin Henry

The operations security domain encompasses all of the other domains of information systems security. This domain is where theory and design meet the reality of daily operations. Ideas, once only a concept, become a critical part of an organization's infrastructure. The policies and procedures developed in a conference room or through a rigorous review and approval process are enacted for the benefit and protection of the organization, the employees, and the various other stakeholders.

Operations entails control, procedures, and monitoring. It involves support for users, communication with outside business partners, emergency actions and response, and in many cases 24-hour vigilance.

There are several areas of operations security that we will look at in this chapter: the importance and types of controls, the role of production support, the use of good supervision, and the protection and continuity of business operations through backups, maintenance, and incident response.

The operations group has evolved over the years from a console-based mainframe administration group to the widespread network administration techies that provide critical support for users halfway around the globe. However, regardless of the environment, whether mainframe, single office, or multinational and multiple platform organizations, the key elements are the same. The operators (for the most part I will include only network administrators in this group) have high-level access and the ability to make or break many companies by virtue of this level of access. Operators execute tasks that often require some of the highest levels of authority on the system. They can see, touch, and alter almost anything. They are required to make decisions in pressure situations that may affect the ability of the organization to continue normal or alternative business operations.

The importance of an understanding of security and best practices is crucial for operations personnel. Operators need to be aware of availability, and their critical role in keeping systems running. They need to understand the risks of disclosure and the need to enforce confidentiality, which includes the concepts of privacy, secrecy, and trust (or confidence). Organizations are under increasing pressure to maintain the privacy of individuals—whether they are customers or employees. Many organizations are either required to, or have chosen to, declare their privacy policy. This is a meaningful statement and the operations group needs to be aware of the risks and potential liabilities to the organization if these policies are violated or disregarded. An organization often depends on the confidence of its customers. A foolish or negligent act—or even a perceived breach of this confidence—may impair the business activity of the organization for years to come. The final part of the information security triad is integrity. Integrity in this instance includes proper, accurate, or reliable processing, change control, storage, and behaviors. Often an operations group may be bound by Service Level Agreements (SLAs) and a failure to provide the contracted level of service prescribed in the SLA can affect the respect, reputation, and even financial viability of an operations group.

Many organizations today outsource operations and network admin functions. This chapter does not deal extensively with outsourcing; however, the concepts and requirements are in many ways similar. Outsource suppliers need to respect and honor contractual obligations and provide the required level of service and support. Suppliers may need to provide more than basic functionality—they may need to provide advice, warnings, recommendations, expertise, and value-added services. They may be the source of hardware, software, and applications support, but moreover they may be providing the expertise and technical skills an organization relies on. No doubt this is a responsible and challenging role.

The firm that has decided to choose an outsourcing solution is relying on the strength of another company to provide the support and service it requires. This decision may have been based on a need for expertise the firm did not have in-house; it may have been a financial decision; it may have been in response to an immediate need that could not be provided through other channels. Whatever the reason for choosing an outsource solution, the organization is under the same pressure it would be if it was an in-house support group—that is, ensuring that the promised services are delivered and that the services meet the cultural, operational, and security requirements of the organization.

197.1 Controls

We will take a look at types of controls and how they may be used in an operations setting. First of all, it is important that controls are seen as a tool to be used prudently and reasonably. A control is a restriction or restraint. Moreover, a control is required to be used as a response to a risk. Once a risk has been identified—that is, we have established what the threats are and the likelihood that these threats will become a reality (or exposure)—then we need to set up controls to respond to these risks. A control may try to prevent a risk or it may be a way to detect a problem.

197.1.1 Preventive Controls

An ounce of prevention is worth a pound of cure. A preventive control is designed to stop an event from happening. It is a type of proactive control that relies on the establishment of procedures and tools that, hopefully, will catch and stop an adverse event from affecting the organization. There are many types of preventive controls and they are continuously changing as the risk environment, threats, cultures, markets, and regulatory conditions change. For example, a programmer who includes an edit in the data entry fields of an online system has implemented a preventive control.

197.1.2 Detective Controls

A detective control recognizes that some untoward activity either has taken place or is taking place, and institutes mechanisms to report, mitigate, limit, or contain the damage. It may also include logging or tracking functionality to record the details of the activity for use in subsequent analysis or possible disciplinary action. Detective controls include reviews and comparisons, audits, account reconciliations, input edit checks, checksums, and message degests.

197.1.3 Corrective Controls

Corrective controls are used when an event has caused some damage and it is necessary to restore or reconstitute operations to a normal or alternative operational state. They may be procedures for network isolation, restriction of traffic, forced lockout of most users, etc.

197.1.4 Compensating Controls

Sometimes no other control is possible. For example, we would not usually grant a user root-level or high-level access to a system. This principle of least privilege—granting a user only the minimal amount of access, authority, or privilege required to do his or her job—is an effective control.[1] It often prevents misuse, accidental errors, and curiosity-based discoveries, and mitigates many risks created by poor access control. However, in the case of network administrators and operators this control is not possible. Such personnel require a high level of access to run the utilities, execute jobs, change configurations, etc., that are a part of their routine duties. Because of this, we require compensating controls, controls that compensate or address a weakness in the control infrastructure that cannot be eliminated using normal controls. Compensating controls often use greater levels of supervision, monitoring, review of activity logs and separation of duties to prevent or detect the types of errors that may come from a weaker control environment.

The following control types are methods of implementing the types of controls listed earlier. An administrative control, for example, may be preventive, deterrent, or detective, depending on whether it is designed to be proactive or reactive. It may also be corrective where it sets forth escalation procedures and incident response programs.

197.1.4.1 Administrative

Administrative controls, often called "soft controls," are procedures and policies to provide direction and declare intent to users and affected personnel. Examples of administrative controls include change control, user registration, visitor logs, hiring and termination practices, punishment for failure to comply, roles, responsibilities and job descriptions, and privacy statements.

197.1.4.2 Technical or Logical

These types of controls are "hard" or functional controls, often depending on the use of tools, software, or hardware to restrict access, limit capabilities, or prevent virus infections, for example. A preventive technical control may be a firewall, or a detective control may include an intrusion detection system.

197.1.4.3 Physical

Physical controls are extremely important in this domain. Operators have responsibility for the core computing platforms and equipment used by the organization. Unauthorized access to these areas may result in catastrophic loss for an organization. All steps must be taken to protect equipment from damage—environmental (lightning, dust, smoke, extreme humidity or temperature conditions), utility-based (gas, water, sewer, or electrical problems), disaster (fire, flood, or structural failure), and man-made (vandalism, accidental damage). Physical controls include locking doors and telephone equipment closets, installing fire detection and suppression equipment, having uninterruptible power supplies and surge protectors and proper installation locations. The principle of separation of duties also applies to segregating the operations staff from other staff (especially programmers) so that no one can usurp the normal workflow procedures and the checks and balances that were established.

197.2 Documentation

One of the most important resources an operations department has is knowledge. It is remarkable therefore how many organizations do not have adequate documentation. Documentation is a key to understanding, maintaining, and reacting to system activities. When we look at incident response later, one of the key factors in mitigating the damage from an incident is to recognize that something is happening. In far too many cases an untoward event is not noticed in a timely manner just because no one knew what "normal" was. They had no record of usual or unusual activity, or if they did, no one

[1] The author also likes to incorporate the condition of timing into the concept of least privilege—that is, that the user is granted the minimum amount of rights necessary to do his or her tasks for the shortest possible time.

looked at it, with the result that an attack or error was allowed to continue much longer than it should have.

When auditing an operations center, one of the first items reviewed should be the documentation of the systems. Where is it kept? Is there a copy off-site? Can it be accessed easily in a disaster? Is it up to date? Does it describe the systems? Does it show the interaction and interdependencies between systems? Does it show normal processing flows and does it contain lists of error codes and proper responses to errors?

Some of the documentation that must be provided includes inventory of equipment, location and configuration of hardware, networks, communications, storage, and support equipment. One firm recently had a major shutdown that lasted for several hours because an electrical circuit-breaker tripped and no one was able to find the electrical distribution panel that supplied the equipment.

A past incident log is often an excellent resource for an organization. It lists system failures, the actions taken, and people involved to correct the failures. Because certain failures may happen only occasionally and the same people may not be involved the next time there is a failure, an available listing of previous incidents and corrective procedures may dramatically reduce the time needed to repair this later failure. This document is also a valuable tool for the production support group, as we will review later in this chapter.

197.3 Operations

The Operations staff is responsible for the day-to-day operation and maintenance of a system. Whether the system is mainframe, client/server, PC based, or stand-alone, there needs to be personnel who are knowledgeable about the system to ensure it is functioning properly, to perform maintenance and backup routines, upload patches and new configuration files, and schedule jobs, maintenance, and upgrades. These tasks may be performed by one group or a series of groups, depending on the size of the organization, the skill level of the staff, the risk involved, and the complexity of the network. Ideally, there still needs to be an exact series of checks and balances to ensure that all work is being done, that backups are performed (it is surprising how many times I have found instances where the backups encountered an error and had not run for several days and no one noticed).

197.3.1 Roles and Responsibilities within the Operations Area

197.3.1.1 The Operator

The operator is the person whose finger is on the pulse of the system. He or she is responsible for daily operations of the systems and applications, performing the routine maintenance work, and monitoring the system for failures, exceptions, and often balancing completed job runs to ensure correct completion.

197.3.1.2 The Scheduler

The scheduler's role in many organizations is to set up and coordinate jobs in preparation for execution. The scheduler is the person usually responsible for exceptional job runs or running tasks out of the ordinary job flow. The separation of scheduling and operations tasks allows a double check of the duties of the scheduler and, quite often, the scheduler is also tasked with double-checking the work of the operations group. It is imperative that all exception processing is documented and reviewed. When a job is run as an "override" or exception, the job may also need to be removed from the normal job stream so that it does not continue to run. All exceptions need to be submitted for approval and have backout or recovery procedures. A person knowledgeable about the exception should also be on call to ensure that recovery procedures can be enacted in the event of a failure.

197.3.1.3 The Librarian

The librarian is responsible for maintaining the various media that are entering or leaving production. Tapes, microfiche, CDs, DVDs, and reports may be passed between departments, business partners, regulatory agencies, clients, or vendors. The librarian is responsible to ensure that discarded media do not contain sensitive information, keeping an inventory of the various media and protecting the organization from corrupt or contaminated media. Distributing backup tapes to offsite storage and recovering aged backups for reuse are important tasks of the librarian. Finally, the librarian is usually responsible for moving updated programs and accompanying documentation into production, as one of the final steps in the change control process.

197.3.1.4 The Help Desk

One of the most visible activities of an operations group is the help desk, which in many cases provides a first-level support for the users. Often it is backed up with a second tier of support by applications or systems experts who respond to problems encountered that are beyond the skill of the help desk personnel or would require more time. The help desk is often the front line between the users and the information technology department. The responsiveness, availability, and friendliness of the help desk staff will often affect the overall attitude of the users to the IT department. Whether the users like or dislike systems and applications may be influenced by their interaction with the help desk. For that reason, continuous supervision of help desk functions should be utilized to gauge the attitude of the users and whether they feel that the help desk personnel are knowledgeable, helpful, and responsive.

The help desk requires specific training in social engineering. This department has tremendous power and privilege, and is often a target of manipulation by internal and external customers. One of the easiest methods of gaining unauthorized access to systems or data can be through cultivating a “friendship” with the help desk personnel. Access also may be gained through intimidation or coercion of help desk personnel and “bullying” them into providing an exception to the normal rules or procedures. A help desk is sometimes staffed by fairly low-paid and inexperienced personnel; oftentimes they are supporting personnel that they will never meet and at odd hours when managers or other experts may not be readily available. Therefore, care must be taken to set up procedures and workflows to assist the help desk personnel in executing their duties in a secure manner. If a person requires or demands some form of exception to the rules, the manner of approving this must be established so that the help desk personnel are not forced or persuaded into breaking policy and jeopardizing operations.

One of the most common calls to a help desk is for password resets. This is a critically problematic area. Who is on the other end of the line? And how do we know that the person requesting the password reset is actually the true owner of the ID? Especially if the password is for an ID with high-level access, some form of controls must be set up to ensure that only the rightful owner of that ID can gain a password reset.

The help desk is often one of the last to know about a change to an application or system. This causes them grief when they begin to receive calls about an application they know nothing about. Therefore, help desk managers should be a part of all change control workflow so that they can ensure their staff is notified and trained on the new system prior to implementation. During a major revision to a system, it is good to have some applications or systems experts on call or even working in the help desk area to assist with problems and other questions.

All calls to a help desk should be logged and the logs reviewed regularly. Review of these logs may indicate problem areas or the need for training users or revising procedures to reduce repeated calls. This can also be put into a knowledge-based system to assist in answering future calls or in setting a menu option on an Integrated Voice Response (IVR) system. A help desk should also have a good communications system through phone and e-mail, including answering queues in case of high-traffic loads, and the ability to take messages instead of users reaching a busy or extended on-hold waiting period.

197.3.1.5 Production Support

Often closely related to the help desk function is a production support group. This group may operate as a second tier to the help desk, handling the production failures, user problems, and emergency fixes to applications. This group needs to be knowledgeable in systems, applications, programming, networks, security, and business unit requirements. Production support is often one of the first groups to learn about problems with applications, user interfaces, and external threats. In the event of a failure, production support should always review the actions taken by the response team. Thorough analysis may lead to better responses in the future, changes to procedures, but most importantly as a double check to detect errors in the recovery process. There have been several documented cases where an error made in the recovery process after hours should have been caught the following morning by production support, and yet, because this crucial double check was missing, it led to the failure of the entire corporation.

Production support is closely linked with quality assurance. When a change to an application, change to configurations, or new network connections are about to take place, production support should be aware of the changes and possibly review the changes to ensure that they are effective, complete, and follow organizational standards.

Monitoring of system activity is an important role of a production support group. Whereas the operators review at a level of job completion, error codes, etc., the production support personnel need to review CPU, bandwidth, and memory usage. Closely monitoring these activities may allow better forecasting of future resource needs so that equipment can be installed before availability becomes a concern, and some applications that are on the verge of failure due to insufficient resources may be provided additional support prior to a full-scale production failure. This data also assists in the scheduling of jobs so that production and maintenance windows can be maximized for ideal efficiency.

197.3.1.6 Incident Response

In the event of a system, application, communication, or peripheral component failure, the operations staff is commonly the first group to know of the failure. As mentioned before, this requires careful monitoring of network activity so that an abnormal condition is noticed as rapidly and identified as accurately as possible. Once identified, a proper and effective response is often detailed in procedural documentation. This may require notification of other departments, capturing of event information (for future analysis or forensic investigation), the alerting of key personnel, or the containment of the event through shutdowns or isolation.

Many operations are migrating toward automated alarm reporting or lights-out operations. These remove the reliance on the operators to be present or vigilant to detect abnormalities. These automated alerts may indicate anything from environmental problems such as fire or temperature, to network or hardware failures. These alarms need to be tested on a regular basis to ensure that they are functioning correctly and that they will alert the proper people. Often the call pattern for the alarm does not get changed when the personnel responsible for answering the alarm changes jobs.

All incidents should be documented so that analysis of the event can be performed. This will also permit the organization to learn from the event and establish new policies, countermeasures, or training to prevent future incidents.

Although operations staff may be familiar with recovery procedures, all recovery should be performed under the direct, careful supervision of skilled staff. This is similar to a medical setting where each person knows his or her limitations and a nurse, despite knowing the correct response, does not perform the responsibilities of a doctor. This allows checks and balances to prevent errors or omissions, or in some cases perhaps even malicious activity on the part of operations personnel.

Escalation procedures and guidelines should also be established. These will provide direction for operations staff about when and how to notify higher management of incidents. In most cases, it is best to notify too early rather than too late!

If the event is a major failure that will require extended recovery procedures, the operations room may become extremely busy and stressful. It is good to have conference rooms and communications set up nearby to permit the coordination of the recovery procedures without having overcrowded and poorly communicated facilities.

The operations group should also be represented on the Business Continuity Planning team. This team is responsible for continuity of business operations or recovery of operations in the event of a major failure to normal operations. The operations group should be knowledgeable about BCP plans and their role in a disaster. They also need to know the corporate priorities for recovery operations in the event that more than one system, application, or department is affected.

197.3.1.7 Supervision

Supervision is one of the most important factors in preventing, detecting, and mitigating errors, malfeasance, or other types of violations of policy, procedure, and operations. Because operations personnel have elevated authority and access to a system, they need extra oversight as a compensating control for this vulnerability. Quite often, many administrator and operator positions are considered entry-level jobs and the people in those positions may not be familiar with corporate policy, culture, loyalty, and regulations. They need frequent review and training to assist them in addressing their tasks securely and effectively. Because much of the effort for an operations group takes place after hours and during times of reduced network usage, the manager must also be prepared to attend the workplace and be available during off hours. This includes performing tests and drills after hours as well—fire, emergency response, network attack, etc.

197.4 Summary

Operations can be described as the heartbeat of most organizations today. For this reason, it requires careful maintenance, oversight, training, and coordination. When all of these factors are addressed, this department can be relied on to provide support and impetus for the organization—resulting in reliable processing, secure data handling, and the confidence of business units, business partners, users, shareholders, and regulatory groups.

198

Why Today's Security Technologies Are So Inadequate: History, Implications, and New Approaches

Steven Hofmeyr

They grab headlines as they cut a wide swath of destruction through corporate America: viruses, worms (such as Code Red and Nimda), and hackers. The unfortunate fact is that even in organizations with extensive deployment of firewall, encryption, and intrusion detection systems (IDS), attacks still occur with alarming frequency. According to a Computer Security Institute/FBI survey of Fortune 1000 organizations that have suffered attacks, 91 percent had deployed firewalls and 61 percent had installed IDS.

So, it is evident that although they provide some initial layers of protection for corporate systems, today's security tools have a distressing tendency to be several steps behind the latest exploits. This chapter explains why security technologies have evolved the way they have and describes the ways in which security systems need to adapt and change to meet the new demands of corporate information protection in the post-September 11 world.

198.1 Historical Perspective

Security for the first isolated mainframes focused primarily on physical access and the authentication and control of users. Experts believed that a provably correct security system could be built, based on the notion of a security kernel; that is, core security code that was verifiably secure. Confidence in this formal methods approach was so strong that researchers declared in 1973 that, "It is our firm belief that by applying these principles we can have secure shared systems in the next few years."[1] In the government's 1983 Orange Book, the most secure system is one that uses formal methods to prove the integrity of a "trusted code base." But these efforts failed because it is not possible to build a nontrivial, provably correct security system, any more than it is possible to write bug-free code.

In addition to security kernels, security teams in those days relied on monitoring user behavior. Audit systems collected extensive logs of user actions that human experts scanned periodically for potential threats. The emphasis was on accountability rather than on timely detection: if a compromise was detected, it was, by definition, an insider job. In the military/government context in which most computing took place, knowing which insiders were involved was key because they represented an ongoing threat to the organization.

With the increasing use of private networking, as well as the advent of the Arpanet and its evolution into the Internet in the late 1980s, it became possible for outsiders to penetrate computer systems. In addition, the interconnectedness of networked computers created a viable environment for new automated threats such as worms. The most famous of these early automated threats was the Morris worm, which took down 25 percent of the Internet in 1988.

Security responses to these new threats continued to rely heavily on human expertise but there was a growing shift toward the network or perimeter, and away from the host, with such technologies as firewalls, which restrict network traffic, and network intrusion detection systems (NIDs), which scan network traffic for signatures of known attacks. However, these technologies are severely limited: firewalls cannot protect vulnerable applications that are legitimately accessed through the firewall, and NIDs suffer from notoriously high rates of false alarms and can only detect attacks already known to the signature writers.

Finally, another major source of security problems emerged with the advent of the desktop computer, which proved a fertile environment for viruses. Security solutions for protection against viruses focused on the host computer itself, in the form of anti-virus (AV) software. AV software maintains a database of virus signatures and scans files to determine if any are infected with known viruses. This technology is similar in principle to NIDs that use signatures and consequently has similar limitations; for example, it cannot detect new types of viruses. However, it is still successful at increasing the security of the desktop—the adoption of AV technology on the desktop is almost universal.

198.2 The Ever-Changing IT Landscape

Of course, the number of computers connected to the Internet continues to grow at a tremendous rate, and with this growth comes a dramatic increase in the numbers and types of threats. In particular, automated threats such as worms and e-mail viruses are on the rise. The notorious ILOVEYOU virus in 2000 is estimated to have affected upward of 10 million users and, more recently, the Code Red worm in 2001 infected over 150,000 systems in a mere 14 hours, resulting in billions of dollars in damages. In addition, the large number of vulnerable desktops connected to the Internet has encouraged distributed denial-of-service (DDoS) attacks, in which a collection of individual machines targets a single victim, bombarding it with traffic.

Not only are the numbers of connected computers increasing, but the patterns of connectivity are also changing. As more business is transacted over the Web, the boundaries between the "trusted" internal network and external networks are dissolving, requiring increasing use of encryption to protect communications in potentially hostile environments. Consequently, network-based security systems are becoming obsolete because they are predicated on the notion of a perimeter and need to scan the contents of network packets, which is not possible if the packets are encrypted.

In addition, today's IT environments are becoming exponentially more complex, incorporating a wider range of applications, middleware, and integration software. There are simply not enough experts to manage such complex systems, and experts cannot react fast enough to deal with the problems seen today. Meanwhile, few businesses today are as concerned about accountability as government organizations have been in the past. With mission-critical corporate data residing in vulnerable enterprise systems, today's corporations place a premium on prevention of attacks, rather than on catching or prosecuting the perpetrators after the fact.

198.3 From Human Expertise to Machine Intelligence

In response to these trends, security solutions are moving away from the network and back onto the host. Securing each host computer individually does not depend on defining a perimeter, and all processing of information can be done after traffic is decrypted at the host. Although this move back to the host is promising, other "old" ideas hold less potential. For example, just as in the days of mainframe computing, the security community is gravitating once again to the idea of "trusted" or "secure" systems, this time with a focus on trusted operating systems. Such operating systems attempt to put all applications and users into specific compartments and then limit functionality based on those compartments. However, if trusted computing could not be made to work in the single-machine mainframe era, it can hardly be expected to succeed now, in today's world of highly complex, interconnected, and vulnerable systems. The task of designing and verifying a set of policies for every variation of every application and operating system for any conceivable user requirement is, quite simply, infeasible.

What, then, is the answer? The security community must embrace a fundamental change in the way security systems are designed and built. A new security paradigm is needed, one based on machine intelligence, not human expertise. Security systems need to be self-aware, adaptive, and autonomous. They also need to focus on prevention rather than just detection and source identification. Key to achieving these goals is the use of anomaly detection methods. With these methods, the computer security system observes the normal behavior of the computer to be protected, learns the profile of that normal behavior, and subsequently detects deviations (anomalies) from the profile that are indicative of attacks. The use of anomaly detection methods is the only way of detecting entirely new attacks; knowledge-based approaches that require knowing what the attacks look like beforehand will always fall short.

To ensure accuracy and avoid high false-alarm rates with anomaly detection, the system must monitor the appropriate characteristics. These characteristics should lead to a compact and stable profile under normal conditions but result in clear deviations from the normal profile during attacks. A poor choice of characteristic is exemplified by early research into anomaly detection that focused on user behavior. Users are inherently variable and thus any anomaly detection system profiling their behavior will generate masses of false alarms. A much better characteristic is paths through program code. If the program being profiled is a server, then its behavior is likely to be very consistent because servers repeatedly perform a few tasks and those tasks have predictable, regular code paths. The behavior of the server program is still driven by user behavior but that behavior is aggregated across many individuals and restricted through the program to a constrained, well-defined set of options.

Every anomaly detection system must have a training phase, during which the anomaly detection system develops a profile of normal behavior. In general, each system to be protected will exist in a different environment, with different configuration requirements and different usage patterns. These differences mean that it is essential for the anomaly detection system to learn the normal profile within each specific local environment. Moreover, even within a single system, the environment will vary over time. New software is added, old software is patched, configurations are changed, machines are removed or added, etc. Every time the system changes it has an effect on the normal profile of the system. Therefore, a key requirement of any useful anomaly detection system is the ability to adapt autonomously to changes in the environment. For example, each time a profiled program is updated to a more recent version, the anomaly detection system should "relearn" the normal behavior. The more similar the program's new behavior is to the old behavior, the more rapid the relearning; that is, the anomaly detection system does not need to throw away all the information it has previously learned.

Of course, the danger in making a system self-aware and more intelligent is that it becomes more difficult to understand what the system is doing and why. This is why any good anomaly detection system should have a comprehensive set of secondary analytics—additional information gathered about the anomaly that is not essential to detecting the anomaly. For example, it may be that anomalies are detected by simply monitoring program code paths, but when an unusual code path is reported, the network connections occurring at the time are also reported, to give a human operator more understanding of the anomaly. Secondary analytics can also be enhanced by the use of signatures, which can help humans understand the attacks through categorization of anomalies. This is different from traditional signature-based systems because the signatures are not used for detection, but only for informing human operators. In this way, the limitations and pitfalls of the signature-based approach are avoided.

198.4 Learning from History

A study of the history of computer security yields some guidelines that should be adhered to by any designer of a security technology for today's open, distributed, and highly interconnected systems.

- *Do not hard-code knowledge.* When designing security systems, people are often tempted to hard-code in their specific expertise about the problem at hand. For example, the designer might fervently believe that an application should never carry out a particular kind of behavior, and so hard-code in a restriction on that behavior. Succumbing to such temptations is shortsighted, destroys flexibility and adaptability, and is subject to human error and bias. It is well known in programming that hard-coding solutions to specific instances of a problem is a bad idea; the same applies to security.
- *Avoid the central weak point.* Designers like to have a system in which all information is gathered centrally at one point so that a human operator can control and monitor a large number of nodes from one location. This in itself is not a bad idea. However, placing too much dependence on the central location is. There is a trend today toward centralized correlation and analysis. Data is taken in from various sensors around the network, then analyzed and correlated in one location. If that one location should be compromised, then the entire security system will fail. The sensors themselves should be able to react autonomously and independently so that even if the central location is compromised, they can continue to protect the network. And if correlation from multiple sensors is required, then this is more robust if done in a distributed peer-to-peer fashion.
- *There is no such thing as a trusted code base.* The resurgence of trusted operating systems is predicated on the belief in a trusted code base. In reality, there is no such thing. Only the most trivial, useless bit of code will be provably secure. Designers should operate under the assumptions that any part of the system is insecure and could be compromised. For example, across a set of distributed sensors, it must be assumed that some of them could be compromised or be in error. However, it can reasonably be assumed that not all of them will be compromised immediately, and so solutions can be designed that rely on voting and other forms of Byzantine agreement to isolate compromised sensors.
- *Profile actions, not data.* A detection system should monitor actions that are a consequence of an application receiving data, and not the data itself. Data, such as network packets, can be forged to look anomalous and flood a data-monitoring detection system with spurious alarms. Actions, by contrast, cannot be forged; if an action is successful, it means the system is truly vulnerable. Furthermore, it is difficult for a detection system to interpret data in exactly the same way as the application it is protecting. Errors in data interpretation are exploited by attackers to evade a detection system; for example, an attack can be hidden in fragmented packets if an NIDs does not properly reconstruct entire packets. Monitoring actions after the data has been interpreted by an application avoids this problem.
- *Do not compromise functionality for security.* A common mistake made when designing security systems is to focus on security measures, without regard to how those measures impact the functionality of the system being protected. The consequence is overly restrictive security systems. The problem with such overly restrictive systems is that legitimate users, in addition to attackers, find ways around the system. A good example is the firewall that restricts all access to and from

the Internet, allowing only http traffic. This is sufficiently restrictive that nonmalicious users design their applications to run on top of http so that they can pass through firewalls. Consequently, more and more traffic is now running on top of http and the firewall is progressively more useless. Security systems must be designed with a clear regard for how they compromise functionality.

198.5 Summary

Today's computing world will never replicate the simplicity and central control of early mainframe environments; for better or worse, enterprise networks today are highly complex, interconnected, and vulnerable to automated and human threats. In moving away from the focus on accountability and the over-dependence on human expertise of past approaches, it is essential to embrace an automated, flexible, and highly adaptive approach—one that applies the best lessons from the past to consistently and reliably protect computing assets in the future.

A cornerstone of this new approach is anomaly detection systems that run on the host computers. These systems must be able to operate autonomously, monitoring appropriate characteristics to accurately profile normal and detect attacks, and using automated responses to stop attacks before they do harm. They should be able to adapt to legitimate changes with minimum human intervention. In addition, these anomaly detection systems should have comprehensive secondary analytics, including signature-based interpretation of anomalies. Of course, such systems will not guarantee security but, if implemented correctly, will raise security to a new level, taking a step ahead in the constant arms race between defender and attacker.

199

Operations Security and Controls

Patricia A.P. Fisher

Operations security and controls safeguard information assets while the data is resident in the computer or otherwise directly associated with the computing environment. The controls address both software and hardware as well as such processes as change control and problem management. Physical controls are not included and may be required in addition to operations controls.

Operations security and controls can be considered the heart of information security because they control the way data is accessed and processed. No information security program is complete without a thoroughly considered set of controls designed to promote both adequate and reasonable levels of security. The operations controls should provide consistency across all applications and processes; however, the resulting program should be neither too excessive nor too repressive.

Resource protection, privileged-entity control, and hardware control are critical aspects of the operations controls. To understand this important security area, managers must first understand these three concepts. The following sections give a detailed description of them.

199.1 Resource Protection

Resource protection safeguards all of the organization's computing resources from loss or compromise, including main storage, storage media (e.g., tape, disk, and optical devices), communications software and hardware, processing equipment, standalone computers, and printers. The method of protection used should not make working within the organization's computing environment an onerous task, nor should it be so flexible that it cannot adequately control excesses. Ideally, it should obtain a balance between these extremes, as dictated by the organization's specific needs.

This balance depends on two items. One is the value of the data, which may be stated in terms of intrinsic value or monetary value. Intrinsic value is determined by the data's sensitivity—for example, health- and defense-related information have a high intrinsic value. The monetary value is the potential financial or physical losses that would occur should the data be violated.

The second item is the ongoing business need for the data, which is particularly relevant when continuous availability (i.e., round-the-clock processing) is required.

When a choice must be made between structuring communications to produce a user-friendly environment, in which it may be more difficult for the equipment to operate reliably, and ensuring that the equipment is better controlled but not as user friendly (emphasizing availability), control must take precedence. Ease of use serves no purpose if the more basic need for equipment availability is not considered.

Resource protection is designed to help reduce the possibility of damage that might result from unauthorized disclosure and alteration of data by limiting opportunities for misuse. Therefore, both the general user and the technician must meet the same basic standards against which all access to resources is applied.

A more recent aspect of the need for resource protection involves legal requirements to protect data. Laws surrounding the privacy and protection of data are rapidly becoming more restrictive. Increasingly, organizations that do not exercise due care in the handling and maintenance of data are likely to find themselves at risk of litigation. A consistent, well-understood user methodology for the protection of information resources is becoming more important to not only reduce information damage and limit opportunities for misuse but to reduce litigation risks.

199.1.1 Accountability

Access and use must be specific to an individual user at a particular moment in time; it must be possible to track access and use to that individual. Throughout the entire protection process, user access must be appropriately controlled and limited to prevent excess privileges and the opportunity for serious errors. Tracking must always be an important dimension of this control. At the conclusion of the entire cycle, violations occurring during access and data manipulation phases must be reported on a regular basis so that these security problems can be solved.

Activity must be tracked to specific individuals to determine accountability. Responsibility for all actions is an integral part of accountability; holding someone accountable without assigning responsibility is meaningless. Conversely, to assign responsibility without accountability makes it impossible to enforce responsibility. Therefore, any method for protecting resources requires both responsibility and accountability for all of the parties involved in developing, maintaining, and using processing resources.

An example of providing accountability and responsibility can be found in the way some organizations handle passwords. Users are taught that their passwords are to be stored in a secure location and not disclosed to anyone. In some organizations, first-time violators are reprimanded; if they continue to expose organizational information, however, penalties may be imposed, including dismissal.

199.1.2 Violation Processing

To understand what has actually taken place during a computing session, it is often necessary to have a mechanism that captures the detail surrounding access, particularly accesses occurring outside the bounds of anticipated actions. Any activity beyond those designed into the system and specifically permitted by the generally established rules of the site should be considered a violation.

Capturing activity permits determination of whether a violation has occurred or whether elements of software and hardware implementation were merely omitted, therefore requiring modification. In this regard, tracking and analyzing violations are equally important. Violation tracking is necessary to satisfy the requirements for the due care of information. Without violation tracking, the ability to determine excesses or unauthorized use becomes extremely difficult, if not impossible. For example, a general user might discover that, because of an administrative error, he or she can access system control functions. Adequate, regular tracking highlights such inappropriate privileges before errors can occur.

An all-too-frequently overlooked component of violation processing is analysis. Violation analysis permits an organization to locate and understand specific trouble spots, both in security and usability. Violation analysis can be used to find:

- The types of violations occurring. For example:
  —Are repetitive mistakes being made? This might be a sign of poor implementation or user training.

  —Are individuals exceeding their system needs? This might be an indication of weak control implementation.

  —Do too many people have too many update abilities? This might be a result of inadequate information security design.
- Where the violations are occurring, which might help identify program or design problems.
- Patterns that can provide an early warning of serious intrusions (e.g., hackers or disgruntled employees).

A specialized form of violation examination, intrusion analysis (i.e., attempting to provide analysis of intrusion patterns), is gaining increased attention. As expert systems gain in popularity and ability, their use in analyzing patterns and recognizing potential security violations will grow. The need for such automated methods is based on the fact that intrusions continue to increase rapidly in quantity and intensity and are related directly to the increasing number of personal computers connected to various networks. The need for automated methods is not likely to diminish in the near future, at least not until laws surrounding computer intrusion are much more clearly defined and enforced.

Currently, these laws are not widely enforced because damages and injuries are usually not reported and therefore cannot be proven. Overburdened law enforcement officials are hesitant to actively pursue these violations because they have more pressing cases (e.g., murder and assault). Although usually less damaging from a physical injury point of view, information security violations may be significantly damaging in monetary terms. In several well-publicized cases, financial damage has exceeded $10 million. Not only do violation tracking and analysis assist in proving violations by providing a means for determining user errors and the occasional misuse of data, they also provide assistance in preventing serious crimes from going unnoticed and therefore unchallenged.

Clipping Levels. Organizations usually forgive a particular type, number, or pattern of violations, thus permitting a predetermined number of user errors before gathering this data for analysis. An organization attempting to track all violations, without sophisticated statistical computing ability, would be unable to manage the sheer quantity of such data. To make a violation listing effective, a clipping level must be established.

The clipping level establishes a baseline for violation activities that may be normal user errors. Only after this baseline is exceeded is a violation record produced. This solution is particularly effective for small- to medium-sized installations. Organizations with large-scale computing facilities often track all violations and use statistical routines to cull out the minor infractions (e.g., forgetting a password or mistyping it several times).

If the number of violations being tracked becomes unmanageable, the first step in correcting the problems should be to analyze why the condition has occurred. Do users understand how they are to interact with the computer resource? Are the rules too difficult to follow? Violation tracking and analysis can be valuable tools in assisting an organization to develop thorough but useable controls. Once these are in place and records are produced that accurately reflect serious violations, tracking and analysis become the first line of defense. With this procedure, intrusions are discovered before major damage occurs and sometimes early enough to catch the perpetrator. In addition, business protection and preservation are strengthened.

199.1.3 Transparency

Controls must be transparent to users within the resource protection schema. This applies to three groups of users. First, all authorized users doing authorized work, whether technical or not, need to feel that computer system protection requirements are reasonably flexible and are not counterproductive. Therefore, the protection process must not require users to perform extra steps; instead, the controls should be built into the computing functions, encapsulating the users' actions and producing the multiple commands expected by the system.

The second group of users consists of authorized users attempting unauthorized work. The resource protection process should capture any attempt to perform unauthorized activity without revealing that it is doing so. At the same time, the process must prevent the unauthorized activity. This type of process deters the user from learning too much about the protective mechanism yet controls permitted activities.

The third type of user consists of unauthorized users attempting unauthorized work. With unauthorized users, it is important to deny access transparently to prevent the intruder from learning anything more about the system than is already known.

199.1.4 User Access Authorities

Resource protection mechanisms may be either manual or automatic. The size of the installation must be evaluated when the security administrator is considering the use of a manual methodology because it can quickly be outgrown, becoming impossible to control and maintain. Automatic mechanisms are typically more costly to implement but may soon recoup their cost in productivity savings.

Regardless of the automation level of a particular mechanism, it is necessary to be able to separate types of access according to user needs. The most effective approach is one of least privilege; that is, users should not be allowed to undertake actions beyond what their specific job responsibilities warrant. With this method, it is useful to divide users into several groups. Each group is then assigned the most restrictive authority available while permitting users to carry out the functions of their jobs.

There are several options to which users may be assigned. The most restrictive authority and the one to which most users should be assigned is read only. Users assigned to read only are allowed to view data but are not allowed to add, delete, or make changes.

The next level is read/write access, which allows users to add or modify data within applications for which they have authority. This level permits individuals to access a particular application and read, add, and write over data in files copied from the original location.

A third access level is change. This option permits the holder not only to read a file and write data to another file location but to change the original data, thereby altering it permanently.

When analyzing user access authorities, the security practitioner must distinguish between access to discretionary information resources (which is regulated only by personal judgment) and access to nondiscretionary resources (which is strictly regulated on the basis of the predetermined transaction methodology). Discretionary user access is defined as the ability to manipulate data by using custom-developed programs or a general-purpose utility program. The only information logged for discretionary access in an information security control mechanism is the type of data accessed and at what level of authority. It is not possible to identify specific uses of the data.

Nondiscretionary user access, on the other hand, is performed while executing specific business transactions that affect information in a predefined way. For this type of access, users can perform only certain functions in carefully structured ways. For example, in a large accounting system, many people prepare transactions that affect the ledger. Typically, one group of accounting analysts is able to enter the original source data but not to review or access the overall results. Another group has access to the data for review but is not able to alter the results. In addition, with nondiscretionary access, the broad privileges assigned to a user for working with the system itself should be analyzed in conjunction with the user's existing authority to execute the specific transactions needed for the current job assignment. This type of access is important when a user can be authorized to both read and add information but not to delete or change it. For example, bank tellers need access to customer account information to add deposits but do not need the ability to change any existing information.

At times, even nondiscretionary access may not provide sufficient control. In such situations, special access controls can be invoked. Additional restrictions may be implemented in various combinations of add, change, delete, and read capabilities. The control and auditability requirements that have been designed into each application are used to control the management of the information assets involved in the process.

Special Classifications. A growing trend is to give users access to only resource subsets or perhaps to give them the ability to update information only when performing a specific task and following a specific procedure. This has created the need for a different type of access control in which authorization can be granted on the basis of both the individual requesting resource access and the intended use of that resource. This type of control can be exercised by the base access control mechanism (i.e., the authorization list, including user ID and program combinations).

Another method sometimes used provides the required access authority along with the programs the user has authorization for; this information is provided only after the individual's authority has been verified by an authorization program. This program may incorporate additional constraints (e.g., scoped access control) and may include thorough access logging along with ensuring data integrity when updating information.

Scoped access control is necessary when users need access only to selected areas or records within a resource, thereby controlling the access granted to a small group on the basis of an established method for separating that group from the rest of the data. In general, the base access control mechanism is activated at the time of resource initialization (i.e., when a data set is prepared for access). Therefore, scoped access control should be provided by the data base management system or the application program. For example, in personnel systems, managers are given authority to access only the information related to their employees.

199.2 Privileged-Entity Control

Levels of privileges provide users with the ability to invoke the commands needed to accomplish their work. Every user has some degree of privilege. The term, however, has come to be applied more to those individuals performing specialized tasks that require broad capabilities than to the general user. In this context, a privilege provides the authority necessary to modify control functions (e.g., access control, logging, and violation detection) or may provide access to specific system vulnerabilities. (Vulnerabilities are elements of the system's software or hardware that can be used to gain unauthorized access to system facilities or data.) Thus, individuals in such positions as systems programming, operations, and systems monitoring are authorized to do more than general users.

A privilege can be global when it is applicable to the entire system, function-oriented when it is restricted to resources grouped according to a specific criterion, or application specific when it is implemented within a particular piece of application code. It should be noted that when an access control mechanism is compromised, lower-level controls may also be compromised. If the system itself is compromised, all resources are exposed regardless of any lower-level controls that may be implemented.

Indirect authorization is a special type of privilege by which access granted for one resource may give control over another privilege. For example, a user with indirect privileges may obtain authority to modify the password of a privileged user (e.g., the security administrator). In this case, the user does not have direct privileges but obtains them by signing on to the system as the privileged user (although this would be a misuse of the system). The activities of anyone with indirect privileges should be regularly monitored for abuse.

Extended or special access to computing resources is termed privileged-entity access. Extended access can be divided into various segments, called classes, with each succeeding class more powerful than those preceding it. The class into which general system users are grouped is the lowest, most restrictive class;

Class	Job assignment	Class access privileges
A	General user	A
B	Programmer	B, A
C	Manager	C, A (sometimes B)
D	Security administrator	D, B, A
E	Operator	E, D, B, A
F	System programmer	F, E, D, B, A
G	Auditor	G, B, A

EXHIBIT 199.1 Sample privileged-entity access.

a class that permits someone to change the computing operating system is the least restrictive, or most powerful. All other system support functions fall somewhere between these two.

Users must be specifically assigned to a class; users within one class should not be able to complete functions assigned to users in other classes. This can be accomplished by specifically defining class designations according to job functions and not permitting access ability to any lower classes except those specifically needed (e.g., all users need general user access to log on to the system). An example of this arrangement is shown in Exhibit 199.1.

System users should be assigned to a class on the basis of their job functions; staff members with similar computing access needs are grouped together with a class. One of the most typical problems uncovered by information security audits relates to the implementation of system assignments. Often, sites permit class members to access all lesser functions (i.e., toward A in Exhibit 199.1). Although it is much simpler to implement this plan than to assign access strictly according to need, such a plan provides little control over assets.

The more extensive the system privileges given within a class, the greater the need for control and monitoring to ensure that abuses do not occur. One method for providing control is to install an access control mechanism, which may be purchased from a vendor (e.g., RACF, CA-TOP, SECRET, and CA-ACF2) or customized by the specific site or application group. To support an access control mechanism, the computer software provides a system control program. This program maintains control over several aspects of computer processing, including allowing use of the hardware, enforcing data storage conventions, and regulating the use of I/O devices.

The misuse of system control program privileges may give a user full control over the system, because altering control information or functions may allow any control mechanism to be compromised. Users who abuse these privileges can prevent the recording of their own unauthorized activities, erase any record of their previous activities from the audit log, and achieve uncontrolled access to system resources. Furthermore, they may insert a special code into the system control program that can allow them to become privileged at any time in the future.

The following sections discuss the way the system control program provides control over computer processing.

Restricting Hardware Instructions. The system control program can restrict the execution of certain computing functions, permitting them only when the processor is in a particular functional state (known as privileged or supervisor state) or when authorized by architecturally defined tables in control storage. Programs operate in various states, during which different commands are permitted. To be authorized to execute privileged hardware instructions, a program should be running in a restrictive state that allows these commands.

Instructions permitting changes in the program state are classified as privileged and are available only to the operating system and its extensions. Therefore, to ensure adequate protection of the system, only carefully selected individuals should be able to change the program state and execute these commands.

Controlling Main Storage. The use of address translation mechanisms can provide effective isolation between different users' storage locations. In addition, main storage protection mechanisms protect main storage control blocks against unauthorized access. One type of mechanism involves assignment of storage protection keys to portions of main storage to keep unauthorized users out.

The system control program can provide each user section of the system with a specific storage key to protect against read-only or update access. In this methodology, the system control program assigns a key to each task and manages all requests to change that key. To obtain access to a particular location in storage, the requesting routine must have an identical key or the master key.

Constraining I/O Operations. If desired, I/O instructions may be defined as privileged and issued only by the system control program after access authority has been verified. In this protection method, before the initiation of any I/O operations, a user's program must notify the system control program of both the specific data and the type of process requested. The system control program then obtains information about the data set location, boundaries, and characteristics that it uses to confirm authorization to execute the I/O instruction.

The system control program controls the operation of user programs and isolates storage control blocks to protect them from access or alteration by an unauthorized program. Authorization mechanisms for programs using restricted system functions should not be confused with the mechanisms invoked when a general user requests a computing function. In fact, almost every system function (e.g., the user of any I/O device, including a display station or printer) implies the execution of some privileged system functions that do not require an authorized user.

199.2.1 Privilege Definition

All levels of system privileges must be defined to the operating system when hardware is installed, brought online, and made available to the user community. As the operating system is implemented, each user ID, along with an associated level of system privileges, is assigned to a predefined class within the operating system. Each class is associated with a maximum level of activity.

For example, operators are assigned to the class that has been assigned those functions that must be performed by operations personnel. Likewise, systems auditors are assigned to a class reserved for audit functions. Auditors should be permitted to perform only those tasks that both general users and auditors are authorized to perform, not those permitted for operators. By following this technique, the operating system may be partitioned to provide no more access than is absolutely necessary for each class of user.

Particular attention must be given to password management privileges. Some administrators must have the ability and therefore the authorization to change another user's password, and this activity should always be properly logged. The display password feature, which permits all passwords to be seen by the password administrator, should be disabled or blocked. If not disabled, this feature can adversely affect accountability, because it allows some users to see other users' passwords.

199.2.2 Privilege Control and Recertification

Privileged-entity access must be carefully controlled, because the user IDs associated with some system levels are very powerful and can be used inappropriately, causing damage to information stored within the computing resource. As with any other group of users, privileged users must be subject to periodic recertification to maintain the broad level of privileges that have been assigned to them. The basis for recertification should be substantiation of a continued need for the ID. Need, in this case, should be no greater than the regular, assigned duties of the support person and should never be allocated on the basis of organizational politics or backup.

A recertification process should be conducted on a regular basis, at least semi-annually, with the line management verifying each individual's need to retain privileges. The agreement should be formalized yet not bureaucratic, perhaps accomplished by initialing and dating a list of those IDs that are to be recertified. By structuring the recertification process to include authorization by managers of personnel empowered with the privileges, a natural separation of duties occurs. This separation is extremely important to ensure adequate control. By separating duties, overallocation of system privileges is minimized.

For example, a system programmer cannot receive auditor privileges unless the manager believes this function is required within the duties of the particular job. On the other hand, if a special project requires a temporary change in system privileges, the manager can institute such a change for the term of the project. These privileges can then be canceled after the project has been completed.

Emergency Procedures. Privileged-entity access is often granted to more personnel than is necessary to ensure that theoretical emergency situations are covered. This should be avoided and another process employed during emergencies—for example, an automated process in which support personnel can actually assign themselves increased levels of privileges. In such instances, an audit record is produced, which calls attention to the fact that new privileges have been assigned. Management can then decide after the emergency whether it is appropriate to revoke the assignment. However, management must be notified so the support person's subsequent actions can be tracked.

A much more basic emergency procedure might involve leaving a privileged ID password in a sealed envelope with the site security staff. When the password is needed, the employee must sign out the envelope, which establishes ownership of the expanded privileges and alerts management. Although this may be the least preferred method of control, it alerts management that someone has the ability to access powerful functions. Audit records can then be examined for details of what that ID has accessed. Although misuse of various privileged functions cannot be prevented with this technique, reasonable control can be accomplished without eliminating the ability to continue performing business functions in an efficient manner.

Activity Reporting. All activity connected with privileged IDs should be reported on logging audit records. These records should be reviewed periodically to ensure that privileged IDs are not being misused. Either a sample of the audit records should be reviewed using a predetermined methodology incorporating approved EDP auditing and review techniques or all accesses should be reviewed using expert system applications. Transactions that deviate from those normally conducted should be examined and, if necessary, fully investigated.

Under no circumstances should management skip the regular review of these activities. Many organizations have found that a regular review process deters curiosity and even mischief within the site and often produces the first evidence of attempted hacking by outsiders.

199.3 Change Management Controls

Additional control over activities by personnel using privileged access IDs can be provided by administrative techniques. For example, the most easily sidestepped control is change control. Therefore, every computing facility should have a policy regarding changes to operating systems, computing equipment, networks, environmental facilities (e.g., air-conditioning, water, heat, plumbing, electricity, and alarms), and applications. A policy is necessary if change is to be not only effective but orderly, because the purpose of the change control process is to manage changes to the computing environment.

The goals of the management process are to eliminate problems and errors and to ensure that the entire environment is stable. To achieve these goals, it is important to:

- *Ensure orderly change.* In a facility that requires a high level of systems availability, all changes must be managed in a process that can control any variables that may affect the environment. Because change can be a serious disruption, however, it must be carefully and consistently controlled.
- *Inform the computing community of the change.* Changes assumed to affect only a small subsection of a site or group may in fact affect a much broader cross-section of the computing community. Therefore, the entire computing community should receive adequate notification of impending changes. It is helpful to create a committee representing a broad cross-section of the user group to review proposed changes and their potential effect on users.

- *Analyze changes.* The presentation of an intended change to an oversight committee, with the corresponding documentation of the change, often effectively exposes the change to careful scrutiny. This analysis clarifies the originator's intent before the change is implemented and is helpful in preventing erroneous or inadequately considered changes from entering the system.
- *Reduce the impact of changes on service.* Computing resources must be available when the organization needs them. Poor judgment, erroneous changes, and inadequate preparation must not be allowed in the change process. A well-structured change management process prevents problems and keeps computing services running smoothly.

General procedures should be in place to support the change control policy. These procedures must, at the least, include steps for instituting a major change to the site's physical facility or to any major elements of the system's software or hardware. The following steps should be included:

1. *Applying to introduce a change.* A method must be established for applying to introduce a change that will affect the computing environment in areas covered by the change control policy. Change control requests must be presented to the individual who will manage the change through all of its subsequent steps.
2. *Cataloging the change.* The change request should be entered into a change log, which provides documentation for the change itself (e.g., the timing and testing of the change). This log should be updated as the change moves through the process, providing a thorough audit trail of all changes.
3. *Scheduling the change.* After thorough preparation and testing by the sponsor, the change should be scheduled for review by a change control committee and for implementation. The implementation date should be set far enough in advance to provide the committee with sufficient review time. At the meeting with the change control committee, all known ramifications of the change should be discussed. If the committee members agree that the change has been thoroughly tested, it should be entered on the implementation schedule and noted as approved. All approvals and denials should be in writing, with appropriate reasons given for denials.
4. *Implementing the change.* The final step in the change process is application of the change to the hardware and software environment. If the change works correctly, this should be noted on the change control form. When the change does not perform as expected, the corresponding information should be gathered, analyzed, and entered on the change control form, as a reference to help avoid a recurrence of the same problem in the future.
5. *Reporting changes to management.* Periodically, a full report summarizing change activity should be submitted to management. This helps ensure that management is aware of any quality problems that may have developed and enables management to address any service problems.

These steps should be documented and made known to all involved in the change process. Once a change process has been established, someone must be assigned the responsibility for managing all changes throughout the process.

199.4 Hardware Control

Security and control issues often revolve around software and physical needs. In addition, the hardware itself can have security vulnerabilities and exposures that need to be controlled. The hardware access control mechanism is supported by operating system software. However, hardware capabilities can be used to obtain access to system resources. Software-based control mechanisms, including audit trail maintenance, are ineffective against hardware-related access. Manual control procedures should be implemented to ensure that any hardware vulnerability is adequately protected.

When the system control program is initialized, the installation personnel select the desired operating system and other software code. However, by selecting a different operating system or merely a different setup of the operating system (i.e., changing the way the hardware mechanisms are used), software access control mechanisms can be defeated.

Some equipment provides hardware maintenance functions that allow main storage display and modification in addition to the ability to trace all program instructions while the system is running. These capabilities enable someone to update system control block information and obtain system privileges for use in compromising information. Although it is possible to access business information directly from main storage, the information may be encrypted. It is simpler to obtain privileges and run programs that can turn encrypted data into understandable information.

Another hardware-related exposure is the unauthorized connection of a device or communications line to a processor that can access information without interfacing with the required controls. Hardware manufacturers often maintain information on their hardware's vulnerabilities and exposures. Discussions with specific vendors should provide data that will help control these vulnerabilities.

199.4.1 Problem Management

Although problem management can affect different areas within computer services, it is most often encountered in dealing with hardware. This control process reports, tracks, and resolves problems affecting computer services. Management should be structured to measure the number and types of problems against predetermined service levels for the area in which the problem occurs. This area of management has three major objectives:

1. Reducing failures to an acceptable level.
2. Preventing recurrences of problems.
3. Reducing impact on service.

Problems can be organized according to the types of problems that occur, enabling management to better focus on and control problems and thereby providing more meaningful measurement. Examples of the problem types include:

- Performance and availability.
- Hardware.
- Software.
- Environment (e.g., air-conditioning, plumbing, and heating).
- Procedures and operations (e.g., manual transactions).
- Network.
- Safety and security.

All functions in the organization that are affected by these problems should be included in the control process (e.g., operations, system planning, network control, and systems programming).

Problem management should investigate any deviations from standards, unusual or unexplained occurrences, unscheduled initial program loads, or other abnormal conditions. Each is examined in the following sections.

Deviations from Standards. Every organization should have standards against which computing service levels are measured. These may be as simple as the number of hours a specific CPU is available during a fixed period of time. Any problem that affects the availability of this CPU should be quantified into time and deducted from the available service time. The resulting total provides a new, lower service level. This can be compared with the desired service level to determine the deviation.

Unusual or Unexplained Occurrences. Occasionally, problems cannot be readily understood or explained. They may be sporadic or appear to be random; whatever the specifics, they must be investigated and carefully analyzed for clues to their source. In addition, they must be quantified and grouped, even if in an Unexplained category. Frequently, these types of problems recur over a period of time or in similar circumstances, and patterns begin to develop that eventually lead to solutions.

Unscheduled Initial Program Loads. The primary reason a site undergoes an unscheduled initial program load (IPL) is that a problem has occurred. Some portion of the hardware may be malfunctioning and therefore slowing down, or software may be in an error condition from which it cannot recover. Whatever the reason, an occasional system queue must be cleared, hardware and software cleansed and an IPL undertaken. This should be reported in the problem management system and tracked.

Other Abnormal Conditions. In addition to the preceding problems, such events as performance degradation, intermittent or unusual software failures, and incorrect systems software problems may occur. All should be tracked.

199.4.2 Problem Resolution

Problems should always be categorized and ranked in terms of their severity. This enables responsible personnel to concentrate their energies on solving those problems that are considered most severe, leaving those of lesser importance for a more convenient time.

When a problem can be solved, a test may be conducted to confirm problem resolution. Often, however, problems cannot be easily solved or tested. In these instances, a more subjective approach may be appropriate. For example, management may decide that if the problem does not recur within a predetermined number of days, the problem can be considered closed. Another way to close such problems is to reach a major milestone (e.g., completing the organization's year-end processing) without a recurrence of the problem.

199.5 Summary

Operations security and control is an extremely important aspect of an organization's total information security program. The security program must continuously protect the organization's information resources within data center constraints. However, information security is only one aspect of the organization's overall functions. Therefore, it is imperative that control remain in balance with the organization's business, allowing the business to function as productively as possible. This balance is attained by focusing on the various aspects that make information security not only effective but as simple and transparent as possible.

Some elements of the security program are basic requirements. For example, general controls must be formulated, types of system use must be tracked, and violations must be tracked in any system. In addition, use of adequate control processes for manual procedures must be in place and monitored to ensure that availability and security needs are met for software, hardware, and personnel. Most important, whether the organization is designing and installing a new program or controlling an ongoing system, information security must always remain an integral part of the business and be addressed as such, thus affording an adequate and reasonable level of control based on the needs of the business.

200

The Nebulous Zero Day

Robert M. Slade

200.1 Introduction

Recently, there has been much written addressing the issue of “zero day” exploits and vulnerabilities. Unfortunately, there seems to be very little agreement upon what this term actually means and implies. Although the phrase has some functional use, it may be that the dilution of meaning from overuse of the term has rendered it worthless.

200.2 Zero Day in Malware Research

In the world of malware, viruses or worms tend to use vulnerabilities that are already known and simply have not been patched or protected against. In the past, there were an embarrassing number of such exploits to choose among, and it might take years between the time that a vulnerability became known, and the time that a specific attack exploited it.

As the field progressed, and high-profile attacks (such as the Morris Internet Worm of 1988) raised awareness of the need to address such venerable and well-known susceptibilities, the blackhat community needed to find newer and lesser-known openings to exploit. Since the turn of the millennium, it has become clear that the time between discovery of a weakness and its exploitation has diminished from years to months, and even to weeks. Therefore, one can talk about a six-month exploit or a five-week exploit to indicate the time between discovery and use of a particular weakness (Jose Nazario, in his book “Defense and Detection Strategies Against Internet Worms,”).

The ultimate and logical conclusion, of course, is that eventually an exploit will occurs as soon as the vulnerability is announced, or that the blackhats will discover a vulnerability before anyone else does, so the first anyone knows about the weakness is when an attack happens. Thus, no days (or fewer than none) would elapse between the discovery of the vulnerability and the exploit: this would then be a zero-day exploit.

Interestingly, the term has existed for many years in military strategy. During World War II, the Germans, in relation to the concept of *blitzkreig* [lightning war], used *null-tag* [zero day] to refer to an attack with no advance warning.

200.3 Use of the Term and Defining Factors

The use of the term “[certain period] vulnerability” or “exploit” may have a number of functional meanings. It may be employed to indicate relative ease or accessibility of exploitation of various vulnerabilities. Or, it may demonstrate either activity or eagerness on the part of the blackhat community. Tracking the reduction in the size of the time window between discovering and exercising a problem may provide us with information to develop or improve policies on to patch management and change control.

The recent excitement over the Windows meta-file format raises another issue for consideration concerning the availability of patches. Microsoft was not “first past the post” with a correction for the situation. Therefore, any definition of a zero-day vulnerability needs to take this factor into account: are we only concerned with the availability of patches or work-arounds from any source, or are we specifically alarmed by the inaccessibility of materials from the original vendor?

Some confusion may result from the use of “zero day” with regard to either a vulnerability or to an exploit. For example, it may be useful to refer to a zero-day exploit in terms of an exploit against a vulnerability for which a patch does not exist. This gives a real measure of security because it refers to a very specific threat for which no definite countermeasure exists, save for avoidance. On the other hand, using the term *zero-day vulnerability* to describe a discovered vulnerability for which a patch does not exist is less helpful. In that case, we do not know if a particular exploit or attack exists. In addition, *zero day* would provide information as to whether the vulnerability has just been discovered, or has been known for some time and is still not covered.

The term *zero day* has been also used both as to discovery and to disclosure, and, of course, these two activities will affect the significance of the phrase. Does the zero day come when the exploit is known to anyone? Or, is it restricted to the time at which a vulnerability is known to the vendor? Or does the clock only start with the problem being known more generally? This determination is not simply another issue in the debate between full, partial, and nondisclosure philosophies and positions. The precise definition of the zeroth day has decided implications for levels of risk and risk management.

200.4 Misuse and Dilution

In the real world, the term is, of course, misused. A web search for the term *zero day* will turn up references to pirated software, movies, and other copyrighted works that are available in unauthorized forms on the day of release of the original work. Although piracy and the unauthorized use of intellectual property are problems, the ability to make illegal copies is not news. The ability to make illicit materials available in ever-shorter timeframes is a definite nuisance, but is not a difference in kind from previous activity of the same sort.

There are also some security and anti-malware vendors pushing zero-day protection from threats. In almost all such cases, the safeguards being sold offer the same generic protections (activity monitoring, heuristic scanning, and sometimes change or anomaly detection) that have been available for many years. Once again, the addition of the term *zero day* offers no new types of countermeasures nor an increase in protection.

There is also a Zero Day Initiative (ZDI) promoted by Tipping Point and 3Com. This project is a reward program for finding vulnerabilities, under a partial or controlled disclosure scheme. Although the system has been designed with some levels of controls in mind, the inherent problems of reward programs for vulnerability, malware, and exploit disclosure are well known. The ZDI does not appear to offer any advantage for faster discovery of software problems.

The misuse of the term also extends to definitions that are too broad. For example, some glossaries are starting to include a zero-day exploit as a new exploit against a known vulnerability. Those who study malware know that any vulnerability can be exploited in a wide variety of ways, so this usage does not lead to additional understanding of risk levels. Other vague definitions encompass an exploit against a vulnerability that is not widely known. Because most computer users know next to nothing about vulnerabilities, that could be said to apply to almost every exploit that exists.

Most recently, the term *zero-day exploit* has been used to refer to polymorphic viruses. Not only is a polymorphic virus not a new entity in each generation, but most will use exploits or vulnerabilities that are already well known. Thus the use of the term in this situation is particularly inappropriate.

200.5 Summary

Although the use of *zero-day exploit* to refer to a particular category of blackhat activity or the use of the term *zero-day vulnerability* to refer to ease of exploitation have some merit, it is unfortunate that the most extensive use of *zero day* appears connected to writings of a sensationalistic nature, and to have impeded technical comprehension or definition. In this environment, it is unlikely that the phrase will be useful or well defined in current or future use.

201

Understanding Service Level Agreements

Gilbert Held

201.1 Overview

A service level agreement (SLA) represents a binding contract between a network service provider (or communications carrier) and a customer. The SLA specifies, in measurable terms, what services the network provider will furnish and the penalties, if any, for not providing a specific level of service. Because an SLA indicates an expected level of service as well as potential penalties for not providing such service, many information systems (IS) departments in large organizations have adopted the concept of providing SLAs to their customers. While such agreements are to be commended because they clarify customer expectations, this article primarily focuses on SLAs issued by network service providers to their customers. For both types of agreements, it is important to have measurable or quantifiable metrics incorporated within the contract. Such measurements should be easily determined by both parties to the agreement, and any penalties resulting from a level of service falling below a specified level should be carefully examined by organizations on the receiving side of an SLA. As discussed later, certain limitations that place a cap on poor performance can result in an organization having a legal obligation to continue to pay for inferior performance while being limited to receiving, at best, a minor amount of credit each month.

201.2 Metrics

Although the metrics defined in an SLA can vary based on the type of service provided, most SLAs include a core set or group of metrics. Those core metrics normally include availability, bandwidth or guaranteed capacity, error rate, and packet delay or latency. The remainder of this section deals with obtaining a detailed understanding of each metric.

201.2.1 Availability

Availability refers to the ability of a client to gain access to the communications carrier network. From a mathematical perspective, availability (A) can be expressed as follows:

$$A\% = 100 \times \frac{\text{Operational time}}{\text{Operational time} + \text{nonoperational time}}$$

From the above equation, you can note that the denominator—“operational time + nonoperational time”—is equivalent to total time. For example, assume that over a 30-day period an organization was almost always able to access the communications carrier’s network except for a two-hour period when an access line became inoperative. Then, availability for the month would become:

$$A\% = 100 \times \frac{30 \times 24 - 2}{30 \times 234} = 100 \times \frac{718}{720}$$

$$A\% = 99.72$$

As an alternative to the previous equation, some service providers express availability in terms of mean time to failure (MTTF) and mean time to repair (MTTR). When expressed in this manner, the total time is MTTF + MTTR, resulting in availability expressed as a percentage as follows:

$$\text{Availability } \% - 100 \times \frac{\text{MTTF}}{\text{MTTF} + \text{MTTR}}$$

It is important to note that some service providers do not automatically start the clock rolling when a failure occurs. Instead, their failure computation begins at the time the customer notifies the help desk. While this may appear to be a reasonable method for computing availability a few years ago, with the growth in diagnostic testing and the ability of network management centers to monitor the status of circuits in real-time, customers should carefully consider when network failure computations begin.

When examining availability levels defined in an SLA, it is also important to note the period for which a specific level is guaranteed. Although most communications carriers define availability on a monthly basis for each 24-hour day in the month, most organizations use the vast majority of network facilities during an eight-hour period each day that corresponds to the working day. Thus, a level of availability expressed over a 24-hour period that appears reasonable could become a problem if all or a majority of network access failures were concentrated into the eight-hour time period, which corresponds to the business day. Thus, it is important to examine the *operational period* associated with availability metrics listed in an SLA.

Another important availability-level consideration is in the expression of availability. While the availability level is most often expressed as a percent, it is important to consider what the percentage represents. For example, an availability level of 99.1 percent for a 30-day month means that the service provider can have the following outage duration per month:

$$30 \text{ days} \times 24 \text{ hours/day} \times 0.009, \text{ or } 6.48 \text{ hours}$$

This means that an organization needs to examine availability expressed as a percentage and convert that percentage into a time period. Then, one needs to ask if the organization is willing to allow the service provider to have, as per this example, almost seven hours of access outages per month.

201.2.2 Bandwidth

Bandwidth or capacity refers to the amount of data a location can transmit per unit time. In the past, the installation of a T1, fractional T1, T3, or fractional T3 line resulted in an organization being able to transmit and receive at the maximum capacity of the access line. Because most organizations only periodically require the full capacity of the access line, service providers commonly set their rates according to the use of the transmission facility, in effect creating a tiered rate plan based on usage. For example, a service provider might establish a four-tiered rate schedule for a customer that installed a T1 access line operating at 1.544 Mbps. The first tier would set a monthly price when the customer's average transmit level was at or under 384 Kbps, while the second tier would have a different monthly price associated with the customer having a monthly average line occupancy level greater than 384 Kbps but less than or equal to 768 Kbps. Similarly, the third-tier pricing level would occur when the average line occupancy level was greater than 768 Kbps but less or equal to 1152 Kbps, with the fourth tier representing an average line occupancy greater than 1152 Kbps.

Because the service provider may oversubscribe the maximum transmission rate of a group of customers within a geographical area above the capacity of a network node, this means that not all customers can burst transmission at the same time. Recognizing this fact, many service providers added a bandwidth or capacity SLA metric to their contract. Under this performance metric, customers are guaranteed the ability to burst up to the maximum access in capacity for a certain period of time, such as 80 percent of the business day.

A more common method associated with bandwidth or capacity can occur when service providers guarantee a percentage of frames or packets that flow from end-to-end through their networks. A negative metric is usually employed, with the service provider guaranteeing that the percentage of dropped frames will not exceed a certain value. For example, the service provider might guarantee that the average number of frames or packets dropped will not exceed 0.0001 percent, or 1 per 10,000.

201.2.3 Error Rate

Although availability and bandwidth are important metrics, it is also extremely important for data to arrive at its destination unaltered. Thus, another performance metric incorporated into many SLAs is an error rate. There are several types of error rates that can be used by service providers. Perhaps the most common method used for error rate is a percentage of unaltered frames or packets. For example, a service provider could include a performance metric that guarantees 99.9 percent of frames or packets arrive at their destination without being in error. A second common method of expressing an error rate within an SLA is obtained by defining a bit error rate (BER), which is typically expressed in terms of the number of bits in error per million (10^6) bits transmitted. Although at first glance the difference between expressing an error rate in terms of frames or packets being in error and a bit error rate may appear minor, in actuality the differences can be considerable, especially when comparing service providers that use different performance metrics in their SLAs. To illustrate the differences between the two metrics, consider Exhibit 201.1, which compares the occurrence of bit errors on two service provider networks to a series of frames or packets transmitted over those networks.

Both service providers are shown to have six bit errors during the same period of time; however, service provider X's bit errors are distributed over time while service provider Y's bit errors occur during one small interval of time, more than likely representing a burst of errors due to electromechanical interference, lightning, or other impairment.

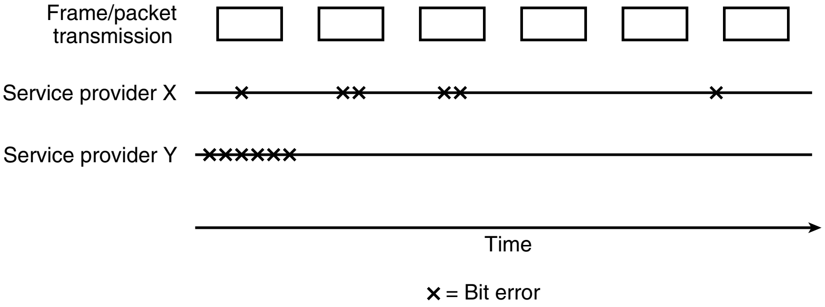

EXHIBIT 201.1 Comparing bit errors of two service provider networks.

If you compare the transmission of frames or packets shown in the top portion of Exhibit 201.1 to the bit errors occurring using service provider X, you will note that the errors adversely affect three frames or packets. In comparison, if you compare the bit errors that are shown occurring on service provider Y's network to the sequence of frames or packets being transmitted, you will note that only one frame or packet is adversely affected.

If you are using a Frame Relay network, errored frames are dropped and a timeout period occurs with a lack of response that results in the frame being retransmitted. In a TCP/IP packet environment, a bit error occurring in a packet results in the receiving destination rejecting the packet, causing the originator to re-send previously transmitted data. Thus, regardless of the type of network used, the result of distributed bit errors is retransmission of frames or packets, which adversely affects throughput. For this reason, we cannot directly compare bit error rates between service providers, and this explains why a majority of service providers express the error rate in their SLAs in terms of either error-free or errored frames or packets and not in terms of a bit error rate.

201.2.4 Packet Delay

The level of packet delay or latency becomes important when an organization transmits time-sensitive information, such as video or voice, over a service provider's network. In addition, it is important to note the manner by which packet delay or latency is computed because key differences can occur between the methods used by different service providers. Concerning the latter, some service providers define packet delay or latency from the ingress point into their network to the egress point out of their network. Other service providers, especially vendors that offer a managed Frame Relay or IPSec VPN service, define packet delay on an end-to-end basis. While the differences between the two may appear trivial, in actuality they can be considerable due to the differences between the types of circuits used for a network backbone and local access line.

Exhibit 201.2 illustrates a comparison of packet delay for network ingress through network egress versus end-to-end delay. Note that the end-to-end delay results in the inclusion of the delays associated with transmitting data over each access line. Service providers specify network delay or latency in terms of milliseconds (msec), with between 100 and 125 msec commonly guaranteed for nationwide transmission, with an extra 25 msec added to latency guarantees when transmission occurs between locations in Europe and North America or between Japan and North America. If the service provider delay is not

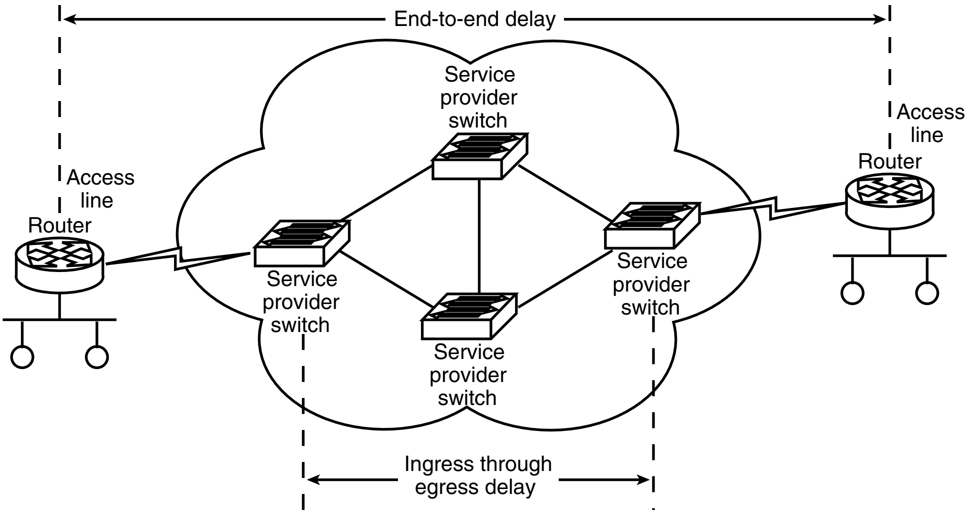

EXHIBIT 201.2 Comparing network delay or (latency) computation methods.

expressed in terms of end-to-end delay, one needs to compute the delay associated with the organization's access lines if one is considering running time-dependent data through the network. Then, one needs to add the access line delay to the service provider's network delay metric to determine if the total end-to-end delay will adversely affect any real-time application the organization intends to use.

To illustrate an example of the computations involved, assume a service provider you are considering offers a 125 msec network delay guarantee. Also assume that your organization plans to transmit digitized voice over the service provider's network, with each digitized packet 128 bytes in length. If the access line operates at 256 Kbps, then the delay associated with transmitting the packet through the access line becomes:

$$\frac{128\ \text{bytes} \times 8\ \text{bits/byte}}{256,000\ \text{bits/sec}} = 4\ \text{msec}$$

If we further assume that the network egress access line operates at 256 Kbps, then that line contributes an additional 4 msec of delay, resulting in the total access line delay being 8 msec. Thus, you would then add 8 msec to the network delay of 125 msec, resulting in a total delay of 133 msec, which would then be compared to the constraints associated with the real-time application you expect to operate over the network. Now that we have an appreciation for the key metrics used in SLAs, we will conclude our examination of SLAs by turning our attention to penalties typically incorporated into SLAs and how a penalty cap needs to be carefully examined.

201.3 Penalties and Penalty Caps

Failure to comply with one or more metrics guaranteed within an SLA results in a penalty assigned to the service provider. Although penalties can vary between service provider SLAs, most penalties result in a cash credit to the customer. Penalties are usually structured on a tiered basis, increasing in tandem with a deterioration in the level of service provided. For example, an SLA might guarantee a packet delivery rate of 99.9 percent. If the delivery rate falls below that level for any 24-hour period, the customer might be provided with a credit similar to the example listed in Exhibit 201.3. Note that the credit to the customer is commonly expressed in terms of credit hours, which is used to reduce the monthly bill. That is, if the customer was billed $2000 per month, a 24-hour credit would be converted to $2000 per month/30 days/month, or $66.66, thus reducing the monthly bill by that amount. While it may appear reasonable to receive a full day's credit when the packet delivery rate falls below 99.7 percent, what happens when the delivery rate remains below that level for an extended period of time? Unfortunately for the customer, all service providers place a cap on the maximum amount of credit that can be applied to any monthly bill. Thus, customers that experience unacceptable levels of packet delivery for a prolonged period of time might be limited to a credit of two or three days' worth of service on their monthly bills. Obviously, an organization would prefer a high level of service in comparison to receiving a credit for a few days of service when the level of service is not acceptable over a prolonged period of time.

While most service providers will not remove credit caps, some will allow a contract exit clause, which should be considered when negotiating a contract. Under an exit clause, the customer is able to terminate a long-term contract without penalty if the level of performance of one or more SLA metrics continues at

EXHIBIT 201.3 Potential Packet Delivery Credit

Credit to Customer	Packet Delivery Rate (%)
No credit	$\geq$99.9
4 hours	99.8–99.9
8 hours	99.7–99.8
24 hours	$<$99.7

an unacceptable level for a prolonged period of time. By insisting on the inclusion of an exit clause in the contract negotiated with a service provider, not only dies this place pressure on the service provider to rapidly correct problems but, in addition, it also permits an organization to change service providers without being locked into a long-term contract where performance degrades and penalties do not rectify the situation.

201.4 Recommended Course of Action

Service level agreements can be quite valuable as they specify the level of network performance an organization is expected to receive and penalties when performance does not reach stated levels. Like any binding contract, it is important to consider all aspects of the SLA to include how metrics are measured, credits issued by the service provider, and the cap on monthly credits. In addition, an exit clause should be written into the contract to allow an organization to consider another vendor if an undesirable level of performance is the rule rather than the exception. By carefully examining SLAs, one can select a service provider that will best meet the requirements of the organization.

Physical Access Control

Dan M. Bowers

The objective of physical access control is not to restrict access but to control it. That is, the data center manager should know who is granted access, when access is granted, and why. This chapter provides overview of the function of access control systems, the physical elements they can use, and the basic techniques they employ. It also describes two popular access control technologies, keypad access control and portable-key access control, and discusses their advantages and disadvantages. The chapter also examines two other technologies, proximity access control and physical-attribute access control, as well as several developing technologies.

202.1 Problems Addressed

Access control devices and systems are an important part of every security system. In a large-scale security system there may be intrusion alarms, motion detectors, exit alarms, closed-circuit television surveillance, guards and patrols, physical barriers and turnstiles, and a variety of other devices and systems. The combined advantages of these elements characterize an effective physical security system. This chapter provides a guide for the data center manager who must determine the optimal combination for an IS installation and networks.

202.2 Types of Access Control

This section discusses access control systems and devices and briefly describes the other elements that make up the total security system.

202.2.1 Portal Hardware

Portal hardware includes some simple and obvious devices. The simplest single-door access control system includes at least an electric strike to automatically unlock the door, a timer to make sure that the door does not stay open all day, and a bell or light to indicate when the door is opened or that it has not reclosed properly. There may also be sensors to ensure that bolts are fully engaged and exit switches or sensors to allow people to exit without activating an alarm.

202.2.2 Physical Barriers

To make certain that all persons entering a facility are scrutinized by the access control equipment, they must be prevented from entering areas in which there is no access control equipment. The design of such physical barriers as walls, fences, windows, air vents, and moats is an important part of a security system.

202.2.3 Turnstiles

These can be incorporated to ensure that only one person enters through a controlled portal at a time.

202.2.4 Guards

Many of the most effective security systems use guards and automated systems rather than relying wholly on one or the other.

202.2.5 Other Sensors and Annunciators

In addition to devices used in portal hardware, sensors are frequently useful and can usually be monitored directly by the access control system. These sensors can include intrusion detectors, motion detectors, object protection alarms, smoke detectors, and tamper alarms.

202.2.6 Multiple Systems

Usually, access control systems are provided in conjunction with other security and safety systems. Frequently, there are closed-circuit television cameras and monitors and object surveillance systems. There may be an extensive alarm-monitoring system. Access control is sometimes combined with a time-and-attendance or job-cost monitoring system, because the data required for these systems frequently can be collected at the access control point. Energy management and other forms of facility automation are increasingly being provided along with the security system. Clearly, the more functions that are provided, the more complex the total system design task becomes and the more vital it is that all of the systems efficiently mesh together.

202.2.7 Processors and Controllers

In a simple one-portal access control device, the controller can consist of a single-circuit board containing circuitry that can verify entry codes and energize a door strike. At the other end of the spectrum, a system encompassing access control, fire detection, alarm handling, time-and-attendance monitoring, and energy management will require a sizable computer and an extensive communications controller, along with a substantial software and maintenance investment. Between these extremes, there are a nearly-infinite number of ways in which the required control intelligence can be distributed within the system.

202.2.8 Central Alarm Station

For monitoring and controlling an electronic security system, one alternative to employing a dedicated in-house processor and response staff is to locate this function in a central alarm station.

202.2.9 Electrical Power System

Any security system relies on an electrical power system. Such systems, however, are subject to numerous aberrations, including blackouts (local or widespread) that must be accounted for in a complete system design.

202.2.10 People

Frequently, one of the last factors to be considered in the design of a system is that people are the reason for the existence of data security systems. There are people who must be admitted to the facility without delay, and there may be different sets of people who must be admitted to different areas of the facility, and perhaps only during certain times. There are people who must not be admitted to the facility at all. Consequently, a data security force is necessary to monitor admission activities, respond to alarms, and handle unusual situations.

202.3 Designing the Total Security System

In the design of the total security system, it is essential that the user begins with an analysis of risks and threats. However, it is not within the scope of this chapter to provide instruction in risk analysis. Some of the more important studies that should be conducted during this process are:

- *Identifying the most serious risks.* The lesser risks can frequently be resolved as by-products of the basic security provided.
- *Determining the requirements for authorized entrants.* Who is granted entry, how often, and at what times?
- *Examining the geography of the facility.* The physical layout is an important determinant of the required security measures and equipment.
- *Will the various security systems be independent or combined?* Access control, alarms, closed-circuit television, and all other systems should be taken into consideration.
- *Should the security system be combined with other functions?* Energy management, time-and-attendance monitoring, and other functions that may be integrated should be considered.
- *Local control or a commercial central station?* The control center should be located in a secure area for monitoring, management, and response of the security system.

202.3.1 Principles of Access Control

A complete access control system performs three essential functions within the security system:

1. Limiting access through a portal to a defined list of authorized persons
2. Creating an alarm if illegitimate access or activity is detected
3. Providing a record of all accesses for use in postincident investigation

Not all systems provide all of these functions.

To identify authorized persons, all access control systems use one or more of three basic techniques, which have been described as involving something a person knows, something a person has, and something a person is or does. Physically, examples of these three security methods are the combination lock, the portable key, and the physical attribute.

The combination lock is also called a stored-code system; the code is a series of numbers that is stored both in the user's memory and in the lock mechanism, and entry of the correct code by the user with a rotary dial or a set of push buttons allows access. Access control systems universally use a set of push buttons for entry of the code in a combination lock system, and they are usually known as keypad access control systems.

The portable key operates on the principle that if the prospective admittee possesses an object that itself contains the proper access code, that person is qualified to be admitted; the ordinary metal key and lock is the simplest example of such a system. Although ordinary metal keys are easily duplicated and ordinary locks are easily picked, there are key-and-lock systems that are the equal of many modern card-access systems in both security and price; both post office boxes and bank safe-deposit boxes are opened with metal keys (and in both cases the portable-key system is combined with other elements to make up an effective total security system).

The most common form of portable-key access control uses a plastic card with a magnetic stripe as the key, but there are also a variety of sizes and shapes of tokens, metal and plastic keys, and even pens and rings. The code is embedded in these devices by various means, and the key is recognized by a mechanism that automatically reads the code when the key is inserted in a slot, groove, or hole.

Another method of portable-key access control (which is discussed later) uses proximity cards that emit a signal that can be picked up by a badge reader to open doors for authorized persons. Often, card access devices are combined with employee badges to minimize the temptation to allow someone else to use the access control card or to prevent an intruder from using a lost or stolen card.

The physical-attribute system, which is also examined later, is based on recognizing a unique physical or behavioral characteristic of the person to be allowed admittance. In the past, this characteristic has been the human face, and the access control system consisted of a guard who compared the actual face with a picture badge or ID card; this is still the most widespread physical-attribute system in use today. There are also automatic and semiautomatic systems using faces, fingerprints, hand geometry, voiceprints, signatures, and the pattern of blood vessels on the wrist and the retina of the eye.

An access control system is not necessarily a personal identification system, and not all personal identification systems are used for access control. The following categorizations of access control systems may be useful:

- *Universal code or card*: All persons who may be admitted know the same code or carry a card containing the same code, and the access control system opens the portal when it recognizes the code.
- *Group coding*: Persons have a code or card-code that identifies them as part of a group to be admitted to a particular area or at a particular time.
- *Personal identification systems*: A unique code number or set of physical attributes is assigned to each person, and the access decision is based upon whether that particular individual is to be admitted to that place at that time. Personal identification systems have other applications as well, including time-and-attendance monitoring and job-cost accounting data collection.

202.3.2 Weaknesses, Combinations, and Features

There are fundamental weaknesses in all of these basic techniques that automation cannot change. A code can be divulged to an accomplice or observed during entry. A key can be stolen, lost, copied, or given to an accomplice. These situations can occur whether the code and key are meant to open $1.98 locks or are recognized by $100,000 computer systems. Physical-attribute systems have inherent false-acceptance and false-rejection errors, and the two kinds of errors are usually balanced against each other.

Combinations of techniques can greatly increase the security of a system. For example, a code-plus-key system requires that the prospective admittee inserts the key into a reader and enters the proper code using a keypad. This removes many of the weaknesses of the two simpler systems; it also costs more than either of the simpler systems alone.

Other features that can improve the security of an access control system are:

- *Tamper alarms*: If a perpetrator can gain access by smashing or opening the electronic controller, the security level obviously has been diminished. The controls should not be accessible from the unprotected side of the portal, and a sensor should be provided that can detect an attack on the unit and create an alarm.
- *Power-fail protection*: Some units have internal batteries so that an access control device continues to perform its function even if power fails.
- *Fail-safe or fail-soft protection*: The equipment must be expected to fail, however infrequently. There should be a mechanical-key bypass to allow access under failure conditions. When failure occurs, the portal defaults to either permanently open or permanently closed.
- *Code changes*: An effective element of the security system can be the periodic changing of the access codes. Both the code that the person has or knows and the code within the access control equipment itself must be changed.

202.4 Keypad Access Control

Keypad access control devices use a combination-lock technique for access control; they require that a correct sequence of numbers is depressed on a set of push buttons or selected from a displayed sequence of numbers using a single push button to gain access. The mechanism may be mechanically operated, in which case the positions of the push buttons operate a mechanism similar to the tumblers in an ordinary lock, allowing the bolt to be manually operated or closing a switch that may operate an electric door strike. Most keypad devices are electronically operated, with the sequence of push buttons being decoded by logic circuits and the door being electrically unlocked.

As in all combination-lock devices, the level of security that is provided depends on the number of combinations available. The number of combinations provided depends on the following factors:

- The number of keys or code numbers provided
- The number of key depressions required to enter the code
- Whether a key may be repeated in the code sequence
- Whether multiple keys may be depressed at one time

Most keypad access control systems use a ten-key pad and a four-digit repeating, nonmultiple code. However, there are systems that use from 5 to 16 keys and from 2- to 10-digit codes, and the number of code combinations ranges from 720 to more than 4 million.

The simplest method of attacking a keypad control system is to try all possible numerical combinations. The defenses against such attack are:

- *Number of combinations*: The greater the number of combinations, the longer the time needed to try them all.

- *Frequent code changes*: A large number of combinations require the perpetrator to try them over a period of days or weeks; changing the code during the period requires the attacker to begin all over again.
- *Time penalty (error lockout)*: This is a feature available with many keypad systems. It deactivates the system for a selected period of time after entry of an incorrect number, so unauthorized persons cannot quickly try a large number of combinations.
- *Combination time*: This option is available with most keypad systems. The system controls the amount of time allowed to enter the combination. Because authorized persons can readily enter their numbers, anyone taking excessive time is likely to be unauthorized.
- *Error alarms*: After an incorrect number has been entered (or in some cases, two or three incorrect numbers), these alarms are activated. This option prevents unauthorized persons from trying a large number of incorrect combinations.

202.4.1 Keypad Options and Features

The most significant options and features found in keypad access control systems are:

- *Master keying*: This option allows supervisory persons access using a code that overrides any restrictions (e.g., time-of-day restrictions) on the code provided to end users, and it usually allows the changing of the ordinary code using the keypad itself.
- *Key override*: Sometimes a metal-key override capability is provided for emergency and supervisory use. If this feature is chosen, it must be recognized that the system has been weakened by allowing both keypad and metal-key access.
- *Door delay*: The length of time that the door is unlocked and can be held open without alarm is controlled and usually is adjustable.
- *Remote indication*: There is usually an electrical means of providing a remote indication (at a guard station or central monitoring facility) that a portal is open.
- *Visitors' call*: A special button may be designated so that persons not possessing the combination may request entry.
- *Hostage or duress alarm*: In the event that an authorized entrant is physically coerced into opening a portal, a hidden alarm can be sounded by depressing an extra or alternative digit.
- *Personal identification*: A few keypad systems provide individual access codes for each authorized person.
- *Weatherproof units:* These are provided by many manufacturers for use on outdoor portals. There are also many forms of indoor units, some with attractive decor, and glow-in-the-dark and lighted keypads.

Most keypad access control devices are self-contained, stand-alone devices intended to operate a single portal using a common code. There are also those that obtain their intelligence from a central control unit that can control multiple portals and may also provide logging, space-and-time zone control, and other relatively sophisticated features. In addition, most manufacturers of card-access systems now offer the option of adding keypad access, thus providing a card-plus-keypad system, as discussed in a later section.

202.4.2 Strengths and Weaknesses of Keypad Systems

The cost of a simple, single-door keypad access control device with simple electronic keypads begins in the $100 range. The keypad alone, with rudimentary electronics, can be bought for as low as $20, but the organization must then add door strikes and battery or power supplies. Mainstream commercial-grade protection begins in the $100 range for mechanical and electrical keypads, and the electrical versions require an equal additional expenditure for a reliable electric strike and other necessary equipment. Installed costs can range from $200 to $500; for pure combination-lock-level access control, without penalties or gadgetry, these units are worth the expense.

Therefore, the first positive attribute of a keypad access system is that it is the least expensive means of providing electronic access control in place of—or in addition to—the conventional metal lock and key. Some other positive attributes are:

- Keypad access control can be made very secure if it provides many possible combinations and is installed as part of a system of secure, frequent code changes.
- Changing the code in a keypad system is a quick and simple process, unlike rekeying a lock-and-key system.
- Keypads are especially effective in combination with other forms of access control (e.g., cards or personal attribute systems).

On the negative side, some characteristics of keypad access systems that should be considered before the security of an operation is entrusted to these devices are:

- The code can be divulged without penalty. An insider can reveal the code to an accomplice, who then can gain illicit entry.
- Longer codes provide better security but also encourage authorized persons to write them down rather than memorize them. Therefore, they can be stolen more easily.
- The code can be determined by trying many combinations, if the precautions described are not implemented.
- The code can be observed as it is entered. Some manufacturers offer privacy panels to prevent such observation. One manufacturer provides a random and always-changing placement of the digits on the keypad, using an LED display, so that the numbers cannot be deduced by observing the positions of the depressed keys; another has a rolling single-digit display that is selected by a single push button, preventing an observer from determining what digit was selected.

The two most serious defects in the keypad access system are being able to divulge the code without penalty and the observability of the code numbers; for these reasons, keypad access should never be used alone except in minimum-security applications.

202.5 Portable-Key Access Control

A portable-key access control system admits the holder of a device (which may be a plastic card or other device) that contains a prerecorded code. The device is inserted into a reader, and if it contains the code that the reader requires, the portal is unlocked. This process is no different in concept from the operation of ordinary metal keys and locks. Modern systems, however, use keys that are more difficult to duplicate, and these systems can provide complex logic, identification, control, and logging functions that a simple key cannot. It should be recognized, however, that some versions of the metal lock-and-key system provide at least as much security as the simplest versions of card-access, at comparable cost.

The plastic, wallet-size card is overwhelmingly the most popular device used for portable-key access control systems. It is offered by 97 percent of the vendors, though 10 percent of these vendors offer other forms of portable keys as well. The second most popular device is a key-shaped token, usually plastic but sometimes metal; Medeco offers a standard metal key that contains an integrated computer circuit. Some versions are small enough to fit on an ordinary key ring. There are also metal cards of various sizes and several other kinds of metal-and-plastic tokens, strips, pens, and even finger rings. There is some merit in selecting a standard system to avoid dependence on a single vendor. On the other hand, there is some additional security conferred by using a relatively unique device.

202.5.1 Coding Methods

Various techniques and technologies are used to store the access code on or in the key device. Many of the early automated systems used simple visible bar codes that were read by photocells. Others used Hollerith-coded cards with punched holes identical to those in conventional computer cards, which were read by a punched-card reader. Some of these systems are still available. Other cards contained an electrical diode matrix reader, and the card made an electrical connection with the reader. These may be viewed as an ancestor of the modern smart card; they functioned with as much intelligence as they could, using the available technology.

Currently, most devices are magnetically encoded, and there are three basic types. The bank-card type has a magnetic stripe. The code is recorded magnetically onto the stripe and can be read, erased, and altered using conventional magnetic tape technology. Because this technology is well-known and readily available, the cards are easily corruptible, and several additional safeguards have therefore been developed for situations requiring high-level security. Some vendors encrypt the data on the card so that even if it is read, it is not useful to the perpetrator. Many users, including banks, use a keypad in conjunction with the card reader, so a code must be entered in addition to an acceptable card. Malco Systems has invented a technique called watermark magnetics, which embeds a code during the card manufacturing process; the code cannot be altered and can be read only by a special reader.

The second type of magnetic encoding uses bits of magnetic material—magnetic slugs—embedded into the card during manufacturing. It is read by an array of magnetic-sensing heads to determine whether there is a slug at each of the possible positions. Wiegand-effect coding is currently the only popular magnetic-slug method in use. Each Wiegand slug incorporates a small bit of wire that is heat-treated under torsion, resulting in a magnetic snap-action. This creates a consistent signal over a wide range of reading speeds, unlike conventional magnetics, in which the read signal is proportionate to the speed of the card past the reader. Wiegand-effect coding yields superior performance in swipe readers, for example, in which the user manually moves the card past the read heads.

The third type of magnetic encoding is a descendent of the magnetic slug. It has a sandwich construction with a sheet of magnetic material in the center of the card; spots can be magnetized at various positions on the sheet, thus creating coding to be read by a magnetic-sensing head. These are usually called barium ferrite cards (named for their magnetic material).

There are several nonmagnetic coding techniques, many that are unique to a specific vendor who has developed the technique for a particular purpose, to be used only in its product line. There have been embedded-slug systems using capacitive and conductive particles that were sensed capacitively; none are known to be currently available. There was once a card using radioactive slugs that were read by a Geiger-counter type of apparatus (it was not enthusiastically received). There are embedded-slug devices using nonmagnetic metal slugs, which are read by eddy-current sensors similar to airport metal-detecting equipment. There are several devices coded by tuned circuits and read using radio waves; because these do not require the insertion of the card or token into a reading mechanism, they are categorized as proximity access control devices (discussed later in this chapter). In addition, there are several devices that use bar codes (frequently infrared-encoded so as not to be visible). There are also holographically encoded devices; several of these have come and gone since the first one was introduced by RCA in 1973.

The smart card is the latest manifestation of a portable key, though it has been highly touted and widely tested for a decade. The smart card comes in various grades of intelligence; it contains one or more integrated circuit chips, varying amounts of memory, sometimes a battery, and even a keyboard and display. Access codes are stored using various forms of encryption and manipulation algorithms and are communicated electronically to the access control system when requested.

The number of possible combinations of cards, personal identifiers, different companies and facilities within companies, time zones, and other factors that can be controlled by an access control system is determined by the number of binary digits that can be encoded on or in the access control device. Ten to forty binary digits will inherently provide 10^3 to 10^{12} combinations respectively, and the digits beyond those needed for pure access control can be used for such purposes as personal information.

In systems that have more than the number of codes required to merely open a portal (and nearly all do), the extra digits can be used to store the employee's number, shift of work, or other useful information. Encoding this information allows control over employee access by time of day and by area of the facility. It can also provide a unique identifying number for each person, which is automatically entered into a log showing who passed through which portal at what time, thus allowing the system to be used as a time clock. With individual identification, cards can be easily deauthorized when an employee is terminated or the card is lost or stolen. Other features such as antipass-back and in-out readers (discussed later) are also made possible when individual identification is provided.

The ease of counterfeiting the credential in a portable-key system is largely determined by the encoding mechanism. Optical bar codes and Hollerith punches are clearly visible, recognizable, decodable, and duplicatable. Magnetic stripes require more expertise and equipment, but do not pose a problem for the professional with some equipment and resources; the specifications are published by the American National Standards Institute, and anyone can purchase an encoder for $2000. Although embedded materials provide another step in security, analytic equipment is capable of detecting and cracking the code. Smart cards are merely very portable computers, and they are vulnerable to most hackers of respectable skill. Organized crime, competitive corporations, and foreign governments all have sufficient resources to breach such security measures.

202.5.2 Portable-Key Options and Features

Options and features available with portable-key access control systems include:

- *Access device*: This can be a card, plastic key, metal token, or other device.
- *Coding means*: Available technologies include magnetic stripes, Wiegand-effect codes, bar codes, Hollerith punches, barium ferrite, and integrated circuits.
- *Individual identification:* This is the ability to identify particular people at access.
- *Maximum number of portals*: Until recently, manufacturers created systems that were designed for niches of a particular size (e.g., one door, a dozen doors, or hundreds of doors), and the user could select a system well suited to the organization's needs. With the advances in computer and communications systems technology, most systems are physically capable of being connected to a virtually unlimited number of doors. This does not necessarily mean that the manufacturer's software or understanding extends to a system with a large number of portals.
- *Space and time zones and access levels*: These are means of controlling access to particular areas by particular persons at particular times.
- *Keypad*: Most systems allow key-plus-keypad access control to be implemented.
- *Alarm handling:* Most access control equipment provides the ability to recognize and report or act on a specified number of electrical contact closures (e.g., alarm points). These points could be door-open contacts associated with the access control function, or they could be unrelated points (e.g., smoke detectors or intrusion alarms).
- *Degraded-mode capability*: This defines the level of control that survives under failure conditions (i.e., the local controller may provide a less-intelligent form of control if the central computer fails).
- *Code changes*: This defines whether the user can recode cards or tokens or whether new ones can be purchased if code changing becomes necessary.
- *Time-and-attendance monitoring*: Data collection capability is available with many systems.
- *Antipass-back*: This is a feature whereby after a person's card has been used to pass through a portal, the card must exit before it can again be used to enter; this requires that readers are provided both for entrance and exit. Some vendors offer timed antipass-back, a version in which a certain amount of time must elapse before the card can again be used to enter.

- *Individual lockout*: This provides the ability to invalidate a single individual card.
- *Computer interface*: If a standard form of communications interface is provided, the access control equipment can be easily linked to other security or facility management or central database systems.
- *Limited-use cards*: These are useful for visitors or contractors. The sundown card expires on a particular date. The one-time card can be used only once; the limited-use card can be used only a certain number of times.
- *Dual-key access (two-person rule)*: Two valid users must insert their cards for the portal to open.
- *Guard tour*: This provides a means of recording that patrolling guards make their appointed rounds at the appointed times.
- *Duress or hostage alarm*: This option is less easy to provide in a pure portable-key system than in a system with a keypad. Methods include running the card through backwards or pushing the card past an over-travel stop on an insertion reader.

202.5.3 Strengths and Weaknesses of Portable-Key Systems

The cost of a simple card reader begins in the $65 range and can go as high as $300. Intelligent single-portal systems with electric strike, power supply, and door contacts may provide some time-period control, individual lockout, and ability to be upgraded by being attached to a central computer; these are in the $500 to $1000 range, and another $2000 can add a logging capability.

Centrally controlled systems begin in the $2000 to $5000 range for mainstream, medium-scale access control and cost about $15,000 for relatively sophisticated features and a large number of terminals. These systems can cost hundreds of thousands of dollars when facility management capabilities are added. To this must be added the cost of the portal equipment. In most cases, costs of about $2000 per portal procure a satisfactory system, including the cost of installation and wiring.

The cost of the access control card or token must be considered during selection of a system. Most of the conventional plastic cards can be obtained for $1 to $2 each in reasonable quantities; the addition of logos, employee pictures, or pocket clips can drive this into the $4 to $6 range. Smart cards are three to four times higher.

The positive attributes of portable-key systems are sufficiently strong to make this method of access control by far the most widely used. The most important assets of portable-key systems are:

- They are pickproof. There is no means of operating the locking mechanism without having an access card that contains the proper code.
- They provide identification of the owner of the card. This is the most important feature. Individuals can be controlled as to when and where they are allowed to enter doors, a log can be kept of what person opened what door at what time, and the access privileges of a particular person can be changed or eliminated at any time.
- Many valuable features can be provided if needed. The two-person rule, sundown cards, antipass-back, timekeeping, and other options are available.
- They can be installed at reasonable cost for the performance they provide.

There are, of course, negative aspects of portable-key systems, namely:

- Cards can be lost, stolen, or given to an accomplice, and the possessor of the card will be granted all of the access privileges of the owner.
- Cards can be copied. This is true regardless of what manner of coding they employ; higher-technology encoding merely requires higher-technology counterfeiting.
- A duress alarm is more difficult to implement in a card system than in a keypad, and few card-access systems have duress alarms.

- The cost per portal is four times that of a keypad and thirty times that of an effective metal-key system, and in many applications it may not be warranted. In addition, if some of the more sophisticated features are not used, the card system may not provide higher security.
- The cost of the card or other forms of portable-key security can be a significant expense if there needs to be a large number of cardholders.

Combinations of individual access control techniques can give the user the best of both worlds, minimizing the defects and maximizing the positive attributes of the individual systems. For example, push-button access control devices are simple, reliable, and inexpensive, and their keys cannot be lost or stolen. However, the keys can be given away without penalty, and there is usually no personal identification capability. All persons possessing the correct code will be accepted by the code recognition unit. Card and other portable-key access control systems can have personal identification capabilities and can be made virtually pickproof; however, cards can be used by nonauthorized persons.

Key-plus-keypad systems combine the positive attributes of both these simpler systems. The person requesting admittance must possess the portable key and must know the numbers to use on the keypad. The numbers may be the same for every entrant, or each may have a different code to remember, or the code can be derived from information on the coded key or be related to the date on the calendar. Other combinations are also in common use; for example, card-plus-face, as on the picture badge, or keypad-plus-fingerprint, using automatic fingerprint recognition equipment.

Portable-key systems are indeed the mainstream in electronic access control, and they are used in every kind of application. When combined with keypad or personal-attribute systems, they provide sufficient security for such demanding applications as automated teller machines and high-security installations of the U.S. government.

202.6 Recommended Course of Action

Every security decision requires the balancing of risk and expenditure, and in choosing an access control system for a facility, the data center manger must decide what expenditure is warranted for the solution to the security problem. A total security and life safety system encompasses perimeter control, internal surveillance, access control, fire detection, walls and barriers, guards, employee screening, and audit trails. In many installations, measures are in place for many or all of these aspects, and the data center manager must weigh the costs of new or additional security measures.

The keypad access control system is simply a combination lock that is quicker to operate and more difficult to defeat and that has more features and options than does the version sold at the corner hardware store. Such features as hostage alarms, error alarms, and remote sensors can be valuable in many cases. Push-button systems cannot be employed alone in situations in which there is a large risk of collusion (because the combination can be divulged without penalty) unless one of the few systems with individual identification is employed. Keypad systems can cost ten times what common locks cost, and the increased security and extra features are well justified in many cases.

The card-only system is equivalent to a conventional lock and key, but it is more difficult to duplicate and can have many additional features. When equipped with personal identification, individual control, and access logs, these systems are virtually undefeatable by an amateur. The risk of lost and stolen cards is still present, and entry may be gained before the card's loss is known and its access privileges canceled. Card-only systems can cost 50 times as much as common locks and can provide sufficient additional security to justify that cost when the security needs require it; additional features and side benefits, such as collecting time-clock information, can also help justify costs.

Because no amount of ultra-high technology can create a card that is immune to loss or theft, it does not make much sense to pay a great deal of money for exotic coding techniques. Although sophisticated codes require more effort and resources to crack and duplicate, it will be done if the stakes are worth it. In addition, the security of card systems is not highly dependent on the code or its embodiment.

Card-plus-keypad systems plug the loss and theft loopholes in card-only systems and the collusion loophole in keypad systems; they cost little more than card-only systems and provide substantially increased security. The increased security provided by adding a keypad to a card system may well allow the use of a simple stand-alone system rather than a much more expensive, centrally controlled system requiring options and expensive wiring. Card-plus-keypad systems can therefore be less expensive than sophisticated card-only systems.

202.7 Proximity Access Control

Proximity access control defied all logic a decade ago by becoming well entrenched and then boosting its primary—and for a while only—promoter, Schlage Electronics, to the top in sales of access control equipment. The technology was more cumbersome than conventional card or keypad access, the cards and readers were more expensive, the reliability was (perhaps marginally) lower, and proximity still meant that in most cases a user had to extract the card from wallet or purse and place it against a reader instead of passing it through a slot.

Proximity access control continues to capture a significant and increasing market share, which supports half a dozen principal vendors. In addition, nearly all significant access control system vendors now feel compelled to offer proximity readers, though most vendors purchase the equipment from the six primary manufacturers and then affix their own brand or label on the equipment.

Proximity access control systems perform the usual functions of unlocking a portal, powering up a computer terminal, or disarming an alarm system by using a device that is in the possession of the person desiring admittance, but there is no necessity for physical or electrical contact between the coded device and the reading and controlling mechanism or system. Some proximity systems operate as card-access systems do, without requiring the card to be inserted into a reader; others are actually keypad systems without wiring between the keypad and the access control system. Some are automatically sensed when they come into the vicinity of a reader; some require an intentional action by the person possessing them.

In every access control system, a code must be communicated from the user-carried device to a reading mechanism; in keypad or card systems, this communication takes place electrically over physical wiring. In a proximity system, it is accomplished with electromagnetic (including radio and other derivative forms), optical (including infrared), or sonic (including ultrasound) transmissions.

202.7.1 Principles of Operation

There are two basic classes of proximity access control systems: those in which the user initiates transmission of the code to the system (e.g., the garage door opener) and those in which the system senses the presence of a coded device without the user's performing any action at all. These two classes are called the user-activated and system-sensing proximity systems, respectively.

The user-activated systems must incorporate a power source in the device carried by the user. This is a battery in all of the current units, but devices having other power sources are known to be in development. The types of user-activated systems are:

- *Wireless keypads*: The user depresses a sequence of keys on an ordinary keypad, and the coded representation of the keys is transmitted by radio (in one case by infrared light); the system detects the transmission and decodes it.
- *Preset code*: The code is set into the device by means of jumpers or switches (the garage door opener is the most common preset-code system), and the user depresses a single key that causes the code to be transmitted—by radio, ultrasound, or infrared—for the system to detect and decode.

The system-sensing systems implement a variety of technologies, range in cost, and operate at widely differing distances. Some require power from a battery inside the portable device, and some use power absorbed from the interrogating system. The several types are listed in the following sections.

202.7.1.1 Passive Devices

These devices contain no power source and communicate the code to their interrogator by reradiating the interrogating radio frequency (RF) signal at a frequency (or frequencies) different from the original. The most common technique incorporates tuned circuits in printed wiring on the card. This is similar to the operation of most electronic article-surveillance antishoplifting systems. One system uses a crystalline structure on the surface of the card.

202.7.1.2 Field-Powered Devices

These devices contain an active electronic circuit, including code storage electronics and an RF transmitter, along with a power supply circuit capable of extracting sufficient electrical power from the RF interrogating field to accomplish a transmission of the code in response to the interrogating signal.

202.7.1.3 Transponders

These devices are automatically operated two-way radio sets. The device, which contains a radio receiver, a radio transmitter, and code storage electronics, is battery powered. The system transmits a coded interrogating signal that is received by the device, and then the device transmits a return signal containing the access code. This operation is a wireless form of the poll-response process through which a computer communicates with its network of terminals, similar to the method used in air traffic control to identify airplanes to ground controllers.

202.7.1.4 Continuous Transmission

The device is battery powered and contains a radio transmitter that continuously transmits the entry code. When the device is a certain distance from a protected portal, the transmission is detected and the code is received by the system. Continuous transmission requires more battery power than the other battery-operated methods do; the batteries must be recharged every night.

202.7.2 Proximity Access Control Features and Functions

Proximity systems vary widely in performance, cost, and convenience. No single choice is best for all applications. Some parameters to be considered are:

- *Activation distance*: The distance at which a proximity system can be triggered varies from two inches to nearly fifty feet, with the battery-powered tokens providing the greatest distance.
- *Hands-off vs. triggered devices*: Some devices require the user to push buttons or keys; others require no action and thus need not be removed from pocket, wallet, or purse.
- *Concealment:* Because there is no need for accessible and visible keypads or card readers, most proximity systems can be installed so that the presence of an access control system is not obvious. This precaution in itself can add to the security of an installation.
- *Physical protection*: Because radio and optical waves can pass through such materials as cement, wood, brick, and bulletproof glass, most proximity access control systems can be easily protected from assault and vandalism by placing the interrogating unit behind a barrier.
- *Form and size of device*: Proximity tokens come in a range of sizes—from one that could fit into an empty medicine capsule to cigarette-pack size.
- *Code changes:* Passive cards and most field-powered devices have codes that are embedded and cannot be changed. All of the other devices (which are more expensive) allow the code to be changed by means of internal switches, jumpers, or an external programming unit.
- *Cost of token*: The system cost for proximity access control differs little from the cost of a conventional card-access system. The cost of the tokens varies widely from the high end of standard cards ($4 to $7) for the passive card versions, to the $10 vicinity for field-powered

devices, to $15 to $75 for active tokens, and $100 or more for the rugged, sophisticated tags used in manufacturing applications.

202.7.3 Strengths and Weaknesses of Proximity Access Control Systems

Proximity access control systems offer several unique features:

- The user is not required to remove a card from the wallet and pass it through a reader, but must be within the prescribed range of the reader.
- Because the readers can, in most cases, read through such materials as wood or plastic, the reader can be concealed, both to hide its presence from intruders and to protect it from vandalism.
- Because the reader can be placed within a wall, for many products it can be made to read on either side of the wall, thus providing both card entry and card exit using a single reader.

The disadvantages of proximity access control systems are:

- The more popular systems have a range of only a few inches; this requires that the user hold the wallet or purse very close to the reader, which somewhat reduces convenience.
- Because the proximity systems are wireless, they are susceptible to errors caused by transmissions and reradiations from sources exterior to the security system.
- Systems that have substantial reader range can have problems discriminating when more than one token-holder is within their field, because they can receive multiple transmissions.
- The cost of proximity access control systems is, in general, higher than that of card-access systems with equivalent features.
- Some proximity systems have a relatively low code capacity, though there is no inherent technical limitation for most kinds of systems.

There are many applications for which proximity access control is quite beneficial, such as those in which persons must open portals while burdened with packages or driving a vehicle. The ability to hide the reader within a wall is also important to applications in which vandalism can be expected and adds to the security of the system. The long-range systems are also used in personnel-locator and personnel-tracking systems, because they can detect a token-holder within the space under surveillance, without any action on the part of the token-holder. Most systems, however, are installed in conventional access control applications, in which card access would have done as well, and these system-sensing, passive-card systems must be considered part of the established mainstream of access control products.

202.8 Physical-Attribute Access Control Systems

The ultimate in reliable access control would uniquely identify a person and admit that person and only that person, regardless of whether the person possessed a particular coded token or knew a particular code. This ultimate system would be based on recognition of one or more physical attributes of the person. Automated systems for performing such a function have been available since the early 1970s; they are variously called physical-attribute systems, personal-characteristics systems, and biometric systems.

For two decades, access control industry experts have predicted widespread use of these systems, saying that only the cost problem stood in the way. For the past five years, these predictions have come almost entirely from those who have a vested interest in the technology, as the market share of physical-attribute systems has dwindled from insignificant to miniscule and the vendors have struggled, disappeared, or sold out. Although these systems eventually may predominate, the immediate prospects seem less promising than they did a decade ago.

Physical-attribute identification systems of the nonautomated variety have been in use for centuries (i.e., recognition of the human face by guards). In this century, picture-badge systems were introduced, allowing the guard to compare the face on the card with the face of the person; such systems use the human face as the unique physical attribute and are still in use in high-security installations of the U.S. government, on passports, and on the drivers' licenses of many states (which have become the most commonly accepted form of identification for banking and credit transactions). Two other physical attributes are also well-accepted means of personal identification: the signature and the fingerprint.

Many automated and semiautomated identification systems using these three basic physical attributes have been developed. Some are still available and are in common use. Three additional physical attributes have been added to most recent systems: the geometry of the hand, the characteristics of the voice, and the pattern of the blood vessels on the wrist and the retina.

202.8.1 Facial Recognition Systems

Access control using recognition of the human face is the most venerable form of access control. There is no fully automatic system using the face as the physical attribute. There are, however, semiautomatic (or machine-assisted) facial recognition systems that are really improvements on the concept of the picture badge; instead of the picture being carried on a card outside the system's control (and therefore subject to counterfeiting), the reference picture is stored internally (on microfilm, video tape, or disk) and presented to the guard for comparison with the actual face. An employee number is used to retrieve the reference picture from the file, thus making this a sort of face-plus-keypad system. Such systems cost several thousand dollars per portal. This kind of stored-face system has been offered by various vendors over the past two decades, beginning with Ampex in 1972.

A new form of machine-assisted facial recognition system has achieved considerable popularity during the past few years. Begun on the seemingly unpromising premise that users would be willing to pay $30,000 or more for a computer and video ID badge-making machine—rather than a $5000 film-based setup—video ID systems have burgeoned into full-fledged access control systems that present the photo of any person stored in the system at any remote station so that a guard can make the comparison with the real person.

There are also face-based access control systems that present a side-by-side display of a prospective entrant's face along with the picture ID that the person presents. These systems are remote picture-badge inspection systems.

A simple form of face-based access control is becoming commonplace in multiunit housing and is also offered for single-family homes. This is the video intercom, which allows the occupant to both speak with a visitor and see the visitor's face before opening the door.

202.8.2 Signature Comparison

The signature is the basis for personal identification in millions of financial transactions every day. When a signature comparison is made—usually at the bank teller's window—it is done by a teller who has no training in the subject, but is aided with the use of a personal identification number (PIN). There are a number of machine-assisted methods for facilitating signature verification by automating the presentation of the signature to the teller; these are not typically used for access control.

There is no fully automated system offered for signature comparison—for example, pattern recognition of a previously written signature against a file signature. All fully automated systems use the manner in which the person writes the signature as the physical attribute—pressure, acceleration, and speed—not the appearance of the finished signature. This technology was developed by the Stanford Research Institute (SRI) during the 1970s, and several companies, including IBM, have promoted it.

202.8.3 Fingerprint Comparison

Fully automatic fingerprint-comparison systems have been available for 20 years from a continually changing cast of vendors. There is, in fact, a substantial and very productive automated fingerprint search operation in place at the FBI, making 14,000 searches a day through a file of 23 million prints, and from which stems the technology of the commercially offered access control systems.

Two fundamental approaches have been taken to the problem of automatic recognition of fingerprints. The first is through pattern recognition—comparison of the form, whorls, loops, and tilts. The second and most accurate is the recognition of the singular points that are the endings and splittings of ridges and valleys, called minutiae. There is also a semiautomatic system that presents the reference print and the actual print of the person in a form convenient to make the recognition decision. The fully automatic systems generally cost in the range of $5000 per portal.

202.8.4 Hand Geometry Systems

Hand geometry as a physical attribute on which to base an access control system stems from a 1971 study by SRI in which glove measurements for U.S. Air Force pilots were statistically measured, with the aim of reducing manufacturing variability and increasing inventory efficiency. SRI concluded that human hand geometry is a distinct, measurable characteristic that can be related to individuals. In addition, SRI concluded that standards can be established that greatly reduce the probability of cross-identifying a particular individual.

On this premise, Identimation Corp. introduced an access control system in 1972 during a time when interest in physical-attribute identification systems was at its peak. Most of the efforts were concentrated on the more conventional attributes of face, fingerprint, and voice, and the professional pattern-recognition community skeptically viewed handprint recognition. Yet the Identimation system survived in the market until it was abandoned by Stellar Systems, Inc. in 1988. Other introductions of hand-geometry products have been made, without great success.

Prices of hand-geometry systems are comparable to those of sophisticated card-access systems.

202.8.5 Retinal Pattern Recognition

In 1983, a personal-attribute access control system was introduced that was based on the premise that the pattern of the blood vessels on the retina of the human eye is a unique identifier, following research presented in a 1935 medical paper. Blood-vessel pattern systems have been introduced from time to time, but none has endured. These mechanisms are best suited for controlling physical access to secure areas with a low volume of traffic because:

- They are too slow to avoid unacceptable backups during significant traffic times (e.g., shift changes).
- Hygiene problems may arise from placing the eye against the eyepiece.

202.8.6 Voice Recognition

Despite considerable research and development work over 20 years, there was no offering of a voice-based access control system product until 1985, when there were two introductions. Voice recognition may prove to have certain significant advantages over other physical-attribute systems: the input device can be an ordinary telephone handset, and the internal workings are entirely electronic and should continue to decrease in cost. Other systems require mechanics, optics, and other relatively expensive technologies. Successful technology has proved elusive, however, and the voice-access companies are either defunct or dormant.

202.9 An Assessment of Physical-Attribute Access Control

Although industry experts predicted for a decade that physical-attribute systems were the future of access control, that future has continued to be much further away than was anticipated. A large part of the problem is cost: the per-portal cost can be more than twice that of a sophisticated card-access system. The second problem is the absolute unavoidability of false-acceptance and false-rejection errors. Even though the physical attribute itself may be unique, the measurement of it may be imprecise. The questions that a designer of a security system must resolve when considering physical-attribute systems are:

Is the system really more secure than the alternatives?
If it is more secure, is it worth the added cost?
Can the attribute be faked, resulting in potential penetration risk?
Is any one attribute more reliable than the others?

As always, there is no standard or universal answer. Each security situation must be analyzed and choices made that are appropriate for that system.

The error rate of a personal-attribute system depends primarily on how it is used within the total system. If the prospective entrant presents a finger (or face, voice, hand, eye, or signature) to the system and the system is required to determine whether this fingerprint exists among a (possibly huge) file of acceptable persons, a relatively high error rate can be expected. If, however, an identifying card or PIN is also presented, the system is required to determine only if the fingerprint does or does not match the fingerprint that is on file for that person; very low error rates, in the tenths to thousandths of a percent, can be achieved with a personal-attribute system that uses this technique. Of course, such a system is really a combination system—attribute-plus-card or attribute-plus-keypad—which always results in increased security.

In addition, there is some concern that the digitized signal of a biometric reader could be captured and played back to bypass the reader and thus defeat the system, though this concern is related more to computer system access than to physical access to a restricted area. Another biometric access control system currently being marketed involves keyboard dynamics, which records the key strokes used to type in a password or passphrase and compares them with the actions of a person trying to gain access. This is similar to the signature comparison process. This system appears to be quite accurate but also is probably more appropriate for computer access control use.

The bottom line on personal-attribute access control systems is that when combined with card or keypad, they are accurate and reliable and provide excellent security; whether they provide sufficient additional security over a card-plus-keypad system to justify the substantial increase in cost must be determined by the buyer.

As to which personal attribute is the most effective identifier, all of the attributes currently used are roughly equivalent in accuracy. High technology does not by itself provide high security; satisfactory security is provided by a well-designed total security system.

202.10 Recommended Course of Action

Physical-attribute systems will one day be the ultimate in access control, but they have yet to achieve any important acceptance or to stand the test of time in the mainstream of access control applications. Still, the data center manager must keep abreast of developments in this and other physical access technologies. To keep their new security systems from becoming obsolete in the near future, they should consider:

- *Smart cards*: Massive investments by major credit card companies have not yet resulted in widespread use of these cards. In security applications, smart cards, like biometrics, are too expensive for what they deliver. Marketing pressure will inevitably result in some penetration of these cards into access control applications; currently, however, they have limited popularity and use.
- *Universal cards*: There are already systems that can use almost any coded card as an access control card rather than requiring the procurement of new and special cards. Despite some

yet-to-be-resolved legal questions over how universal cards may be used, their use could be an interesting and cost-reducing trend.

- *Wireless systems*: These can reduce costs by eliminating a great deal of expensive installation and wiring. Such systems will continue to become more popular, including some of the simpler proximity access devices (e.g., wireless tokens and keypads).
- *Physical-attribute systems*: Although these systems have achieved credibility as an access control means, they have yet to solve the cost-justification problem, and they have achieved no user following. There will be a continuing trend toward reduced prices, but these systems will be viewed as top-of-the-line and justifiable only in particular situations for most of the next decade.
- *Proximity access systems*: These systems will continue to capture a significant share of the card-access market, using the new capabilities conferred by increasingly intelligent devices at increasingly lower costs. Proximity access may well exceed ordinary card access in popularity in the future, but biometrics will ultimately dominate the market.

203
Auditing the Electronic Commerce Environment

Chris Hare

With the proliferation of Internet access and the shift to performing some brick-and-mortar transactions online, the need for stability and reliability in the E-commerce arena is becoming increasingly apparent. E*Trade, one of the many successful E-commerce sites, depends completely on its online presence to stay in business. An outage, regardless of cause, can potentially cost millions of dollars. For example, consider the distributed denial-of-service (DDoS) attacks against Yahoo! and CNN. Once a way to stop the attack had been found, thousands of dollars were spent to facilitate the system cleanup, in addition to the lost revenue. This chapter describes a methodology to assess the security and reliability of E-commerce. Based on this author's previous experiences with risk assessment, security, reliability, and Web "touch and feel—ease of use" can be identified as critical to the ongoing success of E-commerce. The approach described in this chapter can assist any E-commerce Web site owner, manager, or auditor in identifying and securing some of these key risk areas.

203.1 It Is Possible to Get Your E-Commerce Infrastructure under Control

The most significant challenge in the development and implementation of one's E-commerce environment will be gluing it all together. Success is dependent on a careful marriage of process, technology, and implementation to achieve the end result. Achieving the final goal depends on a comprehensive strategy, understanding legal and export issues, the processes in use, as well as the technology available to perform the work. Design the environment with confidentiality, integrity, and availability as priorities—not as after-thoughts.

203.2 Strategy

Do not get caught up in the waves of technology and methods of doing things. Technology is only one part of the entire puzzle. One uses technology to implement already-operational manual processes to reach a larger market. The operational aspect drives the technological requirements, which in turn affect the overall development of the required systems. The implementation of the project is often affected by changing business and legal needs rather than by changes in technology.

Strategy is the key to the development of an effective E-commerce implementation. The people within an organization must have a vision they can use to drive their planning and development activities. This vision determines the goals senior management has and lays the groundwork for how to measure success. Without a strategy, it will be impossible for you, your employees, your shareholders, and customers to determine if you have achieved anything.

Strategy must also be based on the business decisions that an organization will make. The existing corporate policies must be reviewed and implemented to provide consistency in dealing with the public, regardless of the medium the customer uses to access one's services.

203.2.1 Technology Is Only the Method of Implementing Desire

One's team will use the strategy to establish goals they can translate into project plans and then into manageable activities to meet the strategy. When developing an E-commerce strategy, one must consider:

- What are you trying to achieve by moving to E-commerce?
- How closely is your electronic commerce strategy aligned with your existing corporate strategy?
- What existing corporate business processes must be integrated?
- Who is going to use the service? Is it business-to-business, business-to-consumer, or both?
- Who is going to use the services being offered?
- What do our customers want us to offer?

Armed with the answers to these questions, it becomes possible to start addressing the technology solutions that may provide the implementation. As illustrated in Exhibit 203.1, the technology solution is complex and involves many components. Before choosing the individual components to achieve the

technology implementation, one must understand how each component in the business process interacts with the others.

203.3 Legal

It is a challenge for most companies to ensure compliance with the legislation of the country where they are located or the countries in which they do business. There are local, state, national, and international laws. There are additional regulations, depending on the industry and whether you are a publicly traded company. However, doing business electronically poses new challenges.

203.4 Privacy

Consumers are concerned about the privacy of their information, while you are concerned about the privacy of information they provide to you or you share with them. Aside from legal requirements in various parts of the world regarding the privacy of information, it would not be good business not to provide privacy controls. If consumers are aware that you do not take this into consideration, they will not do business with you electronically.

The privacy issue can mean some real challenges for an organization. For example, during 1999, the European Union (EU) enacted standards surrounding privacy and the protections of information. The EU stated it might choose not to do business with companies or countries that do not implement similar

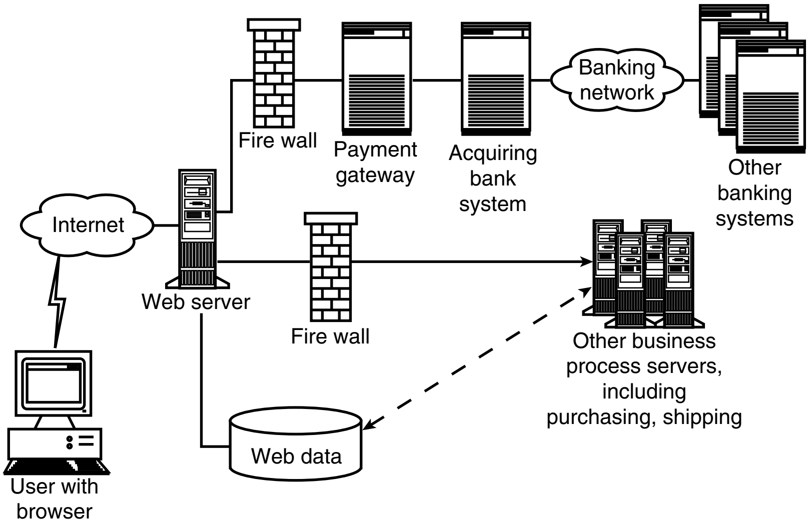

EXHIBIT 203.2 Sample SET transaction environment.

privacy standards. Consequently, one should specifically state what the organization's privacy policy is. This demonstrates a commitment on the organization's part to the protection of its consumer's information.

Solving the privacy issue means that technical implementers will use words like encryption, digital signatures, and digital certificates. These are technologies used to provide the privacy components to help increase the protection of information sent and received while users interact with an electronic business site.

It is the privacy issue regarding consumer purchasing habit information that led to the development of Secure Electronic Transaction (SET) protocols by Mastercard and Visa, as illustrated in Exhibit 203.2.

All transactions must be properly secured to prevent the loss, through transmission or unauthorized access, of important business information. This must be calculated into the strategy. Doing so will mitigate the risk of information loss and poor performance or reliability from improperly implemented processes or technology.

203.5 Export Controls

Export controls are established by governments to regulate export of materials to countries considered dangerous or not in support of the national interest. Most countries do this and in some situations, such as encryption technologies, there are countries that prevent the import of the material.

Compliance with relevant export control legislation is strongly advised. The punishments for noncompliance can be significant, depending on the country and the material exported. Recent years have seen changes in some export rules, again specifically surrounding encryption. Countries have been adopting changes in encryption import/export rules in an effort to allow their producers to compete in the global marketplace.

It is important to review import/export legislation when developing an E-commerce infrastructure. There may be information or technology affected by these rules and they may impact to whom one can deliver the service and resulting products.

203.6 Legislation

Legislation is a major area for many companies. There is a variety of legislation controlling how privacy issues are handled and how business is conducted in general. Much of this legislation is not limited to electronic business. Internet laws and regulations pertain to everything from intellectual copyright to cyber squatting (registering URLs for profit).

The use of a qualified attorney is highly recommended due to the diverse issues and laws involved. With the assistance of an attorney, one should carefully consider the impact of law on the ability to get one's electronic business into full gear.

Considering the vast nature of the law, some areas of concern include, but certainly are not limited to:

- What national and international laws are applicable to E-commerce?
- How is legislative compliance ensured?
- What countries is the business prohibited from selling to through E-commerce?
- Are there distribution agreements and contracts that can be held in force electronically?
- Do the businesses support digital signatures, and are they considered legally binding within the business' jurisdiction?
- How are domestic and international disputes resolved?
- Is there technology or information requiring export permits before it can be available through the E-commerce infrastructure?

203.7 Project Management

With the strategy defined, the team can proceed to define the manageable activities resulting in the actual development and implementation of the infrastructure. However, project management is geared more toward ensuring that everyone understands what work must be done, the timeline in which to do it, and how much to budget.

There are a lot of pitfalls in allowing the team to implement electronic commerce services without project management. It will be difficult to gauge where the project is, and even more difficult to determine when it is finished and how much it will cost.

Project management provides the needed controls to define the project, and ensure it meets the business requirements and is completed on time and within budget. A project management strategy is critical to define the tasks required to complete the project. The project plan defines who owns the project and related subprojects, and how users will be involved in the definition, development, and testing of the E-commerce implementation.

The project manager defines the work breakdown structure and establishes the milestones to measure progress on the project. The project manager allocates responsibilities and manages cost and resource budgets.

Without effective project management, the E-commerce project can become an expensive, never-ending endeavor that fails to meet the business needs.

The ability to plan a project and then properly implement it allows for accurate cost control and planning decisions. Things to consider:

- Does the project plan accurately define the end objectives in a measurable fashion?
- Are there adequate people and other resources to deliver the project on time and without unplanned resource costs?
- Has a standard project management review been conducted?
- How are project costs captured?
- Is the project on track from both a work and a financial perspective?

203.8 Reliability

The E-commerce infrastructure must be available whenever a customer wants to use it (availability), and it must operate as the customer expects it to (integrity). Most people do not realize it but reliability is a major component of security. Consumers want to have confidence that when they go shopping online, the merchant they want to deal with will have all of its systems operating so that they can browse the catalog, enter their order, have any payment transactions properly completed, and then see the order arrive in a reasonable timeframe.

But what happens when things go wrong? Customers need to have a method of contacting the merchant so they can advise that merchant of the problem and seek an acceptable resolution. However, reliability reaches beyond getting problems fixed. It includes the ability of an organization to know there may be a problem now or in the future. How will the performance of the system be measured? How does one resolve a problem for which one of the service providers is responsible?

203.8.1 Performance

The ability of the systems to provide a reliable, friendly, and valuable experience is essential. Users have high expectations about content, access to the services, and quickly finding what they are looking for. Performance, in the eye of the user, is measured by how long it takes to get the information displayed on their screen. A fancy Web site with numerous animations and pretty graphics may be eye-appealing once fully downloaded, but most users get frustrated and are not likely to revisit if the merchant's home page takes forever to load on their system. Develop for the smallest system, and it will work on all others that need to access it.

The customer's view of performance is affected by the capacity planning of the merchant's Internet access and the servers used to offer the customer services. Failure on the part of the merchant to contemplate the actual level of performance one wants people to have will impact that merchant in the end. Capacity planning surrounding the network and server performance must be tempered by how many users one expects to have access to the site.

Having a plan to quickly respond to performance issues regardless of their cause is essential to stay ahead of customer demand. This translates into having capacity planning expertise on the team. These experts monitor performance on a daily basis to maximize the number of customers who can use the site and ensure there is adequate capacity to handle the increased number of users tomorrow.

203.8.2 Architecture

The second component in addressing reliability has to do with the overall system and network architecture. What systems are involved in delivering the service to customers? It is important to understand how they interact with each other in providing the service. Just as capacity planners are important, E-commerce architects who understand the market are critical. Security professionals who understand security architectures to protect the overall corporation and how to implement them are also essential.

203.8.3 Measuring Performance

The collection of metrics for capacity planning, customer satisfaction, and usage is imperative. Operational statistics are collected as part of operating the business and include such items as technology outages and usage. These operational statistics are generally used to provide information regarding problems and assist in determining where efforts should be focused to correct operational problems. Help desks or customer service areas can be invaluable for recording these kind of metrics.

As all of the operational statistics are collected, they must be analyzed and collated into metrics to report the state of the operation. How is the E-commerce environment working? How many customers have used the site? How much was spent and what was bought? However, metrics must be combined

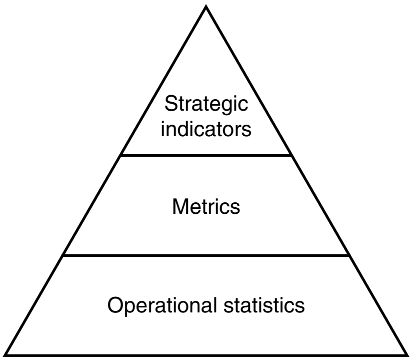

EXHIBIT 203.3 Operational statistics to indicators.

from across the organization to establish the strategic indicators used by top management to determine how the organization is doing and what they should be concerned about. This relationship is illustrated in Exhibit 203.3.

Some things to consider surrounding operational statistics and metrics include:

- What efforts are being made to collect, report, and validate the available metrics?
- What metrics are available from the internal and external service providers?
- Determine the reporting structure for these metrics.
- Determine how these metrics are used.
- What process is in place to use the metrics to create feedback to improve the system or correct problems?

203.8.4 Problem Resolution

The primary users of an E-commerce site are its customers. However, sometimes things go wrong, or customers have questions arise during their visit and would prefer to talk with someone regarding the issue. Consequently, they need to have a place to report these problems or ask their questions.

This requires the implementation of a customer call center where problem reports regarding the Web site can be taken and directed to the correct support groups for resolution, or product questions asked and answers provided. Effectively operating this customer call center requires the use of a call tracking system capable of tracking the customer's issue and a history of what was done to provide resolution.

If operating a global company—and face it, if you are running an E-commerce site, your consumer audience will be global—you will need to establish a method for people to reach you in real-time from anywhere in the world.

The customer call center must be able to respond quickly to customer needs and provide the information they are requesting in a timely fashion. Doing so establishes confidence in the mind of the consumer about your abilities and enhances their buying experience.

When considering the call center, the following questions should be considered:

- How do both you and the customer evaluate satisfaction level?
- How long does it take to solve a problem once reported? Is the customer satisfied with the resolution? Is follow-up necessary?
- What are the common problems reported and what has been done to rectify them?
- What problem tracking and resolution system is in use?
- Are problems recorded so that metrics can be obtained and trending reasonably retrieved?

203.8.5 Service Level Agreements (SLAs)

Service level agreements (SLAs) establish the terms of service, including expected operational performance and problem escalation and resolution. Both issues are important in E-commerce activities. The operational performance of the service provided is critical because poor performance means the E-commerce services will be unavailable to the customer. This in turn can negatively impact both the bottom line and the image of the company on the Internet.

Timely resolution of problems is also important for the same reasons. Customers expect service level timelines for issues to be met. What SLAs are there with service providers, and are there penalties if they do not meet their commitments?

SLAs are also used to assist in measuring the capabilities of your service providers and are useful to have when renewing contracts. Having collected and maintained good information regarding performance and issue resolutions, one will have more success negotiating changes in the contract and price due to good or bad performance in the service delivery.

Things to remember when reviewing the SLAs in place for an E-commerce environment include:

- Obtain SLAs from suppliers such as ISPs and network providers.
- What quality-of-service provisions are in the SLAs? Are the service providers meeting these agreements?
- Do the service providers and your own organization maintain records on their performance?

203.8.6 Maintaining the Business

The ability of the infrastructure to recover from a systems failure, connectivity loss, or other issue is essential. Order entry for product sales is a critical activity that must be maintained. How will the organization handle the partial or complete loss of its E-commerce infrastructure? Are appropriate plans in place to maintain the E-commerce business?

Business continuity and disaster recovery planning form important elements in any business, but are not centered solely on the E-commerce services being offered. Business continuity is centered on maintaining the business operations after a fatal systems failure. For example, can E-commerce operations be maintained if several systems suddenly fail?

These are important questions to ask support organizations. If the organization is heavily dependent on the ongoing operation of the E-commerce environment, then a failure for even a short period of several hours can have disastrous effects on the business. If operating an enterprise based more on "foot traffic," one may be able to afford the downtime.

However, in today's information age, when an online business is offline, everyone hears about it—very quickly.

Areas of concern surrounding business continuity include:

- Has a business impact analysis been conducted to determine how important E-commerce is to the survival of the organization?
- Are the Web servers and other systems involved in the E-commerce delivery part of a contingency plan?
- Are there backup procedures, dependable backups, and regular data and system recovery testing?
- Is the status of systems monitored to maintain integrity and operation?

203.9 Development

As mentioned previously, customers will remember their experience with an E-commerce system based on how it worked for them. Consequently, the development of a consistent interface is required and can only be achieved through good development practices.

203.9.1 Standards and Practices

The key method of ensuring that consumers have a positive experience with an E-commerce site is to establish development standards and practices. These are independent of the "look and feel" established as their interactive experience.

The site developers use standards and practices to provide information and methods on how the applications will be developed. This includes things such as code standards, security, and how information submitted from the consumer will be validated and protected. Accordingly, security needs to be designed into the application from the start and not included as an after-thought.

Developers will make decisions regarding how they will develop and write their particular part of the system based on their previous experience or education. These differences make it difficult for ongoing maintenance and subsequent troubleshooting and issue resolution.

203.9.2 Change Control and Management

Change control is a critical part of the overall development/production cycle. Proper change control reduces the risk of improperly tested application code being placed into production, causing problems with data integrity, confidentiality, or reliability. It is also used to identify the changes that are made from day to day to the application code and allows for proper issue resolution and developer education.

A major issue with the development of application code is the fact that it is often put into production systems and "debugged" while customers are using it. This type of activity not only impacts the development of the system, but also affects the user's perception of the E-commerce site and the online presence of your enterprise.

Proper change control ensures that development code is tested in a development environment and is able to process not only the accurate information that the consumer provides, but also handling errors in the input, made either deliberately or accidentally.

Proper processing of information that is collected on the Web site affects business operations. Failure to process it correctly may result in improper or incorrect charges to the consumer, or delivery errors resulting in lost merchandise and increased costs.

When assessing the configuration and change control environment, one must consider:

- Software release change and version control, including both the application code and operating system changes.
- Is it possible to maintain a stable operating environment in today's fast-paced world? Is it possible to automate the change process?
- Development, implementation, and migration standards.

203.10 Connectivity

Connectivity is specifically concerned with the technologies used to establish network connectivity to public and private networks, how available bandwidth is calculated, and how the network is designed. E-commerce is very dependent on a successful network design and adequate capacity to ensure that consumers can get to a Web site, especially during the winter holiday season.

This means adequate Internet connectivity speed and capacity, and similar connectivity into your corporate network if applicable to your E-commerce design. Many network design people are leaders in their field, but adequate network capacity can be easily overlooked.

A network can also be overbuilt, having too much capacity and other resources built into it that ties up an enterprise's resources unnecessarily. It is necessary for the enterprise to have good technical management and network design staff to take the marketing and sales plans and build a network that will handle expected traffic and scale appropriately as demand increases.

The network staff must understand that an E-commerce site must be located in an appropriate place. This means that if one intends to operate on a global scale, one may want to consider having multiple locations to ensure the best connectivity and performance for the consumer. This can increase the complexity of one's environment in the process and in turn increase one's dependency on good planning.

Part of this planning includes redundancy, which in turn forms part of one's contingency and business continuity planning. If one component or location becomes unavailable for any reason, one is able to maintain presence and continue operation of E-commerce enterprises.

Consumers are looking for a positive, encouraging experience when interacting with an E-commerce environment. Failing to provide this experience reflects negatively on your online presence. This may result in a perception that the company is not prepared to handle E-commerce and consumers will be reluctant to conduct business with your site.

In reviewing network connectivity, remember to consider:

- Location(s) of E-commerce sites
- Network capacity
- Maintaining and monitoring of network availability
- Network topology
- Redundancy of the network
- Security
- How secure are transmission links
- Do you use a switched network
- Is any form of virtual private network (VPN) used in E-commerce delivery

203.11 Security

There are four major components that make up the security area:

- Client or user side of the connection
- Network transmission system
- Protection of the network information during transmission
- User identification and authentication

Protection of the network security elements and the computer systems that reside in the E-commerce infrastructure is a major portion of protecting the data integrity and satisfying legal and best practices considerations. This level of protection is addressed through various means, all of which must be working cooperatively to establish defense-in-depth.

As seen in Exhibit 203.4, the layering is visualized as a series of concentric circles, with the level of protection increasing to the center. Layer 1, or the network perimeter, guards against unauthorized access to the network itself. This includes firewalls, remote access servers, etc. Layer 2 is the network. Some information is handled on the network without any thought. As such, layer 2 addresses the protection of the data as it moves across the network. This technology includes link encryptors, VPN, and IPSec.

Layer 3 considers access to the server systems themselves. Many users do not need access to the server but to an application residing there. However, a user who has access to the server may have access to more information than is appropriate for that user. Consequently, layer 3 addresses access and controls on the server itself.

Finally, layer 4 considers application-level security. Many security problems exist due to inconsistencies in how each application handles or does not handle security. This includes access and authorization for specific functions within that application.

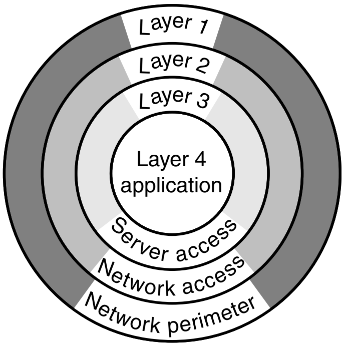

EXHIBIT 203.4 Levels of protection.

There are occasions where organizations implement good technology in bad ways, which results in a poor implementation. For example, the best firewall poorly configured by the user will not stop undesirable traffic to a site, or a database security system that has all of the data tables granted for "public" access does not protect the data they contain. This generally can lead to a false sense of security and lull the organization into complacency.

Consequently, by linking each layer (see Exhibit 203.5), it becomes possible to provide security that the user does not see in some cases, and will have minimal interaction with to provide access to the desired services. Integration between each layer makes this possible.

The same is true when implementing security within the E-commerce environment. It must be considered at all layers: the client, the network, the perimeter, and the associated servers. The Web interface has four primary layers: the operating system, the CGI programs, the Web content, and the Web server. Each layer is dependent on the components of the other layers working correctly.

203.11.1 Client Side (User)

Clients interact with the E-commerce infrastructure through their Web browser. The users, however, have certain expectations about how the interaction will look, act, and perform at their computer. For the experience to be a positive one, certain programming considerations must be addressed during design, development, and implementation.

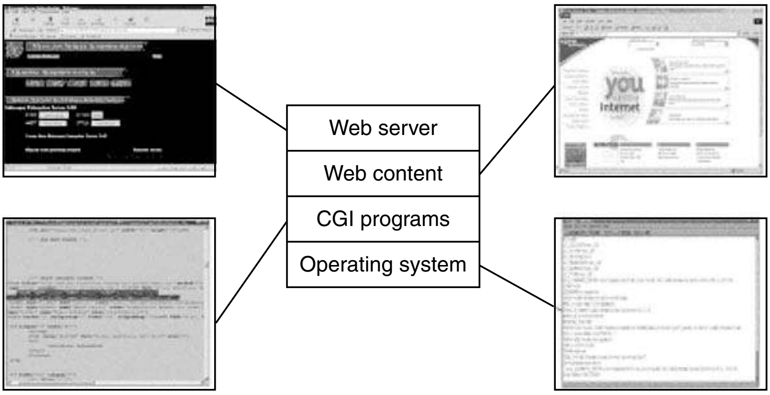

EXHIBIT 203.5 Linking layers.

The experience the user has will be different across the different browser implementations, and choosing to support browser extensions that are not supported by other browsers is not a good business decision. The HTML, dynamic, and graphic content must be compatible with the different Web browsers available. E-commerce applications must consider this requirement. Not all users will want to enable extended features in their browser, such as cookies, Java, and JavaScript. This greatly affects the functionality that can be offered in the design of the application.

The users and businesses that will use a service may not be connected directly to the Internet. They may be using a proxy server to provide security or cache network requests. They may also be using a slow-speed network link. These factors must be included in the design to maintain a positive experience.

When considering client-side issues:

- Examine what types of Web browsers and proxy servers are in use and in what operating environments.
- Determine how a customer registers for E-commerce access.
- Determine the ease of use of the E-commerce interface.
- Decide what applications will be used to develop the interface.

203.11.2 Firewalls

The firewall is an integral part of an E-business architecture. It is accepted that any computer directly on the Internet with no protection is a sacrificial host. One can expect it will be compromised at some point. Although it is not reasonable to hide everything behind the firewall, every system not needing to be directly visible to the Internet should be protected by a firewall. Additionally, no connections from any unprotected systems should pass directly through the firewall to the corporate network.

However, a firewall can be bolstered by the network design through the use of demilitarized zones (DMZs) and service networks (see Exhibit 203.6). The DMZ protects its systems through filters and access control lists in the routers. The service network is a separate network connected to the firewall. Any system that does not need direct Internet connectivity and does not need to be on the corporate network is put in the service network.

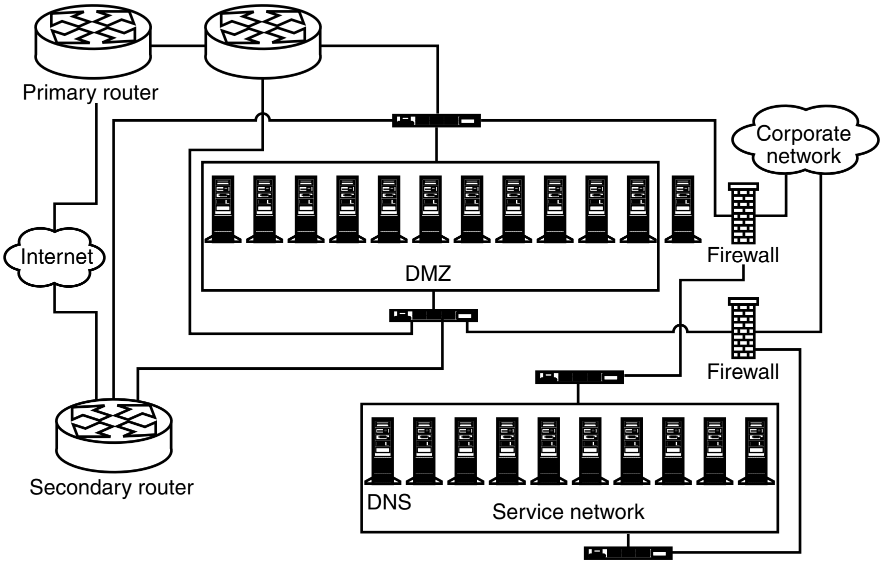

EXHIBIT 203.6 Demilitarized zones (DMZ) and service networks.

The customer interacts with the systems in the DMZ. Additional services required to provide the customer with their experience are obtained by systems in the services network. Any additional information that must be retrieved from systems on the corporate network is retrieved by the intermediate servers. Although this seems to be an overly complex arrangement, there is a high degree of security inherent in the design. The systems outside the firewall have no ability to connect to the corporate network. The firewall is configured to only allow connections from the DMZ to the service network, and then only to specific IP addresses and network services. The systems in the service network are then authorized to connect with systems in the corporate network for the required information.

The use of intrusion detection systems and periodic evaluation using vulnerability assessment tools is also highly recommended as part of an E-commerce security architecture due to the nature of the service and likelihood of attack.

When considering the firewall and network security implementation, examine:

- Vulnerability reports of all network elements using a network vulnerability tool such as Cybercop or ISS
- The DMZ systems to determine if they are "hardened" to reduce the potential attack points
- How the Web client and server negotiate SSL encryption and what encryption strengths are offered
- Non-HTTP ports opened through the firewall(s) for browsing and analyze security implications
- The firewall topology
- Firewall configuration files
- Access control lists of network devices
- Network communication protocols
- Configuration management on the network security elements

203.12 Securing the E-Commerce Server

The E-commerce server consists of a variety of components all connected together to provide the business service. Multiple systems are used to reduce the complexity of any single system in an effort to improve the chances of properly securing each system. These services include the HTTP or Web server itself, personalization systems, directory systems, e-mail gateways, and authentication systems.

203.12.1 Directory Services

Directory services provide a mechanism for maintaining an online repository of registered users and their related information. By using a central repository for this information, any of the systems requiring authentication data or information regarding the user can access it. Additionally, applications can query information regarding the user, including their mailing information when ordering or requesting hardcopy information or when products are shipped to them.

Several directory systems are available, but those based on X.500 and Lightweight Directory Access Protocol (LDAP) technology provide the highest level of integration and availability.

Because all of the information regarding the users is stored in a central repository, special care must be taken to protect the information on those systems and provide authenticated and secure transmission channels for the data. The repository must have high availability, as many systems will be dependent on its ability to provide the information when requested. As previously stated, the consolidation of the data makes it easier for the administrators to provide confidentiality and maintain integrity while the information is stored and during transmission across the network. One can argue that the consolidation of the data also makes the system a target for attack. However, the centralization also provides network security personnel with the opportunity to protect the system.

When evaluating the directory services provided, consider:

- How much data will be stored
- How quickly must the directory provide the response
- How many queries can the directory handle at a single time
- What security functionality is integrated into the directory
- Does the directory support authenticated connections
- Does the customer understand that this data is being stored

203.12.2 Mail Server

Electronic mail is a key component in any E-commerce infrastructure. It allows for the delivery of information from the E-commerce infrastructure systems to a user or business. Customers depend on e-mail to request information and to interact with customer service or support people when questions or problems arise. It can also be used by customers to report things they like or dislike about the experience. E-mail, which is used for many things, should not be used as a transport method for information requiring special protection. Information sent via e-mail is as public as a postcard. Consequently, the distribution of credit card or purchase information, as well as user name and passwords, must not be distributed through e-mail. This can be made possible and secure through encryption technologies such as S/MIME.

The operation of the mail server is critical to the infrastructure. E-mail servers are also regularly used by hackers to access other systems or send unsolicited bulk e-mail, or spam, as they are often not considered to be a major security risk. Many of the available commercial mail servers have idiosyncrasies related to their configuration that both can protect and expose information. Consider the incorrectly configured mail server that allows external users to send e-mail as if they were employees of the company, or using the mail server to relay spam to other mail servers.

Such examples are written and documented on a daily basis in the security industry and are usually related to simple misconfigurations, the use of out-dated software implementations, or not remaining current with software patches.

When addressing e-mail security and availability, consider:

- Which mail transport agents and mail user agents are being used
- Access permissions for the mail transport agent’s (MTA) configuration files
- Periodic review of the mail server’s delivery and error logs to determine the possibility of misuse
- Probing the MTA for common “exploits” to test vulnerabilities to various attacks
- Evaluating the use of virus protection technologies
- Content management and encryption technologies

203.12.3 Web Server

The Web server can be considered the most critical component in the E-commerce infrastructure. It is required to deliver Web-viewable content to the user, run programs to retrieve or send information to the user or other systems, and perform specific checks to determine the validity of requests. It is expected to be available all the time and to provide responses to the user within an acceptable time period. If users have to wait due to poor network or Web server performance, they will quickly leave your site. Once again they will form a negative perception of the business and not be likely to return.

There are a number of Web servers available, both as commercial and freeware software implementations. If one can afford it, buy a commercial implementation to have quick support when issues arise and gain vendor maintenance for the software. Although the initial expense for freeware implementations may be low, and they are quite robust, the post-installation maintenance and support expenses can be quite high. Consider company turnover and retention of experts to maintain the freeware implementation. It is likely to be much easier to find trained experts on commercial software than someone who is familiar with a tailored freeware implementation.

While configuring the Web server itself, development standards are needed for the design of applications and Web content. The Web server software must not execute on the system with any special or administrative permissions. This reduces the risk of an attacker gaining administrative privileges to compromise the server.

The operation of the server is also dependent on the availability of Common Gateway Interface (CGI) scripts to provide access to applications and forms. CGI programs require careful scrutiny during development and before final production to validate that there are no exposures to poorly written code resulting in security issues. Confidentiality and data integrity have been presented several times. The Web server should be capable of providing encrypted sessions through Secure Sockets Layer (SSL) or Transport Layer Security (TLS). Both SSL and TLS require no additional hardware and both use a server-side certificate. The issuance of a certificate for a site is beyond the scope of this chapter. Several reputable firms can issue certificates for Web servers.

Using SSL or TLS, the organization and customer can be confident that the information being displayed or sent is protected while in transit across the network.

When reviewing the Web server, consider the following:

- Review the user ID and account permissions the Web server runs under (i.e., root, administrator).
- Determine which Web sites are public and which are controlled access.
- Analyze access permissions for HTML documents, ASP and CGI, directories and scripts.
- Examine Microsoft IIS or other Web server application configurations and log files.
- Determine how requests received by the Web server from the browser are verified.
- Determine how requests sent to a back-end processor are verified as completed.
- Examine Web-based applications and database connectivity, including Java, JavaScript, and XML.
- Check for the existence of well-known ASP and CGI scripts and utilities that pose a security risk.
- Examine Web and proxy server configuration files.
- Check the Web server configuration files and certificates to enable SSL communications.
- Analyze high-availability components in the E-commerce service.
- Evaluate operating system and Web software patch levels and configuration files on critical servers.
- Evaluate application patch levels and configuration files.
- Determine how external E-commerce systems authenticate to internal systems.
- Consider the certificate authority that issued the server certificate and if there is a method for the customer to validate the authenticity of the certificate.
- Evaluate the requirements of non-repudiation features.
- Evaluate CGI scripts and review the program code.
- Consider Web content management.

203.13 Operating System Security

All of the components previously described rely on the foundation services provided by the operating system. Although each of the individual application components can be made more secure, without a strong, secure foundation, other efforts are affected. Today, the vast majority of E-commerce systems run on either Windows NT or UNIX operating systems. Each of these environments has its own advantages and disadvantages and system vulnerabilities.

203.13.1 Windows NT Operating System

Windows NT is a popular operating system used to perform specific computing tasks in any infrastructure. Proper configuration of the operating system is essential. If not properly configured and security is not properly implemented, it can be trivial to compromise.

Windows NT relies heavily on the registry to provide both operating system and application configuration settings. Several key services in Windows NT operate at the same network service port. This can provide a remote user with the ability to probe the system and collect important registry information. With this information in hand, such as disk sharing information, user names, and system configuration details, a successful attack can be launched against the system.

When using Windows NT as an E-commerce operating system platform:

- Conduct a scan of all Windows NT systems providing E-commerce services using both host- and network-based vulnerability scanners. Analyze the results and attempt to exploit them on the operating system to gain unauthorized access.
- Review unnecessary services and ports.
- Review registry settings and operating system patch levels and configuration files on critical servers.
- Evaluate configuration and change management on the operating system components.
- Implement virus protection technologies.

203.13.2 UNIX Operating System

The UNIX operating system provides a multi-user, multi-processing environment used for many different tasks. Like Windows NT, however, improper configuration of the security modules and operating system can make it trivial to compromise. UNIX is a much more popular E-commerce environment than Windows NT. Despite the relative maturity of the operating system, new problems with UNIX implementations are discovered on a weekly basis. The visibility of some of the new security issues even makes it to the news media due to the dependence in the computing world upon this operating system.

Like Windows NT, UNIX is not intended to be a secure operating environment. Any security expert can provide a multitude of ways to defeat the security systems on either operating system. Considerable effort is required to “harden” the operating system and reduce the vulnerabilities in the E-commerce environment. As a multi-user operating system, UNIX has a large number of network-based services providing major parts of the system’s functionality. Many of these services and ports are not necessary in order to provide E-commerce functionality. These services are often exploited to initiate confidentiality, data integrity, or system availability attacks.

When using UNIX as an E-commerce operating system, be sure to:

- Conduct a scan of all UNIX systems providing E-commerce services using host- and network-based vulnerability scanners. Analyze the results and attempt to exploit them on the operating system to gain unauthorized access.
- Review unnecessary services and ports.
- Evaluate operating system patch levels and configuration files on critical servers.
- Evaluate configuration and change management on the operating system components.

203.14 Back Office Applications

The E-commerce infrastructure has communications paths to various back office applications, including search engines, Oracle, BaaN, and SAP, to facilitate the ordering of products from the catalog. These systems are sufficiently protected, as well as the data sent across the network, to restrict protected information access. In addition, there are specific performance and security considerations for these applications.

203.14.1 Search Engine

The search engine is used to find specific documents or Web pages within the E-commerce environment. The quality of the search engine responses depends on how fast this “crawler” can traverse the Web links and pages to produce an index for the location of relevant material. Most search engines perform this work in two stages. First, the search engine “crawls” through the Web pages and collects information. Second, it builds a searchable index for use later when the user requests the search.

Different search engines offer different levels of performance in the collection of this information. This affects the validity of the search results when the user requests the search. If pages that exist cannot be found when the search is requested, the user will think the information does not exist. Consider the negative perception this can have on the user’s experience at the Web site. If pages no longer exist or contain irrelevant information appear, the user will become frustrated.

For example, consider the graphs in Exhibit 203.7. Both graphs illustrate basic system activity for two different search engines running on exactly the same hardware. The system on the top makes much better use of the system’s resources during the crawling and indexing phases. This improved use of system resources suggests the engine is working effectively. The graph on the bottom shows much lower resource utilization, suggesting the engine may not be capable of handling the workload despite the hardware resources.

User interaction with the search engine is also critical. If the search engine itself has not been properly implemented, it is possible for performance, including the search, to be slow, due either to the software or the hardware on which it is running. Some search engine implementations do not handle simultaneous searches well. Careful review of the product, combined with simulated load testing, is required prior to implementation.

When evaluating the search engine, review:

- How well the crawling and indexing features work
- The success rate and relevance of the returned documents
- The CPU and LAN utilization
- How quickly search responses returned to the user
- The vendor’s reputation

The back office systems provide information to the E-commerce user over which the organization wants to maintain strict control. In general, these same systems will be used to provide the day-to-day operations for the rest of the company. Because they are generally within the protection of the corporate network, they can be considered protected. The “hard and crunchy” network perimeter is becoming less and less practical as more and more users and customers are demanding services and access technologies. However, the issues previously presented regarding development, application, and operating system configuration must all be applied here as well.

Communication to these systems from the external E-commerce system is controlled by the firewall. The firewall will only allow specific external systems to communicate with specific internal systems to minimize the risk of total compromise in the event of an attack.

Being successful in implementing connectivity and protecting these back office systems is dependent on a thorough understanding of how data is moved from one system to another, what protocols and transport methods are used, who creates the data, who processes it on the receiving computer, and the sensitivity of the information itself.

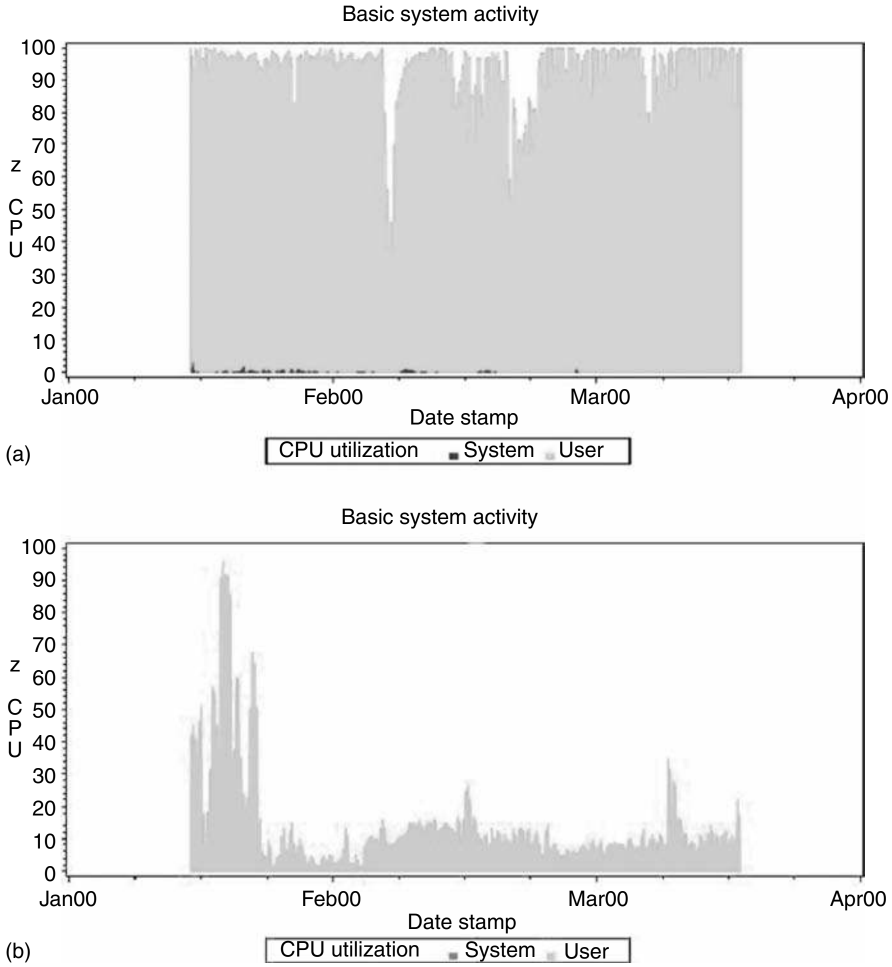

EXHIBIT 203.7 Basic system activity for two different search engines.

When evaluating and implementing connectivity to back office systems, one must:

- Evaluate protection of sensitive organizational data
- Evaluate configuration management on the back office components
- Evaluate the use of virus protection technologies
- Evaluate database configuration and administration practices
- Evaluate order transmission from the Web site to the order management system
- Evaluate the order fulfillment process

203.15 E-Nough!

This chapter has discussed the components of E-commerce architecture and identified what the organization should focus on when developing its environment or preparing to perform an audit. This chapter is by no means an all-encompassing examination of each of the technology areas, but is intended to show the reader the relationship and dependencies of various components that make up an E-commerce environment.

The implementation of an E-commerce environment allows any corporation to economically achieve global presence and enter the global marketplace successfully. In fact, some retailers have no or few storefront (bricks-and-mortar) premises due to E-commerce.This is a challenging and fast-paced world where it is so important to be first, be visible, and be remembered. Do it fast, be quick, and do it right; if you do not, you blow it.

This is the nature of E-business. If one does not get it right the first time, one will not have enough time to fix it later. This is our E-dilemma!

Acknowledgments

Very special thanks to my colleague and close friend, Mignona Cote. Her insight into many areas in technology, business, and risk areas have taught me many things. Without her assistance, this work would not have been completed.

Sarbanes–Oxley Compliance: A Technology Practitioner's Guide

Bonnie A. Goins

204.1 Introduction

A misstatement of financials, perhaps accidental, perhaps not—it can happen and has. People have lost their jobs and their pensions, sometimes their lives' work. Shareholders have lost their investments. Companies have ceased to exist, mired in bankruptcy and scandal. Senior executives have been on display during legal proceedings. Many have fared incredibly well financially, despite losses sustained by the organization's shareholders and its employees. The stories are familiar by now.

What is this all about? What can be done to remedy and report the problems associated with misstatement of financials? How can companies and their leaders be held accountable? In 2002, the federal government introduced the Sarbanes–Oxley Act (also referred to as SOX, Sarbox, or SOA). This piece of legislation is comprised of many sections; however, the section that may best answer our questions is Section 404 of the legislation, which requires senior management of publicly traded companies to assess whether their organizations have implemented appropriate control structures around financial reporting; in addition, senior management must report annually to their boards the results of the assessments of their financial reporting controls.

The reader may be asking, “Well, that’s all well and good, but how can we be sure that everything that has happened in the past can’t happen again? After all, what’s the incentive for the companies and their leaders to watch for and guard against misstatement of financial information?” The Securities and Exchange Commission (SEC), the government body responsible for the regulation of publicly traded equities, has referred to the recommendations of the Committee of Sponsoring Organizations (COSO) of the Treadway Commission in its final ruling that mandates that an appropriate (“recognized”) internal control framework should be used within an organization. The Sarbanes–Oxley legislation, as stated in the work by the IT Governance Institute, mandates “corporate governance rules, regulations, and standards for specified public companies, including SEC registrants,” their implementation improving corporate accountability.

It is important to note that the Sarbanes–Oxley legislation does not, at this time, apply to privately held companies; however, the principles of sound corporate governance map well onto any organization, regardless of its size, which may result in private organizations being added to the compliance expectation at some time in the future. Additionally, the legislation does not take into account aspects of an organization’s business function outside of financial reporting; however, it is clear that the organization can realize a significant benefit through the application of proper internal controls to the remainder of its business functions. This is a theme we will return to periodically during the course of this chapter.

204.2 Senior Management Responsibilities

A common theme in legislation is the notion that senior management is responsible for meeting compliance objectives and, conversely, is held accountable when compliance objectives are not met. This precludes the ability of senior management to point fingers at a subordinate in the event the organization is found not to be in compliance. As stated earlier, senior management is required to produce an annual report on the state of internal controls. This report must contain the following:

- A statement of senior management’s responsibility to create, implement, maintain, monitor, and enforce an appropriate internal control structure around financial reporting for the organization
- A statement indicating the methods used to assess whether the organization has placed effective internal controls around the financial reporting environment
- Assessment results for the last fiscal year, detailing the state of the organization’s internal controls surrounding the financial reporting environment, along with senior management’s statement regarding the effectiveness of the internal controls in use
- A statement that the organization’s auditing partner (that is, registered public accountancy) for the financial reporting environment for the fiscal year has attested (through an attestation report) to the effectiveness of internal controls within the organization, as stated in senior management’s assessment of the effectiveness of its internal control environment

The Act further requires that senior management provide this report in written format, with an *explicit* statement of the effectiveness of its internal controls. It is important to note that senior management may not assert that internal controls surrounding financial reporting are effective if one or more “material weaknesses” (that is, instances of required internal controls that are ineffective or absent) have been identified during assessment of the control environment. Senior management is required to disclose all material weaknesses found within the internal control environment surrounding financial reporting, as of the end of the fiscal year. The only way that senior management can report effective controls with a material weakness present is to design and implement an effective internal control to remediate the material weakness prior to the end of the reporting cycle and to have sufficiently tested the implemented control over a period of time such that it can be determined that the newly implemented control is effective for financial reporting.

204.3 The Role of Information Technology within Sarbanes–Oxley Legislation

It is clear that this important legislation applies to the accounting principles and environment within a publicly traded organization; however, it cannot be denied that appropriately controlled and protected information technology (IT) also plays a major role in the reliability of financial reporting within an organization. As such, information technology resources must be present on the Sarbanes–Oxley compliance team to ensure that compliance objectives are supported by the organization's infrastructure and application environments. Information technology resources can be utilized when the organization is making an effort to:

- Tie systems and infrastructure that provide internal controls around financial reporting to the organization's financial statements; this can be done in tandem with an accounting resource.
- Identify threats to these identified systems and infrastructure.
- Conduct a risk analysis that at least measures the likelihood that the threat will be realized, evaluates the impact on the organization as a result of that event, and calculates risk based on these two metrics. If the organization is more sophisticated in its measurement of risk, probability and frequency can be added to further analyze the risk involved.
- Create, implement, maintain, monitor, and enforce effective internal controls that protect the organization, including systems, software, and infrastructure.
- Create, implement, maintain, monitor, and enforce policies, procedures, and appropriate documentation that details the effective internal controls that protect the organization, including systems, software, and infrastructure.
- Conduct ongoing, periodic testing of the implemented internal controls to ensure that they maintain their effectiveness.
- Update or add appropriate internal controls as the environment surrounding financial reporting changes.
- Report progress and remediation efforts to senior management and the board, as required.

Information technology and security practitioners can take on the role of IT auditor (if from a third party), providing assistance to senior management during the assertion phase, or these professionals can assist the organization in the remediation of material weaknesses discovered during assessment and assertion testing phases. These roles will be discussed in detail in the material that follows.

204.4 "Information Technology" Is Pretty Broad; Where Should I Begin?

In March 2004, the U.S. Public Company Accounting Oversight Board (PCAOB) approved an important auditing standard, known as Auditing Standard Number 2 and titled "An Audit of Internal Control Over Financial Reporting Performed in Conjunction with an Audit of Financial Statements." For those of us who are not professional auditors, this standard, as stated in the IT Control Objective for Sarbanes–Oxley (the IT Governance Institute), "define(s) the IT systems that are involved in the financial reporting process and, as a result, should be considered in the design and evaluation of internal control." These systems include any technology involved in financial transactions, such as servers, databases, network infrastructure, financial applications, and so on. Technology categories used by the PCAOB as areas for audit include program development, program changes, computer operations, and access to programs and data.

Each of the PCAOB areas for audit listed above can be broken down into further detail through the use of the Control Objectives for Information and Related Technology (COBIT) framework. The relationship between the PCAOB auditing standards and the corresponding COBIT control objectives can be seen in Exhibit 204.1 through Exhibit 204.5. Each of the twelve COBIT control objectives used for Sarbanes–Oxley compliance also has its own detailed specifications which it must meet. These specifications can be obtained through the IT Governance Institute at www.itgi.org. A sample of the level of detail in one of the COBIT control objectives is provided in Exhibit 204.6.

EXHIBIT 204.1 PCAOB Audit for Program Development: COBIT Mapping

Acquire or develop application software.
Acquire technology infrastructure.
Develop and maintain policies and procedures.
Install and test application software and technology infrastructure.
Define and manage service levels.
Manage third-party services.

EXHIBIT 204.2 PCAOB Audit for Program Changes: COBIT Mapping

Acquire or develop application software.
Acquire technology infrastructure.
Develop and maintain policies and procedures.
Install and test application software and technology infrastructure.
Manage changes.
Define and manage service levels.
Manage third-party services.

EXHIBIT 204.3 PCAOB Audit for Computer Operations: COBIT Mapping

Acquire or develop application software.
Acquire technology infrastructure.
Develop and maintain policies and procedures.
Install and test application software and technology infrastructure.
Define and manage service levels.
Manage third-party services.
Ensure systems security.
Manage the configuration.
Manage problems and incidents.
Manage data.
Manage operations.

EXHIBIT 204.4 PCAOB Audit for Access to Programs and Data: COBIT Mapping

Acquire or develop application software.
Develop and maintain policies and procedures.
Install and test application software and technology infrastructure.
Manage changes.
Define and manage service levels.
Manage third-party services.
Ensure systems security.
Manage the configuration.
Manage data.
Manage operations.

EXHIBIT 204.5 COBIT Control Objectives at a Glance

IT General Controls (COBIT Process)	Control Objective	Applicable PCAOB General Controls
Acquire or Develop Application Software	Controls exist to reasonably assure that software that is either acquired or developed effectively supports financial reporting.	Program Development Program Changes Computer Operations Access to Programs and Data
Acquire Technology Infrastructure	Controls exist to reasonably assure that the technical infrastructure in the organization supports financial reporting applications.	Program Development Program Changes Computer Operations
Develop and Maintain Policies and Procedures	Controls exist that reasonably assure that policies, procedures, and document exist and are maintained that instruct in proper use and support the financial reporting environment.	Program Development Program Changes Computer Operations Access to Programs and Data
Install and Test Application Software and Technology Infrastructure	Controls exist that reasonably assure that the infrastructure performs as advertised and is able to properly support the financial reporting environment; the infrastructure must be tested and validated for proper function before being put into production	Program Development Program Changes Computer Operations Access to Programs and Data
Manage Changes	Controls exist that reasonably assure that significant system changes to the financial reporting environment are authorized, tested, and validated before being put into production.	Program Changes Access to Programs and Data
Define and Manage Service Levels	Controls exist that reasonably assure that there is a common definition of "service levels," that these service levels will be measured for quality, and that support for financial systems will be appropriately maintained.	Program Development Program Changes Computer Operations Access to Programs and Data
Manage Third-Party Services	Controls exist that reasonably assure that third-party services are appropriately documented contractually; that these services are "secure, accurate, and available," as contracted; and that these services properly support the integrity of financial reporting.	Program Development Program Changes Computer Operations Access to Programs and Data
Ensure Systems Security	Controls exist that reasonably assure that financial reporting systems and subsystems are properly secured.	Computer Operations Access to Programs and Data
Manage the Configuration	Controls exist that reasonably assure that all IT components are properly secured and would prevent any unauthorized changes; controls should also help to document the current state of the configuration (i.e., a configuration management plan).	Computer Operations Access to Programs and Data
Manage Problems and Incidents	Controls exist that reasonably assure that problems are identified as events or incidents and are properly investigated, addressed, resolved, and recorded	Computer Operations
Manage Data	Controls exist that reasonably assure that any financial reporting data that is recorded, processed, and reported stays intact (that is, is complete, accurate, and valid) throughout the processing, transmission, and storage process.	Computer Operations Access to Programs and Data
Manage Operations	Controls exist that reasonably assure that any authorized programs are executed as planned and deviations from any scheduled processing are identified and thoroughly investigated.	Computer Operations Access to Programs and Data

EXHIBIT 204.6 COBIT Control Objectives: Acquire or Develop Application Software

Goal: System software, whether purchased or built in-house, must provide reasonable assurance that it effectively supports the organization's financial reporting requirements.

Control	Evidence of Control
Security, availability, and processing integrity requirements are included in the organization's formal process for the development and acquisition of software (i.e., the system development life cycle).	Review the organization's formal process for development and acquisition to determine whether requirements are included for security, availability, and processing integrity for financial reporting.
Formal policies and procedures exist for development or purchase of new systems, as well as for changes made to existing systems.	Review the organization's formal process for development and acquisition to determine whether formal policies and procedures for additions or changes are included for financial reporting.
The organization's process provides for appropriate integrity controls (i.e., accuracy, validation, authorization, and completion of transactions).	Review the organization's formal process for development and acquisition to determine whether formal application controls are included for financial reporting.
The acquisition and development process should be aligned with the organization's strategic planning process.	Review the organization's formal process for development and acquisition to determine whether or not senior management reviews, acknowledges, and approves all acquisition and development projects, based on the direction of the company and approved technology, for financial reporting.
End users are involved in the acquisition and development process, as well as the testing of the end products, to ensure resilience and reliability of the result.	Review the organization's formal process for development and acquisition to determine whether end users are included in each appropriate step.
Postmortems are conducted at the end of the acquisition or development process to determine whether controls are operating effectively.	Evaluate a sample of the organization's formal postmortems to determine if they adhere to the stated formal process.
Procedures are in place to ensure that the process is monitored and that all relevant acquisition and development efforts adhere to the formal process.	Review multiple acquisition and development projects to determine if they adhere to the stated formal process used by the organization.

It is important to note that the committees interpreting the Sarbanes–Oxley legislation recognize that no one set of recommendations fits every organization, as organizations vary by complexity, size, and other demographics. As such, the sponsoring committees urge the organization to apply internal controls appropriate to its environment. It is also highly recommended that the organization thoroughly document all its decisions regarding internal control design, implementation, and maintenance, but particularly in the case where senior management decides not to implement a control based on business case, lack of resources, or for other reasons. An auditor required to attest to the current state of financial reporting will certainly be looking for these documents during the course of an audit.

204.5 Now That I Know the IT Control Objectives, What Do I Do with Them?

Translating the IT control objectives to real-world remediation activities is not always an easy endeavor. Fortunately, tools are available that can assist the security practitioner in translating the legislative recommendations to a security-oriented framework. The ISO 17799 or the National Security Agency's INFOSEC Assessment Methodology (NSA IAM) can be used to facilitate this process. Another method that can be used to map remediation activities to compliance requirements is to use the COBIT control objectives literally to identify like activities already taking place within the organization. This process will require interviews with business units, information technology, and senior management to uncover details about business function as it exists on a day-to-day level within the organization. A good baseline questionnaire to use is included in Appendix B in the IT Governance Institute document referenced at the end of this chapter.

Typically, business functions that are keyed to compliance are considered to be critical business functions within the organization. Evaluation of the procedures used to complete these critical business functions may shed light on mapping of the function to COBIT control objectives. An approach is to develop process narratives that can be mapped one-to-one with the control objectives. For example, suppose the reader has interviewed the resident security team and discovered how it responds to and reports security incidents within the organization. The following details related to this response are revealed:

- Senior management has been involved with the response team and approves any deliverables the team produces.
- Senior management views the incident response effort as pivotal to the success of the organization, not just as a means to comply with Sarbanes–Oxley.
- As such, the organization, with the approval of senior management, has purchased an incident tracking system and has implemented it.
- A formal process has been documented for reporting and responding to an incident in the organization; it is available on the corporate intranet, and all staff have been trained on its use and their responsibilities for reporting incidents.
- The incident tracking system provides an audit trail on every event or incident that is logged (note that an event such as a hard drive malfunctioning is not necessarily a security incident; however, inventory, replacement time, and other demographics may still be tracked if entered into a system such as the one described above). Logs are retained for seven years in a secure off-site storage facility.
- The organization contracts with outside experts to assist in response that is outside the skill set of internal staff; these experts are accounted for in the incident response and reporting process.
- Senior management is provided with reports of all security incidents; senior management, in turn, reports all security incidents to its board, along with response specifics and resolution to the security incident.

Upon review of the COBIT control objectives for "manage problems and incidents," it is apparent that the organization has exceeded the requirements listed in the control objectives. The information received during this interview must be corroborated and evidence necessary to support the statements must be gathered; however, if everything is in order when the validation is completed, then the interviewer may assume that no material weaknesses are present for this particular COBIT control objective; only eleven to go!

Why would the organization want to exceed requirements for Sarbanes–Oxley compliance? Many organizations understand the value of doing more than the minimum necessary to meet legislative requirements. Often, there is substantive business value in exceeding legislative requirements. Let us take another look at the second to last item in the incident response process we just discussed; that is, the organization utilizes third-party experts to assist in response and reporting that are outside the skill set of internal resources engaged in this critical business function. What might happen if these expert resources were not available to the organization in time of need? Imagine that the organization is breached by a knowledgeable insider and that information is being copied and disclosed from critical systems. Without experts to assist in containment of the incident, eradication of any tools or malicious software that may have been used for the exploit, recovery of the system to normal working order, and preservation of any evidence throughout the incident that can lead back to the perpetrator and possibly the method of attack, the organization may have no method for recovery of critical data, systems or the evidence required to promote successful prosecution, if necessary. To take this a step further, suppose some of the data represents personally identifiable data, and this organization does business around the world, with its corporate headquarters and largest customer base being located in California. The disclosure alone mandates that everyone whose information was affected must be notified (SB 1386); if one of these affected parties goes to the press …

Many organizations have come to understand that security and compliance objectives are valuable to the organization as whole and, as such, the fulfillment of these objectives is applied to the business case, in general, not just to the narrow interpretation of a particular piece of legislation. Doing so may, in some cases, exceed the requirements for the legislation, but will nearly always reap rewards (in the scope of protection) for the organization itself. That said, it is also important for the organization to periodically assess its internal controls so that controls applied in areas of low risk, whether they are simply applied to financial reporting or to the organization as a whole, or "over-applied" to any area can be "right-sized" to save the organization resources, dollars, and time.

204.6 The Assertion and Attestation Process

204.6.1 Step One: Document the Financial Reporting Environment

Individuals in an IT or security role may work as part of a team with a financial resource. This approach works well, as a team focus provides comprehensive coverage of the financial reporting environment. Keeping in mind the earlier tasks that may be assigned to an IT resource on a Sarbanes–Oxley project, it is the job of the IT or security resource to provide sufficient documented information and evidence around the control environment, as it relates to the technology that supports financial processing. This can be accomplished either by diagramming or documenting the information technology processes that are present within the organization and merging this information with processes that are diagrammed or documented by the financial resource. For example, a financial resource is documenting the process by which a particular financial application performs its critical business function. The financial resource is very familiar with the accounting processes that occur within or are facilitated by the application; however, this person is unaware of the IT processes that support the application and draws into the documentation a black box labeled "Something happens in IT." It then becomes the IT or security resource's job to properly document the functions and controls that live inside the "black box." Performing the documentation of the financial reporting environment in this way ensures that the financial and IT functions are tied together from the beginning of the documentation process. Other mechanisms are available to accomplish this task; however, a Sarbanes team should never lose sight of the fact that the IT results should correspond and lend support to the financial functions that rest upon the technology. When the documentation is completed by both the financial resource and the IT or security resource, a joint report or separate reports can be issued to the organization, along with documentation that supports the effort and outlines the work done to date.

204.6.2 Step Two: Work with the Management Assertion Team To Uncover Any Material Weaknesses

When an organization is prepared for assertion, it typically contracts with an outside auditing partner to facilitate the testing of its internal environment. That distinction is very important; this auditing partner is considered an *internal resource*. Testing results are used by the organization to remediate any material weaknesses found in the internal control environment surrounding financial reporting. The IT or security resource may assist the internal auditing team in a number of ways:

The resource may provide details about the current state of IT, security, and internal controls within the financial reporting environment of the organization. These details can be obtained through a survey based on the PCAOB standards or the twelve COBIT control objectives cited for Sarbanes–Oxley compliance and is typically provided to the IT or security resource for completion. Although auditors may be more comfortable using the PCAOB standards, organizations may find the COBIT control objectives easier to understand and marry with compliance objectives. Either approach can work in an organization.

- The resource may provide evidence for the assertion team to test.
- The resource may serve as a liaison between the assertion team and the information technology departments present within the organization.
- The resource may assist in remediation of material weaknesses as the assertion progresses; this saves the organization and the assertion team time and effort later.
- The resource may be called upon to provide appropriate documentation of the effort in IT.
- The resource may be asked to participate in meetings with the attestation (external auditing) partner, in order to keep the partner abreast of activities ongoing and to adapt deliverables, if requested by the attestation team, so the attestation phase is not lengthened.

204.6.3 Step Three: Work with the Assertion and Attestation Teams To Facilitate Attestation of the Organization's Financial Reporting Environment

It is important to note that not all IT or security resources will be asked to participate in the assertion and attestation teams; however, they may be called upon at any time to participate in any function the teams require, with the exception of performing as an auditor. In this case, segregation of duties and, as such, independence would be violated. IT or security resources, who may be called upon to perform IT audits as a third party, will likely not be called upon to serve as a remediation resource. Attestation teams function much like assertion teams; that is, they test the internal controls environment surrounding financial reporting to determine if any material weaknesses can be found. They also prepare an attestation report detailing their findings. This report is provided to senior management and their designees. The PCAOB Audit Standard Number 2 is used to perform this attestation.

204.7 The Compliance Roadmap

Achieving compliance is a highly interdependent, business-oriented endeavor. IT must align itself with the business goals of the organization to have any hope of successfully navigating the compliance and control objectives detailed here. As stated in the IT control objectives for Sarbanes–Oxley, steps in developing a proper roadmap include:

- Planning and scoping
- Performing a risk assessment
- Identifying significant accounts and controls
- Formalizing and documenting control design
- Evaluating the control design
- Testing the control design for effectiveness
- Identifying and implementing remediation of any control deficiencies
- Documenting processes and results
- Building sustainability

For those readers who are practicing security professionals, this roadmap should look familiar. Indeed, it is similar to the design, implementation, and maintenance of sustainable security within an environment. As such, it is appropriate to utilize industry best practice tools to conduct these tasks. For example, the NIST Special Publication 800:30 (*Risk Management Guide for Information Technology Systems*) can be used to facilitate the risk assessment within the organization. Identifying significant accounts and controls is akin to identification of criticality within the environment (hence, “significant”). It is likely that this process will be familiar to any IT professional with life cycle knowledge. That said, it is clear that this path can also be taken to implement proper control environments within the organization in areas outside of financial reporting.

205

Health Insurance Portability and Accountability Act Security Rule

Lynda L. McGhie

The most effective and defensible information security program is one that strictly adheres to a disciplined risk management methodology. Legal authorities warn that laws and regulations regarding information protection and privacy will continue to evolve over the next decade. These rules will continue to dictate how firms and government agencies protect and safeguard customer privacy information. The most effective and efficient way to guarantee compliance to these laws and regulations is through the adoption of risk management systems. Such a framework will provide a foundational information security management system leading to compliance and risk reduction and mitigation. Many functional areas within an organization practice risk management and deal with various aspects of risk management, including information security, business continuity planning (BCP), disaster recovery planning (DRP), insurance, finance, and internal auditing, to name a few. Risk management is the critical first step leading to a successful and compliant implementation of the HIPAA Security Rule.

Security requirements imposed and mandated by the federal government have, for decades, resulted in the development of guidance for agencies, contractors, suppliers, and customers. These requirements, recommendations, and guidelines have proven over and over again to be practical baselines for legal and regulatory compliance. An organization that follows the security and privacy roadmaps provided by the National Institute of Standards and Technology (NIST), Federal Information Processing Standards (FIPS), and International Standards Organization (ISO) 17799 will greatly enhance its ability to comply with existing and future legal and regulatory requirements, and that organization's information security and privacy programs will be compliant and sound. Additionally, implementations based on these standards will ensure the sound practice of risk management up front and throughout the security and compliance process. It is important to acknowledge that this guidance is practical and applicable to public and private enterprises, as well as government and commercial entities. It just makes good sense.

A growing number of federal and state laws and regulations address information protection, privacy, management, and reporting practices, including data retention requirements. Many of these laws and regulations have common and similar requirements and controls. Many recommend or incorporate the audit and control methodologies of the Control Objectives for Information and Related Technology (COBIT) and Committee of Sponsoring Organizations (COSO), as well as other accepted information security standards and guidelines. Integration across these laws and regulations ensures synchronization and consistency of approach and controls. Additionally, a return on investment (ROI) can be demonstrated when one control or process satisfies multiple security requirements, laws, and regulations while streamlining and enhancing administration and technical processes. Additionally, automation and state-of-the-art security tools can reduce overall costs for information security and compliance across the enterprise.

205.1 Mandate

On August 21, 1996, President Clinton signed into law the Health Insurance Portability and Accountability Act (HIPAA) of 1996, Public Law 104-191. In so doing, the healthcare industry was given a far-reaching and complex mandate that would impact every aspect of health care in the United States. After much debate and a major rewrite of the Notice of Proposed Rule Making (NPRM), the final Security Rule was published in the *Federal Register* on February 20, 2003. Covered entities were required to implement reasonable administrative, physical, and technical safeguards to protect the confidentiality, integrity, and availability of electronic protected health information by April 20, 2005 (2006 for small health plans).

The HIPAA Security Rule specifically focuses on the safeguarding of electronic protected health information (ePHI). Only companies producing, utilizing, and storing ePHI are defined as "covered entities." Covered entities include health plans, healthcare clearinghouses, healthcare providers who transmit any electronic information in electronic form in connection with covered transactions, and Medicare prescription drug card sponsors. Although these companies are typically within the healthcare business, other entities such as the federal government and higher education may also utilize ePHI and would therefore also be required to comply with the HIPAA rule.

The HIPAA Security Rule specifically focuses on protecting the confidentiality, integrity, and availability of ePHI as defined and supported in the rule itself:

- *Confidentiality* is the property that data or information is not made available or disclosed to unauthorized persons or processes.
- *Integrity* is the property that data or information have not been altered or destroyed in an unauthorized manner.
- *Availability* is the property that data or information is accessible and useable upon demand by an authorized person.

The ePHI that a covered entity creates, receives, maintains, or transmits must be protected against reasonably anticipated threats, hazards, and impermissible uses or disclosures. Covered entities must also protect against reasonably anticipated uses or disclosures of such information that are not permitted by the Privacy Rule.

205.2 HIPAA Security Rule Overview

The HIPAA Security Rule defines the standards in generic terms and provides little guidance on how to implement them. The security standards are based on three concepts:

- *Flexibility and scalability*—The standards must be applicable from the smallest provider to the largest health plan.
- *Comprehensiveness*—The standards must cover all aspects of security, behavioral as well as technical (process oriented).
- *Technology neutrality*—As technology changes, the standards remain constant

It would be helpful to review and understand information security terminology prior to interpreting or seeking to understand the HIPAA Security Rule. The Security Rule is divided into six main sections, each of which includes standards and implementation specifications that a covered entity must address:

- *Security standards general rules* include the general requirements that all covered entities must meet; establishes flexibility of approach; identifies standards and implementation specifications required and addressable; outlines decisions a covered entity must make regarding addressable implementation specifications; and requires maintenance of security measures to continue reasonable and appropriate protection of electronic protected health information.
- *Administrative safeguards* are defined in the Security Rule as the administrative actions, policies, and procedures to manage the selection, development, implementation, and maintenance of security measures to protect electronic protected health information and to manage the conduct of the covered entity's workforce in relation to protection of that information.
- *Physical safeguards* are defined as the physical measures, policies, and procedures to protect a covered entity's electronic information systems and related buildings and equipment from natural environmental hazards and unauthorized intrusion.
- *Technical safeguards* are defined as the technology and the policies and procedures for its use that protect electronic protected health information and control access to it.
- *Organizational requirements* include standards for business associate contracts and other arrangements, including memoranda of understanding between a covered entity and a business associate when both entities are government organizations, as well as requirements for group health plans.
- *Policies and procedures and documentation requirements* require implementation of reasonable and appropriate policies and procedures to comply with the standards, implementation specifications, and other requirements of the Security Rule; maintenance of written (which may or may not be electronic) documentation or records that include policies, procedures, actions, activities, or assessments required by the Security Rule; and retention, availability, and update requirements for the documentation.

Each Security Rule section contains standards and implementation specifications. A covered entity is required to comply with all standards of the Security Rule with respect to all ePHI. Many of the standards also include implementation specifications. An implementation specification is a detailed description of the method or approach covered entities can use to meet a particular standard. Implementation specifications are either required or addressable; however, regardless of whether or not a standard includes implementation specifications, covered entities must comply with each standard.

- A *required* implementation specification is similar to a standard in that a covered entity must comply with it.
- For *addressable* implementation specifications, covered entities must perform an assessment to determine whether the implementation specification is a reasonable and appropriate safeguard for implementation in the covered entity's environment. In general, after performing the assessment, the organization can implement an equivalent alternative measure that allows the entity to comply with the standard, or it may not implement the addressable specification or any alternative measures if equivalent measures are not reasonable and appropriate within its environment. Covered entities are required to document these assessments and all decisions.

Exhibit 205.1 lists the standards and implementation specifications within the Administrative, Physical, and Technical Safeguards sections of the Security Rule. The table is organized according to the categorization of standards within each of the safeguard sections in the Security Rule:

- Column 1 lists the Security Rule standards.
- Column 2 provides the regulatory citation to the appropriate section of the rule.

EXHIBIT 205.1 HIPAA Security Rule Standards and Implementation Specifications

Standard	Section	Implementation Specifications (R=Required; A=Addressable)
Administrative safeguards		
Security Management Process	164.308(a)(1)	Risk analysis (R) Sanction policy (R) Risk management (R) Activity information system activity review (R)
Assigned Security Responsibility	164.308(a)(2)	None

- Column 3 lists the implementation specifications associated with the standard, if any exist, and designates the specification as required or addressable.

Organizations must determine whether anyone within the company is qualified to interpret the HIPAA Security Rule or if this phase of the project should be outsourced. Perhaps an internal cross-functional team could accomplish this critical initial task. Representatives from the legal, privacy, compliance, security, and technology departments should be able to research the HIPAA Security Rule and propose an interpretation and an implementation of the rule tailored to the organization. Many reference documents are available from the federal government and professional organizations to assist in this task. Many vendors and legal and accounting or audit firms sponsor information-sharing events regarding HIPAA compliance. Also, vertical industry focus groups have formed to share best practices and Security Rule interpretations.

It is absolutely fundamental to an organization's success to quickly gain consensus on interpretation of the rule and its application to the organization's unique healthcare environment. The quicker an organization can agree on an interpretation of the rule (what the rule is actually requiring the covered entity to do), the quicker the organization can document and solidify its approach, direction, and implementation plan for compliance. The plan should include only what is viable, practical, and required for that particular organization. This interpretation will allow the organization to establish the scope of the project and its compliance program.

It is critical that, when this interpretation and its resultant requirements and controls are identified and agreed upon, the project team *not* revisit, second guess, or continue to interpret the rule. When this foundational step is complete, the covered entity must not continue to debate the interpretation of the rule or the project requirements. It is important to document the process and the decisions made during this phase. It is at this point in the process when the covered entity typically gets cold feet, as the scope of the project and the required resources for implementation become clear.

It is apparent that the required controls *must* be implemented, but what about the addressable controls? Of the 42 implementation specifications, 21 are considered to be addressable. To meet the addressable implementation specifications, a covered entity must first assess whether each implementation specification is a reasonable and appropriate safeguard in its environment. The analysis must take into consideration the likely contribution of each control to protecting the entity's electronic protected health information. Remember, organizations should implement a specification only if it is reasonable and appropriate for the covered entity. If implementing the specification is not reasonable and appropriate, the organization must document why and implement an equivalent alternative measure that is reasonable and appropriate.

205.3 Critical Components

A covered entity should very quickly establish a HIPAA compliance governance system with documented and supporting processes. The plan should identify executive sponsorship and define roles and responsibilities. The executives should be high up in the organization and preferably direct reports of the chief executive officer (CEO) or members of the board of directors. These individuals will not only provide governance and oversight but also determine financial allocations, project deliverables, and compliance variables. These same individuals may also be part of the executive advisory board or steering committee. Other functional and business area representatives may also be added to this advisory board, including the chief financial officer (CFO), chief legal representative, procurement officer, chief information officer (CIO), chief information security officer (CISO), chief privacy officer, chief compliance officer, and chief technology officer (CTO). It is suggested that the executive vice president for each business area also be included on the board. Each of these members should be allocated one vote, and majority rules for approvals and decision making. These key individuals are considered stakeholders in the success of the project as well as overall compliance to the HIPAA Security Rule. Key external stakeholders might include business partners or even customers.

In support of the advisory board and the governing process, the organization should define and initiate report, status, and metric processes. The board should meet at regular intervals, at least on a monthly basis, during peak activity such as project initiation, achievement of major milestones, project approvals, financial approvals, and problem resolution. Each meeting should follow a standard agenda with reports from functional areas and business areas. The business areas should report on progress and deliverables for their assigned areas of responsibility. The functional areas should report on the action items and tasks assigned to them. The board meeting should provide a forum not only for information sharing and reporting but also for decision making and approval. It will be the role of the project director to track and report on the progress of the project, to prepare the meeting materials, and to collect status and reporting information from the team. The project director will also be responsible for metrics and metrics tracking and reporting. Selection of the project director is critical to the success of the project.

205.4 Centralized and Decentralized Roles and Responsibilities

Separate companies within a corporation may be separate covered entities in certain situations, but the corporation itself is the highest level covered entity. Although the executive officers, board of directors, and CISO are all culpable for HIPAA Security Rule compliance, the HIPAA documentation set must clearly outline and define separate roles and responsibilities. Some corporations that have decentralized business units or companies that manage their own information systems may want to appoint decentralized security officials who will have a dotted line responsibility to the CISO for implementing HIPAA Security Rule compliance. This team will be responsible for implementing the enterprise information security program, defining and implementing the enterprise information security policies and procedures, and implementing technical and administrative controls for HIPAA Security Rule compliance.

205.5 Identify and Define the Project Team

Several approaches can be used to assemble a HIPAA Security Rule compliance and implementation team. Resources may be derived from existing staff or supplemented with external contractors or even compliance-type organizations. It is best to conduct an assessment of existing resources, conduct a gap analysis, and derive a staffing and resource plan. In general, team representatives should include at least legal, compliance, security, privacy, technology, and business personnel. Individual organizations may require additional representation such as human resources, finance, or audit. The business representatives may or may not be part of this core team. Two separate teams can meet specific to their areas of responsibilities and their roles in the project; the two teams would then join when issues of cross-representation arise.

As with any project or process, the smaller and more representative the team, the more efficient and cost-effective the team will be and hence the project outcome. It is suggested that a small core team as well as a larger broader more representative team be identified. It is critical that roles and responsibilities be established and agreed to at the onset. The success of the project depends on achieving communication, understanding, and approval and buy-in throughout. Each organization will have to determine what existing tools and processes can be used to achieve these objectives and then define additive processes and tools for HIPAA Security Rule compliance. The main objective in the definition of these working teams is to ensure representation, to empower and enable the team, to streamline the process, and to eliminate bureaucracy to the extent feasible. Teams should adhere to strict project management and systems engineering processes.

205.6 Develop and Implement a Communication Plan

A thorough, multifaceted, multimedia HIPAA Security Rule communication plan should be developed early on in the process. Tailored communications should be developed and deployed specific to each phase of the project with the goal of keeping all stakeholders, team members, vendors, contractors, customers, business partners, and workforce members well informed. Communications should include newsletters, regularly scheduled and distributed status reports, and informational Web sites with project and team information and other alerts and bulletins specific to the project. The Web site should include a question box, FAQs, and other ways for workforce members to ask questions and receive information regarding what is coming up and what is changing. The communication plan should adopt a sales and marketing approach to point out and illustrate the outcomes and benefits of the project and compliance. Communication should occur often and on a regular basis; it should be designed to share progress, metrics, achievement of major and minor supporting milestones and any and all ROI, cost-benefits, and other gains achieved through security improvements such as administration simplification.

205.7 Define Project Scope

It is critically important when initiating such a project to propose and agree on the scope of the project; for example, what relevant information systems fall within the scope of the project? In order to determine this, the covered entity must identify all information systems that store or transmit ePHI. This includes all hardware and software used to collect, store, process, and transmit ePHI. To accomplish this task, the project director and team should develop a survey or inventory matrix template. The template should be distributed to the business team members and the functional team members and will be used to define major business units and functional units. The project director should assign responsibility for rolling up and summarizing the findings of the survey. This summary of the collected information will be included in a report presented to the project team and, following their concurrence, to the executive steering committee. The output of this process and this report will define the scope of the project and the systems, applications, network, storage, databases, etc. that house ePHI and therefore require compliant controls.

A companion process, or tool, that can assist in the definition of scope is an analysis of the organization's business functions. A common goal of such an analysis is definition of ownership and controls over these information systems. This information is critical to project initialization, defining project scope, project implementation, and ongoing compliance. At a minimum, policies, procedures, and processes should be implemented to ensure that this information is updated regularly and that the information is available for audit and compliance.

In addition to documentation and inventories of information, ePHI, and applications, system and network configurations should be documented, including internal and external connections. This is particularly critical for those systems processing ePHI. The reason why all systems should be

EXHIBIT 205.2 Administrative Safeguards

Section	Standard	Implementation Specification	Required/ Addressable	Solution	Methodology
164.308(a)(1)	Security management process	Risk analysis	Required	Intrusion detection system (IDS)	Security risks come in many forms and can be both internal and external. IDS enables covered entities to monitor network activity to determine what exposures may be created. Supplemental scanning and vulnerability tools support discovery and provide input to remediation.

documented, controlled, and managed is that over time it is difficult to isolate and control the flow of ePHI. To the extent possible, practical and affordable HIPAA Security Rule compliance should be integrated into the overall security system and program.

205.8 Security Rule Matrix

A Security Rule matrix should be mapped to HIPAA Security Rule requirements, policies, guidelines, actions, and ownership, including HIPAA Security Rule standards and implementation specifications. Our earlier discussion on the HIPAA Security Rule introduced the concept of addressable control mechanisms, including administrative, physical, and technical safeguards. Exhibit 205.1 can be used to create the Security Rule matrix, which adds additional columns to specify controls and solutions. It can also be used to incorporate risk assessment questions and surveys. The benefit of building on information initiated from the HIPAA Security Rule interpretation and, further, decomposition of its requirements is having a single data repository with supporting project documentation for audit and compliance verification. This baseline spreadsheet, as it evolves through each phase of the HIPAA security project, supplements project documentation. Subsequent phases can add additional columns, including risk questions, gap analysis findings, and administrative, technical, and physical controls that must be augmented, enhanced, or initiated for HIPAA compliance.

Exhibit 205.2 is an example of how to build on previous tables and information collected as the HIPAA security project evolves. The previous spreadsheet (Exhibit 205.1) included standards, citation sections, implementation specifications, and required/addressable categories. This spreadsheet adds a column for solutions and supporting methodologies for the solutions. An organization can create its own matrix or spreadsheet for this phase or can continue to build on this sample. Additional columns can be added that are specific to an organization's unique requirements, such as columns indicating existing controls and "to be" controls. Note that organizations should continue to build on this spreadsheet and matrix as risk assessment and gap analysis information is received, organized, and consolidated into meaningful data to be used to update the project plan.

205.9 Risk Assessment

Conducting a risk analysis is a required implementation specification of the HIPAA Security Rule. An entity must identify the risks to and vulnerabilities of the information in its care before it can take effective steps to eliminate or minimize those risks and vulnerabilities. As a first step, the organization must determine an approach and a methodology to set the course and provide a compass for its compliance initiatives. Following are some examples of existing security risk assessment frameworks:

- INFOSEC Assessment Methodology (IAM), from the National Security Agency (NSA)
- Operational Critical Threat, Asset, and Vulnerability Evaluation (OCTAVE), from Carnegie Mellon University Software Engineering Institute (SEI)

- NIST Special Publication 800-26 (*Security Self-Assessment Guide for Information Technology Systems*)

In 2004, draft NIST Special Publication 800-66 (*An Introductory Resource Guide for Implementing the Health Insurance Portability and Accountability Act [HIPAA] Security Rule*) was published. This document is intended to assist in identifying available NIST guidance that can serve as useful reference material in addressing the HIPAA security standards. In addition, it provides a cross-mapping among requirements to ensure that agencies do not do additional unnecessary work because many requirements overlap. The Centers for Medicare and Medicare Services (CMS), working with the Utilization Review Accreditation Committee (URAC), NIST, and the Workgroup for Electronic Data Interchange (WEDI) Strategic National Implementation Process (SNIP), will also be providing additional information on how to integrate NIST guidance into the HIPAA security compliance initiative. NIST guidance for risk assessment can be found in the following publications:

- NIST Special Publication 800-26 (*Security Self-Assessment Guide for Information Technology Systems*), http://csrc.nist.gov/publications/nistpubs/800-26/sp800-26.pdf
- FIPS-199 (*Standards for Security Categorization of Federal Information and Information Systems*), http://csrc.nist.gov/publications/fips/fips199/FIPS-PUB-199-final.pdf
- Administrative Safeguards, Section 164.308(a)(1)(ii)(A), Risk Analysis (Required), which requires covered entities to conduct an accurate and thorough assessment of the potential risks and vulnerabilities to the confidentiality, integrity, and availability of electronic protected health information held by the covered entity

Overall, the risks that must be assessed are the risks of noncompliance with the requirements of Section 164.306(a), General Rules, of the Security Rule: (1) ensure the confidentiality, integrity, and availability of all ePHI that the covered entity creates, receives, maintains, or transmits; (2) protect against any reasonably anticipated threats or hazards to the security or integrity of such information; (3) protect against any reasonably anticipated uses or disclosures of such information; and (4) ensure compliance with this subpart by its workforce. Risk management is the process of identifying and assessing risk and taking steps to reduce risk to an acceptable level. The risk assessment should identify potential risks and vulnerabilities with regard to the confidentiality, integrity, and availability of ePHI held by the covered entity. At a minimum, the risk assessment should determine the characteristics of the hardware, software, systems, interfaces, and information. It should include people, processes, and technology.

The next process or phase expands on information gathered in the previous phases, leading to further definition of the project scope, plan, schedule, resource requirements, and budget forecasting. Information from all inventories and surveys should be reviewed, analyzed, and summarized; this new knowledge should be utilized as input to the enterprisewide risk assessment. Enterprises or even individual business units that have recently completed risk assessments for any reason will be ahead of the game and have valuable input to the risk assessment process. Other inputs or sources of discovery might be audit reports and open audit findings; vendor reviews and contracts; statements of work (SOWs) and service level agreements (SLAs); external connection inventories; output from intrusion detection systems (IDSs); investigation and incident response systems; audit and monitoring systems; and scanning tools. The results and output from system- and application-level testing may also be of some value in putting together the risk assessment puzzle. Information on known project deliverables, life cycles, and known and identified problems should also be incorporated.

Many companies outsource their information technology (IT) services and support, either in their entirety or in smaller portions. Outsourcing partners or providers may be able to provide valuable information. Typically, SLAs are associated with these contracts, and metrics are reported and tracked. This information could also be of value to the risk assessment. A growing trend is to outsource security operations and management through security managed services. These companies constantly monitor a company's network and systems for security anomalies. Many map to known and permitted access and send an alert when violations or even suspected activities are detected. Vendors, managed service providers, and other sources can provide ongoing risk and vulnerability reporting and incident tracking.

Benchmarking within the industry and general security threat analysis information are also of value. This type of information could be specific to the healthcare industry, to security (e.g., Internet), or to compliance, or it could pertain to business operations in general. Such information could include virus alerts and occurrences, patches, code vulnerabilities, attack attempts, etc. If an organization already has a well-established information security program and has defined and implemented information security policies and procedures, then its risk assessment should map not only to the HIPAA Security Rule but also to existing security policies and procedures. The risk assessment must also consider compliance to physical and human resources security policies and procedures and should provide for consistent approaches and controls.

Other input can come from the areas of business continuity planning (BCP) and disaster recovery (DR). Risk assessments and impact analysis are the cornerstones of these functions, in addition to application inventories; defining critical applications; determining ownership of and classifying systems, data, and applications; and incident and crisis management.

Risk can never be totally eliminated. Compliance with the HIPAA Security Rule requires that appropriate and reasonable safeguards be implemented to protect the confidentiality, integrity, and availability of ePHI. In the context of HIPAA security, a covered entity may want to protect more than ePHI (e.g., employment, brand, patent, research and development, and financial information). In addition to integrating compliance with existing security policies and procedures during the risk assessment and inventory processes, it is helpful to ensure compliance to the technical security architecture, guidelines, and standard security configurations. The IT team should be assigned the responsibility to check all hardware and software to determine whether selected security settings are enabled. The output from this effort will provide input to the next process (gap analysis) and will assist in the determination of the effectiveness of current safeguards.

If organizations focus only on HIPAA security compliance, they leave themselves open to other risks. They must also assess change impact, people, business units, and technology. The risk assessment process is labor intensive and yields volumes of information. The team will need to have a predetermined plan for review, analysis, consolidation, interpretation, and summarization of the information gathered. Putting considerable thought into defining the risk analysis criteria, developing a useful assessment format, and determining the questions to ask will result in useful information (remember, "garbage in, garbage out"). Remember that the people filling out the risk assessment questionnaires and gathering the information may not be experts in IT, supporting business processes, or security. The process should include follow-up and information validation processes. The final outcome of the risk assessment process is the risk assessment report.

Covered entities should use a combination of qualitative and quantitative risk assessment methodologies. The process discussed above emphasizes qualitative risk assessment methodologies and processes. Although traditionally seen as subjective when compared to quantitative risk assessment, the resulting risk assessment report may be easier to defend when it is presented to the HIPAA Security Rule advisory board or steering committee.

Qualitative measurement is used to determine if a specific element qualifies. Qualitative analysis could be used to determine the scope of HIPAA security compliance by stating that if a system contains ePHI then it qualifies for inclusion in the risk assessment for the HIPAA Security Rule. Another use of qualitative assessment is for significance or strength. For example, qualitative evaluations such as low, moderate, or high may be used to determine the likelihood that a virus would be introduced to the organization's system via e-mail. Basically, qualitative analysis is used to determine "yes" or "no" with regard to including a specific element and is also used to determine the significance of something using non-numerical terminology. Qualitative analysis is subjective.

The accuracy of qualitative analysis determinations relies on subject matter expertise in the following areas:

- Operations and processes
- Workforce capabilities
- System capabilities
- Compliance program management
- System development lifecycle management

Quantitative measurement is used to determine characteristics in numerical terms, usually expressed in percentage, dollar amount, or number of times a specific event occurs in a stated period of time. If, during a qualitative analysis, it was determined that it was highly likely that a virus could be introduced to the system via e-mail, then the quantitative analysis might determine a probability of 99.99% that the system would have a virus introduced via e-mail.

Algorithm analysis is an example of quantitative analysis. Algorithm analysis can be used to quantify impact in a dollar amount by computing the annualized loss expectancy (ALE). ALE is computed as a function of the single loss expectancy (SLE) in dollars and the annualized rate of occurrence (ARO).The data that is used for the basis of these determinations vary. Usually the determinations are based on regional, national, or worldwide aggregated performance criteria of hardware and software configurations to security threats. Rarely does a covered entity have the capability to collect enough aggregated data to make these computations, so the use of algorithm quantitative analysis usually requires the expertise of vendors that specialize in this type (actuarial science) of risk assessment. Quantitative analysis is objective. The benefit of quantitative determinations relies on:

- Relevance of the data used in the computations
- Current accuracy of the data
- Ability to interpret the meaning of the numerical values
- Ability to translate determinations into risk mitigation

205.10 As-Is State/Gap Analysis

The risk assessment report provides a summarization of the as-is state of the existing information security program. It also highlights where the covered entity is relative to compliance with the HIPAA Security Rule. Utilizing the security rule matrix and the risk assessment report, the next project process or phase is to conduct an enterprisewide gap analysis to determine corrective action plans as well as updates to the compliance plan. It is important to determine gaps or vulnerabilities in the following areas: policy, procedures and processes, training and awareness, implementation or process integration, operational controls, and audit.

A critical and valuable tool in the gap analysis process is the gap analysis checklist, which is a list of the requirements of the HIPAA Security Rule as defined for the covered entity during the HIPAA Security Rule interpretation and in the Security Rule matrix. The checklist is written in a question format, is easy to understand and answer, and does not require specific technical or business process skills.

Project documentation is critical, particularly documentation leading to judgments and decisions. The documentation should be updated throughout each project phase or process. The auditor and accreditation authority will use this documentation to validate compliance initially and on an ongoing basis. A well-defined checklist will provide the auditor with a roadmap for review, leading to an organized list of recommendations for enhancements and remediation. Whether an organization designs or purchases a compliance checklist, the completed checklist will be used to draw up a task list for the remediation plan. The detailed checklist will serve as a tool to compare the organization's current as-is state to the Security Rule matrix. Determine whether or not current safeguards ensure the confidentiality, integrity, and availability of all ePHI. What technical and administrative safeguards are in place to protect and secure ePHI? Where are the gaps? This process allows the organization to easily identify the requirements that it is already meeting and those that still must be addressed within the project plan. The organization will also obtain critical additional information regarding the resources and timeline necessary for the HIPAA Security Rule compliance project.

205.11 Enhancements and Implementation of Administrative and Technical Controls

Although the Security Rule does not require purchasing any particular technology, additional hardware, software, or services may be needed to protect ePHI adequately. If additional technical controls are necessary, the organization should consider conducting a product evaluation in compliance with existing policies and procedures. A cost-benefit analysis should be conducted early on in the process to determine the reasonableness of the investment given the security risks identified. Administrative and manual processes may supplement or replace technology solutions. Members of the technical team should initiate the technology reviews utilizing requirements derived from the above processes or phases as well as ongoing input from the business and functional areas. Vendor presentations and demonstrations will be helpful for management, technical teams, and business functional areas. These will help inform, communicate, and gain concurrence throughout the process.

New technology or even new administrative controls should be integrated into the overall information security and technical architecture and its supporting processes to exploit and take advantage of existing investments. The covered entity should have good security standards already in place that require only supplemental enhancement for HIPAA Security Rule compliance. It is advisable to closely monitor the introduction of new or additional technical and administrative controls to ensure security compliance without imposing undue burdens on the business and its operations.

Requirements and solutions at this stage of the process will come directly from the updated Security Control matrix. Activities will map to a combination of administrative and technical controls integrating this phase or process to both technical and administrative teams. Depending on the strategy that the covered entity has adopted, the focus here will be on centralized or decentralized solutions. Additionally, it may be necessary to look for automated technical solutions or administrative and manual solutions.

Some covered entities may also take a wait-and-see approach pending the outcome of future litigation and fines around HIPAA compliance. Another strategy might be to implement controls of the “low-hanging fruit” variety for initial compliance and then take a slower and longer approach to the hard and expensive solutions. In this case, it is important to document the reasoning in the project documentation management system and to have a solid and approved long-term project plan in place for audit and compliance. To the extent practical, the organization should stick with their major upfront decisions unless they are proven to be illogical or ill founded; they should not continue to second guess or revisit their rule interpretations, previous decisions and directions, or the project plan. Second guessing will cause the organization to lose credibility with its stakeholders and threaten its compliance plan and schedule.

205.12 Training and Awareness

Information security awareness training and regular security updates and reminders are required for all personnel who fall under HIPAA guidelines, including managers, agents, and contractors. A covered entity’s HIPAA compliance training and awareness program should focus on the HIPAA Security Rule to ensure that the program framework meets and exceeds the requirements laid out in Section 142.308(12) regarding:

- Training on vulnerabilities of digital health information and how to protect that information
- Password maintenance

- Incident reporting
- Viruses
- Malicious code

As previously mentioned, a thorough and multimedia HIPAA Security Rule communication plan should be developed early on in the process. Tailored communications should be developed and deployed specific to each phase of the project, with a common goal of keeping all stakeholders, team members, vendors, contractors, customers, business partners, and workforce members well informed. The communication plan builds bridges to other enterprise communications and projects. It also works with the HIPAA Security Rule training and awareness program and the overall enterprise information security training and awareness program.

The primary goal of all Security Rule communication is to ensure that workforce members are well informed regarding executive management's position and direction on HIPAA Security Rule compliance and information security in general. The training course material provides a review of the HIPAA Security Rule specific to the covered entity's implementation and the enterprisewide information security policies and procedures. It establishes workforce member expectations and specifically informs them on new behavior expectations. It clearly outlines and explains what will change, what they need to do, and how they will do it.

The training should be ongoing and intermingled throughout the project, with an emphasis on the readiness of technical and administrative control mechanisms. For example, at project initiation some skill training for the project team may be conducted, in addition to training on how to interpret the HIPAA Security Rule, how to conduct a risk assessment and gap analysis, and how to evaluate the as-is state to determine what new administrative and technical controls might be necessary. Particular emphasis should be placed on training regarding policies, procedures, and technical and administrative tools and processes.

Security awareness and training should already be the cornerstones of an organization's information security program, and initial and annual HIPAA Security Rule training can be incorporated with these overall security training and awareness programs. Training may be tailored to the various roles and responsibilities within the enterprise—detailed training for security and privacy officials; briefer, more high-level training for senior executives and management; and, finally, more detailed training in tools, forms, and processes for those routinely handling and processing ePHI.

A search of the Internet will reveal a number of companies offering various types of HIPAA training, either standard or custom. An organization's training and awareness plan and supporting communication plan may require a combination of in-house and vendor HIPAA Security Rule training material.

205.13 Implement an Ongoing HIPAA Compliance Organization and Infrastructure

Everyone has experienced the breakdown of an implemented project or infrastructure as interest in the project wanes over time and team members are reassigned or overcome by new projects and events. It is critical that the HIPAA Security Rule project sustain its momentum over time and that the ongoing organization structure, designated roles and responsibilities, and compliance infrastructure remain active and effective over time. This will be particularly critical when dealing with new laws and regulations. It is important to note that legal groups estimate that laws and regulations regarding personal privacy will continue to evolve over the next decade; consequently, covered entities must remain knowledgeable, informed, agile, and adaptive. A foundation must be established to quickly integrate new control requirements that are both administrative and technical. An ongoing risk assessment and gap analysis management process must be implemented to integrate controls for new and added risks and vulnerabilities that naturally occur within the business and within information technology.

The HIPAA Security Rule speaks to the need for external accreditation, and many vendors, as well as audit and accounting firms, are ramping up to conduct accreditations and certifications. A growing tendency is for companies to use compliance with laws and regulations (particularly if certified by external accreditation authorities) as a competitive advantage in their sales and marketing programs. Companies are also incorporating compliance certifications and accreditation into their annual reports, Securities and Exchange Commission (SEC) reports, and marketing and advertising.

As noted earlier, internal audit personnel are a critical component of the HIPAA Security Rule project team and not only have ongoing roles and responsibilities throughout the project but also have a critical role at the end of the project for certification of compliance. The documentation, checklists, and audit findings from the internal audit team will also serve as a guideline for external auditors, leading to a more efficient, effective, and compliant report.

It is important to allow enough time to do an in-depth preimplementation audit. The more information that can be acquired for developing task lists and project plans, the more efficient and effective the audit process will be. When the audit has been completed, representatives should meet with the auditors to summarize the results. These results can be transferred to task lists for remediation and corrective actions.

205.14 Checklist for Success

- Do not over-react or panic, and do not overspend but leverage. Do *only* what is required to become compliant, and take the opportunity to enhance the organization’s current security environment in the process.
- Be sure that the covered entity is protected against all reasonably anticipated threats or hazards to the security and integrity of ePHI. Interruption to business process and workflow should be avoided at all cost.
- Be sure business and technology converge to ensure compliance with the HIPAA Security Rule.
- Realize that there can only be one chief and that the governing and advisory boards are integral to the process.
- Understand that, although benchmarking and research are mandatory, the rule purposely and specifically provides guideline only, in recognition of each covered entity’s individual risk, business imperative, and budget.

Jurisdictional Issues in Global Transmissions

Ralph Spencer Poore

206.1 Introduction

In the information age, where teleconferences replace in-person meetings, where telecommuting replaces going to the office, and where international networks facilitate global transmissions with the apparent ease of calling your next-door neighbor, valuable assets change ownership at the speed of light. Louis Jionet, Secretary-General of the French Commission on Data Processing and Liberties, stated that "Information is power and economic information is economic power." Customs officials and border patrols cannot control the movement of these assets. But does this mean companies can transmit the data, which either represents or is the valuable asset, without regard to the legal jurisdictions through which they pass? To adequately address this question, this chapter discusses both the legal issues and practical issues involved in transnational border data flows.

206.2 Legal Issues

All legally incorporated enterprises have *official books of record*. Whether in manual or automated form, these are the records governmental authorities turn to when determining the status of an enterprise. The ability to enforce a subpoena or court order for these records reflects the effective sovereignty of the nation in which the enterprise operates. Most countries require enterprises incorporated, created, or registered in their jurisdiction to maintain official books of record physically within their borders. For example, a company relying on a service bureau in another country for information processing services may cause the official records to exist only in that other country. This could occur if the printouts or downloads to management PCs reflect only an historic position of the company, perhaps month-end conditions, where the current position of the company—the position on which management relies—exists only through online access to the company's executive information system. From a nation's perspective, two issues of sovereignty arise:

1. That other country might exercise its rights and take custody of the company's records—possibly forcing it out of business—for actions alleged against the company that the company's "home" nation considers legal.
2. The company's "home" nation may be unable to enforce its access rights.

Another, usually overriding, factor is a nation's ability to enforce its tax laws. Many nations have value-added taxes (VATs) or taxes on "publications," "computer software," and "services." Your organization's data may qualify as a "publication" or as "computer software" or even as "services" in some jurisdictions. Thus, many nations have an interest in the data that flows across their borders because it may qualify for taxation. The Internet has certainly added to this debate over what, if anything, should be taxable. In some cases, the tax is a tariff intended to discourage the importation of "computer software" or "publications" in order to protect the nation's own emerging businesses. More so than when the tax is solely for revenue generation, protective tariffs may carry heavy fines and be more difficult to negotiate around.

National security interests may include controlling the import and export of information. State secrecy laws exist for almost all nations. The United States, for example, restricts government-classified data (e.g., Confidential, Secret, Top Secret) but also restricts some information even if it is not classified (e.g., technical data about nuclear munitions, some biological research, some advanced computer technology, and cryptography). The USA PATRIOT Act, for example, included provisions for interception of telecommunications to help combat terrorism.

Among those nations concerned with an individual's privacy rights, the laws vary greatly. Laws such as the United States Privacy Act of 1974 (5 USC 552a) have limited applicability (generally applying only to government agencies and their contractors). More recent privacy regulations stemming from the Gramm–Leach–Bliley Act (15 USC 6801 *et seq.*) and the Health Insurance Portability and Accountability Act (HIPAA) (45 CFR Part 164 §§ C&E) provide industry-specific privacy and security strictures. The United Kingdom's Data Protection Act of 1984 (1984 c 35 [*Halsbury's Statutes*, *4th edition*, Butterworths, London, 1992, Vol. 6, pp. 899–949]), however, applies to the commercial sector as does the 1981 Council of Europe's Convention for the Protection of Individuals with Regard to Automatic Processing of Personal Data (an excellent discussion of this can be found in Anne W. Brandscomb's *Toward a Law of Global Communications Networks*, The Science and Technology section of the American Bar Association, Longman, New York, 1986). Privacy laws generally have at least the following three characteristics:

1. They provide notice to the subject of the existence of a database containing the subject's personal data (usually by requiring registration of the database or mailing of a formal notice).
2. They provide a process for the subject to inspect and to correct the personal data.
3. They provide a requirement for maintaining an audit trail of accessors to the private data.

The granularity of privacy law requirements also varies greatly. Some laws (e.g., the U.S. Fair Credit Reporting Act of 1970 [see 15 USC 1681 *et seq.*]) require only the name of the company that requested the information. Other laws require accountability to a specific office or individual. Because the granularity of accountability may differ from jurisdiction to jurisdiction, organizations may need to develop their applications to meet the most stringent requirements, that is, individual accountability. In this author's experience, few electronic data interchange (EDI) systems support this level of accountability (UNCID *Uniform Rules of Conduct for Interchange of Trade Data by Teletransmission*, ICC Publishing Corporation, New York, 1988. All protective measures and audit measures are described as options, with granularity left to the discretion of the parties).

To further complicate data transfer issues, patent, copyright, and trade secrets laws are not uniform. Although international conventions exist (e.g., General Agreement on Tariffs and Trade [GATT]), not all nations subscribe to these conventions; and the conventions often allow for substantial differences among signatories. Rights one might have and can enforce in one jurisdiction may not exist (or may not be enforceable) in another. In some cases, the rights one has in one jurisdiction constitute an infringement in another jurisdiction. For example, one might hold a United States registered trademark on a product. A trademark is a design (often a stylized name or monogram) showing the origin or ownership of merchandise and reserved to the owner's exclusive use. The Trade-Mark Act of 1946 (see 15 USC 1124) provides that no article shall be imported which copies or simulates a trademark registered under U.S. laws. A similar law protecting, for example, trademarks registered in India might prevent one from using the trademark in India if a similar or identical trademark is already registered there.

Disclosure of information not in accordance with the laws of the jurisdictions involved may subject the parties to criminal penalties. For example, the United Kingdom's Official Secrets Act of 1989 clearly defines areas wherein disclosure of the government's secrets is a criminal offense. Most nations have similar laws (of varying specificity), making the disclosure of state secrets a crime. However, technical information considered public in one jurisdiction may be considered a state secret in another. Similarly, biographical information on a national leader may be mere background information for a news story in one country but be viewed as espionage by another. These areas are particularly difficult because most governments will not advise you in advance what constitutes a state secret (as this might compromise the secret). Unless the organization has a presence in each jurisdiction sensitive to these political and legal issues to whom it can turn for guidance, one should seek competent legal advice before transmitting text or textual database materials containing information about individuals or organizations.

From a business perspective, civil law rather than criminal law may take center stage. Although the United States probably has the dubious distinction as the nation in which it is easiest to initiate litigation, lawsuits are possible in almost all jurisdictions. No company wants to become entangled in litigation, especially in foreign jurisdictions. However, when information is transmitted from one nation to another, the rules may change significantly. For example, what are the implied warranties in the receiving jurisdiction?[1] What constitutes profanity, defamation, libel, or similar actionable content? What contract terms are unenforceable (e.g., can you enforce a nondisclosure agreement of ten years' duration?)?

In some jurisdictions, ecclesiastical courts may have jurisdiction for offenses against a state-supported religion. Circumstances viewed in one jurisdiction as standard business practices (e.g., "gifts") might be viewed in another as unethical or illegal. Whether an organization has standing (i.e., may be represented in court) varies among nations. An organization's rights to defend itself, for example, vary from excellent to nil in jurisdictions ranging from Canada to Iran.

Fortunately, companies can generally choose the jurisdictions in which they will hold assets. Most countries enforce their laws (and the actions of their courts) against corporations by threat of asset seizure. A company with no seizable assets (and no desire to conduct future business) in a country is effectively judgment proof in that country's jurisdiction (although treaty arrangements among jurisdictions may give them recourse through other countries). The reverse can also be true; that is, a company may be unable to enforce a contract (or legal judgment) because the other party has no assets within a jurisdiction willing to enforce the contract or judgment. When contracting with a company to develop software, for example, and that company exists solely in a foreign country, your organization should research the enforceability of any contract and, if you have any doubt, require that a bond be posted in your jurisdiction to ensure at least bond forfeiture as recourse.

206.3 Technical Issues

Any nation wishing to enforce its laws with regard to data transmitted within or across its borders must have the ability to (1) monitor/intercept the data and (2) interpret/understand the data. Almost all nations can intercept wire (i.e., telephone or telegraph) communications. Most can intercept radio, microwave, and satellite transmissions. Unless an organization uses exotic technologies (e.g., point-to-point laser, extremely low frequency [ELF], or super high frequency), interception will remain likely.

The second requirement, however, is another matter. Even simple messages encoded in accordance with international standards may have meaning only in a specific context or template not inherent in the

[1] A good discussion (and resource) addressing this and similar questions is Benjamin Wright's *Business Law and Computer Security: Achieving Enterprise Objectives through Data Control*, SANS Press, 2003.

message itself. For example, "412667456043052" could be a phone number (e.g., 412-667-4560x43052), a social security number and birthday (e.g., 412-66-7456 04/30/52), dollar amounts ($41,266.74 $560,430.52), inventory counts by part number (PN) (e.g., PN 412667 45, PN 604305 2), or zip codes (e.g., 41266, 74560, 43052). Almost limitless possibilities exist even without using codes or ciphers. And this example used human-readable digits. Many transmissions may be graphic images, object code, or compressed text files completely unintelligible to a human "reading" the data on a datascope.

From the preceding, one might conclude that interception and interpretation by even a technologically advanced nation is too great a challenge. This is, however, far from true. Every "kind" of data has a signature or set of attributes that, when known, permits its detection and identification. This includes encrypted data where the fact of encryption is determinable. Where transmitting or receiving encrypted messages is a crime, a company using encryption risks detection. Once the "kind" of data is determined, applying the correct application is often a trivial exercise. Some examples of such strong typing of data include:

- Rich-text format (RTF) documents and most word processing documents
- SQL transactions
- Spreadsheets (e.g., Lotus 1-2-3, Microsoft Excel)
- Most executables
- Standardized EDI messages
- Internet traffic

If this were not the case, sending data from one computer to another would require extensive advanced planning at the receiving computer—severely impacting data portability and interoperability, two attributes widely sought in business transactions.

Countries with sufficient technology to intercept and interpret an organization's data may pose an additional problem beyond their law enforcement: government-sponsored industrial espionage. Many countries have engaged in espionage with the specific objective of obtaining technical or financial information of benefit to the countries' businesses. A search of news accounts of industrial espionage resulted in a list including the following countries: Argentina, Peoples Republic of China, Iran, India, Pakistan, Russia, Germany, France, Israel, Japan, South Korea, and North Korea. Most of these countries have public policies against such espionage, and countries like the United States find it awkward to accuse allies of such activities (both because the technical means of catching them at it may be a state secret and because what one nation views as counter-espionage another nation might view as espionage).

206.4 Protective Technologies

For most businesses, the integrity of transmitted data is more important than its privacy. Cryptographic techniques a business might otherwise be unable to use because of import or export restrictions associated with the cryptographic process or the use of a privacy-protected message can be used in some applications for data integrity. For example, symmetric key algorithms such as Triple DES [2], Rijndael (AES) [3], and IDEA [4], when used for message authentication (e.g., in accordance with the American National Standard X9.19 for the protection of retail financial transactions or similar implementations supporting a message authentication code [MAC]), may be approved by the U.S. Department of the Treasury without having to meet the requirements of the International Trade in Arms Regulations (ITAR).

[2] Triple DES is based on a multiple-key implementation of DES. For more information, see ANS X9.52 *Triple Data Encryption Algorithm Modes of Operation.*

[3] The Advanced Encryption Standard (AES) is documented in FIPS 197, available through the National Institute of Standards and Technology (NIST) Web site at http://csrc.nist.gov/publications/fips/fips197/fips-197.pdf.

[4] Xuejia Lai and James Massey developed IDEA in Zurich, Switzerland. Ascom Systec Ltd. is the owner of the encryption algorithm IDEA.

Integrity measures generally address one or both of the following problems:

- Unauthorized (including accidental) modification or substitution of the message
- Falsification of identity or repudiation of the message

The techniques used to address the first problem are generally called Message Authentication techniques. Those addressing the second class of problems are generally called Digital Signature techniques.

Message authentication works by applying a cryptographic algorithm to a message in such a way as to produce a resulting message authentication code (MAC) that has a very high probability of being affected by a change to any bit or bits in the message. The receiving party recalculates the MAC and compares it to the transmitted MAC. If they match, the message is considered authentic (i.e., received as sent); otherwise, the message is rejected.

Because international standards include standards for message authentication (e.g., ISO 9797), an enterprise wanting to protect the integrity of its messages can find suitable algorithms that should be (and historically have been) acceptable to most jurisdictions worldwide. For digital signatures this may also be true, although several excellent implementations (both public key and secret key) rely on algorithms with import/export restrictions. The data protected by a digital signature or message authentication, however, is not the problem as both message authentication and digital signature leave the message in plaintext. Objections to their use center primarily on access to the cryptographic security hardware or software needed to support these services. If the cryptographic hardware or software can be obtained legally within a given jurisdiction without violating export restrictions, then using these services rarely poses any problems.

Digital signature techniques exist for both public key and secret key algorithm systems (also known as asymmetric and symmetric key systems, respectively). The purpose of digital signature is to authenticate the sender's identity and to prevent repudiation (where an alleged sender claims not to have sent the message)[5]. The digital signature implementation may or may not also authenticate the contents of the signed message.

Privacy measures address the concern for unauthorized disclosure of a message in transit. Cipher systems (e.g., AES) transform data into what appears to be random streams of bits. Some ciphers (e.g., a Vernam cipher with a key stream equal to or longer than the message stream) provide almost unbreakable privacy. As such, the better cipher systems almost always run afoul of export or import restrictions.

In some cases, the use of codes is practical and less likely to run into restrictions. As long as the "codebook" containing the interpretations of the codes (see Exhibit 206.1) is kept secret, an organization could send very sensitive messages without risk of disclosure if intercepted en route. For example, an oil company preparing its bid for an offshore property might arrange a set of codes as follows. The message "RED SUN NOVEMBER MAY MAY" would make little sense to an eavesdropper, but would tell your representative the maximum authorized bid is 900 (the units would be prearranged, so this could mean $900,000).

Other privacy techniques that do not rely on secret codes or ciphers include:

1. Continuous stream messages (the good message is hidden in a continuous stream of otherwise meaningless text). For example: "THVSTOPREAXZTRECEEBNKLLWSYAINNTHE-LAUNCHGBMEAZY" contains the message "STOP THE LAUNCH." When short messages are sent as part of a continuous, binary stream, this technique (one of a class known as steganography) can be effective. This technique is often combined with cipher techniques where very high levels of message security are needed.

[5] Note that symmetric techniques for "digital signatures" require an additional step called "notarization" to prevent the receiving party from forging the sending party's message using the shared symmetric key. This technique predates the advent of public key cryptography, which has almost universally displaced it.

EXHIBIT 206.1 Sample Codebook

Code	Meaning
Red Sun	Highest authorized bid is
Blue Moon	Stall, we aren't ready
White Flower	Kill the deal; we aren't interested
June	1.00
April	2.00
July	3.00
December	4.00
August	5.00
January	6.00
March	7.00
September	8.00
November	9.00
May	0.00

2. Split knowledge routing (a bit pattern is sent along a route independent of another route on which a second bit pattern is sent; the two bit streams are exclusive-ORed together by the receiving party to form the original message). For example, if the bit pattern of the message you want to send is 0011 1001 1101 0110, a random pattern of equal length would be exclusive-ORed with the message (e.g., 1001 1110 0101 0010) to make a new message 1010 0111 1000 0100. The random pattern would be sent along one telecommunication path and the new message would be sent along another, independent telecommunication path. The recipient would exclusively OR the two messages back together, resulting in the original message. Because no cryptographic key management is required and because the exclusive-OR operation is very fast, this is an attractive technique where the requirement of independent routing can be met. Wayner describes a particularly clever variation on this using bit images in his book entitled *Disappearing Cryptography*[6].
3. The use of templates (which must remain secret) that permit the receiver to retrieve the important values and ignore others in the same message. For example, our string used above:

"THVSTOPREAXZTRECEEBNKLLWSYAINNTHELAUNCHGBMEAZY"

used with the following template reveals a different message:

"XXXXXXXNNXXXNNNXXXXXXXXXXXNXXXNXXXXXXXXXXXXXXX"

where only the letters at the places marked with "N" are used: RETREAT.

The first technique may also be effective against traffic analysis. The second technique requires the ability to ensure independent telecommunication routes (often infeasible). The third technique has roughly the same distribution problems that codebook systems have; that is, the templates must be delivered to the receiver in advance of the transmission and in a secure manner. These techniques do, however, avoid the import and export problems associated with cryptographic systems. These problems are avoided for two reasons: (1) cryptographic transmissions appear to approach statistical randomness (which these techniques do not) and (2) these techniques do not require the export or import of any special technology. Although no system of "secret writing" will work for citizens of nations that prohibit coded messages, unfortunately, such jurisdictions can claim that any message—even a plaintext message—is a "coded" message.

In addition to cryptographic systems, most industrialized nations restrict the export of specific technologies, including those with a direct military use (or police use) and those advanced technologies easily misused by other nations to suppress human rights, improve intelligence gathering, or counter security measures. Thus, an efficient relational database product might be restricted from export because oppressive third-world nations might use it to maintain data on their citizens (e.g., "subversive activities lists"). Finding a nation in which the desired product is sold legally without the export restriction can

[6] Wayner, Peter, 1996. Disappearing Cryptography: Being and Nothingness on the Net. AP Professional, Chestnut Hill, MA.

sometimes avert restrictions on software export. (Note: check with your legal counsel in your enterprise's official jurisdiction as this workaround may be illegal—some countries claim extraterritorial jurisdiction or claim that their laws take precedence for legal entities residing within their borders). For example, the Foreign Corrupt Practices Act (see 15 USC 78) of the United States prohibits giving gifts (i.e., paying graft or bribes) by U.S. corporations even if such practice is legal and traditional in a country within which you are doing business. Similarly, if the Peoples Republic of China produces clones of hardware and software that violate intellectual property laws of other countries but which are not viewed by China as a punishable offense, using such a product to permit processing between the United States and China would doubtlessly be viewed by U.S. authorities as unacceptable.

206.5 The Long View

New technologies may make networks increasingly intelligent, capable of enforcing complex compliance rules, and allowing each enterprise to carefully craft the jurisdictions from which, through which, and into which its data will flow. North America, the European Community, Japan, and similar "information-age" countries will probably see these technologies in the near term but many nations will not have these capabilities for decades.

Most jurisdictions will acquire the ability to detect cryptographic messages and to process cleartext messages even before they acquire the networking technologies that would honor an enterprise's routing requests. The result may be a long period of risk for those organizations determined to send and to receive whatever data they deem necessary through whatever jurisdictions happen to provide the most expeditious routing.

206.6 Summary

Data daily flows from jurisdiction to jurisdiction, with most organizations unaware of the obligations they may incur. As nations become more sophisticated in detecting data traffic transiting their borders, organizations will face more effective enforcement of laws, treaties, and regulations ranging from privacy to state secrets, and from tax law to intellectual property rights. The risk of state-sponsored industrial espionage will also increase. Because organizations value the information transferred electronically, more and more organizations will turn to cryptography to protect their information. Cryptography, however, has both import and export implications in many jurisdictions worldwide. The technology required to intelligently control the routing of communications is increasingly available but will not solve the problems in the short term. Companies will need to exercise care when placing their data on open networks, the routings of which they cannot control.

207

An Emerging Information Security Minimum Standard of Due Care

Robert Braun

Stan Stahl

207.1 Introduction

The microcomputer revolution, and with it the rise of local area networks, wide area networks, and the Internet, is more than 20 years old. Interconnecting computers and networks has brought great gains in productivity and opened up exciting new realms of entertainment and information. And it has brought the world closer together. But these virtues are not without unintended, and sometimes undesired, consequences.

The Federal Trade Commission (FTC) estimates that approximately 3,000,000 Americans were the victims of identity theft in 2002, with the majority of these originating in thefts of information from computers or computer systems. At the same time, cyber-vandals write computer viruses that propagate from enterprise to enterprise at the speed with which untrained workers open attachments, causing significant economic loss while systems are being repaired. Electronic inboxes are clogged with spam. A Cyber-Mafia cruises the Internet, looking for easy prey from whom to steal money and other cyber-data of value. Dangerous adults too easily hang around children and teenage chat rooms, seeking to prey on legitimate users, often with tragic consequences. And the Department of Homeland Security warns of terrorists taking over large numbers of unsuspecting computer systems to be used in coordination with a large-scale terrorist attack.

Computer crime is a serious challenge. And it is getting worse … exponentially worse. Every computer crime study over the past five years conclusively confirms this. Computer crime is growing exponentially. The speed with which computer viruses spread and the number of security weaknesses in our systems are growing exponentially. Consequently, the total cost to business, in lost productivity, theft, embezzlement, and a host of other categories, is growing exponentially.

Against this backdrop are two legal questions:

1. What responsibility does an enterprise have for protecting the information in its computer systems, particularly information that belongs to others?
2. What responsibility does an enterprise have to keep its information systems from being used to harm others?

As answers to these two questions emerge, we believe they will define an evolving *information security minimum standard of due care* that will serve to establish, at any point in time, an *adequacy baseline* below which an enterprise will have criminal or civil liability. The specific details of any *information security minimum standard of due care* are likely to vary among the patchwork quilt of federal and state laws, industry-specific developments, interpretations by different regulatory agencies, and how the judicial system addresses these issues.

There are three co-evolving forces that will serve to define any evolving information security minimum standard of due care.

1. The evolving legislative and regulatory landscape regarding the duty of information holders to protect nonpublic information about others in their computer systems
2. The evolving interpretation of contract and tort law as it pertains to securing information and information assets
3. The evolving recommended effective security practices of the professional information security community

This chapter begins with an exposition of the privacy and safety issues addressed by legislation and subsequent regulations. It then explores the implications of contract and tort law on information security. Subsequently, this chapter explicates several current information security management practice models, which serve to define "effective security practices" in use by the information security profession. These are then brought together in the context of a *battle of the expert witnesses*, in which we identify what we believe is an *information security minimum standard of due care*. Finally, this chapter discusses how this standard is likely to evolve over the next few years.

207.2 Laws and Regulations Affecting Privacy in Computer Transactions

207.2.1 Gramm–Leach–Bliley (GLB)

> It is the policy of the Congress that each financial institution has an affirmative and continuing obligation to respect the privacy of its customers and to protect the security and confidentiality of those customers' nonpublic personal information.

> In furtherance of the policy … each agency or authority … shall establish appropriate standards for the financial institutions subject to their jurisdiction relating to administrative, technical, and physical safeguards
> (1) to insure the security and confidentiality of customer records and information;
> (2) to protect against any anticipated threats or hazards to the security or integrity of such records; and
> (3) to protect against unauthorized access to or use of such records or information which could result in substantial harm or inconvenience to any customer
>
> **—15USC6801, Gramm–Leach–Bliley Act**

With these words, Congress in 1999 passed the Gramm–Leach–Bliley Act (GLBA) (see also Exhibit 207.1). The GLBA regulates the use and disclosure of nonpublic personal information about individuals who obtain financial products or services from financial institutions.

The GLBA, on its face, applies only to financial institutions. However, the broad definitions in the GLBA mean that it applies not only to banks and other traditional financial institutions but also to a wide variety of firms and individuals that assist in effecting financial transactions. These include not only banks, credit unions, broker dealers, registered investment advisors, and other "obvious" financial institutions, but also mortgage lenders, "pay day" lenders, finance companies, mortgage brokers, account

EXHIBIT 207.1 The Gramm–Leach–Bliley Act (16CFR 314)

Federal Trade Commission
Standards for Safeguarding Customer Information
Sec. 314.3 Standards for safeguarding customer information.

(a) *Information security program.* You shall develop, implement, and maintain a comprehensive information security program that is written in one or more readily accessible parts and contains administrative, technical, and physical safeguards that are appropriate to your size and complexity, the nature and scope of your activities, and the sensitivity of any customer information at issue. Such safeguards shall include the elements set forth in Sec. 314.4 and shall be reasonably designed to achieve the objectives of this part, as set forth in paragraph (b) of this section.

(b) *Objectives.* The objectives of section 501(b) of the Act, and of this part, are to:
  (1) Insure the security and confidentiality of customer information;
  (2) Protect against any anticipated threats or hazards to the security or integrity of such information; and
  (3) Protect against unauthorized access to or use of such information that could result in substantial harm or inconvenience to any customer.

Sec. 314.4 Elements.
In order to develop, implement, and maintain your information security program, you shall:

(a) Designate an employee or employees to coordinate your information security program.

(b) Identify reasonably foreseeable internal and external risks to the security, confidentiality, and integrity of customer information that could result in the unauthorized disclosure, misuse, alteration, destruction or other compromise of such information, and assess the sufficiency of any safeguards in place to control these risks. At a minimum, such a risk assessment should include consideration of risks in each relevant area of your operations, including:
  (1) Employee training and management;
  (2) Information systems, including network and software design, as well as information processing, storage, transmission and disposal; and
  (3) Detecting, preventing and responding to attacks, intrusions, or other systems failures.

(c) Design and implement information safeguards to control the risks you identify through risk assessment, and regularly test or otherwise monitor the effectiveness of the safeguards' key controls, systems, and procedures.

(d) Oversee service providers, by:
  (1) Taking reasonable steps to select and retain service providers that are capable of maintaining appropriate safeguards for the customer information at issue; and
  (2) Requiring your service providers by contract to implement and maintain such safeguards.

(e) Evaluate and adjust your information security program in light of the results of the testing and monitoring required by paragraph (c) of this section; any material changes to your operations or business arrangements; or any other circumstances that you know or have reason to know may have a material impact on your information security program.

servicers, check cashers, wire transferors, travel agencies operated in connection with financial services, collection agencies, credit counselors and other financial advisors, tax preparation firms, non-federally insured credit unions, and investment advisors. The Federal Trade Commission has even held that the GLBA applies to lawyers that provide tax and financial planning services,[1] although that position has, predictably, been contested.

From the standpoint of maintaining the privacy of customer information, the GLBA generally prohibits a financial institution from disclosing non-personal public information to a non-affiliated third party, either directly or through an affiliate, unless the institution has disclosed to the customer in a clear and conspicuous manner, that the information may be disclosed to a third party; has given the consumer an opportunity to direct that the information not be disclosed; and described the manner in which the consumer can exercise the nondisclosure option.

Financial institutions must also prepare and make public *privacy statements* that describe the institution's policies with regard to disclosing non-public personal information to affiliates and non-affiliated third parties; disclosing non-public personal information of persons who have ceased to be customers of the institution; and the categories of non-public personal information the institution collects. The institution is required to disclose clearly and conspicuously those policies and practices at the time that it establishes a customer relationship and not less than annually during the continuation of the customer relationship. This has resulted in an avalanche of paper from banks, brokerage houses, accountants, and others who provide financial services.

In addition to regulating how financial institutions can intentionally share information, the GLBA also regulates what steps a business must take to prevent the unintentional sharing of non-public personal information in its computer systems. Each of the different federal and state agencies having GLBA jurisdiction has written separate information security safeguard regulations.[2] While no two are identical, all have a similar flavor:

- Executive management involvement
- Risk- and vulnerability-driven, based on regular assessments
- Written information security policies
- Employee training
- Control of third parties

There has also been a spill-over effect from regulation under the GLBA. The key regulator under the GLBA is the Federal Trade Commission, and its experience has spurred it to explore areas not directly implicated under the GLBA.[3] Additionally, many industries that are directly impacted by the GLBA, such as the banking and insurance industries, are beginning to apply the standards imposed on them to their clients. For example, insurance companies are beginning to review privacy statements and policies of their insureds, and banks are beginning to consider these issues in their underwriting decisions.

207.2.2 Health Care and Insurance Portability and Accountability Act (HIPAA)

One of the first significant attempts to adopt a standard of care for electronic transactions in the field of health care is the Health Care and Insurance Portability and Accountability Act of 1996 (HIPAA). While much of HIPAA addresses the rights of patients under the health-care insurance plans, HIPAA also

[1] In a letter the American Bar Association, dated April 8, 2002, J. Howard Beales, Director of the Federal Trade Commission Bureau of Consumer Protection, states that attorneys are not exempt from the application of the GLBA privacy rule.

[2] 66FedReg 8616, 12CFR 30 (Office of the Comptroller of the Currency); 12CFR 208, 211, 225, 263, (Board of Governors of the Federal Reserve System); 12CFR 308, 364 (Federal Deposit Insurance Corporation), 12CFR 568, 570 (Office of Thrift Supervision), 16CFR 314 (Federal Trade Commission); 17CFR 248 (Securities and Exchange Commission).

[3] See discussion of FTC Safeguards Rule, below.

includes key provisions relating to the privacy rights of patients in response to the concerns that this information was not being adequately protected. Insurance companies, doctors, hospitals, laboratories, and employers who maintain employee health plans are subject to HIPAA provisions.

The Department of Health and Human Services (DHHS) has issued *privacy rule* regulations providing for the protection of the privacy of "individually identifiable health information" created, received, or otherwise in the possession of entities covered by HIPAA.[4]

HIPAA information security regulations require covered entities to do the following to protect "individually identifiable health information."[5]

- Ensure the confidentiality, integrity, and availability of all electronic protected health information the covered entity creates, receives, maintains, or transmits.
- Protect against any reasonably anticipated threats or hazards to the security or integrity of such information.
- Protect against any reasonably anticipated uses or disclosures of such information that are not permitted or otherwise required.
- Ensure compliance by its workforce.

HIPAA is a broad-ranging act and has spawned significant regulation. Importantly, because it affects so many different entities, one can expect that the standards required by HIPAA will have a significant meaningful impact on non-health care-related industries.

207.2.3 Sarbanes–Oxley Act (SOX)

The Sarbanes–Oxley Act of 2002 (SOX) has been called the most significant new securities law since the Securities and Exchange Commission was created in 1934. SOX places substantial additional responsibilities on officers and directors of public companies, and imposes very significant criminal penalties on CEOs, CFOs, and others who violate the various provisions of SOX.

While the corporate scandals at HealthSouth, Adelphia, Qwest, Tyco, and of course, Enron, the mother of SOX, made headline news, the new requirements under SOX promise to transform the way that all public companies are managed from top to bottom. Even corporations that are not public today, but hope to become publicly owned or to be sold to a public company in the future, need to be aware of the basic requirements for operating a company in compliance with certain requirements of SOX, particularly the requirements for establishing and following detailed internal controls and disclosure of these controls and procedures. These requirements will obligate all public companies to address their information security procedures and practices in a very public way.

Section 404 of Sarbanes–Oxley requires the management of a public company to assess the effectiveness of the company's internal control over financial reporting. Section 404 also requires management to include in the company's annual report to shareholders, management's conclusion as a result of that assessment about whether the company's internal control is effective. While there are a variety of steps companies must take to comply with SOX, it is Section 404 that has the most relevance to information security with its requirement that management develop, document, test, and monitor its internal controls and its disclosure controls and procedures.

The most significant new responsibility faced by the CEO and CFO of every public company is the required personal certification of the company's annual and quarterly reports. The SEC has specified the exact form of personal certification that must be made, without modification, in every annual and quarterly report, including a certification that the CEO and CFO have evaluated the company's internal controls and disclosure controls within the past 90 days and disclosed to the audit committee and outside auditor any deficiencies in such controls. To meet the certification requirements regarding the internal

[4] 45CFR 160, 162, 164.

[5] 45CFR 162, Federal Register, Vol. 68, No. 34, 8377.

controls and disclosure controls, the SEC recommends that every company establish a disclosure committee consisting of the CFO, controller, heads of divisions, and other persons having significant responsibility for the company's principal operating divisions. The disclosure committee should review the company's existing internal controls and disclosure controls and procedures, document them, evaluate their adequacy, correct any material weaknesses, and create monitoring and testing procedures that will be used every quarter to continuously evaluate the company's internal controls and disclosure controls and procedures.

It will be critical for every company to involve its auditors in the design and implementation of the internal controls and disclosure controls and procedures because, beginning in July 2003, the SEC requires a public company's outside auditor to audit and report on the company's internal controls and procedures. The big four accounting firms have issued public advice that they will not be able to audit a company's internal controls without some documentation of the design and procedures, including the monitoring and testing procedures used by the company. This means that a company will need to establish detailed records, as well as reporting, testing, and monitoring procedures that must be reviewed by the company's outside auditors. If a company's outside auditor finds that there are significant deficiencies or material weaknesses in the company's internal controls, the auditor will be required to disclose its findings in its audit report on the company's financial statements. The company will then be forced to correct the deficiencies, or its CEO and CFO will be unable to issue their personal certifications that the internal controls are adequate.

While SOX was adopted in response to perceived inadequacies and misconduct by corporate officers and directors, its focus on systems, and certification of the adequacy of reporting schemes, is likely to have a broad effect on the establishment of corporate controls and standards. A variety of consultants, including accounting firms, software developers, and others, have developed and are actively marketing automated systems to assist in establishing a reporting regimen for corporations, allowing certifying officers and boards of directors to establish compliance with the requirements imposed by SOX and ensuring that corporate controls are followed. These changes, moreover, do not exist in a vacuum; principles of corporate governance that first applied to public corporations have often been extended to private companies, sometimes through application of state laws and regulations applied to non-public companies, other times through market forces, such as auditors and insurance carriers who adopt similar standards for public and non-public companies. According to the American Society of Certified Public Accountants, "Many of the reforms could be viewed as best practices and result in new regulations by federal and state agencies [affecting nonpublic companies]."[6]

207.2.4 Children's Online Privacy Protection Act (COPPA)

The Children's Online Privacy Protection Act (COPPA) became effective April 21, 2000, and applies to any online operator who collects personal information from children under 13. The rules adopted under COPPA spell out what a Web site operator must include in a privacy policy, when and how to seek verifiable consent from a parent, and what responsibilities an operator has to protect the children's privacy and safety online. Unlike HIPAA and GLB, COPPA is designed to address a class of individuals—minors—and not a regulated business. It thus has a scope that is in many ways broader, although in some ways less inclusive, than prior existing laws. In addition to creating challenges for the design of Web sites—for example, many Web operators have redesigned their Web sites to make them less appealing to children under 13—COPPA and the rules adopted implementing COPPA impose requirements on privacy notices and create specific procedures that must be followed before an operator can obtain information from children. COPPA has caused many businesses (and should spur all businesses) to consider their privacy policies, both in form and substance, and develop practice guidelines.

[6] Web site of Hood & Strong at http://www.hoodstrong.com/InStep/2002/NFP%20YREND02%20Articles.html.

207.2.5 FTC Safeguards Rule

As noted above, the Federal Trade Commission has been at the forefront of privacy regulations. In that role, the FTC has adopted a “safeguards rule” that requires each financial institution to:

> develop, implement, and maintain a comprehensive information security program that is written in one or more readily accessible parts and contains administrative, technical, and physical safeguards that are appropriate to your size and complexity, the nature and scope of your activities, and the sensitivity of any customer information at issue.[7]

The FTC regulation is a step that is likely to take us beyond existing laws. Under its authority to protect consumers, the FTC is in a position to adopt regulations that cross the boundaries of all industries. Significantly, it also requires each business to make determinations that are consistent with the size and complexity of its business and activities, as well as a sensitivity of customer information at issue. It does not provide specific rules but does require that businesses regulate themselves. Companies are thus forced to analyze their operations, needs, and vulnerabilities in order to comply with the rule.

207.2.6 FTC Unfair and Deceptive Practice

One of the key tools used by the FTC to address privacy violations has been the application of the FTC’s policy toward unfair and deceptive practices to online privacy practices. Under the FTC Act, the FTC is directed, among other things, to prevent unfair methods of competition, and unfair or deceptive acts or practices in or affecting commerce. The FTC has highlighted its intention to regulate online privacy as part of its privacy initiative:

> A key part of the Commission’s privacy program is making sure companies keep the promises they make to consumers about privacy and, in particular, the precautions they take to secure consumers’ personal information. To respond to consumers’ concerns about privacy, many Web sites post privacy policies that describe how consumers’ personal information is collected, used, shared, and secured. Indeed, almost all the top 100 commercial sites now post privacy policies. Using its authority under Section 5 of the FTC Act, which prohibits unfair or deceptive practices, the Commission has brought a number of cases to enforce the promises in privacy statements, including promises about the security of consumers’ personal information.[8]

In enforcing this power, the FTC has brought and settled charges relating to online privacy with Eli Lilly and Company (relating to sensitive information collected on its Prozac Web site); Microsoft Corp. (regarding the privacy and security of personal information collected from consumers through its “Passport” Web services); and Guess, Incorporated (relating to potential disclosure of credit card and other information).

207.2.7 State Actions

California has been at the forefront of protecting the privacy of online and electronic information. California has attempted to address these matters through laws regarding identity theft, privacy obligations of online merchants, and remedies for disclosure. As with the FTC approach toward enforcement of the Safeguards Rule and claims of deceptive practices, these efforts are directed toward all businesses; in other words, all businesses are directly impacted by California developments because they typically impact any entity that does business in California.

[7] 16CFR 314.

[8] FTC Web site at http://www.ftc.gov/privacy/privacyinitiatives/promises.html.

207.2.8 California Civil Code 1798.84 (SB 1386)

California Senate Bill 1386 became effective July 1, 2003. It is designed to give prompt notice when personal information has been released, and impacts all businesses that do business in California, as well as governmental and nonprofit agencies. Its application to a business does not require an office or significant presence in California; a single employee, a customer, or vendor located in California is enough to trigger the obligations under the law. The law requires these entities to notify their customers anytime they become aware of a breach of their security that involves the disclosure of unencrypted personal information.

The statute defines "personal information" as a person's first name or first initial and last name in combination with any one or more of the following elements, whether either the name or the elements are nonencrypted: (1) social security number; (2) driver's license or identification card number; or (3) account number, credit or debit card number, together with a code that permits access to a financial account. Thus, records with a name attached to any typical identifier can be considered personal information. It is important to know at the same time that the law does not define a financial account or access code, adding to the uncertainty of the law. Because of this, one cannot assume that the law applies to obvious targets, like credit cards and bank accounts. Electronic data interchange accounts, recordkeeping accounts (even if they do not provide for financial transactions), and other data bases are likely targets.

It should be noted that this law does not exist in a vacuum. The law is a reaction to the failure by the State of California's Teale Data Center to promptly notify an estimated 265,000 state employees whose personal data was exposed during a hacking incident in April 2002. The problem has not gone away: as recently as March 13, 2004, *The Los Angeles Times* reported that a malfunctioning Web site may have allowed the social security numbers, addresses, and other personal information of more than 2000 University of California applicants to be viewed by other students during the application process. The data displayed may have included names, phone numbers, birth dates, test scores, and e-mail addresses, in addition to social security numbers.

207.2.9 Senate Bill 27

In 2003, California adopted Senate Bill 27, which becomes operative on January 1, 2005. SB 27 allows consumers to discover how companies disseminate personal information for direct marketing purposes. It obligates companies to designate a mailing address, an e-mail address, or toll-free number or facsimile number at which it will receive requests. It also requires companies to train agents and employees to implement a Web site privacy policy and make information readily available to customers. It opens the possibility that companies could avoid reporting by adopting an "opt-in" policy for third-party disclosures, at the price of restricting the company's ability to engage in cross-marketing and similar opportunities.

It should be noted that, like the other California laws discussed here, this is a broad-ranging law. It covers all businesses and makes specific disclosure requirements. It also incorporates the opt-in concept, which has become a prevalent means by which regulators and legislators seek to allow consumers to control access to their personal and financial information.

207.2.10 Assembly Bill 68: Online Privacy Protection Act

Effective July 1, 2004, all operators of Web sites and other online services are required to implement privacy policies with specific provisions. Each privacy policy must:

- Identify the categories of personally identifiable information that the operator collects and the categories of third parties with which the operator might share that information.
- Describe the process by which an individual consumer may review and request changes to his or her information.

- Describe the process by which the operator notifies consumers who use or visit its commercial Web site or online service of material changes to the operator's privacy policy.
- Identify the effective date of the policy.

The law includes specific requirements regarding the location and prominence of the privacy policy; and businesses should be aware that by adopting a privacy policy, as required by Assembly Bill 68, they are making themselves subject to FTC regulation on this very matter.

207.2.11 Other State Actions

There have been several cases in which a company victimized by cyber-criminals has faced liability under a state's consumer protection statues.

207.2.11.1 Victoria's Secret

On October 21, 2003, New York State Attorney General Eliot Spitzer announced an agreement with Victoria's Secret to protect the privacy of its customers.[9] The agreement follows the discovery that personal information of Victoria's Secret customers was available through the company Web site, contrary to the company's published privacy policy.

Under the terms of the settlement, Victoria's Secret is to provide refunds or credits to all affected New York consumers, and is to pay $50,000 to the State of New York as costs and penalties. Also under the terms of the settlement, Victoria's Secret is required to:

- Establish and maintain an information security program to protect personal information.
- Establish management oversight and employee training programs.
- Hire an external auditor to annually monitor compliance with the security program.

In announcing the agreement, Spitzer said: "A business that obtains consumers' personal information has a legal duty to ensure that the use and handling of that data complies in all respects with representations made about the company's information security and privacy practices."

207.2.11.2 Ziff-Davis Media, Inc.

In November 2001, Ziff-Davis, a New York-based multimedia content company, ran a promotion on its Web site, receiving approximately 12,000 orders for one of its magazines. According to legal briefs, inadequate security controls left these orders—including credit card numbers and other personal information—exposed to anyone surfing the Internet with the result that at least five consumers experienced credit card fraud.

> Ziff-Davis, in its online security policy, made several representations concerning the privacy and security of information it collected from consumers, including the following:
> We use reasonable precautions to keep the personal information you disclose … secure and to only release this information to third parties we believe share our commitment to privacy.

The Attorney Generals of California, New York, and Vermont brought suit against Ziff-Davis, arguing that, in light of the above experience, this representation constituted an unfair or deceptive act. In an agreement reached between the parties, Ziff-Davis agreed to:

- Identify risks relating to the privacy, security, and integrity of consumer data.
- Address risks by means that include management oversight and training of personnel.

[9] Office of New York State Attorney General Eliot Spitzer, *Victoria's Secret Settles Privacy Case*, October 21, 2003.

- Monitor computer systems.
- Establish procedures to prevent and respond to attack, intrusion, unauthorized access, and other system failures.[10]

207.3 Contract and Tort Law

207.3.1 Specific Contractual Obligations Regarding Financial Transactions

The National Automated Clearing House Association (NACHA), along with both Visa and MasterCard, contractually impose information security requirements on their members.[11,12]

Visa's Cardholder Information Security Program (CISP) contractually imposes the following 12 basic security requirements with which all Visa payment system constituents must comply:

1. Install and maintain a working firewall to protect data.
2. Keep security patches up-to-date.
3. Protect stored data.
4. Encrypt data sent across public networks.
5. Use and regularly update anti-virus software.
6. Restrict access by "need to know."
7. Assign a unique ID to each person with computer access.
8. Do not use vendor-supplied defaults for passwords and security parameters.
9. Track all access to data by unique ID.
10. Regularly test security systems and processes.
11. Implement and maintain an information security policy.
12. Restrict physical access to data.

207.3.2 Breach of Contract

While there is, as yet, little case law in the area, it is possible, if not likely, that those harmed by a disclosure of sensitive information will seek redress through a breach of contract claim. An example would be a purchaser of technology or technology services, claiming an explicit or implicit warranty from security defects in the technology.

A second example concerns the unauthorized disclosure of information that could generate a contractual liability if it occurs contrary to a nondisclosure or confidentiality agreement.

Analogously, a statement in an organization's privacy policy could give rise to a contractual liability if it is not effectively enforced, as a potential plaintiff may seek to recast terms of use and privacy statements as a binding contract. As such, plaintiffs will analyze the sometimes "soft" statements made in privacy policies, and may bring breach of contract claims for failure to strictly follow the policy.

If a Web site operator, for example, states that it uses its "best efforts" to protect the identity of users, it may be brought to task for not taking every possible step to prevent disclosure, even if it uses reasonable efforts to do so. Consequently, every privacy statement and terms of use must be analyzed carefully and tailored to its exact circumstances lest it inadvertently subject a business to a contractually higher standard of care than intended.

207.3.3 Tort Law

Numerous legal models are emerging arguing that tort law can be used to establish liability in information security situations. We investigate two of these:

1. Negligence claims
2. Shareholder actions

207.3.3.1 Negligence Claims

Negligence is defined as the "failure to use such care as a reasonable prudent and careful person would use under similar circumstances."[13]

For a victim of a security breach to prevail in a negligence claim, the victim must establish four elements:

1. *Duty of care*. The defendant must have a legal duty of care to prevent security breaches.
2. *Breach of duty*. The defendant must have violated that duty by a failure to act "reasonably."
3. *Damage*. The plaintiff must have suffered actual harm.
4. *Proximate cause*: The breach of duty must be related to the harm closely enough to be either the direct cause of the harm or, if an indirect cause, then it must be (a) a substantial causative factor in the harm and (b) occur in an unbroken sequence linking to the harm.[14]

Beyond the obvious need to establish proximate cause, there are three challenges to a successful negligence claim: duty of care, economic loss doctrine, and shareholder actions.

207.3.3.2 Duty of Care

At the present time, there is uncertainty over whether or not a legal duty exists in the case of an information security breach, except in those circumstances where a clear legal obligation or contractual relationship exists that requires the securing of information. Thus, financial institutions and health-care providers have a clear duty of care, as do businesses possessing nonpublic personal information about California residents. However, as more and more businesses adopt privacy policies or are required to do so (under federal or state law or FTC prodding), a more generalized duty of care may emerge. Thus, even in those circumstances where there is no statutory duty of care, analogous duty of care situations suggest a duty of care may also exist for the securing of information assets.

In the case of *Kline v. 1500 Massachusetts Avenue Apartment Corp*, for example, the U.S. Court of Appeals for the District of Columbia Circuit ruled that a landlord has an obligation to take protective measures to ensure that his or her tenants are protected from foreseeable criminal acts in areas "peculiarly under the landlord's control." The plaintiff in this case had sought damages for injuries she sustained when an intruder attacked her in a common hallway of her apartment building. The court held that the landlord was in the best position to prevent crimes committed by third parties on his property. In remanding the case for a determination of damages, the court stated:

> "[I]n the fight against crime the police are not expected to do it all; every segment of society has obligation to aid in law enforcement and minimize the opportunities for crime."[15]

A similar argument would suggest that a business is in the best position to prevent cyber-crimes against its own computer systems, as these are "peculiarly under the business' control."

To the extent that the claim that business is in the best position to prevent cyber-crimes can be substantiated, it would raise the question of whether they legally "should" take the actions necessary to

[13] *Black's Law Dictionary*, 6th edition, 1032.

[14] *Black's Law Dictionary*, 6th edition, 1225.

[15] *Kline v. 1500 Massachusetts Avenue Apartment Corp.*, 439 F.2d 477, 482 (D.C. Cir. 1970); see also *Morton v. Kirkland*, 558 A.2d 693, 694 (D.C. 1989).

prevent such a crime. The issue is whether the cost of avoidance is small enough relative to the cost of an incident to warrant imposing a duty on the business to take steps to secure its information assets. This cost/benefit analysis follows from Judge Learned Hand's equation "B < PL" articulated in *United States v. Carroll Towing Co*, in which Hand wrote that a party is negligent if the cost (B) of taking adequate measures to prevent harm is less than the monetary loss (L) multiplied by the probability (P) of its occurring.[16] As Moore's law continues to drive down the cost of basic protection and as cyber-crime statistics continue to show exponential growth, Hand's equation is certain to be valid: the cost of protection is often two or more orders of magnitude less than the expected loss.

Breach of Duty. Equally uncertain, at the present time, is what constitutes "reasonable care." On the one hand, "reasonable care" is difficult to pin down precisely as the security needs and responsibilities of organizations differ widely.

On the other hand, two classic legal cases suggest that there is a standard of reasonable care applicable to the protection of information assets, even in circumstances where there is not yet a clear definition of exactly what that standard is. The first of these is the classic doctrine enunciated in *Texas & P.R v. Behymer* by Supreme Court Justice Holmes in 1903: "[w]hat usually is done may be evidence of what ought to be done, but what ought to be done is fixed by a standard of reasonable prudence, whether it usually is complied with or not."[17]

In the second case, *T. J. Hooper v. Northern Barge*, two barges towed by two tugboats sank in a storm. The barge owners sued the tugboat owners, claiming negligence noting that the tugboats did not have weather radios aboard. The tugboat owners countered by arguing that weather radios were not the industry norm. Judge Learned Hand found the tugboat owners liable for half the damages although the use of weather radios had not become standard industry practice, writing:

> Indeed in most cases reasonable prudence is in fact common prudence; but strictly it is never its measure; a whole calling may have unduly lagged in the adoption of new and available devices … Courts must in the end say what is required; there are precautions so imperative that even their universal disregard will not excuse their omission.[18]

Taken together, particularly in the context of the explosive growth in computer crime, these two statements can be interpreted to suggest that for a business to act "reasonably," it must take meaningful precautions to protect its critical information systems and the information contained in them.

207.3.3.3 Economic Loss Doctrine

Courts have traditionally denied plaintiffs recovery for damages if those damages are purely economic, as opposed to physical harm or damage to property. Because victims of information security breaches typically suffer only economic loss, the *economic loss doctrine* could present a challenge to a successful information security claim.

However, in recent decades, a number of courts have carved out exceptions to the economic loss doctrine. For example, the New Jersey Supreme Court in the case of *People Express Airlines v. Consolidated Rail Corp* awarded damages to People Express after the airline suffered economic loss as a result of having to suspend operations due to a chemical spill at the defendant's rail yard. In awarding damages to People Express, the court wrote:

> A defendant who has breached his duty of care to avoid the risk of economic injury to particularly foreseeable plaintiffs may be held liable for actual economic losses that are proximately caused by its breach of duty.

[16] *United States v Carroll Towing Co.*, 159 F.2d 169, 173–74 (2d Cir. 1947).

[17] *Texas & P.R v Behymer*, 189 U.S. 468, 470, 1903.

[18] *T.J. Hooper v Northern Barge*, 60 F.2d 737 2d Cir., 1932.

> We hold therefore that a defendant owes a duty of care to take reasonable measures to avoid the risk of causing economic damages, aside from physical injury, to particular … plaintiffs comprising an identifiable class with respect to whom defendant knows or has reason to know are likely to suffer such damages from its conduct.[19]

207.3.3.4 Shareholder Actions

Shareholders damaged by a drop in the value of a company resulting from the cost of a security breach may seek to sue management for failing to take steps to protect information assets. The nexus of new and developing standards derived from so many new sources—new state laws, federal securities laws, the PATRIOT Act, requirements of auditors and insurers—will have an impact of allowing potential plaintiffs to establish claims based on failure to comply with accepted standards.

Consider, for example, a public company doing business in California that was the subject of a hacker who obtained sensitive personal and financial information regarding clients. Upon discovery, the corporation was obligated, under California law, to publicize the security breach, thus giving shareholders notice of potential wrongdoing. Not surprisingly, the company's stock price was adversely impacted by the disclosure and subsequent negative publicity about the company. Upon further investigation (or perhaps with little or no investigation), a shareholder engaged a class action lawyer to pursue a claim against the company. The attorney couched the claim on the basis that the company had failed to apply broadly accepted security standards, resulting in damage to the company's shareholders.

If the company had, in fact, followed industry standards, it might be able to assert a defense—that it had not been negligent, and that its actions were in full compliance not only with applicable law, but with the standards imposed by regulatory agencies, auditors, insurers and its industry in general. The existence of standards could prove not only to be a sword, but a shield.

207.4 Effective Information Security Practices

At the same time as the legal risk associated with a failure to protect information assets is increasing, the professional information security community is developing a common body of Information Security Management Practice Models for use in effectively managing the security of information.

This section reviews three such models:

1. ISO 17799: Code of Practice for Information Security Management[20]
2. Generally Accepted Information Security Principles (GAISP), Version 3.0[21]
3. Information Security Governance: Guidance for Boards of Directors and Executive Management[22]

Each of these three documents deal at an abstract level with the question of standards for the protection of information assets. Their points of view are quite different, as is their pedigree. ISO 17799 originated in Australia and Great Britain before being adopted by the International Standards Association. GAISP is being developed by an international consortium under the leadership of the Information Systems Security Association, with the majority of participants coming from the United States. Both of these practice models were developed by information security practitioners, whereas

[19] People Express Airlines v. Consolidated Rail Corp., 495 A.2d. 107 (N.J. 1985).

[20] Information Technology—Code of Practice for Information Security Management, International Standards Organization, ISO 17799, 2000.

[21] *Generally-Accepted Information Security Principles* (GAISP), Version 3.0 (Draft), The Information Systems Security Association, 2004.

[22] Information Security Governance: Guidance for Boards of Directors and Executive Management, Information Systems Audit and Control Foundation, ISACA, 2001.

Guidance for Boards of Directors and Executive Management was developed by the Information Systems Audit and Control Association (ISACA).

Our objective in reviewing these three distinctly different practice models is to triangulate around a common set of activities that one could assert would be required for a business to demonstrate that it met a "reasonable" standard of care.

207.4.1 ISO 17799: Code of Practice for Information Security Management

ISO 17799 is an emerging international standard for managing information security. With roots in Australian information security standards and British Standard 7799, ISO 17799 is the first acknowledged worldwide standard to identify a "Code of Practice" for the management of information security.

ISO 17799 defines "information security" as encompassing the following three objectives:

1. *Confidentiality*: ensuring that information is accessible only to those authorized to have access
2. *Integrity*: safeguarding the accuracy and completeness of information and processing methods
3. *Availability*: ensuring that authorized users have access to information and associated assets when required

ISO 17799 identifies ten specific and vital Information Security Management Practices. An organization's information is secure only to the extent that these ten practices are being *systematically* managed. Weaknesses in any single practice can often negate the combined strength in the other nine. The ten Information Security Management Practices are:

1. Security policy
2. Organizational security
3. Asset classification and control
4. Personnel security
5. Physical and Environmental Security
6. Communications and operations management
7. Access control
8. Systems development and maintenance
9. Business continuity management
10. Compliance

207.4.2 Generally Accepted Information Security Principles (GAISP), Version 3.0

The GAISP is an ongoing project to collect and document information security principles that have been proven in practice and accepted by practitioners. The GAISP draws upon established security guidance and standards to create comprehensive, objective guidance for information security professionals, organizations, governments, and users. The use of existing, accepted documents and standards will ensure a high level of acceptance for the final GAISP product, and will enable a number of benefits to be achieved.

The GAISP:

- Promotes good information security practices at all levels of organizations
- Creates an increase in management confidence that information security is being assured in a consistent, measurable, and cost-efficient manner
- Is an authoritative source for opinions, practices, and principles for information owners, security practitioners, technology products, and IT systems
- Encourages broad awareness of information security requirements and precepts

- Enables organizations to seek improved cost structures and program management through use of proven practices and global principles rather than varied, local, or product-specific guidelines
- Is written hierarchically to allow application to any appropriate level of the organization or IT infrastructure, from the corporate board to the technical staff working "in the trenches"

The GAISP is organized around three levels of guiding principles that are applicable at varying levels of the organization:

1. *Pervasive principles*, which target organizational governance and executive management
2. *Broad functional principles*, guidelines to planning and execution of security tasks and to establishment of a solid security architecture
3. *Detailed principles*, written for information security professionals and which highlight specific activities to be addressed in day-to-day risk management

207.4.2.1 Pervasive Principles

The *pervasive principles* outline high-level recommendations to help organizations solidify an effective information security strategy, and include conceptual goals relating to accountability, ethics, integration, and assessment.

- *Accountability principle*. Information security accountability and responsibility must be clearly defined and acknowledged.
- *Assessment principle*. The risks to information and information systems should be assessed periodically.
- *Awareness principle*. All parties, including but not limited to information owners and information security practitioners with a need to know, should have access to applied or available principles, standards, conventions, or mechanisms for the security of information and information systems, and should be informed of applicable threats to the security of information.
- *Equity principle*. Management shall respect the rights and dignity of individuals when setting policy and when selecting, implementing, and enforcing security measures.
- *Ethics principle*. Information should be used, and the administration of information security should be executed, in an ethical manner.
- *Integration principle*. Principles, standards, conventions, and mechanisms for the security of information should be coordinated and integrated with each other and with the organization's policies and procedures to create and maintain security throughout an information system.
- *Multidisciplinary principle*. Principles, standards, conventions, and mechanisms for the security of information and information systems should address the considerations and viewpoints of all interested parties.
- *Proportionality principle*. Information security controls should be proportionate to the risks of modification, denial of use, or disclosure of the information.
- *Timeliness principle*. All accountable parties should act in a timely, coordinated manner to prevent or respond to breaches of and threats to the security of information and information systems.

207.4.2.2 Broad Functional Principles

The second level of the GAISP consists of *broad functional principles*, designed to be the building blocks of the *pervasive principles* and which more precisely define recommended tactics from a management perspective. These principles are designed as guidelines to planning and execution of security tasks and to establishment of a solid security architecture.

- *Information security policy*. Management will ensure that policy and supporting standards, baselines, procedures, and guidelines are developed and maintained to address all aspects of information security. Such guidance must assign responsibility, the level of discretion, and how much risk each individual or organizational entity is authorized to assume.
- *Education and awareness*. Management will communicate information security policy to all personnel and ensure that all are appropriately aware. Education will include standards, baselines, procedures, guidelines, responsibilities, related enforcement measures, and consequences of failure to comply.
- *Accountability*. Management will hold all parties accountable for their access to and use of information (e.g., additions, modifications, copying and deletions, and supporting information technology resources). It must be possible to affix the date, time, and responsibility, to the level of an individual, for all significant events.
- *Information asset management*. Management will routinely catalog and value information assets, and assign levels of sensitivity and criticality. Information, as an asset, must be uniquely identified and responsibility for it assigned.
- *Environmental management*. Management will consider and compensate for the risks inherent to the internal and external physical environment where information assets and supporting information technology resources and assets are stored, transmitted, or used.
- *Personnel qualifications*. Management will establish and verify the qualifications related to integrity, need-to-know, and technical competence of all parties provided access to information assets or supporting information technology resources.
- *Incident management*. Management will provide the capability to respond to and resolve information security incidents expeditiously and effectively in order to ensure that any business impact is minimized and that the likelihood of experiencing similar incidents is reduced.
- *Information systems life cycle*. Management will ensure that security is addressed at all stages of the system life cycle.
- *Access control*. Management will establish appropriate controls to balance access to information assets and supporting information technology resources against the risk.
- *Operational continuity and contingency planning*. Management will plan for and operate information technology in such a way as to preserve the continuity of organizational operations.
- *Information risk management*. Management will ensure that information security measures are appropriate to the value of the assets and the threats to which they are vulnerable.
- *Network and Internet security*. Management will consider the potential impact on the shared global infrastructure (e.g., the Internet, public switched networks, and other connected systems) when establishing network security measures.
- *Legal, regulatory, and contractual requirements of information security*. Management will take steps to be aware of and address all legal, regulatory, and contractual requirements pertaining to information assets.
- *Ethical practices*. Management will respect the rights and dignity of individuals when setting policy and when selecting, implementing, and enforcing security measures.

207.4.2.3 Detailed Principles

The third GAISP level consists of *detailed principles*, written for information security professionals and which highlight specific activities to be addressed in day-to-day risk management. The tactics in the *detailed principles* are step-by-step instructions necessary to achieve the appropriate tactical outcome from the broad principles and the conceptual goals of the *pervasive principles*.

EXHIBIT 207.2 Information Security Management Maturity Levels

Mgmt Maturity	Description
Level 0	Security management is nonexistent The organization does not manage the security of information assets
Level 1	Initial ad-hoc security management Security management is ad hoc and not organized; management responsibility is fragmented or nonexistent
Level 2	Repeatable but intuitive security management Basic security countermeasures and processes are implemented; management responsibility, authority, and accountability are assigned
Level 3	Defined process Security management flows from organizational strategy and from an organizationwide risk management policy; employees receive regular training and education
Level 4	Managed and measurable Security management is monitored and measured; regular feedback is used to assess and improve management effectiveness
Level 5	Security management is optimized Information security best practices are followed

207.4.3 Information Security Governance: Guidance for Boards of Directors and Executive Management

The Information Systems Audit and Control Association (ISACA) has developed a model for the overall "maturity" of an organization's security management. ISACA's model was built upon a software engineering management maturity framework that had been developed in the mid-to-late 1980s by the Software Engineering Institute, a national technology center at Carnegie Mellon University. The model "measures"—on a scale of 0 to 5—the extent to which information security is being formally and proactively managed throughout the organization.

The ISACA model provides an organization with a:

- Snapshot-in-time assessment tool, assisting the organization to identify the relative strengths of its information security management practices
- Tool for identifying an appropriate security management maturity level, to which the organization can evolve
- Method for identifying the gaps between its current security maturity level and its desired level
- Tool for planning and managing an organizationwide Information Security Management Improvement Program for systematically improving the organization's information security management capabilities
- Tool for planning and managing specific information security improvement projects

Note that each organization must determine what maturity level is appropriate for its specific circumstances.

Exhibit 207.2 provides a brief overview of each of the six Information Security Management Maturity levels.

207.5 Information Security Minimum Standards of Due Care: The Battle of the Expert Witnesses

Now consider what Einstein called a Gedanken experiment, a thought experiment. Imagine that company ABC suffers an information security incident resulting in damage to a third party, XYZ. Let us stipulate that ABC is not legally bound by the GLBA, has no printed privacy policy to which it must adhere, does not do business with California consumers, etc., and so has no *explicit duty of care* to protect. Let us also stipulate that XYZ's losses were not just economic. Finally, let us stipulate that ABC has at least 100 employees, 100 workstations, and several servers.[23]

In this situation, the case hinges on two points:

1. A point of law as to whether ABC has an implicit duty of care
2. A point of information security management as to whether the actions ABC took in protecting its information systems were *reasonable*

Let us now further stipulate that the plaintiff establishes that ABC has, indeed, a duty of care. The case now hinges on whether the actions ABC took in protecting its information systems were reasonable. Bring on the experts!

207.5.1 Hypothesis

The actions ABC took in protecting its information systems were reasonable if ABC can find an unimpeachable expert to testify that ABC's actions were reasonable. Correspondingly, XYZ will prevail if ABC's actions were so egregious that any attempt by ABC to present an expert testifying that ABC's actions were reasonable could be impeached by XYZ's attorneys.

In this context, an *unimpeachable* expert is someone with the following qualities:

- Experienced information security professional, respected by colleagues
- Either an information security certification, such as the CISSP designation, or some other credentials of expertise
- Active membership in an organization of information professionals, such as the Information Systems Security Association
- Expert in information security standards of practice, such as ISO 17799, the GAISP, and the ISACA guidelines
- Expert in the GLBA, HIPAA, and other information security standards

Imagine now that we have ABC's expert in the witness chair. She is an information security professional with all the qualities listed above. For this expert to testify that ABC's actions were reasonable, she would have to find evidence of the following six key information security management elements.

1. *Executive management responsibility.* Someone at the top has management responsibility for ABC's information security program, and this program is managed in accordance with its information security policies.
2. *Information security policies.* ABC has documented its management approach to security in a way that complies with its responsibilities and duties to protect information.
3. *User awareness training and education.* Users receive regular training and education in ABC's information security policies and their personal responsibilities for protecting information.
4. *Computer and network security.* ABC's IT staff is securely managing the technology infrastructure in a defined and documented manner that adheres to effective industry practices.
5. *Third-party information security assurance.* ABC shares information with third parties only when it is assured that the third party protects that information with at least the same standard of care as does ABC.
6. *Periodic independent assessment.* ABC has an independent assessment or review of its information security program, covering both technology and management, at least annually.

[23] Duty and reasonableness for a one-person home office would necessarily be different than for our hypothetical ABC. A software firewall, virus protection, regular patching, and the like may be all that a one-person home office need do.

These six management elements form a common core, either explicitly or implicitly, of all three Information Security Management Practice Models examined, as well as the GLBA and HIPAA regulatory standards for protecting information. Therefore, we feel confident in asserting that if ABC's unimpeachable expert can testify that ABC is doing these six things, then ABC's actions are reasonable. We are correspondingly confident that, if the expert is truly an unimpeachable information security professional, then, in the absence of these six elements, she would not testify for ABC that its actions were reasonable. Indeed, we think that, in this case, she would line up to testify on behalf of XYZ.

It is these six key information security management elements, therefore, that we believe form a Minimum Information Security Standard of Due Care.

207.6 Looking to the Future

As computer crime continues to rise, the legal and regulatory landscape will tilt toward more responsibility, not less.

The Corporate Governance Task Force of the National Cyber Security Partnership, a public-private partnership working with the Department of Homeland Security, has recently released a management framework and call to action to industry, nonprofits, and educational institutions, challenging them to integrate effective information security governance (ISG) programs into their corporate governance processes.[24]

Among the recommendations of this task force are:

- Organizations should adopt the information security governance framework described in the report and embed cyber-security into their corporate governance process.
- Organizations should signal their commitment to information security governance by stating on their Web sites that they intend to use the tools developed by the Corporate Governance Task Force to assess their performance and report the results to their board of directors.
- All organizations represented on the Corporate Governance Task Force should signal their commitment to information security governance by voluntarily posting a statement on their Web sites. In addition, TechNet, the Business Software Alliance, the Information Technology Association of America, the Chamber of Commerce, and other leading trade associations and membership organizations should encourage their members to embrace information security governance and post statements on their Web sites.
- The Department of Homeland Security should endorse the information security governance framework and core set of principles outlined in this report, and encourage the private sector to make cyber-security part of its corporate governance efforts.
- The Committee of Sponsoring Organizations of the Treadway Commission (COSO) should revise the Internal Controls-Integrated Framework so that it explicitly addresses information security governance.

According to Art Coviello, president and CEO at RSA Security, and co-chair of the Corporate Governance Task Force, "It is the fiduciary responsibility of senior management in organizations to take reasonable steps to secure their information systems. Information security is not just a technology issue, it is also a corporate governance issue."

Bill Conner, chairman, president, and CEO of Entrust, Inc., who co-chaired the Task Force with Coviello, is quoted as saying "We cannot solve our cyber-security challenges by delegating them to

[24] *Information Security Governance*: A Call to Action, Corporate Governance Task Force, National Cyber Security Partnership, April 2004.

government officials or CIOs. The best way to strengthen U.S. information security is to treat it as a corporate governance issue that requires the attention of boards and CEOs."[25]

Lest the private sector not step up to its responsibilities, the federal government is prepared to strengthen laws and regulations requiring the securing of information. As this is being written, Senator Dianne Feinstein (California) has introduced a bill extending California's "breach disclosure" law to all Americans. Congressman Adam Putnam (Florida), chairman of the House Technology, Information Policy, Intergovernmental Relations and the Census Subcommittee, has introduced legislation that would require every publicly held corporation in the United States to have an information security independent review and include a statement in the annual report that the review established compliance with SEC-mandated information security standards.

Also tilting the landscape toward a greater duty of reasonable care is that businesses, after taking their own security responsibilities seriously, are requiring the same of their trading partners. This will serve to accelerate the adoption of improved information security management that will then, in turn, accelerate the acceptance of the six key information security management elements as a Minimum Information Security Standard of Due Care.

As a result, it is safe to say that over the next few years, the Minimum Information Security Standard of Due Care will, if anything, get tougher—not easier. Thus, while one can expect technology to continue to aid in the battle for security, the need for management at the top, for policies, for training, and for the other key management elements will not go away.

208

ISPs and Accountability

Lee Imrey

208.1 Introduction

Internet service providers (ISPs) are a logical place to require service level agreements (SLAs) for mandated-level Quality-of-Service (QoS) and availability. ISPs and federal legislation should both support this initiative, for pragmatic reasons, as a business differentiator, and to support continued economic growth in electronic commerce. This chapter takes a roundabout course to support this proposition.

To begin this discussion, let us define some terms. While terms such as "Internet service provider (ISP)" are familiar to many people living in today's wired world, this discussion limits itself to a particular segment of service providers. Specifically, in the context of this chapter, the term "ISP" is used exclusively to represent those companies whose business involves providing Internet access to customers in return for financial compensation. These customers may include individuals, such as the market segment targeted by companies such as America Online and smaller local providers, small businesses, which may purchase ISDN, DSL, or Fractional T-1 connectivity, or multinational corporations that purchase multiple international connections, which support fail over Internet gateways for their extensive internal infrastructure. This distinction is made because the latter category is not considered an ISP, although an international entity may provide Internet access to tens of thousands of employees worldwide. An ISP is a company that derives a substantial portion of its revenue stream through the sale, provisioning, and support of Internet access to individual consumers and businesses.

Many ISPs provide service level agreements (SLAs) for business customers, in which they contractually agree to provide certain services. As part of the contract, these services are generally guaranteed to operate at or above a measurable level of service (i.e., speed and quality) for a minimum percentage of the time (i.e., 99.97%). Customers that require service availability for a higher percentage of time (such as "five-nines," or 99.999% of the time) may specify that in their SLA, but will be charged a correspondingly higher rate. In return, the ISPs will provide a guarantee of service, in which not meeting the agreed-upon terms will result in monetary compensation to the customer, up to and including the service cost. In some contracts, the penalty could theoretically exceed the total service cost, but compensation is frequently in the form of credited service. At this time, few ISPs offer compensation to customers in their SLAs for private individuals.

The last of the terms, Quality-of-Service (QoS) refers to the differentiation of service level based on the requirements of traffic. Generally QoS is promoted as enabling different types of traffic to coexist on a single packet-based network, with prioritization of packets associated with more delay-sensitive communications. For example, while a 60-second latency (delay in transmission) will have a negligible impact on the delivery of an e-mail, that same 60 seconds will cause a perceptible interruption in an audiovisual transmission. To draw an analogy to the real world, think about how disruptive a 15-second loss of signal is when one is using a cellular phone. Conversely, almost nobody will notice if a UPS shipment arrives five minutes behind schedule. That is because people have different expectations for the different types of traffic. QoS supports the programmatic distinction between these traffic types, at the hardware level, and allows us to utilize our network infrastructure for more services, with a lower risk of a poorly or maliciously configured device interfering with reliable connectivity.

208.2 Setting the Context

We live in a time of amazing progress, with access to resources that our parents and grandparents could only dream of. Who would have thought that it would be possible to sit at one's home or office desk and make travel arrangements for an international meeting? Today we can reserve and purchase tickets on an airline or a bullet train, travel hundreds of miles, and meet an associate for dinner reservations in another country the same day. Even more surprising, even if you forget to bring travelers checks, you can withdraw money from your own bank from an anonymous machine on a street corner and treat your associate to an after-dinner drink.

While many of us take such capabilities for granted, it can be illuminating to consider all the technologies that are at work "behind the scenes" to give us these opportunities. Principally, these technologies are telecommunication systems and information systems (computers). The computer systems present us with flight schedules, help us select appropriate travel options, reserve our tickets, check our credit, purchase our tickets, transfer funds to the booking and selling agents, communicate our reservation to the providers, and send us electronic receipts confirming our transactions.

These computer systems are generally owned, hosted, and operated by independent businesses, each with their own agenda, their own corporate goals, which they will meet as efficiently and cost-effectively as possible. These businesses may choose to run their systems on high-end servers, symmetrically processing our transactions at multiple processing centers distributed at remote geographic locations, on legacy mainframes, accessed through a Web-enabled GUI (graphical user interface) front end, or even on a refurbished desktop, running a proprietary server process on an open source OS (operating system).

With this in mind, the transparency with which these services interoperate is nothing short of incredible. Despite both device heterogeneity and the dynamic balance of business' competing self-interests, Internet-based transactions typically work effectively, if not always as rapidly as we might like.

208.3 Vulnerability of the System

Even Achilles had his heel.

It is sobering to note that all these systems have one thing in common, *regardless of the service being offered*. They all depend on a consistent and ubiquitous connection from a reliable Internet service provider (ISP).

Every transaction described above, without exception, requires the transfer of information between processes. Some processes internal to a business may be co-located on a single physical device or computer, although best practices place individual server processes on separate sets of redundant machines. Even so, in today's hyper-connected world, almost any transaction will rely on different services (e.g., financial services, booking services, service providers, etc.) provided by different organizations, each of which will host their own services.

Having purchased books, software, flowers, and airline tickets, having in fact made innumerable Internet transactions of one sort or another over the past year, this author can testify that it generally works pretty well. However, my successful experiences with online transactions are tempered by less-satisfying experiences in the past, and an awareness of a growing personal and societal dependence on systems that are less resilient than prudence requires. Although many of today's online services work, we have merely achieved functionality, not reliability. That is, we have demonstrated that we can accomplish a given task but we have not quantitatively demonstrated that we will be able to achieve the same task repeatedly, even under adverse circumstances.

As anyone who lives in a coastal city exposed to hurricane season can tell you, although there may not have been a recent major hurricane, a prudent person will still stock up on supplies before hurricane season arrives, in order to mitigate the impact, should one occur.

Similarly, we should apply a pragmatic perspective to recognizing, measuring, and mitigating the risks, both overt and latent, in our increasingly Internet-reliant economy and world. We need to achieve reliable services, not merely functional services. But how can we measure the risks in what is, after all, still a relatively young industry?

208.4 History as a Crystal Ball

One of the dominant truths of the pragmatist's world is this: past performance is the best indicator of future performance. To predict what might happen in the future of the Internet, we need to examine what has happened in the past. Past? What past?

Studying the past of a relatively recent phenomenon is fraught with difficulties. We discuss two that are particularly vexing. The first problem simply relates to the Internet's lack of tenure. It has not been around that long, and we are still seeing emergent properties of technologies that are changing faster than we are able to study them. That leads directly into the second problem. The dynamic nature of the Internet, one of its strengths and the source of much of its success, makes it difficult to apply the lessons of, say, the late 1980s to today's Internet, which is significantly different in character. For example, in the late 1980s, e-mail-borne macro viruses were not considered a significant risk, while today they dwarf the impact of any virus conceived of ten years ago.

To address this scarcity of data, it is useful to look for analogous systems and discover what insights they can provide to our current situation. One of the most common analogies to be drawn is the equating of the Internet to a heterogeneous biological population, such as a herd of cattle, a field of crops, or even a human population. Doing so allows us to apply the lessons learned in studying biology, epidemiology, and statistics to the electronic environments on which we increasingly depend.

Of course, there are differences that must be acknowledged. To begin with, the rate of change in the computing and networking environment is substantially faster than in the correlating biological environment. In addition, in nature, there are far fewer "hackers" independently modifying the genetic specifications of livestock to optimize characteristics according to their own agenda. That is not to say that this does not happen; but due to the training and equipment required, this capability is limited to a much smaller subset of the population.

Conversely, in the computing environment, there are skilled programmers developing tool-making-tools, which can be downloaded by rank amateurs and used to generate limitless varieties of malicious software. These include obvious examples such as the Virus Creation Labs, to dual-use goods, which can be used by benign programmers to create novel and useful programs, but can also be used by less-benign programmers for malicious purposes. One commonly used example is WordBasic, which has been used to create many e-mail-borne viruses.

Recognizing the limitations of applying other models to the information systems environment, we can still gain insights that we might otherwise miss. This chapter shares such insights with the reader, in a discussion of some notorious biological agents and their tragic impact on the people who have come into contact with them.

208.5 Biology

The consequences of interacting with unknown agents are unpredictable.

208.5.1 The Black Plague, or Vectors within Vectors

In the sixth century AD, a bacterium called *yersinia pestis* killed close to 50 percent of the populations of Europe, Africa, and Asia. The bubonic plague returned in the 1300s. Killing 50 million people by some estimates, it was known as Black Death, and is historically referred to as the Black Plague. Over 50 percent of those infected with the plague died a painful death. Victims were shunned, their corpses burned to prevent the spread of the infection.

The Black Plague is etched in our racial memory as an example of how vulnerable we are to certain microscopic contagions. These contagions overwhelm our defenses, spread relentlessly, and threaten everything we value. In the 14th century, the time of the most devastating outbreak, we did not understand how diseases affected us, or how they propagated.

Centuries before the development of germ theory, it was not conceivable that *yersinia pestis*, tiny organisms invisible to the naked eye, might infect fleas, which themselves would infest the *rattus rattus*, the black rat, or sewer rat, which spread with human commerce from population center to population center. Without understanding the threat, we were entirely unable to protect ourselves against it. The most damaging pandemic is estimated to have killed 25 percent of the human population of the time.

However, it is now largely under control. Although reservoirs of *yersinia pestis* continue to thrive in prairie dog populations in the southwestern United States, and can still hitch a ride into human population centers with the sewer rat, better health and vermin controls have severely limited the spread of this contagion.

We can see a parallel to early computer viruses. Early viruses infected individual computers, which would transmit the infection to a bootable floppy diskette. However, like the fleas, bootable floppy diskettes are not highly mobile. Instead, they would wait for another vector to transmit them to a new potential host, a sewer rat in the case of *yersinia pestis*, versus a system administrator or unknowing user for the computer virus. In both cases, control over the vector of transmission proved to be a very effective way to limit the spread of infection. *Yersinia pestis* primarily traveled city to city as a hitchhiker or a stowaway, infecting fleas that lived on rats that infested ships and wagons. Early computer viruses waited for a diskette to be placed in a drive, accessed by the computer system, and placed in an uninfected computer. The user then had to either reboot the infected computer from the floppy diskette or run an infected application. Breaking any of the links in this chain was enough to slow, if not stop, the spread of the infection, whether digital or biological.

208.5.2 *Ebola Zaire,* and the Person-to-person Vector

Unfortunately, both malicious software authors and nature have other effective strategies. For example, other infectious agents have recently been causing health professionals many sleepless nights. *Ebola Zaire*, a deadly strain of the *Ebola filovirus*, is one of the more well-known, having risen to fame in Richard Preston's excellent book, The Hot Zone. *Ebola Zaire* has a 90 percent mortality rate; is spread through the transfer of bodily fluids, including blood, saliva, and phlegm; and generally causes death within two to twenty-one days. This was demonstrated in a most tragic fashion during an outbreak in 1976 when 88 percent of the infected population of Yambuku, Zaire, died over a two-month period.

If one of these infected people had traveled to a more heavily populated area, particularly a commercially viable area, he could have exposed hundreds or even thousands of urban dwellers and commuters during his deteriorating stages. If each of the exposed parties had continued on with their travels, the virus could have spread like wildfire. It is reasonable to consider the implications if just one of these travelers had continued on to a major metropolitan hub such as London, Tokyo, or New York City. Had this happened, our world today would be considerably different from the one we live in. In fact, the countless minor inconveniences we suffer in the cause of preventing terrorists from crossing our borders would seem far less intrusive, even trivial, compared to the inconveniences we would suffer in trying to mitigating the threat of biological agents being smuggled across borders in unknowing travelers.

As you consider the implications, keep in mind that *Ebola Zaire* spread through the direct transfer of bodily fluids, rather than through a host hitching a ride on another host. This is a much shorter chain than *yersinia pestis*, which would have allowed for much more rapid propagation, as in the scenario described above. This may be seen as loosely analogous to the introduction of early e-mail viruses, which could spread directly from computer to computer. However, they still required a level of human intervention, in that the recipient had to double-click on an infected attachment.

208.5.3 *Ebola Reston* and Airborne Transmission

There were repeated outbreaks of *Ebola* more recently, in 1989 and 1990, when the filovirus was detected in lab animals in Virginia, Pennsylvania, and Texas. Eight people were exposed to the virus, some within a short commute of Washington, D.C. Fortunately, they neither died, nor were they at substantial risk. They were exposed to a different strain of *Ebola, Ebola Reston*, which, while fatal to some primates, is not fatal to humans. This was exceptionally lucky, due to the fact that *Ebola Reston* can spread through airborne particulate matter, making it much more difficult to contain.

Spreading through the air is particularly frightening, as it means that a person can be exposed merely through sharing the same environment as someone who is infected, whether a cafeteria, commuter station, airplane, or city bus. It also means that there is no need for direct contact. The vector of infection merely requires momentary exposure to a carrier. This is similar to recent computer worms, which spread from computer host to computer host without requiring human intervention of any sort. They exploit flaws in the operating systems or applications running on a computer. And due to the astounding success of the Internet, merely attaching a computer to an Ethernet connection, or dialing into an ISP, can expose that computer to every other computer in the world. It is analogous to a person being asked to sit in a waiting room at a hospital, together with every highly contagious patient in the world.

The Centers for Disease Control (CDC) in Atlanta is currently studying a variety of other frighteningly virulent pathogens. It is clear that, despite the success experienced in eradicating smallpox, there are numerous known pathogens as frightening as those discussed above, each with their own unique vector of transmission. And this does not even address unknown pathogens, whether naturally occurring or engineered as part of a biological weapons program.

208.6 Engineering Weapons in an Invisible Lab

> *Tiny digital weapons of mass destruction can fit in a laptop case. And while the authors can spend as much time as they like developing them, we have to defend against them in a matter of hours, if not minutes.*

The same principles that the CDC must consider when investigating biological threats must be applied to threats to our information systems.

In fact, computer pathogens are typically far more malicious than their counterparts in the biological world. While smallpox was extraordinarily deadly, it became deadly through an evolutionary process, not guided by a conscious mind. Computer pathogens are typically created by human agents and guided by the agent's agenda, whether benign or destructive. It is also far easier for a human agent to create electronic pathogens than biological agents. Biological agents require access to specialized equipment (which can be tracked and traced); access to a seed culture (thankfully, these are under stricter control today than in the past); and specialized training, which is not available outside select environments (i.e., schools and research labs).

The ideal laboratory for developing computer pathogens, on the other hand, looks just like the computer this author used to write this chapter. In fact, with virtual machine technology such as VMware, the same principles being applied with great success in creating virtual honey nets can be used to create a testing environment for virtual pathogens. Recognizing that the tools, the knowledge, the motive, and the opportunities exist for malicious parties to create malicious software, we should expect the problems imposed by malicious software to grow worse over time. And an examination of our limited recent history bears out this prediction.

208.6.1 The Future of Engineered Pathogens (of the Electronic Variety)

> *Going out on a digital limb, or armchair evolutionary theory*

What should one expect from these pathogens in the future? Let us return to the analogy with the biological world, and imagine the consequences of certain changes in the context of biological infections.

Hypothetically, imagine if the rats that carried the fleas that spread the plague were invisible. Even knowing that the sewer rat was indirectly responsible for the deaths of millions, it would be difficult to limit the spread of infection, without being able to isolate and control the vector of transmission.

What if the ticks that spread tick-borne encephalitis, another prominent pathogen, traveled at light speed? What chance would we have of removing the tick from our clothing, or bathing our dog in flea dip, if the tick acted so rapidly that our response mechanism would not be able to prevent infection?

Imagine if the infectious agent could jump species at will, or change its constellation of symptoms with every infection, to preclude timely diagnosis. Ebola Reston would have had significantly more impact if it had been pathogenic to human hosts as well as lower primates. And if the symptoms were different from person to person, how could it be diagnosed in time to initiate appropriate treatment, even if there were one?

In fact, imagine if the bacteria, virus, or toxin, did not require a host at all, but could transmit itself over telephone lines, maliciously calling at dinner, masquerading as a telemarketer. Now you have a situation similar to the computer viruses and worms infecting our networks today.

208.7 History Repeated

Are we seeing this type of evolution in the digital world? Are these concerns hyperbolic, or do they reflect a trend in the development of malicious software, if only in its early stages? To answer this question, take a look at a few of the more prominent computer pathogens of the past decade.

In the past ten years, there has been a revolution in the world of computer pathogens. There was Melissa, a virus named after an adult entertainer in Florida. This virus exploited weaknesses in the macro functionality of various Microsoft applications to spread to over 100,000 computers the weekend it was released “into the wild.” This was the first massively pervasive e-mail-borne macrovirus. This change is analogous to the change in vector of transmission seen in different strains of *Ebola*. While many previous viruses required the physical act of exchanging a floppy diskette, Melissa exploited popular software to spread more widely and more rapidly than any previous virus in history.

This was shortly followed by Love letter, in May of 2000, which introduced a new element of social engineering, exploiting our curiosity and our desire for affection, asking recipients of an e-mail to double-click on an icon called loveletter.txt.vbs. It was stunningly successful, infecting computers worldwide within hours of its release.

The following year, CodeRed and Nimda upped the bar by adding worm techniques for host-to-host propagation without human intervention. They infected over a quarter-million hosts, and almost half-a-million hosts, respectively, within a 12- to 48-hour time span.

More recently, in January of 2004, a worm called SQL Slammer achieved what might be called the Andy Warhol of virus propagation, saturating its target environment worldwide within approximately 15 min. SQL Slammer dropped social engineering tactics as superfluous to rapid propagation. By explicitly targeting server processes, in a similar fashion as the Internet Worm of 1988, the Slammer worm was able to spread around the world more rapidly than any previous pathogen, so fast, in fact, that at the height of infection, its own saturation of bandwidth was constraining its spread.

The evolution of malicious software continues with pathogens such as Bagel, Netsky, and MyDoom competing for news coverage as they compete for total number of compromised hosts. It is also suspected by many professionals that some of the more recent pathogens are being used to turn hosts into zombies—that is, computers that can be controlled remotely for malicious purposes, such as attacks on other computers, or the distribution of spam. With the lure of financial gain to spur the development of new malicious tools, it seems unlikely that this problem will go away anytime soon.

208.8 Enabling Environment

We have met the enemy … and he is us.[1]

Impossible as it seems, this situation will continue to get worse and worse, threatening the utility of the Internet, the usefulness of e-mail and similar technologies, and the continued growth of electronic commerce. While advances in technology have created a wonderful opportunity for the sharing of information, opened vast new markets for businesses previously limited by geography, and spawned the development of entirely new business models well-suited for the electronic marketplace, they have also created an environment ripe for exploitation by maliciously designed code.

In fact, two factors have come into play, that, when combined, create what is undoubtedly the largest laboratory environment for computer life ever conceived.

208.8.1 On Monocultures

When common strengths become common weaknesses

The first of these critical factors is the danger of software monoculture, eloquently brought into the public eye by Dan Geer in late 2003.[2] A software monoculture, much like a monoculture in the physical world, is an environment in which a significant proportion of entities, whether computers or living entities, shares characteristics, including propensities or vulnerabilities. An example of a monoculture in the physical world might be a tree farmer who only grows elm, or a chicken farmer who only raises a single breed of chicken. If either of these farmers' stock is exposed to a virulent infectious agent, say Dutch elm disease or Asian bird flu, their business will be in jeopardy. Clearly, that chicken farmer has all of his eggs in one basket.

More sobering cautionary tales can be found in recent history. A similar vulnerability devastated the Aztec nations in the early 16th century. When Spanish explorers came to the New World, they brought with them infectious agents, including smallpox, against which the Aztecs had no immunity. This ravaged the Aztec civilization, which assured the Spaniards of their victory. Smallpox was equally effective against the Incan population 20 years later.

The efficacy of this tactic was noted by an English general during the French–Indian war. By providing the native Americans with smallpox-infected blankets, the defense of a French–Indian fortress was decimated, allowing the English to take control.

208.9 Interesting, but How Does This Apply to ISPs?

In each of the examples discussed above, there were two factors at play in the vulnerability of populations to biological agents. In the case of the Aztecs, the Incas, and the native Americans, it was a homogenous environment, with a resulting widespread lack of immunity to a virulent pathogen. This is analogous to the monocultures discussed by Geer. If you posit a large population with a common vulnerability, then a pathogen that exploits that vulnerability, *and to which that population is exposed en masse*, will decimate the population.

208.9.1 Vectors

Viruses, worms, and data all travel on the same roads.

The overwhelming growth of the Internet has both initiated and grown hand-in-hand with enabling technologies of network-aware software, operating systems, and consumer-oriented hardware.

Businesses are recognizing significant economic benefits of electronic commerce. These include a vastly broader market for small businesses, reduced inventory costs derived from just-in-time warehousing strategies, and highly cost-effective, if morally questionable, e-mail marketing opportunities.

The commercial opportunities at stake have motivated companies to invest heavily in Internet-enabled services. This has, in turn, provided greater motivation for both consumers to participate in the business-to-consumer (B2C) online market, and for companies to migrate their business-to-business (B2B) connections to the public Internet. Previously, business partners utilized expensive electronic data transfer (EDT) connections between offices to transfer critical business information.

However, companies migrating to the electronic environment have tended to regard the Internet as if it were a utility, ubiquitous and reliable, which it is not. One of these facts has to change. Perhaps ISPs should provide and guarantee ubiquitous and reliable service to all their customers, just as other utilities are expected to do. In fact, in 2003, the Pakistani government directed the Pakistan Telecommunication Corporation to do just that, specifying a minimum 95 percent availability in local markets. Hopefully, this trend will continue. Otherwise, businesses and individual consumers will have to recognize the limitations of the Internet as the latest evolutionary stage in the privatization of a grand experimental laboratory, and take appropriate precautions in using the Internet for critical tasks. This may include seeking more reliable alternatives to using the public Internet.

208.9.2 The Internet as a Commons, and the Tragedy of the Commons

If Internet connectivity were like electricity, or the public water supply, anyone in a metropolitan area would have access to it, and it would be reliable from one location to another, and from one time to another. It would be like a city or state park, maintained by the government using public funds to provide an intangible benefit to all.

Or, in a more rural setting, maybe it would be like a common pasture shared by neighbors as a grazing pasture for livestock. This was the original concept of a *commons*, a shared resource supported by common contribution and available for common use. Unfortunately, reality often falls short of the ideal.

The problem with a commons is that without oversight or individualized accountability, the tendency of the individual is to abuse the privileges of the commons, on the grounds that it is in his own short-term best interest to do so. For example, in that rural setting, it would seem fair for the utility of the commons to be shared equally among the parties involved (i.e., everyone would bring the same number of sheep to the party, so to speak). However, from an individual's point of view, they would recognize a financial gain by bringing an extra animal, as the grazing rights would not incur an extra cost and they would thus have a competitive advantage over their fellow farmers.

However, in an emergent property of the commons, as soon as one farmer adds to his livestock, all the other farmers would do so as well to ensure that they got their fair share of the common grazing area. Unfortunately, as we take this to a logical extreme, rather than having a few farmers with a respectable number of sheep, we have those same farmers, each with significantly more sheep and each sheep malnourished.

208.10 Moderation and Oversight: Bringing Law to the Badlands

Because the environment of the Internet does not currently support individualized accountability, for reasons both technical and social, avoiding the tragedy of the commons on the Internet requires that some participant be charged with responsible oversight. This is particularly critical now that the Internet has gained greater acceptance as a legitimate environment for commercial enterprise, and an increasing number of confidential and critical transactions are taking place across this shared medium.

Just as amateur radio operators work within a set of legal constraints regarding the frequencies at which they are allowed to transmit and the power of their transmissions, so too must parties using the Internet treat it as a privilege rather than a right, and respect the needs of other parties to share the commons. Just as amateur radio operators operate under the oversight of the FCC (or local equivalent), so must ISPs be imbued with the responsibility to manage that portion of the Internet under their watch, and the authority to do so effectively.

208.10.1 Responsibility and Accountability

> *In the best of all possible worlds, participants will behave in an appropriate manner because it serves the common interest. However, we do not live in that world. To manage our limited resources, we need to encourage responsibility and provide accountability.*

Of course, if we regard the Internet as a true "commons," then there is no need for accountability. It is a resource shared among N billion users, who we can only hope will care for this fragile resource in a manner preserving its utility for the other N-1 consumers.

However, as Garrett Hardin, who coined the term "tragedy of the commons," observed in his article of the same name, it only takes a single participant in the commons who places his own self-interest above the common good to destroy the utility of the common resource to serve the common interest.[3]

Internet service providers are the logical place from which to manage the commons, as they are the provider of connectivity and bandwidth, for economical and marketing reasons, for legislative reasons, and for ethical reasons.

208.10.2 Marketing Differentiation

> *ISPs can sell better service. We are already seeing America Online and Earthlink marketing and promoting the security of their systems over those of their competitors.*

The first and foremost reason that ISPs are an appropriate place for responsibility to adhere is that most ISP business models are based on the ISP providing a service to consumers in return for a fixed monthly compensation.[4] Because the consumer is paying for a service, there is a reasonable expectation on the part of the consumer that such service will be provided on a reliable basis, with a standard of service either specified in an agreed-upon service level agreement (SLA), or meeting or exceeding a reasonable expectation of service, based on such service provided by competitors in the same geographical area, for a comparable price. That service should also be provided with a minimum of unforeseen interruptions.

Just as consumers who contract for electrical service have a reasonable expectation of having "always-on" electricity, provided they pay their bills, so too should Internet consumers be provided with the same level of service. While some providers will claim that providing that level of managed service would be more costly, or would impact the perceived performance of a connection, it is generally accepted that most consumers would sacrifice quantity-of-service for quality-of-service. For perspective, just imagine an electrical company trying to sell you service, but with frequent, unpredictable outages. Even if they

[3] "The Tragedy of the Commons," by Garrett Hardin. *The Concise Encyclopedia of Economics*. http://www.econlib.org/library/Enc/TragedyoftheCommons.html.

[4] In some cases, the cost of Internet service may be determined by utilization, particularly in limited bandwidth models, such as cellular phones or other wireless devices.

offered to provide higher voltage than their competitor, or a bigger transformer, most consumers' needs will focus more on the reliability of service.

208.10.3 The Legislative Angle

It will be cost-effective for ISPs to begin to integrate appropriate controls into their services now, in a managed fashion, rather than to wait for legislative requirements to force their hands.

Another aspect of the market that might impact the ISP's need to provide guaranteed quality-of-service is the increasing movement of supervisory control and data acquisition (SCADA) systems to the public network. Private corporations are migrating control systems to the Internet for economic reasons; but as increasingly critical systems are subject to increasingly critical failures, we may see legislative requirements being levied on either the ISPs or the corporations migrating systems to the Internet. In the former case, the ISPs may not have a choice, so they might consider trying to achieve compliance with minimum standards in advance of legislation. In the latter case, the ISPs might lose business if they are unable to guarantee adequate service levels, so the same logic applies. Provide a minimum standard of service to ensure that customers are able to utilize the Internet reliably.

208.11 A Service Level Agreement (SLA) for ISPs

To meet the requirements of our market, today and in the future, what controls do ISPs need to embrace?

There are numerous technical controls that ISPs have available, but ISPs have not considered it uniformly cost-effective to place expensive controls on Internet service in advance of explicit customer demand, particularly as those controls generally introduce an overhead requirement. This results in reduced throughput, or colloquially, slows everything down.

However, in every discussion of the issue in which this author has been involved, which customers originally want a faster connection, when presented with the choice between an extremely fast connection with no guarantee of reliability, versus a slightly slower connection with contractually explicit minimum uptime, all customers firmly state a preference for a slower, managed connection with guaranteed uptime. Most customers do not really need a connection "48 times faster than dial-up." They are happier with a connection "24 times faster than dial-up," provided that it is reliable. "The customers have spoken. Now it is time for ISPs to answer customer demand, in advance of legislative requirements if possible, in response to those requirements if necessary."

Some of the basic techniques that might be required include egress filtering, anti-virus and spam filtering, and network-based intrusion detection and prevention technology.

208.11.1 Egress Filtering

The first of these, egress filtering is an exceptionally easy-to-implement control, with a high return on investment for the commons. Egress filtering places limits on outgoing traffic so that only communications appearing to come from legitimate addresses would be allowed to access the Internet. For example, if an ISP has licensed a specific Class B (or Class A, or Class C, or any CIDR subnet) to a school or a business, utilize the controls available on the customer premises equipment (CPE) to drop any traffic trying to get to the Internet with an inappropriate source address (i.e., one not licensed by the school or business). If it does not have a valid source address, there will be no return traffic, so the end user will not notice. And it will have a huge impact on reducing spam and distributed denial-of-service (DDoS) attacks, which frequently use spoofed source IP addresses. And those spammers and DDoS attacks that use valid source IP addresses will be easier to trace.

208.11.2 Anti-virus and Spam Filters

Viruses and spam threaten the utility of the Internet. That threatens the market of the ISP. It is a wise business decision to protect your customers, as they are your future revenue.

Inspect all e-mail traversing the network for malicious content, including viruses, worms, and spam, using anti-virus and spam scanners from at least two vendors, in serial. It will have a performance impact and incur additional expense, but that expense will be amortized over the increased subscriptions from customers who are tired of the excessive spam and viruses they receive. If backed up with independent metrics from an objective source, the decrease in spam and viruses could be used as a marketing differentiator. In addition, dropping that traffic "at the edge" could reduce demand on core networking devices.

208.11.3 Intrusion Detection and Prevention Systems (IDS/IPS)

Consumers do not have the ability to detect, analyze, and mitigate or otherwise respond to threats on an ongoing basis. That is why we have lifeguards at the beach.

The same principle applies to the installation of managed IDSs and IPSs on edge devices, such as those systems connected to customer-premises equipment. Perhaps it will become analogous to the line conditioners that electric companies place on incoming electrical jacks, which prevent transient current on the line from damaging the electrical equipment in a customer's home or business. IDSs and IPSs would help prevent "transient Internet traffic" from damaging or otherwise compromising network-enabled equipment on customer premises.

208.12 ISPs Have the Capability, While the Typical Consumer Does Not

Smoke 'em if you got em?' Asking consumers to handle these processes on their own is as inappropriate as asking an airline passenger to check the oil or change a tire on a Boeing 757.

Why should ISPs be required to provide these services? For the same reason that electric companies are required to provide safe and managed service to their customers. Installing, configuring, maintaining, and updating each of the systems described earlier requires specialized skill sets. While many readers may be perfectly comfortable compiling and configuring these and similar services on a Open BSD or Linux platform in their spare time, this is beyond the capability of the average user. In fact, trying to configure such systems without the appropriate expertise may give customers a false sense of security, and even be more dangerous than not having such systems at all. At least in that case, customers are likely to be aware of their vulnerability. To preserve the utility of the Internet for all of its users, we must address the vulnerabilities for which we have the appropriate expertise and capabilities.

208.12.1 Information Resources

Typically, ISPs will have a greater ability to manage information relating to changing security environments and the internal resources to understand the impact of new information. That can and should be up sold as a service to the consumer, rather than expecting the consumer to learn the technologies themselves.

208.12.2 Control Point

Providing the downstream connection point to the customer, ISPs are automatically the bottleneck between the customer and the Internet. ISPs can use that bottleneck to its highest potential by applying appropriate controls, just as airport security applies control points at the entrance to the terminals as well as to the actual aircraft.

208.12.3 Timely Response Mechanism

ISPs have a high enough investment in the service they provide to make a timely response mechanism cost-effective. The average consumer does not have a similar response mechanism in place. However, to legitimately call their response mechanism "timely," ISPs must be sure to invest sufficiently in development and training of personnel and programs.

208.12.4 Point of Failure

As a single point of failure for customers, an ISP will presumably have already invested in sufficient and appropriate redundancy of equipment and staff to minimize downtime. This can be leveraged into a competitive advantage by marketing the security mechanisms and promoting the ISP as a business-enabling function. Rather than marketing speed of connection, tomorrow's marketing should focus on reliability of connection. Uptime will become as critical to the home market as it is to the business market.

208.12.5 Enabling

Today's customers regard Internet access as ubiquitous, and fail to distinguish between service levels offered by providers. By touting the enabling features of the service, ISPs should be able to sell their accountability and security controls as business-enabling features and more than offset any loss in throughput.

208.13 Cons

Where is the downside?

Of course, investing in services before there is an explicit (and informed) customer demand is not without risk. For example, if an ISP claims to guarantee a certain service level, who will monitor compliance? And who will pay for that service?

208.13.1 Who Will Monitor Compliance?

Monitoring the service level of ISPs can be approached in one of two ways. An independent organization can be charged with that task, much like the Underwriter's Laboratory is now charged with testing of certain appliances. This organization could be privately managed or federally sponsored.

Alternately, software tools could be developed and provided to customers who want to install it. It would provide the customer with real-time feedback of network performance, but would also periodically update a centralized "auditing" service that would compile the results and ensure that the provider is meeting the designated service level agreement.

208.13.2 Who Will Pay for Service?

If it is an independent organization, it could be funded through membership fees paid by ISPs (whether voluntary or legislated). Alternately, if the market leans toward the utility model, the organization could be federally funded.

On the other hand, if the software monitoring approach is chosen, the expense would be rather negligible. In fact, one of the many private ventures providing reporting on broadband providers would likely be happy to host and maintain a reporting server.

208.13.3 Additional Fee for ISP Service?

If necessary, ISPs could even offer "enhanced service" for a premium price, which this author suspects many consumers would pay. However, once the infrastructure for providing such enhanced service is there, it would likely be at least as cost-effective to provide that service to all customers and use it as a competitive advantage over competitors.

208.14 Pros

What is in it for the ISP?

Of course, there are substantial benefits for the ISPs that implement effective security and quality-of-service controls, including more effective control over resources, more consistent service, the ability to minimize inappropriate activity, and potentially reduced liability.

208.14.1 Oversight Will Provide Greater Consistency of Service

An ISP that implements and maintains effective controls will limit the amount of inappropriate traffic that traverses its network. By reducing traffic that violates the ISP's usage policy, more of the bandwidth will be available for legitimate traffic, helping the ISP meet its service level agreement.

208.14.2 Easier to Track Transgressors

In addition to providing greater consistency of service, appropriate controls will limit the effectiveness of denial-of-service attacks, and help the ISP (as well as law enforcement, in some cases) track down transgressors and take reasonable steps to prevent future transgressions.

208.14.3 Liability

In the event that a current subscriber tries to conduct a DDoS attack on a business or an individual, these controls may prevent or at least mitigate the attack, and will also help track down the attacker and stop the attack.

In the event the attack is successful, or at least partially successful, having tried to prevent it may help the ISP demonstrate that the ISP was not negligent, and may prevent claims of downstream liability.

Applying controls proactively to prevent the misuse and abuse of network resources will go a long way toward establishing due care.

208.15 The Future of Legislative Controls

Simply put, legislative controls are in the future. ISPs are in an increasingly critical position in our society as more and more of our citizens, our businesses, and our lives "go online." This author believes that legislative controls are inevitable, but now is the time when ISPs can proactively influence the tone of future legislation. By demonstrating a focused effort to provide a reasonable quality-of-service for a reasonable price, ISPs will serve the consumer and protect their future business from overly onerous legislation.

208.16 Conclusion

ISPs are in a unique position, exercising custodial control over an increasingly critical resource in the industrialized world. They have been providing it in the capacity of a gatekeeper, with the level of control they exercise being akin to a ticket-taker at an access point. But as more users and businesses grow to depend on the resources offered online, effective, reliable, and consistent access becomes more critical, both economically, socially, and, potentially, legally.

Today, ISPs have the opportunity to provide a higher quality-of-service to their consumers. This does not mean they have to offer a constrained interface like America Online, Prodigy, or CompuServe. They can offer IP connectivity, but by utilizing technical controls to enforce their own Internet usage policy, they will be able to provide faster, more consistent, and more reliable service to their legitimate users.

There is also a window of opportunity here for early adopters. It is likely that the first ISPs to provide service level agreements for their subscribers, together with effective and measurable quality-of-service controls, will enjoy a significant market advantage over less-proactive ISPs. If they are able to offer these services at a comparable price, they will likely win a substantial number of crossover customers who have been unhappy with the spotty and unreliable service they have been receiving.

To support the growing online user community, to help ensure the continued growth of electronic commerce, and to make a reasonable profit along the way, ISPs should take an aggressive approach toward developing, rolling out, and marketing SLA-supported Quality-of-Service controls, in conjunction with more proactive inter- and intra-network security controls. It will provide a better experience for the consumer, better protection of the Commons, which will benefit society as a whole, and a better long-term revenue stream for the ISPs that take on this challenge.

209
The Case for Privacy

Michael J. Corby

> Any revelation of a secret happens by the mistake of [someone] who shared it in confidence.
>
> **—La Bruyere, 1645–1694**

It is probably safe to say that since the beginning of communication, back in prehistoric times, there were things that were to be kept private. From the location of the best fishing to the secret passage into the cave next door, certain facts were reserved only for a few knowledgeable friends. Maybe even these facts were so private that there was only one person in the world who knew them. We have made "societal rules" around a variety of things that we want to keep private or share only among a few, but still the concept of privacy expectations comes with our unwritten social code. And wherever there has been the code of privacy, there has been the concern over its violation. Have computers brought this on? Certainly not! Maintaining privacy has been important and even more important have been the methods used to try to keep that data a secret. Today in our wired society, however, we still face the same primary threat to privacy that has existed for centuries: mistakes and carelessness of the individuals who have been entrusted to preserve privacy—maybe even the "owner" of the data.

In the past few years, and heightened within the past few months, we have become more in tune to the cry—no, the public *outcry*—regarding the "loss of privacy" that has been forced upon us because of the information age. Resolving this thorny problem requires that we re-look at the way we design and operate our networked systems, and most importantly, that we re-think the way we allocate control to the rightful owners of the information which we communicate and store. Finally, we need to be careful about how we view the data that we provide and for which we are custodians.

209.1 Privacy and Control

The fact that data is being sent, printed, recorded, and shared is not the real concern of privacy. The real concern is that some data has been implied, by social judgment, to be private, for sharing only by and with the approval of its owner. If a bank balance is U.S.$1240, that is an interesting fact. If it happens to be my account, that is private information. I have, by virtue of my agreement with the bank, given them the right to keep track of my balance and to provide it *to me* for the purpose of keeping me informed and maintaining a control point with which I can judge their accuracy. I did not give them permission to share that balance with other people indiscriminately, nor did I give them permission to use that balance even subtly to communicate my standing in relation to others (i.e., publish a list of account holders sorted by balance).

The focal points of the issue of privacy are twofold:

1. How is the data classified as private?
2. What can be done to preserve the owner's (my) expectations of privacy?

Neither of these are significantly more challenging than, for example, sending digital pictures and sound over a telephone line. Why has this subject caused such a stir in the technology community? This chapter sheds some light on this issue and then comes up with an organized approach to resolve the procedural challenges of maintaining data privacy.

209.2 Rudiments of Privacy

One place to start examining this issue is with a key subset of the first point on classifying data as private: what, exactly, is the data we are talking about? Start with the obvious: private data includes those facts that I can recognize as belonging to me, and for which I have decided reveal more about myself or my behavior than I would care to reveal. This includes three types of data loosely included in the privacy concerns of information technology (IT). These three types of data shown in Exhibit 209.1 are: static, dynamic, and derived data.

209.2.1 Static Data

Static data is pretty easy to describe. It kind of sits there in front of us. It does not move. It does not change (very often). Information that describes who we are, significant property identifiers, and other tangible elements is generally static. This information can of course take any form. It can be entered into a computer by a keyboard; it can be handwritten on a piece of paper or on a form; it can be photographed or created as a result of using a biological interface such as a fingerprint pad, retina scanner, voice or facial image recorder, or pretty much any way that information can be retained. It does not need to describe an animate object. It can also identify something we have. Account numbers, birth certificates, passport

EXHIBIT 209.1 Types of Private Data

1. Static data:
   - a. Who we are:
     - i. Bio-identity (fingerprints, race, gender, height, weight)
     - ii. Financial identity (bank accounts, credit card numbers)
     - iii. Legal identity (Social Security number, driver's license, birth certificate, passport)
     - iv. Social identity (church, auto clubs, ethnicity)
   - b. What we have:
     - i. Property (buildings, automobiles, boats, etc.)
     - ii. Non-real property (insurance policies, employee agreements)
2. Dynamic data:
   - a. Transactions (financial, travel, activities)
   - b. How we live (restaurants, sporting events)
   - c. Where we are (toll cards, cell phone records)
3. Derived data:
   - a. Financial behavior (market analysis):
     - i. Trends and changes (month-to-month variance against baseline)
     - ii. Perceived response to new offerings (match with experience)
   - b. Social behavior (profiling):
     - i. Behavior statistics (drug use, violations or law, family traits)

numbers, and employee numbers are all concepts that can be recorded and would generally be considered static data.

In most instances, we get to control the initial creation of static data. Because we are the one identifying ourselves by name, account number, address, driver's license number, or by speaking into a voice recorder or having our retina or face scanned or photographed, we usually will know when a new record is being made of our static data. As we will see later, we need to be concerned about the privacy of this data under three conditions: when we participate in its creation, when it is copied from its original form to a duplicate form, and when it is covertly created (created without our knowledge) such as in secretly recorded conversations or hidden cameras.

209.2.2 Dynamic Data

Dynamic data is also easy to identify and describe, but somewhat more difficult to control. Records of transactions we initiate constitute the bulk of dynamic data. It is usually being created much more frequently than static data. Every charge card transaction, telephone call, and bank transaction adds to the collection of dynamic data. Even when we drive on toll roads or watch television programs, information can be recorded without our doing anything special. These types of transactions are more difficult for us to control. We may know that a computerized recording of the event is being made, but we often do not know what that information contains, nor if it contains more information than we suspect. Take, for example, purchasing a pair of shoes. You walk into a shoe store, try on various styles and sizes, make your selection, pay for the shoes, and walk out with your purchase in hand. You may have the copy of your charge card transaction, and you know that somewhere in the store's data files, one pair of shoes has been removed from their inventory and the price you just paid has been added to their cash balance. But what else might have been recorded? Did the sales clerk, for example, record your approximate age or ethnic or racial profile, or make a judgment as to your income level. Did you have children with you? Were you wearing a wedding band? What other general observations were made about you when the shoes were purchased? These items are of great importance in helping the shoe store replenish its supply of shoes, determining if they have attracted the type of customer they intended to attract and analyzing whether they are, in general, serving a growing or shrinking segment of the population. Without even knowing it, some information that you may consider private may have been used *without your knowledge* simply by the act of buying a new pair of shoes.

209.2.3 Derived Data

Finally, derived data is created by analyzing groups of dynamic transactions over time to build a profile of your behavior. Your standard way of living out your day, week, and month may be known by others even better than you may know it yourself. For example, you may, without even planning it, have dinner at a restaurant 22 Thursdays during the year. The other six days of the week, you may only dine out eight times in total. If you and others in your area fall into a given pattern, the restaurant community may begin to offer "specials" on Tuesday, or raise their prices slightly on Thursdays to accommodate the increased demand. In this case, your behavior is being recorded and used by your transaction partners in ways you do not even know or approve of. If you use an electronic toll recorder, as has become popular in many U.S. states, do you know if they are also computing the time it took to enter and exit the highway, and consequently your average speed? Most often, this derived data is being collected without even a hint to us, and certainly without our expressed permission.

209.3 Preserving Privacy

One place to start examining this issue is with a key subset of the first point on classifying data as private: what, exactly, is the data we are talking about? Start with the obvious: private data includes those items that we believe belong to us exclusively and it is not necessary for us to receive the product or service we wish to receive. To examine privacy in the context of computer technology today, we need to examine the following four questions:

1. Who owns the private data?
2. Who is responsible for security and accuracy?
3. Who decides how it can be used?
4. Does the owner need to be told when it is used or compromised?

> You already have zero privacy. Get over it.
>
> **—Scott McNealy, Chairman,**
> **Sun Microsystems, 1999**

Start with the first question about ownership. Cyber-consumers love to get offers tailored to them. Over 63 percent of the buying public in the United States bought from direct mail in 1998. Companies invest heavily in personalizing their marketing approach because it works. So what makes it so successful? By allowing the seller to know some pretty personal data about your preferences, a trust relationship is implied. (Remember that word "trust"; it will surface later.) The "real deal" is this: vendors do not know about your interests because they are your friend and want to make you happy. They want to take your trust and put together something private that will result in their product winding up in your home or office. Plain and simple: economics. And what does this cost them? If they have their way, practically nothing. You have given up your own private information that they have used to exploit your buying habits or personal preferences. Once you give up ownership, you have let the cat out of the bag. Now they have the opportunity to do whatever they want with it.

"Are there any controls?" That brings us to the second question. The most basic control is to ask you clearly whether you want to give up something you own. That design method of having you "opt in" to their data collection gives you the opportunity to look further into their privacy protection methods, a stated or implied process for sharing (or not sharing) your information with other organizations and how your private information is to be removed. By simply adding this verification of your agreement, 85 percent of surveyed consumers would approve of having their profile used for marketing. Not that they ask, but they will be responsible for protecting your privacy. You must do some work to verify that they can keep their promise, but at least you know they have accepted some responsibility (their privacy policy should tell you how much). Their very mission will ensure accuracy. No product vendor wants to build its sales campaign on inaccurate data—at least not a second time.

Who decides use? If done right, both you and the marketer can decide based on the policy. If you are not sure if they are going to misuse their data, you can test them. Use a nickname, or some identifying initial to track where your profile is being used. I once tested an online information service by using my full middle name instead of an initial. Lo and behold, I discovered that my "new" name ended up on over 30 different mailing lists, and it took me several months to be removed from most of them. Some still are using my name, despite my repeated attempts to stop the vendors from doing so. Your method for deciding who to trust (there is that word again) depends on your preferences and the genre of services and products you are interested in buying. Vendors also tend to reflect the preferences of their customers. Those who sell cheap, ultra-low-cost commodities have a different approach than those who sell big-ticket luxuries to a well-educated executive clientele. Be aware and recognize the risks. Special privacy concerns have been raised in three areas: data on children, medical information, and financial information (including credit/debit cards). Be especially aware if these categories of data are collected and hold the collector to a more stringent set of protection standards. You, the public, are the judge.

If your data is compromised, it is doubtful that the collector will know. This situation is unfortunate. Even if it is known, it could cost them their business. Now the question of ethics comes into play. I actually know of a company that had its customer credit card files "stolen" by hackers. Rather than notify the affected customers and potentially cause a mass exodus to other vendors, the company decided to keep quiet. That company may be only buying some time. It is a far greater mistake to know that a customer is at risk and not inform them that they should check their records carefully than it is to have missed a technical component and, as a result, their system was compromised. The bottom line is that *you* are expected to report errors, inconsistencies, and suspected privacy violations to them. If you do, you have a right to expect immediate correction.

209.4 Where Is the Data to Be Protected?

Much ado has been made about the encryption of data while connected to the Internet. This is a concern; but to be really responsive to privacy directives, more than transmitting encrypted data is required. For a real privacy policy to be developed, the data must be protected when it is:

- Captured
- Transmitted
- Stored
- Processed
- Archived

That means more than using SSL or sending data over a VPN. It also goes beyond strong authentication using biometrics or public/private keys. It means developing a privacy architecture that protects data when it is sent, even internally; while stored in databases, with access isolated from those who can see other data in the same database; and while it is being stored in program work areas. All these issues can be solved with technology and should be discussed with the appropriate network, systems development, or data center managers. Despite all best efforts to make technology respond to the issues of privacy, the most effective use of resources and effort is in developing work habits that facilitate data privacy protection.

209.5 Good Work Habits

Privacy does not just happen. Everyone has certain responsibilities when it comes to protecting the privacy of one's own data or the data that belongs to others. In some cases, the technology exists to make that responsibility easier to carry out.

Vendor innovations continue to make this technology more responsive, for both data "handlers" and data "owners." For the owners, smart cards carry a record of personal activity that never leaves the wallet-sized token itself. For example, smart cards can be used to record selection of services (video, phone, etc.) without divulging preferences. They can maintain complex medical information (e.g., health, drug interactions) and can store technical information in the form of x-rays, nuclear exposure time (for those working in the nuclear industry), and tanning time (for those who do not).

For the handlers, smart cards can record electronic courier activities when data is moved from one place to another. They can enforce protection of secret data and provide proper authentication, either using a biometric such as a fingerprint or a traditional personal identification number (PIN). There are even cards that can scan a person's facial image and compare it to a digitized photo stored on the card. They are valuable in providing a digital signature that does not reside on one's office PC, subject to theft or compromise by office procedures that are less than effective.

In addition to technology, privacy can be afforded through diligent use of traditional data protection methods. Policies can develop into habits that force employees to understand the sensitivity of what they have access to on their desktops and personal storage areas. Common behavior such as protecting one's territory before leaving that area and when returning to one's area is as important as protecting privacy while in one's area.

Stories about privacy, the compromise of personal data, and the legislation (both U.S. and international) being enacted or drafted are appearing daily. Some are redundant and some are downright scary. One's mission is to avoid becoming one of those stories.

209.6 Recommendations

For all 21st-century organizations (and all people who work in those organizations), a privacy policy is a must and adherence to it is expected. Here are several closing tips:

1. If your organization has a privacy coordinator (or chief privacy officer), contact that person or a compliance person if you have questions. Keep their numbers handy.
2. Be aware of the world around you. Monitor national and international developments, as well as all local laws.
3. Be proactive; anticipate privacy issues before they become a crisis.
4. Much money can be made or lost by being ahead of the demands for privacy or being victimized by those who capitalize on your shortcomings.
5. Preserve your reputation and that of your organization. As with all bad news, violations of privacy will spread like wildfire. Everyone is best served by collective attention to maintaining an atmosphere of respect for the data being handled.
6. Communicate privacy throughout all areas of your organization.
7. Imbed privacy in existing processes—even older legacy applications.
8. Provide notification and allow your customers/clients/constituents to opt out or opt in.
9. Conduct audits and consumer inquiries.
10. Create a positive personalization image of what you are doing (how does this *really* benefit the data owner).
11. Use your excellent privacy policies and behavior as a competitive edge.

210

Liability for Lax Computer Security in DDoS Attacks

Dorsey Morrow

In the middle of February 2000, Internet security changed dramatically when Amazon.com, CNN, Yahoo! E*Trade, ZDNet, and others fell victim to what has come to be known as a distributed denial-of-service attack or, more commonly, DDoS. Although denial-of-service attacks can be found as far back as 1998, it was not until these sites were brought down through the use of distributed computing that the media spotlight focused on such attacks. No longer were the attackers few in number and relatively easy to trace. A DDoS attack occurs when a targeted system is flooded with traffic by hundreds or even thousands of coordinated computer systems simultaneously. These attacking computer systems are surreptitiously *commandeered* by a single source well in advance of the actual attack. Through the use of a well-placed Trojan program that awaits further commands from the originating computer, the attacking computer is turned into what is commonly referred to as a *zombie*. These zombie computers are then coordinated in an assault against single or multiple targets. Zombie computers are typically targeted and utilized because of their lax security. Although a DDoS attack has two victims—the attacking zombie computer and the ultimate target—it is the latter of these two that suffers the most damage. Not only has the security and performance of the victim's computer system been compromised, but economic damage can run into the millions of dollars for some companies. Thus, the question arises: does the attack by a zombie computer system, because of lax security, create liability on the part of the zombie system to the target? To address this issue, this chapter provides a jurisdictional-independent analysis of the tort of negligence and the duty that attaches upon connection to the Internet.

There is a universal caveat in tort law stating that, whenever you are out of a familiar element, a reasonable and prudent person becomes even more cautious. The Internet fits the profile of an unfamiliar element in every sense of the word, be it transactional, jurisdictional, or legal. There is no clear, concise, ecumenical standard for the Internet as it applies to business transactions, political borders, or legal jurisdictions and standards. Thus, every computer user, service provider, and business entity on the Internet should exercise extra caution in travels across the Internet. But, beyond such a general duty to be extra cautious, is there more expected of those who join the broad Internet community and become *Netizens*? Specifically, is there a duty to others online?

Computer security is a dynamic field; and in today's business and legal environments, the demands for confidentiality, integrity, and availability of computer data are increasing at fantastic rates. But at what level is computer security sufficient? For years we have looked to a 1932 case in the 2nd Circuit (see *In re T.J. Hooper*, 60 F.2d 737) that involved a tugboat caught up in a tremendous storm and was subsequently involved in an accident that resulted in the loss of property. Naturally, a lawsuit resulted; and the captain was found guilty of negligence for failing to use a device that was not industry-standard at the time, but was available nonetheless—a two-way radio. The court succinctly stated, "There are precautions so imperative that even their universal disregard will not excuse their omission." In essence, the court stated that, despite what the industry might be doing, or more precisely, failing to do, there are certain precautions we must implement to avoid disaster and liability. What the courts look to is what the reasonable and prudent person (or member of industry) might do in such unfamiliar territory.

Because computer security is so dynamic, instead of trying to define a universal standard of what to do, the more practical method would be to attempt to define what rises to the standard of negligence. Negligence has developed into a common law standard of three elements. First, there must be some duty owed between the plaintiff and the defendant; second, there must be a breach of that duty by the defendant; third, the breach of duty is a proximate cause of damages that result. (See *City of Mobile v. Havard*, 289 Ala. 532, 268 So.2d 805, [1972]. See also *United States Liab. Ins. Co. v. Haidinger-Hayes, Inc.* [1970] 1 Cal.3d 586, 594, 463 P.2d 770.) So it seems we must first address whether there is a duty between the plaintiff (the victim of a DDoS attack) and the defendant zombie computer in such an attack.

Does being tied to the Internet impose a duty of security upon businesses? Do businesses have an implicit requirement to ensure their security is functional and that their systems will not harm others on the wild, wild Internet? It is important to remember that the theory of negligence does not make us insurers of all around us, but rather that we act as a reasonable and prudent person would in the same circumstances. We have already established that the Internet, despite being commercially viable for the past ten years, is still a new frontier. As such, it is challenging historical business and legal concepts. This, of course, creates a new paradigm of caution for the reasonable person or business. The Internet creates an unbridled connection among all who would join. It is undisputed that no one *owns* the Internet or is charged with regulating content, format, or acceptable use. However, there is a duty imposed upon all who connect and become part of the Internet. As in the physical world, we owe a duty to *do no harm* to those around us. Although the ultimate determination of *duty* lies properly within the discretion of the courts as a matter of law, there are a number of *duties* that have been routinely recognized by the courts.

Perhaps the duty from which we can draw the greatest inference is the duty of landowners to maintain their land. This general duty of maintenance, which is owed to tenants and patrons, has been held to include "the duty to take reasonable steps to secure common areas against foreseeable criminal acts of third parties that are likely to occur in the absence of such precautionary measures." (See *Frances T. v. Village Green Owners Assoc.* [1986] 42 Cal.3d 490, 499–501 [229 Cal.Rptr 456, 723 P.2d 573, 59 A.L.R.4th 447].) Similarly, in Illinois, there is no duty imposed to protect others from criminal attacks by a third party, *unless* the criminal attack was reasonably foreseeable and the parties had a "special relationship." (See *Figueroa v. Evangelical Covenant Church*, 879 F.2d 1427 [7th Cir. 1989].) And, in *Comolli v. 81 And 13 Cortland Assoc.*, ___A.D.2d _____ (3d Dept. 2001), the New York Appellate Division, quoting *Rivera v. Goldstein*, 152 A.D.2d 556, 557, stated, "There will ordinarily be no duty imposed on a defendant to prevent a third party from causing harm to another unless the intervening act which caused the plaintiff's injuries was a normal or foreseeable consequence of the situation created by the defendant's negligence." As a shop owner in a high-crime area owes a greater duty of security and safety to those who come to his shop because criminal action is more likely and reasonably foreseeable, thus a computer system tied to the Internet owes a duty of security to others tied to the Internet because of the reasonably foreseeable criminal actions of others. Similarly, if we live in an area where there have been repeated car thefts, and those stolen cars have been used to strike and assault those who walk in the area, it could be reasonably stated we have a duty to the walkers to secure our vehicles. It is reasonably foreseeable that our car would be stolen and used to injure someone if we left it in the open and accessible. The extent to which we left it accessible would determine whether we breached that duty and, pursuant to law, left to the decision of a jury. Whether it was parked in the street, unlocked, and the keys in it, or locked with an active alarm system would be factors the jury would consider in determining if we had been negligent in securing the automobile. Granted, this is a rather extreme and unlikely scenario; but it nonetheless illustrates our duty to others in the digital community.

Statistics that bolster the claim that computer crime is a reasonably foreseeable event include a study by the Computer Security Institute and the San Francisco Federal Bureau of Investigation Computer Intrusion Squad of various organizations on the issue of computer security compiled in March 2001. In their study, 85 percent of respondents detected computer security breaches within the previous 12 months; 38 percent detected DoS attacks in 2001 compared to 27 percent for 2000; and 95 percent of those surveyed detected computer viruses. These numbers clearly show a need for computer security and how reasonably foreseeable computer crime is when connected to the Internet.

When viewed in the light of increasing numbers of viruses, Trojan horses, and security breaches, and the extensive media attention given them, computer crime on the Internet almost passes beyond "reasonably foreseeable" to "expected." A case in Texas, *Dickinson Arms-Reo v. Campbell*, 4 S.W.3d 333 (Tex.App. [1st Dist.] 1999) held that the element of "foreseeability" would require only that the general danger, not the exact sequence of events that produced the harm, be foreseeable. The court went further to identify specific factors in considering "foreseeability" to include: (1) the proximity of other crimes; (2) the recency and frequency of other crimes; (3) the similarity of other crimes; and (4) the publicity of other crimes. Although this is not a ubiquitous checklist to be used as a universal standard, it does give a good reference point with which to measure whether a computer crime could be reasonably expected and foreseeable. Of course, in cyberspace, there is no physical land, tenants, or licensees. However, there is still a duty to secure systems against unauthorized use, whether mandated by statute (Health Insurance Portability and Accountability Act, Graham-Leach-Bliley Act), by regulation, or by common sense. Because of the public nature of the recent DDoS attacks, we now have a better understanding of the synergistic and interconnected nature of the Internet and the ramifications of poor security.

Perhaps the most striking argument for the duty of precaution comes from a 1933 Mississippi case in which the court stated:

> Precaution is a duty only so far as there is reason for apprehension. Ordinary care of a reasonably prudent man does not demand that a person should prevision or anticipate an unusual, improbable, or extraordinary occurrence, though such happening is within the range of possibilities. Care or foresight as to the probable effect of an act is not to be weighed on jewelers' scales, nor calculated by the expert mind of the philosopher, from cause to effect, in all situations. Probability arises in the law of negligence when viewed from the standpoint of the judgment of a reasonably prudent man, as a reasonable thing to be expected. Remote possibilities do not constitute negligence from the judicial standpoint.
>
> —*Illinois Central RR Co. v. Bloodworth*
> 166 Miss. 602, 145 So. 333 (1933)

A 1962 Mississippi case (*Dr. Pepper Bottling Co. v. Bruner*, 245 Miss. 276, 148 So.2d 199) went further in stating that:

> As a general rule, it is the natural inherent duty owed by one person to his fellowmen, in his intercourse with them, to protect life and limb against peril, when it is in his power to reasonably do so. The law imposes upon every person who undertakes the performance of an act which, it is apparent, if not done carefully, will be dangerous to other persons, or the property of other persons—the duty to exercise his senses and intelligence to avoid injury, and he may be held accountable at law for an injury to person or property which is directly attributable to a breach of such duty.… Stated broadly, one who undertakes to do an act or discharge a duty by which conduct of others may be properly regulated and governed is under a duty to shape his conduct in such matter that those rightfully led to act on the faith of his performance shall not suffer loss or injury through his negligence.

We have established the requirement of a duty; but in the context of computer security, what rises to the level of a breach of such a duty? Assuming that a duty is found, a plaintiff must establish that a defendant's acts or omissions violated the applicable standard of care. We must then ask, "What is the standard of care?" According to a 1971 case from the Fifth Circuit, evidence of the custom and practice in a particular business or industry is usually admissible as to the standard of care in negligence actions. (See *Ward v. Hobart Mfg. Co.*, 460 F.2d 1176, 1185.) When a practice becomes so well defined within an industry that a reasonable person is charged with knowing that is the way it is done, a standard has been established. Although computer security is an industry unto itself, its standards vary due to environmental constraints of the industry or business within which it is used. Although both a chicken processing plant and a nuclear processing plant use computer security, the risks are of two extremes. To further skew our ability to arrive at a common standard, the courts have held that evidence of accepted customs and practices of a trade or industry does not *conclusively* establish the legal standard of care. (See *Anderson v. Malloy*, 700 F.2d 1208, 1212 [1983].) In fact, the cost justification of the custom may be considered a relevant factor by some courts, including the determination of whether the expected accident cost associated with the practice exceeded the cost of abandoning the practice. (See *United States Fidelity & Guar. Co. v. Plovidba*, 683 F.2d 1022, 1026 [7th Cir. 1982].) So if we are unable to arrive at a uniform standard of care for computer security in general, what do we look to? Clearly there must be a minimum standard for computer security with which we benchmark our duty to others on the Internet. To arrive at that standard we must use a balancing test of utility versus risk. Such a test helps to determine whether a certain computer security measure ought to be done by weighing the risk of not doing it versus the social utility or benefit of doing it, notwithstanding the cost. In June 2001, in *Moody v. Blanchard Place*, 34,587 (La.App. 2nd Cir. 6/20/01); ___ So.2d ___, the Court of Appeals for Louisiana held that, in determining the risk and utility of doing something, there are several factors to consider: (1) a determination of whether a thing presents an unreasonable risk of harm should be made "in light of all relevant moral, economic, and social considerations" (quoting *Celestine v. Union Oil Co. of California*, 94–1868 [La. 4/10/95], 652 So.2d 1299; quoting *Entrevia v. Hood*, 427 So.2d 1146 [La. 1983]); and (2) in applying the risk-utility balancing test, the fact finder must weigh factors such as gravity and risk of harm, individual and societal rights and obligations, and the social utility involved. (Quoting *Boyle v. Board of Supervisors, Louisiana State University*, 96–1158 [La. 1/14/97], 685 So.2d 1080.) So whether to implement a security measure may be considered in light of economical and social considerations weighed against the gravity and risk of harm. This in turn works to establish the standard of care. If the defendant failed to meet this standard of care, then the duty to the plaintiff has been breached.

Finally, we must consider whether the breach of duty by the defendant to the plaintiff was the proximate cause of damages the plaintiff experienced. To arrive at such a claim, we must have damages. Over the years the courts have generally required physical harm or damages. In fact, economic loss, absent some correlating physical loss, has traditionally been unrecoverable. (See *Pennsylvania v. General Public Utilities Corp.* [1983, CA3 Pa] 710 F.2d 117.) Over the past two decades, however, the courts have been allowing for the recovery of purely economic losses. (See *People Express Airlines v. Consol. Rail Corp.*, 194 N.J. Super. 349 [1984], 476 A.2d 1256.) Thus, although the computer and Internet are not physically dangerous machines (unless attached to some other equipment that is dangerous) and thus incapable of creating a physical loss or causing physical damage, they can produce far-reaching economic damage. This is especially true as more and more of our infrastructure and financial systems are controlled by computer and attached to the Internet. Hence, we arrive at the ability to have damages as the result of action by a computer.

The final question is whether the action or inaction by the defendant to secure his computer systems is a proximate cause of the damages suffered by the plaintiff as the result of a DDoS attack by a third party. And, of course, this question is left to the jury as a matter of fact. Each case carrying its own unique set of circumstances and timelines creates issues that must be resolved by the trier of fact—the jury. However, in order to be a proximate cause, the defendant's conduct must be a cause-in-fact. In other words, if the DDoS attack would not have occurred without the defendant's conduct, it is not a cause-in-fact. Of course, in any DDoS there are a multitude of other parties who also contributed to the attack by their failure to adequately secure their systems from becoming zombies. But this does nothing to suppress the liability of the single defendant. It merely makes others suitable parties to the suit as alternatively liable.

If the defendant's action was a material element and a substantial factor in bringing about the event, regardless of the liability of any other party, their conduct was still a cause-in-fact and thus a proximate cause. In 1995, an Ohio court addressed the issue of having multiple defendants for a single proximate cause, even if some of the potential defendants were not named in the suit. In *Jackson v. Glidden*, 98 Ohio App.2d 100 (1995), 647 N.E.2d 879, the court, quoting an earlier case, stated:

> In *Minnich v. Ashland Oil Co.* (1984), 15 Ohio St.3d 396, 15 OBR 511, 473 N.E.2d 1199, the Ohio Supreme Court recognized the theory of alternative liability. The court held in its syllabus:
>
> "Where the conduct of two or more actors is tortious, and it is proved that harm has been caused to the plaintiff by only one of them, but there is uncertainty as to which one has caused it, the burden is upon each such actor to prove that he has not caused the harm. (2 Restatement of the Law 2d, Torts, Section 433[B][3], adopted.)"
>
> The court stated that the shifting of the burden of proof avoids the injustice of permitting proved wrongdoers, who among them have inflicted an injury upon an innocent plaintiff, to escape liability merely because the nature of their conduct and the resulting harm have made it difficult or impossible to prove which of them have caused the harm.
>
> The court specifically held that the plaintiff must still prove (1) that two or more defendants committed tortious acts, and (2) that plaintiff was injured as a proximate result of the wrongdoing of one of the defendants. The burden then shifts to the defendants to prove that they were not the cause of the plaintiff's injuries. The court noted that there were multiple defendants but a single proximate cause.

This case does not create a loophole for a defendant in a DDoS attack to escape liability by denying his computer security created the basis for the attack; rather, it allows the plaintiff to list all possible defendants and then require them to prove they did not contribute to the injury. If a computer system was part of the zombie attack, it is a potential party and must prove otherwise that its computer security measures met the standard of care and due diligence required to avoid such a breach.

In conclusion, we must look to the totality of circumstances in any attack to determine liability. Naturally, the ultimate responsibility lies at the feet of the instigator of the attack. It is imperative that the Internet community prosecute these nefarious and illegitimate users of computer resources to the fullest and reduce such assaults through every legitimate and legal means available. However, this does not reduce the economic damages suffered by the victim. For that, we look to "deep pockets" and their roles in the attacks. Typically, the deep pockets will be the zombies. But the true determination of their liability is in their security. We must look to the standard of care in the computer security field, in the zombie's particular industry, and the utility and risk of implementing certain security procedures that could have prevented the attack. Could this attack have been prevented or mitigated by the implementation of certain security measures, policies, or procedures? Was there a technological "silver bullet" that was available, inexpensive, and that the defendant knew or should have known about? Would a firewall or intrusion detection system have made a difference? Did the attack exploit a well-known and documented weakness that the defendant zombie should have corrected? Each of these questions will be raised and considered by a jury to arrive at the answer of liability. Each of these questions should be asked and answered by every company before such an attack even transpires.

It is highly probable that those who allow their computer systems, because of weak security, to become jumping-off points for attacks on other systems will be liable to those that are the victims of such attacks. It is incumbent upon all who wish to become part of the community that is the Internet to exercise reasonable care in such an uncertain environment. Ensuring the security of one's own computer systems inherently increases the security of all other systems on the Internet.

211

Operational Forensics

Michael J. Corby

The increased complexities of computer systems today make it difficult to determine what has happened when a malfunction occurs or a system crashes. Sometimes, it is difficult to even make the basic identification of whether the cause was accidental or intentional. If the cause was intentional, legal action may be in order; if the cause was operational, the reason must be identified and corrected. Both require a planned and measured response.

Unfortunately, with today's emphasis on immediate recovery in the networked environment, and with the obligation to get back online as quickly as possible, determining the cause may be impossible. The tendency to restart, or reboot, may remove information that could be valuable in ascertaining cause or providing evidence of criminal wrongdoing.

Operational forensics is a two-phased approach to resolving this problem. The first phase is the proper collection of operational information such as data logs, system monitoring, and evidence-tracking methods. The appropriate attention to this phase makes it much easier to identify the problem in the second phase, the recovery.

At recovery time, the information at hand can be used to decide whether a formal intrusion investigation needs to be initiated and evidence collected needs to be preserved. By responding in prescribed ways, which can include repair/replacement of the equipment, correction of a software weakness, or identification of human-caused error(s) that resulted in the disruption, the system can be returned to operation with a much reduced probability of the same event occurring in the future.

211.1 Related Business Requirements

Technology has been more than an efficiency enhancement to the organization. It has become the lifeblood of the successful enterprise and the sole product of the networked application service provider. As such, the maximum availability of this essential resource is critical. When a failure occurs or the system is not operating at expected levels, proper procedures should be used to accurately identify and correct the situation. Failing to do so will result in unpredictable operations, inefficiencies and possibly lost revenue, tarnished image, and failure to thrive. The business case for investing in the time, procedures, and the relatively small cost of computer hardware or software components seems clear.

Why then, do companies not have operational forensics (or the same functions by other names) programs in place? Well, for two reasons: People have started with the assumption that computers are perfectly reliable and therefore will only fail under rare circumstances if programs are well-written. Why waste resources in pointing the finger at something that should never occur? Second, the topic of methodical, procedural investigations is new to other than law enforcement, and only recently has come into the foreground with the advent of computer crimes, cyber terrorism, and the relationship of vengeance and violence linked to some computer "chat rooms," e-mail, and personal private data intrusions.

The good news is that operational forensics is not an expensive option. There is some additional cost needed to properly equip the systems and the process for secure log creation; but unless the need is determined for a full-scale criminal investigation and trial preparation, the process is almost transparent to most operations.

The business objectives of implementing an operational forensics program are threefold:

1. Maintain maximum system availability (99.999 percent or five-nines "uptime").
2. Quickly restore system operations without losing information related to the interruption.
3. Preserve all information that may be needed as evidence, in an acceptable legal form, should court action be warranted.

The acceptable legal form is what calls for the operational forensics process to be rigorously controlled through standard methods and a coordinated effort by areas outside the traditional IT organization.

211.2 Justification Options

The frequent reaction to a request to start an operational forensics program is one of financial concerns. Many stories abound of how forensic investigations of computer crimes have required hundreds or thousands of hours of highly paid investigators pouring over disk drives with a fine-tooth comb—all of this while the business operation is at a standstill. These stories probably have indeed occurred, but the reason they were so disruptive, took so long, or cost so much, was because the operational data or evidence had to be reconstructed. Often, this reconstruction process is difficult and may be effectively challenged in a legal case if not prepared perfectly.

Operational forensics programs can be justified using the age-old 80–20 rule: an investigation cost is 80 percent comprised of recreating lost data and 20 percent actually investigating. An effective operational forensics program nearly eliminates the 80 percent data recreation cost.

A second way in which operational forensics programs have been justified is as a positive closed-loop feedback system for making sure that the investment in IT is effectively utilized. It is wise investment planning and prudent loss reduction. For example, an operational forensics program can quickly and easily determine that the cause of a server crashing frequently is due to an unstable power source, not an improperly configured operating system. A power problem can be resolved for a few hundred dollars, whereas the reinstallation of a new operating system with all options can take several days of expensive staff time, and actually solve nothing.

No matter how the program is justified, organizations are beginning to think about the investment in technology and the huge emphasis on continuous availability, and a finding ways to convince management that a plan for identifying and investigating causes of system problems is a worthwhile endeavour.

211.3 Basics of Operational Forensics

Operational forensics includes developing procedures and communicating methods of response so that all flexibility to recover more data or make legal or strategic decisions is preserved. Briefly stated, all the procedures in the world and all the smart investigators that can be found cannot reverse the course of events once they have been put into action. If the Ctrl-Alt-Delete sequence has been started, data lost in that action is difficult and expensive, if not impossible to recover. Operational forensics, therefore, starts with a state of mind. That state of mind prescribes a "think before reacting" mentality. The following are the basic components of the preparation process that accompany that mentality.

For all situations:

- Definition of the process to prioritize the three key actions when an event occurs:
  — Evidence retention
  — System recovery
  — Cause identification
- Guidelines that provide assistance in identifying whether an intrusion has occurred and if it was intentional
- Methods for developing cost-effective investigative methods and recovery solutions
- Maintenance of a secure, provable evidentiary chain of custody

For situations where legal action is warranted:

- Identification or development of professionally trained forensic specialists and interviewers/interrogators, as needed
- Procedures for coordination and referral of unauthorized intrusions and activity to law enforcement and prosecution, as necessary
- Guidelines to assist in ongoing communication with legal representatives, prosecutors, and law enforcement, as necessary
- Instructions for providing testimony, as needed

Notice that the evidence is collected and maintained in a form suitable for use in cases where legal action is possible, even if the event is purely an operational failure. That way, if after the research begins, it is determined that what was thought initially to be operational, turns out to warrant legal action, all the evidence is available.

Consider the following scenario. A Web server has stopped functioning, and upon initial determination, evidence shows that the building had a power outage and when the server rebooted upon restoration, a diskette was left in the drive from a previous software installation. Initial actions in response include purchasing a new UPS (uninterruptible power supply) capable of keeping the server functioning for a longer time, and changing the boot sequence so that a diskette in the drive will not prevent system recovery. All set? Everybody thinks so, until a few days after the recovery, someone has discovered that new operating parameters have taken effect, allowing an intruder to install a "trap door" into the operating system. That change would take effect only after the system rebooted. Is the data still available to identify how the trap door was installed, whether it posed problems prior to this event, and who is responsible for this act of vandalism?

An operational forensics program is designed to identify the risk of changes to the system operation when it is rebooted and conduct baseline quality control, but also to preserve the evidence in a suitable place and manner so that a future investigation can begin if new facts are uncovered.

211.4 Building the Operational Forensics Program

211.4.1 Policy

To start building an operational forensics program, the first key element, as in many other technical programs, includes defining a policy. Success in developing this process must be established at the top levels of the organization. Therefore, a policy endorsed by senior management must be written and distributed to the entire organization. This policy both informs and guides.

This policy informs everyone that the organization has corporate endorsement to use appropriate methods to ensure long-term operational stability, and thus ensure that the means to accurately identify and correct problems will be used. It should also inform the organization that methods will be used to take legal action against those who attempt to corrupt, invade, or misuse the technology put in place to accomplish the organization's mission. There is a subtle hint here meant to discourage employees who may be tempted to use the system for questionable purposes (harassing, threatening, or illegal correspondence and actions), that the organization has the means and intent to prosecute violators.

The policy guides in that it describes what to do, under what circumstances, and how to evaluate the results. With this policy, the staff responsible for operating the system components, including mainframes, servers, and even workstations, as well as all other peripherals, will have a definition of the process to prioritize the three key actions when an event occurs:

1. Evidence retention
2. System recovery
3. Cause identification

In general, this policy defines a priority used for establishing irrefutable data that identifies the cause of an interruption. That priority is to first ensure that the evidence is retained; then recover the system operation; and, finally, as time and talent permits, identify the cause.

211.4.2 Guidelines

As a supplement to these policies, guidelines can be developed that provide assistance in identifying whether an intrusion has occurred and if it was intentional. As with all guidelines, this is not a specific set of definitive rules, but rather a checklist of things to consider when conducting an initial response. More detailed guidelines are also provided in the form of a reminder checklist of the process used to secure a site for proper evidence retention. The suggested method for publishing this guideline is to post it on the wall near a server, firewall, or other critical component. Items on this reminder checklist can be constructed to fit the specific installation, but typical entries can include:

Before rebooting this server:

1. Take a photograph of the screen (call Ext xxxx for camera).
2. Verify that the keyboard/monitor switches are set correctly.
3. Record the condition of any lights/indicators.
4. Use the procedure entitled "*Disabling the disk mirror.*"
5. …
6. …
7. etc.

Accompanying these posted instructions are a series of checklists designed to help record and control the information that can be collected throughout the data collection process.

211.4.3 Log Procedures

Policies and guidelines can help provide people with the motivation and method to act thoughtfully and properly when responding to an event, but they are insufficient by themselves to provide all that is needed. Most operating system components and access software (modem drivers, LAN traffic, Internet access software, etc.) provide for log files to be created when the connection is used, changed, or when errors occur. The catch is that usually these logs are not enabled when the component is installed. Furthermore, the log file may be configured to reside on a system device that gets reset when the system restarts. To properly enable these logs, they must be:

- Activated when the service is installed
- Maintained on a safe device, protected from unauthorized viewing or alteration
- Set to record continuously despite system reboots

Additional third-party access management and control logs can and should be implemented to completely record and report system use in a manner acceptable for use as legal evidence. This includes data that can be independently corroborated, non-repudiated, and chain-of-custody maintained.

211.4.4 Configuration Planning

The operational forensics program also includes defining methods for maximizing the data/evidence collection abilities while providing for fast and effective system recovery. That often can be accomplished by planning for operational forensics when system components are configured. One technique often used is to provide a form of disk mirroring on all devices where log files are stored. The intent is to capture data as it exists as close as possible to the event. By maintaining mirrored disks, the “mirror” can be disabled and removed for evidence preservation while the system is restarted. This accomplishes the preservation of evidence and quick recovery required in a critical system.

The process for maintaining and preserving this data is then to create a minimum of three copies of the mirrored data:

1. One copy to be signed and sealed in an evidence locker pending legal action (if warranted)
2. One copy to be used as a control copy for evidence/data testing and analysis
3. One copy to be provided to opposing attorney in the discovery phase, if a criminal investigation proceeds

211.5 Linking Operational Forensics to Criminal Investigation

The value of a well-designed operational forensics program is in its ability to have all the evidence necessary to effectively develop a criminal investigation. By far, the most intensive activity in preparing for a legal opportunity is in the preparation of data that is validated and provable in legal proceedings. Three concepts are important to understanding this capacity:

1. Evidence corroboration
2. Non-repudiation
3. Preservation of the chain of custody

211.5.1 Evidence Corroboration

If one is at all familiar with any type of legal proceeding, from the high profile trials of the 1990s to the courtroom-based movies, television programs, or pseudo-legal entertainment of judicial civil cases, evidence that is not validated through some independent means may by inadmissible. Therefore, to provide the maximum potential for critical evidence to be admitted into the record, it should be corroborated through some other means. Therefore, based on the potential for legal action, several log creation utilities can be employed to record the same type of information. When two sources are compared, the accuracy of the data being reported can be assured. For example, access to a system from the outside reported only by a modem log may be questioned that the data was erroneous. However, if the same information is validated by access to the system from system login attempt, or from an application use log, the data is more likely to be admitted as accurate.

211.5.2 Non-Repudiation

A second crucial element necessary for a smooth legal process is establishing evidence in a way that actions cannot be denied by the suspect. This is called "non-repudiation." In many recent cases of attempted system intrusion, a likely suspect has been exonerated by testifying that it could not have been his actions that caused the violation. Perhaps someone masqueraded as him, or perhaps his password was compromised, etc. There is no way to definitely make all transactions pass the non-repudiation test; but in establishing the secure procedures for authenticating all who access the system, non-repudiation should be included as a high-priority requirement.

211.5.3 Preservation of the Chain of Custody

Finally, the last and perhaps most important legal objective of operational forensics is to preserve the chain of custody. In simple terms, this means that the data/evidence was always under the control of an independent source and that it could not have been altered to support one side of the case. This is perhaps the most easily established legal criterion, but the least frequently followed. To establish a proper chain of custody, all data must be properly signed-in and signed-out using approved procedures, and any chance of its alteration must be eliminated—to a legal certainty. Technology has come to the rescue with devices such as read-only CDs, but there are also some low-technology solutions like evidence lockers, instant photography, and voice recorders to track activity related to obtaining, storing, and preserving data.

For all legal issues, it is wise and highly recommended that the organization's legal counsel be included on the forensic team, and if possible, a representative from the local law enforcement agency's (Attorney General, Prosecutor or FBI/state/local police unit) high-tech crime unit. In the case of properly collecting evidence when and if a situation arises, prior planning and preparation is always a good investment.

211.6 Linking Operational Forensics to Business Continuity Planning

What makes operational forensics an entity unto itself is the ability to use the time and effort spent in planning for benefits other than prosecuting criminals. The key benefit is in an organization's ability to learn something from every operational miscue. Countless times, systems stop running because intruders who only partially succeed at gaining access have corrupted the network connections. In most instances, all the information that could have been used to close access vulnerabilities goes away with the Ctrl-Alt-Delete keys. Systems do not crash without cause. If each cause were evaluated, many of them could be eliminated or their probability of reoccurring significantly reduced.

In the current age of continuous availability, maximum network uptime is directly linked to profit or effectiveness. Implementing an operational forensics program can help establish an effective link to business continuity planning risk reduction and can raise the bar of attainable service levels.

Although evidence collected for improving availability does not need to pass all legal hurdles, an effective method of cause identification can help focus the cost of prevention on *real* vulnerabilities, not on the whole universe of possibilities, no matter how remote. Cost justification of new availability features is more readily available, and IT can begin to function more like a well-defined business function than a "black art."

211.7 Summary and Conclusion

When a system interruption occurs, operational forensics is a key component of the recovery process and should be utilized to identify the nature and cause of the interruption as well as collecting, preserving, and evaluating the evidence. This special investigation function is essential because it is often difficult to conclusively determine the nature, source, and responsibility for the system interruption. As such, to improve the likelihood of successfully recovering from a system interruption, certain related integral services, such as establishing the data/activity logs, monitoring system, evidence collection mechanisms, intrusion management, and investigative management should be established prior to a system interruptions occurrence. This is the primary benefit of operational forensics. One will see much more of this in the near future.

212
Computer Crime Investigation and Computer Forensics

Thomas Welch

Incidents of computer-related crime and telecommunications fraud have increased dramatically over the past decade, but due to the esoteric nature of this crime there have been very few prosecutions and even fewer convictions. The same technology that has allowed for the advancement and automation of many business processes has also opened the door to many new forms of computer abuse. Although some of these system attacks merely use contemporary methods to commit older, more familiar types of crime, others involve the use of completely new forms of criminal activity that have evolved along with the technology.

Computer crime investigation and computer forensics are also evolving sciences that are affected by many external factors: continued advancements in technology, societal issues, legal issues, etc. There are many gray areas that need to be sorted out and tested through the courts. Until then, the system attackers will have a clear advantage, and computer abuse will continue to increase. As computer security practitioners, we must be aware of the myriad of technological and legal issues that affect our systems and its users, including issues dealing with investigations and enforcement.

This chapter will take the security practitioner and investigator through each of the areas of computer crime investigation and computer forensics, so that they are better prepared to respond to both internal and external attacks.

212.1 Computer Crime

According to the *American Heritage Dictionary*, a "crime" is any act committed or omitted in violation of the law. This definition causes a perplexing problem for law enforcement when dealing with computer-related crime, because much of today's computer-related crime is without violation of any formal law. This may seem to be a contradictory statement, but traditional criminal statutes, in most states, have only been modified throughout the years to reflect the theories of modern criminal justice. These laws generally envision applications to situations involving traditional types of criminal activity, such as burglary, larceny, fraud, etc. Unfortunately, the modern criminal has kept pace with the vast advancements in technology, and he has found ways to apply such innovations as the computer to his criminal ventures. Unknowingly and probably unintentionally, he has also revealed the difficulties in applying older traditional laws to situations involving "computer-related crimes."

In 1979, the U.S. Department of Justice established a definition for "computer crime," stating that "a computer crime is any illegal act for which knowledge of computer technology is essential for its perpetration, investigation, or prosecution." This definition was too broad and has since been further refined by new or modified state and federal criminal statutes.

212.1.1 Criminal Law

Criminal law identifies a crime as being a wrong against society. Even if an individual is victimized, under the law, society is the victim. A conviction under criminal law normally results in a jail term or probation for the defendant. It could also result in a financial award to the victim as restitution for the crime. The main purpose for prosecuting under criminal law is punishment for the offender. This punishment is also meant to serve as a deterrent against future crime. The deterrent aspect of punishment only works if the punishment is severe enough to discourage further criminal activity. This is certainly not the case in the United States, where very few computer criminals ever go to jail. In other areas of the world there are very strong deterrents. For example, in China in 1995, a computer hacker was executed after being found guilty of embezzling $200,000 from a national bank. This certainly will have a dissuading value for other hackers in China!

To be found guilty of a criminal offense under criminal law, the jury must believe, beyond a reasonable doubt, that the offender is guilty of the offense. The lack of technical expertise, combined with the many confusing questions posed by the defense attorney, may cause doubt for many jury members, thus rendering a "not guilty" decision. The only short-term solution to this problem is to provide simple testimony in laymen's terms and to use demonstrative evidence whenever possible. Even with this, it will be difficult for many juries to return a guilty verdict.

Criminal conduct is broken down into two classifications, depending on severity. A felony is the more serious of the two, normally resulting in a jail term of more than one year. Misdemeanors are normally punishable by a fine or a jail sentence of less than a year. It is important to understand that if we wish to deter future attacks, we must push for the stricter sentencing, which only occurs under the felonious classification. The type of attack and the total dollar loss has a direct relationship to the crime classification. As we cover investigation procedures, we will see why it is so important to account for all time and money spent on the investigation.

Criminal law falls under two main jurisdictions: federal and state. Although there is a plethora of federal and state statutes that may be used against traditional criminal offenses, and even though many of these same statutes may apply to computer-related crimes with some measure of success, it is clear that many cases fail to reach prosecution or fail to result in conviction because of the gaps that exist in the federal criminal code and the individual state criminal statutes.

Because of this, every state in the United States, with the exception of one, along with the federal government, has adopted new laws specific to computer-related abuses. These new laws, which have been redefined over the years to keep abreast of the constant changes in the technological forum, have been subjected to an ample amount of scrutiny due to many social issues, which have been impacted by the proliferation of computers in society. Some of these issues, such as privacy, copyright infringement, and software ownership, are yet to be resolved, thus we can expect many more changes to the current collection of laws. Some of the computer-related crimes, which are addressed by the new state and federal laws, are

- Unauthorized access
- Exceed authorized access
- Intellectual property theft or misuse of information
- Child pornography
- Theft of services
- Forgery
- Property theft (i.e., computer hardware, chips, etc.)
- Invasion of privacy
- Denial of services
- Computer fraud
- Viruses
- Sabotage (data alteration or malicious destruction)
- Extortion
- Embezzlement
- Espionage
- Terrorism

All but one state, Vermont, have created or amended laws specifically to deal with computer-related crime. Twenty-five states have enacted specific computer crime statutes, while the other twenty-four states have merely amended their traditional criminal statutes to confront computer crime issues. Vermont has announced legislation under Bill H.0555, which deals with theft of computer services. The elements of proof, which define the basis of the criminal activity, vary from state to state. Security practitioners should be fully cognizant of their own state laws, specifically the elements of proof. Additionally, traditional criminal statutes, such as theft, fraud, extortion, and embezzlement, can still be used to prosecute computer crime.

Just as there has been much new legislation at the state level, there have also been many new federal policies, such as the:

- Electronic Communications Privacy Act
- Electronic Espionage Act of 1996
- Child Pornography Prevention Act of 1996
- Computer Fraud and Abuse Act of 1986, 18 U.S.C. 1001

These laws and policies have been established precisely to deal with computer and telecommunications abuses at the federal level. Additionally, many modifications and updates have been made to the Federal Criminal Code, Sections 1029 and 1030, to deal with a variety of computer-related abuses. Even though these new laws have been adopted for use in the prosecution of a computer-related offense, some of the older, proven federal laws, identified in the following list, offer a "simpler" case to present to judges and juries:

- Wire Fraud
- Mail Fraud
- Interstate Transportation of Stolen Property
- Racketeer Influenced and Corrupt Organizations (RICO)

The Electronic Communications Privacy Act (ECPA) is being tested more today than ever before. The ECPA prohibits all monitoring of wire, oral, and electronic communications unless specific statutory exceptions apply. This includes monitoring of e-mail, network traffic, keystrokes, or telephone systems. The ECPA was not meant to prohibit network providers from monitoring and maintaining their networks and connections, thus the ECPA provides an exception for monitoring network traffic for legitimate businesses purposes. Additionally, the ECPA also allows monitoring when the network users are notified of the monitoring process.

The two new laws enacted in 1996, the Child Pornography Prevention Act (CPPA) and the Electronic Espionage Act (EEA), have proved that the legislative process is working, albeit a bit more slowly than one would like. The CPPA is especially impressive in that it eradicates many of the loopholes afforded by newer technology. The CPPA was enacted specifically to combat the use of computer technology to produce pornography that conveys the impression that children were used in the photographs or images, even if the participants are actually adults. The Court held that child pornography, including simulated or morphed images, stimulatess the sexual appetites of pedophiles and that the images themselves may persuade a child to engage in sexual activity by viewing other children. The CPPA was contested by the Freedom of Speech Coalition (FSC), but was upheld by the Court in *FSC v. Reno*.

Hopefully the EEA will curtail some of the industrial espionage that is going on today, but it will also have an impact on how business is conducted in the United States, especially intelligence gathering. According to the EEA, it is a criminal offense to take, download, receive, or possess trade secret information obtained without the owner's authorization. Penalties can reach $10 million in fines, up to 15 years in prison, and forfeiture of property used in the commission of the crime. This could have tremendous, far-reaching consequences for businesses should an employee improperly use information gained from any previous employment.

212.1.2 Civil Law

Civil law (or tort law) identifies a tort as a wrong against an individual or business, which normally results in damage or loss to that individual or business. The major differences between criminal and civil law are the type of punishment and the level of proof required to obtain a guilty verdict. There is no jail sentence under the civil law system. A victim may receive financial or injunctive relief as restitution for his loss. An injunction against the offender will attempt to thwart any further loss to the victim. Additionally, a violation of the injunction may result in a Contempt of Court order, which would place the offender in jeopardy of going to jail. The main purpose for seeking civil remedy is for financial restitution, which can be awarded as follows:

- Compensatory damages
- Punitive damages
- Statutory damages

In a civil action, if there is no culpability on the part of the victim, the victim may be entitled to compensatory (restitution), statutory, and punitive damages. Compensatory damages are actual damages to the victim and include attorney fees, lost profits, investigation costs, etc. Punitive damages are just that—damages set by the jury with the intent to punish the offender. Even if the victim is partially culpable, an award may be made on the victim's behalf, but may be lessened due to the victim's culpable negligence. Statutory damages are damages determined by law. Mere violation of the law entitles the victim to a statutory award.

Civil cases are much easier to convict under because the burden of proof required for a conviction is much less. To be found guilty of a civil wrong, the jury must believe, based only upon the preponderance of the evidence, that the offender is guilty of the offense. It is much easier to show that the majority (51 percent) of the evidence is pointing to the defendant's guilt.

Finally, just as a search warrant is used by law enforcement as a tool in the criminal investigation, the Court can issue an Impoundment Order or Writ of Possession, which is a court order to take back the property in question. The investigator should also keep in mind that the criminal and civil case could take place simultaneously, thus allowing items seized during the execution of the search warrant to be used in the civil case.

212.1.3 Insurance

An insurance policy is generally part of an organization's overall risk mitigation/management plan. The policy offsets the risk of loss to the insurance company in return for an acceptable level of loss (the insurance premium). Because many computer-related assets (software and hardware) account for the majority of an organization's net worth, they must be protected by insurance. If there is a loss to any of these assets, the insurance company is usually required to pay out on the policy. One important factor to bear in mind is the principle of culpable negligence. This places part of the liability on the victim if the victim fails to follow a "standard of due care" in the protection of identified assets. If a victim organization is held to be culpably negligent, the insurance company may be required to pay only a portion of the loss. Also, an insurance company can attempt to deny coverage, arguing that an employee's "dishonest" acts caused the damage.

Two important insurance issues related to the investigation are prompt notification of the loss and understanding that the insurance company has a duty to defend. Regarding prompt notification, insurance companies may deny coverage by arguing that the claim was received too late. Some states even allow an insurance company to void its insurance obligations if the notice or claim is proven to be late.

212.2 Rules of Evidence

Before delving into the investigative process and computer forensics, it is essential that the investigator has a thorough understanding of the Rules of Evidence. The submission of evidence in any type of legal proceeding generally amounts to a significant challenge, but when computers are involved, the problems are intensified. Special knowledge is needed to locate and collect evidence, and special care is required to preserve and transport the evidence. Evidence in a computer crime case may differ from traditional forms of evidence inasmuch as most computer-related evidence is intangible—in the form of an electronic pulse or magnetic charge.

Before evidence can be presented in a case, it must be competent, relevant, and material to the issue, and it must be presented in compliance with the Rules of Evidence. Anything that tends to prove directly or indirectly that a person may be responsible for the commission of a criminal offense may be legally presented against him. Proof may include the oral testimony of witnesses or the introduction of physical or documentary evidence.

By definition, evidence is any species of proof or probative matter, legally presented at the trial of an issue, by the act of the parties and through the medium of witnesses, records, documents, objects, etc., for the purpose of inducing belief in the minds of the court and jurors as to their contention. In short, evidence is anything offered in court to prove the truth or falsity of a fact at issue. This section will cover each of the Rules of Evidence as it relates to computer crime investigations.

212.2.1 Types of Evidence

There are many types of evidence that can be offered in court to prove the truth or falsity of a given fact. The most common forms of evidence are direct, real, documentary, and demonstrative. Direct evidence is oral testimony, whereby the knowledge is obtained from any of the witness's five senses and is, in itself, proof or disproof of a fact in issue. Direct evidence is called to prove a specific act (i.e., Eye Witness Statement). Real evidence, also known as associative or physical evidence, is made up of tangible objects that prove or disprove guilt. Physical evidence includes such things as tools used in the crime, fruits of the crime, perishable evidence capable of reproduction, etc. The purpose of the physical evidence is to link the suspect to the scene of the crime. It is this evidence that has material existence and can be presented to the view of the court and jury for consideration. Documentary evidence is evidence presented to the court in the form of business records, manuals, printouts, etc. Much of the evidence submitted in a computer crime case is documentary evidence. Finally, demonstrative evidence is evidence used to aid the jury. It may be in the form of a model, experiment, chart, or an illustration offered as proof.

It should be noted that in order to aid the court and the jury in their quest to understand the facts at issue, demonstrative evidence is being used more often, especially in the form of simulation and animation. It is very important to understand the difference between these two types of evidence because the standard of admissibility is affected. A computer simulation is a prediction or calculation about what will happen in the future, given known facts. A traffic reconstruction program is a perfect example of computer simulation. There are many mathematical algorithms used in this type of program that must be either stipulated to or proven to the court to be completely accurate. It is generally more difficult to admit a simulation as evidence, because of the substantive nature of the process.

Computer animation, on the other hand, is simply a computer-generated sequence, illustrating an expert's opinion. Animation does not predict future events. It merely supports the testimony of an expert witness through the use of demonstrations. An animation of a hard disk spinning while the read/write heads are reading data can help the court or jury understand how a disk drive works. There are no mathematical algorithms that must be proven. The animation solely aids the court and jury through visualization. The key to having animation admitted as evidence is in the strength of the expert witness. Under Rule 702, the expert used to explain evidence must be qualified to do so through skill, training or education.

When seizing evidence from a computer-related crime, the investigator should collect any and all physical evidence, such as the computer, peripherals, notepads, documentation, etc., in addition to computer-generated evidence. There are four types of computer-generated evidence:

1. Visual output on the monitor
2. Printed evidence on a printer
3. Printed evidence on a plotter
4. Film recorder, including magnetic representation on disk, tape, or cartridge, and optical representation on CD

212.2.2 Best Evidence Rule

The Best Evidence Rule, which had been established to deter any alteration of evidence, either intentionally or unintentionally, states that the Court prefers the original evidence at the trial, rather than a copy, but they will accept a duplicate under the following conditions:

- Original lost or destroyed by fire, flooding or other acts of God, including such things as careless employees or cleaning staff
- Original destroyed in the normal course of business
- Original in possession of a third party who is beyond the Court's subpoena power

This rule has been relaxed now to allow duplicates unless there is a genuine question as to the original's authenticity, or if admission of the duplicate would, under the circumstances, be unfair.

212.2.3 Exclusionary Rule

Evidence must be gathered by law enforcement in accordance with court guidelines governing search and seizure or it will be excluded (Fourth Amendment). Any evidence collected in violation of the Fourth Amendment is considered to be "fruit of the poisonous tree," and will not be admissible. Furthermore, any evidence identified and gathered as a result of the initial inadmissible evidence will also be held to be inadmissible. Evidence may also be excluded for other reasons, such as violations of the Electronic Communications Privacy Act (ECPA) or violations related to provisions of Chapters 2500 and 2700 of Title 18 of the United States Penal Code.

Private citizens are not subject to the Fourth Amendment's guidelines on search and seizure, but are exposed to potential exclusions for violations of the ECPA or Privacy Act. Therefore, internal investigators, private investigators, and Computer Emergency Response Team (CERT) members should take caution when conducting any internal search, even on company computers. For example, if there were no policy in place explicitly stating the company's right to electronically monitor network traffic on company systems, then internal investigators would be well advised not to set up a sniffer on the network to monitor such traffic. To do so may be a violation of the ECPA.

212.2.4 Hearsay Rule

A legal factor of computer-generated evidence is that it is considered hearsay. Hearsay is second-hand evidence, that is not gathered from the personal knowledge of the witness, but from another source. Its value depends on the veracity and competence of the source. The magnetic charge of the disk or the electronic bit value in memory, which represents the data, is the actual, original evidence. The computer-generated evidence is merely a representation of the original evidence.

Under the Federal Rules of Evidence, all business records, including computer records, are considered "hearsay," because there is no first-hand proof that they are accurate, reliable, and trustworthy. In general, hearsay evidence is not admissible in court. However, there are some well-established exceptions (Rule 803) to the hearsay rule for business records. In *Rosenberg v. Collins*, the Court held that if the computer output is used in the regular course of business, then the evidence shall be admitted.

212.2.5 Business Record Exemption to the Hearsay Rule

Federal Rules of Evidence 803(6) allows a court to admit a report or other business document made at or near the time by, or from information transmitted by, a person with knowledge, if kept in the course of regularly conducted business activity, and if it was the regular practice of that business activity to make the (report or document), all as shown by testimony of the custodian or other qualified witness, unless the source of information or the method or circumstances of preparation indicates lack of trustworthiness.

To meet Rule 803 (6) the witness must:

- Have custody of the records in question on a regular basis
- Rely on those records in the regular course of business
- Know that they were prepared in the regular course of business

Audit trails meet the criteria if they were produced in the normal course of business. The process to produce the output will have to be proven to be reliable. If computer-generated evidence is used and admissible, the Court may order disclosure of the details of the computer, logs, maintenance records, etc., in respect to the system generating the printout, and then the defense may use that material to attack the reliability of the evidence. If the audit trails are not used or reviewed (at least the exceptions, i.e., failed log-on attempts) in the regular course of business, then they may not meet the criteria for admissibility.

Federal Rules of Evidence 1001(3) provides another exception to the Hearsay Rule. This rule allows a memory or disk dump to be admitted as evidence, even though it is not done in the regular course of business. This dump merely acts as statement of fact. System dumps (in binary or hexadecimal) is not hearsay because they are not being offered to prove the truth of the contents, but only the state of the computer.

212.2.6 Chain of Evidence (Custody)

Once evidence is seized, the next step is to provide for its accountability and protection. The Chain of Evidence, which provides a means of accountability, must be adhered to by law enforcement when conducting any type of criminal investigation, including a computer crime investigation. It helps to minimize the instances of tampering. The Chain of Evidence must account for all persons who handled or who had access to the evidence in question.

The Chain of Evidence shows:

- Who obtained the evidence
- Where and when the evidence was obtained
- Who secured the evidence
- Who had control or possession of the evidence

It may be necessary to have anyone associated with the evidence testify at trial. Private citizens are not required to maintain the same level of control of the evidence as law enforcement, although they would be well advised to do so. Should an internal investigation result in the discovery and collection of computer-related evidence, the investigation team should follow the same, detailed chain of evidence as required by law enforcement. This will help to dispel any objection by the defense that the evidence is unreliable should the case go to court.

212.2.7 Admissibility of Evidence

The admissibility of computer-generated evidence is, at best, a moving target. Computer-generated evidence is always suspect because of the ease with which it can be tampered—usually without a trace! Precautionary measures must be taken to ensure that computer-generated evidence has not been tampered with, erased, or added to. Tto ensure that only relevant and reliable evidence is entered into the proceedings, the judicial system has adopted the concept of admissibility.

- *Relevancy of Evidence*: Evidence tending to prove or disprove a material fact. All evidence in court must be relevant and material to the case.
- *Reliability of Evidence*: The evidence and the process to produce the evidence must be proven to be reliable. This is one of the most critical aspects of computer-generated evidence.

Once computer-generated evidence meets the Business Record Exemption to the Hearsay Rule, is not excluded for some technicality or violation, follows the Chain of Custody, and is found to be both relevant and reliable, then it is held to be admissible. The defense will attack both the relevancy and reliability of the evidence, so great care should be taken to protect both.

212.2.8 Evidence Lifecycle

The Evidence Lifecycle starts with the discovery and collection of the evidence. It progresses through the following series of states until it is finally returned to the victim or owner:

- Collection and identification
- Analysis
- Storage, preservation, and transportation
- Presented in court
- Returned to victim (owner)

212.2.8.1 Collection and Identification

As the evidence is obtained or collected, it must be properly marked so that it can be identified as being the particular piece of evidence gathered at the scene. The collection must be recorded in a logbook identifying the particular piece of evidence, the person who discovered it, and the date, time, and location discovered. The location should be specific enough for later recollection in court. All other types of identifying marks, such as make, model, or serial number, should also be logged. It is of paramount importance to list any type of damage to the particular piece of evidence. This is not only for identification purposes, but it will also limit any potential liability should a claim be made later that you damaged the evidence. When marking evidence, the following guidelines should be followed:

- Mark the actual piece of evidence if it will not damage the evidence, by writing or scribing your initials, the date, and the case number, if known. Seal this evidence in the appropriate container and, again mark the container by writing or scribing your initials, the date, and the case number, if known.
- If the actual piece of evidence cannot be marked, then seal the evidence in an appropriate container, and mark the container by writing or scribing your initials, the date, and the case number, if known.
- The container should be sealed with evidence tape, and your marking should write over the tape, so that if the seal is broken it can be noticed.
- Be extremely careful not to damage the evidence while engraving or marking the piece.

When marking glass or metal, a diamond scriber should be used. For all other objects, a felt-tip pen with indelible ink is recommended. Depending on the nature of the crime, the investigator may wish to preserve latent fingerprints. If so, static-free gloves should be used if working with computer components, instead of standard latex gloves.

Try always to mark evidence the same way, because you will be asked to testify to the fact that you are the person identified by the evidence markings. Keep in mind that the defense is going to try to discredit you as a witness or try some way to keep the evidence out of court, so something as simple as quick, positive identification of your mark is largely beneficial to your case.

212.2.8.2 Storage, Preservation, and Transportation

All evidence must be packed and preserved to prevent contamination. It should be protected against heat, extreme cold, humidity, water, magnetic fields, and vibration. The evidence must be protected for future use in court and for return to the original owner. It the evidence is not properly protected, the person or agency responsible for the collection and storage of the evidence may be held liable for damages. Therefore, the proper packing materials should be used whenever possible. Documents and disks (hard, floppy, optical, tapes, etc.) should be seized and stored in appropriate containers to prevent their destruction. For example, hard disks should be packed in a sealed, static-free bag, within a cardboard box with a foam container. The box should be sealed with evidence tape and an Electromagnetic Field (EMF) warning label should be affixed to the box. It may be wise to defer to the system administrator or a technical advisor on how to best protect a particular type of system, especially mini-systems or mainframes.

Finally, evidence should be transported to a location where it can be stored and locked. Sometimes the systems are too large to transport, thus the forensic examination of the system may need to take place on-site.

212.2.8.3 Presented in Court

Each piece of evidence that is used to prove or disprove a material fact needs to be presented in court. After the initial seizure, the evidence is stored until needed for trial. Each time the evidence is transported to and from the courthouse for the trial, it needs to be handled with the same care as with the original seizure. Additionally, the Chain of Custody must continue to be followed. This process will continue until all testimony related to the evidence is completed. Once the trial is over, the evidence can be returned to the victim (owner).

212.2.8.4 Returned to Victim (Owner)

The final destination of most types of evidence is back with its original owner. Some types of evidence, such as drugs or paraphernalia (i.e., contraband) are destroyed after the trial. Any evidence gathered during a search, even though maintained by law enforcement, is legally under the control of the courts. Even though a seized item may be yours and may even have your name on it, it may not be returned to you unless the suspect signs a release or after a hearing by the court. Unfortunately, many victims do not want to go to trial. They just want to get their property back.

Many investigations merely need the information on a disk to prove or disprove a fact in question, thus there is no need to seize the entire system. Once a schematic of the system is drawn or photographed, the hard disk can be removed and then transported to a forensics lab for copying. Mirror copies of the suspect disk are obtained using forensic software, and then one of those copies can be returned to the victim so that business operations can resume.

212.3 Computer Crime Investigation

The computer crime investigation should start immediately following the report of any alleged criminal activity. Many processes ranging from reporting and containment to analysis and eradication need to be accomplished as soon as possible after the attack. An Incident Response Plan should be formulated and a Computer Emergency Response Team (CERT) should be organized prior to the attack. The Incident Response Plan will help set the objective of the investigation and will identify each of the steps in the investigative process.

The use of a corporate CERT team is invaluable. Due to the numerous complexities of any computer-related crime, it is extremely advantageous to have a single group that is acutely familiar with the Incident Response Plan to call upon. The CERT team should be a technically astute group knowledgeable in the area of legal investigations, the corporate Security Policy (especially the Incident Response Plan), the severity levels of various attacks, and the company position on information dissemination and disclosure.

The Incident Response Plan should be part of the overall Corporate Computer Security Policy. The plan should identify reporting requirements, severity levels, guidelines to protect the crime scene and preserve evidence, etc. The priorities of the investigation will vary from organization to organization, but the issues of containment and eradication are reasonably standard to minimize any additional loss and resume business as quickly as possible. The following sections describe the investigative process starting with the initial detection.

212.3.1 Detection and Containment

Although intrusion detection is covered elsewhere in this chapter, it must be mentioned that before any investigation can take place, the system intrusion or abusive conduct must first be detected. The closer the detection is to the actual intrusion event will not only help to minimize system damage, but will also assist in the identification of potential suspects.

To date, most computer crimes have either been detected by accident or through the laborious review of lengthy audit trails. Although audit trails can assist in providing user accountability, their detection value is somewhat diminished because of the amount of information that must be reviewed and because these reviews are always post-incident. Accidental detection is usually made through observation of increased resource utilization or inspection of suspicious activity, but again, is not effective due to the sporadic nature of this type of detection.

These types of reactive or passive detection schemes are no longer acceptable. Proactive and automated detection techniques need to be instituted to minimize the amount of system damage in the wake of an attack. Real-time intrusion monitoring can help in the identification and apprehension of potential suspects, and automated filtering techniques can be used to make audit data more useful.

Once an incident is detected, it is essential to minimize the risk of any further loss. This may mean shutting down the system and reloading clean copies of the operating system and application programs. It should be noted that failure to contain a known situation (i.e., system penetration) might result in increased liability for the victim organization. For example, if a company's system has been compromised by an external attacker and the company failed to shut down the intruder, hoping to trace him, the company may be held liable for any additional harm caused by the attacker.

212.3.2 Report to Management

All incidents should be reported to management as soon as possible. Prompt internal reporting is imperative to collect and preserve potential evidence. It is important that information about the investigation be limited to as few people as possible. This should be done on a need-to-know basis. This limits the possibility of the investigation being leaked. Additionally, all communications related to the incident should be made via an out-of-band method to ensure the intruder does not intercept any incident-related information. In other words, do not use e-mail to discuss the investigation on a compromised system. Based on the type of crime and type of organization it may be necessary to notify:

- Executive Management
- Information Security Department
- Physical Security Department
- Internal Audit Department
- Legal Department

212.3.3 Preliminary Investigation

A preliminary internal investigation is necessary for all intrusions or attempted intrusions. At a minimum, the investigator must ascertain if a crime has occurred; and if so, he must identify the nature and extent of the abuse. It is important for the investigator to remember that the alleged attack or intrusion may not be a crime at all. Even if it appears to be some form of criminal conduct, it could merely be an honest mistake. Most internal losses occur from errors, not from overt criminal acts. There is no quicker way to initiate a lawsuit than to mistakenly accuse an innocent person of criminal activity.

The preliminary investigation usually involves a review of the initial complaint, inspection of the alleged damage or abuse, witness interviews, and, finally, examination of the system logs. If during the preliminary investigation it is determined that some alleged criminal activity has occurred, the investigator must address the basic elements of the crime to ascertain the chances of successfully prosecuting a suspect either civilly or criminally. Additionally, the investigator must identify the requirements of the investigation (dollars and resources). If it is believed that a crime has been committed, neither the investigator nor any other company personnel should confront or talk with the suspect. Doing so would only give the suspect the opportunity to hide or destroy evidence.

212.3.4 Determine if Disclosure Is Required

It must be determined if a disclosure is required or warranted, due to laws or regulations. Disclosure may be required by law or regulation or may be required if the loss affects a corporation's financial statement. Even if disclosure is not required, it is sometimes better to disclose the attack to possibly deter future attacks. This is especially true if the victim organization prosecutes criminally or civilly. Some of the following attacks would probably result in disclosure:

- Large financial loss of a public company
- Bank fraud
- Public safety systems (i.e., air traffic control)

The Federal Sentencing Guidelines also require organizations to report criminal conduct. The stated goals of the Commission were to "provide just punishment, adequate deterrence, and incentives for organizations to maintain internal mechanisms for preventing, detecting, and reporting criminal conduct." The guidelines also state that organizations have a responsibility to "maintain internal mechanism for preventing, detecting, and reporting criminal conduct." The Federal Sentencing Guidelines do not prevent an organization from conducting preliminary investigations to ascertain if, in fact, a crime has been committed. One final note about the Federal Sentencing Guidelines: they were designed to punish computer criminals for acts of recidivism and using their technical skills and talents to engage in criminal activity.

If the decision is made to disclose an alleged incident or intrusion, be especially careful when dealing with the media. The media has a history of sensationalizing these types of events and can easily distort the facts that could portray the victim organization as the "Goliath," using the David vs. Goliath analogy. Make sure that you have all the facts and provide the media with the "slant" that best serves your purposes. Do not lie to the media! A "no comment" is better than lieing.

212.3.5 Investigation Considerations

Once the preliminary investigation is complete and the victim organization has made a decision related to disclosure, the organization must decide on the next course of action. The victim organization may decide to do nothing or may attempt to eliminate the problem and just move on. Deciding to do nothing is not a very good course of action as the organization may be held to be culpably negligent should another attack or intrusion occur. The victim organization should at least attempt to eliminate the security hole that allowed the breach, even if it does not plan to bring the case to court. If the attack is internal, the organization may wish to conduct an investigation that might only result in the dismissal of the subject. If it decides to further investigate the incident, it must also determine if it is going to prosecute criminally or civilly, or merely conduct the investigation for insurance purposes. If an insurance claim is to be submitted, a police report is usually necessary.

When making the decision to prosecute a case, the victim must clearly understand the overall objective. If the victim is looking to make a point by punishing the attacker, then a criminal action is warranted. This is one of the ways to deter potential future attacks. If the victim were seeking financial restitution or injunctive relief, then a civil action would be appropriate. Keep in mind that a civil trial and criminal trial can happen in parallel. Information obtained during the criminal trial can be used as part of the civil trial. The key is to know what you want to do at the outset, so all activity can be coordinated.

The evidence or lack thereof may also hinder the decision to prosecute. Evidence is a significant problem in any legal proceeding, but the problems are compounded when computers are involved. Special knowledge is needed to locate and collect the evidence, while special care is required to preserve the evidence.

There are many factors to consider when deciding whether or not to further investigate an alleged computer crime. For many organizations, the primary consideration will be the cost associated with an investigation. The next consideration will probably be the impact to operations or the impact to business reputation. The organization must answer the following questions:

- Will productivity be stifled by the inquiry process?
- Will the subject system have to be shut down to conduct an examination of the evidence or crime scene?

- Will any of the system components be held as evidence?
- Will proprietary data be subject to disclosure?
- Will there be any increased exposure for failing to meet a "standard of due care"?
- Will there be any adverse publicity related to the loss?
- Will a disclosure invite other perpetrators to commit similar acts, or will an investigation and subsequent prosecution deter future attacks?

The answers to these questions may have an impact on how the investigation is handled and who is called in to conduct the investigation. Furthermore, these issues must be addressed early on, so that the proper authorities can be notified if required. Prosecuting an alleged criminal offense is a very time-consuming task. Law enforcement and the prosecutor will expect a commitment of time and resources for the following:

- Interviews to prepare crime reports and search warrant affidavits
- Engineers or computer programmers to accompany law enforcement on search warrants
- Assistance of the victim company to identify and describe documents, source code, and other found evidence
- A company expert who may be needed for explanations and assistance during the trial
- Documents may need to be provided to the defendant's attorney for discovery. They may ask for more than you want to provide. Your attorney will have to argue against broad-ranging discovery. Defendants are entitled to seek evidence they need for their defense.
- You and other company employees will be subpoenaed to testify.

212.3.6 Who Should Conduct the Investigation?

Based upon the type of investigation (i.e., civil, criminal, insurance, or administrative) and extent of the abuse, the victim must decide who is to conduct the investigation. This used to be a fairly straightforward decision, but high-technology crime has altered the decision-making process. Inadequate and untested laws, combined with the lack of technical training and technical understanding, has severely hampered the effectiveness of our criminal justice system when dealing with computer-related crimes.

In the past, society would adapt to change, usually at the same rate of that change. Today, this is no longer true. The Information Age has ushered in dramatic technological changes and achievements, which continue to evolve at exponential rates. The creation, the computer itself, is being used to create new technologies or advance existing ones. This cycle means that changes in technology will continue to occur at an ever-increasing pace. What does this mean to the system of law? It means we have to take a look at how we establish new laws. We must adapt the process to account for the excessive rate of change. Unfortunately, this is going to take time! In the meantime, if a victim is to launch an investigation, the victim must choose from the following options:

- Conduct an internal investigation
- Bring in external private consultants/investigations
- Bring in local/state/federal law enforcement

Exhibit 212.1 identifies each of the trade-offs.

Law enforcement officers have greater search and investigative capabilities than private individuals, but they also have more restrictions than private citizens. For law enforcement to conduct a search, a warrant must first be issued. No warrant is needed if the victim or owner of compromised system gives permission to conduct the search. Issuance of the search warrant is based on probable cause (reason to believe that something is true). Once probable cause has been identified, law enforcement officers have

EXHIBIT 212.1 Trade-offs for Three Options Compensating for Rate of Change

Group	Cost	Legal Issues	Information Dissemination	Investigative Control
Internal Investigators	Time/People Resources	Privacy Issues Limited Knowledge of Law and Forensics	Controlled	Complete
Private Consultants	Direct Expenditure	Privacy Issues	Controlled	Complete
Law Enforcement Officers	Time/People Resources	Fourth Amendment Issues Jurisdiction Miranda Privacy Issues	Uncontrolled Public Information (FOIA)	None

the ability to execute search warrants, subpoenas, and wire taps. The warrant process was formed to protect the rights of the people. The Fourth Amendment to the Constitution of the United States established the following:

> *The right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures, shall not be violated, and no warrants shall issue, but upon probable cause, supported by oath or affirmation, and particularly describing the place to be searched, and the persons or things to be seized.*

There are certain exceptions to this. The "exigent circumstances" doctrine allows for a warrantless seizure by law enforcement when the destruction of evidence is impending. In *United States v. David*, the Court held that "when destruction of evidence is imminent, a warrantless seizure of that evidence is justified if there is probable cause to believe that the item seized constitutes evidence of criminal activity."

Internal investigators (nongovernment) or private investigators, acting as private citizens, have much more latitude in conducting a warrantless search, due to a ruling by the Supreme Court in *Burdeau v. McDowell*. In this case, the Supreme Court held that evidence obtained in a warrantless search could be presented to a grand jury by a government prosecutor, because there was no unconstitutional government search and hence no violation of the Fourth Amendment.

Normally, a private (party) citizen is not subject to the rules and laws governing search and seizure, but a private citizen becomes a police agent, and the Fourth Amendment applies, when:

- The private party performs a search which the government would need a search warrant to conduct
- The private party performs that search to assist the government, as opposed to furthering its own interest
- The government is aware of that party's conduct and does not object to it

The purpose of this doctrine is to eliminate the opportunity for government to circumvent the warrant process by eliciting the help of a private citizen. If a situation required law enforcement to obtain a warrant, due to the subject's expectations of privacy, and the government knowingly allowed a private party to conduct a search to disclose evidence, the Court would probably rule that the private citizen acted as a police agent. A victim acting to protect its property by assisting police to prevent or detect a crime does not become a police agent.

Law enforcement personnel are not alone in their ability to obtain a warrant. A private party can also obtain a warrant, albeit a civil one, to search and seize specifically identified property which the party makes claim to. This civil warrant, also known as a Writ of Possession, allows the plaintiff to seize property that is rightfully theirs. To obtain such a court order, the plaintiff must prove to a judge or magistrate that the property in question is his and that an immediate seizure is essential to minimizing any collateral monetary loss. Additionally, the plaintiff must also post a bond, double the value of the property in question. This places an enormous burden on the plaintiff, should he be unsuccessful in his endeavor, but it also protects individuals and businesses against frivolous requests made to the Court.

The biggest issues affecting the decision on who to bring in (in order of priority) are information dissemination, investigative control, cost, and the associated legal issues. Once an incident is reported to law enforcement, information dissemination becomes uncontrolled. The same holds true for investigative control. Law enforcement controls the entire investigation, from beginning to end. This is not always bad, but the victim organization may have a different set of priorities. Cost is always a concern, and the investigation costs only add to the loss initially sustained by the attack or abuse. Even law enforcement agencies, which are normally considered "free," add to the costs because of the technical assistance they require during the investigation.

Another area that affects law enforcement is jurisdiction. Jurisdiction is the geographic area where the crime had been committed and any portion of the surrounding area over, or through which the suspect passed, is enroute to, or going away from, the actual scene of the crime. Any portion of this area adjacent to the actual scene over which the suspect, or the victim, might have passed, and where evidence might be found, is considered part of the crime scene. When a system is attacked remotely, where did the crime occur? Most courts submit that the crime scene is the victim's location. But what about "enroute to"? Does this suggest that a crime scene may also encompass the telecommunications path used by the attacker? If so, and a theft occurred, is this interstate transport of stolen goods? There seem to be more questions than answers but only through cases being presented in court can precedence be set. It will take time for the answers to shake out.

There are advantages and disadvantages to each of the groups identified above. Internal investigators will know your systems the best, but may lack some of the legal and forensic training. Private investigators who specialize in high-technology crime also have a number of advantages, but usually result in higher costs. Private security practitioners and private investigators are also private businesses and may be more sensitive to business resumption than law enforcement. If you elect to retain the services of a private investigator or computer consultant, it is best if your corporate counsel retains them. This protects the victim organization from unwarranted or untimely disclosure. All communications are treated as privileged communications, under the Attorney-Client Privilege. Additionally, all work product is protected by the same privilege and is protected from disclosure. This includes details of the investigation, witness interviews, forensic analysis, etc. It also includes any past criminal activity by the victim organization which may be uncovered during the investigation.

Should you decide to contact your local police department, call the detective unit directly. Chances are you will get someone who is more experienced and knowledgeable and someone who can be more discreet. If you call 911, a uniformed officer will arrive on your doorstep and possibly alert the attacker. Furthermore, the officer must create a report of the incident that will become part of a public log. Now the chances for a discretionary dissemination of information and a covert investigation are gone.

Ask the detectives to meet with you in plain clothes. When he arrives at your business, have him announce himself as a consultant. If you decide that you would like federal authorities to be present, do so, but you should inform the local law enforcement authorities. Be aware that your local law enforcement agency may not be well equipped to handle high-tech crime. The majority of law enforcement agencies have limited budgets and, as such, place an emphasis on problems related to violent crime and drugs. Also, with technology changing so rapidly, most law enforcement officers lack the technical training to adequately investigate an alleged intrusion.

The same problems hold true for the prosecution and the judiciary. To successfully prosecute a case, both the prosecutor and the judge must have a reasonable understanding of high-tech laws and the crime in question. This is not always the case. Additionally, many of the current laws are woefully inadequate. Even though an action may be morally and ethically wrong, it is still possible that no law is violated (e.g., LaMacchia case). Even when there is a law that has been violated, many of these laws remain untested and lack precedence. Because of this many prosecutors are reluctant to prosecute high-tech crime cases.

Many recent judicial decisions have indicated that judges are lenient toward techno-criminals just as with other white-collar criminals. Furthermore, the lack of technology expertise may cause "doubt," thus rendering "not guilty" decisions. Because many of the laws concerning computer crime are new and untested, many judges have a concern with setting precedents, which may later be overturned in an appeal. Some of the defenses that have been used and accepted by the judiciary are:

- If you have no system security or lax system security, then you are implying that there is no company concern. Thus there should be no court concern.
- If a person is not informed that access is unauthorized, then it can be used as a defense.
- If an employee is not briefed and does not acknowledge understanding of policy and procedures, then it can be used as a defense.

212.3.7 The Investigative Process

As with any type of criminal investigation the goal of the investigation is to know who, what, when, where, why, and how. It is important that the investigator logs all activity and accounts for all time spent on the investigation. The amount of time spent on the investigation has a direct impact on the total dollar loss for the incident. This may result in greater criminal charges and possibly stiffer sentencing. Finally, the money spent on investigative resources can be reimbursed as compensatory damages in a successful civil action.

Once the decision is made to further investigate the incident, the next course of action for the investigative team is to establish a detailed investigative plan, including the search and seizure plan. The plan should consist of an informal strategy that will be employed throughout the investigation, including the search and seizure:

- Identify any potential suspects
- Identify potential witnesses
- Identify what type of system is to be seized
- Identify the search and seizure team members
- Obtain a search warrant (if required)
- Determine if there is risk of the suspect destroying evidence or causing greater losses

212.3.7.1 Identify Any Potential Suspects

The type of crime and the type of attacker will set the stage for the overall investigation. Serious attacks against government sites, military installations, financial centers, or a telecommunications infrastructure must be met with the same fervor as that of a physical terrorist attack. Costs will not be the issue. On the other hand, when an organization plans to conduct an investigation pertaining to unauthorized access or a violation of company policy, all the factors should be considered. This includes the anticipated cost and the chances of success. In either case, there will always be the usual suspects: insiders and outsiders.

Insiders are usually trusted users who abuse their level of authorized access to the system. They are normally the greatest source of loss. They know the value of your assets! They are usually motivated by greed, need (i.e., drug habit, gambling problem, divorce, etc.), or perceived grievance. Most importantly they have the access and the opportunity. Outsiders, as the name implies, attack your systems and networks from the outside. They attack systems for a variety of reasons, with attacks increasing at alarming rates because of advancements such as the Internet. Some examples of outsiders are as follows:

- Hackers and crackers
- Organized crime
- Terrorists
- Pedophiles
- Industrial/corporate spies

Although, individually each of these groups continues to be a problem, it is especially disturbing to realize the potential for collaboration between any two or more of the groups. When organized crime groups or terrorist factions gain access to the technical expertise provided by hackers and crackers, the potential for widespread harm and exorbitant financial losses is intensified. Albert Einstein said it best when he said "technological progress is like an axe in the hands of a pathological criminal."

When commencing the investigation, it is important to understand how and why a system is being attacked. The how will provide you with information pertaining to technical expertise required to conduct the attack. The why will potentially indicate motive. The how and why together, along with the when and the where, may provide the who.

212.3.7.2 Identify Potential Witnesses

It is important to identify potential witnesses early on in the investigation. It is just as important not to alert the suspect to the investigation. Therefore selecting whom will be interviewed, and when, may have an impact on the investigation. The key to obtaining good witness statements is to ascertain the facts in the case, not opinions. Also, it is wise not to ask leading questions. Sources of information may be staff members, expert witnesses, associates, etc. Interviews are not the same as interrogations, and great care should go into not confusing the two. If a hostile witness does not want to be interviewed, then the process should cease immediately. If a witness or potential witness is detained against his will, there may be criminal and/or civil liability to the individuals and business responsible for the investigation. Never intimidate, coerce, or harass a potential witness.

Technically competent personnel should conduct interviews of technical witnesses or suspects. A potential suspect who is technically competent will have a field day if interviewed by a nontechnical investigator. Many times these individuals are arrogant to start with. If they feel that they have the upper hand because of their "esoteric knowledge," they may be less inclined to provide a truthful statement. Also, it is sometimes better to interview a technical suspect (i.e., programmer) before seizing his system. If you advise the suspect that you will be seizing his system if he does not cooperate, he may assist in the investigation.

One final note on conducting interviews. It is always a good idea to have the witness write out and sign his statement in his own handwriting. This statement can then be typed for better readability, but you can always point to the original. This helps to counter statements made by the witness in court.

212.3.7.3 Identify the Type of System that Is to Be Seized

It is imperative to learn as much as possible about the target computer system(s). If possible, obtain the configuration of the system, including the network environment (if any), hardware, and software. The following data should be acquired prior to the seizure:

- Identify system experts. Make them part of the team.
- Is a security system in place on the system, If so, what kind? Are passwords used? Can a root password be obtained?
- Where is the system located? Will simultaneous raids be required?
- Obtain the required media supplies in advance of the operation
- What law has been violated? Discuss the elements of proof. These should be the focus of the search and seizure.
- What is your probable cause? Obtain a warrant if necessary.
- Determine if the analysis of the computer system will be conducted on site or back in the office or forensics lab.

212.3.7.4 Identify the Search and Seizure Team Members

There are different rules for search and seizure based on who is conducting the search. Under the Fourth Amendment, law enforcement must obtain a warrant, which must be based on probable cause.

Regardless of who is conducting the search and seizure, a team should be identified and should consist of the following members:

- Lead Investigator
- Information Security Department
- Legal Department
- Technical Assistance—System Administrator (as long as he is not a suspect)

If a corporate CERT team is already organized, then this process is already complete. A chain of command needs to be established and it must be determined who is to be in charge. This person is responsible for delegating assignments to each of the team members. A media liaison should be identified if the attack is to be disclosed. This will control the flow of information to the media.

212.3.7.5 Obtaining and Serving Search Warrants

If it is believed that the suspect has crucial evidence at his home or office, then a search warrant will be required to seize the evidence. If a search warrant is going to be needed, then it should be done as quickly as possible before the intruder can do further damage. The investigator must establish that a crime has been committed and that the suspect is somehow involved in the criminal activity. He must also show why a search of the suspect's home or office is required. The victim may be asked to accompany law enforcement when serving the warrant to identify property or programs.

If you must take along documents with you when serving the search warrant, consider copying them onto a colored paper to prevent the defense from inferring that what you might have found was left by you.

212.3.7.6 Is the System at Risk?

Prior to the execution of the plan, the investigative team should ascertain if the suspect, if known, is currently working on the system. If so, the team must be prepared to move swiftly, so that evidence is not destroyed. The investigator should determine if the computer is protected by any physical or logical access control systems and be prepared to respond to such systems. It should also be decided what will be done if the computer is on at the commencement of the seizure. The goal of this planning is to minimize any risk of evidence contamination or destruction.

212.3.8 Executing the Plan

The first step in executing the plan is to secure and control the scene. This includes securing the power, network servers, and telecommunications links. If the suspect is near the system, it may be necessary to physically remove him. It may be best to execute the search and seizure after normal business hours to avoid any physical confrontation. Keep in mind that even if a search is conducted after hours, the suspect may still have remote access to the system via a LAN-based modem connection, PC-based modem connection, wireless modem connection, or Internet connection. Many times it is required to seize a disk from the suspect's computer, mirror image a copy of the disk, and then replace the original with a copy of the disk, all without the suspect knowing what is happening. This allows the investigative team to protect the evidence and continue with the investigation, while retaining secrecy of the investigation.

Enter the area slowly so as not to disturb or destroy evidence. Evaluate the entire situation. In no other type of investigation can evidence be destroyed more quickly. Do not touch the keyboard as this may invoke a Trojan horse or some other rogue or malicious program. Do not turn off the computer unless it appears to be active (i.e., formatting the disk, deleting files, initiating some I/O process, etc.). Look for the disk activity light and listen for disk usage. If you must turn off the computer, pull the plug from the wall rather than using the on/off switch. Look for notes, documentation, passwords, encryption codes, etc. The following questions must be answered in order to effectively control the scene:

- Is the subject system turned on?
- Is there a modem attached?

  - — Check for internal and wireless modems
  - — Check for telephone lines connected to the computer

- Is the system connected to a LAN?

The investigator may wish to videotape the entire evidence collection process. There are two schools of thought on this. The first is that if you videotape the search and seizure, any mistakes can nullify the whole operation. The second school of thought is that if you videotape the evidence collection process, many of the claims by the defense can be silenced. In either case, be careful what you say if the audio is turned on!

Sketch and photograph the crime scene before touching anything. Sketches should be drawn to scale. Take still photographs of critical pieces of evidence. At a minimum, the following should be captured:

- The layout of desks and computers (include dimensions and measurements)
- The configuration of the all computers on the network
- The configuration of the suspect computer, including network connections, peripheral connections, internal and external components, and system backplane
- The suspect computer display

A drawing package, such as Visio (Technical Edition) is excellent for these types of drawings. Visio allows the investigator to sketch the scene using a drag-and-drop graphical user interface (GUI). Most computer and network graphics, desk and furniture graphics, etc., are included with the application. The output is a professional product that is made part of the report and can be used later to recreate the environment or to present the case in court.

If the computer is on, the investigator should capture what is on the monitor. This can be accomplished by videotaping what is on the screen. The best way to do this, without getting the "scrolling effect" caused by the video refresh, is to use a National Television Standards Committee (NTSC) adapter. Every monitor has a specific refresh rate (i.e., horizontal: 30 to 66 kHz, vertical: 50 to 90 Hz), which identifies how frequently the screen's image is redrawn. It is this redrawing process that causes the videotaped image to appear as if the vertical hold is not properly adjusted. The NTSC adapter is connected between the monitor and the monitor cable, and directs the incoming signal into the camcorder. The adapter converts the computer's analog signal (VGA) to an NTSC format. Still photos are a good idea too. Do not use a flash, because it can "white out" the image. Even if the computer is off, check the monitor for burnt-in images. This does not happen as much with the new monitors, but it may still help in the discovery of evidence.

Once you have reviewed and captured what is on the screen, pull the plug on the system. This is for PC-based systems only. Mini-systems or mainframes must be logically powered-down. It is best to conduct a forensic analysis (technical system review with a legal basis focused on evidence gathering) on a forensic system, in a controlled environment. If necessary, a forensic analysis can be conducted on-site, but never using the suspect system's operating system or system utilities. See the section on forensic analysis for the process that should be followed.

Once the computer is turned off, remove the cover and photograph and sketch the inside of the computer. The analyst or investigator should use a static-dissipative grounding kit when working inside of the computer. You should note any peculiarities, such as booby traps. Identify each drive and its logical ID (i.e., C drive) by tracing the ribbon cables to the I/O board. Also identify any external drives. Once this has been completed, remove, label, and pack all drives. Check the floppy drives for any media. If a disk is in the drive, remove the disk, and mark on the evidence label where it was found. Next, place a blank diskette into the floppy drive(s). Place evidence tape over the floppy drives and the on/off switch, once it is placed in the off position.

Identify, mark, and pack all evidence according to the collection process under the Rules of Evidence. Identify and label all computer systems, cables, documents, disks, etc. The investigator should also seize all diskettes, backup tapes, PCMCIA disks, magnetic cartridges, optical disks, and printouts. All diskettes should be write protected. Make an entry for each in the evidence log. Check the printer. If it uses ribbons, make sure it (or at least the ribbon) is taken as evidence. Keep in mind that many of the peripheral devices may contain crucial evidence in their memory and/or buffers. Some items to consider are LAN servers, routers, printers, etc. You must check with the manufacturer on how to output the memory buffers for each device. Also, keep in mind that most buffers are stored in volatile memory. Once the power is cut, the information may be lost.

Additionally, check all drawers, closets, and even the garbage for any forms of magnetic media (i.e., hard drives, floppy diskettes, tape cartridges, optical disks, etc.) or documentation. It seems that many computer-literate individuals conduct most of their correspondence and work product on a computer. This is an excellent form of leads, but take care to avoid an invasion of privacy. Even media that appear to be destroyed can turn out to be quite useful. One case involved an American serviceman who contracted to have his wife killed and wrote the letter on his computer. In an attempt to destroy all the evidence, he cut up the floppy disk containing the letter into 17 pieces. The Air Force Office of Special Investigations (AFOSI) was able to reconstruct the diskette and read almost all the information.

Do not overlook the obvious, especially hacker tools and any ill-gotten gains (i.e., password or credit card lists). This will help your case when trying to show motive and opportunity. The State of California has equated hacker tools with burglary tools; mere possession constitutes a crime. Possession of a Red Box or any other telecommunications instrument that has been modified with the intent to defraud is also prohibited under U.S.C. Section 1029. Some of the hacker tools that you should be aware of are:

- Password crackers
- Network sniffers
- Automated probing tools (i.e., SATAN)
- Anonymous remailers
- War dialers
- Encryption and steganography tools

Finally, phones, answering machines, desk calendars, day-timers, fax machines, pocket organizers, electronic watches, etc., are all sources of potential evidence. If the case warrants, seize and analyze all sources of data, both electronic and manual. Document all activity in an Activity Log, and if necessary secure the crime scene.

212.3.9 Surveillance

There are two forms of surveillance used in computer crime investigations: physical surveillance and computer surveillance. The physical surveillance can be generated at the time of the abuse, via CCTV security camera, or after the fact. When done after the fact, physical surveillance is usually performed undercover. It can be used in an investigation to determine a subject's personal habits, family life, spending habits, or associates.

Computer surveillance is achieved in a number of ways. It is done passively through audit logs or actively by way of electronic monitoring. Electronic monitoring can be accomplished via keyboard monitoring, network sniffing, or line monitoring. In any case, it generally requires a warning notice or explicit statement in the security policy, indicating that the company can and will electronically monitor any and all systems or network traffic. Without such a policy or warning notice, a warrant is normally required.

Before you conduct electronic monitoring, make sure you review Chapters 2500 and 2700 of the Electronic Communications Privacy Act, Title 18 of the United States Code as it relates to keystroke monitoring or system administrators looking into someone's account. If you do not have a banner or if the account holder has not been properly notified, the system administrator and the company can be guilty of a crime and liable for both civil and criminal penalties. Failure to obtain a warrant could result in the evidence being suppressed, or worse yet litigation by the suspect for invasion of privacy or violation of the ECPA.

One other method of computer surveillance that is used are "sting operations." These operations are established so as to continue to track the attacker online. By baiting a trap or setting up "honeypots," the victim organization lures the attacker to a secured area of the system. This is what was done in the Cuckoo's Egg. The system attackers were enticed into accessing selected files. Once these files or their contents are downloaded to another system, their mere presence can be used as evidence against the suspect. This enticement is not the same as entrapment as the intruder is already predisposed to commit the crime. Entrapment only occurs when a law enforcement officer induces a person to commit a crime that the person had not previously contemplated.

It is very difficult to track and identify a hacker or remote intruder, unless there is a way to trace the call (i.e., Caller ID, wiretap, etc.). Even with these resources, many hackers meander through communications networks, hopping from one site to the next, via a multitude of telecommunications gateways and hubs, such as the Internet! Bill Cheswick, author of *Firewalls and Internet Security*, refers to this a "connection laundering." Additionally, organizations cannot take the chance of allowing the hacker to have continued access to its system and potentially cause any additional harm.

Telephone traps require the equivalent of a search warrant. Additionally, the victim will be required to file a criminal report with law enforcement and must show probable cause. If sufficient probable cause is shown, a warrant will be issued and all incoming calls can be traced. Once a trace is made, a pen register is normally placed on the suspect's phone to log all calls placed by the suspect. These entries can be tied to the system intrusions based on the time of the call and the time the system was accessed.

212.3.10 Investigative and Forensic Tools

Exhibit 212.2, although not exhaustive, identifies some of the investigative and forensic tools that are commercially available. The first table identifies the hardware and software tools that should be part of the investigator's toolkit, and the second table identifies forensic software and utilities.

212.3.11 Other Investigative Information Sources

When conducting an internal investigation it is important to remember that the witness statements and computer-related evidence are not the only sources of information useful to the investigation. Personnel files provide a wealth of information related to an employee's employment history. It may show past infractions by the employee or disciplinary action by the company. Telephone and fax logs can possibly identify any accomplices or associates of the subject. At a minimum they will identify the suspect's most recent contacts. Finally, security logs, time cards, and check-in sheets will determine when a suspected insider had physical access to a particular system.

212.3.12 Investigative Reporting

The goal of the investigation is to identify all available facts related to the case. The investigative report should provide a detailed account of the incident, highlighting any discrepancies in witness statements. The report should be a well-organized document that contains a description of the incident, all witness statements, references to all evidentiary articles, pictures of the crime scene, drawings and schematics of the computer and the computer network (if applicable), and finally, a written description of the forensic analysis. The report should state final conclusions, based solely on the facts. It should not include the investigator's opinions, unless he is an expert. Keep in mind that all documentation related to the investigation is subject to discovery by the defense, so be careful about what is written down!

EXHIBIT 212.2 Investigative and Forensic Tools

Investigative Tools

Investigation and Forensic Toolkit Carrying Case
Cellular Phone
Laptop Computer
Camcorder w/NTSC Adapter
35mm Camera (2)
Wide Angle & Telephoto Lens
Night Vision Adapter for Camera and Camcorder
Polaroid Camera
Tape Recorder (VOX)
Scientific Calculator
Label Maker
Crime Scene/Security Barrier Tape
PC Keys
1C Removal Kit
Compass
Diamond Tip Engraving Pen Extra Diamond tips
Felt Tip Pens
Evidence Seals (250 Seals/Roll)
Plastic Evidence Bags (100 bags)
Evidence Labels (100 Labels)
Evidence Tape—2″×165′
Tool Kit containing:
Screwdriver Set (inc. Precision Set)
Torx Screwdriver set
25′ Tape Measure
Razor Knife
Nut Driver
Pliers Set
LAN Template
Probe Set
Neodymium Telescoping Magnetic Pickup
Allen Key Set
Alligator Clips
Wire Cutters
Small Pry Bar
Hammer
Tongs and/or Tweezers
Cordless Driver w/Rechargeable Batteries (2)
Pen Light Flashlight
Magnifying Glass 3 ¼″
Inspection Mirror

Static Charge Meter
EMF/ELF Meter (Magnetometer)
Gender Changer (9 Pin and 25 Pin)
Line Monitor
RS232 Smart Cable
Nitrile Anti-static Gloves
Alcohol Cleaning Kit
CMOS Battery
Extension Cords
Power Strip
Keyboard Key Puller
Cable Tester
Breakout Box
Transparent Static Shielding Bags (100 bags)
Anti-Static Sealing Tape
Serial Port Adapters (9 Pin–25 Pin & 25 Pin–9 Pin)
Foam-Filled Carrying Case
Static-Dissipative Grounding Kit w/Wrist Strap
Foam-Filled Disk Transport Box
Computer Dusting System (Air Spray)
Small Computer Vacuum
Printer and Ribbon Cables
9 Pin Serial Cable
25 Pin Serial Cable
Null Modem Cable
Centronics Parallel Cable
50 Pin Ribbon Cable
Laplink Parallel Cable
Telephone Cable for Modem
Batteries for Camcorder, Camera, Tape Recorder, etc. (AAA, AA, 9-volt)

Computer Supplies

Diskettes:
3 1/2″ Diskettes (Double & High Density Format)
5 1/4″ Diskettes (Double & High Density Format)
Diskette Labels
5 1/2″ Floppy Diskette Sleeves
3 1/2″ Floppy Diskette Container
CD-ROM Container
Write Protect Labels for 5 1/4″ Floppies
Tape and Cartridge Media
1/4″ Cartridges
4mm & 8mm DAT
Travan
9-Track/1600/6250

Software Tools

Sterile O/S Diskettes
Virus Detection Software
SPA Audit Software
Little-Big Endian Type Application
Password Cracking Utilities
Disk Imaging Software
Auditing Tools
Test Data Method
Integrated Test Facility (ITF)

Exhibit 212.2 (continued)

Computer Supplies	Software Tools
QIC	Mapping
Zip Drives	Code Comparison
Jazz Drives	Checksum
Hard Disks	File Utilities (DOS, Windows, 95, NT, UNIX)
IDE	
SCSI	
Paper	Zip/Unzip Utilities
81/2×11 laser paper	
80 column formfeed	
132 column formfeed	
Miscellaneous Supplies	**Miscellaneous Supplies**
Paper Clips	MC60 Microcassette Tapes
Scissors	Camcorder Tapes
Rubber Bands	35mm Film (Various Speeds)
Stapler and Staples	Polaroid Film
Masking Tape	Graph Paper
Duct Tape	Sketch Pad
Investigative Folders	Evidence Checklist
Cable Ties/Labels	Blank Forms—Schematics
Numbered and Colored Stick-on Labels	Label Maker Labels

212.4 Computer Forensics

Computer forensics is the study of computer technology as it relates to the law. The objective of the forensic process is to learn as much about the suspect system as possible. This generally means analyzing the system using a variety of forensic tools and processes. Bear in mind that the examination of the suspect system may lead to other victims and other suspects. The actual forensic process will be different for each system analyzed, but the following guidelines should help the investigator/analyst conduct the forensic analysis.

There are many tools available to the forensic analyst to assist in the collection, preservation, and analysis of computer-based evidence. The make-up of a forensic system will vary from lab to lab, but at a minimum each forensic system must have the ability to:

- Conduct a disk image backup of the suspect system
- Authenticate the file system
- Conduct forensic analysis in a controlled environment
- Validate software and procedures

Before analyzing any system, it is extremely important to protect the systems and disk drives from static electricity. The analyst should always use an antistatic or static-dissipative wristband and mat before conducting any forensic analysis.

212.4.1 Conduct a Disk Image Backup of the Suspect System

A disk image backup is different from a file system backup in that it conducts a bit level copy of the disk, sector by sector, rather than merely copying the system files. This process provides the capability to back up deleted files, unallocated clusters, and slack space. The backup process can be accomplished by using either disk-imaging hardware, such as the ImageMaster 1000, or through a variety of software programs. Most of these programs run under DOS or Windows and will back up most any type of hard disk or floppy disk, regardless of the operating system. The image backup process is conducted as depicted in Exhibit 212.3.

212.4.2 Authenticate the File System

File system authentication helps to ensure the integrity of the seized data and the forensic process. Before actually analyzing the suspect disk, a message digest is generated for all system directories, files, and disk sectors. A message digest is a signature that uniquely identifies the content of a file or disk sector. It is created using a one-way hashing algorithm. In the past a 32-bit CRC32 algorithm was used, but due to the advancements in cryptographic research and along with more powerful machines, two more advanced, one-way hashing algorithms are now being used. MD5 is a 128-bit hash, and SHA is a 160-bit hash. These strong cryptographic hashing algorithms virtually guarantee the integrity of the processed data. Doing this now will help refute any argument by the defense that the evidence was tampered with.

The concept of a one-way hash, using MD5 for example, is that a file is read into memory. The file is then processed, bit by bit, until it reaches the end of the file. The hashing process creates a 128-bit signature for the file that is based on the file content. Even the change of a single bit will change the signature produced by the hashing algorithm. The significance of the one-way hash is that it only works one way. Knowledge of the hash value cannot produce the file content itself.

The only problem with executing the authentication process is that it will change the file's last access time. The mere process of reading the file to produce the hash value will change this time. That is why a separate backup is used for the authentication process.

212.4.3 Conduct Forensic Analysis in a Controlled Environment

After restoring at least one of the backup tapes to a disk of equal capacity to the original disk (identical disk, if possible), the restored data should be analyzed. This should be done in a controlled environment on a forensic system. Everything on the system must be checked, starting with the file system and directory structure. The analyst should create an organizational chart of the disk file system and then inventory all files on the disk. There are a number of commercially available utilities that allow the analyst to quickly create a directory tree, list system files, identify hidden files, and to conduct keyword searches. The analyst should make notes during each step in the process, especially when restoring hidden or deleted files, or modifying the suspect system (i.e., repairing a corrupted disk sector with Norton Utilities). The analyst should also note that what may have happened on the system may have resulted from error or incompetence rather than from a malicious user. It is a good idea to check for viruses at this point: first note their existence, and second, avoid potential contamination.

EXHIBIT 212.3 Image Backup Process

Step	Disk Image Backup Procedure
1	Remove the internal hard disk(s) from suspect machine and label (if not already done). Make a note of which logical disk you are removing. Follow the ribbon cables from the disk to the I/O board to accomplish this task. It is a good idea to photograph the inside of the system including the connections to the I/O boards and disk (i.e. IDE or SCSI). Identify the make and model.
3	Identify the disk capacity. Make a note of cylinders, heads and sectors.
4	Place each disk, one at a time, in a clean forensic examination machine). Note, if you are using a hardware-based disk duplication method (i.e. ImageMaster 1000), then this step is not necessary.
5	Backup (Disk Image) the suspect disk(s) to tape—make at least 4 copies of each suspect disk
6	Check the disk image backup logs to make sure that there were no errors during the backup process.
7	Place the original disk suspect disk(s), along with one of the backup tapes, and backup logs, in the appropriate container. Seal, mark and log into evidence.
8	Return a copy of the original disk to the victim (if applicable)
9	Use the last two copies for the forensic analysis (one is used for file authentication)

Because forensic analysis can be a laborious and time-consuming process, it is sometimes better to distribute the workload to other analysts and case agents. Because it would be too costly to have multiple forensic systems and to have to replicate the suspect data on multiple hard drives, it may be more effective to make CD copies of the hard disk contents that can be distributed and analyzed by different individuals. This is certainly more cost effective and may possibly accelerate the analysis process.

When using CD-R or WORM (Write Once Read Many) technology, the data should be structured in a way that will enhance the forensic process. One method of data organization that works quite well is to create a logical directory structure that will store and organize all data from the target disk. This should include all files and directories from the original file structure, deleted files, hidden files, data in slack space, data in unallocated space, compressed data, encrypted data, and data generated from search results.

To initiate this process, the analyst should copy (file copy) the complete file structure, starting from the root directory, from the image copy to a newly created hard disk partition. This type of copy will not pick up deleted files, data in slack space, or data in unallocated space, therefore the analyst must manually copy this data from the target system to the new disk partition. Before copying this data, individual sub-directories must be created for each data type: DELETED, SLACK, UNALLOC. The file copy process will copy the swap file, but it may be best to move the file to a SWAP sub-directory. The next step in the process is to review the information in the original file system, looking for files with hidden file attributes, compressed files, encrypted files, and files that meet the criteria of keyword searches. These, too, should be copied to specific directories, so that later it is understood where the data came from. The following directories should be created to store and organize this data: HIDDEN, COMPRESS, ENCRYPT, and SEARCH.

The final process is to use a disk editor utility to look for "BAD" clusters that have data in them and to run keyword searches at the disk editor level (below the operating system). Any data found during this analysis should be copied to the newly created file system. A BAD sub-directory can be created under the HIDDEN sub-directory, and an EDITOR sub-directory can be created under the SEARCH sub-directory. Once the new file system is populated with all the data, the information can be burnt into a CD-R or WORM drive. This information can then be made available to other forensic analysts or case agents. If damaging evidence is discovered on review of the data stored on the CD-R or WORM drive, the original information can easily be recovered from the original image copy.

A quick background on file times should be given before continuing on. Most computer systems, including Windows 95, NT, and UNIX store three values for file times: creation time, update time, last access time. Any or all of these file times may have an impact on the investigation. The access time is the one most susceptible to modification because any read to access to the file changes this time. The image backup will not change this time, but the file authentication process will! The creation time is the time the file was originally created. It is not accessible from the file manager or the DIR command. The update time is the time the file was last modified (written to). This is the time the file manager displays. The last access time is recorded whenever any other program or command, including read, copy, etc., touches the file. This time is also not accessible from the file manager, but can be seen in the File Properties.

When searching through files and directories, the first things to look for are file names or document content that have case-relevant names. For example, if the case you are working is an espionage or theft of trade secrets case, then look for file names with the word (or partial word) of the trade secret item itself. If the trade secret was related to the release of a new, database software product called SplitDB, then look for files with the name "split.xls," "db.doc," or "database.ppt." Another search may find the word "split," "db," or "database" in the body of a word processing document (i.e., a hidden file named sys.dll with the following phase, "For this database structure to work effectively…"). Another indicator that something is afoul is when the file extension does not match the file signature. All files have a signature that identifies the type of file, somewhere in the first 50 characters of the file. This file signature normally correlates to a particular file extension. For example, a bitmap graphic file normally has a file extension of.bmp and a file signature of BM as the first two bytes of the file. If these two items do not match up, then it may mean that someone modified the file extension to hide the presence of the file. A pedophile can use this technique to hide a bitmap image containing child pornography in the c:\windows\system directory as system.dll. A cursory review of the system may miss this file completely, seeming to be a Windows system file when in fact it is damaging evidence.

212.4.3.1 Search Tools

There are many search tools that can assist the forensic analyst in his endeavor to locate damaging evidence. Most of these tools are commercial off-the-shelf (COTS) applications that were created for some reason other than forensics. It just so happens that these applications work well in a forensic environment. Norton Utilities, although not the end-all, is a must for all forensic investigators. Norton provides file searching utilities, disk editor functions, data recovery, etc. Some other tools are:

- Quick View Plus
- Expert Witness
- Computer Forensics Laboratory
- Drag and View
- Rescue Professional
- Super Sleuth
- Outside/In

212.4.3.2 Searching for Obscure Data

Once the basic analysis is complete, the next step is to conduct a more detaileded analysis of more obscure data. It may be necessary to use forensic data recovery techniques to locate and recover:

- Hidden files
  - Hidden by attributes
  - Hidden through steganography
  - Hidden in slack space
  - Hidden in good clusters marked as BAD
- Modifying the size of the file in the directory entry
- Hidden directories
- Erased or deleted files
- Reformatted media
- Encrypted data
- Overwritten (wiped) files

The fact that a file is hidden is a good indicator of its evidentiary value. If someone took the time to hide the file, it was probably hidden for a reason. The simplest way to hide a file is to alter the file attribute to Hidden, System, or Volume Label. Files with these attributes do not normally appear in a DIR listing or even in the Windows file manager. Simply changing the attribute back will make the file accessible. Files with the Hidden attribute set are usually further hidden in a hidden directory. An example of a hidden directory is the.directory in UNIX or creating a directory with the ALT 255 character in a Windows or DOS system. Many times these hidden directories are deeply nested to avoid discovery. The chkdsk utility will display the number of hidden files on the DOS system, and Norton Utilities will display a listing of the hidden file and its location.

A file can also be hidden in slack space. Slack space is the area left over in a cluster that is not utilized by a file. For example, if a 2 kb file is stored in a 32 kb cluster, then there is 30 kb of slack space, which may contain data from a previous file. This area can also be used to hide data. A cluster, which is the basic allocation unit, is the smallest unit of space that DOS uses for a file. The amount of slack space for a given file varies based on the file size and cluster size. The cluster size usually expands as hard disk capacity increases.

Another, more elaborate way to hide data is to first write data to a file in the normal way. When this is complete, the suspect can use a disk editor to ascertain the sector and cluster of the newly created file, go to that cluster and mark the cluster as BAD. When the operating system sees a BAD cluster, it simply ignores the area. The data is still present on the disk even though it cannot be accessed. The analyst will need to locate the cluster by using a sector-searching utility, then go to the specific cluster and remove the BAD label.

Files and directories can also be deleted. But when DOS or Windows deletes a file, it only changes the first character of the file name to 0xE5, which merely makes the file space available. The file is not actually removed. The data in the cluster previously allocated by the file is still available until overwritten by a new file. On DOS and Windows systems, the analyst can use the unerase utility to recover deleted files. These utilities only recover the first cluster that the file occupied. If the file occupied multiple clusters, this data may be lost, as the cluster chain is no longer available. Cluster chains can be rebuilt, although not reliably.

If the disk is formatted, the analyst can attempt to use the unformat command in the DOS or Windows environment. If the disk has been wiped, which is also known as shredding, the data is not easily recoverable. The cost of recovery is usually exorbitant, far exceeding the initial loss.

212.4.3.3 Steganography

Steganography is the art of hiding communications. Unlike encryption, which utilizes an algorithm and a seed value to scramble or encode a message in order to make it unreadable, steganography makes the communication invisible. This takes concealment to the next level—that is to deny that the message even exists. If a forensic analyst were to look at an encrypted file, it would be obvious that some type of cypher process has been used. It is even possible to determine what type of encryption process was used to encrypt the file, based on a unique signature. However, steganography hides data and messages in a variety of picture files, sound files, and even slack space on floppy diskettes. Even the most trained security specialist or forensic analyst may miss this type of concealment during a forensic review.

Steganography simply takes one piece of information and hides it within another. Computer files, such as images, sound recordings, and slack space contain unused or insignificant areas of data. For example, the least significant bits of a 24-bit bitmap image can be used to hide messages, usually without any material change in the original file. Only through a direct, visual comparison of the original and processed image can the analyst detect the possible use of steganography. Because many times the suspect system only stores the processed image, the analyst has nothing to use as a comparison and generally has no way to tell that the image in question contains hidden data. There is research under way that will help in the forensic process when dealing with steganography. New tools are being developed that will look at the file contents to determine if there is a steganographic signature within the file. But with over 25 different types of steganography being used today, this new research may take some time.

212.4.3.4 Review Communications Programs

A good source of contact and associate information can many times be found online. Because many technically competent individuals use technology for the same reasons businesses do, electronic Rolodexes, databases of contacts, and communication programs should be searched. Applications like Microsoft Outlook, ACT, and others can be tremendously beneficial during an investigation to link your suspect to other individuals or businesses. Some computers store caller ID files, and others may contain war dialer (or demon dialer) logs. Review communications programs, such as Procomm, to ascertain if any numbers are stored in the application.

212.4.3.5 Microprocessor Output

One final note before moving on to the next step in the forensic process is to understand that not all microprocessors are created equal. If a forensic analyst is forced to dump the contents of a file in binary or hexadecimal format, he must not only understand how to read these hieroglyphic notations, but must know the type of microprocessor that produced the output. For example, the Intel 30286 is a 16-bit, little endian processor. A 16-bit microprocessor is capable of working with binary numbers of up to 16 places or bits. That translates to the decimal number 65,536. The Intel 30486 and newer Pentium processors are 32-bit computers, capable of handling binary numbers of up 32 bits or up to the decimal number 4,294,967,296. The little endian attribute of the Intel chip signifies the byte, not bit, ordering sequence. In this case the bytes are reversed, where the high-order byte(s) is stored in a low-order byte location. A big endian processor does not reverse the byte order. It is important to understand that the same value dumped out on two different systems may produce different results.

212.4.4 Reassemble and Boot Suspect System (with Clean Operating System)

The next step in the process is to reassemble the suspect system, using one of the copies of the suspect disk. Place a clean copy of the forensic operating system (usually DOS or Windows) into the floppy drive. Start the boot process and enter the CMOS setup. Check the CMOS to make sure that the boot sequence looks to the floppy drive first, then the hard disk second. This will allow the investigator to boot from the clean operating system diskette. Also, if the system is password protected at the CMOS level, remove and reinstall or short out the CMOS battery. Continue with the boot process and pay particular attention to the boot-up process, looking for a modified BIOS or EPROM.

It is very important to boot from a clean operating system, as the target system utilities may contain a Trojan horse or logic bomb that will do other than what is intended. (e.g., modified command.com—conducting a Delete with the Dir command). The first thing to do once the system is booted is to check the system time. This time, even if not accurate, will give the analyst or investigator a reference for all file times. After the system time is obtained, run a complete systems analysis report. This report should, at a minimum, provide the following:

- System Summary (contains basic system configuration)
- Disk Summary
- Memory Usage w/Task List
- Display Summary
- Printer Summary
- TSR Summary
- DOS Driver Summary
- System Interrupts
- CMOS Summary
- Listing of all environment variables as set by autoexec.bat, config.sys, win.ini, system.ini, etc.

Audit trails can be viewed any time subsequent to the image backup, but before a thorough analysis can be completed, the analyst will need a time reference, which is obtained from booting the suspect system. Check the audit logs for system and account activity. Check with the victim organization to ascertain if the audit logs are used in the normal course of business. The following questions must be asked:

- Is there a corporate security policy on how the logs are to be used? If so, has the policy been followed?
- What steps have been taken to ensure the integrity of the audit trail?
- Has the audit trail been tampered with? If so, when?

212.4.5 Boot Suspect System (with Original Operating System)

The next step in the forensic process is to boot the target system using the original operating system. This is done to see if any rogue programs were left on the system. The analyst should let the system install all background programs (set by autoexec.bat and config.sys). Once this has been done, the analyst should check what programs (including TSRs) are running and what system interrupts have been set. The goal is to learn if there are any Trojan horses or other rogue programs, such as keystroke monitors, activated. Execute some of the basic operating system commands to see if the command.com file has been altered.

212.4.6 Searching Backup Media

Remember that if the data is not on the hard disk, it may be on backup tapes or some other form of backup media. Even if the data was recently deleted from the hard disk, there may be a backup that has all of the original data. Many times a "snapshot" of the system is taken on a weekly or monthly basis and saved in the long-term archives for disaster contingency purposes. Search for PCMCIA flash disks, floppy diskettes, optical disks, Ditto tapes, Zip and Jazz cartridges, Kangaroo drives, or any other form of backup media. Restore and review all data. Many organizations store backups off-site, and although a warrant may be required to obtain the media, do not forget to ascertain if this practice is being done. Before analyzing floppy diskettes, always write-protect the media.

212.4.7 Searching Access Controlled Systems and Encrypted Files

During a search the investigator may be confronted with a system that is secured physically and/or logically. Some physical security devices, such as CPU key locks, prevent only a minor obstacle, whereas other types of physical access control systems may be harder to break.

Logical access control systems may pose a more challenging problem. The analyst may be confronted with a software security program that requires a unique user name and password. Some of these systems can be simply bypassed by entering a Control+c or some other interrupt command. The analyst must be cautious that any of these commands may invoke a Trojan Horse routine that may destroy the contents of the disk. A set of "password cracker" programs should be part of the forensic toolkit. The analyst can always try to contact the publisher of the software program in an effort to gain access. Most security program publishers leave a back door into their systems.

The investigator should look around the suspect's work area for documents that may provide him with a clue to the proper user name/password combination. Check desk drawers, the suspect's Rolodex, acquaintances, friends, etc. It may be possible to compel a suspect to provide access information. It is a good idea to first ask the suspect for his passwor, before going through the process of compelling him to do so. The following cases set precedence for ordering a suspect whose computer is in the possession of law enforcement to divulge password or decryption key:

- *Fisher v. US* (1976), 425 U.S. 391, 48 LED2 39
- *US v. Doe* (1983), 465 U.S. 605, 79 LED2d 552
- *Doe v. US* (1988), 487 U.S. 201, 101 LED2d 184
- *People v. Sanchez* (1994) 24 CA4 1012

The caveat is that the suspect might use this opportunity to command the destruction of potential evidence. The last resort may be that the system needs to be hacked. This can be done as follows:

- Search for passwords written down (it may be part of the evidence collected)
- Try words, names, or numbers that are related to the suspect
- Call the software vendor and request their assistance (some charge for this)
- Try to use password cracking programs that are readily available on the net
- Try a brute-force or dictionary attack

212.5 Legal Proceedings

A brief description of the legal proceedings that occur subsequent to the investigation is necessary so the victim and the investigative team understand the full impact of their decision to prosecute. The post-incident legal proceedings generally result in additional cost to the victim, until the outcome of the case, at which time they may be reimbursed.

212.5.1 Discovery and Protective Orders

Discovery is the process whereby the prosecution provides all investigative reports, information on evidence, list of potential witnesses, any criminal history of witnesses, and any other information except how they are going to present the case to the defense. Any property or data recovered by law enforcement will be subject to discovery if a person is charged with a crime. However, a protective order can limit who has access, who can copy, and the disposition of the certain protected documents. These protective orders allow the victim to protect proprietary or trade secret documents related to a case.

212.5.2 Grand Jury and Preliminary Hearings

If the defendant is held to answer in a preliminary hearing or the grand jury returns an indictment, a trial will be scheduled. If the case goes to trial, interviews with witnesses will be necessary. The victim company may have to assign someone to work as the law enforcement liaison.

212.5.3 The Trial

The trial may not be scheduled for some time based on the backlog of the court that has jurisdiction in the case. Additionally, the civil trial and criminal trial will occur at different times, although much of the investigation can be run in parallel. The following items provide tips on courtroom testimony:

- The prosecutor does not know what the defense attorney will ask.
- Listen to the questions carefully to get the full meaning and to determine that it is not a multiple part or contradictory question.
- Do not answer quickly; give the prosecutor time to object to the defense questions that are inappropriate, confusing, contradictory, or vague.
- If you do not understand the question, ask the defense attorney for an explanation, or answer the question by stating, “I understand your question to be…”
- You cannot give hearsay answers. This generally means that you cannot testify to what someone has told you.
- Do not lose your temper and get angry, as this may affect your credibility.
- You may need to utilize expert witnesses.

212.5.4 Recovery of Damages

To recover the costs of damages, such as reconstructing data, reinstalling an uncontaminated system, repairing a system, or investigating a breach, you can file a civil lawsuit against the suspect in either Superior Court or Small Claims Court.

212.5.5 Post Mortem Review

The purpose of the post mortem review is to analyze the attack and close the security holes that led to the initial breach. In doing so, it may also be necessary to update the corporate security policy.

All organizations should take the necessary security measures to limit their exposure and potential liability. The security policy should include an:

- Incident Response Plan
- Information Dissemination Policy
- Incident Reporting Policy
- Electronic Monitoring Statement
- Audit Trail Policy
- Inclusion of a Warning Banner to:
  — Prohibit unauthorized access
  — Give notice that all electronic communications will be monitored

One final note is that many internal attacks can be avoided by conducting background checks on potential employees and consultants.

212.6 Summary

As you probably gleaned from this chapter, computer crime investigation is more an art than a science. It is a rapidly changing field that requires knowledge in many disciplines. Although it may seem esoteric, most investigations are based on traditional investigative procedures. Planning is integral to a successful investigation. For the internal investigator, an Incident Response Plan should be formulated prior to an attack. The Incident Response Plan will help set the objective of the investigation and will identify each of the steps in the investigative process. For the external investigator, investigative planning may have to happen post-incident. It is also important to realize that no one person will have all the answers and that teamwork is essential. The use of a corporate CERT team is invaluable, but when no team is available, the investigator may have the added responsibility of building a team of specialists.

The investigator's main responsibility is to determine the nature and extent of the system attack. From there, with knowledge of the law and forensics, the investigative team may be able to piece together who committed the crime, how and why the crime was committed, and maybe more importantly, what can be done to minimize the potential for any future attacks. For the near term, convictions will probably be few, but as the law matures and as investigations become more thorough, civil and criminal convictions will increase. In the meantime, it is extremely important that investigations be conducted so as to better understand the seriousness of the attack and the overall impact to business operations.

Finally, to be successful, the computer crime investigator must, at a minimum, have a thorough understanding of the law, the rules of evidence as they relate to computer crime, and computer forensics. With this knowledge, the investigator should be able to adapt to any number of situations involving computer abuse.

213
What Happened?

Kelly J. Kuchta

Envision coming across the dead bodies and the related carnage of a crime scene at night. It is a place of chaos and confusion, smoke, shadows, and debris. Victims wander around dazed and stumble into each other; bystanders and the curious mill around in anxious speculation and anticipation. No one really knows what happened, or even when. They just know that it has happened. The authorities are supposedly on the way. Then suddenly, someone runs up to you and puts you in charge. Why? Because you know the neighborhood.

This sounds like a nightmare and in reality, it is—especially when the crime scene is somewhere in your network and involves your information systems.

I use the crime scene analogy because forensics issues involving information systems are like a crime scene. From decades of watching TV cop shows (or the O.J. trial), most people know that you do not trample over evidence because valuable information and clues about the crime could be inadvertently destroyed or tainted. At the crime scene, we know to check to see whether there is anyone who needs medical assistance and then just pick up the phone and dial 911—thereby letting those who have the requisite training, background, and expertise analyze the crime scene and work it.

What do you do when you find out later that something bad has happened in your network and you need information about an event in the past? If someone in your organization has the appropriate skills, that person will appreciate early notice about the incident and your efforts to leave the crime scene intact.

As emergency personnel will often tell you, the initial decisions made following an incident have the greatest impact on the outcome. Today's information systems usually do not leave many outward signs that something is terribly wrong. Actually, it is the people that using the system who will provide insight into incidents.

With increasing frequency, we are seeing theft of confidential data and other misuse of computers. The best advice I can give people and corporations in handling future incidents is to develop a "behavioral pattern matrix" (see Exhibit 213.1) of personnel security-related events that need closer scrutiny (more on this later) and when in doubt preserve the evidence by removing the hard drive of the victimized computer. Hard drives are inexpensive, and the amount of downtime from pulling a hard drive and installing a new hard drive with your organizations' standard loadset is minimal. The effort to do this can save the organization money and headaches.

Consider the employee who resigns after working in a sensitive area of your business. If anything illegal or unethical has taken place, you will probably not find out about it until 30 to 60 days after the employee has left, if ever. I suggest saving the hard drives from laptops or desktops of resigned and terminated employees for a minimum of 60 to 90 days and longer if possible. At the end of this period of time, cleanse the disk and put it back into production. Why? Because once the hard drive and the residing data is reformatted and placed back into circulation, the chances of recovering any usable information from

EXHIBIT 213.1 Sample of Behavioral Matrix

Employee	Risk Score **Yes = 1 No = 0**	Weight 100 (percent)	Weighted Score
Did the employee work with sensitive information?	1	5	0.05
Was the separation hostile?	0	20	0
Did the employee go to work for a competitor?	1	20	0.2
Could the employee have been involved in any unexplained events?	0	5	0
Was the separation unexpected?	0	10	0
Is there a chance that the employee's actions might be involved in litigation?	0	25	0
Has the entity been the target of intelligence gathering?	1	15	0.15
Evidence preservation score			40 percent

Guidelines for evidence preservation

0 to 24 percent no apparent need to preserve evidence
25 to 49 percent good reason to preserve evidence
>49 percent strong reason to preserve evidence
This is a sample behavioral matrix you can customize to your needs.

that hard drive for forensic analysis will be next to impossible and limited by the amount of time and money you have to spend.

In most instances when evidence is tainted, it is through ignorance, not through intentional acts of deception. I have witnessed corporations and individuals who attempt to use their investigative skills after an incident by having the system administrator look for clues or evidence. In one case, they were able to find incriminating data; however, after finding the information, they opened the file and copied it to a floppy disk. This action modified the key dates and contaminated the electronic evidence, preventing its use in a court of law.

Computer forensic professionals view the system dates as vital pieces of information. Created, last written, and last access dates are used to establish a chain of events that give important insight into what happened in the past. Computer forensics methodology dictates that computer forensics professionals must not change any piece of evidence, including the dates. When reviewing the data on a suspected system, great lengths are taken to prevent the operating system from writing to the hard drive. Even if you are not a computer forensics professional, you owe your organization the opportunity to fight back by preserving the original evidence.

When a computer is started, right away the operating system changes or modifies a large number of file dates on the system. The actual number of files may vary depending on what type of system, anti-virus applications, or network protocols the organization is using. A typical Windows 98 machine will have over 12,000 files loaded on it. During the start-up process, hundreds of these files may be changed during the POST (power on self test) process. If the anti-virus application is set to inoculate any viruses found, having the malicious code removed will modify the file. This process will change the last access and last written dates.

To keep as many options available as possible, consider setting the hard drives aside for a reasonable amount of time. If you think that putting each hard drive in a probationary period will not work because of the potential expense, consider doing it on a limited basis. Earlier I mentioned developing a behavioral pattern matrix for exiting employees who might give you reason to preserve their hard drives. The objective is to find predictors that would indicate the future need to review the hard drive of the computer.

My experience has shown that human behavior is a key predictor that must be considered at a digital crime scene. Each organization will experience different behaviors that constitute a warning. Each organization will need to develop its own behavior pattern that fits its culture. In this case, past events can be good indicators of future events. The sources of information to consider should come from human resources, corporate investigations, information security, as well as the legal department and the business units themselves.

Some factors that might weigh into your behavioral pattern matrix are as follows: Did the employee work with sensitive data? Was the resignation a surprise? Is the termination likely to result in legal proceedings? Is the employee going to work for a competitor? Have there been any events that are of concern to the organization in which the employee might have been involved? Was the employee vague about why he or she was leaving? The answer "yes" to any of these questions should trigger at least considering saving the hard drive for a reasonable period of time.

I often hear, "I knew there was something suspicious about the person!" when working on employee or former employee issues. There are other signs that are frequently overlooked, but by considering all the facts, organizations realize in retrospect that they missed the warning signs. The warnings are generally spread out over multiple areas, such as human resources, corporate investigations, business units, and information security.

Human resources and the business units hold the keys about the behavior of the individual and the possible reason for the departure of the employee. Corporate investigations might be able to provide insight on external events and intelligence information. This could include events under investigation but not publicly known, attempts by competitors to gain proprietary information, and other possible related matters. Information security might have some information about suspicious behavior the individual demonstrated recently. Examples of suspicious behavior could be linked to attempting access to restricted information, copying large amount of data, allegations of technology misuse, or browsing suspicious Internet sites.

The best process I have witnessed was to have the human resources personnel in charge of the employee exit process give notice to the three groups listed previously. They should give each group a reasonable amount of time to respond that they would like the hard drive held for the proscribed period of time or want immediate analysis relating to a specific event. Of course, Human Rresources personnel might make this request themselves based on their information.

Do not forget the importance of having an "acceptable use" policy to guide new employees. As exiting employees are getting ready to turn in their PCs, they should be instructed on what they can or cannot do. Depending on business needs and culture, you might establish a policy that restricts the employee's ability to use wipe utilities (especially nonstandard products) or other products that could sabotage forensics results. Although this is a difficult subject to deal with in corporate America, it is vitally important. On more than one occasion, I have seen cases in which a mildly disgruntled employee deliberately erased valuable client information and used a wipe utility to make the information unrecoverable. You should make a conscious decision about this issue, even if it is to have no policy on this issue!

To develop a process that is customized to your organization, consider getting input from the above-named individuals and your legal counsel. If the employee is part of a unionized labor force, special rules may apply. There may also be special considerations based on state law or if the organization fulfills government contracts. The preserved evidence is probably discoverable with a subpoena. Your legal counsel can help you determine what legal requirements you need to adhere to.

Assume that you have adopted a process similar to the one outlined. The organization has made the decision to preserve a hard drive. How do you go about it? The major concerns are establishing a chain of custody, documenting specific details, and securing the hard drive. Each of these areas is vitally important if there is a chance that the electronic evidence you have preserved will be presented in a court of law.

You must establish a chain of custody to prove authentication and refute allegations of evidence tampering. Many defense attorneys have successfully argued that if you cannot prove that the evidence has been under your control, you cannot prove that it has not been changed or modified to construct the incriminating evidence. To establish the chain of custody, you must document possession from the point of acquiring it until the matter is resolved. This includes an appeals process through the court system.

Part of the documentation process will be to identify as many details about the original PC that the evidence came from as possible. This is important because an analysis completed later will go much smoother if a few key pieces of information are known. You should document the following:

- What types of operating system are on the hard drive?
- What are other systems specifications (RAM, SCSI, or IDE; processor type)?
- Are any partitions likely to be found?
- What applications are known to be on the hard drive?
- What, if any, encryption was used?
- Is there a list of any known passwords, keys, or certificates?
- To what systems did the owner of the hard drive have access?
- What type of system did the hard drive come from (manufacturer, model)?
- Is there a history of hardware problems, including any maintenance logs?

Having the answers to these questions will make the forensics analysis a much faster and efficient process.

A master log should accompany the evidence from the time it is acquired. It should include date and time, a detailed description of the evidence, and who seized the evidence. The log should also include a transfer-of-custody section, which should include reason for transfer, method (hand-delivered or courier), released by and date (signature and date of person transferring custody), and received by and date (signature and date of person taking custody). People listed as having custody of the evidence will need to demonstrate that the evidence was under their control and secured to prevent tampering.

A secured location is a lockable container that has limited access. It can be a file cabinet with locks, a safe, an evidence locker, or even a room with a lock. The best possible scenario is to have only one person with access to the evidence. If that is not possible, the evidence must be stored in a limited area and everyone with access to the area should be documented. The more persons with access to evidence will mean more people testifying that they did not modify the evidence. It is easier to provide a lockable container with single access than one with multiple access. If you will be securing evidence on a regular basis, consider purchasing an evidence locker. Your evidence locker should also include a master log of evidence it holds. When evidence is stored, it should be logged in. Each time it is removed, custody should be transferred out to the individual removing it. The design of the log outlined above can also be utilized here. The purpose of this log is to document each and every time the evidence locker is accessed as well as to provide supporting documentation about particular evidence.

If it is necessary to send evidence to another location, I recommend using a courier service that can provide documentation of its custody. This should include tracking forms and numbers. Most of the traditional delivery services provide this service. The senders should seal the package themselves and the recipients observe that the package has not been breached. For additional protection, it is suggested that the evidence is sealed in a container so that the recipient can attest that the document has not been tampered with. Reasonable steps should be taken to protect the evidence during shipping. The evidence will do little good if it has been damaged.

Taking these steps will increase the odds of determining what happened in the past. Understanding history to change the future is the ultimate goal. To understand the history we must have good information. To preserve information, you do not need to be a computer forensics professional—just understand the process and why it is important. Also, practice techniques that will work for your company and be prepared to have good information on "what happened."

214

Potential Cyber Terrorist Attacks

Chris Hare

Ask any fiction writer about their next novel and you will find any number of events engineered by known terrorist organizations or groups of people banded together to achieve a common goal. Terrorists use violence to achieve a purpose, often of a political nature. Common methods of achieving their goal include bombings, kidnappings, and assassinations to perpetrate their particular brand of terror.

The list of movies and novels depicting terrorist or potential terrorist events is almost endless. Some of them are mentioned in this chapter, and many more are not. The specific concern, however, is Hollywood's almost unlimited imagination and budget. If anyone can think it, they can. With advances in technology, they can show it happening as well. This, however, could be used as an example of a specific attack, with some ideas on how to do it.

This chapter looks at a number of potential terrorist attacks examining the impact to the national economy, public confidence, loss of life, etc. There are countless papers written by specialists in many of these fields describing in infinitesimal detail how specific attacks would be carried out and how to protect the infrastructure against them. Those studies in industrial or national security should be examined for specific concerns.

214.1 Introduction to Cyberterrorism

Although cyber threats are a major concern, many successful attacks will require elements of physical or human access as well as cyber attacks to gain control over elements in today's society. Admittedly, some aspects of our society are so over-controlled by automated data and decision systems that they could be compromised by cyber-attack methods alone. However, some systems, such as those in highly secured areas or to which there is no external access can still be compromised by putting a human into a position where they have access to those systems.

That being said, the term *cyberterrorism* means something different to every reader. Such is part of the current problem in the information security field. The lack of a cohesive and agreed upon definition makes understanding cyberterrorism difficult and blurs the line between what is and what is not cyberterror. The lack of agreement on the definition means protection measures are subjective at best, based upon both the defender's definition and skill, and the specific business their organization is involved in.

Dorothy Denning's testimony to the Special Oversight Panel on Terrorism of the U.S. House of Representatives could be considered one of the most cited works on cyberterrorism. Consider the following from Ms. Denning's testimony:

> Cyberterrorism is the convergence of terrorism and cyberspace. It is generally understood to mean unlawful attacks and threats of attack against computers, networks, and the information stored therein when done to intimidate or coerce a government or its people in furtherance of political or social objectives. Further, to qualify as cyberterrorism, an attack should result in violence against persons or property, or at least cause enough harm to generate fear. Attacks that lead to death or bodily injury, explosions, plane crashes, water contamination, or severe economic loss would be examples. Serious attacks against critical infrastructures could be acts of cyberterrorism, depending on their impact. Attacks that disrupt nonessential services or that are mainly a costly nuisance would not. (Denning 2000)

Interestingly, in a subject given such wide media coverage that is the basis for many hypotheses, there is a limited amount of relatively useful statistics regarding cyberterrorism. This lack of cyberterrorism statistics may only suggest that there has not been an event everyone could agree was cyberterrorism. Of course, correcting the currently vague definition may suddenly reap large amounts of data as people realize previously considered innocuous attacks met the cyberterrorism criteria.

With a possible, but highly defensible, definition for cyberterrorism in place, our discussion can now examine some of the possible cyberterrorism scenarios facing our society today. Additionally, the chapter also discusses some concerns or defensive actions for each of the scenarios.

214.2 Air Traffic Control

The mass movement of people and goods using air travel is critical to our global economy. Without the benefits of air travel, notably speed and ease of movement, people and corporations would have to rely upon shipping, rail, and trucking systems as the primary methods of moving themselves and their business products.

In the interest of creating stimulated competition, the deregulation of airlines in 1978 led to the bankruptcies of several major airline carriers during the 1980s, most notably Pan American, Eastern, and Continental (Continental was the only one to survive of these three, although they are still experiencing financial problems; there have been 22 airline bankruptcies). Consequently, the airline transportation market is highly volatile and fragile, with many companies experiencing massive and continuing losses since September 11, 2001. The impact of the deregulation bankruptcies is important to the cyberterrorism view as there are also fewer airlines as targets. Crippling any of the major airlines would also have a devastating impact as passengers and freight were lost, moved to other carriers, or simply left on their own to find new transportation.

The tragic events of September 11, 2001 impacted air travel forever through increased security procedures and shaken consumer confidence in an already fragile market. Increases in crashes or accidents would impact this fragile market further. Consequently, terrorist activities in this arena could have a significant impact on the global economy.

Although similar events to the hijackings on September 11, 2001, are possible and plausible even with the heightened security procedures, efforts to compromise the national air traffic control system could have a devastating effect, even if no lives were lost in the process. A disruption in air traffic control could impact global air traffic movement and further impact the financial viability of the industry as a whole. Loss of the air traffic industry would significantly affect the American economy.

Affecting air traffic control systems is not a new idea. It has been a major element in various books and films, such as the 1990 film *Die Hard 2*. The premise of the movie was the takeover of an airport and its air traffic control systems to achieve the goal of “rescuing” a criminal being extradited to the United States. During the movie, the terrorists altered the air traffic control systems and caused an aircraft to crash. As the control of the airport was lost, all other traffic either destined for the closed airport or traveling through its airspace had to be re-routed.

Everyone has experienced flight delays of one kind or another due to mechanical problems, crew shortages, weather, etc. The impact of an airport outage is significant and can create delays of many hours. With 71 major airports in the United States and countless smaller ones, the impact due to air traffic control changes is significant. The Federal Aviation Administration Air Traffic Control System Command Center provides publicly available information on air traffic control status, delays, re-routes, etc.

The likelihood of the air traffic control system being shutdown without inside help is reasonably remote: “cybersecurity experts give some of their highest marks to the Federal Aviation Authority, which separates its administrative and air traffic control systems” (Weimann 2005). This only means the cyberterrorists must find a way to have access to the air traffic control systems and the ability to bypass data security controls. This is not unheard of, although it would likely take several or more people to accomplish. The often “unlimited” funding terrorists have could make employees targets for collusion.

Currently, however, air travel is still one of the safest means of moving from one destination to another. Another threat is economic. The cost of purchasing the transportation tickets is borne by the passenger through the country’s financial systems. The ability of the airlines to buy gas, the government to pay the air traffic controllers, and ultimately the passenger to purchase a ticket would all be affected by a financial systems attack.

214.2.1 Defending the System

As noted, the Federal Aviation Administration has taken significant steps to protect the air traffic control infrastructure from possible attack. Significant changes to flight rules, regulations, and aircraft has resulted in enhanced security onboard the aircraft. Security personnel should evaluate the background and security screening processes to verify supplied information and reduce the possibility of an airport employee being influenced by undesirable forces into providing system or physical access. Ongoing system audits and a continuous monitoring processes should be implemented to ensure established procedures are followed and process bypasses are identified quickly and reviewed, regardless of the reason. Process changes, personnel training or additional technology enhancements to address deficiencies should be quickly implemented once identified and approved.

214.3 Stock Market and Financial Markets

The phrase “money makes the world go “round” is something every person on the planet can relate to. “There is never enough of it” is another adage most consumers can relate to as well. Much of what we refer to in our economy is driven by forces outside the control of the majority: the stock market.

The stock market crash of 1929 ushered in the Great Depression and had lasting effects upon the American economy. However, the stock market crash of 1987 was actually worse in many respects than 1929. An article in the Wall Street Journal on October 7, 1987 stated “Stocks Plunge; Interest Rate Fears, Computerized Sell Programs Cited.”

Reliance upon technology in the stock markets in 1987 was relatively high, only to be surpassed by the electronic trading systems used today. The trading system networks, applications, and systems used are highly protected secrets, but a terrorist foray into the stock market could have disastrous effects by devaluating the entire market, or picking selected companies and stocks to impact. The latter could be used in extortion attempts to control the market capitalization of a company based purely upon the electronic manipulation of the stock price. Targeting specific companies and causing significant drops in their stock prices could affect the economy overall or be limited to a specific industry and/or company. This type of approach could be used to “edge out the competition.”

The stock market crash of 1987 was partially influenced by fears of rising interest rates, further demonstrating the speculative and emotional aspect to trading. However, the converse can also be true: as stock markets fall, interest rates can go up, forcing action from financial groups such as the United States Federal Reserve to control the money supply. If the money supply drops, interest rates go up, inflation rises, and the economy suffers.

As the economy suffers, consumers lose confidence in their elected officials such as the president of the United States. If this was to occur during a presidential election campaign, it is feasible to consider a significant impact and change in voter turnout and how they cast their ballots. Consequently, terrorists could affect not only the economy, raise inflation and interest rates, and increase unemployment, but they could also affect the political landscape as well.

Impacts to the market and resulting fluctuations in currency prices mean changes to national and international demand. Consumers will buy fewer goods if prices go up because they will have less cash to spend. They will borrow more and interest rates will go up. Inflation rises. Imports drop because the lower currency values relative to other countries make the imports more expensive. Exports rise because they are cheaper due to the lower currency values. However, since the price is lower, profits are lower or virtually nonexistent. This again affects the economy. Consequently, terrorist controlled changes or manipulations of the entire market or specific pieces of it would undermine consumer confidence in the market, negatively affect the economy and possibly alter the political landscape.

With that basic understanding of economics, it is easier to see why a terrorist cell would target financial institutions. Using computer technologies, the cyberterrorists could finance their operations through petty thefts, until they had everything in place to “take down” the financial systems. Financial trading could be blocked, companies taken out of business, or government finances disrupted as to prevent the acquisition or operation of part of or a portion of the government. One of the most attacked departments in any government is the military or defense department.

214.3.1 Defending the Financial Infrastructure

Ongoing legislative changes and directives from the Federal Reserve Bank or the Office of the Comptroller of the Currency in the U.S. Department of the Treasury helps regulate the banking industry to maintain its operation and safeguard its assets. Likewise, the Securities and Exchange Commission provides similar guidance for the U.S.-based stock exchanges. However, one of the most important safeguards is implementation of the evaluation and monitoring controls established by the Committee of Sponsoring Organizations of the Treadway Commission (COSO). While more applicable to an audit role, organizational implementation of the COSO objectives can strengthen the organizational processes, technology implementations, and information security.

214.4 Military Command and Control

Assuming control of one of the most offensive public organizations, the military, unleashes many possibilities from a terrorist perspective. Most people would consider attacks against the military communications, command, and control (C3) systems as beyond the reach of terrorist organizations. September 11, 2001 changed that view with the attack against the Pentagon. Aside from the loss of life, systems and services provided by Pentagon staff were disrupted. These disruptions can prevent orders from being communicated between commanding authorities and the individual units deployed in the various operational theatres.

Terrorists could launch specific cyber attacks to disrupt military communications or attempt to take control of automated data systems including missile targeting, guidance systems, fleet, and personnel locations. For example, knowing the precise location of a group of troops and being able to direct them into a potentially dangerous area through seemingly legitimate orders could increase the number of military casualties.

Movies such as *War Games* pose different possibilities. The premise of *War Games* was a youthful hacker finding his way into a Department of Defense computer and initiating a simulation perceived by the command authority as real. The 1992 movie *Under Siege* saw the U.S.S. Missouri attacked and taken control of by a group of terrorists to steal and sell nuclear weapons while the battleship was on her final voyage back to harbor for decommissioning.

The 1987 movie *No Way Out* demonstrated how through time and careful planning, the military could be infiltrated, intelligence could be gathered, and positions of command could be gained. Embarking upon this type of terrorist activity would take many years, but patience and time is something the enemy has a lot of. Assuming command authority allows for decisions to move troops, equipment, and other resources into areas where targeted hostilities could be launched and valuable equipment could be acquired by the terrorists.

In today’s environment, given our dependence upon technology from a defensive posture, a terrorist could obtain employment on sensitive military projects and embed logic bombs or trap doors into software, allowing later access or the control of specific systems.

Almost every military system in use today depends upon some form of technology—smart bombs, radar, radio, encryption, satellite communications, imaging, range finders, tanks, ships, etc.; all depend upon software and critical systems to operate correctly. Given the wide range and use of subcontractors in the software development world, a cyberterrorist organization could hire themselves out as software developers and build entire systems.

The latter idea was the premise for the 1995 movie *Under Siege 2: Dark Territory*, where the lead developer of a joint military and CIA project faked his own death and took control of an offensive satellite. The satellite was then used for his personal financial gain. In the end, the bad guy lost. However, fiction often has a strange way of becoming reality in many facets of our history.

Military and defense systems wield enormous power whether they are in the hands of the “good guys” or the “bad guys.” These weapons that are often portable can inflict a massive amount of damage, whether it be fear or the actual loss of life. However, the majority of these weapons pale in comparison to the awesome power of nuclear energy.

214.4.1 Safeguarding National Defense

The military often comes under fire, both figuratively and literally. The U.S. Department of Defense currently has programs underway to identify unused application and system access and remove those accounts. Although many organizations do that today, attempting to efficiently manage such a task can be daunting for large organizations. Many systems are breached using unused accounts; therefore, disabling and removing these accounts in a timely and efficient fashion can reduce the likelihood of a compromise through this manner. Likewise, military systems are complex by nature, making them complex to secure and monitor. Consequently, improved design and development processes should be considered to not only build security in from the "ground up," but to also test, validate, and re-validate the expected operation of these security capabilities from design to implementation and beyond. Organizations who provide services to the military should be implementing security procedures that are as good if not better, to reduce the possibility of a compromise through their trusted networks, information systems, processes, or people.

214.5 Nuclear Power Supervisory Systems

An attempt to take control of or cause damage to a nuclear power plant would likely need more than a little bit of cyber attack effort, but not much. The enormity of the situation must be considered when considering the safety and security of people everywhere. The (Three Mile Island Alert 2004) Website describes the threat to a nuclear plant this way:

> Considering the fact that a nuclear plant houses more than a thousand times the radiation as released in an atomic bomb blast, the magnitude of a single attack could reach beyond 100,000 deaths and the immediate loss of tens of billions of dollars. The land and properties destroyed (your insurance won't cover nuclear disasters) would remain useless for decades and would become a stark monument reminding the world of the terrorists' ideology. With more than 100 reactors in the United States alone, if one is successfully destroyed, just threatening additional attacks could instill the sort of high impact terror which is being sought by a new breed of terrorists.

From a cyber attack perspective, the obvious targets include systems controlling the reactor and reactor safety systems. The potential outcomes could include damage to the radioactive cores and the release of radioactive gases; or the leakage of deuterium, or heavy water, from the coolant systems into the sewer or water systems; or the shutdown of the plant or damage to the electrical grids the plant services. In any of these examples, the effects include widespread power outages, and potential loss of life from radiation poisoning.

If we consider the power outages alone from a massive blackout and not a nuclear "meltdown," the cost of recovery very quickly scales into the billions of dollars. Each affected business cannot adequately service its customers and, therefore, loses sales. Those same businesses do not buy from their suppliers, in turn affecting revenues. Bills cannot be paid on time; employees are not working and, therefore, not being paid. Consumers cannot buy the products they need to survive, including water, food, and gas. The basic necessities we take for granted are affected. The massive power failure in 2003 and the northeast ice storm in 1998 showed the leaders of our country the impact of massive power outages. The impact to other critical infrastructures is quickly felt, including transportation, healthcare, and financial systems.

Of course, terrorists could also use events resulting from a nuclear accident as propaganda and force the government to shut off the reactor, or plant the negative seed in the population and then, before the government can turn it off, the terrorists cause even a small accident to prove the point. This type of event would undermine the existing government.

The nuclear accident or even simply massive power outages poses significant burdens on other infrastructure systems. While not cyberterrorism related, Hurricanes Katrina and Rita quickly demonstrated to the rest of the world how quickly otherwise adequate systems are overloaded and/or destroyed.

214.5.1 Preventing Nuclear Disaster

The prevention of nuclear disasters is on the forefront of everyone's mind, both from a citizen's perspective and from the perspective of those working in a nuclear facility. As seen in this chapter and the wealth of online material, many security incidents involving nuclear power plants are a result of ineffective physical security. “Guns, guards, and dogs” cost money, although improvements in video surveillance (including IP-based video) can enhance the physical infrastructure. Some possible improvements could include motion-sensitive lighting and cameras, reduced-light cameras for subtle or covert monitoring of exterior areas, and improved lighting in general. The physical side is clearly insufficient to do the job on its own. All employees should undergo periodic retraining to remind them of their security obligations, not to prop exterior doors open and to challenge people or vehicles they do not recognize.

214.6 Transportation Systems

Millions of people use transportation systems every day, including air, ship, rail, bus, car, and truck. Millions of pounds of product move across the country each week to meet the needs of the market. Affecting one or more of these transportation systems can have a significant impact on the economy.

Earlier in the chapter, the impact of affecting air traffic control and the resulting effects on air travel were discussed. Disabling the air traffic systems will put a larger strain on the other transportation systems to try and make up for the lack of air travel. A coordinated move against air travel and rail, for example, could almost cripple the cargo-carrying capabilities in the U.S.

However, terrorists could use more local methods. The 2003 remake of *The Italian Job* showed the cyber attack against the Los Angeles transportation department. The objective was to seize control of the traffic signals on a given route to enable the getaway of the thieves. The same premise could apply to terrorists planting a bomb or undertaking some other crime against the people of the city. Even if no crime is perpetrated, the impact of improperly operating traffic signals in the downtown of any major city would quickly reach disastrous proportions.

Continuing this theme, terrorists could lockup the traffic signal systems and then create a massive secondary event targeted at the heavily populated and traffic-flow-restricted area to maximize the devastation involved. Alternatively, they could simply lock the traffic signals in a pattern to create maximum gridlock and leave it there, possibly even preventing authorities from being able to correct the system -level problem. On its own, this type of “prank” does not fall within Denning’s definition of cyberterrorism. However, with the addition of a bomb or some other event to inflict fear or real injury, the issue becomes a cyberterrorist attack.

An alternate transportation system attack is against the natural gas and refined oil product pipelines. Monitored by sensors and computers, the flow of product at any given point can be measured and changes made across the pipeline to maintain pressure and proper flow rates. Cyber attacks against these control systems could result in decreased or terminated flow of these critical products, or remotely opened valves resulting in massive spills. Along with the breach of the information systems comes the massive clean-up required, and risk to both human and animal life, fire, and damage to environmental habitats and water systems. The effect is massive, as seen in the Exxon Valdez disaster.

However, Hurricane Katrina in 2005 demonstrated the devastating effect of a pipeline breach or loss of physical infrastructure. Although not cyberterrorism related, the hurricane’s damage illustrated the possible effects of a cyberterrorism attack large enough to devastate a city. The hurricane events in 2005 demonstrated one of the critical lessons also learned during the World Trade Center attacks in 2001: the fragility of the national communications infrastructure.

214.6.1 Keeping Things Moving

The fragility of the transportation infrastructure and its massive size makes it difficult to effectively protect. There will never be enough police officers, cameras, security personnel, dogs or related technology to do it effectively. Each individual transportation system will have to undergo its own analysis of the threats for their specific service and determine how to best mitigate those threats. However, changes to the availability of short- or long-term lockers in bus terminals, airports, railways, etc., and the efficient monitoring for unclaimed items and their speedy removal by qualified personnel can help reduce the possibility of bombs being placed in those facilities. Likewise, access to restricted areas should be more closely scrutinized. Finally, access systems to restricted areas should be granted using unique access codes to identify the person who last opened the door. This sounds simple, but in practice can be extremely complicated. For example, airline pilots need to open jet way access doors for every airport they fly through or someone has to be there to open the door. The problem is not insurmountable, it just needs the design, funding and implementation of a national transportation security infrastructure.

214.7 National Communications Infrastructure

Another important element in our daily lives is the national communications infrastructure, including traditional telephony, wireless/cellular phones, the Internet, satellite communications, and broadcast services such as radio and television. Being able to cripple a significant part of the communications infrastructure could prevent safety information and evacuation notices from reaching people in danger. Other examples include safety services not being able to get information about injured people, or not being able to retrieve information about hostile subjects.

Additionally, many of the infrastructure elements discussed in this paper rely heavily upon communications systems including telephone, radio, and data. Financial and other commercial information carried on the Internet have made this resource critical to daily life. The original Internet was designed to maintain operation even if a significant part of it was disconnected. Considering the impact of outages today's users experience, the level of redundancy and operability could be questioned. In fact, one could probably argue the Internet has become the single biggest communications infrastructure and its ability to "self-heal" is negligible compared to 30 years ago during its inception.

For example, should attackers exploit commonly known vulnerabilities in specific types of hardware on the Internet, it could be possible to restrict, alter, or prevent communications. Rerouting of traffic from one destination to another, preventing the traffic from reaching its destination, or simply disconnecting massive parts of the network are examples of other attacks. For the most part, however, people could exist without Internet communications for some period of time—at least from a personal aspect. Business and commercial interests could be significantly impacted, however.

Other potential areas of concern include emergency services such as 911 and call routing to the appropriate public safety access point. An attacker could gain access to public safety access point data and change location information, thereby routing emergency calls to some other location, making it impossible to obtain emergency services. The result would be a high level of fear on the part of the citizens about their ability to obtain help when needed. Instead of rerouting the telephone call to an incorrect call handling center, the attacker could alter the telephone database used to reverse lookup the address from the phone number. If the address data is incorrect, help will not be sent to the correct location.

Other potential problem areas are disrupting emergency services radio traffic. Although regulated by the Federal Communications Commission in the United States, the radio frequencies for most police, fire, ambulance, and other emergency service departments can be easily retrieved from the Internet. By launching a disaster, or even the threat of disaster, and then crippling the radio communications systems or creating fake "calls" in the automated systems or disrupting the actual radio signals, the system can easily become overloaded. With the commonly seen lack of communications ability between government departments such as police and fire, the problem is not easily addressed. Crippling these systems can be done in ways that are not easily found or corrected.

Finally, cyber attacks could be used to change the input signal to broadcast radio and television sources. For example, using radio and satellite technologies, the attackers could assume control of the transmitters and send their own propaganda or message to the listeners and viewers. Likewise, newspaper and magazine systems could be compromised and stories intended to incite the population, provide propaganda or instruct other terrorist cells to proceed with their plans could be distributed. For example, if a massive disaster occurred, and then a broadcast communication was interrupted with further propaganda, it would likely create a significant level of fear in the general public.

The general public, business, and government depend upon the services provided by the public utilities. Without those capabilities, the communications infrastructure as discussed has a defined operational lifetime.

214.7.1 Keeping the Data Moving

The national communications infrastructure is reasonably resilient. Most failures happen on a small scale, just as no phone or cable service to a specific geographic area. Voice communication systems, just as telephony, are highly resilient. Most people are aware the phone system typically keeps operating in a severe storm long after the power fails. Service providers need to expand their protection and monitoring capabilities. However, the general population needs a higher level of understanding regarding the impact of flooding emergency services and specific geographical areas during an event. Many wireless and landline circuits were tied up across the country from people trying to reach family or loved ones in the hurricane affected areas. This affected relief communications which needed the use of those available circuits. Efforts are underway on local and national levels to improve the radio systems used by emergency services personnel and facilitate joint operations. Finally, like the transportation infrastructure, communications will be not only hard to effectively protect, but at the time difficult to effectively impact except on a specific geographical scale.

214.8 Public Utilities

The notion of "public utilities" brings to mind things like electricity, natural gas, telephone service, water, and sewer. Each of these services relies upon information systems for financial services. Telephone companies use computers to complete the phone calls and voice mail. Kevin Mitnick was renowned for using social engineering techniques to gain the information required to access telephone systems. Numerous companies have experienced toll fraud or other problems at various times.

Electricity and natural gas are important elements for providing light and heat to the nation's citizens. In the context of a city, however, the use of computer systems to control and regulate the electricity and gas flow is relatively small.

One public utility is especially vulnerable and can pose significant health risks to the population: water and sewer. Automated systems are used to deliver chlorine, fluoride, and other chemicals and manage sewage and water treatment plants. Attacks altering those automated systems could result in too much or not enough of those chemicals. For example, fluoride is added to our drinking water. The use of fluoride in water and dental products is generally considered a good thing.

Fluorine and fluoride are poisonous, toxic substances of their own right. Consequently, widespread illness and death could be perpetrated by terrorists by compromising the automated chemical delivery systems and increasing the fluorine levels. Incidentally, longer-term poisoning could be accomplished by compromising systems at toothpaste manufacturing sites. Because many people cook their food in fluoridated water, which increases the concentrations of fluoride in the cooked food, any significant increase in the fluoride levels could have disastrous effects.

The most significant part is people will not just be dropping dead. They will suffer from fluoride-related illnesses for years, increasing fear and the burden upon private health insurance companies and the government. Consequently, cyberterrorists could defeat controls used to monitor and adjust the release of these chemicals. At the point where people start becoming ill or dying due to chemical imbalances in the water system, the group would come forward.

The other system is sewage. Raw sewage is a breeding ground for bacteria, especially *E. coli*. This highly potent bacteria, commonly found in the intestines of humans and animals, most commonly occurs in undercooked beef, although infections from improperly treated drinking water would not be uncommon in a failed or tampered sewage treatment facility. Due to the public stigma involving sewage, a cyberattack against a sewage treatment plant would likely reach highly visible proportions.

As the sewage treatment plants are commonly operated by municipal governments, attacks against specific facilities such as sewer and water could likely involve attacks against other government services as well.

214.8.1 Keeping it Clean

The problems of water and sewage systems were keenly evident during Hurricane Katrina and the relief efforts. The lessons learned from that single event will result in thousands of programs and improvements for many years. It also identified how quickly a populated area could be plunged into medieval times where sewage was literally dropped in the street. Physical and environmental engineers will play key roles in planning defenses for systems where the health of the population, including the probable contamination of food supplies. Likewise, systems used to monitor, manage, and respond automatically to changes in water pollutants, chlorination, etc. should all undergo regular testing for proper operation. Additionally, the monitoring and detection of pollutants outside the normal ranges should be immediately reported and investigated before allowing the automated system to respond, thereby possibly preventing the release of unsafe levels of normal chemicals into the treatment systems and the environment.

214.9 Government Services

National, state, county, and city governments provide a multitude of services to their citizens and to each other. Unfortunately, the breadth of services they provide means they are targets for both hackers and terrorists alike.

Various government services providing financial support, such as the Social Security Administration, could be attacked by terrorists and false recipients added to the database and money collected from the federal government. These funds could then be used to help finance the terrorist activities. This same approach could be used to obtain grants from the federal and state governments. The theft of or fraudulent use of Social Security numbers is not unknown; indeed, many criminals use previously issued Social Security numbers from deceased individuals to acquire new identities. Other attacks against the Social Security Administration include removing people from eligibility, thereby creating mass panic about income sources, putting significant strain on the government department and jeopardizing the health and welfare of the public.

Additionally, department Web sites could be attacked and terrorist propaganda inserted on the Web sites or into documents citizens download. This is nothing new and frequently in the news when any U.S. government department has their Web site hacked. Although more of a nuisance than cyberterrorism on its own, the occurrence of these events is not without effect. These events create a lack of trust in the government's ability to protect its own information and, therefore, calls into question the government's ability to protect the citizens' information.

Other departments terrorists could impact include the Internal Revenue Service, where information regarding taxpayer data, refund amounts, and direct deposit information for taxpayer refunds could be corrupted. Additionally, ingenious programmers could insert code into the IRS computers to automatically add $10 to every taxpayers return and divert that money into a special fund for the terrorist cell. This money would then be used to acquire weapons and other tools to inflict attacks against the population.

Alternatively, cyberterrorists could cause the IRS to launch audits at a much higher than normal number of citizens, or target specific groups and launch audits. They could also just arbitrarily adjust the calculated tax owing and launch an audit, issue an order for the seizure of funds and property, etc. The IRS is already one of the U.S. Government's most feared agencies, and a little extra press would only increase the general public's fear.

Any of the government branches with strategies regarding homeland security, defense, or financial services are all targets due to the type of information and opportunity to manipulate it to satisfy terrorist objectives. Among other infrastructures that feel the heat during and after an event are doctors, hospitals, and other medical services.

214.9.1 Keeping the Country Running

The government has a particularly difficult challenge due to the number of systems and networks and the vast amount of information on individuals, businesses, other governments, etc. Government agencies exist to enact and enforce the will of the elected government. These groups need to be providing leadership and direction for the rest of us on what we need to do to achieve compliance and make it easier for law enforcement to protect us and catch the bad guys. Each government agency will have its own challenges, but attention should be paid to updating and retiring legacy systems to take advantage of new processors and updated, more secure code. Additional effort should be focused on understanding where the application programs and program code for government application was written. Using an application in the Secret Service or Diplomatic Corps that was written by a terrorist cell or a potentially unfriendly government could spell disaster.

214.10 Hospitals and Health Care

Hospitals today use information systems for a wide range of services from patient charts, to pharmacy records, to patient monitoring. Tampering with one or more of these services could have disastrous effects on the healthcare provided to the patient. In fairness, we also have to be fairly liberal about what constitutes an information system in a hospital. Many hospitals have not yet fully deployed computers for all aspects of their systems. In some cases, it is not immediately practical.

One example of how a terrorist could alter patient care is illustrated in the 1993 movie *The Fugitive*. In this film, Harrison Ford's character changes the patient diagnosis and instructions before taking a young boy to surgery. Although this is not an example of a terrorist activity, a terrorist could alter patient diagnosis information, altering drugs and required treatments to ultimately harm the patient or discredit the hospital.

Another example is using cyberterrorism to launch an outbreak of a specific disease by causing the release of ineffective or contaminated vaccine from a pharmaceutical company. After the vaccine is released and patients start getting sick, the cyberterrorists become aware of patient diagnosis based upon compromised hospital systems. Once the affected people are identified, the patient drug and treatment information is altered to cause death. As the death would be linked to the illness caused by the vaccine, the terrorists will strike fear into the public for taking a specific vaccine or seeking specific medical care.

Perhaps two of the most well-known medical fiction authors are Robin Cook and Michael Crichton. Both are doctors who have concocted some incredible healthcare and medical fiction in their careers. Most of their stories do not involve information systems in a significant manner—yet.

Today there are many information systems used in hospitals. Patient records and treatment plans, insurance and billing systems, radiographs, pharmacy information, etc. Successfully compromising any of these systems by terrorist organizations can have dramatic impact on the population. Modifying diagnoses, treatment plans, changing drugs or dosages, and releasing confidential medical records and histories to the press are examples. When it comes to healthcare and the well being of individuals, not many things pose so significant a threat as the penetration and manipulation of healthcare information.

Here are several examples of potential terrorist activities in healthcare:

- The terrorist compromises patient treatment records and alters drug names and dosages, which ultimately kill the affected patients. Given a sufficient number of patients, this would create a significant scare.

- The terrorist compromises patient histories and publicly identifies those with specific diseases, such as HIV, or those who might be candidates for organ donors.
- Patient billing information is compromised and sold to burglars who steal the property of the patient while they are in the hospital. Alternatively, patient billing information could be changed, charges to insurance companies falsified, simply to wreak havoc on the system and damage the hospital's reputation.

One final example involves altering patient information so doctors treat a non-specific or false illness, while the real problem is not treated resulting in the patient's death. The scariest aspect of health care information systems involves the potential for loss of life. Unfortunately, identity theft often occurs after the real owner has passed away.

214.10.1 Keeping Security Alive

Healthcare institutions have a difficult job just providing good quality care, maintaining life, complying with legislation, and keeping the budget balanced without having to deal with theft, information loss, potential terrorist attacks, natural disasters, and new viruses. The healthcare institution, no matter how big or small, must, therefore, be diligent in designing and implementing information systems to achieve these goals, while minimizing the risk of service disruptions and information loss, both possibly resulting in a loss of life. With the wide variety of wireless devices today, some of which are used for healthcare purposes, such as wireless cardiac telemetry, security personnel need to work with qualified radio spectrum engineers to determine what wireless threats exist and properly assess the ability of the hospital to deploy 802.11-based wireless networks if that is a goal. Likewise, hospital staff must be trained to recognize visitors or suspicious people in or around nurses' stations who may be accessing and/or tampering with hospital records. Finally, there should also be controls in place to ensure an electronic order for a procedure, medication, or even the transcription of a report is signed with a verified digital signature before any action is taken.

214.11 Identity Theft

Identity theft is a significant problem in today's economy, but it is not new. Identity theft did not just magically appear with the Internet and changes in computing and communication systems. Identity theft bas been around for a long time, originally involving mail theft, the stealing of wallets, and breaking into houses to obtain the needed information.

With today's computers, communications systems, and online databases, extracting information about people has become easier. Terrorists can use these massive online databases for their own purposes. As mentioned previously, identity thieves can also use the Social Security number and other identity information for individuals who have passed away. They can then assume their identity, credit history, etc. Cyberterrorists can also launch attacks against utility and telephone company information systems. Terrorists can issue widespread disconnect requests or maliciously alter financial records.

Correcting these problems will cost the consumers and companies time and money. Once the problem becomes known, people will want to know what other potentially useful information may have been compromised. As most utility companies require the consumer to provide their Social Security number, the consumer is pretty much assured their name, address, phone numbers, date of birth, and Social Security number are in the hands of the cyberterrorists.

Alternatively, terrorists could target banks and credit card companies to obtain the necessary information to steal an identity or perpetrate fraud that the unsuspecting consumer then has to pay for.

Terrorists could use identity theft tactics for blackmail, extortion, and changes to the political or leadership landscapes. For example, a terrorist group decides to focus on several important members of Congress and through the Internet obtain the information to steal their identities. With that information, the terrorists then launch attacks against multiple court jurisdiction and police department computers to discredit the individuals. False documents and information, including lawsuits, criminal charges, and arrest warrants could be issued for the government members. After the warrants are issued, the police departments must act on them. After the new charges and arrests make the news, their political careers may be in jeopardy.

These false charges may be enough for Congress to initiate a congressional hearing or article of impeachment. The end result is hopefully, from the cyberterrorists' perspective, to have the elected officials removed from office or extort them into providing information or services directly to the cyberterrorists. In either case, the cyberterrorists are using identity theft to specifically force their politics onto the government. The terrorists use the existing legal system to suit their own specific agendas.

Alternatively, terrorists can gain access to important government systems and establish false identities that are then used to obtain legal documents, including driver licenses, passports, etc. In this situation, the documents are not forged; they are simply created using the information in the computer system. Using such tactics, terrorists could establish positions of authority within government and possibly within private industries using identity theft and fraudulent identities, as required.

214.11.1 Keeping My Identity Mine

Aside from concerns about how companies handle their personal information, people themselves must take the first step. Education is a principle outcome in this area that involves teaching people to read and understand e-mail messages before responding. Phishing attacks can lead to identity theft by having people complete personal information about themselves on a hacker's Web site. Consequently, when the user receives an e-mail to their work e-mail account from their bank and they realize they use their home e-mail for banking, they must not respond and must advise their organization's computer security team. Identity theft can be minimized through implementing good practices at the corporate level to protect the data. However, identity theft protection is largely about the user doing the right thing to protect their information.

214.12 Summary

This chapter has considered a number of potential cyber attacks or combinations of cyber and physical attacks and some general recommendations for defense. These potential terrorist scenarios are amongst thousands of ideas and, as explained here, not outside the realm of possibility. Some of the examples here have been used as stories in fiction novels and in film.

Regardless of fact or fiction, these examples illustrate how reliant upon technology our society is and the level of impact a single cyber attack could have. It does not take much imagination, however, to see the potential for massive infrastructure destruction, loss of life, and resulting chaos should a terrorist element be successful in a significant attack.

If nothing else, these pages should cause security professionals around the world to consider every possibility, no matter how remote, and consider the risk of several events occurring at once. The destruction of New Orleans during Hurricane Katrina should be a somber lesson of the impact of multiple events. A single event may, on its own, be insignificant. When combined with two or more, the magnitude of possibilities and extent of impact increases dramatically.

Each security professional in the various industries named (and not named) here needs to examine every possible risk, determine if it is a factor, and push their organization to establish appropriate defenses for themselves and, if appropriate, cooperate to establish regional, statewide, and national responses to industry-specific concerns. Only through considering all possibilities and possible combinations and outcomes can information security professionals make informed decisions regarding risk, preparedness, and response.

The Evolution of the Sploit

Ed Skoudis

Computer attackers use exploit code, little snippets of software, to compromise systems. These exploits, known informally as *sploits*, allow an attacker to undermine a vulnerable program by launching them at a target machine. Inside of a vulnerable program, a sploit can give the attacker complete control of the target machine. The world of sploits has recently experienced major developments and software releases that have really honed the attackers' game. In this chapter, we will analyze some of the building blocks underlying these evolutionary changes so we can better understand the magnitude of the threat.

To begin, we need to better define exploits. What are they? Let us begin by saying what they are not. Many people think that vulnerability scanners are exploit tools. They are not. Although the two are related, vulnerability scanners craft packets to measure whether a target system is vulnerable to an attack. Vulnerability scanners, such as Nessus or ISS Internet Scanner, have a database of known vulnerabilities and check to see if these flaws are present on the target by looking for old version numbers and analyzing system behavior. A relatively small number of the tests performed by vulnerability scanners will go further by crafting a bit of benign code to take advantage of the vulnerability and then checking for evidence that the benign code worked. Such tests are approaching exploits, but they do not give the bad guy access to or control over the target machine like sploits do. For a typical vulnerability scanner, approximately only one in ten of the tests actually sends the benign code to execute on the target, taking advantage of a flaw to measure whether a system is vulnerable. Because most of their efforts are focused on measuring whether a vulnerability is present, vulnerability scanners are typically useful as audit tools but not for gaining access. An attacker can use a vulnerability scanner as a prelude to gaining access, using it to measure what is vulnerable to help choose the appropriate exploit to utilize. Still, the scanner does not exploit the target.

What, then, is an exploit? Many vulnerability announcements from vendors ominously say that the vulnerability allows the attacker to "execute arbitrary code." Exploits are the programs that the attacker uses to tickle the vulnerability, inject code of the attacker's choosing (the "arbitrary" part) into the victim machine, run the attacker's code, and thereby get access to the target machine. The access given by an exploit typically involves invoking a command shell in the memory of the target machine, which is why the code inside the exploit is often referred to as *shell code*. The attacker's command shell runs with the permissions of the vulnerable program. Thus, if a target program is running with system or root privileges, the attacker can have complete control over a target machine using a suitable exploit against that program. Some exploits run locally, and others run across the network. This chapter will focus on the latter (network exploits) because that is where many of the attackers have been focusing over the past several years and where we have seen the most interesting tool development.

215.1 Types of Sploits

Before we discuss the evolution of exploit code, we must look at the different types of exploits available today and analyze how they operate. Anyone who reads information security headlines knows that many types of vulnerabilities are discovered on a regular basis. Many of these vulnerabilities deal with improper memory management techniques by software developers. Buffer overflow vulnerabilities, an example of improperly dealing with moving information around in memory, are very common, and new holes are discovered on an almost daily basis. Buffer overflow flaws involve not checking the size of user input before moving it into a memory location. The user input overflows the memory allocated for a variable, changing not only that variable but also other nearby elements in memory.

Buffer overflow vulnerabilities can plague variables stored in several different memory regions of running processes. Many buffer overflows are stack based; that is, they overflow memory locations on the stack, which is a data structure used to store information associated with function calls, such as function call arguments or local variables of functions. Other buffer overflows target the heap, an area of memory that is allocated dynamically by programs using functions such as malloc (short for "memory allocation") in C and C++. Another memory area that can be altered via buffer overflow is the BSS (block started by symbol), which holds global variables and static variables used within a process.

In addition to buffer overflows, attackers can take advantage of other vulnerabilities resulting from sloppy coding that lets them alter nearby memory locations. Format string attacks are another example; they are based on the improper use of the printf family of C library functions (including printf, sprintf, snprintf, and fprintf). Other examples include integer overflows, which take advantage of an integer wrapping beyond the maximum value allowed for a signed integer, resulting in a negative number or a small positive number. Another category, off-by-one flaws, takes advantage of sloppy code where a developer inadvertently increments through a variable using the wrong size of that variable, typically one byte more or one byte less than the proper size.

Of all of these vulnerability types, the most popular of all is the stack-based buffer overflow. By dissecting one example, we will have the base knowledge necessary to see how these beasts have evolved over time. For a quick refresher on stack-based buffer overflows, consider the normal stack and the smashed stack displayed in Exhibit 215.1. In general, when a program calls a function, the function call arguments and a return address pointer are stored on the stack. The return pointer contains the address in the program to return to when the function call has completed execution. This return pointer is crucial, as it controls the flow of program execution after the function call finishes running. In other words, the return pointer is how the program remembers where to go back to when the function is done. After pushing the function call arguments and return pointer on the stack, the system pushes a frame pointer on the stack to indicate the top of the stack before the function call started. The system then allocates space for any local variables (i.e., buffers) for the called function.

When programs do not check and limit the amount of data copied into the assigned space of a variable, that space can be overflowed. A developer who does not include logic to check the size of user input before moving it around in memory could allow a bad guy to provide input that not only completely fills a buffer on the stack but also keeps going. When that buffer is overflowed, the data placed in the buffer will flow into the spaces of neighboring variables, clobber the frame pointer, and eventually even alter the return pointer itself. Attackers take advantage of this stack layout by precisely tuning the amount and contents of user input data placed into an overflowable buffer. The data that the attacker sends usually

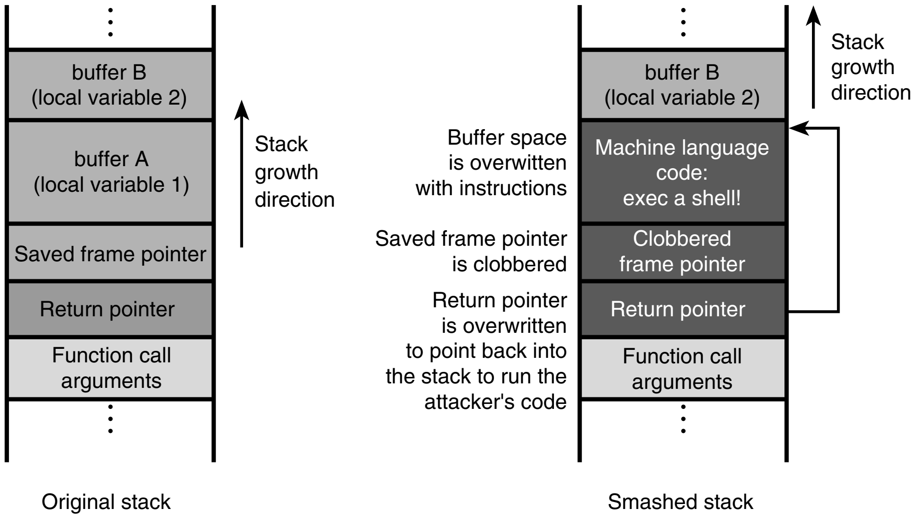

EXHIBIT 215.1 The original stack and the smashed stack of a stack-based buffer overflow attack.

consists of machine-specific bytecode (low-level machine language instructions) to execute a command, plus a new address for the return pointer. In a stack-based buffer overflow, this address points back into the address space of the stack, causing the program to run the attacker's instructions when it attempts to return from the function call. So, the attacker's exploit package typically consists of some machine language code to execute a command of the attacker's choosing (often a shell), plus a return pointer to make that code run. These elements are included in the user input shot across the network at the target vulnerable process as user input.

Because the stack is typically a very dynamic place, with functions being called and returned on a continual basis, the attacker typically does not know the exact value to provide for the return pointer in the user input. To help improve the odds that the return pointer's value will actually hit the code the attacker places in the variable stored on the stack, attackers often prepend a series of no-operation (NOP) or null commands in front of the machine language code they want to run. Most processors have a NOP instruction that tells the processor to do, well, nothing. Just burn this clock cycle and jump to the next instruction. With a long series of NOPs prepended to the machine language code of the exploit, as long as the return pointer hits the NOPs, execution will slide down the NOPs until the attacker's desired code is executed. For this reason, the prepended NOPs are referred to as a NOP *sled* or *slide*. The value of a NOP sled can be appreciated by considering a dart game, where the object is to hit the bull's eye. Setting the return pointer is something like throwing a dart. If the attacker guesses the proper location of the start of the machine language code on the stack, that code will run and he has hit the bull's eye; otherwise, the program will crash, something akin to the dartboard exploding. A NOP sled is like a cone placed around the bull's eye on the dartboard. As long as the dart hits the cone (the NOP sled), the dart will slide gently into the bull's eye, and the player wins!

So, the fundamental building blocks of many exploits, including stack-based, heap-based, and BSS-based buffer overflows, as well as many format string attacks and other exploits, include the following elements:

- *NOP sled*—This is used to help improve the odds that the return pointer will hit valid code.
- *Code to invoke some system call on the target machine*—This code must be written in machine language for a given processor type (e.g., x86, PowerPC, SPARC) and tailored for a given type of operating system (e.g., Windows, Linux, Solaris). Typically, some system call that is associated with executing a program (such as the Linux execve system call used to invoke a given program of the attacker's choosing) will be activated.

EXHIBIT 215.2 The exploit package contents, including the payload.

- *Code for invoking a shell to run on the target (typically)*—Attackers usually invoke a shell (such as the UNIX or Linux /bin/sh or Windows cmd.exe) on the target. Shells are nice, because attackers can feed them commands to execute.
- *Instructions for that shell to execute (typically)*—This is the command the attacker wants to run on the victim. It could involve installing a back door or attaching a shell to an active Transmission Control Protocol (TCP) connection or a variety of other items.
- *A return pointer, to trigger the whole package*—This pointer aims execution flow back into the memory location to get the exploit to run. This return pointer is set using some exploit, such as a buffer overflow that overwrites a return pointer on the stack or a format string exploit that lets the attacker change values on the stack.

The NOP sled, machine code, and command are collectively referred to as the *payload*. Code that overwrites the return pointer is the *exploit*. Sometimes, people refer to the payload and exploit together as simply the exploit. The entire package is shown in Exhibit 215.2.

215.2 Evolutionary Progress

Now that we have seen the essential components of the exploit package, let us focus on developments over the past several years in the creation and packaging of this structure for an exploit. Exhibit 215.3 depicts some of the major milestones in the creation of modern exploit code that we will discuss throughout the

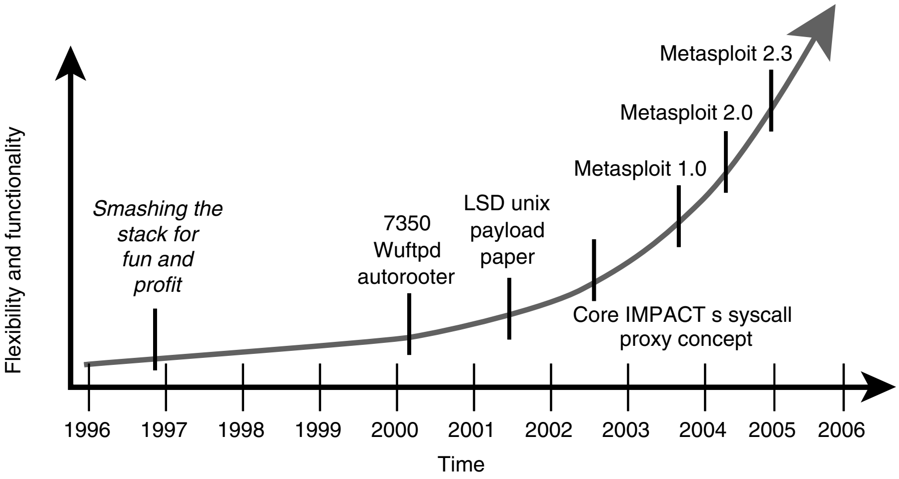

EXHIBIT 215.3 Milestones in exploit evolution.

remainder of this chapter. As you can see, the flexibility and functionality of these tools are increasing dramatically over time. But before we get ahead of ourselves, let's review these crucial milestones to establish an overall context. Some of the biggest events in the evolution of the sploit over the past decade have been:

- *Late 1996*. A white paper by Aleph1, *Smashing the Stack for Fun and Profit*, described how stack-based buffer overflows worked. His concepts brought the previously esoteric ideas underlying buffer overflows into the mainstream and resulted in the development and release of numerous exploits that are continuing to this very day.
- *2000*. The TESO (in elite-speak, "7350") wu-ftpd auto-rooter exploit code was some of the most well-written code at the time; it included several major features in a nice package.
- *2001*. A white paper on UNIX exploit payloads, *The Last Stage of Delirium*, described a dozen different exploit functions and included code to execute them on a half-dozen different UNIX variations, including Linux, Solaris, and HP-UX, among others.
- *2002*. The syscall proxy concept, originally publicized by Maximiliano Cáceres from the vendor Core Security Technologies, is extremely innovative because it allows attackers to maximize the flexibility of their exploits while keeping them small and efficient. The concept is included in some commercial products, such as Core IMPACT and Immunity CANVAS.
- *Late 2003*. Metasploit 1.0, by H. D. Moore and Spoonm, revolutionized the packaging of exploits and greatly increased their flexibility. The original release, however, was quite limited, acting as more of an example and toolbox than a full-fledged exploit tool.
- *2004*. Metasploit 2.0 fulfilled the promise of the original Metasploit, with two dozen different exploits and dozens of payloads for a variety of target system types. With these capabilities, it is widely used by the bad guys as a general-purpose exploit tool and the good guys for penetration testing. It also holds great promise as a development environment kit for creators of new exploits.
- *January 2005*. Metasploit 2.3 drives Metasploit forward even more and includes several new, useful capabilities, including a very flexible command shell (the meterpreter) and vulnerability discovery tools, which we will discuss later. This tool just keeps getting better, with each major release a huge leap forward.

With these major milestones under out belts, let us zoom in on various evolutionary steps that led to the milestones of Exhibit 215.3. In particular, exploits over the past ten years have evolved through the following phases:

1. Rooter
2. Auto-rooter
3. Mass-rooter
4. Exploitation engine
5. Exploitation framework
6. Syscall proxy

I have numbered these major steps in the evolutionary trends, and each section of the remainder of this chapter includes this number to help illustrate the transition and increase in flexibility of each phase.

215.2.1 Step 1. Rooter

A rooter is a piece of exploit code that gives the attacker a command shell on a target box, typically running with root privileges on UNIX or administrator or system privileges on Windows. We saw such code really take off in 1996 with the publication of Aleph1's *Smashing the Stack for Fun and Profit* white paper; however, such code is still regularly released even today, with several new single-purpose exploits released each week. The structure of a rooter is a fixed package: a program that generates fixed shell code with a fixed payload, launching it at a single target chosen by the attacker. This class includes hundreds of different exploits. A quick trip to www.packetstormsecurity.org or www.frsirt.com will show the reader a bunch of them. They often have names that include the word "exploit" and end in ".c" because most are written in the C programming language. Although these exploits are numerous and highly useful for the bad guys, they do have some major limitations. They typically work against a single target type. So, for example, it is possible to have an exploit for a buffer overflow in sshd that works against Linux. Then, a different exploit might work against sshd on Solaris. Then, still another one might work on another operating system, and so on. Furthermore, these rooters have a hard-coded payload of functionality to execute on the target, typically a simple command shell. This is one of the most useful capabilities to have, but it has little flexibility. Finally, these rooters tend to be throw-away code. When everyone has applied the patch, the exploit is not that useful anymore, unless someone finds a very old, unpatched system.

215.2.2 Step 2. Auto-Rooter

Auto-rooters expand upon the idea of the simple rooters by including a scanning engine in the package. We have seen such tools rise in use from 1999 to today, often bundled inside of a worm. The attacker takes a simple rooter, with its fixed payload (usually a command shell), and wraps around code to check to see if an attacker-chosen range of targets is vulnerable. The auto-rooter works on target systems of a single type, such as a single operating system or even a single service pack or patch level of the target. Examples of this type of exploit include the CodeRed worm from 2001 and the Sasser worm of 2004. Because they automatically find vulnerable systems in the target range on the attacker's behalf, the auto-rooter is more flexible than the simple rooter; however, auto-rooters share many of the limitations of the rooters—namely, they hit only one type of target machine, and their payload is still fixed to the functionality hard coded in the auto-rooter itself, typically a command shell.

215.2.3 Step 3. Mass-Rooter

Next, we move to mass-rooters, which are tools that lift one of the major limitations we have seen so far: working against a single target type. Mass-rooters include scanners, as we saw before, but the scanner is smarter; it can look for multiple target types, such as different operating systems or different service packs.

When the mass-rooter scanner finds a vulnerable machine from its list of known possible target types, it invokes the appropriate exploit to break into that machine. The tool then launches its fixed payload (again usually a command shell) against the discovered target. One of the finest examples of mass-rooter code is the TESO (or "7350") wu-ftpd exploit from June 2000. This tool included a variety of nifty capabilities, including:

- A scanner to look for vulnerable systems
- Command shell payloads that run on various versions of both Linux and FreeBSD
- Intelligence to launch the appropriate payload against the appropriate target
- A nifty bind-to-existing-socket capability that allows the exploit to spawn a command shell for the attacker over the existing File Transfer Protocol (FTP)-control connection

With regard to this last item, no separate network connection is required, as the existing incoming FTP socket is used. That is very helpful to the attacker, because the bad guy can ride in on a connection that is allowed through the firewall to get to the FTP server in the first place.

But, all is not well with the mass-rooter. We still have some major limitations. In particular, most of the mass-rooter code is still throw away, as it is for its cousins the rooter and auto-rooter. The scanning engine could be repurposed by recoding it to find other vulnerabilities, but the majority of what makes a mass-rooter useful disappears when someone has patched the vulnerability. Another major limitation with all of the exploit code types we have seen so far is their fixed payloads. They can do only one possible thing on the target. Finally, with many different people writing rooters, auto-rooters, and mass-rooters, we have seen the rise of an "exploit mess:"

In the olden days of 2003 and before, when a new vulnerability such as a buffer overflow or format string flaw was discovered, crafting exploit code to take advantage of the flaw was usually a painstaking, manual process. Developing an exploit involved handcrafting software that would manipulate memory locations on a target machine, load some of the attacker's machine-language code into the memory of the target system, and then calculate various offsets needed to make the target box execute the attacker's code. Some exploit developers then released each of these individually packaged exploit scripts to the public in the form of rooters, auto-rooters, and mass-rooters, setting off a periodic script-kiddie feeding frenzy on vulnerable systems that had not yet been patched. On the other hand, due to the time-consuming exploit development process, defenders had longer timeframes to apply their fixes. Also, the quality and functionality of individual exploits varied greatly. Some exploit developers fine-tuned their wares, making them highly reliable in penetrating a target. Other exploit creators were less careful, turning out junky sploits that sometimes would not work at all or would even crash a target machine most of the time. Some developers would craft exploits that created a command shell listener on their favorite TCP or User Datagram Protocol (UDP) port, others focused on adding an administrative user account for the attacker on the target machine, and still others embedded even more exotic functionality in their sploits. The developers and users of exploits were faced with no consistency, little code reuse, and wide-ranging quality; in other words, the exploit world was a fractured mess. There was no rhyme nor reason to a lot of these rooters, auto-rooters, and mass-rooters floating around on the Internet. How could someone tame such a mess?

215.2.4 Step 4. Exploitation Engine

To help tame this mass of different exploits, two brilliant information security researchers, H. D. Moore and Spoonm, released the Metasploit framework. This tool, which runs on Linux, BSD, and Windows (with a Perl interpreter such as ActiveState Perl), creates a modular interface for tying together exploits, payloads, and targeting information. By creating a simple yet powerful architecture for stitching together custom exploits from modular building blocks, the Metasploit framework is an ideal tool for attackers and penetration testers.

Exploit frameworks try to tame the exploit mess by creating a consistent environment for developing, packaging, and using exploits. In a sense, these tools act as assembly lines for the mass production of exploits, doing about 75 percent of the work needed to create a brand-new, custom sploit. It is kind of like what Henry Ford did for the automobile. Ford did not invent cars. Dozens of creative hobbyists were handcrafting automobiles around the world for decades when Mr. Ford showed up on the scene. Henry revolutionized the production of cars by introducing the moving assembly line, making automobile production faster and less expensive. In a similar fashion, exploit frameworks partially automate the production of sploits, making them easier to create and therefore more plentiful.

The essential components of Metasploit are shown in Exhibit 215.4. The tool holds a collection of exploits themselves, little chunks of code that force a victim machine to execute the attacker's payload. Metasploit has over 50 different exploits today, including numerous common buffer overflow attacks. Next, the tool offers a set of payloads, the code the attacker wants to run on the target machine. Some payloads create a command-shell listener on a network port, waiting for the attacker to connect and get a command prompt. Other payloads give the attacker direct control of the victim machine graphical user interface (GUI) across the network by surreptitiously installing virtual network computing (VNC), the GUI remote-control tool. Users of any of these exploit frameworks do not even have to understand how the exploit or payload works. They simply run the user interface, select an appropriate exploit and payload, and then fire the resulting package at the target. The tool bundles the exploit and payload together, applies a targeting header, and launches it across the network. The package arrives at the target, and the exploit triggers the payload, running the attacker's chosen code on the victim machine. These are the things of which script-kiddie dreams are made.

The Metasploit user interface comes in three forms: a console interface (for simple navigation between various options), a command-line interface, and a Web-based interface (for using a browser and Web server to configure the tool). The attacker first selects the exploit that will be included in the package. Some

EXHIBIT 215.4 The components of Metasploit, an exploitation framework.

exploits have an option simply to check if the target is vulnerable, without actually executing any payload. Other exploits just attack the system, running the attacker's chosen payload. The attacker then sets the target, which includes the Internet Protocol (IP) address and destination port. Additionally, for those payloads that require communication back with the attacker's machine, such as a reverse shell, the attacker can include a system address and port number where a listener is waiting to catch a shell shoveled back from the victim machine. Finally, the attacker selects the payload. Most of the exploits have payloads, which include firing up a command shell listener or a reverse shell. For the few exploits that do not have payloads, the attacker can select a command to run on the target. After configuring each of these items, as well as any options, the attacker can launch the exploit against the target.

The Metasploit framework currently includes about 50 different exploits, with a heavy focus on Windows machines. Given the flexibility of the tool and the prolific work of the tool's authors, we are likely to see many more exploits added in the future. When new holes are discovered and exploitation code is written, adding a new exploit to the Metasploit framework is quite straightforward. The current exploits include some of the most widely used exploits over the past several years on Windows, Linux, Solaris, and other operating systems. It is quite a powerful exploitation tool and a framework for rapid expansion.

The primary goals of the Metasploit payloads include functioning in most environments (e.g., working across various operating system patch levels, hotfix installs, service packs) and cleaning up after themselves (e.g., do not leave the system or a service crashed). The payloads available within the framework include:

- *Bind shell to current port*—This payload opens a command shell listener on the target machine using the existing TCP connection used to send the exploit.
- *Bind shell to arbitrary port*—This opens a command shell listener on any TCP port the attacker chooses.
- *Reverse shell*—This payload shovels a shell back to the attacker on a TCP port of the attacker's choosing. That way, a session is initiated from the victim machine, outbound toward the attacker machine, with a much greater likelihood of being allowed out through a firewall. From the perspective of the firewall, this is an outbound connection. From the attacker's perspective, it behaves like inbound command shell access, with the victim machine polling the attacker for commands to run.
- *Windows VNC server DLL inject*—This payload allows the attacker to remotely control the GUI of the victim machine, using the VNC tool, sent as a payload. The VNC runs inside the victim process, so it does not have to be installed on the victim machine. Instead, it is inserted as a dynamic link library (DLL) inside the vulnerable process.
- *Reverse VNC DLL inject*—This payload inserts the VNC as a DLL inside the running process and then tells the VNC server to make a connection back to the client, in effect shoveling the GUI. Such functionality is scary and amazing at the same time.
- *The meterpreter*—This general-purpose payload carries a DLL to the target box to give command-line access. Its beauty is threefold: (1) The meterpreter does not create a separate process to execute the shell (such as cmd.exe or /bin/sh would) but instead runs inside the exploited process; (2) the meterpreter does not touch the hard drive but gives access purely by manipulating memory; and (3) if the target machine has been configured in a chrooted environment so the vulnerable program does not have access to critical commands, then the meterpreter can still run its built-in commands within the memory of the target machine, regardless of the chroot limitation.
- *Inject DLL into running application*—This payload injects an arbitrary DLL into the vulnerable process and creates a thread to run inside that DLL. Thus, the attacker can make any target process take any desired action, subject to the privilege limitations of that target program.
- *Create local admin user*—This payload creates a new user in the administrator group with a name and password specified by the attacker

So, the Metasploit engine is pretty nifty and immensely useful in penetration testing. By itself, however, the engine is only part of the story. The engine is limited in that only a certain number of exploits and payloads are built in. When the existing vulnerabilities are patched, the exploits will wither on the vine, unless they are continuously renewed.

215.2.5 Step 5. Exploitation Framework

To help bust through this limitation, Metasploit goes much further than the engine. It includes a framework for the development of new exploits and new payloads. That framework is the item that is likely to give Metasploit the chance to become a *de facto* standard for developing exploits. In discussions with exploit developers, many of them have cited at least an interest in developing new sploits inside the Metasploit framework, and some others have already developed a half dozen or more personal exploits within the framework.

The Metasploit framework is built on top of a library created by the Metasploit team. This library is the Perl Exploit Library, or Pex. Pex provides code for several functions useful to developers of exploit code. The overall Pex application programming interface (API) includes functions such as:

- Various payloads, as discussed earlier
- XOR encoders and decoders to create morphing code to evade detection and filtering
- A wrapper for shell-code generation; the attacker can specify specific characters that should be avoided because they are filtered on the target system, and this code generates shell-code payloads that do not have these bytes in any OpCode or addresses
- Routines for finding the exact offset in a buffer that overwrites a return pointer; to help an attacker identify where in the submitted input the modified return pointer should be loaded, this code provides input of a specific pattern, and it then includes a routine to look for this pattern starting at a given address on the stack
- Shell-code creation, which packages up the shell code created based on all of the routines listed above in a tight piece of code ready to launch at the victim

Metasploit also includes some programs that help an exploit developer analyze code to find possible flaws in it. In particular, Metasploit includes two programs, msfelfscan and msfpescan, that search Linux/UNIX ELF (executable and linking format) or Windows PE (portable executable) binary programs, respectively. These tools look for machine language code that could be a point of vulnerability, including jump equivalents (which are a sign of transition within a program to a subroutine), pop + pop + return sequences (which are a sign that a function call has finished and is returning back to the calling routine), and any other regular expression the user devises. When each tool finds the specific elements being sought, the user can then print out disassembled machine language just before and after the searched-for code. Additional elements of the Metasploit framework include tools to dump the symbols (in essence, the variables) used within a program for analysis.

Numerous researchers in the computer underground are working on this area of automating the analysis of executable code to find vulnerabilities. Both within Metasploit and as separate projects, some researchers are trying to create automated tools to find the differences between newly released patches and the original code to help create exploits for unpatched systems in much shorter timeframes, possibly as short as minutes or hours, instead of days. Over the next couple of years, watch for the already short timeframe between vulnerability notification and exploit release to shorten even more. Further, with additional automation of the exploit development craft, expect more plentiful and higher quality exploits as we move forward.

So, why would exploit developers write their wares inside of the Metasploit framework? First off, many features are already built into the framework, such as Windows Service Pack independence, being able to determine the offset of the return pointer, and other capabilities. These features simplify the development process greatly. Second, the framework includes over 50 exploits from which to learn. Developers can see how H. D. Moore, Spoonm, and various other Metasploit developers handled various issues and use that as a starting point. Third, when an exploit is developed in the framework, the developer can choose from any one of the payloads already included in the framework, which offers instant flexibility without any additional development effort (in fact, less development effort). Further, if a developer works in Metasploit to create an exploit, the resulting code can be inserted directly into Metasploit by just placing its code in the appropriate directories. That is really simple integration, giving the developer three really good user interfaces to choose from. No user interface has to be created, because all of that work has already been done. Also, developers who want a lot of people to start using their exploits will have a relatively large number of users with Metasploit already installed. An embedded base of Metasploit users exists who will more rapidly adopt and utilize the new exploit.

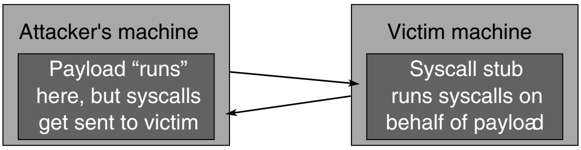
So, the Metasploit engine and framework are pretty darned nifty, but they do have some limitations—namely, the prepackaged payloads can only do so much. Although the built-in payloads have some great capabilities, more functionality incurs a cost—size. That means more exploit data has to be created, encoded, and transported across the network to squeeze inside a buffer on the target. The Metasploit developers deal with some of these limitations by supporting staged payloads, which break a payload into smaller chunks for sending to the target. Another limitation of the existing framework is that the canned and compiled payloads of the built-in Metasploit payloads are less flexible. They are a done deal, and creating new ones requires software development.

215.2.6 Step 6. System-Call Proxy Concept

All the exploit-related payloads that we have seen so far have a problem: they essentially hard code the actual behavior of the payload into a piece of software that is transmitted to the target system, where it is executed. This is a problem for at least two reasons. First, to change the functionality of the payload, an attacker will have to completely recompile the payload or write brand-new machine language code. This is time consuming and not trivial. Additionally, more complex payloads could get relatively large in size and therefore are less likely to fit into a buffer on the target machine.

To avoid these problems, the folks at Core Security Technologies introduced a concept in their commercial IMPACT exploitation tool: syscall proxying. In this approach, shown in Exhibit 215.5, the attackers use a payload that is really a stub to execute system calls on the kernel of the victim machine. An exploit inserts a small (<100 bytes) payload stub on the victim machine. This stub receives syscall requests from the attacker's machine across the network and runs the system calls on the victim machine. Then, the attacker runs a program of the attacker's choosing on the *attacker's machine*, but, as it runs, whenever it needs to make a call into the kernel (to do anything, such as read a file, open a network socket, or write a file), this program sends the syscall request across the network. Instead of calling into the kernel of the attacker machine, the kernel calls get transmitted to the target, where they are run.

In essence, the payload is running on the attacker's machine from a user-mode perspective and can be of arbitrary length and complexity. It could be a port scanner, a vulnerability scanner, or any other program. But, whenever this program tries to interact with the local machine, those system calls are sent across the network to the victim machine. This concept is something like syscall-level remote procedure calls and is incredibly flexible. The syscall concept is described in detail by Maximiliano Cáceres from Core Security Technologies at http://www1.corest.com/common/showdoc.php?idx=259&idxseccion=11. Their product implementing



Attacker's machine
Payload “runs” here, but syscalls get sent to victim
Victim machine
Syscall stub runs syscalls on behalf of payload

EXHIBIT 215.5 The syscall proxy concept.

these ideas is available commercially at http://www1.corest.com/products/coreimpact/index.php. A similar commercial product is the CANVAS tool by Immunity, available at www.immunitysec.com.

To really push this syscall proxy forward, consider the scenario illustrated in Exhibit 215.6. An attacker uses a system, which we will call system A, to launch an attack. The attacker uses system A to compromise system B. The attacker then uses the syscall proxy concept to push a syscall stub to system B. The attacker then runs a vulnerability scanner on system A but pushes all of its system calls to system B. System B then, in effect, scans for more vulnerable machines. Suppose it discovers one, which we will call system C. It can then take that over, installing a syscall proxy on B and a stub on C and iterating the process.

All code executes on the attacker's box (system A) but takes effect on the remote systems, giving the attacker staged, level-by-level access through various targets across the network. Making matters even more interesting, because the syscall proxies run in the memory of the vulnerable process of the victim machine, they do not even have to touch the hard drive. If an attacker is careful and deploys the proxy stubs entirely in memory, they can all be rolled back at the end of the attack, returning all compromised systems to their original state. No alterations to the file system on the hard drive are required. Fantasy? Nope. The commercial Core IMPACT and Immunity CANVAS tools already do this.

In effect, these tools act as automated penetration testing tools, deploying "agents" (which are the syscall proxy stubs) to vulnerable hosts that are then used to scan for and compromise more hosts. It is all packaged up in a slick GUI as well with many dozen exploits built-in.

215.3 Future Evolution

So, where is all of this headed? We can expect to see many more developers beginning to write exploits and payloads for Metasploit in the near future, given its free and open-source nature. Watch for a flourishing of capabilities within the Metasploit framework. We will also likely see additional flexible exploit and payload creation tool kits that let attackers use pieces parts written by others. Finally, we may see "GUI-ification" of

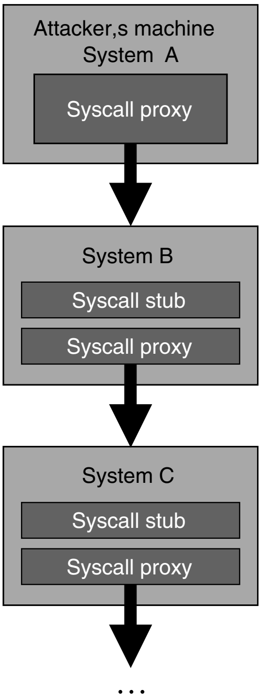


EXHIBIT 215.6 Using the syscall proxy concept to undermine a series of machines.

the freely available exploit tools to make them easier to use. Sure, Metasploit already includes a GUI, but it is not as point-and-click intuitive as commercial tools such as Core IMPACT and Immunity CANVAS. These tools auto-discover a vulnerable system, let their user click on it to deploy a syscall proxy, and then use it to further explore the network. We may see something approaching that ease of use for the free tools in the future. So, as we have seen, the exploit code has undergone a revolution recently. With the more flexible concepts and tools now released, we can expect to see a rapid increase in the number, quality, and capabilities of future exploits.

At the SANS Institute's Internet Storm Center (isc.sans.org), when a new vulnerability is announced, we often see widespread port scanning for the vulnerable service begin immediately, even before an exploit is released publicly. Some of this scanning may be caused by developers who have already quickly created an exploit, but a lot of it is likely due to anticipatory scanning. That is, even script-kiddie attackers know that an exploit will likely soon be created and released for a choice vulnerability, so they want an inventory of juicy targets as soon as possible. When the exploit is then actually released, they pounce. Today, quite often, the exploit is released as part of an exploit framework first.

In fact, exploit frameworks such as Metasploit have produced a large number of script kiddies who are better armed than ever. Today's exploits are easier to use, even for those who do not understand how the underlying tools work. It is trivially easy to operate Metasploit. Our situation is comparable to the original days of the SATAN security scanner back in 1995. Back then, some security professionals complained that SATAN made discovering vulnerable systems too easy for the attackers, turning their system-by-system discovery of vulnerable systems by hand into an automated affair. Now, when security people see a demo of Metasploit for the first time, they complain that the tool makes conquering a target just too easy for the bad guys. Sometimes, again, they moan that it is just not fair. But, who cares about whether or not these tools are fair? The attackers use them anyway, and we need to be ready.

Furthermore, in addition to shortening development time and effort, exploit frameworks have simultaneously increased the quality of exploit code, making the bad guys much more dangerous. Unlike the handcrafted, individual exploit scripts of the past, the sploits written in an exploit framework are built on top of time-tested, interchangeable modules. Some seriously gifted exploit engineers created these underlying modules and have carefully refined their stuff to make sure it works reliably. Thus, an attacker firing an exploit at a target can be much more assured of a successful compromise.

215.4 Using Exploit Frameworks for Good Purposes

Exploit frameworks are not just evil. They can also help us security professionals to improve our practices as well. One of the most common and obvious ways the good guys use exploit frameworks is to enhance their penetration testing activities. With a comprehensive and constantly updated set of exploits and payloads, a penetration tester can focus more on the overall orchestration of an attack and analyzing results instead of spending exorbitant amounts of time researching, reviewing, and tweaking individual exploits. Furthermore, for those penetration testers who devise their own exploit code and payloads, the frameworks offer an excellent development environment. Exploit frameworks do not completely automate pen test exercises, though. An experienced hand still needs to plan the test; launch various tools, including the exploit framework; correlate tool output; analyze results; and iterate to go deeper into the targets. Still, when performing penetration testing in-house, the team could significantly benefit from these tools, performing more comprehensive tests in less time. Those readers who rely on external penetration testing companies should ask them which of the various exploit frameworks they use and how they apply them in their testing regimen to improve their attacks and lower costs.

One of the most valuable aspects of these tools for information security professionals involves minimizing the glut of false positives from vulnerability-scanning tools. Chief information security officers (CISOs) and auditors often lament the fact that many of the high-risk findings discovered by a vulnerability scanner turn out to be mere fantasies, an error in the tool that thinks a system is vulnerable when it really is not. Such false positives sometimes comprise 30–50 percent or more of the findings of an assessment.

Getting the operations team to do the right thing in tightening and patching systems is difficult enough without sending them vulnerability information that is wrong half the time, in this boy-who-cried-wolf scenario. Exploit frameworks help alleviate this concern. The assessment team first runs a vulnerability scanner, and generates a report. Then, for each of the vulnerabilities identified, the team runs an exploit framework to actually verify the presence of the flaw. Real problems can then be given a high priority for fixing. Although this high degree of certainty is invaluable, it is important to note that some exploits inside of the frameworks still could cause a target system or service to crash; therefore, be careful when running such tools and make sure the operations team is on standby to restart a service if the exploit does indeed crash it.

In addition to improving the accuracy of security assessments, exploit frameworks can be used to check the functionality of intrusion detection system (IDS) and intrusion prevention system (IPS) tools. Occasionally, an IDS or IPS may seem especially quiet. Although a given sensor may normally generate a dozen alerts or more per day, sometimes an extremely quiet day might occur, with no alerts coming in over a large span of time. When this happens, many IDS and IPS analysts start to get a little nervous, worrying that their monitoring devices are dead, misconfigured, or simply not accessible on the network. Compounding the concern, we may soon face attacks involving more sophisticated bad guys launching exploits that actually bring down IDS and IPS tools, in effect rendering our sensor capabilities blind. The most insidious exploits would disable the IDS and IPS detection functionality and put the system in an endless loop, making it appear as though things are fine but in reality they are blind to any actual attacks. To make sure the IDS/IPS tools are running properly, consider using an exploit framework to fire some sploits at them on a periodic basis, such as once a day. Sure, it is possible to run a vulnerability-scanning tool against a target network to test its detection capabilities, but that would trigger an avalanche of alerts. A single sploit will indicate whether or not a detector is still running properly.

One final benefit offered by exploit frameworks should not be overlooked—improving management awareness of the importance of good security practices. Most security professionals have to work really hard to make sure management understands the security risks their organizations face, with an emphasis on the need for system hardening, thorough patching, and solid incident response capabilities. Sometimes, management's eyes glaze over hearing for the umpteenth time the importance of these practices. Yet, a single sploit is often worth more than a thousand words. Set up a laboratory demo of one of the exploit frameworks, such as Metasploit. Build a target system that lacks a crucial patch for a given exploit in the framework, and load a sample text file on the target machine with the contents "Please do not steal this important file!" Pick a very reliable exploit, such as the MS RPC DCOM attack against an unpatched Windows 2000 system. Then, after testing the demo to make sure it works, invite management to watch how easy it is for an attacker to use the point-and-click Web interface of Metasploit to compromise the target. Snag a copy of the sensitive file and display it to your observers. When first exposed to these tools, some managers' jaws drop at their power and simplicity. As the scales fall from their eyes, the plea for adequate security resources may now reach a far more receptive audience.

216
Computer Crime

Christopher A. Pilewski

216.1 What Is Computer Crime?

Computer crime is not easily defined. Metaphorically, computer crime is a universe of technology and exploits that expands and shifts on a daily basis. Practically, we are left with the most basic and intuitive of definitions for computer crime: criminal activity that involves the use of one or more computers. Though simple, this definition serves to separate computer activity that may only be obnoxious, irritating, or offensive from that which is actually in violation of law. This is the essence of criminality, computer-related or otherwise. This chapter examines computer crime in three stages: concepts, common computer crimes, and tactics of the security professional in dealing with computer crime.

216.2 Concepts

Computer crime commonly takes one of a few familiar, highly general forms: (1) fraud, (2) theft, (3) destruction, (4) disruption, and (5) conspiracy. Examination of these abstract forms will lend insight into computer crime and what the security practitioner can do about it.

216.2.1 Fraud

Fraud is the misrepresentation of information. The end goal of fraud may be monetary or some other type of specific gain, or it may grant a more general advantage to the perpetrator. Depending on the exact circumstances, fraud may be criminal in itself, whether it leads to any further ends or not. This fact is particularly evident in certain areas of legal and regulatory compliance such as the Health Insurance Portability and Accountability Act (HIPAA), Sarbanes–Oxley, and others.

216.2.2 Theft

Theft is probably the most familiar type of computer crime; in fact, identity theft has become a household word. Theft is not restricted to only this type, however. Computer-related theft also may include theft of funds, theft of information, theft of physical property, or theft of intellectual property. This category can encompass anything from the misappropriation of computer hardware to various forms of industrial espionage. The end goal, however, is typically a targeted, tangible, or economic gain of some kind.

216.2.3 Destruction

Destruction is one of the most familiar forms of computer crime. Information (or the devices that it resides on) may be destroyed for any number of reasons. Perhaps a database is destroyed as a punitive act against its owner, or a log file is altered or destroyed because it contains something damaging about other criminal activity. Most security professionals encounter destruction of information in a more familiar form: computer viruses and other kinds of malware. Malware threats represent one of the most damaging and costly areas of computer crime because malware threats are both numerous and diverse. Although viruses, Trojans, worms, and other kinds of malware have specific definitions (depending on the way they are propagated and spread), more and more malware threats are classified as multivector or blended threats, because they have characteristics of more than one specific type. A computer virus, Trojan, or worm may destroy files, sectors on a disk, or entire file systems. Depending on the specifics of the threat, it may spread by infecting other files and drives, the local area network, a Web page, e-mail, or any combination of these. What distinguishes malware from most other types of computer crime is that, unlike simple fraud or theft, the end goal of malware authors is often unclear and devoid of any direct gain for the perpetrator. An author of a virus or worm may release it without any idea of where (or how many places) it will eventually strike. The unfocused nature of this type of computer crime makes it difficult to understand and even more difficult to predict.

216.2.4 Disruption

Disruption is also a familiar concept. Examples of criminal disruption would include triggering a fire alarm without cause, making a bomb threat, or yelling “fire” in a theater. It is questionable in these situations if the perpetrator intends to do permanent harm or not, but there is clear intent to disrupt the prevailing activity or the well-being of the victims. Disruption may be focused (against specific individuals or against a specific firm), or it may be relatively unfocussed and target the public at large. The most common type of disruption in computer crime is the denial of service (DoS) attack. This type of attack typically immobilizes or crashes a system by sending large amounts of network traffic to it such that it is unable to process legitimate requests, or the attack may use a series of crafted datagrams to exploit a known service vulnerability or simply fill up the system’s disk. The variety of DoS attacks is almost endless. These attacks frequently target specific destination hosts belonging to a company or to an individual, but they also may target gateway nodes or servers of an Internet service provider in an attempt to disrupt service on the Internet. Some DoS attacks have targeted computer systems that control community services, such as traffic lights, government agencies, and emergency response. Goals and motivations for this type of computer crime are similar to those that may appeal to authors of malware. Service disruption is often devoid of direct economic gain for the perpetrator, but, unlike malware, service and system disruptions are frequently targeted in one fashion or another. Computer criminals may direct DoS attacks against online businesses or fellow computer hackers that they have something against. Also, a particular DoS attack may be launched by a perpetrator simply to test or demonstrate their skills in this area.

216.2.5 Conspiracy

Conspiracy represents one of the least understood forms of computer crime. At a conceptual level, a conspiracy is simply an agreement between two or more individuals to commit an illegal act. Legally, conspiracy has been expanded to include agreements and consultations, as well as acts that are either illegal or injurious to the public or to specific individuals. This type of crime may become a computer crime whenever computers, networks, e-mail systems, chat rooms, instant message agents, and other systems are used to facilitate such an agreement or consultation. The almost unlimited examples of conspiracy are large and small, simple and complex. What the security practitioner must understand is that the actual illegal or injurious act does not have to take place for conspiracy itself to take place. In other words, planning a crime may be an offense in and of itself, whether the crime is actually committed or not. The following brief anecdotes illustrate examples of conspiracy involving computers:

- In a series of instant messages, the murder of an individual is materially discussed between two participants.
- During a chat room session, participants detail a plan to steal credit card numbers from an online business.
- In an exchange of e-mails between business executives, they agree to release fraudulent financial reports for their publicly traded firm.

Note that conspiracy takes place between two or more individuals. Demonstrated intent (by a single individual) to commit a crime may also be criminal (as in the case of terrorist threats) but would not constitute conspiracy as this chapter defines it. Security practitioners and system administrators must be acutely aware of the role that computer systems, logs, and other files play in the chain of evidence when conspiracy is prosecuted and should be equally aware of their obligations to report when they possess knowledge of agreements or discussions that constitute conspiracy or of other types of criminal activity.

216.3 Common Computer Crimes

The two basic tactics of computer criminals are attacking the computers and attacking the people. Attacking the computers can be thought of as system and network penetration. Attacking the people introduces the world of social engineering. Both are commonly used, and they are often used in combination.

216.3.1 System Attack and Penetration

Computer systems can be penetrated in a variety of ways. The most common way is the exploitation of technical vulnerabilities locally or remotely over a network interface, or simply "exploits." Successful exploitation of a technical vulnerability typically leads to one of two outcomes: denial of service or privilege escalation. Denial of service, as noted earlier, refers to any attack that keeps a system from servicing legitimate, intended requests. Privilege escalation results from successful exploitation of specific services or applications that run at a higher privilege level than that intended for normal access. Privilege escalation may provide an intruder with root access to a particular system. This would allow the attacker full, uninhibited access to the systems services, applications, databases, accounts, and file system, Because the system is still (apparently) operating normally, however, system penetration resulting in privilege escalation may be more subtle and more difficult to detect.

216.3.2 Exploit Examples

216.3.2.1 The Slammer Worm

A well-known example of an exploit leading to denial of service is the Slammer worm, also called "sapphire" or "SQL Slammer." On January 25, 2003, the Slammer worm began infecting vulnerable versions of Microsoft SQL Server 2000 and MSDE 2000. The function of the worm was conceptually simple: Exploit the host, scan for more vulnerable hosts, and then exploit them. The Slammer worm was able to exploit a buffer-overflow vulnerability in the indexing service of vulnerable machines with a single

User Datagram Protocol (UDP) packet on port 1434. When it became infected, the host began scanning. The scanning process of this worm is what made it unique. The Slammer worm used a form of pseudo-random number generation for its scanning process that had very different characteristics from those used in previous worms (such as CodeRed), allowing it to spread much faster. When a vulnerable host was detected by the infected system, it was quickly infected with the UDP packet. In the first 30 minutes after Slammer was launched, it managed to infect nearly 75,000 systems. A single infected system could scan thousands of new systems per second, limited primarily by the available bandwidth of the system's connection to the Internet. This rapid scanning, in fact, was the real Achilles heel of the Slammer worm. The scanning process consumed so much bandwidth on the Internet that propagation of the worm was inhibited. Although the Slammer worm caused a great deal of damage simply because of its DoS characteristics, it did not contain a destructive payload within its code. It simply spread very aggressively. Had the author (or authors) of the worm inserted a destructive payload that deleted database tables, transposed numbers, added characters, or otherwise corrupted information, the effects of the Slammer worm would have been infinitely worse.

216.3.2.2 Iiscrack

A well-known example of an exploit leading to privilege escalation is "iiscrack." Iiscrack is an exploit utility that allows a remote intruder to crack Microsoft IIS 5.0 and execute commands on the server. A typical attack can be performed by compiling or downloading iiscrack (it is freely available on the Internet) and copying it to the scripts directory of the target server. It can then be loaded with a Web browser to provide system-level access (higher than administrator). The attacker may use this access to deface the server's Web content, use the system to launch other attacks, load additional tools, or simply use iiscrack alone.

216.3.3 Exploit Types

216.3.3.1 Buffer Overflows

Although these two exploit examples have different end results (DoS and privilege escalation), they have something in common as well. Both exploits use a general attack technique known as buffer overflow. Buffer overflows are at the center of many exploits. At its simplest level, a buffer overflow occurs when a program writes information beyond the allocated end of a data buffer in memory. Buffer overflows may be caused by software programming errors and thus result in random information being written beyond the end of the buffer. In turn, the error may cause the application, the service, or the entire system to hang or crash. Buffer overflows also occur maliciously. Input can be crafted to exceed input buffers with machine code. Malicious code can overwrite the instruction pointer in the system stack and change the execution path, thus executing arbitrary code at a location arranged by the attacker. If the application or service is running with root permission on the system, typically the chained arbitrary code will also run at this level. This is exactly what happens when iiscrack is used against Microsoft IIS version 5.0. Buffer overflow vulnerabilities have been discovered in virtually all major production operating systems and many applications. They are most common in software written with the programming languages C, C++, and Assembly. This is because these languages require the programmer to manage memory allocation. Other languages manage memory more dynamically or include other mechanisms to reduce or prevent buffer overflows. They may, however, still have library dependencies that introduce the risk of buffer overflows.

216.3.3.2 Format Strings

Format string vulnerabilities closely resemble buffer overflow vulnerabilities in many respects. The general theme is the same: Crafted input that differs from what the programmer anticipates and codes for can result in DoS or privilege escalation. The vulnerable population is also similar—operating systems and application software coded in the C language that use certain language functions, specifically functions that use formatted input such as the printf() function. The source of this problem is the fact that the C programming language passes function arguments without type checking or validation. Recall that C is a medium-level language built for speed that relies entirely on the programmer for input validation. In a correctly written C program, input and output must conform to the format strings that the programmer includes in the function call. But, if the user input is not validated against the format string, the user may intentionally or unintentionally compromise the system. C language functions known to be vulnerable include printf(), sprintf(), snprintf(), and syslog(), among others. Hundreds of format string vulnerabilities have been cataloged on the common vulnerabilities and exposures (CVE) list, and many have multiple exploits. Format string attacks vary, but common methods include using multiple "%s" descriptors to read data from the stack until an illegal address is read, resulting in DoS, or using other descriptors (such as %u, or %x) to overwrite the instruction pointer and execute arbitrary code.

216.3.3.3 Cross-Site Scripting

Cross-site scripting (also called XSS) is typically not thought of as an attack on a particular system; instead, it can be thought of as an attack on the communication between a Web server and a user to gather specific information that belongs to the user. The information gathering itself is usually performed from a contaminated HTML hyperlink. Because many desktop applications are HTML aware, many applications can facilitate this kind of information gathering, including Web browsers, e-mail clients, instant message clients, and message boards. Technically, neither the computer system belonging to the user nor the Web server is penetrated as they are in the exploit examples above. Instead, this type of attack exploits the trust that a user has for a given Web site on the Internet.

The most common way that this type of attack is carried out is to first append additional code into a hyperlink. The code itself can be in several different scripting languages: JavaScript, VBscript, or others. ActiveX, Flash, or other platforms may be used as well. The script itself can be imbedded into a HTML hyperlink simply by using the "<script>" HTML tag. The script is often executable in clear text, but many times it will be encoded in HEX to make it appear less suspicious. The hyperlink can be delivered through a compromised Web page or simply through an e-mail or a post to an Internet forum. An e-mail may be crafted to appear to be from a vendor that the user trusts, or it may use social engineering techniques to manipulate a user to click on it (such as "remove your e-mail address from our list." When the hyperlink is clicked, the resulting Web page may appear perfectly normal, but the script may have also captured the user's cookie, delivering the user to another site set up by the attacker. This is by no means the only type of information that a computer criminal may be after, but cookie theft is a common goal of cross-site scripting.

When the cookie has been acquired, the cookie thief can often reverse engineer it to obtain a number of details about the user. Precisely how damaging this type of attack can be will depend on the information actually stored in the cookie, but typically cookies contain a username and often a password as well. Depending on the type of site, the cookie may contain account numbers, residential information, financial information, or all of these. Even if the cookie contains very little, more information can be gathered from the Web site itself if the stolen cookie facilitates the ability to log-in to the Web site. After logging in with the user's username and password, the thief can steal various account details or hijack the account by resetting the password. The username and password could also be used on other Web sites where the user is likely to have accounts. For example, stealing a cookie from an online book seller would provide a computer criminal with a set of credentials to try against other online booksellers' Web sites. A computer criminal who can gain access to a user's e-mail will likely have also gained access to a quick summary of the online purchases that the user has made because most online businesses send order and shipping confirmation e-mail messages.

216.3.3.4 Cross-Site Request Forgery

Cross-site request forgery can be thought of as almost the reverse of cross-site scripting. Also called session riding, this is an attack on the communication between a Web site and a user, just like cross-site scripting, but this time it is the Web site's information that is under attack rather than the users. This type of attack uses cookies without the owner's knowledge or permission, again usually with a crafted HTML hyperlink that the user is persuaded to click on. The crafted hyperlink uses a Web application path (that must be known in advance) that sends the user's cookie along with a specific request. Note that, for the attack to be successful, the user's computer must have a valid (and unexpired) cookie for the Web site under attack. Also, the attacker does not need to steal the cookie or know anything specific about its contents for the attack to be successful.

Ultimately, cross-site request forgery is an attack on trust. Any request from a user's browser reflects that user's true intentions. Although this type of attack has a variety of potential targets, auction sites seem to be a particular favorite. In a typical attack on an auction site, the attacker will use cross-site request forgery to issue spoofed bids for an item he has placed on the site to increase its selling price. The attacker must experiment with the auction site itself to determine the execution path and parameters of the Web application and develop a crafted hyperlink. The attacker can then deliver the hyperlink via a mass mailing, another Web page, or some other means. The message and hyperlink often take the form of "You've just won a [prize]" or "Click here to redeem your [prize]." They may be more subtle, however, such as: "Your bid for the item has been received; click here to cancel." Ordinary users are often easily persuaded to click on these hyperlinks because they are unaware that doing so can be dangerous. A mass mailing with such a hyperlink may never reach a large population of computers that contain eligible cookies, but it does not need to. Only a few successful attacks will accomplish the attacker's goal of raising the selling price of the item.

216.3.4 Social Engineering

Social engineering can be thought of as hacking people rather than computers and networks or, more often, as hacking people as a means to hacking computers and networks. When legendary hacker Kevin Mitnik wanted to hack telephone systems, he did not start with buffer overflows, format string vulnerabilities, cross-site scripting, or session riding. Instead, he did something much more effective; he called the help desk. Mitnik used social engineering to gain the confidence of engineers and business people at telecoms and their equipment vendors, and he acquired the technical details necessary to hack not only telephone switches but also the very electronic surveillance systems that law enforcement were using to track his activities. Successful social engineering takes advantage of ignorance, fear, greed, ego, or other human attributes to manipulate behavior for information gathering or other goals.

In spite of the widespread nature of network, operating system, and application technical vulnerabilities, social engineering is more prevalent today than ever before, although most applications of social engineering are less dramatic than the example above. Note also that many of the technical attacks described earlier contain within them one or more social engineering components, such as persuading the user to click a hyperlink to facilitate the attack. The effectiveness of social engineering can be demonstrated by this example of a technique commonly used by hackers and professional penetration testers. Call a company's help desk (around 5:00 p.m. works best), and state that you are the president (or vice president) of the company and you are trying to give a presentation. Request and insist that your password be reset immediately. Although this example may seem absurd, it is all the more absurd in that it frequently works. Many organizations have insufficient safeguards to prevent a social engineering attack as obvious as this one. Two common social engineering attacks on the Internet are phishing and something now known as the Nigerian letter scam. These became quite popular when, shortly after the invention of spam, computer criminals faced the challenge of how to make spam pay.

216.3.4.1 Phishing

Phishing can be thought of as a form of identity theft and is usually performed via e-mail. In a typical phishing scam, an e-mail is crafted to appear as though it came from an Internet retailer. It asks recipients to provide missing account information, apply for a new service, or in some other way provide information. The e-mail itself may appear to have been sent from the correct e-mail address and be quite convincing visually, including logos, artwork, and fonts lifted directly from the retailer's real Web page. Although Internet retailers are a favorite, the e-mail may appear to come from a bank, a credit card company, or other financial entity. Mortgage, student loan, and debt consolidation firms have all been used.

216.3.4.2 Nigerian Letter Scam

The Nigerian letter scam can loosely be classified as confidence fraud but often involves wire fraud and monetary damages, as well. The scam has several different versions, but generally the attack occurs in two stages. Stage one begins with an e-mail from someone identifying himself as an attorney, a banker, or some other professional. The first e-mail almost never asks for money or for personal information. Instead, it informs the recipient that an inheritance awaits from the recipient's long-lost relative (usually in Nigeria) who has just died in a plane crash, oil fire, or some other tragic way. If the recipient responds to the e-mail, the scam proceeds to stage two, where the recipient is told that fees must be paid, bank account details provided, or accounts established in foreign banks to facilitate transferring the money that the recipient has inherited. These e-mail messages often use compassionate rhetoric and emotion to make them sound more convincing. They may also contain hyperlinks to news stories about real disasters where many deaths occurred to validate the claims of the e-mail. In some variations of this scam, the e-mails are supposedly from figures in the entertainment industry, famous humanitarians, or figures in world politics such as a recent example where the e-mail appeared to come from Charles Taylor, the former leader of Liberia.

It is all too easy to ask ourselves who would fall for something like this and dismiss social engineering as a gimmick attack. This is not the case. These scams are effective for two reasons. First, attacks like these only have to be successful a few times to be economical for the computer criminal. A successful social engineering attack like the Nigerian letter scam will typically result in a $2,000–$5,000 monetary loss for each victim. The perpetrator does not care that they had to send 10 million e-mail messages to find one or two victims. They made spam pay. The second reason why social engineering is effective is that human behavior is something difficult to upgrade. An offer like these may actually seem plausible if a potential victim is in a difficult economic predicament.

216.4 Tactics of the Security Professional

Why does computer crime continue to thrive? One answer might be because of our two oldest friends, ignorance and apathy. While this is partially true, it is not a complete answer. New technical threats and other exploits are found almost daily. Even when networks are defended, systems are patched and hardened, and applications are well coded, new exploits can cause tremendous damage before vendors can create appropriate software patches and before scanners can detect them. What is even more alarming is the number of exploits that are being found in applications (as opposed to network devices and operating systems), because this can be the most difficult area of technology to assess properly. Security practitioners are left with basic principles to guide their efforts:

- Comprehensive security
- Layered technical safeguards
- Active vulnerability management
- Strong security awareness

216.4.1 Comprehensive Security

Comprehensive security must be practiced in today's environments to control the spread of computer crime. Corporate policies, operating procedures, and decisions must reflect the results of proper security risk analysis and regulatory requirements. A top–down approach with properly constructed policies and operating procedures will make specific security measures easier to implement and maintain.

216.4.2 Layered Technical Safeguards

Layered technical safeguards are also essential. Technical safeguards must be present in all levels of the information technology environment: networks, systems, and applications. Technical safeguards (such as network firewalls) must be used properly at all entry points to the network and must be configured to restrict network access to only those systems and services necessary for the organization's business relationships. Individual computer systems and applications must have properly configured (and up-to-date) access controls.

216.4.3 Active Vulnerability Management

Vulnerability management must also be practiced in all levels of the IT environment. Although technical vulnerabilities are more and more numerous, the overwhelming majority can be mitigated with software patches to network devices, operating systems, and applications. Network and system administrators must maintain consistent and up-to-date patch levels on all of their equipment. Although this task can be expensive in administrator time, if performed manually, the software patches themselves are usually free from most vendors. Many software vendors (including Microsoft) have also implemented automated or semiautomated patching systems to keep individual systems or entire environments up to date. Although vulnerability management may be a thankless, boring, and unglamorous endeavor, it should be recognized as an ongoing cost of operating an information technology environment, not something left for the administrator's spare time. Recall that the Slammer worm was one of the most damaging worms of all time, even though it lacked a destructive payload. It is worth mentioning that the specific buffer-overflow vulnerability that allowed the Slammer worm to spread had been published and patched by Microsoft, a full six months before the worm was launched.

216.4.4 Strong Security Awareness

Awareness, more than any other single factor, constitutes the most effective measure available to the practitioner. Security practitioners must make others more aware of security issues and must become more aware themselves. Today's computer criminal is more sophisticated and better armed than ever before, and if this were not enough computer crimes are growing more numerous each year. Computer crime strikes at every level of our technology infrastructures, our business and service infrastructures, and even in our personal economics and communications. Security practitioners should adopt a structured approach to pervasive security awareness, encompassing the organization's senior executives, management, employees, partners, and customers. Senior management must understand that security is a business wide issue and not a compartmentalized project. Management (in all departments) must understand that every employee (especially analysts, developers, administrators, support staff, and others) has a role in implementing proper security. Employees must be educated to understand the security threats relevant to their specific jobs functions and how corporate policies affect these functions. Customers must also be made aware of security risks, especially identity theft. At minimum, customers of online businesses should be sent periodic e-mails that warn them never to disclose their account numbers, log-in credentials, or other personal data in response to an e-mail. Phishing scams would be virtually stopped cold if online businesses took the initiative to educate their customers about the threat.

216.5 Conclusion

This chapter was intended to offer the security practitioner some practical information about specific computer crimes that occur today but also to provide a new lens on the subject as a whole: Computer crime is a new and ever-evolving manifestation of fundamentally old ideas. What is really happening in computer crime? The same sort of activities that were happening before there were computers—fraud, theft, destruction, disruption, and more—all of which occurred before computers became a ubiquitous part of our lives. The successful security practitioner will adapt established security concepts and principles to meet new, ever-evolving situations and challenges in computer crime.

Phishing: A New Twist to an Old Game

Stephen D. Fried

217.1 Introduction

Today's media, as well as many security professionals, often create the impression that identity theft is a modern creation, a result of the marriage between large-scale access to instantaneous information and an age-old desire of certain members of society to acquire knowledge and wealth that are not rightfully theirs. Although the creation and mass adoption of inexpensive computers, networks, and online data repositories in the last 30 years has, perhaps, accelerated the growth of this area of crime, identity theft is a problem that has plagued humans since the earliest of times.[1]

Successful identity theft requires two components. The first involves the subversion of applicable technology. In this case, the term "technology" does not necessarily refer to computers and networks but rather refers to any method of capturing, storing, copying, or transmitting information. In ancient days, technology may have referred to the King's official seal or official signature. The ability to capture or duplicate either one gave an identity thief enormous potential power. More recently, before online credit verification became the norm, the theft of carbon paper sheets from credit card receipts was a highly successful method of gaining access to a victim's identification and credit credentials. By obtaining and controlling the technological component of a person's identity, the thief is halfway down the road to using that identity for nefarious purposes.

A potential information thief must also compromise the human element that governs most (if not all) information transactions. Although it may not appear to be the case in modern society, at the extreme endpoints of all transactions are human beings wishing to exchange something of value, whether it is financial reward or important information. Given this fact, it reasonably follows that an effective way to forward the theft of one's identity is to subvert the human element at either end of the communications chain. When combined with the previously mentioned subversion of applicable technology, this can be a powerful weapon for the information thief.

The latest weapon in the history of identity theft, and one that has received increasing security industry scrutiny and hype, is the act of tricking an unsuspecting user into revealing personal information through the distribution of mass e-mail. This latest scam has been dubbed *phishing* and has proven to be quite effective as a means to advance identity theft on a large scale. It attacks both the technology used to conduct business on the Internet and flaws in the human element utilizing online transactions.

Because of the attention surrounding this latest practice and the related commercial and consumer panic surrounding these attacks, this chapter examines the modern practice of phishing in all its aspects. The chapter explores the evolution of phishing, its implementation, and its effect on modern Internet usage and discusses ways to identify and prevent phishing attacks.

217.2 Phishing Defined

Although the term "phishing" has been used a great deal in the media lately, it is best to begin this discussion with a firm definition of the term and its usage. For the purposes of this chapter, phishing is defined as:

> The act of sending to a user an e-mail falsely claiming to be an established legitimate enterprise in an attempt to trick the user into surrendering personal or private information. The e-mail typically directs the user to visit a Web site where the user is asked to update personal information, such as passwords and credit card, Social Security, and bank account numbers, that the legitimate organization already has. The Web site, however, is bogus and set up only to steal the user's information.[2]

To further clarify the definition, phishing in today's common usage involves not just the delivery of a single e-mail to a single user but the distribution of thousands of e-mails to thousands of users. The modern act of phishing, like its correctly spelled synonym, is an act perpetrated by an attacker (the "phisher") who casts a wide net (large-scale e-mail distribution) to see how many victims (or "phish") can be caught in that net. Although phishing as a technological threat is a relatively recent phenomenon, it is, in fact, merely the latest ploy used to advance the act of identity theft, which has a much longer history in both technological and nontechnological forms. At its core, phishing is a technically advanced form of the classic con game: Trick a victim into giving up something of value, then use that for personal gain.

217.3 A Brief History of Phishing

The spelling of the term "phishing" comes from the early annals of computer hacking, when the misuse of the phone system for fun or profit was called "phreaking." Phone hackers came to be known as "phreakers" or "phreaks" in some circles. The first known reference to the term "phishing" as an activity came in 1996, when a user on the alt.2600 news group posted the following message:

> It used to be that you could make a fake account on AOL so long as you had a credit card generator. However, AOL became smart. Now they verify every card with a bank after it is typed in. Does anyone know of a way to get an account other than phishing? (mk590, "AOL for free?" alt.2600, January 28, 1996)

Hacked accounts became known as "phish" and were used as currency in the hacking underground. They would be traded for other phish (from a desirable or valuable service) or in exchange for stolen or unlicensed software.

The popular and trade media picked up on the term around 1997. By 2002, the use (and practice) had become common. Early phishing attempts showed all the indications of unsophisticated amateurs trying to develop a new technology. Phishing e-mails riddled with spelling and grammar mistakes indicated a large presence of non-U.S. nationals for whom English was not a primary language. Despite their apparent lack of sophistication, however, these early attempts were extremely successful. With success came more attention, and the second generation of phishers entered the field. These new entrants sharpened their skills and increased the level of sophistication. They cleaned up the basic grammar and formatting issues that gave their predecessors away and introduced elements that are now common: use of graphics to enhance the authenticity of the e-mail, exploitation of HTML features (and security vulnerabilities) to advance their goals, and spamming and targeted-marketing techniques to increase the potential for a large "catch."

By 2004, the level of sophistication and profit potential of phishing rose such that it attracted a third generation of exploiters. Organized crime has embraced phishing and funded much of the most recent developments in the art, with Russian and Eastern European syndicates leading the way in perpetuating these crimes. The attacks are more sophisticated than ever. Rather than relying on unsophisticated universal resource locater (URL) links and hastily crafted Web pages, today's phishing artists use complex attacks such as URL obfuscation, man-in-the-middle attacks, cross-site scripting, and exploitation of client vulnerabilities. Phishing is now also an international phenomenon. Phishing attacks have targeted most major banking organizations in the United States, the United Kingdom, and Australia. According to the Anti-Phishing Working Group, the United States hosts the largest percentage of phishing sites (by far), followed by China and Korea.[3]

217.4 Lies, Darned Lies, and Phishing Statistics

The increased acceptance of online commerce and, in particular, online banking has boosted the dramatic rise in phishing. Consumer product companies and financial institutions have been feverishly working en improving the online access capabilities of their wares and services. Financial services companies have been particularly eager to encourage customers to sign up for online access to their accounts, which provides customers with a convenient and easy way to access their money while at the same time lowering the company's transaction costs and enhancing customer loyalty. Consumers and client businesses, for their part, have welcomed the trend and have begun using Internet-enabled account access as a comparison point and service differentiator when shopping for banks.

According to the Tower Group, as of late 2004 over 30 percent of all securities were traded over the Internet, more than 33 million households were taking advantage of online banking services, and almost 10% of all credit card purchases were made online.[4] Other research suggests that the numbers might vary somewhat (higher or lower) than those of the Tower Group, but all agree on one theme: Online commerce is big and getting bigger. Moreover, when it comes to the size of the phishing phenomenon, most researchers agree that the numbers are likewise growing. The results of various studies on the subject do not always agree, however. A Gartner survey in April 2004 indicated that 41 percent of survey respondents had received, or believed they had received, a phishing e-mail.[5] Another study sponsored by TRUSTe in September 2004 showed that "76 percent of online consumers are experiencing an increase in spoofing and phishing incidents and that 35 percent receive fake e-mails at least once a week."[6] A study by the Federal Deposit Insurance Corporation (FDIC) showed that, of the 2 million U.S. adult Internet users that experienced some form of identity theft, over half believed they received a phishing e-mail.[7]

Some of the figures regarding phishing are staggering. In January 2005, 2560 phishing sites were reported, representing a 28% increase in the last six months of 2004. In January 2005 alone, nearly 64 product brands were the targets of phishing attacks, 80% of them from the financial services industry.

The average time a phishing site was online before being shut down was a little over five days, but the longest window was 31 days.[8] The statistical and anecdotal survey results all seem to lead to the conclusion that, as is the case with online commerce, phishing is also big and getting bigger; nevertheless, when it comes to the financial impact of phishing, the research that has been conducted leads to widely differing conclusions. Gartner research in June 2004 estimated that the cost to banks and credit card issuers from phishing attacks and related identity theft losses has been U.S.$2.4 billion,[9] or roughly U.S.$1200 per user. By contrast, the previously mentioned TRUSTe study estimated the total monetary loss to be only U.S.$500 million, or U.S.$115 per user. In addition, a recent report by the Information Security Forum puts the loss per personal account at around $200.[10] Why the large contrast in numbers? In many ways, this is merely an extension of the well-known problem of obtaining accurate statistics on security incidents and their impact. The companies involved do not want to publicly admit their security or financial failures, and the victims keep silent out of embarrassment. Alternatively, companies may elect to disclose such information only to trusted parties (such as a government agency) and not to consulting or research organizations (or *vice versa*), thus causing a disparity between the various research studies.

So, is phishing truly a financial crisis worthy of all the attention it is getting? The real numbers may never be truly accurate; however, to paraphrase Leonard Henry Courtney,[10] when it comes to finding accurate metrics on the effects of phishing, there are "lies, [darned] lies, and statistics." While the numbers appear to be large and growing, when compared to other types of fraudulent crime (for example, credit card or telephone toll fraud), the phishing numbers pale by comparison. To the targeted institutions and the people who are directly affected, however, the numbers are real and worthy of definitive action. Most security professionals agree that the trend is both alarming and moving most definitely upward. The degree to which the available statistics can be used to bolster or refute a particular viewpoint on the growth of phishing is therefore a matter of how such statistics are interpreted and applied.

217.5 How Phishing Works

The remarkable thing about phishing (and the aspect that makes it so successful) is the relative simplicity with which it operates. At its core, phishing is fundamentally a social engineering attack,[11] preying on the victim's naiveté to click on an altered URL or enter personal information into a Web site. Although it is true that recent phishing attacks are becoming increasingly sophisticated in their execution and maliciousness, underneath any overlaid technology is an attempt to fool a user into giving out information he normally would not. This section describes the basic steps most phishing attacks use.

The first step involves the phisher choosing a target organization to hide behind and against whom to perform the attack. How that organization is selected will vary from attack to attack, but the basic criteria are that the user must know the organization and the user most likely has an existing electronic relationship with the organization. For these reasons, the most often-selected organizations are financial institutions (with their current push to increase their customers' use of electronic banking), large online retailers such as Amazon or eBay, or Internet Service Providers (ISPs) such as EarthLink or America Online. After selecting an organization, the phisher must construct a Web site that looks and feels like the target organization's Web site. It may be a direct copy of the organization's official site (copied through the use of any number of available Web crawling and site-cloning tools), or it may simply include an adequate supply of the layout symbol logos, and corporate colors of the target organization to be convincingly real to the phish. Whichever path the phisher chooses, the result will be a convincing Web site purporting to belong to the target organization.

The next step is for the phisher to cast the net for the phish. The traditional method for this is for the phisher to compile a list of target phish to receive the e-mail; however, the most recent phishing attacks are much more sophisticated, forgoing this manual (and limited) step in favor of more modern targeting. Many modern phishing attacks will use sophisticated spamming techniques to address the e-mail to a large audience. Typically, a phisher will use one of the Internet's ever-present bot nets (networks of computers infected with Trojan horse programs) to distribute e-mails to the phish. Although this increases the likelihood that the e-mail will be sent to phish who do not have a relationship with the target organization (thus ignoring the message), the economics of large-scale spam mean that the phisher can send hundreds of thousands of e-mails for a relatively low cost. In an attempt to increase the number of phish who will actually take the bait, the most sophisticated attacks will use modern targeted-marketing methods to narrow the list of phish to those who will most likely respond to a communication from the target organization.

Next, the phisher must create an e-mail that will entice the phish into going to the phisher's Web site. The most common ploy is to tell users that there is a problem with their accounts or that they need to act immediately in order to continue to use the organization's services. A basic common phishing letter is shown below:

> Dear BigBank customer,
>
> In order to comply with new federal regulations designed to protect consumers from fraudulent use of their accounts, BigBank has recently performed a review of all customer information. During that review, we noticed several pieces of information missing from your records.
>
> In order to ensure proper processing of your financial transactions, please visit our Web site at www.bigbank.com/updatecustomer. There you can update our records with your most recent information. To avoid any disruption of service to your account, please update this information immediately.
>
> We appreciate your assistance in this matter.
>
> Sincerely,
>
> *BigBank*

The e-mail may be enhanced with graphics, colors associated with the target organization, and the company's logo. All increase the apparent legitimacy of the e-mail and fool the phish into believing the e-mail really came from the organization.

When a phishing e-mail is launched, 50,000–1 million e-mails (or more) may be sent to potential phish. Because of the large volumes of e-mail, most of these are caught in spam filters set up by Internet Service Providers and individual organizations, resulting in a small percentage of the original e-mail sent reaching actual consumers, Estimates on the delivery rate vary, but even if only 0.1 percent of the original 1 million e-mails reaches live consumers, that translates into 1000 potential victims. Of these, most recipients will either ignore it (believing it to be harmless spam) or act on it, This latter group can be split into three subgroups: (1) those who believe it is legitimate and respond to it, (2) those who will recognize it as a phishing attack and ignore it, and (3) those who will recognize it as a phishing attack and report it to the target organization. The first subgroup represents the "catch of the day" for the phishers; however, of this group, only 5 percent will click on the link in the e-mail, and only 1–2 percent will actually lose any money.[10]

The second subgroup poses no real threat to the phishers. Although they recognize it as a phishing attempt, they choose just to ignore and delete the e-mail. It is the third subgroup that poses the greatest threat to the phishers. It is generally a race to see how many phish (the first group) can be caught in the net before the scam is halted, which occurs when people in the third subgroup notify the target organization, which then works to get the site shut down, or the legitimate owner of the collecting site notices it has been taken over by phishers and strengthens the defenses of its site.

The phish who do respond to the e-mail will most likely be told that their relationship with the target organization is under review or that there is some problem with their information on file with the organization. They will be presented with an innocent-looking URL link that they can click to correct the problem. When they click on the link they are directed to the false Web site set up by the phisher where they are asked to enter their personal information. Because the false Web site looks almost exactly like the real one, very few of the phish will be able to tell the difference and will believe they are giving their personal information to the actual organization.

While all of this is going on, however, other events are also likely to be taking place. The large number of e-mails sent out in the name of the target organization will most likely be noticed by that organization, either because the organization has been contacted in relation to the "spam" it appears to be sending or a concerned customer has contacted the organization to notify it that they received a suspicious-looking e-mail and are questioning its validity. The organization may also receive a high volume of bounced e-mail replies due to the large number of phishing e-mails sent to invalid e-mail addresses. When the attack is recognized, many organizations (particularly those that have had previous phishing attacks targeted at them) will mobilize into action. They will investigate the e-mails to see if the origin can be determined. If it can, they will use any contacts they have (or can establish) with the offending site's ISP to attempt to get the site taken down. They may also elect to contact law enforcement officials to report the incident and request their assistance. Because of the rise in phishing attacks, most financial institutions and law enforcement agencies are getting much better at quickly identifying attacks and working cooperatively with the inter-national Internet and hosting community to shut down offending sites before much damage can be done.

If the organization reacts quickly enough they can get the offending site taken down before any customers fall for the con and disclose personal information. If they do not, some of the phish will have wandered into the net, gotten caught, and given up their valuable personal information, which the phisher can then use to perform identity theft, gain access to credit or services, or sell to another party for profit.

217.6 Variations on a Theme

The process described in the last section shows the most basic steps involved in a phishing attack; however, as with all Internet attacks, several variations to the basic steps can be used to increase the sophistication of the attack or further obfuscate the origin of the attack. As users become more aware of phishing risks, some phishers have devised methods of forcing a phish to the false Web site without requiring that they click on a specific link in the e-mail. These attackers use HTML-based e-mail that includes a hidden script. When the HTML is processed by the phish's e-mail program, that hidden script is executed so the phish's computer redirects a connection to the target organization's Web site to that of the phisher. Even if the user later enters the organization's real Web site address directly into the browser, the alteration performed by the script will instead open up a connection to the fraudulent site.

In some cases, the goal of the attack is not simply to gather personal information from the users on a bogus Web site but rather to gather information or perform other malicious acts over the long term. In these cases, users may be directed to a Web site that has been falsified to look like the target organization's site or they may be enticed there by the promise of exciting content (gambling or adult content, for example). Instead of asking for personal information from a user, though, the site downloads a keystroke logger, worm, or Trojan horse program to the phish's computer.[12] The logger or Trojan horse can then gather up the phish's IDs and passwords from multiple sites and send them back to the phisher later. The Trojan can also display pop-ups asking for personal information on specifically targeted Web sites. If a virus or worm is installed, it can also spread to other computers and gather similar information from multiple computers. Trojans and worms also find their way onto users' computers through all the traditional methods, including operating system and browser vulnerabilities and peer-to-peer file services. Because they are not readily apparent to the user, Trojan-based phishing attacks have the potential to steal much more sensitive user information over a longer period of time than a standard e-mail-based attack.

Some phishers do not want to go through the trouble of duplicating an organization's Web site. One way to make the process of collecting personal information much more efficient is to simply break into the target organization's real Web site through the exploitation of any security holes that may be present on that site. When phishers get inside the site, they can set up sniffers or scripts to capture user information as it is entered into the site. The phishers can then just wait for users to log into the site or, if they are impatient, they can send out an e-mail to users of the site (whose addresses may be obtained by perusing the site's user database), inviting them to log into the organization's Web site. This reduces the number of e-mails sent to nonaffiliated users and lessens the likelihood that the organization will be reported for sending out spam.

A common way to keep the phish from recognizing that a con is underway is to use a URL that closely resembles that of the target organization. Using special characters in place of standard alphabetic characters in the URL can do this. For example, www.bankportal.com can be changed to www.bank-porta|.com. Note that in the second URL the vertical bar character ("|") was used in place of the "l." Another example would be www.sh0pping.com, where the number zero was used instead of the letter "o." Phishers can also nest URL links inside one another to further disguise the true address of a site. An example of such a URL might be:

www.aol.com/account/update/getupdated.info@www.attacker.com/stealinfo.html

Most users, should they bother to look at the URL at all, will see the beginning of the URL: www.aol.com/account/update/getupdated. The unsophisticated (or unobservant) phish will stop there, believing that the link is legitimate; however, when the link is properly processed, it will actually send the user to www.attacker.com.

Because much phishing e-mail is sent in HTML format, the phisher can use various HTML formatting techniques to mask the real destination of the link contained in the e-mail. Using the sample phishing e-mail from BigBank provided earlier, the HTML code for a legitimate link in the e-mail would be:

…visit our Web site at <a href=http://www.bigbank.com/updatecustomer>www.bigbank.com/updatecustomer</a>. There…

The text inside the <a…> bracket indicates the link where customers will be sent if they click on the link. The text between the <a…>and </a> symbols is what the customer sees when the HTML has been processed and displayed by the browser. However, the phisher can use this to mask the true origin by changing the HTML to the following:

…visit our Web site at <a href=http://www.evilattacker.com/grabsensitivedata>www.bigbank.com/updatecustomer</a>. There…

Recipients will still see the link as www.bigbank.com/updatecustomer, but if they click on the link they will be directed to www.evilattacker.com/grabsensitivedata.

Phishers often use flaws found in the Simple Mail Transfer Protocol (SMTP), which is used to deliver most e-mail on the Internet, to mask the true origins of an attack. It is a simple matter to falsify the "Mail From:" header in an outgoing e-mail in order to make the e-mail appear as if it came from the target organization. Of course, this means that if the phish decides to reply to the e-mail it may be returned with an error message, thus tipping off the phish that something is wrong. To counter this problem, the phisher can falsify the "RCPT To:" field in the e-mail, substituting an e-mail address under the phisher's control, so any replies to the e-mail will be directed to a working mailbox (most likely a hijacked account to prevent tracing ownership back to the phisher).

Another common obfuscation technique is to establish so-called "cousin" domains in the name of the phisher that look very much like the target organization's domain. Examples of this would include myebay.com or amazonaccountupdate.com. These sites are not registered to the target organizations (eBay and Amazon, respectively), but to the unwary end user they look like they are.

Like all computer attacks that have evolved over time, from the earliest buffer overflows to today's most sophisticated viruses and worms, the sophistication of phishing attacks has steadily risen while the requisite skill set has decreased. In the early days (actually, just a couple of years ago), creating and executing a phishing attack took a fair amount of skill. Recently, however, the emergence of phishing “starter kits” has enabled more amateurs to enter the field and made it much easier to carry out phishing attacks. In addition, because of the widespread distribution properties that phishing attacks have, they have become a common carrier mechanism for worms, viruses, spyware, and keystroke loggers.

217.7 The Effects of Phishing

While most stories and articles about phishing focus on the impact to consumers and cases of financial loss and identity theft, phishing actually has two classes of victims. Both the consumer and the targeted organization share the burden of a successful phishing attack. For the consumer, the potential for direct financial loss may be frightening enough. Given the proper information, the phisher may use the consumer’s bank account numbers, credit card information, and home and family data (addresses, birth dates, relatives’ names, and Social Security numbers) to establish credit in the consumer’s name, purchase goods and services, or perform illegal acts posing as the consumer. Although U.S. law limits the consumer’s liability for unauthorized credit card use, no such limits exist for general bank account misuse. In addition, the consumer’s credit rating, reputation, and financial stability may be seriously jeopardized by the fraudulent use of information gained through a successful phishing attack. Add to that the time, effort, and cost required by the victims to correct their financial and credit information as well as the emotional toll on the victims as their good names are potentially ruined.

Financial institutions and other commercial organizations feel the effects on a much larger scale. Call center volume may rise dramatically as customers call an organization to inform them of the e-mail and to question its validity. The organization will need to mobilize its anti-phishing resources, taking them away from other important tasks. Efforts then focus on identifying the source of the e-mail and shutting down the offending server. If the organization’s own systems were compromised as part of the attack, they may require reconfiguration or reloading, making them unavailable for processing customer transactions and potentially resulting in loss of revenue.

Should the attack succeed in catching some phish, the organization must take steps to clean up and reinforce its defenses. Customers of the organization may have to be notified that their account information has been (or has potentially been) compromised. This may be done as a matter of law (for example, compliance with the California Security Breach Information Act[13]) or as proactive recognition of responsibility on the part of the organization. In extreme cases, the organization may decide to reset the passwords of all its users. This can be a costly course of action, as it is bound to increase support costs due to customers needing assistance with the change, in addition to the cost of notifying users. This solution also has the unattractive quality of placing a burden or inconvenience on end customers. Finally, the potential loss in customer confidence can have a highly negative impact. If several repeat and severe events happen to the same organization, customers who value the security and integrity of their information may choose to take their business elsewhere. As of early 2005, despite the fact that several major banks and consumer product organizations have been the victims of repeated phishing attacks, large-scale customer defection has not yet occurred. Only time will tell if organizations can keep this threat from becoming a reality.

217.8 Underlying Problems

It would be easy to write off phishing as simply the latest version of the age-old con game or the newest fad du jour in Internet attacks. Such an approach minimizes some of the underlying issues that make phishing such a dangerous proposition for companies and consumers alike. An examination of these underlying issues reveals a large number of individual weaknesses, all contributing to the overall problem.

The first underlying problem is that, for the most part, commercial organizations do not own or maintain their customers’ computers. This leads to a wide diversity in configuration and maintenance styles amongst the masses, ranging from the extremely well configured (typically the technically savvy or extremely paranoid users) to the hopelessly vulnerable (e.g., the typical Internet user who knows little and couldn't care less about the inner workings of a computer). If companies could assume full ownership of and responsibility for the maintenance of their customers' equipment, they could ensure that it was well maintained, up to date with the latest security patches, and configured with the appropriate settings and technology controls to recognize and resist such attacks. Alas, this is not the case, and the burden of maintaining tight security has shifted from the organization (who has the resources and expertise) to the consumer (who may have neither).

Another underlying cause is the anonymity of Internet transactions. A bank's customers do not need to walk into a branch to perform a deposit or withdrawal in person, nor do they have to do their banking only from Monday to Friday, 9:00 a.m. to 5:00 p.m. Banking (indeed, most Internet-based commerce) can be done 24 hours a day, every day of the year. Because of the lack of a personal relationship between the consumer and the seller, identity impersonation is easier, and direct observation of customers by the company's personnel is eliminated. This anonymity and the lack of proximity also work for the phisher. The phisher does not have to be located close to the phish. Phishers have no storefront to assemble or infrastructure to present to the phish other than the appearance of a recognized institution.

The barriers to entry in the phishing game are extremely low. Scammers as wide-ranging as individual con artists to large international organized crime rings have flocked to phishing because, to use the oft-misquoted Willie Sutton, "That's where the money is."[14] All it takes to start a basic phishing attack is a Web site (obtainable for less than US$100[15]), access to an e-mail server (preferably someone else's) or anonymous remailer, some HTML coding skill (or the use of any of a dozen popular Web page building programs), and a list of potential e-mail addresses gained through Internet purchases, UseNet postings, mailing lists, or Web pages.[16] The use of advanced techniques, such as implanting keystroke logging software on a target organization's server or implanting a worm or virus in the e-mail, will, of course, raise the cost. Additionally, the risk of discovery and capture is relatively low. If done properly, none of the links (the e-mail or Web server) can be traced to the actual phisher. Moreover, depending on how and where the information or money is transferred from the phish to the phisher, detection, apprehension, and prosecution can be extremely difficult. When low cost of entry is combined with low risk of detection, it results in a winning combination for exploitation.

The final contributor to the problem, and the one that is most affected by the human element, is the fact that most people are simply too trusting of the world around them and too willing to accept that everything they see on their computer screen is as it appears to be. This trust, of course, is the basis for all social engineering attacks, and phishers exploit it as much as possible. Most people like to be (and be seen as) helpful and, when asked with just the right degree of authority and sincerity, will do almost anything to appear helpful and cooperative, Even the act of disclosing highly personal information can be justified by the victim who believes the cause is right (for example, helping ”your bank” correct its account errors).

217.9 Phishing Detection

Sadly, the first line of defense in phishing detection is the end user who receives a phishing e-mail. Because of the lack of sophistication of many Internet users, many of these schemes go undetected. This section provides a couple of examples of phishing attacks that have occurred. In each example, indications that should lead to suspicion are explored. Although this is not intended as an exhaustive survey of all possible phishing techniques, it does highlight some of those that are common.

Exhibit 217.1 shows an actual example of one such e-mail sent by a phisher impersonating a large ISP. Starting from the top of the e-mail, the use of an altered "From" address can be seen. Instead of staff@earthlink.net, the phisher used staff@earth|ink.net as the sending e-mail address, substituting the vertical bar for the letter "l". The e-mail was sent to a valid Earthlink account holder, indicating that the phisher somehow obtained a list of valid e-mail accounts at the ISP or used a name-generating program to come up with potential account names.

Subject: EarthLink account billing verification

Hello,
Dear member,
During our regular update of all accounts , we could not verify your current stored information.This maybe due to our payment processing failure, billing system overload, invalid card number, exp date, daily limit, insufficient funds, or other reasons. We need you to re-enter valid payment and verification information.

Your information is submitted via a secure server. EarthLink keeps all of your contact and billing information confidential and private.

Click here to verify your information https://www.earthlink.net/aw-confirmation/verify.jsp?.

Important Notice:EarthLink never asks about bank accounting number, bank routing number or bank checking number,But you should enter card pin number for bank call verification and recharge your account fast.

EarthLink billing Department Assistant,
Ibraham Michael.

EXHIBIT 217.1 Sample phishing e-mail 1.

As previously mentioned, early phishing e-mails suffered from a distinct lack of grammatical accuracy. In this example, some of the errors are obvious. The use of the double greeting ("Hello, Dear Member,") is one tip-off. Grammatically, "current stored information" and "… this maybe due to…" show that English was not a primary language for this writer. No self-respecting public relations department would have allowed this e-mail to go out under this company's logo, nor would they have allowed the writer to publicly admit to any "payment processing failure" or "billing system overload." These examples clearly indicate that, at a minimum, the author did not have the company's official approval to send this e-mail and, most likely, it was not sent from the company at all.

Moving down the e-mail a bit more, we see the URL where the phish is supposed to click to correct his information. The URL looks valid enough, but looking closer at the underlying HTML behind this e-mail[17] reveals that the link actually points to the following address:

http://www.earthlink.net|aw-confirmation|verify.jsp@www.badguy.com/images/firstpagel.html

Although the URL does contain www.earthlink.net, it is merely used as a diversionary tactic. The browser will parse the URL and see that it points to a server at www.badguy.com. Thus, it is clear that any users who click on this link to update their account information will not be going anywhere near an official EarthLink server.

In order to add an air of legitimacy to the effort, the e-mail includes an encouraging reminder to the phish: "EarthLink never asks about bank accounting number, bank routing number, or bank checking number, But you should enter card pin number for bank call verification and recharge your account fast." Aside from the additional grammatical and idiomatic problems, it includes an interesting psychological twist that is common to many phishing scams. It alludes to the privacy concerns of many Internet customers and attempts to show that EarthLink is concerned about them as well. Because it is a common perception among the public that criminals would never call attention to themselves or their actions, this act of calling attention to the problems of sending sensitive information over the Internet subtly causes the user to believe this could not be from someone performing such an act.

Another example shows the type of information that phishers attempt to get through their e-mails. The e-mail shown in Exhibit 217.2 purports to come from the online auction site eBay. This example shows some of the classic phishing "window dressing" already discussed, including the use of the eBay logo, the mention of eBay's attempt to protect the customer, and even the use of copyright and trademark notices at the bottom of the e-mail. When the phish clicks on the complicated link provided in the e-mail, however, the Web page shown in Exhibit 217.3 is displayed. The first thing to note about this page is the address of the Web page in the browser's URL bar at the top of the screen. This page shows an IP address rather than a Domain Name System (DNS) name. This is a major tip-off that the site may not be legitimate. In order for consumers to be able to easily find and identify their sites, as well as enforce their brand recognition, legitimate retailers use DNS names in their URLs. The use of the IP address in the example shows that the phisher is trying to hide the actual location of the server. Also note the inclusion of the security "reassurance" message at the top of the page: "For security reasons the following information must be confirmed."

This page asks for a number of different data items from the phish. Asking for the eBay user ID and password serves two purposes. The first is that it allows the phisher to log onto eBay and perhaps buy (or sell) items using the phish's identity. The second reason for obtaining this information relies on the predictability of most typical Internet users. Today's disjointed Internet commerce landscape requires users to establish IDs and passwords at multiple Web sites. To manage all of those IDs and passwords, most users use the same ID and password at every site. By getting the phish's eBay ID and password, there is a better-than-average chance that the same ID and password will work at Amazon, Expedia, AOL, or the user's ISP. The request for an additional password is a nice touch, hedging the fact that phish may have a couple of passwords that they use regularly.

The page goes on to ask for the phish's personal information. The user's Social Security number is a standard request on such pages, as is the credit card number and expiration. In consideration of the fact that many Web sites are requesting that customers enter the card verification value (CVV) code from their credit cards,[18] the page asks for that as well. Just for good measure, the page asks for the personal identification number (PIN) for the card, just in case it is a debit card instead of a credit card. The fact

To:

Dear eBay member,
As part of our continuing commitment to protect your account and to reduce the instance of fraud on our website, we are undertaking a period review of our member accounts.
You are requested to visit our site by following the link given below
http://arribba.cgi3.ebay.com/aw-cgi/ebayISAPI.dll?UpdateInformationConfirm&bpuser=1

Please fill in the required information.
This is required for us to continue to offer you a safe and risk free environment to send and receive money online, and maintain the eBay Experience.
Thank you
Accounts Management
As outlined in our User Agreement, eBay will periodically send you infomation about site changes and enhancements. Visit our Privacy Policy and User Agreement if you have any questions.

Security Update Need Help?

For security reasons the following information must be confirmed.

eBay User ID

You can also use your registered email.

Password

Please re-enter your complete name and confirm your Date of Birth

First name Last name

Date of birth
January 01 Year

Please re-enter your Social Security Number (SSN)
(The SSN consists of nine digits, commonly written as three fields separated by hyphens: AAA-GG-SSSS)

Important In order to prevent any fraudulent activity from occuring we strongly advise you to specify an alternative eBay password. This process allows us to give back sole control of the account to you in case something goes wrong with instructions regarding the account and its future safety.

Alternative password (6 character minimum)

Please note that when choosing a password we strongly recommend that you choose a password that can be easily remembered.

Please confirm your credit or debit card on file to help verify your identity. Your information is kept safe and private.

Credit or debit card number

Visa, Mastercard, American Express, or Discover
Your card will not be charged!

Expiration date
January –Year–
Please make sure your card expiration date is correct.
If your card has expired, please enter another one.

CVV2 code

The CVV2 code is the three-digit code on the back of the card following your credit card number

ATM PIN (Bank Verification) #:

EXHIBIT 217.3 eBay information confirmation Web page.

that most people repeatedly use the same (predictable) PINs may aid the phisher in gaining access to other Web sites or accounts.

217.10 Combating Phishing

The effort to combat the phishing problem is being fought on many fronts. Phishing is a multifaceted problem, attacking at both a technology and personal level and targeting both an organization and its customers. As such, successful prevention, detection, and response to a phishing threat must likewise take a multifaceted approach.

217.10.1 Consumer Awareness

Because the average user is an unknowing ally to the phisher, much effort has been spent on raising the level of awareness among the general population on how to identify and combat phishing. Information security practitioners whose organizations deal directly with consumers should begin formulating a strategy to inform their organizations' customers of the dangers of phishing and what they can do to prevent it. Common themes in such information awareness efforts include:

- *Never disclose personal information in an e-mail.* Personal information should not be disclosed through unencrypted Internet e-mail. If personal information, such as account numbers or Social Security numbers, must be given to the organization and a secured Web site is not available, contact the organization via telephone and verbally give them the information. Bowing to increased consumer concerns about privacy and the Internet, most established retailers allow for this type of information disclosure.
- *Do not dick on embedded links in an unsolicited or unexpected e-mail.* If an organization sends a customer a request for information that looks suspicious, the customer should contact the company directly via telephone or by independently entering the organization's Web URL into the browser. Avoiding embedded links in unsolicited e-mails is a good way to prevent phishing and malware infections. Some common sense must be employed here. For example, if a consumer

purchases a product from a retailer and immediately receives a confirmation e-mail with an embedded link, chances are that the e-mail is legitimate and the link is safe. On the other hand, if an e-mail arrives from a familiar site showing some of the previously discussed warning signs and asking the user to click a link to update information, extreme caution is advised. As with many other aspects of security, the context of the interaction matters a great deal in such cases.

- *Examine the URL in the browser's title bar and in any embedded links in an e-mail.* Do they make sense? Do they contain any unusual characters or spellings? Check the target URL in any embedded links by holding the mouse pointer over the link for a few seconds. The target address displayed should be the same as the address shown in the e-mail.
- Be *suspicious of urgent demands for information.* Phishers realize that it is only a matter of time until their scam is discovered by the target organization and their site is shut down. As a result, phishing e-mails will often use verbiage to urge phish to act quickly.
- *Look for spelling and grammatical errors.* As demonstrated by the examples, spelling and grammar mistakes ate en immediate due that something is amiss. As phishers have become more sophisticated the incidence of such mistakes is getting rarer, but it does still occur.
- *Check for the use of SSL.* Any Web site asking for personal information should have its transmissions protected by SSL encryption. Two indicators that SSL is enabled are the use of "https://" in the URL of the page and the display of a closed lock icon at the bottom of the browser window (an open lock indicates that SSL is not in use.) These assure that the transmission between the user's browser and the organization's Web server is encrypted. It is possible for a crafty phisher to falsify these indicators through the use of overlaying windows, frames, and graphics on the phishing Web site, but the average user is unlikely to detect this. The absence of such indicators, however, is a clear signal to any user (sophisticated or not) that the information is not protected at all.
- *If SSL is in use, check the certificate.* All SSL-based sessions use digital certificates to validate the Web server to the end user. If a site is using SSL, check the certificate for that site.[19] The certificate will indicate the organization to which the certificate was issued. If the name of that organization is different than the name of the organization the user thinks he is connected to, that could be an indication that a problem exists.
- *Enable virus scanning and anti-spam software and keep it updated.* Many modern anti-virus and anti-spam programs have capabilities to detect and stop activities associated with phishing attacks, including attempts to install keystroke loggers and the ability to block unauthorized outbound connections. The most important aspect to using these programs is to keep them updated with the latest updates and signature files. Most programs have the ability to do this automatically without user intervention.
- *Disable HTML e-mail.* The use of cleverly formed HTML code in e-mail messages covers a wide variety of phishing techniques. Users should turn off the ability of their e-mail programs to display HTML-based e-mail. Although this may render some mail difficult to read, the added protection this affords the user far outweighs the inconvenience. Bowing to the increased use of this protection mechanism on the part of their customers, many large retailers now give their customers a choice of whether they would like to receive e-mail form the organization in HTML or plain text formats.
- *Check for e-mail personalization.* The salutation in many phishing e-mails begins with "Dear Big Bank Customer" or "Dear User." In an effort to provide a more pleasurable interaction with their customers, most organizations like to address their e-mail more personally, such as "Dear Mr. Jones" or "Dear Gertrude." The lack of a personal greeting is not a definitive indicator that the message is a phishing attempt, but it is an added indicator if other clues are also present. In addition, an incorrect greeting or an e-mail addressed to the wrong person is another similar indicator.

217.10.2 Organization Policies

Not all anti-phishing responsibility belongs to the end consumer. Many organizations are taking a much more proactive approach to phishing than they did previously. Some of the steps a proactive organization might take include:

- *Develop an organization communications policy.* The organization should develop a policy mandating specific ways that contact with customers (including e-mail) will and will not be constructed and managed. It is common for large organizations to contain several business lines that all contact customers directly. Each of those businesses should comply with any policies governing customer contact. When such a policy is in place (and enforced), the organization should inform its customers about the policy and how it may affect the organization's e-mail communications.
- *Never ask for personal or financial information in an e-mail.* The organization should not ask for personal information in e-mail. If personal information is required, it should only be obtained on a secured Web site during a user-initiated session or over the telephone through a user-initiated phone call.
- *Do not embed hotlinks in customer e-mail.* The use of malformed URL hotlinks in phishing e-mails is a major source of customer misdirection. By not embedding hotlinks in the e-mail the customer must enter the URL manually into the browser. This will limit the use of URL redirection and character substitution in the URL itself. This activity, however, may meet with some resistance within the organization. The marketing departments in most organizations feel that embedding hotlinks in the e-mail allows for easier customer interaction and increases the likelihood that the customer will act on the e-mail (because it is mush easier to click on a link rather than entering a URL into a Web browser). Removing this capability may reduce customer response and hurt the organization. This is a classic "security *versus* convenience" trade-off problem that many security practitioners face and will have to be decided based on the business and security needs of the organization.
- *Use only well-known Web addresses.* Organizations should direct users to well-known addresses on their site, such as the organization's home page or a single level down from the home page. Directing the user to an address such as http://www3.customers.bigbank.com instead of http://www.bigbank.com/customers allows users to feel more confident that they are going to the proper site.[20] Short URLs also increase the likelihood that the user will spot any URL anomalies in the address.

217.10.3 Organization Preventative Activities

The preventative policies and measures discussed in the last section are not yet widespread, although many organizations are considering their implementation. To date, most of the activity undertaken by organizations to combat phishing has been reactionary in nature. Because of the unpredictable nature of phishing attacks and the limited technology in place to prevent its occurrence, the primary focus of most organizations has been to identify phishing attacks as soon as they begin and to work feverishly to take down the offending sites as quickly as possible. Most large financial institutions and online retailers have a dedicated person or team to handle phishing events. In some cases, this task is given to the organization's incident response team as an added responsibility. Because of the recent growth in the number and intensity of phishing incidents, anti-phishing response is now as standard a process as virus response in many organizations.

When building such a team, it is important to develop a response plan before the organization experiences an attack. As all good incident response teams know, planning the activities, roles, responsibilities, and processes that such a team will use can streamline the response immeasurably and lead to a faster and more effective response. The team should be cross-functional in nature, including diverse membership from the security, information technology (IT), communications, public relations, marketing, customer service, and legal areas within the organization. The specific process the team uses will vary based on available resources, organization culture, and business needs, but the process should consider the following in its planning:

- *Who has primary and supportive responsibilities within the team?* Roles of team members may shift during an incident. For example, the security and IT members may have more responsibility in the early phases of an attack, but the public relations and customer service members may have a bigger role in the latter stages of the event.
- *How will customers be informed?* This is particularly important if customer information was, in fact, obtained by the phisher. Even if the organization was not at fault in the disclosure, the customer may be looking to it to do something about it.
- *What should the help desk or customer service center tell customers?* A standard communication template should be developed with place holders for specific details about each event.
- *How will third-party contact be managed?* During the course of an attack, an organization may have to contact its own ISP, other local ISPs, or service providers in other countries. The organization should begin to build relationships with its own ISP as soon as possible (before an attack begins) to discuss response processes in the event of an attack. If the organization is in regular contact with other service providers it should hold similar discussions with them as well. Likewise, law enforcement officials at the local, state, or federal level may also have to be contacted. Knowing who those contacts are and establishing a working relationship with them before an incident will save valuable time during an incident. If international law enforcement assistance is needed, these contacts can make that happen much faster than an organization can on its own.

Recent years have also seen a rise in "brand protection" services. These are companies that will constantly scan the Internet (Web sites, news groups, blogs, and news sources) to see if a client organization is mentioned and in what context. Recently, that service has been expanded to include a search for unauthorized use of the organization's name, logo, or likeness. Because most e-mail-based phishing attacks involve the use of Web pages cloned from the organization's official site, such a search can reveal a phishing attempt in preparation or in progress. The usefulness of such services as anti-phishing prevention is a matter of debate. Most organizations will hear about a phishing attack from customers or others receiving phishing e-mails long before a service may identify the phishing site itself; however, the use of such a service might be considered when formulating a defense-in-depth phishing strategy.

217.10.4 Prevention through Technology

Because phishing relies on technology (such as e-mail, browsers, and Internet transport) to deliver an attack, companies are investing heavily in technology research to combat the problem. This work is taking place on a number of different fronts.

217.10.4.1 Enhanced User Authentication

Because phishing relies primarily on impersonation and obfuscation, much of the work has been focused on providing more advanced authentication tools for both the consumer and organizations providing Web services. The most obvious is to require stronger authentication of users before they are allowed to enter Web sites. The most ubiquitous authentication method in use today is the simple password. The security deficiencies of passwords are numerous and legendary, so advanced, multifactor forms of authentication (for example, tokens, certificates, smart cards, or biometrics) have been proposed. The theory behind this is that these authentication methods require an enhanced interaction between the customer and the legitimate organization that cannot be duplicated by a phisher simply cloning the target organization's Web site or obtaining a simple password. This raises the barrier to entry and makes a successful attack more expensive and more difficult to successfully complete. On the other hand, many organizations (particularly marketing and customer service professionals) fear that these advanced (and sometimes complicated) forms of user authentication will lead to widespread customer dissatisfaction. Consumers seem to agree. In an April 2004 survey by Gartner, only 14 percent of those surveyed would favor using a separate device (such as a token or cell phone) for Web site authentication.[21] In the fall of 2004, AOL and RSA announced a plan to offer AOL subscribers enhanced authentication through the use of RSA's SecurID® token device. It is not known how many customers will be willing to spend the extra $1.95 to $4.95 per month for the heightened security.

Other methods that have been deployed to overcome the limitations of static passwords have used multiple one-time passwords deployed in bulk to end users. Each password in the list is used only once then discarded. Typical distribution methods include a large grid containing multiple passwords (where the user matches row and column values supplied by the server during log-in to indicate the cell in the grid where the correct password can be Found) or as scratch-off cards that require the user to scratch off a protective layer of film (similar to many modern lottery games) to reveal the next password in the sequence. These methods are similar to the electronic token devices produced by RSA and others, but with a lower technology investment required. Use of this type of technology has been growing in Europe, but its acceptance in the United States has been very slow.

217.10.4.2 Enhanced Server Authentication

The other half of advanced authentication involves the organization validating itself to the end user. Almost all authentication in place today requires that the user authenticate to the Web site, but the user takes it on faith (based solely on visual inspection) that the Web site to which he or she is connected is the official Web site of the desired organization. A stronger method of validating the Web server is needed. The concept of "shared secrets," where both the user and the organization share a common piece of knowledge that can be used to enhance authentication, has been used somewhat successfully in the past, but primarily for end-user authentication. The best example of the use of shared secrets is the use of questions that only the user will be able to answer, such as "What's your mother's maiden name?" or "What was your high school mascot?" or "What is the air-speed velocity of an unladen swallow?" Answering such questions aids in mutual authentication because only the organization knows what questions to ask and only the users can answer them. Unfortunately, many of the questions that are currently asked, such as the classic "mother's maiden name" query, are so universally used that they have lost much of their true value as authenticators. Some sites have implemented a better question-and-response process by asking the user multiple questions (five to ten) at registration, then rotating those questions randomly during successive log-in sessions. Still others allow the user to supply both the questions and the answers, allowing for a truly unique series of questions for each customer not easily duplicated by a phishing site.

Another interesting implementation of shared secret technology uses pictures along with the secret. A user who wants to access the organization's Web server enters his ID and password. The server then displays a predefined graphic and custom message back to the user. Full access is only granted when the server has authenticated the user (through the ID and password) and the user authenticates the server (by indicating that the picture and message were correctly displayed).

217.10.4.3 Browser-Based Validation

Some technologies install add-on software into the user's Web browser to determine if the site a user is visiting is legitimate or not. These plug-ins perform real-time assessments of the structure of the URL, domain name, and server location, in addition to evaluating the images and links on the page. In some cases, site referrals, page depth, and editing history are also evaluated. The intent of these technologies is to stop access to potentially spoofed sites and, if spoofing is suspected, disable users from entering their user names and passwords.

217.10.4.4 E-Mail Authentication

Because phishing relies heavily on the use of e-mail to propagate, and many of those e-mails have forged header information to hide the true origin of the sender, some solutions have focused on strengthening the authentication of e-mail messages. A large initiative, backed by Microsoft, EarthLink, and AOL, is called SenderID. The idea behind SenderID is to verify that every e-mail sent to a user actually comes from the site or organization that it purports to come from and has not been forged or altered. Under SenderID, e-mail senders advertise the addresses of their official e-mail servers within their DNS infrastructure. When a mail server receives an e-mail for delivery, it requests the list of official e-mail servers from the sender's DNS service and then compares that with the address of the server that actually delivered the e-mail. If the sending address is authorized to send mail for that domain the e-mail is allowed to pass. This validation is performed before the e-mail message is delivered to the end user.

Another initiative to combat e-mail forgery is the DomainKeys system proposed by Yahoo!. This system uses public-key cryptography and digital signatures to validate the authenticity of e-mail sources. Under DomainKeys, an organization generates a pair of public and private encryption keys. The public key is published in a DNS record for the organization. When an authorized user in that organization sends an e-mail, the e-mail system uses the private key to generate a digital signature of that message. This signature is then prepended as a header to the e-mail, and the e-mail is sent on to the destination mail server. When the e-mail is received by the destination server, the public key is retrieved from the DNS server of the sending organization (as defined within the e-mail) and used to verify the digital signature of the e-mail. If the verification process is successful, the e-mail is allowed to pass. The DomainKeys initiative requires more embedded technology and computing resources than the SenderID method, but its use of cryptography and digital signatures is more highly resistant to attack than the DNS record-matching process employed by SenderID.

Some companies also compile "white" and "black" lists as a service for subscribers. These are compiled lists of domains that are known to be good and bad, respectively. List providers scour the Web looking for potential spamming and phishing Web sites. In addition, service subscribers provide the services with the names of domains that have sent them troublesome e-mail. Continuously updated lists are then made available to subscribers. When an organization receives an e-mail, it can check the domain of the sender against these lists. If the sender is on the white list it is allowed to pass; if it is on the black list, it is blocked. These listing services were originally developed to combat the problems of spam and have been extended to apply to phishing e-mails, as well.

217.10.4.5 Trusted Third Parties

If the basic problem inherent in e-mail spoofing is that the parties cannot authenticate each other, an answer would lie in the requirement for each organization to establish trust relationships (through digital key exchanges or other technological mechanisms) with other organizations with which it exchanges information (including e-mail). Unfortunately, many organizations exchange e-mail with dozens, or even hundreds, of other parties, often sporadically and randomly. Requiring each organization to maintain that sort of trust infrastructure with every other entity would tax the organization beyond practicality. To solve that problem requires the use of a trusted third party (TTP). The role of the TTP is to establish trust with many different organizations through the use of established, verified protocols. When an organization has satisfied the TTP's requirements for trust, it can then file its credentials (typically a digital certificate) with the TTP. When a second organization receives an e-mail from the first, it can check the credentials for the first organization on file with the TTP against the credentials included with the e-mail. If they match, the e-mail is acknowledged as valid.

The process of using TTPs is similar to that used by SenderID and DomainKeys. The difference is that those two initiatives are based on the vigilance of each organization to maintain comprehensive and secure processes for ensuring the integrity of the validation information. If one of those organizations fails in this role, the entire system breaks down. The TTP, on the other hand, stakes its entire business model and commercial reputation on its ability to maintain a high level of integrity and security.

Although this is certainly not infallible, it provides a much higher degree of assurance to participating organizations.

217.10.4.6 Attacking the Attackers

A new (and somewhat controversial) proposed countermeasure to combat phishing will identify and locate the Web site responsible for an active phishing attack. Rather than aiming to shut it down, the service will begin to feed the site phony information about fictitious customers. The idea behind this activity is to dilute the information about real customers with an avalanche of bogus information. Although it does not remove the real customer data from the phishing site, it does reduce the likelihood that the real information will be found (and used) by the offending phishers when they collect the information their site has gathered.

217.11 Anti-Phishing Organizations

Like viruses and spam before it, phishing cuts across a wide range of industries and organizations. Because of this, several coalitions of industry and government participants have been formed to combat this growing threat. The more active (and effective) anti-phishing organizations are led by commercial organizations. As the targets of phishing attacks, these organizations have the most to lose when it comes to loss of business and reputation. The companies participating in these groups believe that by cooperating and sharing information they can make a much bigger dent in the problem than would be possible by each working individually:

- *Anti-Phishing Working Group (APWG)* — The APWG is one of the largest and well-known groups in existence. It describes itself as an "industry association focused on eliminating the identity theft and fraud that result from the growing problem of phishing and e-mail spoofing."[22] It does this by collecting information about current and past phishing attacks, including an archive of past attacks describing in detail the type of attack, the e-mail used to propagate the attack, identifying characteristics of the attack, and the source. Publishing victims (organizations and consumers) can report their experiences to APWG. More information on APWG can be found at http://www.anti-phishing.org.
- *BITS*—BITS is a financial services industry consortium of the 100 largest financial institutions in the United States. Because the financial services industry has been a primary target for phishing attacks, BITS members actively share information about phishing attacks and countermeasures. BITS also issues advisories to its membership on ways to identify and combat phishing. More information on BITS can be found at http://www.bitsinfo.org/index.html.
- *Digital PhishNet*—Launched in December of 2004, Digital PhishNet is a collaboration between industry and law enforcement to identify, prevent, and prosecute those who launch phishing attacks. Its stated goals are "to identify, arrest, and hold accountable those that are involved in all levels of phishing attacks to include spammers, phishers, credit card peddlers, reshippers, and anyone involved in the further abuse of consumers' personal information."[23] As a relatively new initiative, it remains to be seen how effective Digital PhishNet will be, but a cooperative effort between those hardest hit by phishing and those charged with investigation and prosecution of those crimes holds a great deal of promise. More information on Digital PhishNet can be found at http://www.digitalphishnet.org/default.aspx.
- *Phish Report Network*—The newest addition to the anti-phishing groups is the Phish Report Network. Launched in February 2005 by Visa U.S.A, Microsoft, eBay, and WholeSecurity, the group describes itself as an aggregation service that allows subscribers to report incidents of phishing attacks that are then entered into a central database. Subscribers can also query the database to determine if a particular site or organization is associated with phishing attacks. This can be useful to large Internet service providers, hosting companies, and Internet

monitoring services. More information about the Phish Report Network can be found at http://www.phishre-port.net/index.html.

217.12 Conclusions

The problem of combating phishing has taken on near-crisis proportions. Unfortunately, no bullet-proof solution has yet been devised, although many avenues are being explored. The fundamental impediment to finding a “cure” for phishing comes from its split personality. On the one hand, phishing is a technology problem, most closely resembling spam but also carrying traits of malware and spyware in its makeup. As a technology problem, several potential solutions are in the works to identify, prevent, and trace phishing attacks quickly and efficiently. Additionally, as for spam, malware, and spyware, a continuous game of “cat and mouse” will be played while the phishers and anti-phishing forces develop techniques, countermeasures, and anti-countermeasures. Security researchers and technology developers will continue to improve the security of the products and protocols used on the Internet, and methods for verifying the identity and authenticity of Internet messages and transactions will inevitably work their way into the fabric of daily Internet life. At the core, however, phishing as a technology problem is a solvable or at least containable problem.

Phishing is not simply a technology problem, however. The other half of the phishing equation is the end user who responds to the e-mails and divulges personal information simply because he was asked or the user who does not keep anti-virus software up to date and allows a worm or Trojan horse to infect his computer. This is the “uneducated user” problem and is not so easily solved. It has plagued security practitioners from the earliest of days (“Hey, that big wooden horse looks innocent enough! Let’s bring It Inside the city gates and have a look!”), and no amount of technology can solve it. Recent heightened coverage of phishing and identity theft in the media has raised consumer and commercial awareness of the problem considerably, and lawmakers across the globe are struggling with how to enact legislation, raise consumer awareness, and increase corporate liability regarding the security of their products and services. In the end, though, it comes down to individual users making a conscious decision to assume a proactive role in maintaining the security of their personal information and decide whether or not to type their credit card numbers or Social Security numbers into a Web site. Preventing the uneducated user from making the wrong decision in the face of overwhelming (and falsified) evidence that the action is safe is the most difficult problem.

It's All About Power:Information Warfare Tactics by Terrorists, Activists, and Miscreants

Gerald L. Kovacich

Andy Jones

Perry G. Luzwick

> The terrorists practice a fringe form of Islamic extremism that has been rejected by Muslim scholars and the vast majority of Muslim clerics—a fringe movement that perverts the peaceful teachings of Islam. The terrorists' directive commands them to kill Christians and Jews, to kill all Americans, and make no distinction among military and civilians, including women and children. This group and its leader—Al Qaeda and a person named Osama bin Laden—are linked to many other organizations in different countries, including the Egyptian Islamic Jihad and the Islamic Movement of Uzbekistan. There are thousands of these terrorists in more than 60 countries. They are recruited from their own nations and neighborhoods and brought to camps in places like Afghanistan, where they are trained in the tactics of terror. They are sent back to their homes or sent to hide in countries around the world to plot evil and destruction.
>
> **—George W. Bush, President of the United States of America**

218.1 9/11/01: A Date in Infamy

This chapter was in the process of its initial editing when the Massacre of September 11, 2001, took place. While it would be wrong to rewrite this chapter in response to that one terrible event, it would be shameful to fail to acknowledge the effects and the losses. The attacks on the World Trade Center and the Pentagon were extreme but conventional terrorist attacks, but some of the retaliatory action that took place in the following days and weeks occurred in cyberspace. The outcome of these actions must be judged by the results. This chapter discusses the publicly known terrorist nation, drug cartel, and hacktivist (cyber disobedience) capabilities, such as those of animal rights groups, freedom fighters, and the like. Examples include terrorists such as Osama bin Laden using the Internet and encrypted communications to thwart law enforcement, the drug cartels' use of computers to support their drug money laundering operations, and the Zapatista movement in Mexico, outnumbered and outfinanced by the Mexican government, taking to the Internet to support its cause (the Zapatistas conducted denial of service attacks against the Mexican and U.S. governments).

218.2 Information Warfare Tactics by Terrorists

The first group examined are terrorists. The motivation of a terrorist is to undermine the effectiveness of a government by whatever means it chooses. It is worth remembering at this point that a terrorist in one country is a freedom fighter in another, and as a result, there is no stereotype. When you take into account the differing cultures around the world and the differing political regimes that exist, it is easy to understand that a variety of actions may be terrorist actions when carried out for political means or the actions of a hooligan, or, in computer terms, the actions of a hacker.

Let us first address a term that is in current and widespread use—cyber-terrorism. While it can be accepted that this term can be used to convey a general meaning, it is not possible to accept the current use of the term to be anything more. The definition of terrorism that was adopted by the gateway model in the United Nations in the spring of 1995 is:

> A terrorist is any person who, acting independently of the specific recognition of a country, or as a single person, or as part of a group not recognized as an official part of division of a nation, acts to destroy or to injure civilians or destroy or damage property belonging to civilians or to governments to effect some political goal.
>
> Terrorism is the act of destroying or injuring civilian lives or the act of destroying or damaging civilian or government property without the expressly chartered permission of a specific government, thus, by individuals or groups acting independently or governments on their own accord and belief, in the attempt to effect some political goal.
>
> All war crimes will be considered acts of terrorism.
>
> Attacks on military installations, bases, and personnel will not be considered acts of terrorism, but instead acts by freedom fighters that are to be considered a declaration of war towards the organized government.[1]

A very different definition was offered at the Fifth Islamic Summit that was convened to discuss the subject of international terrorism under the auspices of the United Nations, which is as follows:

> Terrorism is an act carried out to achieve an inhuman and corrupt (mufsid) objective, and involving threat to security of any kind, and violation of rights acknowledged by religion and mankind.[2]

[1] Definition of Terrorism Adopted by Gateway Model, United Nations, Spring, 1995, http://www.inlink.com/~civitas/mun/res9596/terror.htm.

[2] Ayatollah Muhammad Ali Taskhiri. Towards a definition of terrorism. *Al-Tawhid*, 5 (1), 1987.

It is notable that in the main body of this definition there is no reference to the nation-state, something that, in the West, would be fundamental to any understanding of terrorism. The author then goes on to make a number of additional points to clarify the definition, the most significant of which are:

- We have used the term "human" instead of "international" for the sake of wider consensus, official or otherwise, so as to emphasize the general human character of the statement.
- We have referred to various types of terrorism with the phrase "security of any kind."
- We have mentioned the two criteria (i.e., religious and human), first to be consistent with our belief and then to generalize the criterion.

This totally different approach to the issue of terrorism is significant and a clear reminder to the nation-states that consider themselves to be "Western" that not all cultures view the issue in the same manner as Anglo–Americans.

Even given these diverse views of the meaning of terrorism, there is an underlying trend of physical destruction and of the actions being of such a magnitude and type as to cause "terror" to the people. This does not fit well within the "cyber" environment because there is no direct physical destruction (other than 0's and 1's) and, without the effect of the bullet, the blast, or carnage of the bomb, "terrorization" of the people is difficult in our current state of technological advancement. It is more likely that as our cultural values change and we become more highly dependent on technology than we currently are, that the cyber-terrorist in the true sense will come into being. For example, today and more so into the future, as we increase our proliferation and dependence on telemedicine, a terrorist might:

- Attack a computer system to shut off a patient's life support
- Change the dosage of a patient's medicine to kill the patient
- Manipulate blood bank information, causing the wrong blood type to be given to patients and resulting in numerous deaths

218.2.1 What Do They Want To Achieve?

Let us first look at what a terrorist will want to achieve through the use of the Internet. This may be one or more of a number of things. The terrorist organization may wish to use this medium for the transmission of communications between individuals and groups within the organization. Look at the potential:

- The terrorist has been offered all of the facilities that the Cold War spy always dreamed of. It is possible to be anonymous on the Internet, with pay-for-use mobile phones and free Internet accounts.
- No attempts are made by the service providers to ascertain that the details provided by a customer are real and actually do relate to the user.
- Once online, the user can further disguise his or her identity in a number of ways.
- Anonymous re-mailers and browsers can disguise the identity of the user.
- High-grade encryption is freely available that law enforcement cannot yet break, and some civil liberty groups want to ensure that this situation remains so. The desire of civil liberty organizations to maintain the privacy of messages on the Internet has actually nothing to do with the terrorist—they have the liberty and privacy of the individual at heart, but the terrorist is just one of the beneficiaries of the pressure that they seek to exert.

A well-reported example of terrorist use of the Internet in this way is the activity of Osama bin Laden, who is reported to have used steganography (the ability to hide data in other files or the slack space on a disk) to pass messages over the Internet.[3] Steganography has become a weapon of choice because of the

[3] Declan McCullagh, *Bin Laden: Steganography Master?*, February 7, 2001.

difficulty in detecting it. The technique hides secrets in plain sight and is especially important when there is a concern that encrypted communications are targeted.

It was reported that bin Laden was "hiding maps and photographs of terrorist targets and posting instructions for terrorist activities on sports chat rooms, pornographic bulletin boards, and other Web sites." According to another report, couriers for bin Laden who have been intercepted have been found to be carrying encrypted floppy disks.[4] Other references to the use of the Internet by bin Laden describe the use of a new form of the Cold War "dead letter box," which was a predetermined place where one agent deposited information to be collected by another agent. A June 2001 report indicated that bin Laden was suspected of using encryption for his messages for at least five years.[5]

According to reporter Jack Kelley,[6] FBI director Louis Freeh stated that, "Uncrackable encryption is allowing terrorists—Hamas, Hezbollah, Al Qaeda (another name for bin Laden's organization), and others—to communicate about their criminal intentions without fear of outside intrusion." Kelley also reported that according to other unnamed officials, bin Laden's organization uses money from Muslim sympathizers to purchase computers from stores or by mail, after which easy-to-use encryption programs are downloaded from the Internet. As evidence, they cite the case of Wadih El Hage, one of the suspects of the 1998 bombing of two U.S. embassies in Africa, who is reported to have sent encrypted e-mails under a number of aliases, including "Norman" and "Abdus Sabbur," to associates of Al Qaeda.

Also cited as evidence is the case of Ramzi Yousef, the man convicted of masterminding the World Trade Center bombing in 1993, who is reported to have used encryption to hide details of the plot to destroy 11 U.S. airlines. The computer was found in his Manila apartment in 1995 and was passed to U.S. officials who cracked the encryption and foiled the plot. The same report goes on to say that two of the files took more than a year to crack. This is, in itself, revealing because it gives some indication of the level of effort that government and law enforcement agencies are prepared to invest in their efforts to bring to justice this type of criminal, as well as the level of effort and sophistication that is being used by terrorists.

Osama bin Laden is also skilled in the use of the media to promote the aims and the aura of the organization. This is evident from his use of the press to provide interviews. He is a well-educated and, through his family, a wealthy man. He has a good understanding of the way in which the media can be used to influence public opinion and has used the media to promote his philosophy.

218.2.2 Tactics

Having identified some of the types of effects that terrorists might want to use the Internet to achieve, let us now examine the tactics and tools that they would use to realize their aim. In the case of Osama bin Laden, he is apparently communicating via the Internet using steganography and encryption. Dealing with the two issues separately for the purposes of describing them in no way implies that the two (steganography and encryption) do not go together; in fact, quite the reverse. If you are paranoid and you want to make sure that your messages get through undetected and in a state that is unreadable to anyone who might detect their presence, then the combination of techniques is a powerful one.

218.2.2.1 Data Hiding

What is steganography? The word "steganography" literally means "covered writing" and is derived from Greek. It includes a vast array of methods of secret communications that conceal the very existence of the message. In real terms, steganography is the technique of taking one piece of information and hiding it within another. Computer files, whether they are images, sound recordings, text and word processing files, or even the medium of the disk itself, all contain unused areas where data can be stored. Steganography takes advantage of these areas, replacing them with the information that you wish to hide. The files can then be exchanged with no indication of the additional information that is stored

[4] Robert Windrem, Bin Laden's Name Raised Again—A Primer on America's Intelligence Archenemies, NBC News, http://www.ummah.net.pk/dajjal/articles/ladenagain.html.

[5] Jack Kelly, Terrorist instructions hidden on line, *USA Today,* June 19, 2001.

[6] Jack Kelley, Terror groups hide behind Web encryption, *USA Today,* June 19, 2001.

within. A selected image, perhaps of a pop star, could itself contain another image or a letter or map. A sound recording of a short conversation could contain the same information. In an almost strange twist in the use of steganography, law enforcement, the entertainment industry, and the software industry have all started to experiment with the use of steganography to place hidden identifiers or trademarks in images, music, and software. This technique is referred to as digital watermarking.

How does it work? Well, the concept is simple. You want to hide one set of data inside another but the way that you achieve this will vary, depending on the type of material in which you are trying to hide your data. If you are hiding your data in the unused space of a disk,[7] you are not, primarily, constrained by the size of the data because you can break it into a number of sections that can be hidden in the space described below. Storage space on disks is divided into clusters that in Microsoft DOS and Windows file systems are of a fixed-size. When data is stored to the disk, even if the actual data being stored requires less storage than the cluster size, an entire cluster is reserved for the file. The unused space from the end of the file to the end of the cluster is called the slack space. For DOS and older Windows systems that use a 16-bit File Allocation Table (FAT), this results in very large cluster sizes for large partitions. As an example, if the partition on the disk was 2 Gb in size, then each cluster would be 32 Kb. If the file being stored on the disk only required 8 kb, the entire 32-Kb storage space would be allocated, resulting in 24 Kb of slack space in the cluster. In later versions of the Microsoft Windows operating system, this problem was resolved (or at least reduced) by the use of a 32-bit FAT that supported cluster sizes as small as 4 Kb, even for very large partitions. Tools to enable you to do this are available on the Internet for free; examples of this type of tool include:

- *S-Mail.* This is a steganographic program that will run under all versions of DOS and Windows. The system uses strong encryption and compression to hide data in EXE and DLL files. (Yes, it is possible to hide files within full working programs; after all, that is what a virus does.) The software has a pleasant user interface and has functions in place to reduce the probability of its hiding scheme being detected by pattern or ID string scanners (these are tools that can identify the use of steganographic techniques).
- *Camouflage.* This is a Windows-based program that allows you to hide files by scrambling them and then attaching them to the end of the file of your choice. The camouflaged file then appears and behaves like a normal file, and can be stored or e-mailed without attracting attention. The software will work for most file types and has password protection included.
- *Steganography Tools 4.* This software encrypts the data with one of the following: IDEA, MPJ2, DES, 3DES, and NSEA in CBC, ECB, CFB, OFB, and PCBC modes. The data is then hidden inside either graphics (by modifying the least significant bit of BMP files), digital audio (WAV files), or in unused sectors of floppy disks.

If you are attempting to hide data in files, no matter what the type, then you have two options:

- You can hide your material in the file by adding to the data that is already there and thus increase the size of the file.
- You can replace some of the data that is already in the file with the information that you want to hide and retain the same file length but have a slightly reduced quality in the original representation.

To explain this in more detail, if you are using an image file to hide data, the normal method is to use the least significant bit of each information element as a place to store hidden data. In doing this, the changes to the image are so subtle as to be undetectable to the naked eye, but the changes are significant enough for steganographic software to be able to hide relatively large quantities of information in the image and also for the software to recognize a pattern within the image that it can use to reveal hidden material. It would not be unrealistic to hide the contents of this chapter in a relatively small image; for example, if you look at the two images that are reproduced in Exhibit 218.1, they are relatively small and yet it is

[7] Webopedia definition, from http://webopedia.internet.com/TERM/S/slack_space.html.

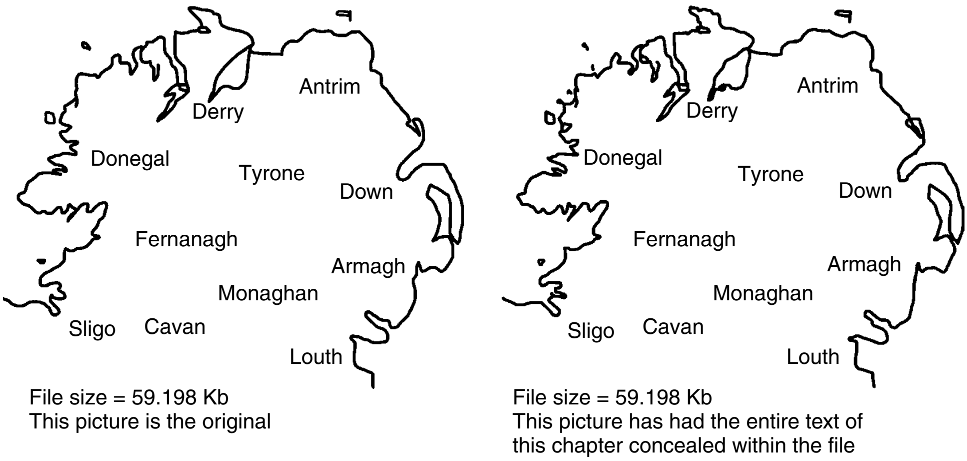

EXHIBIT 218.1 Steganography.

possible to hide more than 30 pages of text within one of them with no noticeable degradation in the quality of the image.

For the most part, the size of the file and the quality of the image are not significant; after all, if you do not have the before and after copies of the file or image on hand, how can you tell that the file has grown or that the image has been degraded? Even when you look at the two images above side by side, it is not possible to detect any significant difference.

Other methods that can be used to hide data in other types of files include:

- The use of programs such as Snow, which is used to conceal messages in ASCII text by appending white spaces to the end of lines. In a conventional page of text, there are normally 80 columns of information to the page. When we use a text file to save information that we have created on a computer screen, we do not use all 80 columns. If the word at the end of the line falls short of the 80th column, then we get a carriage return character after the last letter. If it is the last line of a paragraph, then there may be a considerable number of unused columns in the row. The Snow program fills in all of these unused spaces and uses the least significant bit of each of the bytes to hold an element of the hidden message.
- Software such as wbStego lets you hide data in bitmaps, text files, HTML, and PDF files. The data is encrypted before it is embedded in the carrier file.
- If you want to hide messages in music and sound files (MP3), then software such as MP3Stego will hide information in these files during the compression process. The data is first compressed, encrypted, and then hidden in the MP3 bit stream. Although MP3Stego was written with steganographic applications in mind, again there is the potential for it to be used for the good of the music and movie industries by allowing them to embed a copyright symbol or watermark into the data stream. An opponent who discovers your message in an MP3 stream and wishes to remove it can uncompress the bit stream and recompress it, which will delete the hidden information. The data hiding takes place at the heart of the encoding process, namely in the inner loop. The inner loop determines the quantity of the input data and increases the process step size until the data can be coded with the available number of bits. Another loop checks that the distortions introduced by the process do not exceed the predefined threshold.
- Linux enthusiasts have programs such as StegFS,[8] which is a steganographic file system for Linux. Not only does it encrypt data, but it also hides it such that it cannot be proved to be there.

[8] StegFS homepage can now be found at http://www.mcdonald.org.uk/StegFS/

This large choice of software and encoding schema gives terrorists a wide set of options to suit the chosen methods of communication. If the selected method of covering the communications is through a newsgroup that exchanges music, then the use of an MP3 encoder is most sensible. After all, if the other users of the newsgroup have the same taste in music as the sender and recipient of the message, there is no problem; they can download the file, play it, enjoy it, and yet be totally unaware of the hidden content. If the chosen method of communication is one of image sharing, then again, the images can be posted in public, with anyone able to view the images, but only those who are aware of the additional content are likely to use tools to extract it. On the plus side of this is that, increasingly, it is possible to detect the use of steganography. Software is now becoming available that will identify the use of an increasing range of the steganographic packages in use.

One example of a tool that can detect the use of steganography is the Steganography Detection & Recovery Toolkit (S-DART), which was sponsored by the U.S. Air Force Research Laboratories[9] and commissioned by WetStone Technologies, Inc. The aim of this kit was to develop algorithms and techniques for the detection of steganography in digital image files, audio files, and text messages. The aim of the project was to develop a set of statistical tests that could detect the use of steganography and also identify the underlying method that was used to hide the data.

Another tool is Stegdetect, an automated tool for detecting steganographic content in images. It is capable of revealing a number of different steganographic methods used to embed hidden information in JPEG images. Currently, the methods that can be detected by this software package are jsteg, jphide for UNIX and Windows, invisible secrets, and outguess 01.3b. While these tools are still limited in the range of data hiding techniques that they can detect, their range will increase rapidly; however, as with viruses and most other forms of malicious code on the Internet, the detection tools will always lag somewhat behind the tools that provide the capability.

218.2.2.2 Cryptography

It makes sense that if you are a terrorist and you want to communicate using the Internet, you are not going to risk your life or your liberty when people are not able to recognize the use of steganography on its own. Because the steganographic software is not interested in the type of material that it is incorporating into the carrier file, it will hide an encrypted message just as happily as it will hide a clear text message.

An encryption program scrambles information in a controlled manner through the use of a cryptographic key. In the past, you sent a message encrypted with a particular key to someone and they had to be in possession of the same key to decrypt the message. This is known as symmetrical cryptography. This, unfortunately, meant that you had to communicate the key to the person to whom you were sending the message.

This was achievable for governments that have the infrastructure to distribute the cryptographic keys in a secure manner; however, this type of approach is just not realistic for the general public to consider. Only in recent years has such technology been increasingly found in the public domain. Perhaps the best known of the publicly available high-grade encryption systems is Pretty Good Privacy (PGP), the system developed by Phil Zimmerman. As a result of the prominence that PGP has achieved, this discussion will concentrate on a description of cryptography on this system.

PGP is a public-key encryption software package that was initially intended for the protection of electronic mail. When PGP was published domestically in the United States as a freeware offering in 1991, it was very quickly adopted all over the world, with the result that it has become the *de facto* worldwide standard for encryption of e-mail.

The author of the PGP software was under investigation for a period of about three years by authorities (the U.S. Customs Service) who were investigating a possible breach in arms control relating to the export of weapons, including high-grade encryption. It is one of the nonsenses of the age of technology that it

[9] Air Force Research Laboratories, http://www.afrl.af.mil/if.html.

was considered to be an offense to export the software package that incorporated the encryption algorithm, but there seemed to be no problem with leaving the country with the algorithm printed on a t-shirt. The investigation into the situation was finally closed, without Zimmerman being indicted, in January 1996.

It is interesting that, in at least one interview, Zimmerman stated, as part of the rationale for the development of PGP, that the software was now used all over the world, particularly in Central America, in Burma, and by the government in exile from Tibet, as well as by human rights groups and human rights activists who were documenting the atrocities of death squads and keeping track of human rights abuses. He went on to state that he had been told by these groups that, if the governments involved were to gain access to the information that had been encrypted, all of the individuals involved would be tortured and killed. Again, who is the terrorist? Who is the freedom fighter?

218.3 Propaganda

Another reason why a terrorist organization might use the Internet is to spread the organization's message and further its cause. For this, the Internet is an outstanding tool. It is the most widely used, uncontrolled medium that has international reach. The number of organizations that have exploited this reach and lack of censorship is huge. Some of the better examples include the Provisional Irish Republican Army (PIRA), the Euskadi Ta Askatasuna (ETA), the Mexican Zapatistas, and the Chechen rebels.

The PIRA has a well-founded presence on the Internet through the auspices of its political wing, Sinn Fein, and publications with a strong online presence such as An Phoblact. Web sites that support the aspirations and the "cause" of the PIRA have been initiated in a number of countries; some good examples are the Sinn Fein home page[10] and Sinn Fein Online.[11] Other informative sites can be found at the Irish Republican Network[12] and the Trinity Sinn Fein Web sites.[13] In addition to the large number of sites that provide information on the IRA, other sites provide a different perspective on the conflict in Northern Ireland, with some of the sites providing a more balanced view than others, but undoubtedly that statement in itself demonstrates a prejudice, as other people might take a different view of the balance of reporting of the sites. The conflict in Northern Ireland is one of the longest-running "terrorist" actions that has taken place in the English-speaking world; not surprisingly, it attracts a lot of comment and debate and has a significant presence on the Web. Although the PIRA is the best known of the groups that represent one side of the conflict, a large number of other groups claim to be active in the province, including:

- Continuity Irish Republican Army
- Combined Loyalist Military Command
- Irish National Liberation Army
- Irish People's Liberation Organization
- Irish Republican Army
- Loyalist Volunteer Force
- Real Irish Republican Army
- Ulster Defence Association
- Ulster Freedom Fighters

[10] Sinn Fein Web site, http://www.sinnfein.ie/

[11] Sinn Fein Online, http://www.geocities.com/sinnfeinonline/

[12] http://www.geocities.com/diarmidlogan/

[13] http://www.csc.tcd.ie/∼sinnfein/

The majority of these also have, to a greater or lesser degree, a Web presence, some of the more notable of which are:

- The Irish People's Liberation Organization,[14] which represents another view of the republican perspective
- A loyalist view found at the Ulster loyalist Web page[15]
- The Ulster Volunteer Force (UVF) presence at the UVF page of the Loyalist Network[16]

In addition to all of these many partisan views of the situation are a number of sites that allegedly attempt to provide a "neutral" view of the situation. Examples of these sites can be found at Rich Geib's Universe[17] or the Irish Republican Army Information Site.[18] Other sites that provide insight into the attitudes of, and toward, the various parties in the province can be found at Vincent Morley's flags Web page[19] and a unionist Mural Art from Belfast page.[20]

An example of a terrorist site from another part of Europe is the case of the Euskadi Ta Askatasuna (ETA). This violent terrorist group, which lays claim to a portion of northern Spain and southern France, has its own Web presence to present the case for its grievances, to explain its culture and history, and to justify its actions and seek support. As with other similar groups, it has its supporters and detractors, both of which use the Web to try to influence the opinions of the readership. In the case of supporters of ETA and the Basque state, which they themselves refer to as "Euskal Herria," the primary Web pages are the *Euskal Herria Journal,* which promotes itself as *Basque Journal*[21] and puts forward the aims and expectations of the group that it represents, and the Basque Red Net[22], which puts forward a very well-developed argument based on the culture and history of the area. A view of ETA from the Spanish government can be seen at the Ministry of the Interior page that has the title "ETA—Murder as Argument."[23] This Web page is produced in three languages (Spanish, French, and English) to enable the widest reasonable readership of the arguments presented. One French view of the issues can be seen at the Web site of the Mediapaul Project.[24]

In an example from Central America, the Zapatista rebels in the Chiapas region of Mexico have become one of the most successful examples of the use of information systems and communications by a hugely outnumbered and outresourced group of activists. The Zapatistas used the Internet to outmaneuver the Mexican government and to bring world pressure to bear on a situation that was entirely internal to Mexico. The use of the Internet gained the Zapatistas not only support from throughout Mexico but also from the rest of the world. It will also now be used as a template for actions in other parts of the world, and the implications of the Zapatista rebellion will have an effect on other confrontations with contemporary capitalist economic and political policies. The surge of support for this (to European and North American eyes) very parochial action in a Central American republic came when a report, written for Chase Emerging Markets clients by Riordan Roett, was apparently leaked to Silverstein and Cockburn's *Counterpunch* newsletter. The report was found to call for the Mexican government to "eliminate" the Zapatistas to demonstrate its command over the internal situation in Mexico. When this news and the report were posted on the Web, there was worldwide reaction against the Mexican government, America, and the American bank that had commissioned the report.

Part of the response to this news was an increase in the hacking of Mexican government Web sites. In addition, the Electronic Disturbance Theater (EDT)[25] released what they referred to as a digital translation of the Zapatista Air Force Action, which they called the Zapatista tribal port scan. This was carried out to commemorate a nonelectronic act that involved, on January 3, 2000, the Zapatista Air Force "bombarding" the Mexican Army federal barracks with hundreds of paper airplanes on each of which was written a message for the soldiers monitoring the border.

Despite the fact that the action in the Chiapas region has effectively been underway since 1994, there was still support and online action such as that by the EDT in 2001.

In the former Soviet Union, the situation with regard to the ongoing conflict in Chechnya is one that the media is now starting to class as an "information war." The Chechen separatists are primarily represented on the Internet by two sites: one from the Chechen Republic of Ichkeria and the other from Kavkaz–Tsentr.[26] The Ichkeria site is seldom updated, but the Kavkaz–Tsentr site is reported as an example of a professional approach to information war. This site is kept up to date with daily reports on Chechen military successes against Russian forces, as well as more light-hearted items and events that surround Chechnya.

According to numerous reports from organizations, including the BBC, Moscow is applying the same tactics that it observed NATO using in the former Republic of Yugoslavia to try to win the information war in Chechnya. In the previous Chechen war that started in 1994, the then-fledgling commercial station NTV showed graphic pictures from both sides of the conflict; however, now the Russian broadcasters and press are much more selective in their reporting of the fighting.

The Kavkaz–Tsentr site has been repeatedly targeted by hacker attacks since at least 1999. The hackers have repeatedly defaced the Web site with anti-Chechen images and slogans and have redirected traffic intended for the site to a Russian Information Center site; however, the site has normally managed to restore normal operations within 24 hours.

218.4 Reaction to the World Trade Center and Pentagon Attacks

This has been inserted here because the case to be highlighted shows the dangers of "vigilantes" and people who, for the best of intentions, take actions for which they have not researched the background information. The action in question was reported by Brian McWilliam of "Newsbytes"[27] on September 27, 2001. He revealed that members of a coalition of vigilante hackers had mistakenly defaced a Web site of an organization that had had offices in the World Trade Center. The hacker group, called the Dispatchers, attacked the Web site of the Special Risks Terrorism Team, which in fact was owned by the Aon Corporation. The other sites that were attacked by this group were both in Iran, which for the geographically challenged is not in Afghanistan, and both were in fact hostile to the Taliban regime and Osama bin Laden. One can understand the anger and frustration and the desire to strike out in the aftermath of the attacks, but this type of action by uninformed and nonrepresentative individuals does much to damage relationships with countries and organizations that have not (at least in recent years) caused any offense and are in fact sympathetic to the cause.

218.5 Denial of Service

When a terrorist organization cannot achieve its objective by the means that are normally used—the bullet and the bomb—it has the potential to use the Internet and the connectivity of the systems on

[25] Electronic Disturbance Theater Web site, http://www.thing.net/~rdom/ecd/ecd.html.

[26] Kavkaz Tsentr Web site, www.kavkaz.org.

[27] Brian McWilliam, Hacking vigilantes deface WTC victim's site, *Newsbytes,* September 17, 2001.

which we now rely so heavily to gain the desired impact. There are a number of advantages and disadvantages to this approach, but if the normal techniques cannot be used it provides another vector of attachment to be utilized that has the advantages of being untraceable to the source and nonlethal.

When compared to the average activity of a hacker, who has limited capability in terms of equipment and sustainability, the terrorist will normally have a greater depth of resources and of motivation. An action that is taken in support of a cause that is believed in will have a much higher motivation to succeed than the whim of an idle mind or simple curiosity.

218.5.1 What Is a Denial of Service Attack?

A denial of service (DoS) attack is characterized by an attempt by an attacker or attackers to prevent legitimate users of a service from using that service. Types of DoS attacks include:

- Network flooding, resulting in the prevention of legitimate network traffic
- Attempts to disrupt connections between two machines, resulting in the prevention of access to a service
- Attempts to prevent a particular individual from accessing a service
- Attempts to disrupt service to or from a specific system or person

Not all disruptions to service, even those resulting from malicious activity, are necessarily DoS attacks. Other types of attack include denial of service as a component, but the denial of service itself may be part of a larger attack. The unauthorized use of resources may also result in denial of service; for example, an intruder might make use of an organization's anonymous FTP area as a location where they can store illegal copies of software, using up disk space and CPU time and generating network traffic that consumes bandwidth.

218.5.1.1 The Impact

Denial Of Service attacks can disable either the computer or the network. In doing so, this can neutralize the effectiveness of an organization. DoS attacks can be carried out using limited resources against a large, sophisticated, or complex site. This type of attack may be an "asymmetric attack." An asymmetric attack is one in which a less capable adversary takes on an enemy with superior resources or capabilities. For example, an attacker using an old PC and a slow modem might be able to attack and overcome a much faster and more sophisticated computer or network.

218.5.1.2 Types of Attack

Denial of service attacks can manifest themselves in a number of forms and can be targeted at a range of services. The three primary types of DoS attacks are:

- *Destruction or alteration of configuration information for a system or network.* An incorrectly configured computer may not operate in the intended way or operate at all. An intruder may be able to alter or destroy the configuration information and prevent the user from accessing his computer or network. For example, if an intruder can change information in your routers, the network may not work effectively, or at all. If an intruder is able to change the registry settings on a Windows NT machine, the system may cease to operate or certain functions may be unavailable.
- *Consumption of precious resources.* Computers and networks need certain facilities and resources to operate effectively. This includes network bandwidth, disk space, CPU time, applications, data structures, network connectivity, and environmental resources such as power and air conditioning.
- *Physical destruction or modification of network elements.* The primary problem with this type of attack is physical security. To protect against this type of attack, it is necessary to protect against

any unauthorized access to the elements of your system—the computers, routers, network elements, power and air conditioning supplies, or any other components that are critical to the network. Physical security is one of the main defenses used in protecting against a number of different types of attacks in addition to denial of service.

Denial of service attacks are normally targeted against network elements. The technique that is normally used in an attack is to prevent the host from communicating across the network. One example of this type of attack is the synchronization (SYN) flood attack. In this type of attack, the attacker initiates the process of establishing a connection to the victim's machine. It does this in a way that prevents the completion of the connection sequence. During this process, the machine that is the target of the attack has reserved one of a limited number of data structures required to complete the impending connection. The result is that legitimate connections cannot be achieved while the victim machine is waiting to complete bogus "half-open" connections.

This type of attack does not depend on the attacker being able to consume your network bandwidth. Using this method, the intruder is engaging and keeping busy the kernel data structures involved in establishing a network connection. The effect of this is that an attacker can execute an effective attack against a system on a very fast network with very limited resources.

According to a report posted on May 23, 2001, the Computer Emergency Response Team/Coordination Center (CERT/CC), one of the most important reporting centers for Internet security problems, was offline for a number of periods on a Tuesday and Wednesday as a result of a distributed denial of service (DDoS) attack.[28]

The CERT/CC posted a notice on its Web site on Tuesday saying that the site had been under attack since 11:30 a.m. EST that day and, as a result, at frequent intervals it was either unavailable or access to the site was very slow. The CERT/CC is a government-funded computer security research and development center that is based at Carnegie Mellon University in the United States. The site monitors Internet security issues such as hacking, vulnerabilities, and viruses, and issues warnings related to such issues and incidents.

The center issues warnings and sends alerts via e-mail. According to the report, the organization was still able to conduct its business and had not lost any data. News of the attack on CERT/CC came on the day after researchers at the University of California at San Diego issued a report stating that over 4000 DoS attacks take place every week.

A DDoS attack such as the one experienced by the CERT/CC occurs when an attacker has gained control of a number of PCs, referred to as zombies, and uses them to simultaneously attack the victim. According to an unclassified document[29] published November 10, 2001, by the NIPC, technologies such as Internet Relay Chat (IRC), Web-based bulletin boards, and free e-mail accounts allow extremist groups to adopt a structure that has become known as "leaderless resistance." Some extremist groups have adopted the leaderless resistance model, in part, to "limit damage from penetration by authorities" that are seeking information about impending attacks. According to the report, which was prepared by NIPC cyber-terrorism experts, "An extremist organization whose members get guidance from e-mails or by visiting a secure Web site can operate in a coordinated fashion without its members ever having to meet face to face."

In addition to providing a means of secure communications, the range and diversity of Internet technologies also provide extremists with the means to deliver a "steady stream of propaganda" intended to influence public opinion and also as a means of recruitment. The increasing technical competency of extremists also enables them to launch more serious attacks on the network infrastructure of a nation-state that go beyond e-mail bombing and Web page defacements, according to the NIPC.

[28] Sam Costello, CERT goes down to DoS attacks, IDG News Service, May 23, 2001.

[29] The NIPC publication is available at http://www.nipc.gov/publications/highlights/2001/highlight-01-10.pdf.

According to a separate article on international terrorism by a professor at Georgetown University, the leaderless resistance strategy is believed to have been originally identified in 1962 by Col. Ulius Amos, an anti-Communist activist, and this approach was advocated in 1992 by a neo-Nazi activist, Louis Beam.

218.6 Information Warfare Tactics by Activists

What does an activist seek to achieve by using information warfare techniques? It is likely that the types of activity that an activist will undertake will be very similar to those of a terrorist group, with the main difference being the scale and the type of target. One of the main aims of activists is to achieve their goals by exerting pressure through a route other than the government or a corporate process, although they may also use this route. If they can exert this pressure on the targeted organization through denial of service or through propaganda, they will do so, but they will also use the Internet to communicate with their colleagues and fellow activists and to gain information or intelligence on their target to identify its weak points. Activists were, historically, groups of people with a common cause who wanted to bring pressure to bear on the "establishment." The establishment might be a government, an international organization such as the World Trade Organization, or even an industry sector, such as the petrochemical industry or the biotech sector.

Denial of service attacks do not have to be sophisticated to have an impact. In 1995, during the detonation of nuclear tests in the Pacific, a number of groups, including Greenpeace, took online action to put pressure on the French government. The actions ranged in scope and type from those reported by Tony Castanha,[30] who said that the Hawaii Coalition against Nuclear Testing would be conducting its second protest of the summer on Sunday, September 3, 1995, at 8:30 a.m. He reported that the Coalition would be gathering at the Diamond Head end of Ala Moana Park and then march to Kapiolani Park. The Coalition requested readers' help to support a nuclear test ban and to voice their concern on French nuclear testing. The online posting also requested that people attending the protest bring signs and banners with them. This was an effective use of the online resource to inform people of a physical gathering and to keep them informed of the latest local news with regard to their issues.

Another online action that was part of the Greenpeace campaign against the French nuclear tests was an international fax campaign. The campaign was advertised online and details of the fax numbers that were nominated as targets were listed, together with printers that were apparently available. An extract from the material on the Web page is given below.

> E-Mail the French Embassy in Wellington—Tell Monsieur Chirac what you think mailto: remote-printer.french_embassy/wellington/NZ@6443845298.iddd.tpc.int

The Greenpeace postings also advocated that participants should send e-mails to one of the leading French newspapers, *Le Monde*—mailto:lemonde@vtcom.fr.—to express their concern. The postings urged participants to:

> …inundate these numbers with protest e-mail. Note: Jacques Chirac's e-mail address was closed within one day of posting here so... if you could send one fax every week to any or every number below, that would be brilliant!
> THE NUMBERS ARE:
> Jacques Chirac, President de la Republic
> +33 1 47 42 24 65
> +33 1 42 92 00 01 (not working at present)
> +33 1 42 92 81 88 (not working at present)

[30] Tony Castanha, The French Nuclear Protest, August 31, 1995.

+33 1 42 92 81 00
Fax Number: +33 1 42 92 82 99
Charles Millon, Ministere de la Defense (Defence Minister)
+33 1 43 17 60 81 (not working at present)
Herve de Charette, Ministere des Affaires Etrangeres
+33 1 45 22 53 03 (not working at present)

Also given were the fax numbers of a number of leading French individuals and organizations. The individuals included Alain Juppe (Prime Minister), and the organizations included the French Embassy in London, the French Institute in Taipei, the French Nuclear Attaché in Washington, and the Nuclear Information Centre at the French Embassy in Washington. This relatively early example of the use of the Internet by activists to bring pressure to bear (in this case, on the French government) showed a range of ways in which the technology could be used. These included e-mail protests to individuals and a newspaper, the dissemination of fax numbers for use by people who could then block these numbers with the volume of calls that were made to them, and the dissemination of information about local actions that could be accessed by a large number of people.

Another example of online activity by pressure groups can be seen in the September 2000 fuel protests that took place across Europe. Not only was the Internet used to post news of the current situation with the fuel protest to keep the people involved informed of the latest situation in each of the countries and regions, but it was also used to mobilize activists to considerable effect.

An example of the results achieved can be seen in the online news posting that was headlined “Berlin stands firm over fuel protest.” This was posted on September 20, 2000. The news item reported that Germany’s transport minister, Reinhard Klimmt, had said that the government would not hand out any concessions to German haulers, despite the fact that concessions had been handed out elsewhere in Europe, and that any such move would have to be part of a coordinated European Union effort. This statement was made after German truckers and farmers held up traffic in a series of protests over the high price of fuel on Tuesday, but the government refused to cut taxes and criticized other European governments that had done so, with both France and Italy having offered to cut tax on diesel fuel to appease truckers in those countries.

Another online action by activists targeted the world trade summit. This action was planned by a coalition of cyber-protesters who intended to flood 28 Web sites associated with the free trade negotiations at the Summit of the Americas with e-mail messages and requests for Web pages. The participants hoped to gain enough support to effectively mount a DoS attack. The action was apparently led by a group called the Electrohippies. This hacktivist action was intended to mirror the summit’s schedule, which started on Friday evening and ran through the weekend to Sunday in Quebec City. Leaders from 34 nations were meeting there to discuss the establishment of a single free-trade zone that would extend from Canada in the north to Chile in the south.

One of the fastest growing activities on the Web is the defacement of Web pages. The rationale for the defacement and the selection of the target for the attack is totally dependent on the cause that the attacker is supporting. Examples of this type of attack include:

- The attack on the Kriegsman fur company by the hacker “The Ghost Shirt Factory” on November 12, 1996—The Web site was defaced by the animal rights activists who made clear their dislike of the fur trade.
- An attack on the Web site of the Republic of Indonesia by a hacker known as “TOXYN” on February 11, 1997—This attack was on the Web site of Indonesia’s Department of Foreign Affairs and was claimed to be an action taken in protest against Indonesia’s occupation of East Timor.
- Another attack on the Republic of Indonesia took place the following year when hackers known as “LithiumError/ChiKo Torremendez” defaced approximately 15 Indonesian domains at the same time. This was claimed to be a part of an anti-President Suharto campaign.

- Another example, this time from France, occurred when the French National Front Web site was defaced by a hacker known as "RaPtoR 666." The attack took place on January 28, 1999, and the hacker defaced the Web site in French, but an English-language version was also made available by a hacker known as the "GrandMeister."

These examples are but a tiny fraction of the thousands of Web site defacements that now take place every day around the world. Archives of hacked Web sites can be found in a number of locations, but some of the more popular sites are the Onething Archive[31] and the 2600 magazine archive.[32]

The use of propaganda by activists is an effective weapon in their armory. Through its distributed nature and the lack of control that exists on the Internet, it is extremely easy to get a message published, and with determination and resources anyone can put up a very effective presence to support a cause. It could be said that any terrorist or activist Web sites, or the sites of the regimes or topics that they oppose, are placed on the Web for the purposes of propaganda. It is worth remembering that plain and simple facts that to you or me are indisputable are, to others, propaganda produced by a system that they oppose. A number of Web sites have dealt with this subject in some depth and have largely poked fun at the more obvious cases of propaganda, whether they are from governments or from other organizations. One of these sites, Propaganda & Psychological Warfare Studies,[33] looks at the situation in Africa, and another, the Extremist propaganda Web page,[34] pokes fun primarily at the American culture.

Another group becoming more of a domestic terrorist factor in the United States is the eco-terrorists, who appear to be out to "save the planet from human destruction." Currently, they appear to be happy blowing up buildings and destroying laboratory research equipment which ironically are in some cases being used to help the environment.

218.7 Information Warfare Tactics by Miscreants in General

The catch-all category of *miscreant* is really here because many other people and groups out there cannot be classified as either terrorist or activist but can still have a significant impact on a country, an organization, or an individual. This includes groups such as drug cartels and other organized crime groups such as the Mafia. The tactics that they will use will depend on the level of skill they possess, the target of their attention, and the effect they are trying to cause.

One small but significant grouping is that of the anarchists and techno-anarchists. It is surely surprising that the anarchists that are active on the Internet can organize themselves well enough to have an impact, given that the definition of an anarchist is:

> *An-ar-chist \an-er-kist, -ar- \ n* (1) one who rebels against any authority, established order, or ruling order; (2) one who believes in, advocates, or promotes anarchism or anarchy, esp. one who uses violent means to overthrow the established order.

Does their joining together in a common cause mean that they are not true anarchists, or does it mean that the definition is wrong?

Typically, the targets for anarchists have been governments and large multinational companies, but in recent years there has been a significant shift toward targeting meetings of the G8 and other institutions perceived to have an effect on the world economy, such as the World Bank. Recent meetings of the heads of governments have increasingly come under violent attack from the anarchists and this has been mirrored in the activity seen on the Internet. The cause of a denial of service attack from this portion of

[31] Onething defaced Web site archive, http://www.onething.com/archive/

[32] 2600 hacker magazine defaced Web site archive, http://www.2600.com/hacked_pages/

[33] Propaganda & Psychological Warfare Studies Web site, http://www.africa2000.com/PNDX/pndx.htm.

[34] Extremist propaganda Web page, http://scmods.home.mindspring.com/index.html.

the population will be totally dependent on the relationship between the attacker and the target. The attack may be as the result of a perceived slight on an individual by another individual or an organization, or as part of a concerted attack that is part of a wider event. One set of observed attacks that fall into this group is the well-documented but totally unexplained attacks on a site known as GRC.COM:

> On the evening of May 4th, 2001, GRC.COM suddenly dropped off the Internet. I immediately reconfigured our network to capture the packet traffic in real-time and began logging the attack. Dipping a thimble into the flood, I analyzed a tiny sample and saw that huge UDP packets—aimed at the bogus port "666" of grc.com—had been fragmented during their travel across the Internet, resulting in a blizzard of millions of 1500-byte IP packets. We were drowning in a flood of malicious traffic and valid traffic was unable to compete with the torrent. At our end of our T1 trunks, our local router and firewall had no trouble analyzing and discarding the nonsense, so none of our machines were adversely affected. But it was clear that this attack was not attempting to upset our machines, it was a simple brute-force flood, intended to consume all of the bandwidth of our connection to the Internet... and at that it was succeeding all too well. Gibson Research Corporation is connected to the Internet by a pair of T1 trunks. They provide a total of 3.08 megabits of bandwidth in each direction (1.54 megabits each), which is ample for our daily needs.
>
> We know what the malicious packets were, and we will soon see (below) exactly how they were generated. But we haven't yet seen where they all came from. During the seventeen hours of the first attack (we were subsequently subjected to several more attacks), we captured 16.1 gigabytes of packet log data. After selecting UDP packets aimed at port 666… I determined that we had been attacked by 474 Windows PCs. This was a classic "Distributed" Denial of Service (DDoS) attack generated by the coordinated efforts of many hundreds of individual PCs.

After some investigation, the victim of the attack was contacted by the attacker who posted the following messages to him:

> hi, its me, wicked, im the one nailing the server with udp and icmp packets, nice sisco router, btw im 13, its a new addition, nothing tracert cant handle, and ur on a t3 … so up ur connection foo, we will just keep coming at you, u cant stop us "script kiddies" because we are better than you, plain and simple.

[In this message, the attacker revealed himself to be 13 years old.]

> to speak of the implemented attacks, yeah its me, and the reason me and my 2 other contributors, do this is because in a previous post you call us "script kiddies," at least so i was told, so, I teamed up with them and i knock the hell out of your cicso router

In this posting, the attacker reveals that he has had the help of a couple of friends, subsequently named as hellfirez and drgreen, but reveals that the denial of service attacks (there were six in all) were caused because someone has told him (WkD) that the victim had referred to him as a "script kiddie." If such a perceived (but unconfirmed) insult generates this level of reaction, then the consequences of a real event are impossible to guess.

Some of the easier-to-remember cases of theft on the Internet are cases that originated in Russia, the most notorious being the Citibank theft that was perpetrated by Vladimir Levin. Although the eventual result of this attack was reported to be a loss of $400,000, the exposure of the bank during the attack was reported as $10 million to $12 million. Levin was captured as he passed through London and in 1998 he was sentenced to three years in jail. Another Russian case was that of "Maximus," a cyber-thief who stole a reputed 300,000 credit card numbers from Internet retailer CD Universe during 1999 and demanded a $100,000 ransom not to release them onto the Internet. When the money was not paid, he posted 25,000 of the credit card numbers onto a Web site. The impact of this was that 25,000 people had their credit details exposed to the world. The only possible outcome of this action would be the replacement of all the affected cards with the respective cost implications. It is notable that in Russia, according to Anatoly Platonov, a spokesman for the Interior Ministry's "Division R" that handles computer crimes, there had been 200 arrests made in the first three months of the year 2000, which was up from just 80 in all of 1998. He speculated that this rise in the number of arrests may reflect an increased police effectiveness rather than a growth in crimes.

In the United States, an incident that was given the name of Solar Sunrise, which was first reported in 1998 in the "Defense Information and Electronics Report," exposed the Department of Defense's poor state of computer security. The Pentagon initially believed that the attack was very serious and probably originated in Iraq; however, two teenagers in California were eventually arrested for breaking into the military networks. The teenagers were able to breach computer systems at 11 Air Force and Navy bases, causing a series of denial of service attacks and forcing defense officials to reassess the security of their networks. The two Californian kids were assisted by an Israeli youth, Ehud Tenenbaum, who was known as "The Analyzer," and were described by Art Money, the acting Assistant Secretary of Defense for Command, Control, Communications, and Intelligence, and the DoD's CIO, at the time as kids "having a hell of good time."[35]

For some of the groups in this category, the online collection of intelligence is currently a major issue. It is now almost irrelevant as to whether you refer to this activity as spying, as open source intelligence collection, or as industrial espionage; the net results are very similar, as are the methods used. In the past, if you were planning an action against an adversary, you would carry out a reconnaissance of the target and gain as much information as possible to enable you to identify the specific targets and to learn as much as possible about their habits, practices, and history.

You would visit the public offices and the libraries and read newspapers to gather background information and you would visit the site to gather more specific information through observation, or through methods such as dumpster diving (yes, it did exist before we had computers; it was just that the information that the dumpster diver was looking for was different). Now, most of the information that exists with regard to a person or an establishment is held in computer text files or databases, so the need for protagonists to expose themselves to identification by visiting the site or by being seen in local libraries or public offices is greatly reduced.

Another form of attack that this category of attacker might use is identity theft. It is now trivially easy to gain all the information you need to assume someone else's identity (identity theft) or draw all of the information needed with regard to an organization or a company. Identity theft is still largely confined to the United States; however, the number of recorded incidents has risen dramatically in recent years. When an individual is the victim of an identity theft, the results can be startling and the restoration of a state that is similar to that which existed before the identity was stolen is extremely difficult and time-consuming. It also has terrorist implications as one can imagine.

If there is a recorded case that exemplifies the damage that can be caused to an organization if details of it are known to hostile activists, it is worth looking at the case of the Huntingdon Life Sciences in the United Kingdom. The organization had resisted intense pressure from animal activists for a considerable time, first experiencing direct action against the organization and its staff and then, more recently, through indirect action which was highlighted by the protesters putting pressure on the banks that were providing finance and banking facilities to the organization. Where did the animal rights activists get the information on where Huntingdon Life Sciences banked? There are actually a number of ways in which they could have obtained this information, but, in reality, if you know where to look for it, it is actually freely available online. Once the protesters had this innocuous item of information, they could bring the organization to the brink of disaster by putting intense pressure on the banks and intimidating their staff members.

[35] Anne Plummer, Defense Information and Electronics Report, October 22, 1999, http://www.infowar.com/hacker/99/hack_102599b_j.shtml.

Since its early days, the Internet has been exploited for espionage. What better medium could the modern information broker, activist, or spy want? They have been provided with a low-risk means of access to a country and a facility or organization, a means of communication that is both anonymous and untraceable, the potential to use cryptography without raising the slightest suspicion, an updated version of the Cold War "dead letter box," and a set of obstacles to overcome to gain access to industrial and government information that, in previous times, would have been considered laughable.

The first case of online espionage was reported when Cliff Stoll documented his actions and discoveries of 1985 in his book *The Cuckoo's Egg.*[36] In this case, the Soviet Committee for State Security (Komitet Gosudarstvennoi Bezopasnosti, or KGB) is known to have paid an East German hacker, Markus Hess, to penetrate U.S. defense agency systems. In a present-day case, the heavily reported Moonlight Maze attacks have been occurring for some time, probably since 1997 or before. Hackers from eastern Europe have broken into a large number of systems, including the Pentagon's systems, accessing "sensitive information about essential defense technical research matters." Although the stolen information has not been classified, it is still invaluable to foreign governments, terrorist groups, and private companies because these networks hold information on military logistics, planning, payrolls, purchases, personnel, and routine Pentagon e-mails between departments. The most sophisticated attacks observed to date apparently came from just outside Moscow and were eventually traced to the Russian Academy of Sciences laboratory, the country's leading scientific research body.

The average miscreant in this category will have one of two driving motivators for his activity on the Internet. Either it will be for curiosity (the "can I do that" factor) or it will be for financial gain. The following discussion takes a look at some of the techniques used for financial gain.

Unusually, there is a report from a country that we consider to be "closed" to us in a number of ways and which, if we believe all the stories we are presented with, is now run by the Mafia and organized crime. According to a report by Ruth Alvey[37] in July 2001, the level of cyber-crime that was recorded in Russia has grown rapidly in recent years. In 2001, there were 1375 crimes registered in the high-technology field, a growth of 18 percent from 1999. The report highlights the fact that this type of expansion is particularly worrying because only approximately 4.5 percent of the Russian population is connected to the Internet, which compares with connectivity rates of approximately 49.1 percent in the United States. The report also gives a conservative estimate of between 250 and 500 hackers operating in Russia today, with 15 to 20 of these hackers available for hire working in the Moscow area and around 10 working in the area of St. Petersburg. The reporter also gives further details of hacker activity in Russia, such as the level of sales of hacker magazines (30,000 copies per month) and cites that 1605 Russians participated in a single hacking competition on a Russian Web site (www.hackzone.ru) in the year 2000, suggesting that the actual number of active hackers is much higher.

From the United States comes a report from Florida in which it was stated[38] that an FBI sting operation resulted in the arrest of Fausto Estrada for allegedly stealing various confidential documents from the credit card company MasterCard International and offering to sell them to MasterCard's competitor, Visa International. A five-count complaint charged Estrada with theft of trade secrets, mail fraud, and interstate transportation of stolen property. According to the complaint, in February 2001, Estrada, using the alias "Cagliostro," mailed a package of information he had stolen from MasterCard to Visa's offices located in California. Estrada allegedly offered to sell to Visa sensitive and proprietary information that he had stolen from MasterCard's headquarters. According to the complaint, among the items Estrada offered to sell to Visa was a business alliance proposal valued in excess of $1 billion between MasterCard and a large U.S. entertainment corporation.

[37] Ruth Alvey, *Russian Hackers for Hire—The Rise of the E-Mercenary,* July 1, 2001, http://www.infowar.com/hacker/01/hack_080301a_j.shtml.

[38] U.S. Department of Justice, FBI Sting Captures New York Man Who Stole Trade Secrets from MasterCard and Offered Them for Sale to Visa, March 21, 2001, http://www.usdoj.gov/criminal/cybrcrim/Estrada.htm.

As part of a sting operation conducted by the FBI's Computer Intrusion and Intellectual Property Squad, an FBI agent posed as a Visa representative and negotiated for the purchase of the MasterCard documents in Estrada's possession. If convicted, Estrada faces a maximum sentence of ten years in prison and a fine of $250,000, or twice the gross gain or loss resulting from the crime on each of the two charges of theft of trade secrets and the two interstate transportation of stolen property charges, and five years in prison and a $250,000 fine, or twice the gross gain or loss resulting from the crime on the wire fraud charge. This was a fairly straightforward theft, but hitting at the heart of the electronic trade bedrock—the credit card.

In another report from the United States, a 16-year-old New Jersey teenager, Jonathan G. Lebed, settled a civil fraud lawsuit filed against him by the Securities and Exchange Commission (SEC), which alleged that he had hyped stocks on the Internet before selling them for a total profit of $272,826. He settled the charges brought by the SEC by paying the government $285,000, which included his alleged illegal profits plus interest. The SEC accused Lebed of using the Internet, beginning when he was 14 years old, to tout nine small stocks he owned, driving up their prices. He sold the shares, usually within 24 h of the promotional e-mail, making as much as $74,000 on a single stock sale, the agency's suit alleged.

This is a classic case of using the power that is provided by the freedom of the Internet, together with the lack of verification that takes place with online publishing, to influence the opinions of people. This is a trivial example of how, when it started, a 14-year-old youth could exert enough influence to affect the price of stocks on the stock exchange. Imagine the potential for influencing people that could be achieved by a well-funded and well-trained organization.

The next example is the first of what will inevitably be repeated. In this case, the Italian police arrested 21 people who were accused of involvement in a massive online banking fraud that could have cost the Sicilian regional government more than 1 trillion lire (US$465 million), according to a statement by the Italian authorities in October 2000.

Members of a criminal group with links to the Cosa Nostra allegedly managed to "clone" an online branch of the Banco di Sicilia and were preparing to remove funds from an account belonging to the Sicilian regional government, officials said. The scheme was operated with the assistance of two members of the bank's staff, using stolen computer files, codes, and passwords. With these facilities, the gang managed to gain access to the bank's information systems.

It was alleged that the group was planning to steal 264 billion lire from the bank. According to the Italian news agency AGI, one of the possible destinations of the stolen money was the branch of a Portuguese bank, the Banco Espirito Santo e Comercial of Lisbon, in Lausanne, Switzerland.

Police identified the leader of the gang as Antonio Orlando, 48, described as being close to one of Palermo's leading Mafia families and with previous arrests for fraud, money laundering, and receiving stolen property. According to an official from the Palermo police, "The operation was certainly authorized by the Mafia, because here in Sicily any operation of economic importance requires the Mafia's permission."

Another type of miscreant would be those who are engaged in nefarious activities and use the Internet for the purposes of communication. They take full advantage of currently available technologies that will either allow them to remain anonymous or let them send and receive messages that cannot be intercepted and reduced to a meaningful state by either law enforcement or their opposition. The promise of such anonymity will always attract them to technology and the Internet.

Let us look at the case for anonymity. In the United Kingdom, because of the way the Internet industry has developed, it is possible to take out a "free" Internet connection through an ISP. While the user is required to provide personal details for the account, because the service provider is not trying to gain any money for the use of the service from the user, there is normally only a cursory check that the details that have been provided are correct. (If you were the ISP and the user was not the direct source of revenue, how much effort and resource would you invest in checking out the details provided?) It is also possible in the United Kingdom to purchase from any High Street store a pay-for-use mobile phone. These can be purchased for cash and replacement cards or top-up cards can also be purchased for cash from a large number of outlets. The result is anonymous communications and access to the Internet. There are any number of ways to obtain free telephone calls, most of which are illegal, but the combination of untraceable telephone calls and connectivity over the Internet is a powerful one.

Having looked at a number of criminal group types, it would be unrealistic not to look at the material available on the Cali drug cartel from Colombia. In a paper written by a Los Angeles policeman,[39] he states that not only are criminals using the available technologies to make their illegal activities more profitable but they are also using computers, cellular phones, and other sophisticated electronic devices to gather intelligence information on police operations to prevent themselves from being caught. He cites as an example:

> When agents of the United States Drug Enforcement Administration recently conducted a raid at the Cali drug cartel headquarters in Colombia, they discovered two large IBM mainframe computers. The computers were hooked into the national telephone service of Colombia and stored the phone records of millions of Cali residents. These phone records were routinely cross-checked against calls made to the United States Embassy in Colombia and the Colombian Ministry of Defense in an effort to identify Colombians who were cooperating with government drug enforcement efforts.

In a court case in California:[40]

> Cali cartel is reputed to be using sophisticated encryption to conceal their telephone communications and to scramble transmissions from computer modems.

Also referred to in the same court case was the Italian Mafia downloading copies of Pretty Good Privacy (PGP) from the Internet and the fact that Dutch criminal organizations encrypt their communications and computers with PGP and IDEA.

If the drug cartels and Mafia have this type of capability at their disposal (and there is no reason to doubt that they do, as un traceable money will buy you almost anything), then the potential is frightening. There is considerable paranoia regarding the capabilities of various "Big Brother" governments to intercept an individual's e-mail (and just because you are paranoid does not mean that they are not out to get you), but governments are at least voted into office and can be removed. Criminals with the same potential powers have no such constraints placed on them.

As noted earlier, activists are groups of people with a common cause who want to bring pressure to bear on the "establishment." The establishment might be a government, an international organization such as the World Trade Organization, or even an industry sector such as the petrochemical industry or the biotech sector. One of the tools in the hands of the activist is the denial of service attack. The case below is an illustration of the effect that such an attack can have and the seesaw motion between the capabilities of the hackers and those of the defenders of the systems as they develop countermeasures.

In a report[41] by Rutrell Yasin on February 5, 2001, he stated, "Roughly a year after cyber-terrorists paralyzed some of the Web's most trafficked sites, technology is finally emerging to stop such distributed denial of service attacks before they ever reach their target sites. The new tools are designed to thwart attempts to bombard routers with large volumes of bogus requests that overwhelm servers and deny access to Web sites."

Denial of service attacks have been a major problem for Microsoft, especially after an employee apparently misconfigured one of the routers on the system. In this case, the attackers were able to

[39] Marc D. Goodman, *Why the Police Don't Care About Computer Crime* (Marc Goodman is a sergeant with the Los Angeles Police Department and student in the Public Administration program at Harvard).

[40] No. 97-16686 in the U.S. Court of Appeals for the Ninth Circuit, *Daniel J. Bernstein, plaintiff-appellee, v U.S. Department of Commerce et al., defendants-appellants,* on appeal from the U.S. District Court for the Northern District of California.

[41] Rutrell Yasin, Tools stunt DoS attacks, monitor dam packet floods at ISP routers, *Internetweek,* February 5, 2001, http://www.internetweek.com/newslead01/lead02051.htm.

capitalize on this human error and bombarded the routers with bogus data requests. The defensive measure brought to bear was an intrusion detection system. In this case, Arbor Networks, a relatively new company that has been jointly funded by Intel and Cisco, was about to announce the launch of a managed service that it claims can detect, trace, and block DoS attacks. This type of technology is not unique, and similar services have been produced in the United Kingdom by the Defence Evaluation and Research Agency (DERA) for use by the U.K. Ministry of Defence and have subsequently been used to provide a service for both government and industry. Other commercial organizations such as IBM and SAIC also offer similar services.

The service relies on sensors that are placed at strategic locations within the network to allow the monitoring agent to detect abnormal behavior on the system. The primary type of activity monitored is the system penetration; however, if the sensors are placed in front of the routers, the monitors can collect information about traffic patterns and identify anomalies, such as excessive traffic coming from a given IP address. In some cases, the software is capable of generating a fingerprint that can be used to trace the origins of the attack; however, this type of functionality has proved to have limited success to date (how do you identify the attacker in a DDoS attack that uses thousands of zombies?). Operators at the customer site or Arbor's network operations center can take corrective action, such as blocking excessive traffic.

The defacement of Web sites has been occurring for some time but has increased in recent years to the point where the Web site (www.atrition.org) that became famous for its up-to-date reporting of defaced Web sites stopped trying to keep up with the list of damaged sites. This Web site ceased activity after more than two years of tracking such defacement.

A German Web site, Alldas.de,[42] now attempts to provide an up-to-date listing of the Web sites that have been hacked each day, together with a considerable amount of useful and related information (see Exhibit 218.2). This Web site also maintains league tables of which hacker groups have been responsible for which attacks during the period.

An example of this type of information is given in the small extract below, showing the name of the Web site defacer, the number of Web sites that were claimed to be defaced, and the percentage of the overall number of Web site defacements that this represents:

- *A-I-C* defaced four Web sites, which is 0.02 percent of all archived defacements.
- *A-jaX* defaced four Web sites, which is 0.02 percent of all archived defacements.
- *A-Open* defaced one Web site, which is 0 percent of all archived defacements.
- *A1L3P5H7A9* defaced one Web site, which is 0 percent of all archived defacements.

EXHIBIT 218.2 Extract of information from Alldas.de.

[42] Alldas Web site, http://www.alldas.de.

- *Abfgnytvp* defaced one Web site, which is 0 percent of all archived defacements.
- *Abu Sayaff* defaced two Web sites, which is 0.01 percent of all archived defacements.
- *Abu Sayaff Boys* defaced one Web site, which is 0 percent of all archived defacements.
- *Abuzittin* defaced one Web site, which is 0 percent of all archived defacements.
- *AC* defaced seven Web sites, which is 0.03 percent of all archived defacements.
- *AccessD* defaced eight Web sites, which is 0.04 percent of all archived defacements.
- *ACE* defaced eight Web sites, which is 0.04 percent of all archived defacements.
- *Acecww* defaced four Web sites, which is 0.02 percent of all archived defacements.
- *Acid* defaced one Web site, which is 0 percent of all archived defacements.
- *Acid Blades* defaced one Web site, which is 0 percent of all archived defacements.
- *Acid fAlz* defaced 13 Web sites, which is 0.06 percent of all archived defacements.
- *Acid klown* defaced three Web sites, which is 0.01 percent of all archived defacements.

It is interesting to note that this Web site (Alldas.de) was itself the victim of collateral damage when the service provider on which it depends, Telenor, apparently suffered significant problems at the beginning of July (2001) for more than 40 h. The site was also the target of a distributed denial of service attack during the middle of July 2001 that prevented it from operating for four days.

In Europe during the protest about the cost of fuel and the tax that the governments were levying on fuel, a number of Web sites came into being that provided not only communications within the local environment but also allowed for the coordination of activity over the wider area. The material that is shown on these pages is from Web pages and newsgroups, all of which are semipermanent; however, a great deal of the information that was passed during these and other activities is now passed through services such as the Internet Relay Chat (IRC) channels, which can be as public or as private as the participants wish and for which there is less of a permanent record created.

In the United Kingdom during the fuel protest, sites such as Bogush's Lair[43] served as excellent examples of Web sites that can provide communication regarding international situations as well as local events. Bogush's Lair provided details of meetings and actions that were kept up to date throughout the protest. The Web pages provided a network of related pages that gave a good overall picture of the situation as it developed and provided a good barometer of public opinion with regard to the situation. It is interesting that governments in the areas affected were slow to realize the potential that was being exploited and did not appear to capitalize on the information that was being made available on the Internet.

The United Kingdom has an interesting mix of online activists that includes concerned citizens who would not normally be viewed as activists; political parties and groups, such as the West Berkshire Conservative Association;[44] the more expected trade group and industry sites; and truckers' forums.

Electrohippies, a group based in England, used DoS attacks against the World Trade Organization (WTO) in December 1999. The Electrohippies claimed that 452,000 supporters bombarded the WTO's Web site. The Electrohippies are hacktivists (i.e., computer-aided activists who hack) with a conscience. They will not intrude into computer systems and, in fact, abhor physical violence, preferring to send e-mail bombs rather than real ones that can hurt or kill.

iDEFENSE reported that the cyber-activist group RTMark has used eBay to help raise funds to support a variety of cyber-protest campaigns. RTMark utilizes an array of cyber-protest methods to target large companies and organizations. The group also solicits funds for developing hacker tools to be used against its targets.[45]

218.7.1 The Harsher Side of Activism

Urban terrorists from disparate factions across Europe used the Internet and mobile phones to orchestrate the rioting that marred a European summit. Operating from a back-street bar and neighboring cyber café, under the noses of the 6000-strong security force surrounding Nice's Acropolis conference center, four men dispatched reports.[46]

When the International Monetary Fund and World Bank met in September 2000, the Federation of Random Action and an affiliate, toyZtech, orchestrated thousands of online protesters. Employing a new DDoS tool for people with almost no computer expertise, the attack was to force the Web sites off line.[47] In addition to the inconvenience resulting from this act, the groups also hoped to cause monetary loss.

Activists are usually cash strapped, preventing them from being able to afford the best technology. This creates a capabilities gap, but that is overcome with creativity. Activists adapt and improvise what they have to achieve their goals. This has been the case for thousands of years. Today, activists use that creativity and adaptability to bring to bear the technologies they can acquire.

218.8 Summary

In this chapter the different types of techniques and tools that a number of different types of individuals with a cause may use, or be perceived to have used, have been examined. In some cases, the action is intended to be an act of warfare, but the primary issue is that it is now impossible to determine whether an incident on a network or system has been the result of an accident, is an act of warfare, is a criminal activity, or is the action of curious youths experimenting with tools they had found on the Internet. The Solar Sunrise incident clearly demonstrates that what was initially thought to be an action by a hostile nation was eventually traced, some considerable time later, to the activities of three youths (two in California and one in Israel).

219

Social Engineering: The Human Factor in Information Assurance

Marcus K. Rogers

219.1 Introduction

In the world of information technology (IT), four years is akin to an eternity. To say that there have been changes in the last four years would be an understatement. Looking back at the previous chapter a colleague and I wrote on the topic of social engineering (SE) back in 2002, there have been few changes in some regards and many changes in others, not all for the good. In 2006, SE is still a topic for discussion and efforts continue to come to terms with the risks that it poses. There has been no satisfying answer reached on how to mitigate the risk, no meaningful or valid statistics related specifically to SE exist, and most organizations have opted for the ostrich approach—burying their heads in the sand and hoping it will all go away. Sadly, this is the same landscape that existed in 2002 and prompted the original chapter on this topic. One thing that has changed, however, is the fact that attacks using SE have skyrocketed (e.g., identity theft, phishing). This chapter is a call to arms, of sorts. If proactive steps in dealing with SE are not taken (and not just throwing more technology at the problem), its impact will become even greater than it is today.

It has been speculated that IT security is starting to come of age in these days of governmental regulations, malware, spam, phishing, identity theft, and other affronts against our privacy, both personal and business. The public is beginning to recognize that not only has the Internet and IT created an unparalleled opportunity for knowledge and business growth, it has also created an equally unparalleled opportunity for the abuse of information, increased criminal capacities, and corporate malfeasance. As we step back and look at the maturation of IT security, several aspects become readily apparent: overall, the IT community is still reacting to threats, as opposed to be being proactive, and there is still tunnel vision in thinking that the solutions to all problems can be found in technology.

Recent surveys indicate that businesses, government agencies, and private citizens are spending more money on technology based security controls than ever before (Gordon et al. 2005). Despite this increased expenditure, systems are actually no more secure now than in the past. The monetary losses to businesses as a result of attacks against IT systems are estimated to range from hundreds of millions to billions of dollars. The cost of ID Theft in the U.S. alone is estimated to be in the tens of millions (Center 2006; Commission 2006). It is obvious that more technology is not the answer and that, to stem the rising tide, it is necessary to examine the roots of the problem.

A quick review of the studies and surveys not commissioned by vendors or companies with a vested interested in selling some type of service (few and far between) highlights a common theme—people/employees are the biggest vulnerability. This has been a consistent trend for years, yet, it has gone ignored. It is time that the issue is met head on.

As was noted in the opening section, several years back (2002), I co-authored a chapter on Social Engineering along with a colleague, John Berti, that appeared in this series of books. While crafting the chapter little did my colleague or I realize how prophetic it would be. In 2006, SE remains a very real threat. This chapter will attempt not only to spur interest in recognizing and appreciating the risks but also to focus on understanding why SE is so effective, why society is so susceptible to these attacks, and how to effectively deal with this criminal tradecraft.

Although this chapter will not be a rehashing of the previous work, some redundancy is necessary to set the context for the remainder of the discussion. Like so many other terms that are used in the IT world, *SE* was borrowed and mutated from the field of political science. *Social engineering* originally referred to attempts to sway the will or attitude of society or some sub-sector; in essence, to engineer society toward a certain outcome (Arthurs 2005). In its simplest form, it is persuasion on a societal scale. Inherently there are no negative connotations associated with the term. Social engineering is a tool wielded by politicians, business leaders, teachers, sales and marketing people, and even parents. It is hard to think of any vocation that does not consider the ability to effectively persuade or change another's opinion in a desired direction, an admirable and much sought after quality.

Within the field of IT security, the term *SE* has taken on a different connotation. The term has a definite stigma attached to it and is synonymous with hacking and other deviant behavior. It is certainly not viewed by the mainstream as a desirable quality for a professional to have or aspire to. The term, although still incorporating the notion of persuasion, has evolved from the context of being a wide spread phenomenon at the societal scale to being extremely interpersonal.

For the purposes of clarity, SE will be examined in the context of its IT definition which, simply stated, deals with attempts to obtain information or unauthorized access, or to commit fraud or some other criminal activity, using deception and/or persuasion (Rusch 1999; Granger 2001; Berti and Rogers 2002; Wright 2003; Dolan 2004). By deconstructing the phenomena, it becomes apparent that we are dealing with attackers who are skilled manipulators, deceivers, and, for lack of a better term, good at turning a con.

219.2 Scope of the Problem

As with other areas in IT security, it would be advantageous to provide some hard facts, data, or metrics that we could point to and say there are *X* number of attacks or that the cost of SE annually is *Y*, but unfortunately these statistics do not exist. In reality, they cannot even be extrapolated from the meager statistics on the impact of IT attacks in general. This area is one of the many blind spots that currently exist in the field of information assurance and security. Ironically, this blind spot was identified in our 2002 chapter and the problem has not gotten any better. So how does one build a case to justify the current discussion, let alone devoting budget dollars and scarce resources? If the numerous books, news articles, and stirring testimonials of individuals who have made their criminal careers deceiving people are to be believed, we are in the midst of an epidemic. Unfortunately, anecdotal evidence alone is difficult to take to a budget meeting or input into a cost benefit analysis when trying to determine the scope of the problem and the monetary impact of SE.

Although there are no figures that focus on SE as a real subclass of attacks, the increased awareness regarding email based attacks and scams has led some groups to begin tracking this attack vector. In particular, phishing and pharming attacks have become so pervasive and lucrative that we have some limited statistics. Industry groups such as the Anti-Phishing Working Group (APWG), a pan-industry and law enforcement working group, tracks methods of attack and victims but, unfortunately not the financial impact. The group defines *phishing* and *pharming* as:

> Phishing attacks use both *SE* and *technical subterfuge* to steal consumers' personal identity data and financial account credentials. Social-engineering schemes use "spoofed" e-mails to lead consumers to counterfeit websites designed to trick recipients into divulging financial data such as credit card numbers, account usernames, passwords and social security numbers. Hijacking brand names of banks, e-retailers and credit card companies, phishers often convince recipients to respond. Technical subterfuge schemes plant *crimeware* onto PCs to steal credentials directly, often using Trojan keylogger spyware. *Pharming* crimeware misdirects users to fraudulent sites or proxy servers, typically through DNS hijacking or poisoning. (Group 2006)

According to the APWG, reported in November 2005, there were 16,882 unique phishing attacks, 4630 unique phishing sites, 93 brands hijacked. The United States hosted the most phishing websites. The deputy assistant director of the FBI testified before congress in 2004 that phishing scams were the nexus to identity theft (Martinez 2004). Identity theft also has the dubious distinction of being the fastest growing non-violent criminal activity in the United States. The estimated financial impact of ID Theft has been estimated in the billions of dollars (Commission 2006).

Based on the volume of phishing attacks that employ SE, and the fact that phishing plays a role in ID Theft, we now have an indirect measure of how large the SE problem is. Although this indirect approach is no substitute for more exacting statistics, it appears that at this point in time it is the best we have to work with.

219.3 How Social Engineering Works

As Rusch (1999) pointed out, SE has more to do with psychology and sociology than it does with technology; persuasion and deception are core components of SE. These two concepts have been studied by behavioral scientists and several theories have been derived to explain the mechanism behind their apparent operation.

Behavioral science studies indicate that people are very susceptible to being deceived and persuaded—some more than others (Booth-Butterfield 1996a; Wood 2000; Sagarin et al. 2002; Masip, Garrido, and Herrero 2004). The two primary models that are used to determine the exact mechanism by which this occurs are Chaiken's Heuristic System Model (HSM), and Petty and Wagner's Elaboration Likelihood Model (ELM). Both theories posit that an individual's motivation and ability to process relevant information affect the susceptibility to attitude change (Wood 2000). A high level of motivation and the opportunity to carefully process information leads to attitude changes based on a more logical appraisal of information. On the other hand, when an individual is not highly motivated (no personal connection to the task) or are unable to deep process information (time constraints, attention deficits) decisions regarding attitude changes (susceptibility to being persuaded) are based on simple rules (e.g., rules of thumb, attractiveness of the source) (Wood 2000). Thus people are more easily swayed and their attitudes and decisions can be manipulated.

According to the HSM model, people tend to operate in one of two modes of thinking, heuristic and systematic. These can be thought of as two opposite ends of a spectrum (Booth-Butterfield 1996a, Wood 2000). Heuristic thinking does not involve a great deal of effort or much critical analysis is occurring. With systematic thinking, the individual is making more of an effort and is more carefully analyzing what is occurring (Booth-Butterfield 1996a). Given the fact that we only have a finite amount of energy to devote to the numerous tasks we have, people tend to operate primarily at the heuristic level—this has some interesting ramifications that we will explore later.

The ELM uses the concept of an elaboration continuum based on motivation and ability to think about and analyze information critical to the task or decision at hand (Petty et al. 2004). The model holds that persuasion follows one of two paths, central or peripheral (Petty et al. 2004). The central path, or route, requires a fair amount of effort and thought before a decision is reached, and the peripheral consists of attitudinal changes that arise when elaboration is low—relatively little effort/thought is required (Petty et al. 2004). Here again the research indicates that the majority of us operate in the peripheral mode.

219.4 Current Factors

In 2002, we discussed the various business environment and human factors/variables that were significantly correlated with the ease and effectiveness of SE attacks. The human condition has not changed much in four or five years, so there is little utility in rehashing this (interested readers are directed to the 2002 chapter in HISM—Berti and Rogers 2002). On the other hand the business environment has been going through near convulsions since the dot com bust and the increasingly competitive global economic landscape. Outsourcing and now insourcing is a major part of the new business paradigm, change appears to be the only constant, as even some of the venerable juggernauts of our economy (e.g., the automotive industry) are in the midst of radical business overhauls and downsizing.

The ease of causing someone to change his or her attitude, judgment, or opinion has not been lost on the criminal element in our society. The confidence men or con men have historically relied on the mechanisms described above to ply their criminal tradecraft. The adage that, "you can fool some of the people all of the time and all of the people some of the time," seems to be disturbingly accurate. This vulnerability of people, as we have discussed, is compounded by the individual or victim being unmotivated and not personally connected with the outcome of a decision, judgment, or consequences of the actions in question.

If we step back for a moment and look at the current state of much of the work force in North America, it becomes quite apparent that most employees would fit the description just given (i.e., the category of not feeling personally connected to their jobs or not feeling a sense of loyalty to their employers). Current job satisfaction studies confirm that most of today's workers feel this way, especially in light of recent corporate downsizing and foreign outsourcing (Rogers 2006). Recall that both the HSM and ELM models discuss how important being motivated and expending mental energy is to making good decisions about whether to change one's opinion or judgment (Wood 2000; Petty et al. 2004).

We could spend an entire chapter on the various reasons why workers are feeling disenfranchised (Rogers 2006). At a very high level, these factors include transient work force, customer service above all else, downsizing yet being forced to do more with less resources, and eroding employer/employee trust and loyalty (Rogers 2006). The phenomenon of the transient work force has been discussed in-depth in so many publications that discussion will be omitted here. Moreover, the factors of downsizing and customer service above all else (Berti and Rogers 2002) have become even more salient in recent years.

Today, workers are multitasking like never before. Humans have only a finite amount of both physical and mental energy. To preserve our resources we tend to become cognitive misers meaning that we only expend the minimum amount of mental energy required to minimally perform a task. Unless something wakes them up to devoting more energy, people tend to operate on a kind of mental cruise control. Between responding to the hundreds of email and phone calls they receive in the day, there is little if any time available to devote to their jobs, let alone someone asking for information they may or may not be authorized to have, or bothering them to provide social security numbers, account passwords, etc., so that they can reset accounts on systems that routinely go down, are constantly upgraded, or never really worked properly in the first place.

The concept of the disenfranchised worker may also play a major role in why people seem so open to being socially engineered. The various studies that measure workplace satisfaction and contentment seem pretty clear that workers today are uncertain about their future, feel no real sense of reciprocal loyalty between themselves and their employers, and are aware that they will probably have many different jobs or careers during their lifetime (Rogers 2006). This general workplace malaise is not conducive to being highly motivated or vested in the well being of the organization. As the models of persuasion indicated, a lack of motivation and unconnectedness to the outcome of a decision leads to a psychological state that makes being persuaded relatively easy (Petty et al. 2004).

It becomes apparent that the various forces/factors have resulted in a context that is conducive to SE. It is important that we remember that criminals in general are not proponents of the protestant work ethic. They tend to look for short cuts and the path of least resistance to satisfy their wants, needs, and desires. The same can be said for criminals that use and target computer systems. These individuals tend to be opportunistic and look for the most vulnerable or weakest victims or marks (a term used in the confidence scams). Many of the more infamous computer criminals have stated that they would rather engineer someone into providing them the information or the access to the system than spend time attacking the technology and corresponding security controls (e.g., firewalls, virtual private networks (VPNs)) (Mitnick and Simon 2003). The rationale provided for this preference in attack vectors is varied. Some indicate that it is more thrilling conning a real person than executing a buffer over run on a system. These individuals get a rush or high from the mental gymnastics that they claim they engage in and the constant risk that their adversary may discover they are being conned. It is safe to say that, with some SE attacks, the gymnastics would be on the level of a simple somersault as opposed to anything more grandiose.

Other convicted computer criminals indicate that their choice is based on the ease of the attack (some claim a 100% success rate) coupled with a complete lack of audit trails or logging related to phone conversations—other than customer service reps. The limited information on SE attacks indicate that, apart from phishing scams that use email, the weapon of choice is the lowly telephone (Hoeschele and Rogers 2005). The phone is more ubiquitous in society than computers. Almost everybody has a phone on their desk (or on their hip, in the case of cell phones). Contrary to the predictions of the imaginative science fiction writers of the 50 and 60 s, we have yet to see video or holographic phone systems that would allow us to visually verify a caller's identity. We do have caller ID, true. However, we rarely know the originating number of everyone that calls us during the course of our business day should be. The current phone system is an anachronism in today's high tech workplace. We really do not have any reliable method of authenticating phone calls or callers other than by asking them a series of questions—which is time consuming.

We don't usually focus our IT security controls on our phone systems as private branch exchange (PBX) hacking has taught us, and thus unless the call is recorded for some ancillary reason, there are no traces or records of what transpired. Even the phone companies that own the switching facilities can only provide limited records (e.g., last true caller ID records). They do not, unless tipped off in advance or so ordered (usually by some court mandate—subpoena, court order, or warrant) record their customer's communications. This may come as a shock to those inclined to believe the numerous conspiracy theories.

Let's review what has been discussed thus far, people are still people—human nature has not changed, the business climate/environment is even more conducive to fostering mistrust and lack of loyalty, the primary attack vector (the telephone) does not have any real security controls built in and little if any real audit and logging capabilities. What exists is, in fact, a recipe for disaster that is being realized by the less than scrupulous members of our society, as witnessed by the prevalence, frequency and impact of ID Theft and phishing scams. Let's not forget that the posture most frequently used by organizations to deal with the risk, is to deny the problem exists and play ostrich. The current state of affairs paints an awfully bleak picture, but things are rarely as hopeless as they first appear.

219.5 Dealing with Social Engineering

It is relatively easy to be the harbinger of doom gleefully pointing out all of the problems and shortfalls. It is much harder to step back, analyze the data and come up with some practical solutions at the tactical and strategic level. In the 2002 chapter, the suggested solutions centered on education, awareness, and training combined with proper technical solutions. For the most part these suggestions still hold, but they have been untested as no one is actually doing this in regard to SE. Agreeing that these suggested solutions for mitigating the risk have not been battle tested, they have also rarely been presented at a level of detail that is of any real practical use. I doubt we would find anyone that would argue that increased education, training and awareness in of itself are very worthwhile—just as world peace is a great idea. What is needed now is the what and the how.

Some authors and gray beards in the industry have joked that the only way to have any hope of IT security, is to get rid of the end-user; take the human element completely out of the equation. Although this provides for some interesting philosophical debates, it is not overly practical. If we place the removal of all people at one end of the spectrum, then it is necessary to examine the remainder of the spectrum for solutions that have a high probability of success.

As mentioned there are no specific SE safeguards available at the technical level. The tried and true security controls such as firewalls, VPNs, two-factor authentication, and biometrics, although having limited success against more traditional attacks, are all but useless for mitigating the risk of SE (especially when implemented in isolation). If technical controls are not effective then it becomes incumbent upon us to look to the remaining control domains of physical security, operational/administrative security, and personnel security.

The success of physical security alone in dealing with SE attacks is doubtful, as these attackers are not usually physically present. Although better physical security would reduce the risk of the very bold SE attacks that involve actual physical entry into an organization, based on the assumption that technology based attacks (e.g., email-phishing) and telephone attacks are more prevalent, the utility of physical security is limited.

Operational/administrative security that includes the development of policy, procedures, and guidelines is definitely a component of effective SE risk mitigation. However, policy, etc., are just documents and despite giving the organizations the ability to terminate someone's employment for being in violation, these documents do not in and of themselves provide any protective function. The development and implementation of education, training and awareness related to SE is another matter and will be discussed in a separate section.

Using personnel security alone is also problematic. Although the victim is internal, the threat agent—the attacker, is external and outside of the purview of any background screening etc. Background screening on employees is also of limited use here, as I doubt anyone would find a notation in someone's permanent record that the potential employee is easily deceived or operates primarily in a heuristic processing mode.

So what then is the ultimate answer?[1] Some authors have professed that education, awareness and training (EAT), will solve all our problems. Although this is definitely an exaggeration, EAT is actually an essential element of the SE mitigation Equation (Arthurs 2001; Granger 2001; Berti and Rogers 2002; Gragg 2002; Wright 2003; Dolan 2004; Hoeschele and Rogers 2005; Rogers 2006). What must be realized is that EAT does not replace the other security control domains and needs to be used in conjunction with the physical, administrative/operational, technical and personnel security controls. EAT compliments these other controls and assists in creating an effective defense in depth approach.

We also need to be cautious that we are implementing the proper type of EAT. Simply employing a program without planning, forethought, and a valid understanding of what we are trying to accomplish is actually counter productive as it provides a false sense of security. This lesson was learned the hard way

[1] I know you are all thinking, "It's 42." Well, maybe only the Douglas Adams fans.

for some with firewalls. Many companies at one time bought firewalls and truly believed the vendor hype that these devices would cure all their security woes. Reality soon proved these claims to be rather dubious.

Almost all of us have been exposed to EAT programs that were so bad that they were in fact counter productive. Often organizations implement these programs merely to be in compliance with some piece of legislation or regulation. These programs are really about going through the motions and being able to (at least on paper) demonstrate due diligence and deflect liability back onto the employee who is now fully trained and aware. These programs are often focused on boiler plate like computer based training with talking heads, poorly developed content, and quizzes so simple that a six year old could guess the correct answer. Hardly conducive to real learning of any kind and it actually highlights the lack of importance that the organization really places on whatever the content of the training was about.

So how to ensure that these errors aren't repeated? First, it must be determined what type of training, education, and awareness has been successful in assisting individuals in becoming harder to deceive. This area has actually been studied, and we can turn to the body of research to see what can be reused and repurposed for IT. The next factor to consider is the proper method of delivery/teaching for the content, context, and audience. Here, look to the discipline of pedagogy for answers. Finally, we must combine EAT with the other security controls domains that we have mentioned. A task that may not be so simple!

219.5.1 SE Inoculation Training

The concept of inoculation training comes from the health community and is the theory behind giving adults and children shots to prevent polio, diphtheria, measles, etc. (Booth-Butterfield 1996b). Flu shots are also an example that most of us are familiar with these days. The notion is that by introducing us to small amounts or a weakened form of a virus, our bodies are able to develop the proper antibodies and we become immune to the full-blown virus in the future. This model has been extremely successful at controlling or wiping out some diseases such as polio—albeit only in the industrialized nations.

The U.S. army for several decades has also looked at inoculation theory as a model for developing soldiers that are better able to handle the stress of combat, being captured, tortured and attempts at being brainwashed. The latter problem of susceptibility to brainwashing is actually a problem of being persuaded to change one's attitudes and is very important for our discussion.[2]

Other research has focused on the effects that prior training and preparedness has on reducing stress in general. During World War II, several studies were commissioned that looked how best to prepare troops for combat. The findings from this research indicated that realistic information on what to expect and the very real psychological and physiological reactions these soldiers would encounter were significant in reducing the overall stress and allowing the soldiers to better function not only in combat, but also be better able to function once they return home from combat (Meichenbaum 1996).

For the purpose of inoculation from attacks on our belief systems, the underlying principle centers on the idea of an attack just sufficiently strong enough to challenge the receiver, but not strong enough that it overwhelms them (Booth-Butterfield 1996b). This causes the receiver to respond but in a manner that allows them to be successful in repelling or overcoming the attack. Each subsequent successful defense strengthens their belief or attitude and makes it harder for them to be swayed. The notion of an active defense is also important (Booth-Butterfield 1996b). According to Booth-Butterfield (1996b), "An active defense occurs when the receiver does more than merely think, but rather performs actions." This active component further builds the attitude immune system.

[2] Interested readers should refer to the article by Booth-Butterfield (1996b).

To be effective, the inoculation training should contain these three steps or phases (Booth-Butterfield 1996b):

- Warn the receiver of the impending attack
- Result in a weak attack
- Get the receiver to actively defend the attitude

We will examine each phase in more depth in the following sections.

219.5.2 Effective Education, Awareness, and Training for SE

Armed with a better understanding of the mechanics of susceptibility to attitude changes, common attack vectors for SE, and the concept of inoculation training, we now need to combine these into a remedy for the less than stellar EAT programs we have been exposed to thus far.

The foundation for any effective program is identifying the audience and then placing the EAT into the correct context to generate the greatest impact. The audience for our anti-SE EAT program is actually a group of "audiences." This group can be divided into executive management, management, and employees (including contractors, sub-contractors etc.)—from the j-suite (janitorial) to the c-suite (chief execute office (CEO's), chief information officer (CIO's), chief technology officer (CTO's) etc.). Each of these audiences represents a distinct audience that requires the materials to be placed in a unique context. The employee group can also be sub-divided by logical business units/duties (e.g., HR, tech support, administrative support, call center). Here again these groups need a different context for the materials to move the program from the abstract to the concrete.

Once we have identified the proper categories of audience (each organization will have to conduct their own audience categorization, as one size may not fit all here), then the appropriate modality for delivering the program and its content must be determined (e.g., computer based training, seminars, lunch learning series, scenarios). For the purposes of this chapter, we will limit the discussion to seminar/group scenario based training. This does not in anyway preclude the other traditional EAT methods.

The next decision to be made is what learning modes best fit our audience. Research indicates that people tend to learn in one of three different modalities: auditory, visual, and kinetic (Bransford et al. 2000). People will have an innate preference for one of these. A well constructed program should include all three of these modes or dimensions of learning so that everyone gets something useful from the learning experience. Coupled with offering all three modes is the necessity to be clear on what you want the learning outcomes to be, and then working backwards in a method known as an outcomes-based learning approach. Blooms taxonomy of learning should be consulted so the appropriate learning dimensions are covered (Gronlund 2000). Most basic texts on pedagogy and adult learning contain the taxonomy.

One of the most important things to remember is that people will be more motivated to learn and have better retention if you can make the learning experience personal. Regardless of the audience, you need to make a connection or illustrate how it effects not only the organization but also the individual, both directly and indirectly. With SE attacks this is fairly easy. Most people use the Internet outside of the business environment for personal uses such as electronic banking, email, travel reservations, etc. The same attacks that target confidential business information also target individuals. ID Theft is a prime example of both a business risk and a personal risk. People also receive spam both at home and at work, and phishing scams attack both personal and business accounts. Furthermore, giving out information that results in an IT security breach could result in liability to both the company and the individual (legislation such as health insurance portability accountability act (HIPAA) make the individual in violation, personally liable both civilly and criminally).

Once the framework has been set, the program should focus not just on providing awareness of the risk of SE and its impact, but also on inoculating as many employees as possible against SE attacks. The inoculation training phase needs to incorporate the warning, weak attack and active defense concepts as described by Booth-Butterfield (1996b).

219.5.2.1 Warning Phase

Employees should attend a general information session about SE where they are introduced to what SE is, how prevalent it is, what the impacts of SE are to businesses and them personally, and how SE attacks work (i.e., what are the common methods used). These sessions should challenge employees to start thinking about how they would react if placed in a situation where someone was trying an SE attack against them? This internalization and self-rehearsal is very important. It kick starts the individual's defense mechanisms and helps make what was once abstract, SE attacks in general, into something more concrete, attacks against them personally. It also starts to pull the person from his/her normal heuristic thinking process to a more systemic deeper level of critical thinking. As was previously discussed, these individuals have now moved into a level of thinking that is more resistant to attitude change (Wood 2000; Petty et al. 2004). This shift in thought processes alone is significant. However, simply warning people is not sufficient for long term protection from attacks. People will soon slip back into their previous mode of thinking and processing if nothing further is done.

219.5.2.2 Attack Phase and Active Defense

These two phases are combined as they work in conjunction with each other and are intertwined. Once employees have sufficient time to rehearse how they should deal with an SE attack, it is time they are given a chance to act out these defenses. Actually acting out the defense strengthens the defense mechanism as it again causes the individual to operate at the higher or deeper level of processing.

Scenario based training is one effective method and helps the individual overcome the mistaken belief that, although others may be vulnerable to attacks, they are not. This illusion of invulnerability to deception is quite common and unless dealt with, it can interfere with the training (Sagarin et al. 2002). The attack used in the scenario needs to be believable yet weak enough to be successfully overcome, resulting in a successful defense for the individual. If we overwhelm the individual then the training actually becomes counter productive as there is a real risk that the individual will fall into a state of learned helplessness, where they learn to not even try and resist these attacks. Any one of several realistic scenarios can be played out in a controlled environment. Because the primary attack vectors for SE tend to be email or phone calls, it would be prudent to incorporate these into the scenario. The attack phase allows the individual to move from the self-rehearsed internal dialogues to the actual active defense where they practice and develop skills at countering the attacks in a positive environment. This builds up their confidence and produces a more long lasting effect than merely passively thinking about what they may or may not do.

The scenario training can be done in a group environment, or individually depending upon factors such as time, training resources, and facilities. Although it is true that we can learn certain behaviors and attitudes via modeling or vicariously, the current research in this area tends to stress the importance of first hand experience by the participants (Booth-Butterfield 1996b; Sagarin et al. 2002).

219.5.2.3 Evaluation and Remediation

Two of the most important aspects of EAT, and probably the most neglected, are evaluation/assessment and remediation. Far too often a program is assumed to be effective and initiating a change in behavior or attitude merely because of positive feedback from the participants. Unfortunately this is not a truly reliable or accurate measure of success. What needs to be done is actual testing of the individuals once they have had time to potentially slip back into their old mode of thinking and processing (Gragg 2002). A vulnerability analysis (VA) focusing on SE attacks should be conducted shortly after the training and then periodically during the year. This testing or analysis can be done with internal resources and should be unannounced to provide a valid measure of the success of the initial training and also to determine when it is time to renew the training enterprise wide (i.e., a significant increase in the success rate of the SE attacks during the VA).

What is also necessary is to make sure that SE is front and center in any larger yearly IT security review or audit. Although this may seem painfully obvious most organizations do the exact opposite. From personal experience and discussion with other consultants in this field, the number one area that is deemed “out of scope” on most security reviews (especially by external consultants) is SE. The first thing the representatives of the organization say at the planning meeting is, “yes we know we are vulnerable to SE so let’s not test it!” This is baffling, why wouldn’t you test those areas that you assume *a priori* are bad? Several consultants have responded by saying “Great, here is my invoice; I don’t have to look any further, you failed!” Humor aside, in my experience their rationale is that they do not want to be embarrassed or look particularly bad to their bosses. But just image how bad it looks when six months down the road they get attacked through SE and have to admit that they purposely ignored this vulnerability—more than one CSO/CISO has lost their job because of this convoluted logic.

Remediation or better put, remedial training is also essential. Even the best EAT programs in the world don’t work on everyone. The reasons for this are diverse and range from lack of motivation on the part of the individual, to failure to make the context personally relevant. So we are faced with the issue of how to address those individuals that, for whatever reason, are still vulnerable to SE attacks despite the EAT program? These individuals may have been identified during the VA used to assess the effectiveness of the program or by management. The solutions vary but ultimately some kind of remedial training is necessary. A good rule of thumb in these cases is to put the blame on the EAT program and not the individual. The individual should be interviewed to determine what the cause of the issue might be and then appropriate modifications should be made and a customized EAT program developed for the individual(s). The worst thing that can happen at this stage is for the individual to feel they are being punished. Learning theory has shown that punishment is very ineffective at changing behaviors and may place the entire EAT program in a negative light for the entire organization—hardly conducive to further effectiveness. It is more effective to use positive reinforcement such as recognizing good behavior (i.e., reporting attempted SE attacks to IT security personnel) than focusing solely on the negatives (Berti and Rogers 2002).

In those rare occasions where someone just does not get it no matter what is tried, it may be necessary to reassign him or her to a job function that does not allow him or her to divulge sensitive information. It may also be necessary to terminate someone’s employment if they are a chronic risk to the organization.

219.6 Combining Security Controls

As was mentioned in Berti and Rogers (2002), the most effective defense for any attack is a holistic approach. Mitigating the risk of SE attacks is no different (Gragg 2002; Winkler and Wright 2003; Lafrance 2004). The cliché, “you are only as secure as your weakest link” is a truism in this case. If we merely focus on EAT and ignore the other security controls we are guilty of being imprudent if not foolish (Gragg 2002; Dolan 2004). The preceding sections indicated that each of the controls (e.g., technical, physical, administrative/operational, and personnel security) individually were inherently ineffective at mitigating the risk of SE; however, if combined together and properly layered with EAT, they are more effective at detecting when an SE attack occurs and hopefully better at decreasing the impact and success of these attacks (Arthurs 2001; Hoeschele and Rogers 2005).

Obviously an in-depth discussion of all the possible methods by which these controls can be combined or layered is beyond the scope of this chapter. Therefore, we will constrain the coverage to a single example to illustrate the effectiveness of this approach. Because we seem to be chronically suffering from what some have coined firewall envy,[3] the model will leverage technical solutions that are currently available or are on the horizon as the primary defense layer, with the other controls (including EAT) acting as compensating controls (see Exhibit 219.1).

The compensating controls have a reciprocal relationship with each other as feedback from each control serves as input for the modification of the other control.

[3] For those unfamiliar with the term, it refers to the phenomena of purchasing firewalls and technology just for the sake of bragging that yours is the biggest and the best, with no real thought to the effectiveness or the long term management/administration needs (e.g., updated rules, patches, tweaking of thresholds).

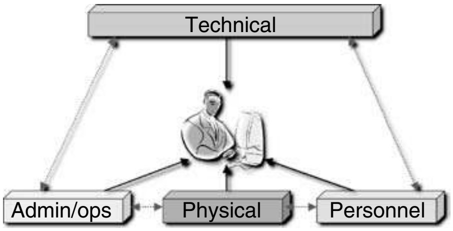

EXHIBIT 219.1 Reciprocal compensating controls.

For our model the specific technical control is multi-factor authentication—using biometrics, password, and a time sequenced token. The physical control identified for this model is console/administrative workstation access and a secure data center. The personnel security is periodic background checks (e.g., upon hire, and then once per year or if there is a change in job function to a category of higher trust). The admin/operational control is a well planned and executed education, awareness, and training program focusing on inoculation training for SE attacks. The model assumes that a policy is in place dealing with corporate wide IT security including EAT, incident response, acceptable usage, etc., and that there is a positive business culture that supports IT security initiative—isn't fantasy wonderful.

The following scenario is used to illustrate the interactions of the security controls. The attack vector will be the telephone; the SE attacker will attempt to obtain a password to gain access to a critical database server that houses the organizations' confidential client list. The attacker has already obtained a userid by harvesting news group postings by employees of the targeted company (this information is readily available as certain websites track news group postings and have a searchable archive of postings that go back several years). The SE attacker has also been able to obtain the company's organizational chart (publicly available on the company's website) and now has several names to drop. Furthermore they have ascertained that the individual whose user id they have is currently on holidays thanks to a greeting that has been left on that individual's automated telephone answering system. The SE attacker decides to call the help desk of the organization, as this function has been out sourced to a company in a different geographical area. This information was obtained by reading a media posting by the company that highlighted this new relationship. The attacker has deactivated sending caller ID information on his phone and calls the help desk seeking an individual that is an easy mark.

The SE attacker now pretends to be the real owner of the account, states they are on holidays but were paged as there is a serious issue with one of the servers, but they have been locked out of their account. They request an account reset and that the help desk person provide them the new password. They indicate that time is of the essence as the server is critical to the day-to-day operations of the company.

This scenario is realistic and combines actual attack methods and intelligence gathering that has occurred in several documented real life attacks (Mitnick and Simon 2003, 2005). On average, the probability of success for an attack following this type of scenario is high (Mitnick and Simon 2003). However, in our case 95% of the help desk personnel have taken and successfully passed an EAT program directed at SE attacks. The company has a strict policy about password resets and requires the employee's supervisor to authorize the reset. The reset must be logged as part of a standard trouble ticket recording system. Once the supervisor authorizes the reset, the new password is sent to the employee via email, but is encrypted using the employee's public key (only someone in possession of the employee's unshared private key can decrypt the password). As per a contractual agreement between the organization and the outsourcing company, all employees that work at the help desk or have an equivalent or higher level of trust, under go a thorough background check (both name and criminal record check verified by fingerprints) upon hire and then yearly.

Unbeknownst to the SE attacker, all employees who have administrative access to critical servers must use a multi-factor method to gain access and authorization to the system. This requires the individual to enter their password, thumbprint from a portable scanner into a portable device that then generates a time sequenced login string that must be entered upon login to the system. The password alone is simply one factor in this multi-factor authentication system.

The servers are also located in a locked data center that also requires a hand geometry scan to gain access to the center. To actually login at the terminal or console the same multi-factor authentication that is required for remote access is also used.

The first time the SE attacker calls they are met with strong resistance (the employee has taken the SE EAT program) and the attacker quickly terminates the call. The EAT program was successful and all is right with world! However, undaunted the SE attacker, who knows that the chances of getting connected with the same help desk employee is very low, calls again. As luck would have it the SE attacker is connected to a new hire that has not taken the SE EAT program, is under pressure to meet the average time per call standard and does not want to bother their supervisor with questions—might reflect badly on their end of probationary period assessment. Again, this is a realistic situation for employees of call centers and help desks. The SE attacker is able to convince the employee to reset the account and due to time constraints (and the fact the caller is on holidays), provide the password over the phone. Once the call is terminated the help center employee moves onto the next call blissfully unaware that they have been the victim of an SE attack.

The SE attacker buoyed by the success of getting the password soon realizes that due to the compensating controls (i.e., physical, personnel, administrative/operational, and technical) their ill gotten prize is useless, it is only one element in the holistic authentication process and security controls used by the targeted company. The impact of the successful SE attack has been significantly decreased and the risk mitigated to an acceptable level. In a perfect world the employee who fell victim will undergo the SE EAT training program and will react more appropriately the next time someone attempts an SE attack. At the very least the next time a security audit or VA is conducted employees like the one that was duped will be identified for additional/remedial training. These same audits and VA's should also provide proactive scorecards or health checks for all the compensating controls and their dependencies, and allow the organization to modify the controls accordingly.

219.7 Conclusions

There are few real truisms in the world of IT security; however the statement that people are the greatest risk to security may be one of them. People in this context refer to not only our employees and ourselves that behave in a manner that causes problems (e.g., clicking opening email from unknown parties, falling for phishing scams, or divulging confidential or sensitive information), but also to those whom are attacking our systems. It is people who write the code, execute the programs, share malicious software, devise the scams and carry out SE attacks.

This chapter set out to add to the topic of understanding SE that was started in the 2002 chapter by Berti and Rogers. The chapter attempted to not just rehash what was said in the past, but to update the reader with what is occurring in the present and will continue to happen in the future if SE is left unabated. The thesis boldly stated, that to effectively and efficiently deal with SE our efforts should focus on how to integrate EAT into the defense-in-depth or compensating security controls model. A cry to arms was given to move away from blindly following the path of more technology as the cure for all that ails us, to a holistic approach that relegates technical controls to being more of a team player along with education, awareness, and training, physical, operational/administrative, personnel controls. This relegation must not be confused with any notions of replacing or abandoning technical controls altogether. Those purists who claim that we need to abandon the other security controls in lieu of EAT programs are not only being foolish, but are also negligent.

The mechanics behind the how and the why we so easily fall prey to SE attacks (Heuristic System Model and ELM) provided a glimpse at how our mode of thinking and personal connectedness to the task at hand affects our decision making process. Insight into the mechanics of deception and persuasion allowed us to examine the business factors that exacerbate this vulnerability (e.g., lack of job satisfaction, eroding employer/employee trust, and disenfranchised workforce), and why certain attack vectors such as the phone have become the predominate choice of those engaging in SE attacks.

As was stated, it is easy to sit back and pontificate about what is wrong, it is more difficult to provide possible solutions to the problems identified. By looking to the concept of inoculation theory, a plausible approach to mitigating the risk of SE was identified. This helped to identify concepts that could and should be integrated into anti SE education and awareness training programs.

The holistic approach of including EAT programs with reciprocal compensating IT security controls provides a practical and realistic approach to mitigate the risk and thus the impact of SE attacks, as was illustrated by the scenario. Although simplistic, and merely a thought experiment, the proof of concept/scenario provides one layer of testing and validation. The obvious next step is to move to empirical testing, but as the adage goes, "we need to walk before we can run." Hopefully this chapter has shown we can at least crawl now.

Unfortunately several questions related to SE and its mitigation still remain. One of the largest is determining what the return on investment (ROI) is for EAT programs in general and those directed at SE attacks in particular. Although there are numerous anecdotes about how EAT results in the greatest ROI of any of the IT security controls, no real valid statistics could be found to support this. Although the high ROI seems intuitively correct, we have been fooled in the past by things we thought were obvious (e.g., the earth was stationary). As IT security professionals we face an uphill battle to secure sufficient budgets and resources to implement EAT programs and security controls if we cannot provide a believable business case based on an accurate cost benefit analysis. Without valid numbers to input into our formulas we are guessing at best; most of the executives I have met are reluctant to spend money on hunches and guesses.

Truthfully, there has been nothing novel said in this chapter. The ideas, concepts, approaches, etc., have been discussed and debated by others and by ourselves in other venues and in other contexts. What this chapter has done is taken these good ideas and approaches and woven them together into an efficient, pragmatic and arguably effective framework for gaining back some much needed ground from those that wish to use technology and ourselves for their own selfish and deviant gains. The days of ignoring SE are long gone, as those using these and other attacks are not ignoring us.

Privacy Breach Incident Response

Rebecca Herold

220.1 Do You Know Where Your Personal Data Is?

On October 1, 2005, confidential health records originating from the Toronto Clinic dating back to 1992 were purposefully blown and scattered about the streets of Toronto, Ontario. The Clinic had given the Paper Disposal Company, which provided their shredding services, boxes containing health records. Reportedly due to a misunderstanding, the records were then given to a recycling company that subsequently sold the intact records to a film company that then used the records as props for a film about the immediate aftermath of the September 11, 2001, terrorist attacks on the World Trade Center. On October 31, 2005, Ontario's privacy commissioner found both the clinic and disposal company at fault and liable.

Do you know who is peeking at the personally identifiable information (PII) for which your organization is responsible? Do you know if that vendor to whom you have outsourced the processing of your PII has allowed your PII to get into the hands of a competitor or criminal without even knowing it? Do you know if they may have donated your unshredded confidential papers to the local public kindergarten to use as scrap paper? Do you have bells, whistles, and processes in place to notify you when PII is inappropriately used or accessed? Do you have tools implemented to notify you when someone is inappropriately grabbing your PII? Have you even thought about these issues? Or, do you think someone else in your company has already taken care of all these possibilities? Or perhaps you think that such an incident is very unlikely and would have very little impact on your organization.

If you have not yet done so, and do not have it on your short to-do list, you need to plan to review the protection practices currently in place for your PII and how your organization would be impacted by a privacy breach. Or, perhaps your organization has already experienced one of the thousands of incidents that have already occurred and needs to re-examine, or create, your privacy breach incident response plan. Breaches happen and will continue to proliferate; businesses must be prepared.

220.2 Increasing Incidents, Increasing Anxiety

The Privacy Rights Clearinghouse started keeping track of reported PII breaches within the United States on February 15, 2005, starting with the ChoicePoint incident, and by February 25, 2006, they had chronicled 129 breaches that had been reported in the news. These breaches cumulatively involved the information of at least 53.4 million people. Other sites are also keeping similar chronologies. Keep in mind that these are just the reported incidents.

I know at least four other organizations that experienced and addressed significant breaches during 2005 that did not get publicized or included within these accumulated statistics. And, yes, they contacted all their customers quickly. I am certain there have been many more organizations that have also quietly addressed breach incidents while working diligently to keep the incident from being reported. The types of breaches varied greatly and included such incidents as:

- Dishonest authorized insiders inappropriately using PII
- E-mail messages with confidential information sent or forwarded inappropriately
- Fraud activities perpetrated by outsiders, insiders, and combinations of both
- Hackers gaining unauthorized access to the information
- Information exposed online because of inadequate controls
- Lost or stolen backup media
- Confidential paper documents not being shredded and given to people outside the organization
- Password compromise
- Stolen or lost computing devices, such as laptops, PDAs, and so on

220.3 Increasing Breaches, Lost Customers

A Ponemon Lost Customer Information study released in November, 2005 sponsored by PGP Corporation (http://www.pgp.com) reveals that businesses suffer greater breach incident impact from lost customer confidence and business than what the actual breach itself costs. A survey of over 9000 people revealed:

- Close to 12% had been notified about a data breach by companies with whom they did business.
- Twenty percent of them said they immediately closed their accounts or stopped doing business with the company.
- Companies reported the percentages of all customers lost following incidents ranged from 2.5 to 11%.

Another study released in December, 2005, conducted in Canada by Leger Marketing and sponsored by Sun Microsystems of Canada, showed 58% of consumers said they would immediately stop doing business with a company that experienced a breach that put their personal information in jeopardy. This is significantly higher than the numbers found in the Ponemon study. The loss of customers will depend greatly on the type of breach, the service or product the company provides, how quickly the company contacts customers following a breach, and the history the customer has had with the company, along with the general reputation. The same survey reported 55% of companies indicate that the customer information for which they are responsible is not safe or secure. The study also indicated 14% of Canadian consumers believe they have already been identity theft victims.

220.4 Increasing Breaches, Decreasing Revenues

Another Ponemon PGP Corporation-sponsored consumer breach study (http://www.pgp.com), also released in November, 2005, revealed that the average impact to each of the 14 companies studied following a security breach was $14 million. Actual costs included internal investigations, external legal fees, notification and call center costs, investor relations, promotions such as discounted services and products, lost personnel productivity, and the cost of lost customers. In fact, the costs to the organizations following a breach were more than the immediate costs of addressing a breach.

In addition to the costs identified within the Ponemon report, there can also be additional costs involved with breaches, such as when an organization's customers are other business organizations. For example, if you have customers that are companies that distribute your services or products to their employees or customers (such as if you provide group health insurance policies), then you will not only need to notify the individuals, but also demonstrate to the companies that are your customers what you are willing to do to keep their business. This will likely be pricey. You may need to fly representatives from the companies to your site to meet with your executives to discuss the situation, all on your dime.

Additional breach response costs are also involved for notifications to individuals who are located outside your country, such as the costs for resources to work with the applicable country privacy commissioners, costs for translation services, call centers with multilingual capabilities, and so on. And, depending upon your industry, locations, services, and products, there could be many other areas a breach could financially impact. It is worth periodically taking an afternoon to brainstorm the possible impacts to help you better prepare to respond to a breach. I created a privacy impact "calculator" (http://www.informationshield.com/privacybreachcalc.html) that organizations have used to demonstrate to their business leaders just how much a breach could cost when considering multiple possibilities and factors. Such an exercise is truly an eye-opener and gets the attention of the leaders who can relate best to information presented as profits and losses. It helps to get the resources to do the activities necessary to create a privacy breach incident response plan and implement the associated tools and procedures.

220.5 Increasing Laws, Increasing Liabilities

In 2005, breach notification legislation was passed in at least 23 U.S. states. One of many sites listing these laws is http://www.pirg.org. All organizations must now effectively notify all affected U.S. residents for PII breaches. Trying to notify only those within the states that have notification laws would not only be impossible to manage, it would also be a very bad business decision from a public relations perspective, not to mention the fact that the number of states with such laws is increasing rapidly, and that doing so could still leave you open for civil suits.

With most of the U.S. states having passed privacy-breach notification legislation, and several federal breach notification bills of various flavors looming on the horizon, the issue of how to not only better protect personal information, but also respond to breaches of personal information, certainly should be on the radar of organizations. There was a spate of federal bill-writing activity during the summer of 2005, just before the August U.S. Congress recess, and personal information security was at the top of the agenda. Three different federal bills were proposed at that time addressing the protection of personal information. It is widely expected that a federal bill will be passed in 2006.

220.6 Privacy Breaches Significantly Impact Business

Privacy breaches have significant and long-lasting impact on business. Just a few examples of incidents and the resulting business impacts include:

Incident	Business Impact
October, 2005: Confidential health records originating from the Toronto Clinic dating back to 1992 were purposefully blown and scattered about the streets of Toronto, Ontario. The Clinic had given the Paper Disposal Company, which provided their shredding services, boxes containing health records. Reportedly due to a misunderstanding, the records were then given to a recycling company that subsequently sold the intact records to a film company that then used the records as props for a film about the immediate aftermath of the September 11, 2001 terrorist attacks on the World Trade Center	Ontario's privacy commissioner found both the clinic and disposal company at fault and liable and ordered the following • The Toronto Clinic to implement information practices, including proper training, to the security of personal health information in all forms; to use written contracts with any agent it retains to dispose of personal health information records, and to provide written confirmation through an attestation once secure disposal has been conducted • The Paper Disposal Company to implement a written contractual agreement with any health information custodian for whom it will shred personal health information and to provide an attestation of destruction; to ensure that any handling of personal health information by a third party company is documented within contracts; to implement procedures that prevent paper records containing personal health information designated for shredding from being mixed together with paper that is being disposed of through the recycling process • These requirements were identified by the commissioner as establishing the practice to be followed by all health information custodians and their agents in Ontario, with respect to the Commissioner's expectations for the secure disposal of health information records under Ontario's Health Information Privacy Law
June 2005: A network intruder exploiting network vulnerabilities stole information about 40 million credit card holders from CardSystems Solutions, Inc. This company had processed $15 billion annually in credit-card transactions for Visa, American Express, MasterCard, and Discover	• According to the FTC, the security breach resulted in millions of dollars in fraudulent purchases • VISA cancelled their contract with CardSystems • CardSystems, facing bankruptcy, sold their assets to Pay By Touch for $13 million • The FTC settlement requires CardSystems and Pay By Touch to implement a comprehensive information security program, including data protection education, and obtain audits by an independent third-party security professional every other year for 20 years • A class action suit was being tried in early 2006 against Card Systems, VISA and MASTERCARD in California
February 2005: Criminals posing as legitimate businesses accessed critical personal data stored by ChoicePoint, Inc., which maintains databases with personal information on virtually every U.S. citizen. 162,000 individuals have been impacted as of February 2006	• $1 billion in lost stock value $20 million loss in top-line revenue $3 million cost and counting for credit reporting, legal and other expenses Federal lawsuit for violation of the Fair Credit Reporting Act (FCRA) FTC investigation SEC lawsuit Shareholder lawsuit California state investigation for violation of SB 1386 Estimated personal damage: $500 per customer, not including loss of time

(Continued)

(Continued)

Incident	Business Impact
	Class action lawsuit filed in Los Angeles for $75,000 per victim
June 2001: An Eli Lilly employee accidentally included clear text e-mail addresses of 669 Prozac patients in a message sent for its Prozaccom5 service	The FTC required Lilly to not make security misrepresentations; establish and maintain a four-stage information security program; designate appropriate personnel to coordinate and oversee the program; perform ongoing risk analysis; provide ongoing personnel training; implement intrusion detection mechanisms; conduct an annual written effectiveness review for at least 20 years; adjust the program according to the findings Eight states (California, Connecticut, Idaho, Iowa, Massachusetts, New Jersey, New York, and Vermont) filed lawsuits. To settle Lilly agreed to install automated checks in its software systems to prevent a recurrence and to annually report to the states the results of their security evaluations

220.7 Now Is the Time to be Prepared

The Ponemon Consumer Breach study highlights the importance of having an effective breach response plan in place to quickly notify customers. Companies that took longer to notify customers of a breach were four times as likely to lose customers than if the customers were notified quickly and consistently. A significant consideration determining customer retention was also the method of breach notification; the companies surveyed indicated they were three times more likely to lose customers if they notified them using a form letter or e-mail instead of calling them on the phone or sending them a personalized letter.

What steps should companies take to help stem the tide of PII breaches, and to be prepared in the event they still experience a breach? Even if organizations were not required by law to report breaches, it would still be wise for organizations to be prepared for how to handle PII breaches, not only to protect the individuals involved, but also to demonstrate due diligence, retain customers, and in turn help to reduce the negative financial impact that a breach could have upon the organization.

Preparing a privacy breach incident response plan as part of a solid information security management and privacy assurance program is, of course, no guarantee of avoiding bad publicity or having a negative impact to your business following a breach. However, performing the activities to prepare for a beach response will certainly help to mitigate and lessen the impact of a breach if and when one occurs, and it could very possibly help prevent the organization from going out of business. The more quickly, comprehensively, and efficiently an organization can respond to and resolve a breach incident, the less financial, brand, and likely legal impact and damage it will have on the organization. Remember, doing less following a breach will hurt an organization more in the long run.

220.8 Privacy Incident Response Plan Preparation

An information security and privacy program should include a privacy incident response plan that addresses privacy and security breaches and incidents including unauthorized access to or acquisition of PII. To ensure timely notice to affected individuals when appropriate, the following practices are among those that should be included in a privacy incident response plan:

1. *Define personally identifiable information*. Before you can determine if you have had a breach of PII, you need to specifically define what is considered as PII within your organization. Clearly define and document the information within your organization that is considered, or labeled, as PII.

Currently, there is no one existing list of what constitutes PII. Consider all applicable laws in all locations where you have consumers, employees, and business partners. Some countries include within their PII list information that is completely out of the consideration of most U.S. business leaders, such as IP addresses and serial numbers. You need to identify the privacy-related laws for the countries in which you do business and have offices, then compile a list of the items that are considered as PII within all of them.

Many organizations assume PII is just the types of information listed in HIPAA or California's SB 1386. Be very aware that numerous laws, not only U.S. federal and state level, but international, exist that define many other types of items as personal information. In 2004, I reviewed multiple data protection laws from around the world and identified at least 47 different items specifically named as being legally considered as personal information, and some laws consider certain items when combined with other information, such as racial or ethnic origin, political and religious affiliations, and sexual activity information as being personal or sensitive information that organizations must protect.

Items specifically stated within various data protection regulations as being personal information	
First Name or Initial	Last Name
Hospital dates of: birth, admission, discharge, death	Geographic subdivisions smaller than a state (street address)
Fax number	Telephone number
Social security number	E-mail address
Health plan beneficiary numbers	Medical records numbers
License and certificate numbers	Account numbers
Credit card numbers	Vehicle identifiers (e.g., license plate number)
California ID numbers	Debit card numbers
Internet URLs	Device identifiers (e.g., serial numbers)
Personnel files	Internet Protocol (IP) addresses
Unique identifiers that can be attributed to a specific individual	Full-face (and comparable) photographic images
Any identifier the FTC determines permits the contacting of a specific individual	Medical care information (e.g., organ donations, medications, disability info)
Biometric identifiers (such as DNA, finger, iris and voice prints)	Information concerning children
Employment history	Body identifiers (e.g., tattoos, scars)
Payment history	Income
Credit card purchases	Loan or deposit balances
Military history	Criminal charges, convictions and court records
Customer relationships	Credit reports and credit scores
Merchandise and product order history	Financial transaction information
Fraud alerts	Service subscription history
Video programming activity	"Black Box" data
Conversations (recorded or overheard)	Voting history
Education records	Descriptive consumer listings

Generally, some law or court may consider PII as being any information by which an individual may be identified.

When compiling your PII list, consider the information your organization handles and obtains from consumers, customers, employees, and business partners, as well as the information that may be purchased from data warehouses by some areas such as marketing, sales, or even government relations. Consider and include not only electronic information, but also information on paper, in voice mails, within faxes, and in other forms.

List all the items identified and convene a meeting with your business unit leaders and corporate area leaders, including information security, human relations, legal counsel, and physical security, and see if you have missed anything. If you already have an information security and/or privacy oversight board in place, this would be a great group to use. Discuss the information items, and come to consensus on the items your organization will consider and define as PII for the purposes necessary to meet legal and regulatory compliance, as well as compliance with your own posted privacy policy and your business partner contracts.

2. *Locate PII within the organization.* Create an inventory of all such PII items and where they are located, such as within specific systems, files, paper, CDs, backup tapes, and so on.

When considering where PII is located, consider where PII is colleted. In the course of a business day, organizations collect PII in a number of ways, such as when:

- Customers register their products
- Individuals respond to marketing campaigns or request product information
- Customers call for help or service for their products
- Individuals apply for and accept employment
- Employees enroll in benefits and other company-sponsored programs
- Entering into certain business agreements with third parties

This information resides within organizations in multiple forms, and widely spread locations. Much of this information is in the form of unstructured data, meaning it is basically under the complete control and whims of the end-user. Examples of unstructured data include e-mails, Word documents, spreadsheets, and so on.

Unstructured data, much of which likely includes PII in most organizations, multiplies at an amazing rate. According to a 2004 IDC study, unstructured data doubles every two months in large corporations. The ratio of unstructured data to structured is significant. A 2004 Goldman–Sachs study reported 90% of data within a corporation is unstructured data.

Locating and inventorying your PII will be no small task, but it is a critical task to accomplish to be able to identify when a breach occurs, not to mention knowing how to respond to customer questions and regulatory audits.

Be as comprehensive as possible identifying PII storage locations. Some of the most well-publicized and biggest-impact incidents have involved little-considered storage devices, such as handheld computer devices, backup media, and paper documents. Make sure you consider the following:

- File servers, application servers, mail servers
- Desktops, laptops, and notebooks
- PDAs, Blackberries, and other handheld computing devices
- Smart phones
- Voice mails
- Printed documents
- Fax machines and photocopiers
- Printers
- Backup tapes and media

And do not forget about those often-overlooked and even unsuspecting storage areas where massive amounts of PII could be hiding, such as:

- USB drives
- Scanners
- Telephones and camera phones
- Optical media
- CDs and diskettes
- Webservers
- DVDs
- iPods
- Employee-owned computers
- MP3 players
- Windows recycle bins

Once you have completed the important and necessary project to create your PII inventory, be diligent in keeping it up-to-date. This will not be nearly as hard as creating the initial inventory if you establish and implement procedures for reporting and cataloging all new PII and changes in existing PII. There are now many tools that make this job easier than it once was. Assign a role the responsibility for keeping the PII inventory up-to-date in a centralized location.

3. *Define a breach*. The term “breach,” sometimes with “security” as a qualifier and sometimes with “privacy,” has been published many times over the past few years. A significant vulnerability within many organizations is that they have not defined a breach as it applies to their organization. Some assume it is just a hacking event. Others consider a breach only as being inappropriate access to a person’s name and Social Security number. Organizations need to define what constitutes a breach within each of their own organizations based upon the industry, services, products, and geographic locations for not only where the offices are locates, but also where customers are located, in addition to the applicable laws and regulations.

When defining breach categories, consider this: generally, a privacy or security breach is defined as unauthorized access to information that compromises the security, confidentiality, or integrity of personal information collected or maintained by the organization. Good faith acquisition of personal information by an employee or agent of your company for business purposes is usually not considered a breach, provided that the personal information is not used or subject to further unauthorized disclosure.

Use the list of incidents at the beginning of this chapter as examples of types of breaches that you can use to establish your own set of organizational breach definitions. Define a breach, and the different levels of severity, as they apply to the organization.

In determining whether unencrypted PII has been acquired, or is reasonably believed to have been acquired, by an unauthorized person, consider the following factors, among others:

- Indications that the information is in the physical possession and control of an unauthorized person, such as a lost or stolen computer or other device containing unencrypted notice-triggering information.
- Indications that the information has been downloaded or copied.
- Indications that the information was used by an unauthorized person, such as fraudulent accounts opened or instances of identity theft reported.

4. *Create your breach identification and notification plan*. A 2005 Ponemon Institute survey of corporate privacy practices revealed only one-third of companies had a formal process in place to monitor and report security breaches. As more companies create breach monitoring and reporting procedures, and as companies improve upon them, there will be more incidents reported. Customer confidence will surely be impacted. Customer inquiries to companies demanding to know how their PII is protected will surely increase.

A June, 2005 Conference Board survey reported 41% of customers are making fewer online purchases than in 2004 because of fears their personal information will not be adequately secured. This does not just impact companies with substandard security programs; it impacts all companies that offer services and products to customers.

A privacy breach notification program and plan should include at a minimum the following components:

- Team member roles and clearly documented descriptions of the responsibilities for each; this is discussed in more detail in item 5.
- Definitions of breach categories; define when or if individual notifications must be made for each type of breach category.
- Documentation of the types of alerts that will be used for each of the breach categories.
- Forms and action checklists for each of the roles to use during the breach identification and response activities.
- A list of situations describing when individual notification is necessary.

- Procedures for making contacts with customers, credit card associations, business partners, legal staff, the board of directors, and other outside entities as applicable; this is discussed in more detail later.
- Directions for the information, actions and outcomes for each of the roles should clearly documented and logged.
- A report template for communicating to upper management a breach occurrence, how the breach was resolved, the impact to the business, subsequent changes made (or planned) to reduce the likelihood of a similar breach occurring again, and a breach follow-up time-table to identify any other unknown business impact that resulted three, six and twelve months following the breach resolution; a sample privacy breach incident report template is provided in Appendix B.

Use clearly documented procedures to contain, control and correct all privacy and security incidents involve PII.

Require data custodians and anyone else who detects an information privacy or security incident, including business partners to whom you have entrusted your PII, to immediately notify the person responsible for incident response coordination upon the detection of any incident that may involve unauthorized access to systems or any type of media containing PII.

5. *Notification planning*. An international privacy principle, and a requirement within many data protection laws, is informing individuals about incidents such as privacy or security breaches that have caused their PII to be acquired, or likely acquired, by unauthorized persons. Notifying individuals of such incidents enables them to take actions to protect themselves against, or mitigate the damage from identity theft or other possible harm, as well as complies with legal requirements.

To ensure you can notify individuals in a timely and efficient manner, consider the taking the following actions:

- Collect contact information, such as postal mailing address, telephone number and e-mail address, from individuals when you collect their PII.
- If one of the ways you plan to contact impacted individuals is by e-mail, be sure to get the individuals' prior consent to use e-mail for that purpose, as required by various laws in the U.S. and worldwide. Do not depend solely upon e-mail notification, though, because many people may think such messages are phishing messages.
- Formally document the procedures for notifying individuals whose PII has been, or is reasonably believed to have been, acquired or accessed in unauthorized ways. Too many organizations depend upon ad-hoc notification; but to demonstrate due diligence as well as to consistently and efficiently provide such notifications, the procedures must be formally documented.
- Before sending individual notices, make reasonable efforts to include only those individuals whose PII was acquired. Undue notifications can have negative impacts. If you cannot identify the specific individuals whose PII was acquired, though, notify all those in the groups likely to have been effected, such as all whose information is stored in the files or on the media involved.
- Avoid sending notifications inappropriately. This can happen when the required notice of a PII breach is sent using a blanket approach to individuals who should not receive it because their PII was not involved with the breach.
- Notify impacted individuals in situations involving unauthorized acquisition of PII in any format, including computer printouts, storage media, and other forms where PII is located, as indicated within your breach definitions.
- Consider providing notice for breaches involving PII, even when if it is not "notice-triggering" information under applicable laws, but if you believe harm can come to the individual as a result. Notifying individuals will allow them to take action to protect themselves from possible harm.
- Implement procedures for determining who should get breach notifications and who should not. Document your process for determining inclusion in the group to be notified. Check the mailing list before sending the notice to be sure it is not over-inclusive.
- Notify impacted individuals as quickly as is reasonably possible after the discovery of an incident involving unauthorized access to notice-triggering information, unless law enforcement authorities

indicate you cannot because it would impede their investigation. Law enforcement involvement is discussed at greater length in item 10.

- Follow a pre-planned documented procedure to contain and control the systems and files involved with the breach and have trained and qualified individuals conduct a preliminary internal assessment to determine the scope of the breach. Use computer forensic procedures to most effectively accomplish this.

6. *Define roles*. Effectively responding to a breach requires participation from and coordination between virtually all areas of your company. Your breach notification team will have primary members who are involved continuously in the breach response process, and secondary members who will participate as needed based upon the type of breach. Members of your breach identification and notification team should include representatives from:

- Information security
- Privacy
- Public relations
- Law
- Human resources
- Customer relations
- Information technology operations
- Network architecture
- Operating system architecture
- Business services and applications
- Sales and marketing
- Internal auditing

Effectively responding to a breach requires participation from and coordination throughout all areas of the organization. Make the responsibilities for each role very clear and make sure your team members know and understand these roles. Make the responsibilities for each role very clear and make sure your team members know and understand these roles. Designate one individual, an incident response coordinator, to be responsible 24/7 for responding to and coordinating the privacy breach response activities.

Many organizations fail in their response efforts because the people involved either assumed someone else was performing a critical response activity, or multiple people were trying to perform the same activity and ended up at the least being inefficient by duplicating efforts, or even making the situation much worse by giving conflicting direction to personnel, or by sinking into political in-fighting and power struggles.

Collect 24/7 contact information for incident response team members and provide to team members. Each role should have backup personnel identified.

7. *Provide training to the breach identification and notification team members*. Require the team members to participate in regular response drills, perhaps once or twice a year, to ensure they fully understand what they need to do when a breach occurs. Provide training to the team members, and provide ongoing awareness messages so they stay up-to-date with incident response issues and news of incidents that have occurred at other organizations. Provide training to the breach identification and notification team members.

8. *Communicate the plan*. After investing all this work in creating a PII inventory and a breach identification and response plan, do not drop the ball by not communicating the plan throughout the organization. It is likely most, if not all, personnel handle or access some type of PII during the course of fulfilling their job responsibilities. Regularly train all personnel, including all new, temporary, and contract employees, in their roles and responsibilities in the incident response plan. Define key terms and activities within the incident response plan and identify responsible individuals.

Make sure you communicate to all personnel:

- The descriptions of the breach categories you have defined
- The items your organization considers as being PII

- An overview of the breach notification plan
- The names and contact information of the persons filling the primary privacy breach response team roles
- The potential impact a breach could have upon your organization

Regularly communicate information related to breaches and PII through a variety of awareness methods. Cover not only incidents within your own organization, but perhaps just as important for raising awareness, let your personnel know what has been happening within other organizations. Include this information within your yearly personnel information security and privacy training courses.

9. *Require third-party service providers and business partners to adopt and follow the privacy and security incident notification procedures*. When incidents happen with your business partners to whom you have entrusted personal information, it impacts your organization you must quickly be notified. You must ensure business partners have sound privacy breach identification and response procedures in place that at least match or exceed your organization's breach notification practices. Monitor and contractually enforce third-party compliance with the incident response procedures. Train key business partner contacts for their responsibilities for privacy breach response activities.

10. *Identify appropriate law enforcement contacts to notify on privacy or security incidents that may involve illegal activities*. Appropriate law enforcement agencies include your state's regional high-tech crimes task forces, the Federal Bureau of Investigation, the U.S. Secret Service, the National Infrastructure Protection Center, the local police or sheriff's department, the privacy commissioners within the countries where you do business, and so on.

Prepare a directory of privacy incident law enforcement contact information. Consider including within your response plan law enforcement with expertise in investigating high-technology crimes.

Contact your organization's legal counsel (who should be part of your response team) immediately to determine when law enforcement should contacted, especially if you believe that the incident may involve illegal activities.

When notifying law enforcement, inform the law enforcement official in charge of the investigation that you intend to notify affected individuals within ten business days, or sooner if possible. If the law enforcement official in charge tells you that giving notice within that time period would impede the criminal investigation, ask the official to inform you as soon as you can notify the affected individuals without impeding the criminal investigation. Typically, it should not be necessary for a law enforcement agency to complete an investigation before notification can be given.

Collect the following information and have it ready to provide to law enforcement if necessary:

- Description of the incident
- Date and time the incident occurred
- Date and time the incident was discovered
- Approximate number of impacted individuals
- Locations of impacted individuals

11. *Review and update*. Review the incident response plan at least annually and whenever there is a material change in your business practices that may reasonably impact the security of personal information. Test the plan at least annually, and whenever major changes are made:

- In the types of PII your organization handles
- In the systems and devices that process and store the PII
- When establishing a new business partner who will handle your PII in some manner
- When going through an acquisition, merger, divestiture or downsize

Implement a process to review and update the breach identification and notification program and plan:

- At the conclusion of an incident according to lessons learned.
- To incorporate changes resulting from industry developments and new legal and regulatory requirements.

12. *Communicate incidents*. Regularly communicate with your business leaders, partners, and personnel information related to breaches and PII using a variety of awareness methods. Cover not only incidents within the organization, but perhaps just as important for raising awareness, let them know what has been happening within other organizations. Include this information within yearly personnel information security and privacy training courses, as well as your ongoing awareness messages.

220.9 Coordination with Credit Reporting Agencies

It is becoming standard practice for organizations to not only help the impacted individuals to get in touch with the consumer credit reporting agencies (Equifax, Experian, and TransUnion) following a breach, but also to pay for credit monitoring services for impacted individuals for anywhere from two to five years. Your can work with the consumer credit reporting agencies to help determine the best ways to tell impacted individuals how to contact the agencies.

If there are a large number of individuals involved, it could have a significant impact on the ability of the reporting agencies to respond efficiently if all the impacted individuals called them at once without prior notification. Contact the agencies before you send out notices, without causing the notices to be delayed, to more than 10,000 individuals.

Organizations can contact the consumer credit reporting agencies as follows:

- *Experian*: E-mail to BusinessRecordsVictimAssistance@experian.com.
- *Equifax*: Customer Services, Equifax Information Services, LLC, Customer Service: 1-800-685-5000; Cust.Serv@equifax.com.
- *TransUnion*: E-mail to fvad@transunion.com, with "Database Compromise" as subject.

220.10 Breach Notifications

Organizations need to plan ahead the types of notifications that will be sent if a privacy breach occurs. See Appendix A for sample notification letters the State of California has created for organizations to use as models.

220.10.1 Notification Content

The following information should be included within your breach notification communications to impacted individuals:

1. A general description of what happened.
2. A general description of the types of personal information involved. Note: do not include the actual Social Security number or other actual items of information within the communications.
3. Actions taken since the incident to protect the individual's PII from further unauthorized access.
4. Actions the organization will take to assist individuals, including providing an internal contact telephone number, preferably toll-free, individuals can call for more information and assistance, providing information on the organization's website regarding the incident and what impacted individuals can do check for improper use of their PII, and so on.
5. Information describing what individuals can do to protect themselves from identity theft and other fraud. Include contact information for the three credit reporting agencies. Include contact information for the privacy commissioners of the applicable states or countries where individuals are located and/or the Federal Trade Commission for additional information on protection against identity theft.

Make the communication easy to read and understand, using simple language and plenty of white space. Do not use condescending or flippant language. Do not use a standardized format, which could be result in the recipients thinking it is a form or marketing letter and throwing it away without reading. Do not combine the notification communication as part of another mailing.

220.10.2 Communicating the Notification

Here are some guidelines and considerations for sending the breach notifications:

1. Send individual notification communications to those impacted whenever possible.
2. Send the notifications by first class mail, not as bulk discount mailings.
3. Depending upon the nature and urgency of the breach, consider calling each impacted individual.
4. Use caution to send notifications by e-mail. Make sure you have received prior consent of the individuals for this type of notification. Consider if you normally communicate with the impacted individuals by e-mail; if you don't, the notifications will possibly be mistaken as being phishing messages.
5. California SB1386, and a few other state breach notification laws, indicate if more than 500,000 individuals are impacted, or if the cost of giving individual notice to impacted individuals is greater than $250,000, organizations can use all three of the following "substitute notice" procedures:
   - Send the notice by e-mail to all affected parties whose e-mail address you have; AND
   - Post the notice conspicuously on your web site; AND
   - Notify major statewide media (television, radio, print).

However, consider carefully whether it will be good for your organization to notify ONLY in these substitute ways; doing so could alienate customers and possibly even result in civil suits. Most customers want organizations to contact them directly when a breach occurs. Consider the substitute notices to be used in addition to the first class mail as opposed to instead of first class mail.

220.11 Additional Resources

Here are some additional good resources you can use to help plan your privacy breach incident response and notification activities:

- VISA paper, "What to Do if Compromised": http://usa.visa.com/download/business/accepting_visa/ops_risk_management/cisp_What_To_Do_If_Compromised.pdf?it=il, http://usa.visa.com/download/business/accepting_visa/ops_risk_management/cisp_tools_faq.html What%20To%20-Do%20If%20Compromised
- State of California recommended breach notification practices: http://www.privacy.ca.gov/recommendations/secbreach.pdf
- Federal Trade Commission privacy initiatives: http://www.ftc.gov/privacy/index.html.

Appendix A Sample Notice Letters

Sample Letter 1
Provided by the State of California Privacy Office
http://www.privacy.ca.gov
(Data Acquired: Credit card Number or Financial Account Number)

Dear:

I am writing to you because a recent incident may have exposed you to identity theft.

[*Describe what happened in general terms, what kind of personal information was involved, and what you are doing in response.*]

[*Name of your organization*] is writing to you so that you can take steps to protect yourself from the possibility of identity theft. We recommend that you immediately contact [*credit card or financial account issuer*] at [*phone number*] and close your account. Tell them that your account may have been compromised. If you want to open a new account, ask [*name of account issuer*] to give you a PIN or password. This will help control access to the account.

To further protect yourself, we recommend that you place a fraud alert on your credit file. A fraud alert lets creditors know to contact you before opening new accounts. Just call any one of the three credit reporting agencies at the number below. This will let you automatically place fraud alerts and order your credit report from all three.

- Equifax: 800-525-6285
- Experian: 888-397-3742
- Trans Union: 800-680-7289

When you receive your credit reports, look them over carefully. Look for accounts you did not open. Look for inquiries from creditors that you did not initiate. And look for personal information, such as home address and Social Security number that is not accurate. If you see anything you do not understand, call the credit agency at the telephone number on the report.

If you do find suspicious activity on your credit reports, call your local police or sheriff's office and file a report of identity theft. [*Or, if appropriate, give contact number for law enforcement agency investigating the incident for you.*] Get a copy of the police report. You may need to give copies to creditors to clear up your records.

Even if you do not find any signs of fraud on your reports, the California Office of Privacy Protection recommends that you check your credit reports every three months for the next year. Just call one of the numbers above to order your reports and keep the fraud alert in place. For more information on identity theft, we suggest that you contact the Office of Privacy Protection. The toll-free number is 866-785-9663. Or you can visit their web site at www.privacy.ca.gov. If there is anything [*name of your organization*] can do to assist you, please call [*phone number, toll-free if possible*].

[*Closing*]

Sample Letter 2
Provided by the State of California Privacy Office
http://www.privacy.ca.gov
(Data Acquired: Driver's License or California ID Card Number)

Dear:

I am writing to you because a recent incident may have exposed you to identity theft.

[*Describe what happened in general terms, what kind of personal information was involved, and what you are doing in response.*]

[*Name of your organization*] is writing to you so that you can take steps to protect yourself from the possibility of identity theft. Since your Driver's License [*or state Identification Card*] number was involved, we recommend that you immediately contact your local DMV office to report the theft. Ask them to put a fraud alert on your license. This will cut off government access to your license record. Then call the toll-free DMV Fraud Hotline at 866-658-5758 for additional information.

To further protect yourself, we recommend that you place a fraud alert on your credit file. A fraud alert lets creditors know to contact you before opening new accounts. Just call any one of the three credit reporting agencies at the number below. This will let you automatically place fraud alerts and order your credit report from all three.

- Equifax: 800-525-6285
- Experian: 888-397-3742
- Trans Union: 800-680-7289

When you receive your credit reports, look them over carefully. Look for accounts you did not open. Look for inquiries from creditors that you did not initiate. And look for personal information, such as home address and Social Security number, which is not accurate. If you see anything you do not understand, call the credit agency at the telephone number on the report. If you do find suspicious activity on your credit reports, call your local police or sheriff's office and file a report of identity theft. [*Or, if appropriate, give contact number for law enforcement agency investigating the incident for you.*] Get a copy of the police report. You may need to give copies to creditors to clear up your records.

Even if you do not find any signs of fraud on your reports, the California Office of Privacy Protection recommends that you check your credit reports every three months for the next year. Just call one of the numbers above to order your reports and keep the fraud alert in place. For more information on identity theft, we suggest that you contact the Office of Privacy Protection. The toll-free number is 866-785-9663. Or you can visit their web site at www.privacy.ca.gov. If there is anything [*name of your organization*] can do to assist you, please call [*phone number, toll-free if possible*].

[*Closing*]

Sample Letter 3
Provided by the State of California Privacy Office
http://www.privacy.ca.gov
(Data Acquired: Social Security Number)

Dear:

I am writing to you because a recent incident may have exposed you to identity theft.

[*Describe what happened in general terms, what kind of personal information was involved, and what you are doing in response.*]

[*Name of your organization*] is writing to you so that you can take steps to protect yourself from the possibility of identity theft. We recommend that you place a fraud alert on your credit file. A fraud alert lets creditors know to contact you before opening new accounts. Then call any one of the three credit reporting agencies at the number below. This will let you automatically place fraud alerts and order your credit report from all three.

- Equifax: 800-525-6285
- Experian: 888-397-3742
- Trans Union: 800-680-7289

When you receive your credit reports, look them over carefully. Look for accounts you did not open. Look for inquiries from creditors that you did not initiate. And look for personal information, such as home address and Social Security number, which is not accurate. If you see anything you do not understand, call the credit agency at the telephone number on the report.

If you do find suspicious activity on your credit reports, call your local police or sheriff's office and file a police report of identity theft. [*Or, if appropriate, give contact number for law enforcement agency investigating the incident for you.*] Get a copy of the police report. You may need to give copies of the police report to creditors to clear up your records.

Even if you do not find any signs of fraud on your reports, the California Office of Privacy Protection recommends that you check your credit report every three months for the next year. Just call one of the numbers above to order your reports and keep the fraud alert in place. For more information on identity theft we suggest that you contact the Office of Privacy Protection. The toll-free numbers is 866-785-9663. Or you can visit their web site at www.privacy.ca.gov. If there is anything [*name of your organization*] can do to assist you, please call [*phone number, toll-free if possible*].

[*Closing*]

Appendix B Sample Privacy Incident Breach Report Template for Communication to Organization Leaders

1. Executive Summary
   a. Date incident was discovered
   b. How the incident was discovered
   c. Date incident occurred
   d. Number of individuals involved
   e. Types of personal information involved
   f. Cost of the incident to the organization including:
      - Value of hardware and software lost
      - Notification costs (postage, calls, staff, website changes, etc.)
      - Lost customers
      - Legal costs
      - Public relations and advertising costs
      - Cost of additional staff to answer customer questions
      - Forensics costs
      - Fines and penalties
      - Cost to prevent the reoccurrence of a similar incident
      - Lost share value
      - Related ravel costs
      - Credit monitoring services for impacted individuals
      - Other related costs
   g. Cost to impacted individuals
      - Identified incidents of identity theft and fraud
      - Other
   h. If the incident within organization, or with a business partner
   i. Current status of incident resolution
   j. Changes made to prevent reoccurrence of the same type of incident
   k. Detail any public reports of the incident
2. Incident Details
   a. Who reported the incident or determined an incident had occurred?
   b. If someone outside the organization notified the company, what was that information told by the person within the company?
   c. Who was notified internally after the incident was discovered or reported?
   d. List the sequence events that happened from including:
      - Internal personnel involved and their assigned responsibilities
      - Time for each action
      - Meetings involved
      - Communications with news media
      - Outside persons or companies contacted to help
3. Incident Flow
   a. Diagram the movement and/or location of the impacted PII
   b. Include dates and times
4. Investigative Procedures
   a. Describe the forensic activities followed during the investigation
   b. List the forensic tools used during investigation

5. Findings
   a. Types of information compromised:
      - Name
      - Address
      - Birth date
      - Social Security number
      - Phone number
      - Medical information
      - Account number
      - Password
      - Credit card number
      - Other

   b. Number of accounts/individuals impacted
   c. Timeline of accounts/individuals at risk
   d. Timeline of compromise and source of compromise
   e. Data files compromised
   f. Were the PII data items encrypted?
   g. Were the PII data items taken on removable storage media? What kind? Has the media been recovered?
   h. Were PII data items accessed on computer systems through a network or remote access compromise? What kind of compromise?
   i. Provide details about the firewall, infrastructure, host, and personnel findings.
   j. Describe the hacking tools and utilities used.
   k. If no hacker utilities/tools were found, explain how the intrusion occurred, or could have occurred.
   l. Describe any third-party involvement with the incident, and the actions they have taken and plan to take.
6. Actions taken by compromised individuals
   a. Describe actions taken by notified individuals
   b. Include feedback from impacted individuals
7. Recommendations
   a. Procedural changes
   b. Contractual changes
   c. Technology changes
   d. Policy changes
   e. Business partner relationship changes
   f. Education activity changes
   g. Other
8. Contact information
   a. Contact information for persons participating in incident resolution
   b. Contact information or file locations for impacted individuals

221

Security Event Management

Glenn Cater

In addition to traditional security devices such as firewalls and intrusion detection systems, most systems on a typical network are capable of generating security events. Examples of security events include authentication events, audit events, intrusion events, and anti-virus events, and these events are usually stored in operating system logs, security logs or database tables.

In many organizations, security policies or business regulations require that security events are monitored and that security logs are reviewed to identify security issues. Information captured in security logs is often critical for reconstructing the sequence of events during investigation of a security incident, and monitoring security logs may identify issues that would be missed otherwise. The problem is that the amount of information generated by security devices and systems can be vast and manual review is typically not practical. Security event management (SEM, or SIM—security information management) aims to solve this problem by automatically analyzing all that information to provide actionable alerts. In a nutshell, security event management deals with the collection, transmission, storage, monitoring and analysis of security events.

221.1 Introduction

When implemented correctly, a security event management solution can benefit a security operations team responsible for monitoring infrastructure security. Implementing SEM can relieve much of the need for hands-on monitoring of security systems such as intrusion detection systems, which typically entails staring at a consoles or logs for lengthy periods. This allows the security monitoring team to spend less time monitoring consoles, and more time on other tasks, such as improving incident response capabilities.

This improvement is achieved by implementing rules in the SEM system that mimic the know-how or methods used by the security practitioner when reviewing security events on a console or in a log. The SEM system can even go beyond this and look for patterns in the data that would not be detected by human analysis, such as "low and slow" (deliberately stealthy) attacks. Building this intelligence into the system is not a trivial task however and it can take many months to start realizing the benefits from implementing a SEM system.

When planning a security event management solution, the following issues should be considered:

- Which systems should be monitored for security events?
- Which events are important and what information should be collected from logs?
- Time synchronization, time zone offsets, and daylight savings
- Where, how, and for how long should the logs be stored?
- Security and integrity of the logs during collection and transmission
- Using the SEM system as a system of record
- How to process security events to generate meaningful alerts or metrics?
- Tuning the system to improve effectiveness and reduce false positives
- Monitoring procedures
- Requirements for choosing a commercial security event management solution

The remainder of this chapter discusses the factors associated with planning and implementing a security event management (SEM) system, and factors to consider when purchasing a commercial SEM solution.

221.2 Selecting Systems and Devices for Monitoring

Systems or devices to be monitored will typically fall into one of three categories:

- Security systems: includes systems and devices that perform some security function on your network. For example, authentication systems, firewalls, network intrusion detection and prevention systems (IDS/IPS), virtual private network devices (VPNs), host-based intrusion detection systems (HIDS), wireless security devices, and anti-malware systems
- Business critical systems: includes those systems that are important for running the network. For example, mail servers, DNS servers, web servers, authentication servers. When establishing which infrastructure systems are most critical, try to determine what the business impact would be if the system was unavailable. This category of system also includes more traditional network devices such as routers, switches and wireless network devices.
- Critical infrastructure systems: includes those systems that are important for running the network. For example, mail servers, DNS servers, Web servers, authentication servers. When establishing which infrastructure systems are most critical, try to determine what the business impact would be if the system was unavailable. This category of system also includes more traditional network devices such as routers, switches, and wireless network devices.

Because budgets, time, and resources are not unlimited, you will have to do some up-front work to define the set of systems that should be monitored by the SEM system. It is a good idea to start with a risk assessment to determine which systems are most important to your business. Each of the categories (security, business and infrastructure) above should be taken into account during the assessment. If regulatory requirements are a driving factor, then those requirements will help to define which systems should be monitored.

When prioritizing the order in which monitoring should be implemented, take into account the following:

- The criticality of the system to the business. Critical systems that process high value data will have a higher priority.
- Risk of inappropriate access. Internet facing systems or systems that process information from untrusted networks should have a higher priority.
- The "security value" of the available events. If a security system generates events that provide more value than another system, it makes sense to prioritize those first. For example, an IDS system typically generates more valuable information than a firewall.

221.3 Determining which Security Events are Important

Security logs allow administrators or security personnel to proactively identify security issues or to backtrack through the timeline of events to investigate a security incident after it has occurred. Normally, a company's security policy will outline which security events need to be logged and what the requirements are for storage and review of those events, so it is likely that some or all systems are already configured to log security events.

It is important to perform a review for each type of device that will feed into the SEM system to identify which security events are important. Administrator's manuals should provide details on the logging capabilities of a device, although manual review of log samples is recommended to determine which events should be logged.

During this review you will probably find that many of the events being logged do not provide that much value. For example, perimeter firewalls are always dropping packets on their external interfaces due to Internet "noise." Although this information might be useful in rare cases, it is much more useful to know which connections made it through your firewall, or if a connection was allowed somewhere it was not supposed to be allowed. When planning an SEM system, unimportant events like these can be filtered or suppressed so that only more important events are collected and analyzed. This has the advantage of reducing the processing and storage needs of the SEM system.

Use the following checklist when reviewing the logging capabilities for each type of device:

- Review the manual that describes the logging capabilities.
- Obtain samples of logs from the device.
- Ensure that events which must be logged because of security, regulatory or business requirements are included in the log configuration.
- For other types of events, assess the value of including that type of event in the log configuration. Some events do not provide much value and can probably be ignored.

The overall value of the SEM system is affected by the value of the data it processes and stores, so ensure that valuable data is not missed because of an incorrect logging configuration.

After the review is completed, standard logging configurations can be created for each type of device. Standardization is important to ensure that devices are logging common information. The standard logging configurations can be included with the organization's security requirements, and can be rolled out across all devices during implementation of the SEM system.

221.4 Time Synchronization, Time Zones, and Daylight Savings

In addition to a defining a standard logging configuration, it is also important to ensure that all monitored devices and systems, and especially the SEM servers, are synchronized with a reliable and accurate time source. For smaller organizations, public Network Time Protocol (NTP) servers could be used for this purpose. There are lists of public NTP servers available on the Internet which can be used for time synchronization. It is good etiquette to limit usage of public servers and to notify the hosting organization before using their time servers. Larger organizations can set up local NTP servers that are synchronized with public NTP servers. To avoid having to change server names across many devices if authoritative NTP servers change, standard DNS aliases (such as time1.organization.com and time2.organization.com) should be created for the time servers to be used in lieu of the real server names.

For systems that are geographically dispersed across time zones, time zone offsets become an issue. Even if the systems are all located in the same time zone, it is important to be aware of the time zone so that there is no confusion when presenting logs to third parties such as law enforcement. Ideally, timestamps on all logs should be converted to Universal Time (UTC), as this eliminates the possibility of confusion. Alternatively, the time zone offset can be stored with the logs; for example, −0500 for Eastern Standard Time (meaning 5 h behind UTC). Time offset changes due to daylight savings time is something to be aware of as well and there are a couple of ways to deal with this issue. For monitored systems where having local time is important, the time zone and time zone offset can be set as normal on the system; then when logs are collected, the collection agent can note the time zone and include it with the logs. Another way to deal with this situation is to create a database on the logging servers that contains the time zone information for each system. The time zone information can then be used during conversions or preprocessing of the data.

Possibly the easiest way to deal with the time zone problem is to set the time zone on monitored systems to Universal Time (UTC), then as long as administrators know that the time zone is UTC it becomes a nonissue. This might not be feasible for all systems, but it might work for certain devices, such as routers or intrusion detection systems, that are managed by network operations or security operations teams. Something to note is that although the data is stored with UTC timestamps, it can be shown in reports or on screen as local time with a simple conversion. This is beneficial if personnel are also spread out geographically because timestamps are shown to them in their local time.

221.5 Centralized Logging Architecture

Commercial SEM systems all have their own solutions for collection, processing and storage of security events. However, generally the approach is to centralize these functions so that security events are forwarded to centrally managed, dedicated SEM servers. There are many advantages to this approach such as centralized backups, searching, and analysis capabilities. For scalability, the SEM servers can be organized in a hierarchical manner, with local SEM servers situated near to the monitored systems. The function of local SEM servers is to collect, process, and queue events for transmission to the next tier. Exhibit 221.1 depicts a hierarchical system with local SEM servers and a master SEM server.

The primary requirement of the master SEM server is plenty of local storage (hard disk, optical disk, tape). If searches, analysis, or other processing is performed on this server, it also needs fast CPUs, RAM, and disk. Local SEM servers will have leaner specifications because they do not need to store or process as much information. In more complex environments, a relational database (RDBMS) is typically used to store security events. Relational databases organize and index security logs, alerts, and other information for rapid searches and report generation. Commercial SEM systems use databases to organize and store security events for analysis, reporting, and display.

EXHIBIT 221.1 Centralized logging architecture.

After security events reach the central SEM server, they will be stored on disk for some period of time. How long the logs are on disk depends on the size of the logs, budget, security requirements, and business requirements. Typically, logs will be stored on disk ("online") for a few weeks or months, and this is mostly dependent on how much disk space is available. It is advantageous to keep logs on disk because this allows for convenient access to the data, and all operations such as searching will be quicker. There might be a security requirement to store logs in a read-only form in which case a write-once, read-many (WORM) form of media such as optical disk will be necessary. Encryption may also be a requirement, in which case encryption software or a hardware encryption solution will also be necessary. Online storage is usually at a premium, so periodically the logs will need to be archived to cheaper offline storage such as tape and removed from disk to make space for newer logs.

To save disk or tape space in long term storage, compression techniques such as GZip or Zip will maximize the amount of data that can be stored. Short term "online" storage should remain uncompressed to improve searching or processing of the data. For example, there may one month of "online" uncompressed data on disk, another five months of compressed data on disk for quick access, then up to seven years of compressed data archived onto tape. These periods are only an example, and should be dependent upon business and security policies, and the amount of available disk space. Batch jobs can be set up to periodically compress, archive and remove old data from storage.

An organization's data retention policies should dictate how long information such as logs must be stored, and what requirements there are for storage and disposal of the information. If there is no data retention policy, then this needs to be defined so that information is kept for as long as it is needed, but for no longer than is necessary. There may be local legal or regulatory requirements which dictate a minimum term for which information needs to be stored (usually a maximum of seven years, depending on the type of information).

The security of the SEM servers is very important. These servers need to be hardened and locked down to expose only the minimum services to the outside. It is a good idea to firewall these servers from the rest of the network, or to utilize the built-in firewall capability of the operating system to limit access to the servers. When building an SEM server, the following steps should be performed:

- Implement standard operating system security hardening techniques.
- Limit services exposed and listening on the network.
- Limit access to the server only to the administrators or security personnel that require access.
- Perform periodic network and host-based vulnerability scans on the SEM servers.
- Use external or built-in firewalls to limit connectivity to and from known hosts only.
- Ensure that the server is synchronized to a reliable and accurate time source (such as a public NTP server).

To avoid having to change server names across many devices if logging servers change, standard DNS aliases (such as log1.organization.com and log2.organization.com) should be created for the SEM servers to be used in lieu of the real server names.

221.6 Integrating Systems and Collecting Security Events

Commercial SEM systems typically provide "agents" or other mechanisms to securely gather security events or logs from systems, but it is possible that the SEM system does not have an agent or mechanism for every type of system in a network. It is also possible to entirely roll your own SEM system, so some techniques are presented here for gathering and transmitting security logs in a secure manner. Because it is important to maintain the integrity of the security logs, care must be taken in choosing methods for collection and transmission, and methods used must meet the organization's security requirements.

There are three general methods for collection of logs or events. Commercial SEM systems typically use all three approaches, depending on the type of system or device that is being monitored:

- Direct transmission of events to the SEM servers, for example via RADIUS accounting or SNMPv3 traps. Direct transmission is a good method if the device supports it and the mechanism is appropriately secure.
- Agent-based collection and transmission of logs or events. A software agent runs continuously or periodically on the monitored system and sends new security events over to the SEM servers.
- Server-based collection of logs from monitored systems. A SEM server will periodically poll the monitored systems for new security events. This requires that the SEM system has an appropriate level of permission on the target system.

The method chosen will depend on the capability of the target system and security requirements. For example, hosts located within a DMZ (de-militarized zone), usually have strict security policies applied to them and outbound data connections to the internal network might not be allowed. In this situation, a server-based polling mechanism is probably the best approach if the SEM server is not located within the DMZ.

Generally, encrypted and/or authenticated connections should be used to transmit events between devices and the SEM servers to maintain integrity of the logs; however, this is not always possible. Following are various options for gathering events (see Exhibit 221.2).

- SSL (Secure Sockets Layer) or TLS (Transport Layer Security). For example, Web servers can be used to “serve” logs to trusted hosts via an SSL connection.
- SCP (Secure Copy) or SFTP (Security File Transfer Protocol). SCP or SFTP are simple protocols that can be scripted into batch jobs.
- IPSec connections or tunnels between systems. IPSec can be used to secure specific connections or all traffic for a host.
- VPN tunnels. VPN tunnels can be used if the target system and SEM server are far apart, or if the target system does not support any other method of transmission.
- RADIUS accounting. RADIUS accounting is a good option that is supported by many network devices.
- SNMPv3 traps, which are common with network devices. SNMPv1 is not encrypted so its use is not recommended.
- Encrypted file transfer over FTP (using PGP or another file encryption tool). This is another option that can be scripted for use in batch jobs.
- Secured database connections can be used to read events directly from logs stored in databases.
- Syslog-ng combined with s-tunnel. Standard syslog uses cleartext UDP packets so security and integrity is difficult to maintain. Syslog-ng can use TCP and can be combined with s-tunnel to transmit logs securely.
- Native authenticated file sharing mechanisms, such as CIFS (Windows) with appropriate security applied. NFS could be used if secured appropriately. This can be a simple solution if the target system supports it.
- E-mail alerts sent directly to the SEM server. Often anti-virus, IDS or other systems have the ability to send alerts via e-mail. The SEM server can be configured to receive and process e-mail alerts via SMTP. Although not the most secure method it can be convenient.
- Third-party monitoring solutions, typically used to monitor and manage the network, have the ability to gather logs from systems. These systems can be configured to send logs to a SEM system for analysis.

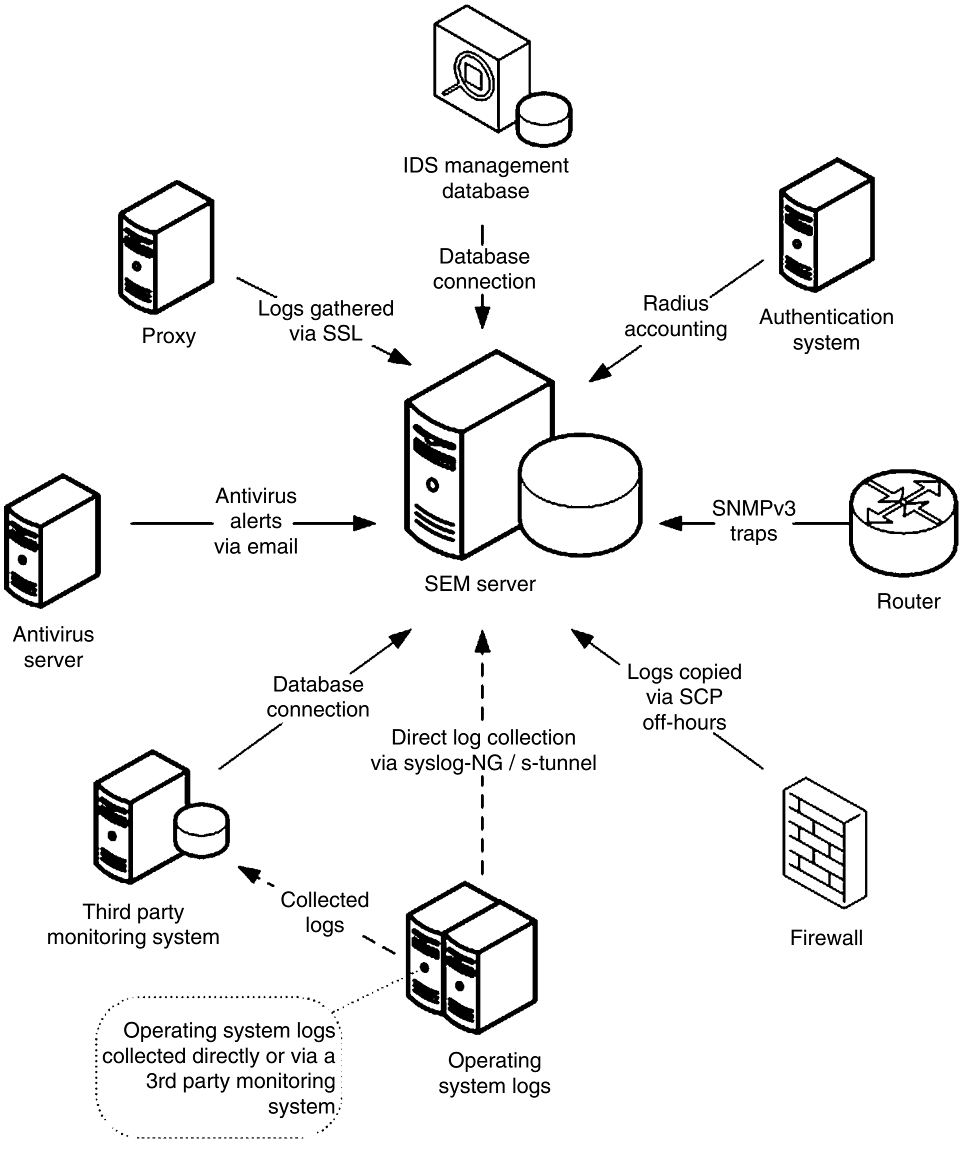

EXHIBIT 221.2 Secure transmission of data.

Encryption keys used with SSL, SCP, or other connections should be stored securely and in accordance with security policies. Because security log collection is almost always automated, the agents or batch jobs that perform collection and transmission need to have access to the encryption keys. Possibly the cleanest way to do this is to run the agents with a nonprivileged account with just enough permission to read the logs and to access the encryption keys. If security requirements do not prohibit it, the encryption keys can be stored without passwords but with file-level security so that only the agent is allowed to access them. Each system (including the SEM servers) should have a unique key pair so that compromise of one system does not compromise the whole SEM infrastructure. There are other ways to provide automated access to encryption keys that may be more secure but will also be more difficult to automate and maintain.

Because log files tend to be large, it is beneficial to use compression techniques such as GZip or Zip before encryption or transmission. Text files will usually compress to a fraction of their original size, which saves disk space and network bandwidth. Processes can compress data before encryption and transmission, and uncompress data on the other side after it has been received and decrypted. Compression should always be done before encryption because the random nature of encrypted data makes compression ineffective.

Whatever collection and transmission mechanisms are used, they should have fault tolerance built in to detect and recover from failures such as system outages, network outages, or insufficient disk space. This is important to ensure integrity and completeness of the collected events.

221.7 Using the SEM System as a System of Record

Because a SEM system collects and stores security logs from many devices across the network, it can be implemented as the "system of record" for security logs. This means the SEM system will be considered the definitive and authoritative source for security logs for the organization. This distinction places additional requirements on the system because it becomes important to ensure the integrity and timeliness of data feeds, so that the SEM system has complete, accurate, and up-to-date logs. Access to the information should be strictly controlled via approved mechanisms, and updates to the information should be logged so that the integrity of the data can be audited. Cryptographic checks such as hashes or digital signatures can help to ensure the integrity of the data from collection through to storage.

221.8 Events, Alerts, and the Rule System

As discussed, "events" are the individual log messages gathered from systems and devices, such as firewalls, intrusion detection systems, hosts, routers, etc. For example, a single "login" event will contain a hostname, a username, and a timestamp. After events are gathered by the SEM system, they pass through a series of "rules" for processing events called the "rule system." The rule system will generate "alerts" based on characteristics of events being processed. Alerts indicate that a significant event or series of events has happened that needs attention. Alerts are typically intended for review by a security analyst, and will normally be displayed on the SEM console and stored in the database for tracking and reporting purposes.

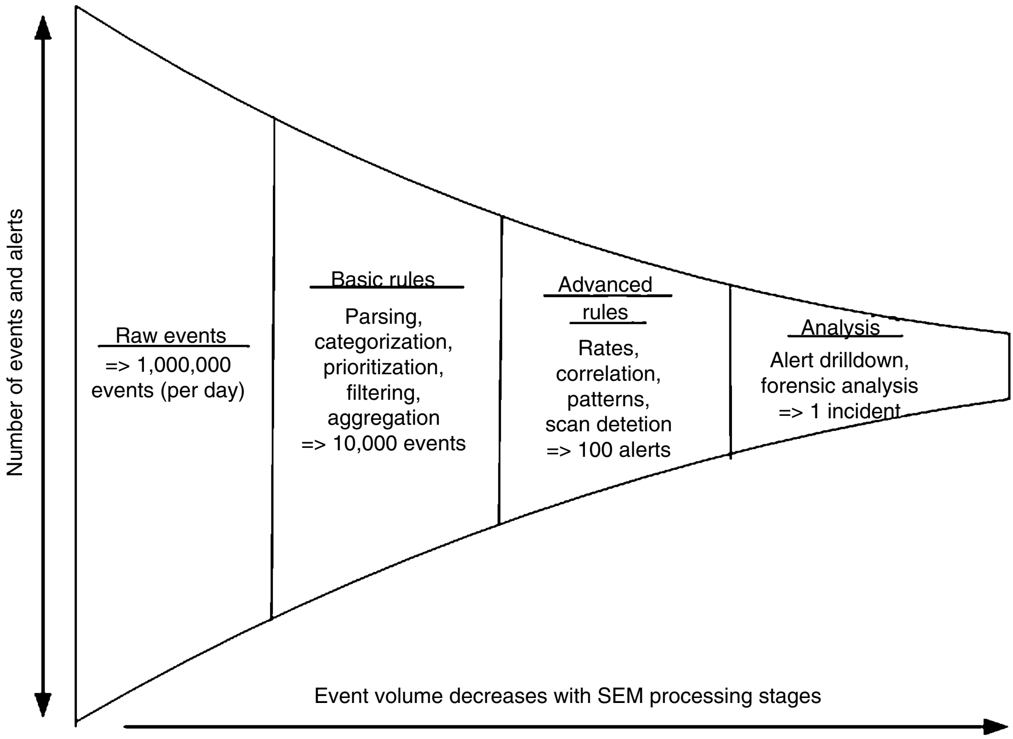
221.9 Techniques for Processing Security Events

The goal of the SEM rule system is to reduce the data volume from an unmanageable number of events down to a small number of actionable alerts that can be reviewed by security analysts. Security events are collected by the system, and pass through categorization, prioritization, filtering, and other stages in which alerts are generated. The end result is that a smaller number of actionable alerts are generated for security analysts to review. Commercial systems generally operate in a similar way with several processing stages. Exhibit 221.3 depicts how processing stages affect event volume.

Following is a discussion of some techniques used to process security events in the SEM rule system. Commercial SEM systems provide pre-built rules to perform many functions and normally allow customized rules to be created to meet customer needs. For this reason, SEM systems need to be very flexible and are usually scriptable or programmable to allow advanced customization. Flexibility and programmability are key features of any SEM system.

221.9.1 Event Parsing

Event parsing is usually the first stage in a SEM system. The goal of this stage is to extract useful information from the security events so that they can be further processed by later stages. Security events are extracted into "fields" of information such as timestamp, event source, event type, username, hostname, source IP address, target IP address, source port, target port, message, etc. Because each device



Number of events and alerts
Raw events
=> 1,000,000 events (per day)
Basic rules
Parsing, categorization, prioritization, filtering, aggregation
=> 10,000 events
Advanced rules
Rates, correlation, patterns, scan detetion
=> 100 alerts
Analysis
Alert drilldown, forensic analysis
=> 1 incident
Event volume decreases with SEM processing stages

EXHIBIT 221.3 Effect of processing on event volume.

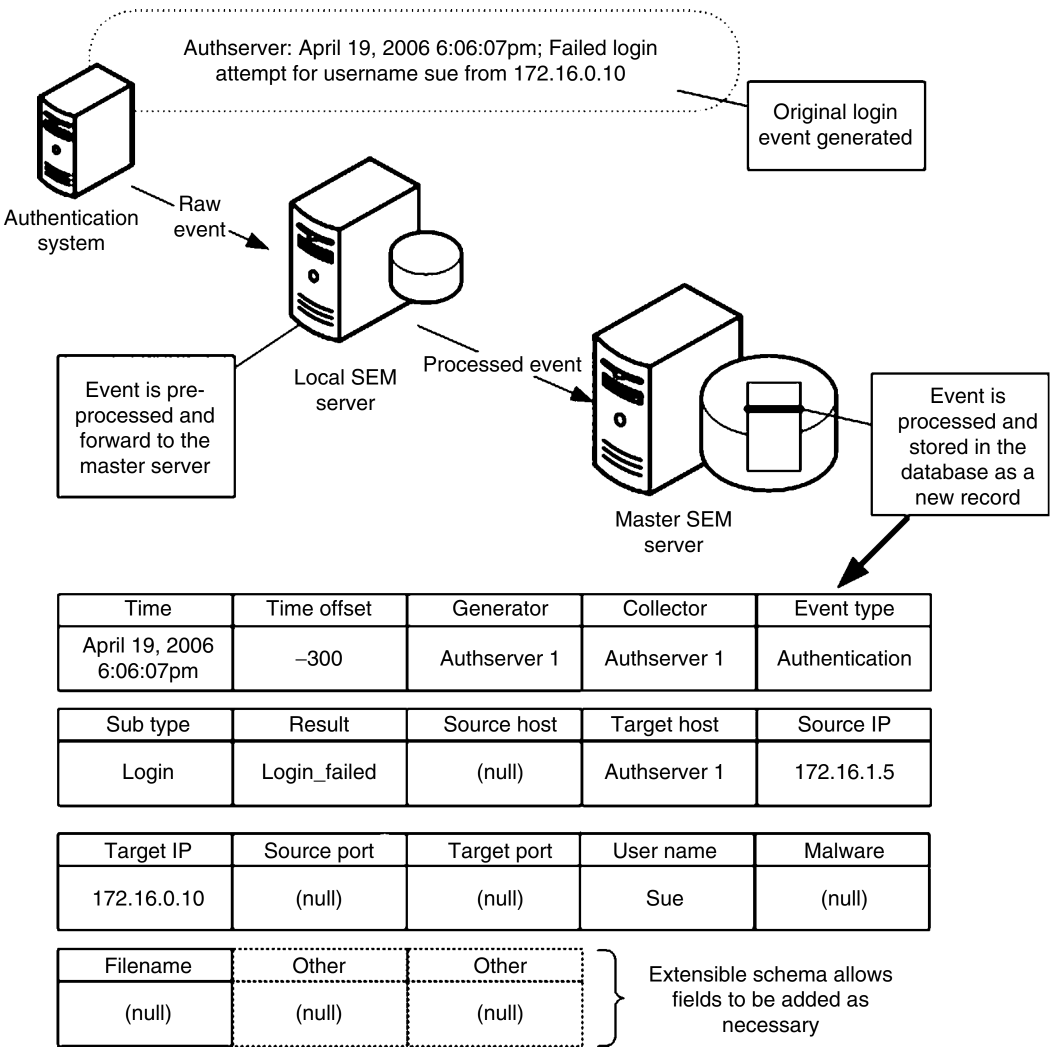
generates events in a different format, specific parsers need to be created for each type of device. The parsing stage needs to be very flexible to handle many event formats. Vendors of commercial SEM systems usually provide a list of devices that they directly support, but the SEM system is usually flexible enough to allow customized parsing rules to be built for unsupported devices. The output from this stage is a parsed event, with fields separated out so that they are available to the rest of the rule system. Parsed security events may be stored as rows in a database table with fields populated with information from the event. The overall value of the SEM system is affected by the value of the data it processes and stores, so ensure that all valuable fields are parsed and stored properly. Exhibit 221.4 depicts a sample "failed authentication" event, and shows how it is parsed into fields for storage in the SEM database. This example also shows why an extensible database schema is useful for capturing important fields from differing message formats.

221.9.2 Event Categorization

After events are parsed usually the next step is to assign categories, and subcategories, to the events. For example, an event category of "virus" and a sub category of "quarantined," meaning that the event was caused by a virus that was detected and quarantined. Categorization aids in display and analysis, reporting, and further processing of events.

221.9.3 Event Prioritization

After events are categorized, the next step is to assign a priority to the event. Priorities could be on a numeric scale, for example 0–100, with "0" meaning that the event has no relevance and "100" meaning that the event is a critical issue that needs to be investigated. The priority can be used to filter events of little significance to reduce the volume for later processing stages.



Authserver: April 19, 2006 6:06:07pm; Failed login attempt for username sue from 172.16.0.10

Filename	Other	Other
(null)	(null)	(null)

EXHIBIT 221.4 Example of message parsing.

221.9.4 Event Aggregation or Summarization

Event aggregation or summarization functions look for many events that are similar. The events do not necessarily need to arrive at the same time, so the function will store state. Events are summarized into one “aggregated” event that is passed to the next stage with an aggregate count that indicates how many events comprise the aggregated event. For certain types of devices, such as firewalls, this can significantly reduce the volume of data. For example, if a firewall logs 50 connection (SYN) attempts to a particular port, it could be summarized to one event with a count of 50. The aggregated count may then cause another rule to fire because of a high volume of SYN packets, for example. The problem with summarization is that information is lost as part of the summarization operation, so only fields that are included in the summarization operation will be available to the next stage. The more fields that are included, the less effective the summarization becomes. Therefore, with the firewall event example, it is possible that the only fields included in the summarization operations are the event type (SYN) and the port number; all other fields would be discarded.

221.9.5 Pattern Matching

Pattern matching is a simple technique that looks for patterns in the event fields. Exact matches, substring matches, or regular expressions are used to extract important events from the stream. Typically, the pattern-matched events will then become alerts for display and review. For example, a pattern matching rule could look for the words "buffer overflow" in an IDS event, which could result in that event being promoted to an alert for display.

221.9.6 Scan Detection

Scan detection refers to port scans, vulnerability scans, ping sweeps, and other scanning activities and works best with firewall or IDS events. Scanning is usually a prelude to an attack of some sort, so it is a useful rule. Network worms use this technique to locate systems to infect, so this rule can be useful to identify infected hosts on a network. The scan detection rule looks for a large number of events from a source host with many target hosts, ports, or event types. The scan detection rule may also look for a large number of different types of events against a host, which can indicate a vulnerability scan. Because state can be kept for a long time, scan detection rules can also be tuned to look for "low and slow" or stealthy scanning techniques that would not normally be discovered by human review.

221.9.7 Event Counts and Rate Thresholds

Event counts are simply counts of a certain type of event, such as virus detections. After this count reaches a pre-defined threshold, the rule will fire and generate an alert for display. Rate thresholds work by calculating the rate of a certain type of event; for example, 20 failed login messages within a minute is indicative of a password-guessing attack.

221.9.8 Event Correlation

Correlation refers to the ability of a SEM system to take multiple events or pieces of information from various sources and to infer that some activity is happening. For example, if vulnerability scan data is available to a SEM system, it can determine whether an attempted attack on a system is likely to succeed because it can correlate IDS "attack" events with known system vulnerabilities. The priority can then be raised to indicate a successful attack. In another example, host information has been loaded into the SEM system, and a UNIX-specific attack is detected against a Windows host. Because this attack could not succeed, the SEM system can lower the priority and discard the event. Other possibilities exist when correlating events across sources because patterns indicative of malicious behavior can be detected and alerted upon.

221.10 Tuning and Customizing the Rule System

After event sources have been integrated into the security event management system and events start to flow, the system will initially generate too many alerts, or a lot of false positive (erroneous) alerts. Like intrusion detection systems, security event management systems need to be tuned to be effective because the default rules are built in a generic way and need to be customized for local conditions. To get the best results, tuning requires expert knowledge of the SEM system, the network, and many of the devices being monitored. Depending on the size of the network, this may require input from many people.

If too many false positives or insignificant alerts are being generated, begin at the event sources generating those alerts (systems or devices) and determine methods to limit the events being collected so that only the more significant events are allowed through. Often the monitored system can be configured to filter out insignificant events. For example, IDS systems can be tuned to filter out low priority "informational" events. Be careful not to tune out events that could adversely affect the value of the SEM system.

Another way to reduce the volume of alerts is to filter out lower priority events after the event prioritization step (see the section on event prioritization above). Care should be taken with this type of "blanket" approach so that significant alerts triggered by low priority events are not affected.

To continue tuning, follow the event flow through the rule system to locate points where alerts are generated and determine if the alerting criteria, such as a thresholds or counts, are valid. Because alerts are getting through that are not significant, there should be ways to reduce or eliminate them entirely without affecting legitimate alerts. If not, then a compromise will be necessary to reduce false positives or insignificant alerts in favor of important alerts.

221.11 Monitoring the SEM System

Alerts generated by the rule system are usually stored in a relational database (RDBMS) along with the original security events for fast querying capability. Alerts are also normally presented on a console for review by an analyst. Documented procedures should be developed for analysts describing how to monitor the system and respond to alerts. During audits, auditors will look for evidence that these procedures are being followed. SEM systems may provide workflow type features or integrate with ticketing systems to track incidents and document actions taken by analysts and incident managers. This documentation will provide evidence that procedures are being followed.

SEM systems normally offer the ability to "drill down" into alerts to perform "forensic analysis." Typically, the analyst will be able to select the alert and perform various queries to determine what caused the alert to fire. For example, if "vulnerability scan" alert was detected against a system, the console should allow the operator to query the event store to pull up more details about which events comprised the alert. The analyst can then make an informed decision about the criticality of the alert, and whether to escalate it into an incident. Analysts typically need strong technical and analytical skills to perform this function.

A lot of data is collected by a security event management systems and this data can contain valuable nuggets of information. Data mining tools exist to perform deep analysis of the data to extract information that is not immediately apparent. These tools tend to be CPU and resource intensive, so they need to be used carefully. For larger organizations with numerous security events, it might make sense to take periodic samples of data for analysis, or run analysis in a batch mode at off-peak times. Security event management systems also include the ability to generate pre-canned and custom reports. Reports can be useful to provide metrics to upper management showing trends and graphs of activity over time.

221.12 Criteria for Choosing a Commercial Security Event Management System

It is important to evaluate and compare different solutions when choosing a commercial security event management system. Following are some of the more important factors, other than cost, to take into account during the evaluation:

- Types of devices supported: Ensure that all devices, software, and operating systems that need to be monitored are supported by the SEM system.
- Event collection mechanisms: Ensure that methods used to collect events (such as agent based collection) will work within the environment and meet security or architectural requirements.

- Usability of rule system: Review the rule system to ensure that it is understandable and that alerting criteria are clear. Also review how locally customized rules can be distinguished from built-in system rules.
- Storage flexibility and completeness: Ensure that the SEM database (or store) is flexible enough to store all information fields valuable to your organization. This is an important factor because if data is not stored in the database it won't be available to the SEM system for reporting, analysis or display which reduces the value of the whole system.
- Upgrade path: Review the upgrade policy and the process of applying upgrades to the SEM system to ensure that upgrades do not interfere with local customizations.
- Handling of time zones and daylight savings time: If the monitored systems are spread over multiple time zones, ensure that the SEM system can readily handle time zone offsets and daylight savings time.
- Scalability and performance: Ensure that the SEM system is capable of processing the maximum expected rate of security events generated from all devices. Also ensure that there is enough capacity to meet future needs.
- Security: Ensure that the SEM system meets the organization's security requirements. This includes the security of the whole event collection mechanism, SEM servers and applications, databases, and user interfaces. Also ensure that the system keeps adequate audit logs. Review the requirement to separate functions by role such as system administrator, security analyst, and incident manager, and ensure that the SEM system can accommodate role separation.
- Usability and functionality of the user interfaces: Probably the most important function is the act of monitoring the SEM system. The analyst's console needs to present all information in an understandable and intuitive way. Review the ability to perform analyst functions such as alert inspection, drill down, canned and custom queries, work flow, and escalation features. Also review the reporting system to ensure that canned reports are usable and meet requirements and that custom reports can be created in cases where canned reports are not adequate.
- Ability to integrate with external databases: If there is a need to integrate with other databases such as Configuration Management Databases (CMDB), ticketing systems, or company directories, then this capability should be reviewed.
- Programming interface: To allow advanced customizations, programmability is a key feature of a SEM system. The usability and flexibility of the programming interface should be reviewed.

221.13 Conclusion

A correctly implemented security event management solution will improve the effectiveness of security monitoring and incident response functions. Analysts will spend less time monitoring consoles and reviewing security logs because this function is automated by the SEM system. Senior analysts can build expert know-how into the rule system to improve the quality of alerts for all analysts, and reduce cases of false positives.

Having all security events collected into one central database is a key benefit of a SEM system. This information is very valuable for security analysts, incident response teams, and other IT teams. Reports and security metrics can be generated for managers and data mining tools can uncover interesting information from the data.

The benefits do come at a cost, however, and it will take several months to start realizing the benefit of implementing an SEM system. In addition to the cost of purchasing a commercial solution, perhaps two of the most resource intensive efforts are integrating security event sources into the system and performing tuning of the rule system. Vendors offer professional assistance, but it is beneficial for analysts to be involved in the implementation process to understand the workings of the whole system. Analysts will also need training in the use and administrator of the system.

Perhaps one of the most important factors when implementing a SEM system is to ensure that all data of importance is collected and available within the database. If the data is not available, then it cannot be queried or displayed and it is frustrating to run a query or report only to find that a needed field is not available because it has not been collected. The value of the SEM system then is only as good as the information it contains.

DCSA: A Practical Approach to Digital Crime Scene Analysis

Marcus K. Rogers

> One should always look for a possible alternative and provide against it. It is the first rule of criminal investigation. —Sherlock Holmes (*The Adventure of Black Peter*, by Sir Arthur Conan Doyle)

The world of criminalistics has changed in the last few years. Not only has there been a shift in how the popular media portray crime scene investigations (e.g., television shows such as *CSI*, *CSI Miami, NCIS*), but there has also been a change in demands placed on crime scene investigators. It has been estimated that, today, 80% of all cases have some form of digital evidence. As evidence quickly moves from being physical and document based to digital and electronic, the knowledge, skills, and abilities of those charged with identifying, collecting, and analyzing evidence must adapt to meet these new demands. Some, in the new emerging field of digital forensics, have suggested that, due to the unique nature of computers, networks, and digital evidence, traditional approaches to crime scene analysis must be abandoned in favor of new methods, techniques, and tools (Rogers and Seigfried 2004).

The Department of Justice in the United States, the Royal Canadian Mounted Police (RCMP) in Canada, the Australian National Police, and Scotland Yard, to name just a few, are literally scrambling trying to develop new procedures and checklists to allow investigators to effectively deal with digital evidence and digital crimes scenes. Researchers such as Baryamureeba, Beebe, Carrier, and Mocas have developed various models to assist law enforcement and the judiciary in dealing with digital evidence. Despite these theoretical efforts, what is still lacking is an applied or practical approach to dealing with digital crime scenes and the digital evidence contained therein.

The thesis of this chapter is that, although digital crime scenes and electronic evidence may introduce some unique requirements, these requirements will be at the higher strata of the process (e.g., specific tools). The lower, more conceptual layers of a crime scene, as discussed by Lee et al. Saferstein, Nickell, and Fischer, will not be drastically different for physical and digital investigations; therefore, a common approach can be defined. This common approach will assist digital forensics in meeting the current and future requirements for being a forensic science and in satisfying the judicial criteria for admissibility as scientific evidence (i.e., *Daubert*) (Bates 1997). The common ground also makes it possible to repurpose much of what we already know in criminalistics and physical crime scene analysis and provides a practical approach for examiners, analysts, and investigators.

This chapter provides a brief background on criminalistics and general crime scene analysis. The reader is also introduced to some of theoretical frameworks that have been developed specifically for digital crime scenes and how common concepts can be reintroduced back into the general crime scene frame work. A simplified process model is discussed that not only allows for a pragmatic approach to dealing with digital scenes but also is consistent with established protocols, thus increasing the probability that discovered evidence, either inculpatory or exculpatory, will be admissible in a court of law.[1] It has been said that “there is no new thing under the sun” (*Ecclesiastes*, 1:9–14), and this chapter is no exception. It merely examines what has already been done in the areas of physical crime scene analysis and digital investigative models and provides a pragmatic marrying of the two analogous disciplines.

222.1 Brief Overview of Crime Scene Analysis

Crime scene analysis can trace its roots back to the early 1900s when Edmund Locard published his now famous principle of exchange. The principle states: “When a person commits a crime something is always left at the scene of the crime that was not present when the person arrived” (Saferstein 2004, p. 5). This relatively simple principle reshaped the manner in which the law enforcement community would forever more view the scene of a crime. The revelation suggested that not only could the crime scene provide clues as to what had transpired but it could also provide information on who might have been involved, either as a suspect or at the very least as a material witness.

Law enforcement investigators were now challenged to protect the scene and identify and collect potential evidence in a timely manner, as most scenes contained semipermanent evidence (e.g., holes, broken glass) and transient or dynamic evidence (e.g., fingerprints, bodily fluids). The demands for identifying and collecting evidence had to be balanced with the concern over contamination (i.e., introducing items into the scene that were not originally there or destroying existing evidence). The various demands required that the law enforcement community develop protocols and standard operating procedures (SOPs). These SOPs eventually became universal and, having survived judicial scrutiny, became the framework for current-day crime scene analysis (Nickell and Fischer 1998).

Basic textbooks such as Henry Lee’s *Crime Scene Handbook* present this framework as part of the foundations of criminalistics. The process encompasses five phases (Lee et al. 2001; Saferstein 2004):

- *Recognition*—Recognition involves knowing what to look for, what constitutes potential evidence, and, more importantly, what can be ignored. This phase also includes the collection of evidence.
- *Identification*—When evidence or potential evidence has been recognized, it must be identified. Identification consists of classification at the most basic level based on class characteristics (e.g., hair, blood, fingerprint). This acts as the foundation for the next phases.

[1] Due to the unique characteristics of the practice of law and jurisprudence, the criteria for acceptance will be based on the U.S. common law standard.

- *Comparison*—The collected and identified evidence must be compared to some standard or control to determine that it came from a particular class (e.g., paint from a 1975 Ford Mustang).
- *Individualization*—The evidence is then further examined to determine any unique characteristics that would allow it to be differentiated from the larger category to a specific person or object based on its unique characteristics (e.g., paint from a 1975 ford Mustang owned by the primary suspect).
- *Reconstruction*—The last phase ties together the previous phases and allows the investigator to pull together the pieces of what has been to this point part of a jigsaw puzzle with no real picture to follow into a logical sequence of events consistent with established timelines.

Assumed within this model are the concepts of interpretation and reporting. Interpretation in this context refers to assumptions and postulations based on evidence and the facts at hand. Obviously, the final output of the process is the production of a report that becomes discoverable and provides a chronology of what, when, why, where, and how the scene and identified evidence were handled or managed; this is critical when proving an unbroken chain of custody, which is one of the cornerstones of good crime scene and evidence management (Ahmad 2002; Lee et al. 2002; Saferstein 2004).

The crime scene model is purposely high level and focuses on concepts as opposed to minute details. This allows the model to be used in various types of investigations (e.g., arson, homicide, sexual assault), while providing sufficient latitude for the analyst or investigator to be flexible and deal with the eccentricities and context of each particular scene/investigation.

222.2 Cyber Crime Scenes

An interesting phenomenon has appeared within the field of digital investigations. For whatever reason, the forensic and law enforcement community has assumed that the introduction of technology has so drastically changed the nature of investigations and crime scenes that we must reinvent the wheel and develop new and different approaches to digital or computer crimes and their corresponding scenes. This opinion exists despite a lack of evidence to support it and actually runs contrary to what courts are demanding—adherence to a criteria for the admissibility of scientific and technical forensic evidence (Smith and Bace 2002). In the United States and Canada, the courts have decided on the *Daubert criteria* [2] for determining whether evidence is scientific and thus given more weight. Briefly, the criteria state that the method or theory should be testable and generally agreed upon by the relevant scientific community, the error rate must be known or have the potential to be known, and the method used must have been peer reviewed and published (Meyers and Rogers 2004). The Daubert criteria and the subsequent Carmichael [3] ruling, which extended the criteria to technical and engineering methods, place the judge in the position of "gatekeeper," whose role it is to decide what evidence becomes admissible and what will be heard by a jury. The criteria are designed to give assistance to judges, whom are not necessarily scientists, when determining true science from junk science.

As mentioned, the Department of Justice in the United States and its counterparts throughout the world have felt the pressure to develop standard operating procedures for dealing with digital-based evidence. The development of these SOPs is problematic given the fact that, although various *ad hoc* approaches exist, no international consensus has yet been reached on how to deal with the evidence.

[2] *Daubert v Merrell Dow Pharmaceuticals, Inc.*, 509 U.S. 579, 1993. In a case involving the admissibility of scientific expert testimony, the U.S. Supreme Court held that: (1) such testimony was admissible only if relevant and reliable; (2) the federal rules of evidence (FRE) assigned to the trial judge the task of ensuring that an expert's testimony rested on a reliable foundation and was relevant to the task at hand; and (3) some or all of certain specific factors—such as testing, peer review, error rates, and acceptability in the relevant scientific community—might possibly prove helpful in determining the reliability of a particular scientific theory or technique.

[3] In *Kumho Tire v Carmichael*, the Daubert criteria were expanded to include testimony by engineers and other technical witnesses who are not scientists.

High-level concepts have been discussed by organizations such as the International Organization on Computer Evidence (IOCE) and the Scientific Working Group on Digital Evidence (SWGDE); however, apart from agreeing that evidence should not be altered and that everyone needs to be trained and adhere to the country's laws, nothing concrete has been accomplished. The lack of defined standards combined with the judicial scrutiny has placed the field of digital forensics in the precarious position of vacillating between a true scientific discipline and a pseudo science or art form. This is definitely not a comfortable position to be in for any protracted period of time.

To meet the criteria for scientific evidence, digital forensics must determine what actually constitutes a digital investigation (Noblett et al. 2000; Reith et al. 2002). This requires the identification of process models and investigative elements (Mocas 2003). Although several theoretical digital crime scene process models have been developed, we will confine our discussions to the *integrated digital investigation process* (IDIP) (Carrier and Spafford 2003) and the *hierarchical objectives-based framework* (HOBF) (Beebe and Clark 2004). These two models encompass earlier models, such as the incident response model, law enforcement process model, and the U.S. Air Force abstract process model.

222.3 Definitions

Before examining the digital crime scene process models, it is important that several key terms be agreed upon. Although the term *digital evidence* has found its way into the common vocabulary, it has never been sufficiently defined by the digital forensic community. Carrier and Spafford (2003) defined digital evidence as:

> Digital data that establish that a crime has been committed, can provide a link between a crime and its victim, or can provide a link between a crime and the perpetrator. (p. 6)

This is a modification of the definition of physical evidence as presented by Saferstein (2004). Accordingly, the datum can exist in storage media, primary or secondary memory, and volatile memory or on the wire in transit between systems. This definition will suffice for the purposes of our discussion.

Given the definition of digital evidence, we can define a digital crime scene as the *electronic environment where digital evidence can potentially exist*. This is a slight modification of the Carrier and Spafford (2003) definition. The terms "software" and "hardware" were dropped from the original definition, and the term "virtual" was replaced by "electronic." It was felt that the original terms introduced unnecessary constraints on the definition.

222.4 Current Process Models

222.4.1 Integrated Digital Investigation Process

The integrated digital investigation model (IDIP), one of the most well-known models of digital investigations, maps digital elements to physical investigative methods. Carrier and Spafford (2003) examined earlier approaches from the areas of incident response, the military, and law enforcement. They concluded that any digital model must meet the following criteria:

- The model must be based on existing theory for physical crime scene investigations.
- The model must be practical and follow the same steps that an actual investigation would take.
- The model must be general with respect to technology and not be constrained to current products and procedures.
- The model must be specific enough that general technology requirements for each phase can be developed.

- The model must be abstract and apply to law enforcement investigation, corporate investigations, and incident response.

Based on these criteria, the IDIP has seventeen phases combined into five groups:

- Readiness phase
- Deployment phase
- Physical crime scene investigation phase
- Digital crime scene investigation phase
- Review phase

Carrier and Spafford (2003) break each of these five phases down into more basic elements and relate each back to physical investigations concepts and analogous requirements. The authors conclude that the IDIP provides a valid investigative model and argue that digital investigations encompass more than forensics, which they contend is primarily focused on issues related to comparison and identification, and is thus differentiated from digital forensics. They specifically point to the reconstruction of digital evidence as support for differentiating investigations from forensic analysis (Carrier and Spafford 2003).

The IDIP has been criticized for being too theoretical and relegating the computer to being simply a "dead body" upon which a postmortem is to be conducted, as opposed to an actual crime scene analogous to the physical environment (Baryamureeba and Tushabe 2004). Given that the computer system, network, or storage media can be thought of as a distinct crime scene, a container for potential evidence inside a primary scene, and a victim upon which the incident has been perpetrated, the term *corpus delicti* is more fitting. *Corpus delicti* encompasses not only the notion of the body but also the sum total of the evidence that exists in the environment containing the body. Baryamureeba and Tushabe (2004) further criticize the lack of specificity of the model and its vagueness in differentiating between multiple scenes such as the perpetrator's and the victim's computer systems.

222.4.2 Hierarchical Objectives-Based Framework

Beebe and Clark (2004) leveraged the work of Carrier and Spafford (2003) and defined an investigative framework based on concrete principles as opposed to single-tier, high-order principles. The goal was to use objectives-based subphases in order to make the framework more pragmatic (Beebe and Clark 2004). The authors combined what they considered to be first-tier phases from previous approaches to construct their first-tier framework. This framework consists of:

- Preparation
- Incident response
- Data collection
- Data analysis
- Presentation of findings
- Incident closure

A second tier framework was then added. The second tier was meant to cover all contingencies and types of digital evidence, as well as possible categories of crimes (Beebe and Clark 2004). The authors further indicated that this layer was comprised of objectives-based subphases (OBSPs), which should be consistent across various contexts, and specific tasks and subtasks that were situational dependent. The remainder of the discussion was confined to illustrating the model focusing only on the analytical phase and defining the appropriate subphases such as survey, extract, and examine (see data analytical approach).

Beebe and Clark (2004) concluded that an objectives-based, multitiered approach had more utility than the first-tier-only models, as the multitiered model was more practical and at the same time more specific. They contended that a more detailed approach would assist researchers and tool developers; however, they cautioned against moving to a level of specificity that would produce standardized checklists due to the quirks that can arise in real-world investigations.

As the authors point out, the model is incomplete and adds several layers of complexity (Beebe and Clark 2004). The model also tries to be too all encompassing. The goal of being technology and operating system neutral is not practical given the reality of today's investigations. Certain technologies (e.g., cell phones, flash drives) and operating systems or file systems may have peculiarities that affect both the first tier and the objectives layer. This would lead to the necessity of defining additional subtiers within the model that would further increase the complexity and adversely affect its parsimony, thus limiting its real-world applicability. The model also attempts to be both generic and broad yet provide sufficient specificity to be practical—these two goals appear to be mutually exclusive in this context.

222.4.3 General Model Limitations

The most fundamental issue with the majority of the models to date is their reliance on incident response as both a framework and point of reference as opposed to being based on a solid criminalistics framework. While incident response seems like a logical foundation for the development of digital investigative models, it lacks some crucial components—namely, compliance with the rules of evidence, standard of proof, and chain of custody considerations (McKemmish 1999). Incident response procedures are predicated on computer science, networking, and information technology theory and standards. These disciplines look at the mechanical aspects of the devices, packets, and interconnections. This is crucial for troubleshooting and root-cause analysis at the mechanical level, but the models give little or no consideration to proper evidence handling or admissibility requirements (McKemmish 1999).

Current models also tend to reinforce the lack of stratification of various digital crime scene functions. In the traditional forensic disciplines, particular forensic disciplines have certain areas of specialty. Most larger law enforcement agencies, and increasingly smaller agencies as well, have crime scene technicians who are skilled in crime scene analysis. When a first responder arrives at a major crime scene, the scene is controlled and then the specialists are brought in to collect the appropriate evidence in a forensically sound manner. The evidence is then transported to other specialists whose function it is to deal with the evidence based on context or content (e.g., blood, hair and fiber, ballistics, DNA, fingerprints). The first responders will more than likely turn the case over to trained investigators (e.g., homicide, arson, robbery). Currently, digital investigations do not usually follow this same approach. It is not uncommon for the first responder to be expected to perform the role of a crime scene technician, investigative specialist, pathologist or coroner, and forensic scientist schooled in several different scientific disciplines. The mere fact that the scene is digital does not alter the reality that no one can live up to this unrealistic expectation of multiple domain expertise.

An additional limitation is that the investigative models are overly broad and do not lend themselves to a practical real-world approach for dealing with an entire investigation. This lack of pragmatism should come as no surprise, as no one model exists for all possible investigations based on evidence collected from a physical scene. Imagine trying to define an investigative model that covers every type of traditional crimes (e.g., homicide, rape, arson, break and enter) and every possible kind of physical evidence that can be collected from the scene (e.g., fingerprints, DNA, gun powder residue). When put into this context, it seems rather odd to define investigations solely based on the modality (i.e., physical versus digital) of the scene that contained the evidence. It will be impossible to have a generic investigative approach to all digital cases. Models must deconstruct the investigative process into more logical, practical phases. These phases should be based on the demarcation between the crime scene, analysis, and reporting activities (see Exhibit 222.1). Based on this framework, we need to concentrate our attention on the crime scene phase, as this forms the foundation upon which the analysis phase and reporting phases are built. This is also the primary target for activities related to the admissibility or suppression of evidence. If doubt is cast on the initial collection and management of evidence, output from the other phases is moot.

Developing a practical general approach dealing with the higher level investigative phases (analysis and reporting) is problematic, as these phases are context and content dependent, as are their equivalents in

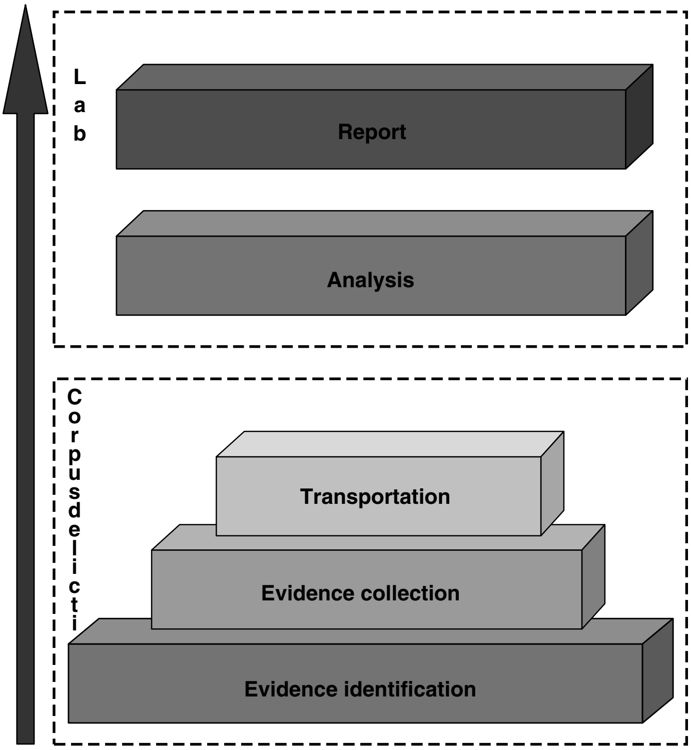

EXHIBIT 222.1 Crime scene deconstruction.

the more traditional physical-based investigations (Mocas 2003). Context relates to what type crime has been committed or assumed (e.g., hacking incident, internal fraud or malfeasance, child porn, intellectual property theft). Content relates to the type of operating system and corresponding file system (Windows 2000, OS X, Solaris, VMS), nature of the system (personal computer, workstation, server), and, in some cases, volume of potential evidence. Thus, confining the discussion to the lower layers makes more sense.

222.4.4 Practical Approach

The overriding principle behind the current approach is that computer crime scene analysis and computer forensics are not based on some tool, technology, or piece of software (McKemmish 1999). The exact tools, applications, etc. are irrelevant. What is important is adhering to the principles of being methodical and accurate, ensuring the authenticity and reproducibility of evidence, maintaining the chain of custody, and minimizing contamination of the original scene. Like a carpenter who uses various tools (e.g., hammer, saw, screwdriver), a forensic investigator uses various tools as needed; the tools do not define the discipline.

Although most of the current research has been directed toward all-encompassing generic models, a more realistic approach to assisting investigators—and at the same time appeasing the courts—is to develop investigative guidelines, or at the very least forensically sound tasks (FSTs) that are constrained to the actual crime scene or *corpus delicti layer.* By limiting the scope or domain of discussion in this fashion, several advantages arise. The first advantage stems from the fact that such an approach mirrors the real-world physical crime scene model, thus allowing for identification of analogous elements. A second advantage is that at the lower layer one can truly be generic and technology or platform neutral. The need for unique approaches based on context and content does not occur until the higher levels (i.e., analysis layer; see Exhibit 222.1). As suggested by previous researchers and scholars, for digital crime scene analysis to be consistent with established forensic principles it must develop some basic formalisms. As already discussed, formalism will help to appease the courts' concerns and meet the criteria for scientific evidence.

Rather than reinvent the wheel, an approach is required that incorporates generally accepted practices and standards. Because so-called best practices do not really exist, the use of generally accepted practices is sufficient. This is not only consistent with physical crime scene practices but is also consistent with information technology approaches (McKemmish 1999; Mocas 2003; Rogers 2003). The information technology security field has struggled to identify best practices and has opted instead for generally accepted principles and practices (e.g., GAASP GAISP ISO 17799). These practices are based on higher order concepts dealing with confidentiality, integrity, and availability (the information security triad). Within the field of digital crime scene analysis and forensics, equivalent standards come from various governmental sources (e.g., the U.S. Department of Justice, National Institute of Justice, National White Collar Crime Center (NW3C), RCMP Secret Service, Interpol, Scotland Yard, Department of Defense, GCHQ, G8), as well as the private sector (e.g., HTCIA, KPMG, Deloitte and Touche) and quasi-academia (e.g., IOCE, SWGDE). The current approach draws on work already conducted by these groups; the previous academic investigative models of Carrier and Spafford (2003), Beebe and Clark (2004), McKemmish (1999), and Mocas (2003); and the traditional crime scene approaches of Lee et al. (2002) and Saferstein (2004).

As stated, the current approach is not new; it is based on the five phases or layers as proposed by Carrier and Spafford (2003) but adds an additional hierarchy of *corpus delicti* (see Exhibit 222.1) and lab. The *corpus delicti* layer encompasses what is traditionally thought of as the crime scene as well as a transportation phase. In this lower foundational phase, the computer can be part of a larger physical crime scene (secondary scene), its own primary scene, a material witness to events, or the corpse to be examined. The higher layers denoted as lab (analysis, examination, report) are not addressed, as they require unique approaches based on content and context. The term "lab" is used in the broadest sense to denote processes that usually occur in a controlled environment; the use of the term is not meant to indicate that these activities must be undertaken in some form of officially sanctioned or accredited laboratory (e.g., state ASCLD-Lab/ISO 17025 certified facility).[4]

The *corpus delicti* layer is further subdivided into the subphases of (1) identification and recognition, and (2) collection. Identification includes not only identifying what might constitute individual pieces of evidence but also identifying what devices or digital storage media could contain evidence. On the surface, this sounds rather sophomoric, but with the trend toward small-footprint storage devices (e.g., USB thumb drives, watches with USB connections, USB pens, music players such as the iPod) the process of recognition becomes very complicated. The advent of digital storage capacity and network capability in entertainment systems (e.g., Tivo, DVRs), game systems such the Xbox, and now even refrigerators further complicates the matter of identification for first responders or investigators. When the identification and recognition phase has been completed, the evidence must be collected in a forensically sound manner (we will discuss what this actually means in subsequent sections). The collection phase encompasses the traditional bagging and tagging of computer systems and storage devices in some cases, as well as the acquiring of bitstream images from digital storage media in other cases.

For simplicity's sake, the forensically sound tasks are presented in a linear fashion; realistically, naturally occurring iterative relationships exist between various phases and tasks. Before proceeding further, an obligatory caveat is warranted: Never exceed your level of knowledge, skills, and abilities (KSA) or the abilities of the tools, applications, or techniques. Despite what vendors would have us believe, their tools have limitations (apologies to the vendor community who might actually read this) (McKemmish 1999). This is without a doubt the best advice one can follow in any set of circumstances.

[4] American Academy of Crime Lab Directors (SCLD-Lab) is the current U.S. standard and is in the process of becoming compliant with the ISO 17025 lab certification standard.

222.4.5 Properties and Rules

McKemmish (1999) and Mocas (2003) identified several fundamental properties or rules of computer forensics. These properties or rules are derived from the areas of information security and incident response, are sensitive to standards of proof, and are presumably compatible with private-sector functional requirements (e.g., getting back up and running in a reasonable amount of time). These properties consist of integrity, authenticity, reproducibility, maintaining the evidence chain (chain of custody), and minimalization. Integrity relates to the fact that the evidence was not changed from the time it was collected until it is presented in a court, hearing, etc. Integrity and authenticity are often interdependent. To be authentic, the courts need to be satisfied that the evidence is a true copy of the original or as true as is possible. An example is producing identical hash totals (MD5, SHA 256) of the original drive contents and the bitstream image. Reproducibility relates to the reliability of the methods or techniques used. Ideally, another individual following the exact same steps as the original technician should find the same results. The evidence chain of custody is sacrosanct, and proving an unbroken chain to the court is a minimum requirement for admissibility. Minimalization refers to contaminating crime scenes as little as possible; realistically, some minor contamination is introduced into all scenes. The fundamental properties have also been identified by the SWGDE and High-Tech Crime Investigators Association (HTCIA) and form the basis of their approach to training, in the case of the HTCIA, and policy and accreditation and certification standards, for the SWGDE. The properties or rules form the basis for a framework for the development of forensically sound tasks.

222.4.6 Forensically Sound Tasks

The focus of the tasks in Exhibit 222.2 is on the application of crime scene techniques to the real world. The tasks are also technology neutral to the extent that they are conceptual based and purposely high level; the real world requires a certain amount of flexibility albeit within some parameters. The parameters for our purposes are the rules of evidence, standard of proof, and chain of custody. The importance of proper documentation with all the tasks cannot be stressed enough. Although some might argue that too much documentation may provide fertile ground for others to criticize what was done or omitted, the inability to recall important steps or variations of technique usually results in the proverbial death sentence—full suppression of any and all evidence derived from the tasks.

222.4.7 Control the Scene

Controlling the scene is one of the most fundamental tasks. Failure to control a scene will negatively affect all of the other tasks and directly influences the five principles. The objective here is to create an adequate environment in which to carry out the subsequent tasks; however, unlike a pristine lab environment, the real world is not fully controllable. It is extremely rare to have absolutely no contamination, as an individual's mere presence at the scene has altered the original state to some extent, however minute (Farmer and Venema 2004). Heisenberg's uncertainty principle would argue that merely viewing the scene causes changes at the quantum level; therefore, every scene is contaminated. Luckily, most courts have opted not to adopt such a literal interpretation of contamination (Farmer and Venema 2004; Smith and Bace 2002). It is vital that detailed notes be taken describing all the actions taken. Also, it is important to:

- Quickly control the scene and all people and potential sources of evidence (e.g., isolating suspects, witnesses, systems from networks including the Internet). This may include disconnecting a system from any connections (wired and wireless networks, cable modems, dial-up modems) that may allow remote connections.
- Contain the scene, which is of the utmost importance in order to minimize the amount of contamination.

EXHIBIT 222.2 Forensically Sound Tasks

Task	Objective	Principle/Rule
Control the scene.	Create the proper environment to conduct the evidence collection.	A, C, I, M, R
Survey the scene.	Determine the scope of the scene and the need for assistance in the next phases. Establish the context of the investigation.	M, R
Document the scene.	Allow investigators to describe the scene in detail and place activities conducted at the scene in context. Also, indicate the location of evidence, people, or evidence containers for possible use at the higher investigative levels.	C, R
Identify potential evidence and containers of evidence.	Locate sources of potential evidence or objects that may contain evidence. If the search is conducted under a court order, determine that the order is valid or must be amended.	A, C, R
Determine the evidence modality (e.g., digital, physical, dynamic).	Begin categorizing the evidence or containers of evidence to determine the best process by which to handle the evidence or container.	A, I, M, R
Collect evidence based on modality.	Use techniques and tools appropriate to the modality of the evidence.	A, C, I, M, R
Collect any necessary standards.	Determine if any standards will be required for comparison at the higher levels and collect same if necessary.	A, I, R
Package for transport.	Ensure that no damage or contamination occurs and that all evidence is accounted for.	A, C, I, M, R
Turn over to lab or appropriate offsite facility.	Allow for detailed examination and analysis of evidence in a scientifically controlled environment and for the determination of long-term storage needs.	C, I, R

Note: A, authenticity; C, chain of custody; I, integrity; M, minimalization; R, reproducibility.

222.4.8 Survey the Scene

Understanding exactly what you are up against is necessary in order to determine what resources will be needed, both in terms of additional personnel, and equipment. The survey task should be conducted in a methodical, well-documented manner. This holds true whether the digital scene is primary, secondary, or the corpse. The ability to articulate the exact context of the scene and in some case reproduce the scene is an absolute necessity; this type of detail is often required when interpreting evidence in the analysis and examination phases, especially with event reconstruction. A survey will also assist in determining the approach that should be taken to the actual evidence identification and collection. It will also allow for determining strategies that minimize contamination and maximize the reproducibility of the actions taken. The investigator should:

- Step back and observe the scene from the perspective of a neutral third party. Obtain a mental picture of the environment, its contents, and their interactions and dependencies.
- Based on the observations, determine the approach that offers the greatest probability of obtaining the necessary evidence while at the same time producing the least amount of contamination.

222.4.9 Document the Scene

When a mental map of the scene has been processed, proceed to document the scene either diagram matically or digitally (e.g., still camera, video). This task is the lynch pin for articulating the context and relationships of any evidence that is found. A picture or a video is really worth a thousand words when trying to describe to a forensic analyst, boss, tribunal, judge, jury, etc. what the scene looked like. This task is necessary even when the scene is confined to the actually computer itself (primary scene, corpse). One only has to think of trying to describe a small home network with four to five systems all intercon nected or to remember what exact peripherals were attached to the suspect system. The chain of custody is dependent on effectively articulating the original location of evidence, thus the necessity for accurate documentation. In addition,

- Make detailed notes, sketches, and diagrams, and take pictures from various angles to ensure a sense of context for those reviewing the case details at some future time.
- If possible, take pictures of both the front and rear of all computer systems, devices. This will illustrate the state of connected peripherals and any unique cabling and connections.

222.4.10 Identification

Although it sounds odd to reiterate the need for identification, the fact that we are dealing with digital evidence that does not come in a one-size-fits-all mode requires this. Advances in technology have drastically altered what is considered storage media. As storage media is often the primary source of evidence, care must be taken not to overlook the obvious and now the unobvious. To counter claims of tunnel vision and neglect in conducting a thorough investigation, all evidence and potential containers of evidence (e.g., storage devices) must be identified. This accurate and complete identification is required to satisfy the principles of authenticity, reproducibility, and the evidence custody chain. The investigator should:

- Identify and recognize all possible storage media including both traditional devices (e.g., diskettes, hard drives, CDs, DVDs) and nontraditional devices (e.g., thumb drives, PDAs, cell phones, digital video recorders, Xboxes, USB devices).
- Do not ignore analog and document-based sources of potential evidence (e.g., printouts, log books, journals, diaries, manuals, drawings).

222.4.11 Evidence Modality and Collection

Determining the type of evidence (modality) allows the investigator to formulate a plan to effectively collect the evidence while minimizing the likelihood of contamination, maximizing authenticity and reproducibility, and maintaining the chain of custody. The modalities include physical, digital or electronic, and analog, as well as dynamic/transient (e.g., volatile memory, cache) and relatively stable (e.g., secondary memory storage, firmware, printouts). A thorough identification process greatly reduces the time required to carry out this task. Understanding the evidence modality and degree of transience also allows the investigator to prioritize the actual collection process. Dealing with both physical and digital or electronic evidence requires a diverse repertoire of tools, techniques, and processes. It is beyond the scope of this limited chapter to discuss all possible contingencies. It suffices to say that if an investigator, technician, or first responder has correctly and diligently carried out the previous tasks, this task becomes more a matter of mechanics (i.e., the appropriate tool, technique, and process for the type of evidence). The same approach holds for the traditional crime scene analysis approach and is in fact the direct result of following a formal, methodical approach. The challenge becomes one of collecting the evidence without introducing any unnecessary contamination. The exact approach to this depends on the modality of the evidence, the degree of control over the scene (e.g., amount of isolation), and the overall context of the investigation:

- Determine priority by order of volatility (i.e., most transient first).
- Focus on digital or electronic evidence first, as it is usually more volatile than physical evidence.
- Further prioritize digital or electronic evidence based on its volatility.
- Use the correct tools, techniques, and processes.
- Document every step taken, and be prepared to discuss what was done and what may have been omitted from the task.

222.4.12 Collection Standards

The requirement for the comparison of any collected evidence to some standard is not just a concern for physical crime scenes and evidence. It may be the case that printouts, photographs, scans, etc. must be compared to electronic or digital versions of these same items discovered on a storage device or system. This goes to the authenticity of digital evidence and indirectly to the integrity. Successfully determining that the document in question and the file located on the suspect system are related is strong proof in the eyes of the court or jury that the digital evidence is trustworthy. It is therefore necessary to identify any potential standard. Again, the exact nature of what this constitutes is dependent on the context of the investigation and the environment being examined. Regardless, understanding that comparison and event reconstruction are important activities in the analysis and examination phases allows the individual collecting the evidence to be more observant:

- Do not overlook analog or document evidence such as printouts, pictures, photocopies, etc.
- Thoroughly document the relative position of any item seized as a potential standard for comparison.

222.4.13 Package for Transport

This task is probably the second most crucial event in crime scene analysis. More than a few investigations have crumbled because of a lack of attention to proper transportation or care in handling. It is only natural, with the "end of the tunnel" in sight, to rush this task and take short cuts. The potential negative impact on the evidence custody chain cannot be stressed enough. Evidence, for probably the first time since the scene was controlled, will leave the controlled "scientific" environment and enter the "no man's" land that lies between the scene and the lab. It is crucial to remember that the chain of evidence extends to all activities related to the life cycle of the evidence (this is often referred to as "from the birth to death of the evidence"). Any inability to account for the who, when, what, where, how, and why of the evidence greatly increases the chances of its being suppressed or at the very least having its authenticity and integrity questioned. This task also impacts on the potential for being held liable for damages directly or indirectly related to the negligent handling of evidence (e.g., loss of critical data, physical damage to computer systems or devices). Here, again, a thorough understanding of the sensitivity of various data or equipment is necessary (e.g., tolerable temperature and humidity ranges, sensitivity to vibrations and electromagnetic radiation, tolerance to long-term storage without electricity). The investigator should:

- Use common sense and package evidence in appropriate containers (e.g., antistatic bags, bubble wrap).
- Understand the tolerance of various sources of evidence to electromagnetic sources (e.g., magnets, radio transmitters).
- Document all decisions made and be prepared to articulate the reasons for making decisions that could be considered outside of the norm (e.g., leaving computer systems exposed to extreme temperatures or particulates such as dust or transporting the components for prolonged periods without adequate protection from vibrations or external pressures).

222.4.14 Turn Over to the Lab

As already mentioned, the term "lab" is used in the loosest sense. The lab can be merely a controlled environment back at the office or police station, a private lab, or a governmental lab facility. Regardless of the actual facility, it must have procedures, standards, and processes in place to ensure that the integrity and chain of custody are maintained until the end of the evidence life cycle, which includes returning the system or device back to the owner, repurposing the system, returning the system or device or data back into the production environment, destroying it, storing it until appeal, etc. The lab environment is usually where the analysis, examination, and report phases and tasks take place. Depending on the exact circumstances of the investigation, the analysis and examination may take place on site (*in situ*). In these cases, the field examination is often just a cursory look to confirm the grounds for probable cause or the issuance of a court order or to assist in the field interview of any suspects. The investigator should:

- Document and have the person to whom the evidence has been turned over sign for the said evidence.
- Ensure that any facility has proper equipment, standards, and procedures in place to store digital or electronic evidence.[5]
- Be sure that all persons in contact with the evidence have the prerequisite knowledge, skills, and abilities, as well as up-to-date training on how to deal with digital evidence.

222.5 Conclusions

Despite the introduction of technology to the crime scene, digital crime scenes are not all that different from the traditional physical crime scene, at least at the lower or more fundamental levels (McKemmish 1999; Meyers and Rogers 2004; Mocas 2003). This similarity, while often overlooked in the development of all encompassing investigative models, allows digital crime scene analysis to be judged by the same scientific evidence criteria (i.e., *Daubert*) as the other more common forensic disciplines (e.g., DNA, fingerprint analysis). With the ever-increasing scrutiny and, in some regards, understanding of digital forensics, the judiciary is becoming more stringent in determining what evidence will be admissible.

On the criminal side, the field of computer forensics has historically relied on a lack of understanding and the fear of technology by judges, defense attorneys, and jurors. Times have changed. Judicial training programs are now incorporating workshops on digital evidence; bar associations are providing similar professional development training for both prosecutors and defense attorneys. Certificate, degree, and masters programs are popping up at colleges and four-year degree granting institutions. The private sector has also jumped on the bandwagon with consulting services and training programs. Vendors and private for-profit groups are offering various certifications and "boot camps." This attention is placing a great demand on the discipline to mature rapidly and move from *ad hoc* approaches to some sort of formalized approach based on a strong theoretical foundation and pragmatic objectives.

Although it is not realistic to believe that the formalization will occur overnight, it is not unrealistic to demand that certain foundations be laid appropriately from a legal, scientific, or criminalistic and practical perspective. This chapter was an attempt to nudge the field into a logical direction: the development of basic crime scene analysis processes analogous to what is currently being done and standardized with the traditional physical crime scenes. Rather than reinvent the wheel, following in the footsteps of Lee et al. (2001) and adopting or repurposing a tried and tested approach only makes sense.

The theoretical work in the area of digital crime scene analysis and investigations provides a good launching point but is far from sufficient to meet the goal of developing a common approach. It is illogical to try to develop an approach that covers all contingencies and types of digital crime. Digital or computer crime is a vacuous term that is so all encompassing as to be of little utility when attempting to work at a granular level. We do not have one common investigative approach for all physical crimes, so why think digital would be any different? However, if we step back and deconstruct the digital investigation into its basic elements or phases, we find that, at certain levels, like in traditional investigations, generic or at least generalizable tasks across all cases can be identified (see Exhibit 222.1). This also allows us to define overarching forensic principles or rules that act as constraints

[5] Several organizations outline minimum standards for the storage and care of digital evidence (e.g., www.swgde.org, ASCLAD-LAB Standards, ISO 17025).

for gauging the degree of forensic "soundness." By focusing on these levels, forensically sound tasks can be identified and mapped to objectives and to the defined forensic principles.

The nine tasks as outlined in Exhibit 222.2 are consistent with the methodology and tasks carried out with more traditional physical crime scenes. The tasks are high level, fairly generic, and consistent with the common principles of criminalistics and provide a necessary if not sufficient framework for conducting a digital crime scene analysis. The fact that the tasks may not be completely sufficient is understandable, as the approach is designed to be a minimum framework and not a maximum or checklist in the true sense. As Beebe and Clark (2004) stated, a checklist can be a negative, as it tends to be restrictive and constrains the actual investigative process.

The approach described in this chapter is not new. It is merely taking what has already been done in criminalistics, IT security, incident response, and theoretical digital forensics and combining the outputs into an approach that maps well to both the real world and the legal requirements that define a discipline as forensics. The objective was to provide some insight on crime scene analysis in general and on practical digital crime scene analysis in particular. More work is obviously necessary in order to mature digital forensics into a real forensic discipline that will assist government, law enforcement, and the private sector in dealing with the increasing amount of computer or cyber crime. What is ultimately required is a better marriage between traditional criminalistics and technological processes. This can only happen if the field becomes more future oriented and looks to the near- and long-term foreseeable challenges and issues, as opposed to the current approach of focusing on what has happened in the past. I believe that this chapter is a step in that direction.

There is nothing more deceptive than an obvious fact."—Sherlock Holmes (The *Boscombe Valley Mystery*, by Sir Arthur Conan Doyle)

What a Computer Security Professional Needs to Know about E-Discovery and Digital Forensics

Larry R. Leibrock

223.1 Relevance

The profession of the systems security officer has become well defined as agencies and business entities have established and proactively manage information protection programs that involve the use of computers, networks, and digital devices supporting the flow of information, communications, business, and financial transactions. The role of a computer security officer (CSO) is increasingly involved with supporting the collection, safeguarding, and production of computer-based data which is needed for investigation and litigation of administrative, civil, and criminal matters. The CSO is sometimes tasked with providing both advice and assistance in collecting and producing digital information that has been requested by the investigating parties in these matters. As the utility of electronic discovery and digital forensics investigations becomes more apparent, the security professional should become more aware of these matters.

223.2 Introduction

Personal computers and the Internet have revolutionized communication, work, and leisure. Consider these facts:

- In 2004, an estimated 224 million personal computers were in use in the United States, 69 million in Japan, and 46 million in Germany.
- In 2001, over 60% of U.S. households owned at least one personal computer.

- E-mail and instant messaging are the dominant applications in personal computing.
- Some analysts estimate that our need to create, access, and store digital data increases about 50–100 percent each year.
- Both internal investigation and litigation frequently center on the discovery and legal review of documents that are in digital form.

223.3 Investigative and Legal Discovery

According to *Legal Definitions* on the Web, "discovery" is the process of gathering information in preparation for trial. This legal process is based on proper discovery of data, materials, and facts relevant to judicial disputes. Traditionally, the courts have used paper-based documentation to support or refute allegations. The legal investigation of digital information is a fairly new occurrence. Recently, many investigations have focused on electronic personal or business communications, such as e-mail and instant messaging. Examples that come to mind are the white-collar and improper stock-trading litigations dealing with both civil and criminal allegations. As our legal system becomes more aware of electronic discovery and the forensics processes of recovering data, we should expect more use of these types of investigations in a wide range of administrative, civil, and criminal issues. With the increasing range and capacities of digital devices, much evidence exists only in digital forms.

Many people believe that modern science founded electronic discovery and digital forensics, but the underlying scientific principle is historical. In 1910, Edmond Locard in Lyon, France, framed Locard's exchange principle, which states that when two objects (for example, a person and a computer) come into contact, there is always transference of material from each object onto the other. The Locard exchange principle can be restated for our purposes as:

> Each user's interaction with digital devices leaves *both user and usage* data on the particular computer device and certain remnants of data remain on the device.

Electronic discovery is the practice of analyzing and developing opinions about data and information that once were stored in digital form and have been extracted, culled, sorted, and produced in paper or viewable formats. Typically, electronic discovery does not focus on binary data in the deleted, recycled, or unallocated form. In contrast to electronic discovery, digital forensics investigations focus on allocated, unallocated, and fragmentary data. As a working term, *digital forensics* is the legal and ethical practice of collecting, examining, investigating, reporting facts, and developing expert opinions about digital data in its native binary form. Procedures are based in science. Both electronic discovery and digital forensics investigations deal with these established processes: collection, examination, investigation, and reporting. The processes were developed to properly:

- Safeguard the original suspect data.
- Retrieve the suspect data, while not altering or potentially interfering with the original state of the suspect data.
- Investigate the suspect data for the presence of applications or contraband information and the matching of key search terms.
- Report opinions about findings in the suspect digital data. The opinions involve making expert characterizations of these items:

  Person (user account)

  Platform (the device, such as computer, cell phone, digital camera, or e-mail server)

  Application program

  Data and fragments of data

  Time and date tokens

These digital forensics tools perform the tasks listed above:

- *Collection*—Protect the data from any potential changes, chain of custody documentation, contemporized records with enumerated devices or media.
- *Copy*—Perform a sector-to-sector physical (not logical) copy, which serves to extract digital data and fragments contained on the media, and acquire suspect data. (Note that this is not an operating system copy or move, which alters certain data). The sector-to-sector copy of the suspect media is typically completed with the use of a verification hash (SHA 1 or MD5) that serves to verify the integrity of the forensics copy.
- *Examination*—Use a forensics tool that serves to "undelete" digital data in the unallocated file space of the suspect platform; this serves to forensically recover the unallocated and data fragments in order to conduct further forensics investigations.
- *Investigation*—Conduct a series of key term searches of the extracted data for the presence of programs, graphic images, keywords, or cryptographic tokens (known as string or term searching).
- *Reporting*—Prepare bench notes, investigator comments, specific screen captures, and a series of interim, final, and supplemental expert forensics reports that reflect the forensics examiner's opinions and the basis for these opinions.

223.4 Examiner Focus

The forensics examiner usually will focus on the following areas during the typical forensics examination of a computer system. This is the general step-by-step forensics examiner procedure:

- Sector-to-sector copy with hash integrity tools for verification
- File signature analysis
- Recycle bin review
- E-mail review
- Allocated files characterization
- Deleted files characterization
- Special operating files (SWAP, SLACK) review
- Browser history review
- Special or notable programs characterization
- Accounting and credit card data review
- Graphics and pictures review

223.5 Typical Data Morphology from a Forensics Perspective

Digital data contained in devices typically has distinct forms:

- *Archival*—Data stored on backup tapes or removable media (such as CDs or thumb drives)
- *Active*—Data that is in use by the operating system
- *Unallocated*—Data that is no longer in use by the operating system; the data is residual and the space it occupies subsequently may be used to store active data not now in use and available for future use

223.6 The Allocation and Deallocation of Data

Operating systems in most computer devices have constraints in efficiently controlling input/output storage needs and effectively conducting file management operations, such as:

- Creating data
- Writing data
- Accessing data
- Retiring unneeded data

All of these file management operations take place on the physical storage media, such as the magnetic disk, or removable storage device, such as a diskette or USB storage dongle. Most operating systems deallocate data from the operating system file table and write to the next available file space rather than overwriting the current data. This approach efficiently uses computational resources and saves system time. Reiterated, the allocation and deallocation of files efficiently balances computational resources and time. System users do not recognize that most environments do not delete data; rather, data is deallocated and subsequently overwritten by successive files, as the system performs file management operations.

223.7 Security Professionals in Electronic Discovery and Digital Forensics

Computer security professions should consider these suggestions:

- Information security managers or computer security officers should develop a close collaboration with the organization's legal office or corporate counsel. Communicate your roles and responsibilities to them and understand the different ways in which you can help in answering questions, developing responses to legal inquiries, managing requests for production of digital records needed in investigations, and aiding electronic discovery and digital forensics matters. Spend time understanding recent legislation (for example, Sarbanes–Oxley).
- Spend some time with your legal staff to develop an understanding of legal terms relevant to lawsuits and investigative processes. Typically, after a legal suit arises, the parties exchange requests to produce and exchange certain materials. Given some requirements for digital data, the opposing party may provide a written notice to preserve, which is sent to the counsel representing your agency or business. If your counsel receives this preservation notice and you are given a copy, carefully read the details and recognize the potential scope of the discovery requirements. Work with the IT staff to locate the potential storage points for the request, and notify the executive or legal team of any concerns you have about proper safeguarding and preservation.
- You may be asked to help map your networks and prepare lists of servers or client platforms that may contain data needed by the parties in this litigation. Be sure the mappings and reports are accurate and detailed. Make sure you communicate details about data archives, back-up locations, and potential repositories of digital data. These details should be recorded, and you should keep your own copy of these records.
- Do not undertake any forensics investigation unless you have:

  Been authorized by management to undertake the specific investigation

  Received competent forensics technical education

  Achieved the necessary skills with forensics protocols

  Current and practical experience in dealing with the forensics discovery and proper examination of specified types of computer devices (e.g., clients, servers, personal digital assistants, cell phones, digital cameras)

A professional and personal disinterested relationship with the subjects of this investigative matter

- If you have received any administrative or legal notice to preserve digital devices or data, work with IT systems staff and management to immediately stop using any utility programs, archiving utilities, disk compaction tools, file managers, or virus programs that may potentially alter digital data in use on these devices. Prevent potential data destruction by immediately ceasing archival tape overwriting.
- Ensure that you have fully accounted for any subject equipment or digital devices by serial numbers, and make sure these devices are physically protected until they can be forensically examined as necessary in any discovery notice or court order for both inventory and evidentiary purposes.
- For digital devices that are specified for further forensics examinations, remember the following rule—If the digital device is on, let it stay on until a forensics sector-by-sector data extraction can be performed by a competent forensics specialist. If the device is off, keep it off until a forensics specialist is available to conduct the examination.
- Properly safeguard, in locked containers or restricted access rooms, backup media, archival data records, and disk storage replacements that are within the scope of the preservation notice. Access to the containers or room should be carefully controlled to maintain a chain of custody, which is necessary to properly preserve the data and records during the course of the litigation.
- Keep complete and correct records of your notices, preservation activities, and digital devices that are in the scope of your notice to preserve.
- Secure copies of the agency records retention policy, systems security policies, and agency or corporate acceptable use policy. These should be protected in your professional files and properly produced when requested by management or counsels.
- As the security professional in the security organization, provide all suitable technical aid and support for the forensics team in the scope of its investigation. Typically you will be asked to support certain activities necessary for the collection and production of media, systems, or records.
- Understand that you may be deposed in adversary settings and your actions and your records will be subject to review and depositional questioning. As an information security professional, you must act to ensure that you have been diligent in performing your assigned duties to secure and protect digital data in these electronic discovery and forensics matters. Your record keeping should be both correct and complete.

In recent litigation involving agencies and business entities, we have seen that frequently both the chief information officer (CIO) and the computer security officer (CSO) are named parties and, therefore, the center of adversarial review in discovery matters. As named parties, these positions will have to respond to many requests for information, records, files, and materials for review by the opposing counsels. Also as named parties in a litigation matter, they should prepare and expect to undergo depositions for these electronic discovery matters. In the depositions, the records, agency or business policies, and actions and decisions of the CSO and CIO will undergo adversary scrutiny. Accordingly, the information security professional should build awareness and maintain high levels of currency in the skills necessary to meet these challenges of electronic discovery and digital forensics.

How To Begin A Non-Liturgical Forensic Examination

Carol Stucki

When you have obtained the go-ahead from management to begin an investigation, you will find the steps and procedures for many types of investigations in this chapter. The most common and main type of investigation that this chapter discusses is the non-liturgical examination. The non-liturgical investigation is one that is not foreseen to be taken to trial or involve litigation; however, you should always conduct the investigation using the same procedures as if you are going to trial. By conducting an investigation in this manner, you will have all the evidence you need in the necessary format to present to company management or in a courtroom.

One of the first things to consider is whether or not you need to isolate equipment or files. If it is necessary to do so, you will need to move quickly on this in order to preserve any possible evidence. What you preserve and find on the equipment, most likely a PC, will be the basis of your forensic examination. This chapter reviews such topics as the isolation of equipment, isolation of files, tracking Web sites visited, tracking log-on duration and times, tracking illicit software installation and use, and how to correlate the evidence found.

224.1 Isolation of Equipment

Should you need to isolate or quarantine equipment as a part of your investigation, you need to take a few steps to (1) ensure protection of the equipment, (2) isolate and protect data from tampering, and (3) secure the investigation scene. First, you need to make sure that you have the authority to take the equipment. If you are taking any equipment, you should first get authorization from management, and if you take working equipment arrangements will have to be made to replace it while you conduct your investigation.

The first thing to do is to be sure that the PC you are about to take as part of your investigation is the correct unit, the one actually used in the illegal activity by the employee under investigation. This can be done by checking the asset records, or the records that are kept in some corporations by the operations department. If you need to take an employee's PC, you must have a witness and have the employee sign a form stating that you took the PC. Record the serial number, make, and model; when you took it; and the reason for taking it. If you do not have such a form, still somehow record what action was taken, obtain the employee's signature, and secure the suspect equipment. Any time it becomes necessary to take an employee's PC, you must move quickly to ensure that the evidence is preserved intact and not tainted, altered, or even destroyed.

When you have the PC in your possession, you need to preserve the "chain of evidence." You can preserve the chain of evidence by making sure that neither you nor anyone else is left alone with the equipment. You should always record your actions with the equipment. A good way to record all the actions and whereabouts of equipment or any other piece of evidence under investigation is to keep a log. This log should show (1) who has access to the equipment, (2) who retains control over the log, and (3) where the log is stored. Additionally, you should record the when (dates and times), where, and why of your every action, so every minute you have the equipment or data in your possession is accountable. Even if you put the PC in a locked cabinet or secured area, this action must be recorded in the log.

One of the first things you should do with the PC is to "ghost" it by backing up everything on the PC. In this way, you can make sure that you will not lose any data when you are conducting your investigation. Ghosting the data preserves the original data that might be disturbed during the investigation. For the backup of any data under investigation it is very important to make sure that the programs used to perform this backup are independent and have integrity; that is, the programs should not be under the influence or control of any person or other program or system that is outside the investigation team. The integrity of the data and equipment has to be ensured by the use of programs that will not alter the original data in any way, either intentionally or accidentally. A number of programs are used to perform such backups that are independent and have integrity. One such program is SafeBack, freeware that is available on the Web.

224.2 Isolation of Files

Not all the data required for an investigation will reside on a user's PC; therefore, you will need to gain access to the same files and directories that the user has access to. The first thing to do is to disable the user's ID. Be sure that the administrator verifies how the user's profile and accounts might be affected if the user's ID is disabled. Only after verifying that no data will be lost, altered, or destroyed by disabling the ID should the administrator proceed to disable the user's ID. Security personnel or someone with administrative authority should disable the user's ID. Operations personnel or a systems/data security office can do this. The easiest way to disable the user's ID is to change the password, but this is not the best approach, as the user could regain access if he or she is able to guess the new password. Be sure that the administrator disables the ID but does not delete it. In some security setups, deleting a user ID will cause data and files to be deleted as well. Because this is not what you want to happen, only disable the ID. When the ID is disabled, the next and most important step is to copy all the files to which the user had access. This provides a backup for your investigation, as the data cannot be quarantined. The confiscated data, however, cannot be used by the business for as long as it takes to conduct your investigation.

Operations or security personnel should have paper files with access requests, and they can run a report that shows what the user had access to on the system. Make sure the list or report they give you contains the group access and public access files for the user. You need to investigate all of the places a user could have copied or hidden data. For the investigation, you might be able to ignore those files with read-only access, but it is always best to be sure and get it all. Now that you know what the user had access to, request that operations personnel copy the files into a secure location that only you and your team have access to. Copy the file structure as well—all directories and subdirectories. Make two copies of the data: one as a backup and one for you to use in the investigation. This is similar to taking a picture of the crime scene before you start moving things around. Now that you have a copy of the data to use, refer to the following sections in this chapter which provide various examples of potential investigative areas and demonstrate how you can use the data collected as part of your investigation.

224.3 Tracking Web Sites Visited

If your investigation requires that you track what Web sites have been visited by an employee, you should begin by reviewing the following items:

- Cookies
- Bookmarks
- History buffer
- Cache
- Temporary Internet files

Here we briefly define each of these items, where to find them, how to capture the findings, and how to evaluate what you have found.

224.3.1 Cookies

Cookies are messages given to a Web browser by a Web server. The browser stores the message in a text file called *cookie.txt*. The message is then sent back to the server each time the browser requests a page from the server. The main purposes of cookies are to identify users and possibly prepare customized Web pages for them. When you enter a Web site that uses cookies, you may be asked to fill out a form providing such information as your name and interests. This information is packaged into a cookie file and sent to your Web browser, which stores it for later use. The next time you go to the same Web site, your browser will send the cookie to the Web server. The server can use this information to present you with custom Web pages. Thus, for example, instead of seeing just a generic welcome page, you might see a welcome page with your name on it.

The name *cookie* evolved from UNIX objects called *magic cookies*. These are tokens that are attached to a user's ID or program and change depending on the areas entered by the user's ID or program. Cookies are also sometimes called *persistent cookies* because they typically stay in the browser for long periods of time. You will find cookies on the hard drive of the PC, usually the C: drive. Cookies is a subdirectory under the Windows directory. The best way to access the Cookies subdirectory and subsequent files stored there is via MS Windows Explorer (see Exhibit 224.1). When you open this directory using Windows Explorer, you will find a listing of the Cookies for those Web sites that you have visited. If there are no files under this directory, they have been deleted. If there are files under this directory, you can view the dates and times they were last accessed. You will also see the ID that was used to access these sites on this PC.

Cookies can be deleted in several ways. One way is manually. The user can access the cookies folder and delete all information from the folder. If the deletion was done manually, one place to look for cookies is in the Recycle Bin. There is a Disk Cleanup program that comes with Windows 98 and higher that deletes the information in the following folders: Cookies, Temporary Internet, Downloadable Program Files, Recycle Bin, Old ScanDisk Files, and Temporary Files. See Exhibit 224.2 for a look at the Disk Cleanup program. The Disk Cleanup program does not leave any place to look for deleted files. There are also Cookie Manager programs that will automatically delete old or expired cookies from the cookie folders. These programs allow users to set their own expiration and archive dates. For example, the user can set the Cookie Manager to delete or archive all cookies more than five days old. Some of these manager

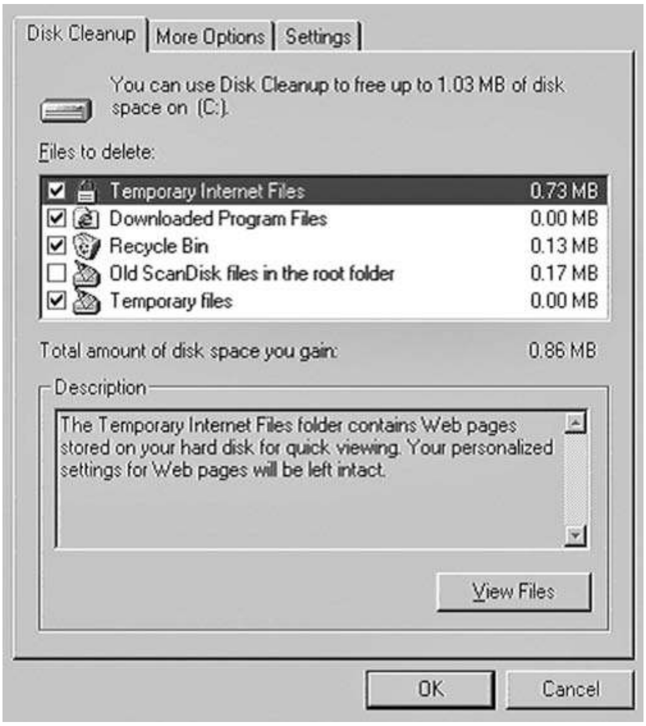
EXHIBIT 224.1 Cookies subdirectory file contents.

programs put the deleted cookies into the Recycle Bin, and some put them in a temporary archive folder. To find these archive folders, it is necessary to research the program.

For your investigation, you need to determine where each cookie takes you, keeping in mind that cookies can be named many things (see Exhibit 224.1). By seeing where each cookie takes you, you can determine what the user has been doing on the Web sites where the cookies came from. Note the date and



You can use Disk Cleanup to free up to 1.03 MB of disk space on (C:).

Files to delete:

☑	Temporary Internet Files	0.73 MB
☑	Downloaded Program Files	0.00 MB
☑	Recycle Bin	0.13 MB
☐	Old ScanDisk files in the root folder	0.17 MB
☑	Temporary files	0.00 MB

Total amount of disk space you gain: 0.86 MB

Description

The Temporary Internet Files folder contains Web pages stored on your hard disk for quick viewing. Your personalized settings for Web pages will be left intact.

EXHIBIT 224.2 Disk clean-up program from Windows 98.

time of each cookie; these indicate when the cookies were created or accessed by the user for the first time for a particular site. However, some cookies are generated without the user actually visiting a particular site. These magic cookies, which are generated without a user having to actually access a particular site, are often marketing gimmicks or ploys to get the user to go to their Web site. To determine where a user actually visited, you need to compare the cookies files to the history files. History files are described later in this chapter.

224.3.2 Bookmarks

A bookmark is a marker or address that identifies a document or a specific place in a document. Bookmarks are Internet shortcuts that users can save on the Web browser so they do not have to remember or write down the URL or location of Web sites they might like to revisit in the future. Nearly all Web browsers support a bookmarking feature that lets users save the address (URL) of a Web page so they can easily revisit the page at a later time. Bookmarks or favorites are stored in two places. One is in the Web browser under Favorites (see Exhibit 224.3). Another is on the C: (or hard) drive under the Windows folder, in a subfolder called Favorites (see Exhibit 224.4).

The bookmarks or favorites are stored under the user's desired names. By clicking on each of the bookmarks, you can visit the same Web sites the user has. Because bookmark names can be changed by the user, by sure to examine each one carefully. Avoid casually skipping over an apparently irrelevant bookmark simply because it does not look like it would be pointing to an unauthorized Web site (e.g., PrettyFlowers@Home). There is no real way to hide a bookmark, but users can bury a bookmark in a folder they create in the bookmark area, so be sure to open any folders you see in the Bookmarks listing. An advantage of viewing the favorites listing in the C: drive view is that you can see the dates and times when the bookmarks were created or modified; however, this does not provide you with a listing of the times and dates when the sites were actually visited or indicate how frequently they have been visited.

224.3.3 History Buffer

A buffer is a temporary storage area, usually in RAM. The purpose of most buffers is to act as a holding area that allows the CPU to manipulate data before transferring it to a device (e.g., a printer or other external device). Because the process of reading and writing data to a disk is relatively slow, many programs keep track of data changes in a buffer and then copy the buffer to a disk; for example, word

EXHIBIT 224.4 Bookmarks from hard-drive view.

processors employ a buffer to keep track of changes to files. When the user actively saves the file, the word processor updates the disk file with the contents of the buffer. This is much more efficient than accessing the file on the disk each time a change is made to the file. Note that because changes are initially stored in a buffer, not on the disk, all changes will be lost if the computer fails during an editing session. For this reason, it is a good idea to save files periodically. Most word processors automatically save files at regular intervals.

A history buffer is a Web browser storage area of URL sites. The Web browser's history buffer shows you a list of what URLs or sites have been visited and what screens have been opened under each URL (see Exhibit 224.5). To get to the history buffer, go to the Web browser. On the tool bar you will find an icon or button called History (see Exhibit 224.5). The history buffer can be cleared out by the user simply by highlighting and deleting the items on the list. The deleted contents from this list are not stored anywhere else in the Web browser, but they can still be found in the hard-drive history buffer. Viewing the hard-drive history buffer is done in a little different way (see Exhibit 224.6). This history buffer can be viewed via the path Windows→History. This history buffer will show you the days of the week that the user actually accessed the Web. By opening one of the days of the week subfolders, you can see the actual listings of the URLs visited by the user and the time and dates the sites were last visited. By combining each day's lists, you can identify a pattern of visitation (and browser utilization) for each Web site.

EXHIBIT 224.6 History buffer from hard-drive view.

Such information may document or prove that an employee (or at least the individual who sat at the particular PC under review) was accessing the Web: (1) in violation of company policy; (2) during working hours instead of only during predetermined allowable times (i.e., lunch breaks); (3) on weekends or during other off-schedule, non-normal times when employees or other personnel should not be in the building; or (4) to visit unapproved or unauthorized sites.

224.3.4 Cache

Cache can be either a reserved section of main memory or an independent high-speed storage device. Two types of caching are commonly used in personal computers: memory caching and disk caching. A memory cache, sometimes called a cache store or RAM cache, is a portion of memory made of high-speed static RAM (SRAM) instead of the slower and less expensive dynamic RAM (DRAM) used for main memory. Memory caching is effective because most programs access the same data or instructions over and over. By keeping as much of this information as possible in SRAM, the computer avoids accessing the slower DRAM. Some memory caches are built into the architecture of microprocessors. The Intel 80486 microprocessor, for example, contains an 8 K memory cache, and the Pentium has a 16 K cache. Such internal caches are often called Level 1 (L1) caches. Most modern PCs also come with external cache memory, referred to as Level 2 (L2) caches. These caches sit between the CPU and the DRAM. Like L1 caches, L2 caches are composed of SRAM but are much larger.

Disk caching works under the same principle as memory caching, but, instead of using high-speed SRAM, a disk cache uses conventional main memory. The most recently accessed data from the disk (as well as adjacent sectors) is stored in a memory buffer. When a program needs to access data from the disk, it first checks the disk cache to see if the data is there. Disk caching can dramatically improve the performance of applications because accessing a byte of data in RAM can be thousands of times faster than accessing the same byte on a hard disk. When data is found in the cache, it is called a *cache hit*, and the effectiveness of a cache is judged by its hit rate. Many cache systems use a technique known as smart caching, in which the system can recognize certain types of frequently used data.

Why is this cache important to computer forensics? The last set of instructions or data that was saved in the cache might provide the evidence you need for your investigation. Unfortunately, capturing the cache information is tricky and can only be done with special programs.

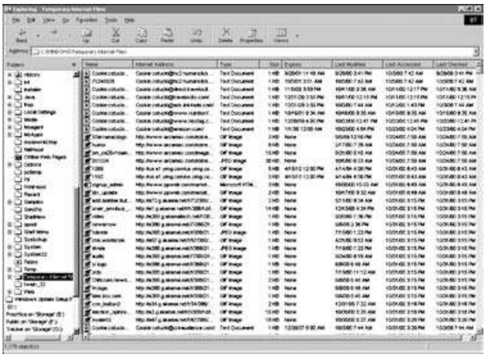

EXHIBIT 224.7 Temporary Internet files.

224.3.5 Temporary Internet Files

Temporary Internet files are "image captures" of each screen or site that you visit when you access the Internet or an intranet (see Exhibit 224.7). Temporary Internet Files is a sub folder under the Windows folder on the C: drive (or hard drive) of the PC. The advantage of looking at the temporary Internet files compared to any other files is that they show you the address of the site visited and when it was last modified, last accessed, and last checked. This can be very useful when gathering evidence regarding too much Internet access or inappropriate Internet access. These files can also be useful in proving a pattern of log-on and duration times.

224.4 Tracking Log-On Duration and Times

If you need to review log-on duration and times for a given user, you should contact the organization's network operations group (or similarly named or empowered department). This group can provide reports on any given IP address, user ID, and the times that the IP address and ID were logged into the network. Some of these reports can actually tell what addresses the user accessed and when. The most basic report should be able to tell when the ID was logged into the system and when it logged off. With some of the current system architecture, the reports track and log all user activity down to the keystroke; however, this kind of detailed logging can drag down the performance of servers so logging is not always done to this level of detail. You must ask your network operations personnel what type of reporting and subsequent information is available.

Ask for the entire detail report and see what they record; do not just ask for the basics. You might save time and effort if you ask for everything up front. You should ask for not only the activity report but also server monitor reports that pertain to the user, traffic monitoring reports, and site click-through reports. You want every report that exists that might show what a given user was doing at any moment. You might be surprised at just how much information is available and how eager operations staff personnel are to apply their expertise. Some of the evidence you can gather to help determine log-on and duration times can be derived from the Temporary Internet Files and Recent Documents lists. These files can help establish and support patterns of use. Although a smart user might clean up these files frequently by using the Disk Cleanup utilities that Windows provides, it is always a good idea to check to see what information is still available. The cleanup utilities can be accessed by Start Menu → Programs → Accessories → Disk Cleanup. These utilities erase the Internet files, temporary files, and most cookies. See prior sections of this chapter on how to find and access temporary files.

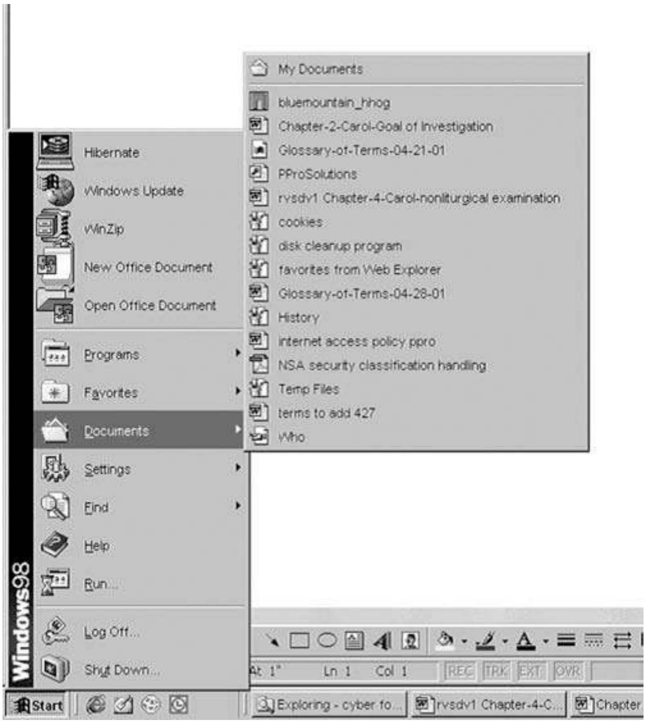

EXHIBIT 224.8 Recent document list from Start menu.

224.5 Recent Documents List

The Recent Documents list can show you the latest documents that a user has accessed. There are two ways to see this list of documents, but only one shows you when the items on the list were accessed. First, you can see the documents from the Start menu, under the Documents "tab"/selection. You can click on any one of the documents listed to bring the document is up on the screen (see Exhibit 224.8). You can also access the same list, via the Recent subfolder under the Windows folder (see Exhibit 224.9).This view

will give you the name of the document and when each was last modified. Windows 95 does not have this directory; only Windows 98 and more recent copies of Windows have a Recent directory.

224.6 Tracking Illicit Software Installation and Use

If you are investigating a user who may be loading illegal, illicit, or non-work-related software on his or her PC, there are a number of places to check within the user's PC to prove or disprove these unauthorized (and maybe even illegal) actions. Some of these key places include the System Registry and System Information, or the contents of the hard drive can be viewed. Before you begin this part of an investigation, you must first get a listing of all approved software that can reside on a given PC. This list most probably contains things such as Word, Excel, Microsoft Office, and other work-related software. There should be a master list (i.e., database) of what software resides on every PC that operations maintains; however, due to some site license agreements, software appearing on a master checklist that operations personnel use to set up new PCs might not be on every PC.

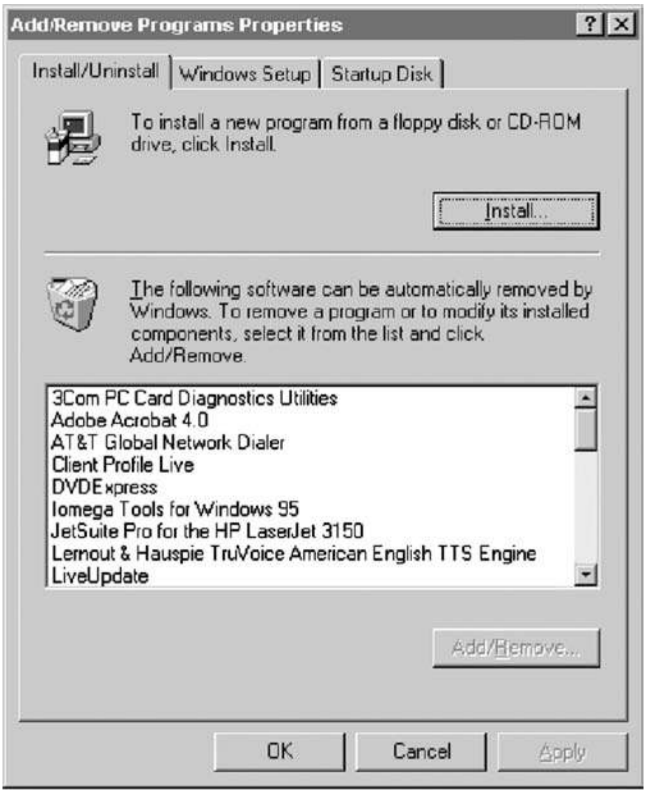
The company policies and procedures should have an outline of the software that is not permitted to be loaded on a company-owned PC. The most recognizable programs that are usually not work related are games. When looking for these types of programs, look carefully at the names of the files; users often change the names to avoid detection. To double-check the legitimacy of a program, launch all.exe files to reveal what is actually behind a file name and what resides on the PC. Remember that this procedure should be carried out on the mirror-imaged, working copy data, not on the original PC. This prevents corrupting seized data as well as disrupting networked services or other legitimate data that may reside on the PC in question.

As you are checking the software list, you should also note all the serial numbers and registration numbers of all software that resides on the PC. These numbers should be compared to the software licenses held by the company to ensure that the loaded software is both legal and authorized. For example, a user might have MS Access on his or her PC, but the company might not have authorized or actually loaded this software on that user's PC. The user might have obtained certain software packages in some manner not complying with company procedures and thus it has been illegally installed on the PC. This is the most common incidence of illegally installed software on company equipment today. Such software installations are risky to a company because software license infringement can be expensive if it is discovered and not corrected.

So, how do you actually begin to search for this evidence? First, you need your lists of what can be on any given PC and what is registered to be on the specific PC you are investigating. You are also looking for a list of all information that pertains to the PC under review—specifically, information such as verification of assignment of the PC to a specific employee and, if available, all software licensed for the given PC. You should then check and compare the information on these lists against the master list maintained by operations personnel. Next, you should list all the programs that currently reside on the PC. One way to do so is to use the System Registry files, referred to as a system review. Another method is to review all files via the PC directories (i.e., Explorer), referred to as a manual review. Both methods are discussed briefly in the following paragraphs.

224.6.1 The System Review

The system review can be conducted using some automated methods. One of these methods is to use the System Registry files. There are several system registries. We will discuss the two primary Microsoft registry files: (1) a list of all software loaded on the PC, and (2) a more comprehensive list of what is loaded, when it was loaded, and how it is configured. Both can be used to verify that illegal or non-work-related software was loaded onto a given PC or hardware added. A simple list of what has been loaded can be viewed by accessing the path from the Control Panel to the Add/Remove Programs icon (see Exhibit 224.10). A more comprehensive list of software and hardware that have been loaded onto a PC can be obtained via the Microsoft System Information panels. The following path can access



To install a new program from a floppy disk or CD-ROM drive, click Install.

The following software can be automatically removed by Windows. To remove a program or to modify its installed components, select it from the list and click Add/Remove.

these: Start → Programs → Accessories → System Tools → System Information (see Exhibit 224.11). This screen shows basic system information for the PC being investigated. The most useful information about a PC can be found under the Components directory. This is where you will find some history—when things were loaded and last modified (see Exhibit 224.12). Three levels of information are shown on this screen: Basic, Advanced, and History. All three can provide needed information in an investigation, depending on what you are looking to prove.

The Components/System/Basic information can help determine if illegal or non-work-related software was loaded onto a PC (see Exhibit 224.12). T0 determine if there is illegal software or non-work-related software on the PC, first you need a list of all legal software that should be on the machine, along with any

EXHIBIT 224.12 System components/System/Basic information.

serial or license numbers for the software. This list should be available from operations personnel who distribute and fix the PCs. Next, take this list and verify what software is on the machine; be sure to check the serial numbers. The components/system/basic information list tells you what software is on the machine and when it was loaded, but the serial numbers will be in the "About" information or start-up screen for the software. If the software is not work related, it will not be on your list from the operations department.

Another view to see if software has been loaded onto the PC from the Web is available via Windows Explorer, in the Windows Directory under the Download Program subfolder (see Exhibit 224.13). The Components/System/History information can show when a component (piece of hardware or firmware) was loaded and when it was last modified (see Exhibit 224.14); however, many components are modified when the user reboots or turns on the computer. The "red herring" items to look for in this history would be things that were not issued with the computer and the user added himself. These might include graphics cards, emulators, or sound cards. The Component/History files are not much different in the information that they provide (see Exhibit 224.14). Exhibit 224.15 shows what has been updated in the

224.6.2 The Manual Review

One of the reasons for conducting a manual review in addition to a system review is to be sure that you have covered all of the bases. What the manual review will tell you that the system review will not is what actual applications reside on the PC. The first step in the manual review is to locate all executable programs and applications on the PC. Start Explorer—not the Web browser Internet Explorer, but Microsoft Explorer. From the top menu select Tools → Find → Files and Folders. This will give you a pop-up box where you can identify what you want to search for. In this case, we use a wild card query to find all files ending with.exe, or all executable files. Set the "Look in" field to the drive you are investigating, which is usually the C: drive. Select the option to look at all of the C: drive. See Exhibit 224.16 for an example of the results of this search. This can be quite an extensive list; however, you should check each of

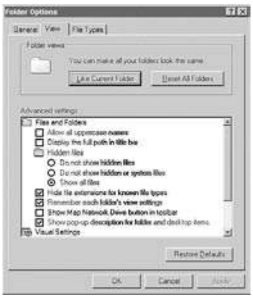
these references to ensure that they do belong to authorized programs. Most unauthorized programs are put under the Programs directory, but do not assume anything; check them all. You can check them by actually launching them. You can do this by clicking on the file from the Find screen. To record your findings, it might be best to print this screen and manually check off each item on the list as you verify it. A quick review of the items in the list might narrow your investigation. If you see icons on the far left that represent something suspicious, you might investigate these first. Suspicious items might include game or playing card icons. See Exhibit 224.17 for an example of an excerpt of the full list. Exhibit 224.17 shows an item on the list with a playing card icon—see the freeplus item? This is actually a game, and for most companies and systems may be a violation and it should not be installed on the PC. Another thing to watch out for on your listing of files are Hidden files (see discussion below). You need to check the system standards and settings to determine if the File Manager allows you to see these or not before assuming that your file list is complete.

224.7 Hidden Files

A hidden file is a file with a special hidden attribute turned on so the file is not normally visible to users. Hidden files are not listed when you execute the DOS DIR command, but most file management utilities allow you to view hidden files. DOS hides some files, such as MSDOS.SYS and IO.SYS so you cannot accidentally corrupt them. You can also turn on the hidden attribute for normal files, thereby making them invisible to casual snoopers. On a Macintosh, you can hide files with the ResEdit utility. Why are hidden files important to your investigation? If the Folder Options is not set to allow you to view hidden files, you might miss evidence. To review the settings on the PC you are investigating to verify that you are seeing hidden files, you need to launch Explorer. From the top menu within Explorer, select



You can make all your folders look the same

Advanced settings:

Files and Folders
- □ Allow all uppercase names
- □ Display the full path in title bar
- Hidden files
  - ○ Do not show hidden files
  - ○ Do not show hidden or system files
  - ● Show all files
- ☑ Hide file extensions for known file types
- ☑ Remember each folder's view settings
- □ Show Map Network Drive button in toolbar
- ☑ Show pop-up description for folder and desktop items

Visual Settings

EXHIBIT 224.18 Folder options to see hidden files.

View→Folder Options→View tab on the pop-up box (see Exhibit 224.18). If the radio buttons are marked so the hidden files are not to be shown, you will not see all the files. You should reset these so you can see the hidden files and know that you have a complete list.

224.8 How To Correlate the Evidence

Now that you have captured the file evidence and the data, you can graph an access pattern or list the illegal software and when it was loaded. Next, you need to check the access and download dates and times against the timesheets, surveillance, and other witness accounts to ensure that the suspect under investigation actually had the opportunity to engage in unauthorized acts using the PC in question. In other words, you need to ensure that the employee under investigation actually had access to the equipment on the dates and times listed in the evidence. For example, if the employee had a desktop PC and did not come to work on the date that illegal software was downloaded on his PC, then you might need to look for other supporting evidence (e.g., access logs indicating potential access from an external/remote location). Be advised that the investigator must obtain solid evidence that the employee under investigation actually had an opportunity and was actually using the PC at the time that the unauthorized action took place. Failing to link the employee to the PC and to corroborate and substantiate the evidence, in an irrefutable manner, will result in an inability to hold the employee accountable for his or her actions and prosecute the employee via the existing legal system.

When reviewing the evidence you have gathered, you need to follow and show the facts—and only the facts. If you have to make leaps in your logic to get from point A to point B, then you do not have enough evidence to substantiate a claim. Also, you need to ensure that you can adequately explain how the employee under review was able to commit the offense, illegal act, unauthorized action, etc., and must also be able to present evidence regarding how it was done. This proof should be simple to follow so there is no doubt that the offense was committed. Someone's career, in addition to his or her legal freedoms, could be on the line as a result of your findings, as well as the organization's liability (for a wrongful or unsubstantiated accusation). Thus, you want to be sure of what you have found.

Honeypot Essentials

Anton Chuvakin

This chapter discusses honeypot (and honeynet) basics and definitions, and then outlines important implementation and setup guidelines. It also describes some of the security lessons a company can derive from running a research honeypot, based on this author's experience running a research honeypot. This chapter also provides insight into the techniques of attackers and concludes with considerations useful for answering the question, "Should your organization deploy a honeynet?"

225.1 Introduction and Background

Although known to security processionals for a long time, honeypots recently became a hot topic in information security. However, the amount of technical information available on their setup, configuration, and maintenance is still sparse, as are qualified people able to run them. In addition, higher-level guidelines (such as need and business-case determination) are similarly absent.

What is a honeypot? Lance Spitzner, a founder of the Honeynet Project (http://project.honeynet.org/) defines a honeypot as "a security resource whose value lies in being probed, attacked, or compromised." The Project differentiates between *research* and *production* honeypots. The former are focused on gaining intelligence information about attackers and their technologies and methods, and the latter are aimed at decreasing the risk to company IT resources and providing advance warning about the incoming attacks on the network infrastructure. Honeypots of any kind are difficult to classify using the "prevention–detection–response" metaphor, but it is hoped that after reading this chapter their value will become clearer to readers.

This chapter focuses on operating a research honeypot or a "honeynet." The term "honeynet," used in this chapter originated in the Honeynet Project and means a network of systems with fairly standard configurations connected to the Internet. The only difference between such a network and a regular production network is that all communication is recorded and analyzed, and no attacks targeted at third parties can escape the network. Sometimes, the system software is slightly modified to help deal with encrypted communication, often used by attackers. The systems are never "weakened" for easier hacking but are often deployed in default configurations with a minimum of security patches. They might or might not have known security holes. The Honeynet Project defines such honeypots as "high-interaction honeypots," meaning that attackers interact with a deception system exactly as they would with a real victim machine. On the other hand, various honeypot and deception daemons are "low-interaction," as they provide only an illusion to an attacker, and one that can hold their attention for a short time only.

Such honeypots have value as an early attack indicator but do not yield in-depth information about the attackers.

Research honeypots are set up with no extra effort to lure attackers—blackhats locate and exploit systems on their own. It happens due to the widespread use of automatic hacking tools, such as fast, multiple vulnerability scanners and automatic penetration scripts. For example, an attacker from our honeynet has attempted to scan 200,000 systems for a single FTP vulnerability in one night using such tools. Research honeypots are also unlikely to be used for prosecuting intruders; however, researchers are known to track hacker activities using various covert techniques for a long time after the intruder broke into their honeypot. In addition, prosecution based on honeypot evidence has never been tested in a court of law. It is still wise to involve the company's legal team before setting up such a hacker study project.

Overall, the honeypot is the best tool for looking into malicious hacker activity. The reason is simple: all communication to and from the honeynet is malicious by definition. No data filtering, no false-positives, and no false-negatives (the latter only if the data analysis is adequate) are obscuring the picture. Watching the honeypot provides insight into intruders' personalities and can be used to profile attackers. For example, during the summer of 2002, the majority of penetrated Linux honeypots were hacked by Romanian attackers.

225.2 Setting Up a Honeypot

What are some of the common-sense prerequisites for running a honeynet? First, a honeypot is a sophisticated security project, and it makes sense to take care of security basics first. If your firewall crashes or your intrusion detection system (IDS) misses attacks, you are clearly not yet ready for a honeypot deployment. Running a honeypot also requires advanced knowledge in computer security. After running a honeynet for netForensics (http://www.netForensics.com) and as a member of the Honeynet Research Alliance, I can state that operating a honeynet presents the ultimate challenge a security professional can face. The reason is simple: no "lock it down and maintain secure state" model is possible for such a deception network. It requires in-depth expertise in many security technologies and beyond.

Additionally, a honeypot system should not be allowed to attack other systems or, at least, such ability should be minimized. This requirement often conflicts with a desire to create a more realistic environment for malicious hackers to "feel at home" so that they manifest a full spectrum of their behavior. Related to the above is the need for proper separation of a research honey network from company production machines. In addition to protecting innocent third parties, similar measures should be utilized to prevent attacks against your own systems from your honeypot. Honeypot systems should also have reliable out-of-band management. The main reason for having this capability is to be able to quickly cut off the network access to and from the honeypot in cases of emergency (and they do happen!), even if the main network connection is saturated by an attack. That sounds contradictory to the above statement about preventing outgoing attacks but Murphy's law might play a trick or two and "human errors" can never be totally excluded.

The Honeynet Research Alliance (http://project.honeynet.org/alliance/) has guidelines on data control and data capture for the deployed honeynet. They distill the above ideas and guidelines into a well-written document "Honeynet Definitions, Requirements, and Standards" (http://project.honeynet.org/alliance/requirements.html). This document establishes some "rules of the game," which have a direct influence on honeynet firewall rule sets and IDS policies.

Data control is a capability required to control the network traffic flow in and out of the honeynet in order to contain the blackhat actions within the defined policy. For example, rules such as "no outgoing connections," "limited number of outgoing connections per time unit," "only specific protocols and/or locations for outgoing connections," "limited bandwidth of outgoing connections," "attack string filtering in outgoing connections" or their combination can be used on a honeynet. Data control functionality should be multi-layered, allow for manual and automatic intervention (such as remote disabling of the honeypot), and make every effort to protect innocent third parties from becoming victims of attacks launched from the honeynet.

Data capture defines the information that should be captured on the honeypot system for future analysis, data retention policies, and standardized data formats that facilitate information sharing between the honeynets and cross-honeynet data processing. Cross-honeypot correlation is an extremely promising area of future research because it allows for the creation of an early warning system about new exploits and attacks. Data capture also covers the proper separation of honeypots from production networks to protect the attack data from being contaminated by the regular network traffic. Another important aspect of data capture is timely documentation of attacks and other incidents occurring in the honeypot. It is crucial for research to have a well-written log of malicious activities and configuration changes performed on the honeypot system.

225.3 Running a Honeynet

Consider some of the practical aspects of running a honeynet. Our example setup, a netForensics honeynet, consists of three hosts (see Exhibit 225.1): a victim host, a firewall, and an IDS. This is the simplest configuration to maintain. However, a workable honeynet can even be set up on a single machine if a virtual environment (such as VMW are or UML-Linux) is used. Combining IDS and firewall functionality using a gateway IDS (such as Hogwash) allows one to reduce the requirement to just two machines. A gateway IDS is a host with two network cards that analyzes the traffic passing through it and can make packet-forwarding decisions (like a firewall) and send alerts based on network packet contents (like an IDS). Currently, the honeynet uses Linux on all systems but various other UNIX flavors will be deployed as "victim" servers by the time this chapter is published. Linux machines in default configurations are hacked often enough to provide a steady stream of data on blackhat activity. "Root"-level system penetration within hours of being deployed is not. UNIX also provides a safe choice for a victim system OS due to its higher transparency and ease of reproducing a given configuration.

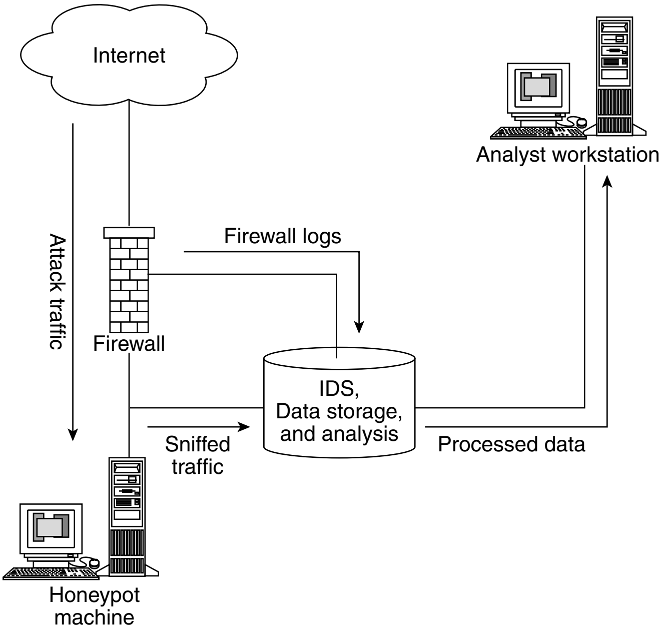

EXHIBIT 225.1 Example setup.

The honeypot is run on a separate network connection—always a good idea because the deception systems should not be seen as owned by your organization. The firewall (hardened Linux "iptables" stateful firewall) allows and logs all the inbound connections to the honeypot machines and limits the outgoing traffic, depending on the protocol (with full logging as well). It also blocks all IP spoofing attempts and fragmented packets, which are often used to conceal the source of a connection or launch a denial-of-service attack. The firewall also protects the analysis network from attacks originating from the honeypot. In fact, in the above setup, an attacker has to pierce two firewalls to get to the analysis network. The IDS machine is also firewalled, hardened, and runs no services accessible from the untrusted network. The part of the rule set relevant to protecting the analysis network is very simple: no connections are allowed from the untrusted LAN to an analysis network. The IDS (Snort from www.snort.org) records all network traffic to a database and a binary traffic file via a stealth IP-less interface and also sends alerts on all known attacks detected by its wide signature base (approximately 1650 signatures as of July 2002). In addition, specially designed software is used to monitor the intruder's keystrokes and covertly send them to a monitoring station.

All data capture and data control functionality is duplicated as per Honeynet Project requirements. The 'tcpdump' tool is used as the secondary data capture facility, bandwidth-limiting device serves as the second layer of data control and the stealth kernel-level key logger backs up the keystroke recording. Numerous automated monitoring tools, some custom-designed for the environment, monitor the honeypot network for alerts and suspicious traffic patterns.

Data analysis is crucial for the honeypot environment. The evidence—in the form of system, firewall and IDS log files, IDS alerts, keystroke captures, and full traffic captures—is generated in overwhelming amounts. Events are correlated and suspicious ones are analyzed using the full packet dumps. It is highly recommended to synchronize the time via Network Time Protocol on all the honeypot servers for more reliable data correlation. netForensics software can be used to enable advanced data correlation and analysis. Unlike in the production environment, having traffic data available in the honeypot is extremely helpful. It also allows for reliable recognition of new attacks. For example, a Solaris attack on the "dtspcd" daemon (TCP port 6112) was first captured in one of the Project's honeypots and then reported to CERT.

The above setup has gone through six system compromises, several massive outbound denial-of-service attacks (all blocked by the firewall!), major system vulnerability scanning, serving as an Internet Relay Chat server for Romanian hackers, and other exciting stuff. It passed with flying colors through all the above "adventures" and can be recommended for deployment.

225.4 Lessons Learned

What insight have we gained about the attacking side from running the honeynet? It is true that most of the attackers "caught" in such honeynets are "script kiddies"; that is, the less enlightened part of the hacker community. Although famous early honeypot stories (such as those described in Bill Cheswick's "An Evening with Berferd" and Cliff Stolls' "Cuckoo's Nest") dealt with advanced attackers, most honeypot experiences will probably be related to script kiddies. Opposite to common wisdom, companies do have something to fear from the script kiddies. The number of scans and attacks aimed by the attackers at Internet-facing networks ensures that any minor mistake in network security configuration will be discovered fairly soon. Every unsecured server running a popular operating system (such as Solaris, Linux, or Windows) will be taken over fairly soon. Default configurations and bugs in services (UNIX/Linux ssh, bind, ftpd, and now even Apache Web server and Windows IIS are primary examples) are the reason. We have captured and analyzed multiple attack tools using the above flaws. For example, a fully automated scanner that looks for 25 common UNIX vulnerabilities, runs hundreds of attack threads simultaneously, and deploys a rootkit on the system is one such tool. The software can be set to choose a random A class (16 million hosts) and first scan it for a particular network service (currently, FTP is the favorite, see http://www.dshield. org site for some global scan and attack statistics). Then on the second pass, the program collects FTP banners (such as "ftp.example.com FTP server (Version wu-2.6.1-16) ready") for target selection. On the third pass, the servers that had the misfortune of running a particularly vulnerable version of the FTP daemon are attacked, exploited, and back-doored for convenience. The owner of such a tool can return in the morning to pick up a list of IP addresses that he now "owns" (meaning, has privileged access to).

In addition, malicious attackers are known to compile Internet-wide databases of available network services, complete with their versions so that the hosts can be compromised quickly after the new software flaw is discovered. In fact, there is always a race between various groups to take over more systems. This advantage can come in handy in case of a local denial-of-service (DoS) war. While "our" attackers have not tried to draft the honeypot in their army of "zombie" bots, they did use it to launch old-fashioned, point-to-point DoS attacks (such as UDP, ping floods, and even the ancient modem hang-up ATH DoS).

Attacker behavior seems to indicate that attackers are accustomed to operating with no resistance. One attacker's first action was changing the "root" password on the system—clearly an action that will be noticed the next time the system admin tries to log in. Not a single attacker bothered to check for the presence of the Tripwire integrity checking system, which is included by default in many Linux distributions. On the next Tripwire run, all the "hidden" files are easily discovered. One more attacker had created a directory for himself as "/his-hacker-handle," something that every system admin worth his or her salt will see at once. The rootkits (i.e., hacker toolkits to maintain access to a system that include backdoors, Trojans, and common attack tools) now reach megabyte sizes and feature graphical installation interfaces suitable for novice blackhats. Research indicates that some of the script kiddies "own" networks consisting of hundreds of machines that can be used for DoS or other malicious purposes.

The exposed UNIX system is most often scanned for ports 111 (RPC services) and 21 (FTP). Recent (2000–2002) remote "root" bugs in those services account for this phenomenon. The system with a vulnerable FTP daemon is compromised within two to five days via the WU-FTPD hole described in CERT advisory CA-2001-33.

Another benefit of running a honeypot is a better handle on the Internet noise. Clearly, security professionals who run Internet-exposed networks are well aware of the common Internet noise (such as CodeRed and now SQL worms, warez site FTP scans, etc.). A honeypot allows one to observe the minor oscillations of such noise. Sometimes, such changes are meaningful. In the recent case of the MS SQL worm, we detected a sharp increase in TCP port 1433 access attempts just before the news of the worm became public. The number of hits was similar to a well-researched CodeRed growth pattern. Thus, we concluded that a new worm was out.

An additional value of the honeypot is in its use as a security training platform. Using the honeypot, a company can bring up the level of incident response skills of its security team. Honeypot incidents can be investigated and then the answers verified by the honeypot's enhanced data collection capabilities. What tool was used to attack? Here it is, on the captured hard drive or extracted from network traffic. What did they want? Look at their shell command history and know. One can quickly and effectively develop network and disk forensics skills, attacker tracking, log analysis, IDS tuning, and many other critical security skills in the controlled but realistic environment of the honeypot.

More advanced research uses of the honeypot include hacker profiling and tracking, statistical and anomaly analysis of incoming probes, the capture of worms, and analysis of malicious code development. By adding some valuable resources (such as E-commerce systems and billing databases) and using the covert intelligence techniques to lure attackers in, more sophisticated attackers can be attracted and studied.

Note that these advanced techniques will increase the operating risks.

225.5 Conclusion

Trying to answer the question "Should you do it?" concludes the discussion. The precise answer depends on your organization's mission and available security expertise. Again, the emphasis here is on research honeypots and not on "shield" or protection honeypots. If your organization has taken care of most routine security concerns, has a developed in-house security program (calling an outside consultant to investigate your honeypot incident does not qualify as a wise investment), and requires first-hand knowledge of attacker techniques and last-minute Internet threats, the answer tends toward a tentative "yes." Major security vendors and consultancies or universities with advanced computer security programs might fall into this category. If you are not happy with your existing security infrastructure and want to replace or supplement it with the new, cutting-edge "honeypot technology," the answer is a resounding "no." Research honeypots will not *directly* impact the safety of your organization. Moreover, honeypots have their inherent dangers. They are analyzed in chapters posted on the Honeynet Project site. The dangers include uncertain liability status, possible hacker retaliation, and others.

226

Managing the Response to a Computer Security Incident

Michael Vangelos

Organizations typically devote substantial information security resources to the prevention of attacks on computer systems. Strong authentication is used, with passphrases that change regularly, tokens, digital certificates, and biometrics. Information owners spend time assessing risk. Network components are kept in access-controlled areas. The least privilege model is used as a basis for access control. There are layers of software protecting against malicious code. Operating systems are hardened, unneeded services are disabled, and privileged accounts are kept to a minimum. Some systems undergo regular audits, vulnerability assessments, and penetration testing. Add it all up, and these activities represent a significant investment of time and money.

Management makes this investment despite full awareness that, in the real world, it is impossible to prevent the success of all attacks on computer systems. At some point in time, nearly every organization must respond to a serious computer security incident. Consequently, a well-written computer incident response plan is an extremely important piece of the information security management toolbox. Much like disaster recovery, an incident response plan is something to be fully developed and practiced—although one hopes that it will never be put into action.

Management might believe that recovering from a security incident is a straightforward exercise that is part of an experienced system administrator's job. From a system administrator's perspective, that may be true in many instances. However, any incident may require expertise in a number of different areas and may require decisions to be made quickly based on factors unique to that incident. This chapter discusses the nature of security incidents, describes how to assemble an incident response team (IRT), and explains the six phases of a comprehensive response to a serious computer security incident.

226.1 Getting Started

226.1.1 Why Have an Incident Response Plan?

All computer systems are vulnerable to attack. Attacks by internal users, attacks by outsiders, low-level probes, direct attacks on high-privilege accounts, and virus attacks are only some of the possibilities. Some attacks are merely annoying. Some can be automatically rejected by defenses built into a system. Others are more serious and require immediate attention. In this chapter, incident response refers to handling of the latter group of attacks and is the vehicle for dealing with a situation that is a direct threat to an information system.

Some of the benefits of developing an incident response plan are:

- *Following a predefined plan of action can minimize damage to a network.* Discovery that a system has been compromised can easily result in a state of confusion, where people do not know what to do. Technical staff may scurry around gathering evidence, unsure of whether they should disable services or disconnect servers from the network. Another potential scenario is that system administrators become aggressive, believing their job is to "get the hacker," regardless of the effect their actions may have on the network's users. Neither of these scenarios is desirable. Better results can be attained through the use of a plan that guides the actions of management as well as technicians during the life of an incident. Without a plan, system administrators may spend precious time figuring out what logs are available, how to identify the device associated with a specific IP address, or perform other basic tasks. With a plan, indecision can be minimized and staff can act confidently as they respond to the incident.
- *Policy decisions can be made in advance.* An organization can make important policy decisions before they are needed, rather than in the heat of the moment during an actual incident. For example, how will decisions be made on whether gateways or servers will be taken down or users disconnected from the network? Will technicians be empowered to act on their own, or must management make those decisions? If management makes those decisions, what level of management? Who decides whether and when law enforcement is notified? If a system administrator finds an intruder with administrative access on a key server, should all user sessions be shut down immediately and log-ins prohibited? If major services are disrupted by an incident, how are they prioritized so that technicians understand the order in which they should be recovered? Invariably, these and other policy issues are best resolved well in advance of when they are needed.
- *Details likely to be overlooked can be documented in the plan.* Often, a seemingly unimportant event turns into a serious incident. A security administrator might notice something unusual and make a note of it. Over the next few days, other events might be observed. At some point, it might become clear that these events were related and constitute a potential intrusion. Unless the organization has an incident response plan, it would be easy for technical staff to treat the situation as simply another investigation into unusual activity. Some things may be overlooked, such as notifying internal audit, starting an official log of events pertaining to the incident, and ensuring that normal cleanup or routine activities do not destroy potential evidence. An incident response plan will provide a blueprint for action during an incident, minimizing the chance that important activities will fall through the cracks.
- *Nontechnical business areas must also prepare for an incident.* Creation of an incident response plan and the act of performing walk-throughs or simulation exercises can prepare business functions for incident response situations. Business functions are typically not accustomed to dealing with computer issues and may be uncomfortable providing input or making decisions if "thrown into the fire" during an actual incident. For example, attorneys can be much better prepared to make legal decisions if they have some familiarity with the incident response process. Human resources and public relations may also be key players in an incident and will be better able to protect the

organization after gaining an understanding of how they fit into the overall incident response plan.

- *A plan can communicate the potential consequences of an incident to senior management.* It is no secret that, over time, companies are becoming increasingly dependent on their networks for all aspects of business. The movement toward the ability to access all information from any place at any time is continuing. Senior executives may not have an appreciation for the extent to which automation systems are interconnected and the potential impact of a security breach on information assets. Information security management can use periodic exercises in which potential dollar losses and disruption of services in real-life situations are documented to articulate the gravity of a serious computer security incident.

226.1.2 Requirements for Successful Response to an Incident

There are some key characteristics of effective response to a computer security incident. They follow from effective preparation and the development of a plan that fits into an organization's structure and environment. Key elements of a good incident response plan are:

- *Senior management support.* Without it, every other project and task will drain resources necessary to develop and maintain a good plan.
- *A clear protocol for invoking the plan.* Everyone involved should understand where the authority lies to distinguish between a problem (e.g., a handful of workstations have been infected with a virus because users disabled anti-virus software) and an incident (e.g., a worm is being propagated to hundreds of workstations and an anti-virus signature does not exist for it). A threshold should be established as a guide for deciding when to mobilize the resources called for by the incident response plan.
- *Participation of all the right players.* Legal, audit, information security, information technology, human resources, protection (physical security), public relations, and internal communications should all be part of the plan. Legal, HR, and protection may play an important role, depending on the type of incident. For some organizations, public relations may be the most important function of all, ensuring that consistent messages are communicated to the outside world.
- *Clear establishment of one person to be the leader.* All activity related to the incident must be coordinated by one individual, typically from IT or information security. This person must have a thorough knowledge of the incident response plan, be technical enough to understand the nature of the incident and its impact, and have the ability to communicate to senior management as well as technical staff.
- *Attention to communication in all phases.* Depending on the nature of the incident, messages to users, customers, shareholders, senior management, law enforcement, and the press may be necessary. Bad incidents can easily become worse because employees are not kept informed and cautioned to refer all outside inquiries concerning the incident to public relations.
- *Periodic testing and updates.* The incident response plan should be revisited regularly. Many organizations test disaster recovery plans annually or more frequently. These tests identify existing weaknesses in the plan and uncover changes in the automation environment that require corresponding adjustments for disaster recovery. They also help participants become familiar with the plan. The same benefits will be derived from simulation exercises or structured walk-throughs of an incident response plan.

226.1.3 Defining an Incident

There is no single, universally accepted definition of incident. The Computer Emergency Response Team Coordination Center (CERT/CC) at Carnegie Mellon University defines incident as "the act of violating an explicit or implied security policy."[1] That may be a great way to describe all events that are bad for computer systems, but it is too broad to use as a basis for the implementation of an incident response plan. The installation of a packet sniffer without management authorization, for instance, may be a violation of policy but probably would not warrant the formality of invoking an incident response plan. However, the use of that sniffer to capture sensitive data such as passwords may be an incident for which the plan should be invoked. The Department of Energy's Computer Incident Advisory Capability (CIAC) uses this definition for *incident*:

> Any adverse event that threatens the security of information resources. Adverse events may include compromises of integrity, denial-of-service attacks, compromise of confidentiality, loss of accountability, or damage to any part of the system. Examples include the insertion of malicious code (e.g., viruses, Trojan horses, or backdoors), unauthorized scans or probes, successful and unsuccessful intrusions, and insider attacks.[2]

This, too, is a good definition and one that is better aligned with the goal of identifying events that should trigger implementation of an incident response plan. To make this definition more useful in the plan, it should be complemented by guidelines for assessing the potential severity of an incident and a threshold describing the level of severity that should trigger invocation of the plan. Responding to an incident, as described in this chapter, involves focused, intense activity by multiple people in order to address a serious condition that may materially affect the health of an organization's information assets. Therefore, as the incident response plan is developed, an organization should establish criteria for deciding whether to invoke the plan.

226.1.4 Developing an Incident Response Team

There is no singularly correct makeup of an incident response team (IRT). However, it is generally agreed that if the following functional units exist in an organization, they should be represented: information security, information technology, audit, legal, public relations, protection (physical security), and human resources. In an ideal situation, specific individuals (preferably a primary and secondary contact) from each of these areas are assigned to the IRT. They will be generally familiar with the incident response plan and have an understanding of what kinds of assistance they may be called upon to provide for any incident. Exhibit 226.1 lists the participants and their respective roles.

Some organizations successfully manage incidents by effectively splitting an IRT into two distinct units. A technical team is made up of staff with responsibility for checking logs and other evidence, determining what damage if any has been done, taking steps to minimize damage if the incident is ongoing, and restoring systems to an appropriate state. A management team consists of representatives of the functional areas listed above and would act as a steering committee and decision-making body for the life of the incident. An individual leading the response to an incident would appoint leaders of each team or serve as chair of the management team. The two teams, of course, should be in frequent communication with each other, generally with the management team making decisions based on input from the technical team.

226.2 Six Phases of Incident Response

It is generally accepted that there are six phases to the discipline of incident response, and the cycle begins well before an incident ever occurs. In any one incident, some of these phases will overlap. In particular, eradication and recovery often occur concurrently. The phases are:

[1] CERT/CC *Incident Reporting Guidelines*, available at http://www.cert.org/tech_tips/incident_reporting.html

[2] CIAC *Incident Reporting Procedures*, available at http://doe-is.llnl.gov/

EXHIBIT 226.1 Incident Response Team Roles

Function	Probable Role
Information security	Often has responsibility for the plan and leads the response; probably leads the effort to put preventive controls in place during preparation phase; staff may also be involved in the technical response (reviewing logs, cleaning virus-infected workstations, reviewing user definitions and access rights, etc.)
Information technology	Performs most eradication and recovery activities; probably involved during detection phase; should be active during preparation phase
Audit	Independent observer who reports to highest level of the organization; can provide valuable input for improving incident response capability
Legal	May be a key participant if the incident was originated by an employee or agency hired by the victim organization; can also advise in situations where downstream liability may exist (e.g., there is evidence that a system was compromised and subsequently used to attack another company's network); may want to be involved any time a decision is made to contact law enforcement agencies; should have input to decisions on whether to prosecute criminal activity; would advise on any privacy issues
Public relations	Should coordinate all communication with the outside world; probably creates the messages that are used
Protection	May be necessary if the incident originated from within the organization and the response may involve confronting a potentially hostile employee or contractor; might also be the best entity to take custody of physical evidence
Human resources	Provides input on how to deal with a situation in which an employee caused the incident or is actively hacking the system

- Preparation
- Detection
- Containment
- Eradication
- Recovery
- Follow-up

Exhibit 226.2 briefly describes the goal of each phase.

226.2.1 Preparation Phase

If any one phase is more important than the others, it is the preparation phase. Before an incident occurs is the best time to secure the commitment of management at all levels to the development of an effective incident response capability. This is the time when a solid foundation for incident response is built. During this phase, an organization deploys preventive and detective controls and develops an incident response capability.

Management responsible for incident response should do the following:

- Name specific individuals (and alternates) as members of the IRT. Each functional area described in the preceding section of this chapter (audit, legal, human resources, public relations,

EXHIBIT 226.2 Goal of Each Incident Response Phase

Phase	Goal
Preparation	Adopt policies and procedures that enable effective incident response
Detection	Detect that an incident has occurred and make a preliminary assessment of its magnitude
Containment	Keep the incident from spreading
Eradication	Eliminate all effects of the incident
Recovery	Return the network to a production-ready status
Follow-up	Review the incident and improve incident-handling capabilities

information security, information technology) should be represented by people with appropriate decision-making and problem-solving skills and authority.

- Ensure that there is an effective mechanism in place for contacting team members. Organizations have a similar need for contacting specific people in a disaster recovery scenario. It may be possible to use the same process for incident response.
- Include guidelines for deciding when the incident response plan is invoked. One of the key areas of policy to be considered prior to an incident is answering the question, "What are the criteria for declaring an incident?"
- Specify the relative priority of goals during an incident. For example,
    - Protect human life and safety (this should always be first).
    - Protect classified systems and data.
    - Ensure the integrity of key operating systems and network components.
    - Protect critical data.
- Commit to conducting sessions to exercise the plan, simulating different types of incidents. Exercises should be as realistic as possible without actually staging an incident. An exercise may, for example, prompt legal, human resources, and protection to walk through their roles in a situation where an employee and contractor have conspired to compromise a network and are actively hacking the system while on company premises. Exercises should challenge IT and information security staff to identify the logs and other forensic data or tools that would be used to investigate specific types of incidents.
- Decide on the philosophy to be used in response to an intrusion. Should an attacker successfully hack in, does the victim organization want to get rid of the intruder as quickly as possible and get back to business (protect and proceed)? Or does the organization want to observe the intruder's movements and potentially gather data for prosecution (pursue and prosecute)?
- Ensure that there is a reasonable expectation that the skills necessary to perform the technical tasks of the incident response plan are present in the organization. Enough staff should understand the applicable network components, forensic tools, and the overall plan so that when an incident occurs, it can be investigated in a full and competent manner.
- Make adjustments to the plan based on test scenario exercises and reviews of the organization's response to actual incidents.
- Review the organization's security practices to ensure that intrusion detection systems are functional, logs are activated, sufficient backups are taken, and a program is in place for regularly identifying system vulnerabilities and addressing those vulnerabilities.

226.2.2 Detection Phase

The goal of the detection phase is to determine whether an incident has occurred. There are many symptoms of a security incident. Some common symptoms are:

- New user accounts not created by authorized administrators
- Unusual activity by an account, such as an unexpected log-in while the user is known to be on vacation or use of the account during odd hours
- Unexpected changes in the lengths of timestamps of operating system files
- Unusually high network or server activity or poor system performance
- Probing activity such as port scans
- For Windows operating systems, unexplained changes in registry settings
- Multiple attempts to log in as root or administrator

Various tools are available to help detect activity that could indicate a security incident. First, there are system logs. Systems should be configured so that logs capture events such as successful and failed log-ins of administrator-level accounts. In addition, failed log-ins of all accounts should be logged. Because log data is relatively worthless unless someone analyzes it, logs should be reviewed on a regular basis. For many systems, the amount of data captured in logs is so great that it is impossible to review it without a utility that searches for and reports those records that might be of interest.

Data integrity checkers exist for UNIX and Windows platforms. These utilities typically keep a database of hash values for specified files, directories, and registry entries. Any time an integrity check is performed, the hash value for each object is computed and compared to its corresponding value in the database. Any discrepancy indicates that the object has changed since the previous integrity check. Integrity checkers can be good indications of an intrusion, but it can take a great deal of effort to configure the software to check only those objects that do not change due to normal system activity.

Intrusion detection systems (IDSs) claim to identify attacks on a network or host in real-time. IDSs basically come in two flavors—network based and host based. A network-based IDS examines traffic as it passes through the IDS sensor, comparing sequences of packets to a database of attack signatures. If it finds a match, the IDS reports an event, usually to a console. The IDS may also be able to send an e-mail or dial a pager as it detects specific events. In contrast, a host-based IDS examines log data from a specific host. As the system runs, the IDS looks at information written to logs in real-time and reports events based on policies set within the IDS.

Organizations become aware of security incidents in many ways. In one scenario, technical staff probably notices or is made aware of an unusual event and begins to investigate. After some initial analysis, it is determined that the event is a threat to the network, so the incident response plan is invoked. If so, the IRT is brought together and formal logging of all activity related to this incident begins. It should be noted that early detection of an incident could mean a huge difference in the amount of damage and cost to the organization. In particular, this is true of malicious code attacks as well as intrusions.

In this phase, the IRT is formally called into action. It is important that certain things occur at this time. Perhaps most importantly, one person should take charge of the process. A log of all applicable events should be initiated at this time and updated throughout the incident. Everyone involved in responding to the incident must be aware of the process. They should all be reminded that the incident will be handled in accordance with guidance provided by the plan, that technical staff should communicate all new developments as quickly as possible to the rest of the team, that everyone must remember to observe evidence chain-of-custody guidelines, and that all communication to employees as well as the outside world should flow through official channels. Some organizations will specify certain individuals who should always be notified when the incident response plan is invoked, even if they are not members of the IRT. For example, the highest internal audit official, COO, the highest information security official, or, in the case where each division of an organization has its own incident response capability, corporate information security may be notified.

226.2.3 Containment Phase

The goal of the containment phase is to keep the incident from spreading. At this time, actions are taken to limit the damage. If it is a malicious code incident, infected servers and workstations may be disconnected from the network. If there is an intruder on the network, the attacker may be limited to one network segment and most privileged accounts may be temporarily disabled. If the incident is a denial-of-service attack, the sources may be able to be identified and denied access to the target network. If one host has been compromised, communication to other hosts may be disabled.

There is much that can be done prior to an incident to make the job of containment easier. Putting critical servers on a separate subnet, for example, allows an administrator to quickly deny traffic to those servers from any other subnet or network known to be under attack.

It is prudent to consider certain situations in advance and determine how much risk to take if faced with those situations. Consider a situation where information security staff suspects that a rogue NT/2000 administrator with privileges at the top of the tree is logged in to the company's Active Directory (AD). In effect, the intruder is logged in to every Windows server defined to the AD. If staff cannot identify the workstation used by the intruder, it may be best to immediately disconnect all workstations from the network. On the other hand, such drastic action may not be warranted if the intrusion occurs on a less sensitive or less critical network segment. In another example, consider a devastating e-mail-borne worm spreading through an enterprise. At what point is the e-mail service disabled? The incident response plan should contain guidance for making this decision.

The containment phase is also the time when a message to users may be appropriate. Communication experts should craft the message, especially if it goes outside the organization.

226.2.4 Eradication Phase

Conceptually, eradication is simple—this is the phase in which the problem is eliminated. The methods and tools used will depend on the exact nature of the problem. For a virus incident, anti-virus signatures may have to be developed and applied; and hard drives or e-mail systems may need to be scanned before access to infected systems is allowed to resume. For an intrusion, systems into which the intruder was logged must be identified and the intruder's active sessions must be disconnected. It may be possible to identify the device used by the intruder and either logically or physically separate it from the network. If the attack originated from outside the network, connections to the outside world can be disabled.

In addition to the immediate effects of the incident, such as an active intruder or virus, other unauthorized changes may have been made to systems as a result of the incident. Eradication includes the examination of network components that may have been compromised for changes to configuration files or registry settings, the appearance of Trojan horses or backdoors designed to facilitate a subsequent security breach, or new accounts that have been added to a system.

226.2.5 Recovery Phase

During the recovery phase, systems are returned to a normal state. In this phase, system administrators determine (as well as possible) the extent of the damage caused by the incident and use appropriate tools to recover. This is primarily a technical task, with the nature of the incident determining the specific steps taken to recover. For malicious code, anti-virus software is the most common recovery mechanism. For denial-of-service attacks, there may not even be a recovery phase. An incident involving unauthorized use of an administrative-level account calls for a review of (at least) configuration files, registry settings, user definitions, and file permissions on any server or domain into which the intruder was logged. In addition, the integrity of critical user databases and files should be verified.

This is a phase where tough decisions may have to be made. Suppose, for example, the incident is an intrusion and an administrative account was compromised for a period of two days. The account has authority over many servers, such as in a Windows NT domain. Unless one can account for every action taken by the intruder (maybe an impossible task in the real world), one can never be sure whether the intruder altered operating system files, updated data files, planted Trojan horses, defined accounts that do not show up in directory listings, or left time bombs. The only ways to be absolutely certain that a server has been recovered back to its preincident state is to restore from backup using backup tapes known to be taken before the intrusion started, or rebuild the server by installing the operating system from scratch. Such a process could consume a significant amount of time, especially if there are hundreds of servers that could have been compromised. So if a decision is made not to restore from tape or rebuild servers, an organization takes on more risk that the problem will not be fully eradicated and systems fully restored. The conditions under which an organization is willing to live with the added risk is a matter deserving of some attention during the preparation phase.

226.2.6 Follow-Up Phase

It should come as no surprise that after an incident has been detected, contained, eradicated, and all recovery activities have been completed, there is still work to do. In the follow-up phase, closure is brought to the matter with a thorough review of the entire incident.

Specific activities at this time include:

- Consolidate all documentation gathered during the incident.
- Calculate the cost.
- Examine the entire incident, analyzing the effectiveness of preparation, detection, containment, eradication, and recovery activities.
- Make appropriate adjustments to the incident response plan.

Documentation should be consolidated at this time. There may have been dozens of people involved during the incident, particularly in large, geographically dispersed organizations. If legal proceedings begin years later, it is highly unlikely that the documentation kept by each participant will still exist and be accessible when needed. Therefore, all documentation must be collected and archived immediately. There should be no question about the location of all information concerning this incident. Another potential benefit to consolidating all of the documentation is that a similar incident may occur in the future, and individuals handling the new incident should be able to review material from the earlier incident.

The cost of the incident should be calculated, including direct costs due to data loss, loss of income due to the unavailability of any part of the network, legal costs, cost of recreating or restoring operating systems and data files, employee time spent reacting to the incident, and lost time of employees who could not access the network or specific services.

All aspects of the incident should be examined. Each phase of the plan should be reviewed, beginning with preparation. How did the incident occur—was there a preventable breakdown in controls, did the attacker take advantage of an old, unpatched vulnerability, was there a serious virus infection that may have been prevented with more security awareness? Exhibit 226.3 shows questions that could apply at each phase of the incident.

Appropriate adjustments should be made to the incident response plan and to information security practices. No incident response plan is perfect. An organization may be able to avoid future incidents, reduce the damage of future incidents, and get in a position to respond more effectively by applying knowledge gained from a postincident review. The review might indicate that changes should be made in any number of places, including the incident response plan, existing controls, the level of system monitoring, forensic skills of the technical staff, or the level of involvement of non-IT functions.

226.3 Other Considerations

226.3.1 Common Obstacles to Establishing an Effective Incident Response Plan

It may seem that any organization committed to establishing an incident response plan would be able to put one in place without much difficulty. However, there are many opportunities for failure as you address the issue of incident response. This section describes some of the obstacles that may arise during the effort.

- There is a tendency to think of serious computer security incidents primarily as IT issues to be handled on a technical level. They are not. Security incidents are primarily business issues that often have a technical component that needs prompt attention. Organizations that consider security incidents to be IT issues are more likely to make the mistake of including only IT and information security staff on the IRT.

EXHIBIT 226.3 Sample Questions for Postincident Review

Preparation

- Were controls applicable to the specific incident working properly?
- What conditions allowed the incident to occur?
- Could more education of users or administrators have prevented the incident?
- Were all of the people necessary to respond to the incident familiar with the incident response plan?
- Were any actions that required management approval clear to participants throughout the incident?

Detection

- How soon after the incident started did the organization detect it?
- Could different or better logging have enabled the organization to detect the incident sooner?
- Does the organization even know exactly when the incident started?
- How smooth was the process of invoking the incident response plan?
- Were appropriate individuals outside of the incident response team notified?
- How well did the organization follow the plan?
- Were the appropriate people available when the response team was called?
- Should there have been communication to inside and outside parties at this time; and if so, was it done?
- Did all communication flow from the appropriate source?

Containment

- How well was the incident contained?
- Did the available staff have sufficient skills to do an effective job of containment?
- If there were decisions on whether to disrupt service to internal or external customers, were they made by the appropriate people?
- Are there changes that could be made to the environment that would have made containment easier or faster?
- Did technical staff document all of their activities?

Eradication and Recovery

- Was the recovery complete—was any data permanently lost?
- If the recovery involved multiple servers, users, networks, etc., how were decisions made on the relative priorities, and did the decision process follow the incident response plan?
- Were the technical processes used during these phases smooth?
- Was staff available with the necessary background and skills?
- Did technical staff document all of their activities?

- Technical staff with the skills to create and maintain an effective incident response plan may already be overworked simply trying to maintain and improve the existing infrastructure. There can be a tendency to have system administrators put together a plan in their spare time. Typically, these efforts lead to a lot of scurrying to get a plan thrown together in the last few days before a management-imposed deadline for its completion.
- It can be difficult to get senior management's attention unless a damaging incident has already occurred. Here is where it may help to draw parallels between business continuity/disaster recovery and incident response. By and large, executives recognize the benefits of investment in a good business continuity strategy. Pointing out the similarities, especially noting that both are vehicles for managing risk, can help overcome this obstacle.
- One can think of a hundred reasons not to conduct exercises of the plan. Too many people are involved; it is difficult to stage a realistic incident to test the plan; everybody is too busy; it will only scare people; etc. Lack of testing can very quickly render an incident response plan less than adequate. Good plans evolve over time and are constantly updated as the business and technical environments change. Without periodic testing and review, even a well-constructed incident response plan will become much less valuable over time.

226.3.2 The Importance of Training

It is crucial that an organization conduct training exercises. No matter how good an incident response plan is, periodic simulations or walk-throughs will identify flaws in the plan and reveal where the plan has not kept pace with changes in the automation infrastructure. More importantly, it will keep IRT members aware of the general flow as an incident is reported and the organization responds. It will give technical staff an opportunity to utilize tools that may not be used normally. Each exercise is an opportunity to ensure that all of the tools that might be needed during an incident are still functioning as intended. Finally, it will serve to make key participants more comfortable and more confident during a real incident.

226.3.3 Benefits of a Structured Incident Response Methodology

As this chapter describes, there is nothing trivial about preparing to respond to a serious computer security incident. Development and implementation of an incident response plan require significant resources and specialized skills. It is, however, well worth the effort for the following reasons.

- *An incident response plan provides structure to a response.* In the event of an incident, an organization would be extremely lucky if its technicians, managers, and users all do what they think best and those actions make for an effective response. On the other hand, the organization will almost always be better served if those people acted against the backdrop of a set of guidelines and procedures designed to take them through each step of the way.
- *Development of a plan allows an organization to identify actions and practices that should always be followed during an incident.* Examples are maintaining a log of activities, maintaining an evidentiary chain of custody, notifying specific entities of the incident, and referring all media inquiries to the public relations staff.
- *It is more likely that the organization will communicate effectively to employees if an incident response plan is in place.* If not, messages to management and staff will tend to be haphazard and may make the situation worse.
- *Handling unexpected events is easier if there is a framework that is familiar to all the participants.* Having critical people comfortable with the framework can make it easier to react to the twists and turns that sometimes occur during an incident.

Years ago, security practitioners and IT managers realized that a good business continuity plan was a sound investment. Like business continuity, a computer incident response plan has become an essential part of a good security program.

Cyber-Crime: Response, Investigation, and Prosecution

Thomas Akin

> Any sufficiently advanced form of technology is indistinguishable from magic.
>
> **—Arthur C. Clark**

As technology grows more complex, the gap between those who understand technology and those who view it as magic is getting wider. The few who understand the magic of technology can be separated into two sides—those who work to protect technology and those who try to exploit it. The first are information security professionals, the latter hackers. To many, a hacker's ability to invade systems does seem magic. For security professionals—who understand the magic—it is a frustrating battle where the numbers are in the hackers' favor. Security professionals must simultaneously protect every single possible access point, but a hacker only needs a single weakness to successfully attack a system. The lifecycle in this struggle is:

- Protection
- Detection
- Response
- Investigation
- Prosecution

First, organizations work on protecting their technology. Because 100 percent protection is not possible, organizations realized that if they could not completely protect their systems, they needed to be able to detect when an attack occurred. This led to the development of intrusion detection systems (IDSs). As organizations developed and deployed IDSs, the inevitable occurred: "According to our IDS, we've been hacked! Now what?" This quickly led to the formalization of incident response. In the beginning, most organizations' response plans centered on getting operational again as quickly as possible. Finding out the identity of the attacker was often a low priority. But as computers became a primary storage and transfer medium for money and proprietary information, even minor hacks quickly became expensive. In attempts to recoup their losses, organizations are increasingly moving into the investigation and prosecution stages of the life cycle. Today, although protection and detection are invaluable, organizations must be prepared to effectively handle the response, investigation, and prosecution of computer incidents.

227.1 Response

Recovering from an incident starts with how an organization responds to that incident. It is rarely enough to have the system administrator simply restore from backup and patch the system. Effective response will greatly affect the ability to move to the investigation phase, and can, if improperly handled, ruin any chances of prosecuting the case. The high-level goals of incident response are to preserve all evidence, remove the vulnerability that was exploited, quickly get operational again, and effectively handle PR surrounding the incident. The single biggest requirement for meeting all of these goals is preplanning. Organizations must have an incident response plan in place before an incident ever occurs. Incidents invariably cause significant stress. System administrators will have customers and managers yelling at them, insisting on time estimates. Executives will insist that they "just get the damn thing working!" Even the customer support group will have customers yelling at them about how they need everything operational now. First-time decisions about incident response under this type of stress always lead to mistakes. It can also lead to embarrassments such as bringing the system back online only to have it hacked again, deleting or corrupting the evidence so that investigation and prosecution are impossible, or ending up on the evening news as the latest casualty in the war against hackers.

To be effective, incident response requires a team of people to help recover from the incident. Technological recovery is only one part of the response process. In addition to having both IT and information security staff on the response team, there are several no technical people who should be involved. Every response should include a senior executive, general counsel, and someone from public relations. Additionally, depending on the incident, expanding the response team to include personnel from HR, the physical security group, the manager of the affected area, and even law enforcement may be appropriate.

Once the team is put together, take the time to plan response priorities for each system. In a Web server defacement, the top priorities are often getting the normal page operational and handling PR and the media. If an online transaction server is compromised and hundreds of thousands of dollars are stolen, the top priority will be tracking the intruder and recovering the money. Finally, realize that these plans provide a baseline only. No incident will ever fall perfectly into them. If a CEO is embezzling money to pay for online sex from his work computer, no matter what the standard response plan calls for, the team should probably discreetly contact the organization's president, board of directors, and general counsel to help with planning the response. Each incident's "big picture" may require changes to some of the preplanned details, but the guidelines provide a framework within which to work.

Finally, it is imperative to make sure the members of the response team have the skills needed to successfully respond to the incident. Are IT and InfoSec staff members trained on how to preserve digital evidence? Can they quickly discover an intruder's point of entry and disable it? How quickly can they get the organization functional again? Can they communicate well enough to clearly testify about technology to a jury with an average education level of sixth grade? Very few system or network administrators have these skills—organizations need to make sure they are developed. Additionally, how prepared is the PR department to handle media inquiries about computer attacks? How will they put a positive spin on a hacker stealing 80,000 credit card numbers from the customer database? Next, general counsel—how up to date are they on the ever-changing computer crime case law? What do they know about the liability an organization faces if a hacker uses its system to attack others?

Without effective response, it is impossible to move forward into the investigation of the incident. Response is more than "just get the damn thing working!" With widespread hacking tools, a volatile economy, and immature legal precedence, it is not enough to know how to handle the hacker. Organizations must also know how to handle customers, investors, vendors, competitors, and the media to effectively respond to computer crime.

227.2 Investigation

When responding to an incident, the decision of whether to formally investigate will have to be made. This decision will be based on factors such as the severity of the incident and the effect an investigation will have on the organization. The organization will also have to decide whether to conduct an internal investigation or contact law enforcement. A normal investigation will consist of:

- Interviewing initial personnel
- A review of the log files
- An intrusion analysis
- Forensic duplication and analysis
- Interviewing or interrogating witnesses and suspects

Experienced investigators first determine that there actually was an intrusion by interviewing the administrators who discovered the incident, the managers to whom the incident was reported, and even users to determine if they noticed deviations in normal system usage. Next, they will typically review system and network log files to verify the organization's findings about the intrusion. Once it is obvious that an intrusion has occurred, the investigator will move to a combination of intrusion analysis and forensics analysis. Although they often overlap, intrusion analysis is most often performed on running systems, and forensic analysis is done offline on a copy of the system's hard drive. Next, investigators will use the information discovered to locate other evidence, systems to analyze, and suspects to interview. If the attacker came from the outside, then locating the intruder will require collecting information from any third parties that the attacker passed through. Almost all outside organizations, especially ISPs, will require either a search warrant or subpoena before they will release logs or subscriber information. When working with law enforcement, they can provide the search warrant. Nonlaw enforcement investigators will have to get the organization to open a "John Doe" civil lawsuit to subpoena the necessary information. Finally, while the search warrant or subpoena is being prepared, investigators should contact the third party and request that they preserve the evidence that investigators need. Many ISPs delete their logs after 30 days, so it is important to contact them quickly.

Due to the volatility of digital evidence, the difficulty in proving who was behind the keyboard, and constantly changing technology, computer investigations are very different from traditional ones. Significant jurisdictional issues can come up that rarely arise in normal investigations. If an intruder resides in Canada, but hacks into the system by going first through a system in France and then a system in China, where and under which country's laws are search warrants issued, subpoenas drafted, or the case prosecuted? Because of these difficulties, international investigations usually require the involvement of law enforcement—typically the FBI. Few organizations have the resources to handle an international investigation. Corporate investigators can often handle national and internal investigations, contacting law enforcement only if criminal charges are desired.

Computer investigations always involve digital evidence. Such evidence is rarely the smoking gun that makes or breaks an investigation; instead, it often provides leads for further investigation or corroborates other evidence. For digital evidence to be successfully used in court, it needs to be backed up by either physical evidence or other independent digital evidence such as ISP logs, phone company records, or an analysis of the intruder's personal computer. Even when the evidence points to a specific computer, it can be difficult to prove who was behind the keyboard at the time the incident took place. The investigator must locate additional proof, often through nontechnical means such as interviewing witnesses, to determine who used the computer for the attack.

Much of technology can be learned through trial and error. Computer investigation is not one of them. Lead investigators must be experienced. No one wants a million-dollar suit thrown out because the investigator did not know how to keep a proper chain of custody. There are numerous opinions about what makes a good investigator. Some consider law enforcement officers trained in technology the best. Others consider IT professionals trained in investigation to be better. In reality, it is the person, not the specific job title, that makes the difference. Investigators must have certain qualities. First, they cannot be afraid of technology. Technology is not magic, and investigators need to have the ability to learn any type of technology. Second, they cannot be in love with technology. Technology is a tool, not an end unto itself. Those who are so in love with technology that they always have be on the bleeding edge lack the practicality needed in an investigation. An investigator's nontechnical talents are equally important. In addition to strong investigative skills, he or she must have excellent communications skills, a professional attitude, and good business skills. Without good oral communications skills, an investigator will not be able to successfully interview people or testify successfully in court if required. Without excellent written communications skills, the investigator's reports will be unclear, incomplete, and potentially torn apart by the opposing attorney. A professional attitude is required to maintain a calm, clear head in stressful and emotional situations. Finally, good business skills help make sure the investigator understands that sometimes getting an organization operational again may take precedent over catching the bad guy.

During each investigation, the organization will have to decide whether to pursue the matter internally or to contact law enforcement. Some organizations choose to contact law enforcement for any incident that happens. Other organizations never call them for any computer intrusion. The ideal is somewhere in between. The decision to call law enforcement should be made by the same people who make up the response team—senior executive management, general counsel, PR, and technology professionals. Many organizations do not contact law enforcement because they do not know what to expect. This often comes from an organization keeping its proverbial head in the sand and not preparing incident response plans ahead of time. Other reasons organizations may choose not to contact law enforcement include:

- They are unsure about law enforcement's computer investigation skills.
- They want to avoid publicity regarding the incident.
- They have the internal resources to resolve the investigation successfully.
- The incident is too small to warrant law enforcement attention.
- They do not want to press criminal charges.

The reasons many organization will contact law enforcement are:

- They do not have the internal capabilities to handle the investigation.
- They want to press criminal charges.
- They want to use a criminal prosecution to help in a civil case.
- They are comfortable with the skills of law enforcement in their area.
- The incident is international in scope.

All of these factors must be taken into account when deciding whether to involve law enforcement. When law enforcement is involved, they will take over and use state and federal resources to continue the investigation. They also have legal resources available to them that corporate investigators do not. However, they will still need the help of company personnel because those people are the ones who have an in-depth understanding of policies and technology involved in the incident. It is also important to note that involving law enforcement does not automatically mean the incident will be on the evening news. Over the past few years, the FBI has successfully handled several large-scale investigations for Fortune 500 companies while keeping the investigation secret. This allowed the organizations to publicize the incident only after it had been successfully handled and avoid damaging publicity. Finally, law enforcement is overwhelmed by the number of computer crime cases they receive. This requires them to prioritize their cases. Officially, according to the Computer Fraud and Abuse Act, the FBI will not open an investigation if there is less than $5000 in damages. The actual number is significantly higher. The reality is that a defaced Web site, unless there are quantifiable losses, will not get as much attention from law enforcement as the theft of 80,000 credit card numbers.

227.3 Prosecution

After the investigation, organizations have four options—ignore the incident, use internal disciplinary action, pursue civil action, or pursue criminal charges. Ignoring the incident is usually only acceptable for very minor infractions where there is very little loss and little liability from ignoring the incident. Internal disciplinary action can be appropriate if the intruder is an employee. Civil lawsuits can be used to attempt to recoup losses. Criminal charges can be brought against those violating local, state, or federal laws. Civil cases only require a "preponderance of evidence" to show the party guilty; criminal cases require evidence to prove someone guilty "beyond a reasonable doubt."

When going to trial, not all of the evidence collected will be admissible in court. Computer evidence is very different from physical evidence. Computer logs are considered hearsay and therefore generally inadmissible in court. However, computer logs that are regularly used and reviewed during the normal course of business are considered business records and are therefore admissible. There are two points to be aware of regarding computer logs. If the logs are simply collected but never reviewed or used, then they may not be admissible in court. Second, if additional logging is turned on during the course of an investigation, those logs will not be admissible in court. That does not mean additional logging should not be performed but that such logging needs to lead to other evidence that will be admissible.

Computer cases have significant challenges during trial. First, few lawyers understand technology well enough to put together a strong case. Second, fewer judges understand technology well enough to rule effectively on it. Third, the average jury has extremely little or no computer literacy. With these difficulties, correctly handling the response and investigation phases is crucial because any mistakes will confuse the already muddy waters. Success in court requires a skilled attorney and expert witnesses, all of whom can clearly explain complex technology to those who have never used a computer. These challenges are why many cases are currently plea-bargained before ever going to trial.

Another challenge organizations face is the financial insolvency of attackers. With the easy availability of hacking tools, many investigations lead back to teenagers. Teenagers with automatic hacking tools have been able to cause billions of dollars in damage. How can such huge losses be recovered from a 13-year-old adolescent? Even if the attacker were financially successful, there is no way an organization could recoup billions of dollars in losses from a single person.

It is also important to accurately define the losses. Most organizations have great difficulty in placing a value on their information. How much is a customer database worth? How much would it cost if it were given to a competitor? How much would it cost if it were inaccessible for three days? These are the type of questions organizations must answer after an incident. It is easy to calculate hardware and personnel costs, but calculating intangible damages can be difficult. Undervalue the damages, and the organization loses significant money. Overvaluing the damages can hurt the organization's credibility and allow opposing counsel to portray the organization as a money-hungry goliath more interested in profit than the truth.

Any trial requires careful consideration and preparation—those involving technology even more so. Successful civil and criminal trials are necessary to keep computer crime from becoming even more rampant; however, a successful trial requires that organizations understand the challenges inherent to a case involving computer crime.

227.4 Summary

For most people, technology has become magic—they know it works, but have no idea how. Those who control this magic fall into two categories—protectors and exploiters. Society uses technology to store and transfer more and more valuable information every day. It has become the core of our daily communications, and no modern business can run without it. This dependency and technology's inherent complexity have created ample opportunity for the unethical to exploit technology to their advantage. It is each organization's responsibility to ensure that its protectors not only understand protection but also how to successfully respond to, investigate, and help prosecute the exploiters as they appear.

227.5 Response Summary

- Preplan a response strategy for all key assets.
- Make sure the plan covers move than only technological recovery—it must address how to handle customers, investors, vendors, competitors, and the media to be effective.
- Create an incident response team consisting of personnel from the technology, security, executive, legal, and public relations areas of the organization.
- Be flexible enough to handle incidents that require modifications to the response plan.
- Ensure that response team members have the appropriate skills required to effectively handle incident response.

227.6 Investigation Summary

- Organizations must decide if the incident warrants an investigation.
- Who will handle the investigation—corporate investigators or law enforcement?
- Key decisions should be made by a combination of executive management, general counsel, PR, and technology staff members.
- Investigators must have strong skills in technology, communications, business, and evidence handling—skills many typical IT workers lack.
- Digital evidence is rarely a smoking gun and must be corroborated by other types of evidence or independent digital evidence.
- Knowing what computer an attack came from is not enough; investigators must be able to prove the person behind the keyboard during the attack.
- Corporate investigators can usually successfully investigate national and internal incidents. International incidents usually require the help of law enforcement.
- Law enforcement, especially federal, will typically require significant damages before they will dedicate resources to an investigation.

227.7 Prosecution Summary

- Organizations can ignore the incident, use internal disciplinary action, pursue civil action, or pursue criminal charges.
- Civil cases require a "preponderance of evidence" to prove someone guilty; criminal cases require evidence "beyond a reasonable doubt."
- Most cases face the difficulties of financially insolvent defendants; computer-illiterate prosecutors, judges, and juries; and a lack of strong case law.
- Computer logs are inadmissible as evidence unless they are used in the "normal course of business."

- Due to the challenges of testifying about complex technology, many cases result in a plea-bargain before they ever go to trial.
- Placing value on information is difficult, and overvaluing the information can be as detrimental as undervaluing it.
- Most computer attackers are financially insolvent and do not have the assets to allow organizations to recoup their losses.
- Successful cases require attorneys and expert witnesses to be skilled at explaining complex technologies to people who are computer illiterate.

Glossary

45 CFR Code of Federal Regulations Title 45 Public Welfare.

802.11 Family of IEEE standards for wireless LANS first introduced in 1997. The first standard to be implemented, 802.11b, specifies from 1 to 11 Mbps in the unlicensed band using DSSS direct sequence spread spectrum technology. The Wireless Ethernet Compatibility Association (WECA) brands it as *Wireless Fidelity* (*Wi-Fi*).

802.1X An IEEE standard for port-based layer-two authentications in 802 standard networks. Wireless LANS often use 802.1X for authentication of a user before the user has the ability to access the network.

A/S, A.S., or AS Under HIPAA, see administrative simplification.

AAL ATM adaptation layer.

AARP AppleTalk Address Resolution Protocol.

abduction A form of inference that generates plausible conclusions (which may not necessarily be true). As an example, knowing that if it is night, then a movie is on television and that a movie is on television, then abductive reasoning allows the inference that it is night.

abend Acronym for abnormal end of a task. It generally means a software crash. The abnormal termination of a computer application or job because of a non-system condition or failure that causes a program to halt.

ability Capacity, fitness, or tendency to act in specified or desired manner. Skill, especially the physical, mental, or legal power to perform a task.

ABR Area border router.

abstraction The process of identifying the characteristics that distinguish a collection of similar objects; the result of the process of abstraction is a type.

AC Access control (Token Ring).

ACC Audio communications controller.

acceptable risk The level of *residual risk* that has been determined to be a reasonable level of potential loss/disruption for a specific IT system. See also total risk, residual risk, and minimum level of protection.

acceptable use policy A policy that a user must agree to follow to gain access to a network or to the Internet.

acceptance confidence level The degree of certainty in a statement of probabilities that a conclusion is correct. In sampling, a specified confidence level is expressed as a percentage of certainty.

acceptance inspection The final inspection to determine whether or not a facility or system meets the specified technical and performance standards. Note: this inspection is held immediately after facility and software testing and is the basis for commissioning or accepting the information system.

acceptance testing The formal testing conducted to determine whether a software system satisfies its acceptance criteria, enabling the customer to determine whether to accept the system.

access The ability of a subject to view, change, or communicate with an object. Typically, access involves a flow of information between the subject and the object.

access control The process of allowing only authorized users, programs, or other computer system (i.e., networks) to access the resources of a computer system. A mechanism for limiting use of some resource (system) to authorized users.

access control certificate ADI in the form of a security certificate.

access control check The security function that decides whether a subject's request to perform an action on a protected resource should be granted or denied.

access control decision function (ADF) A specialized function that makes access control decisions by applying access control policy rules to a requested action, ACI (of initiators, targets, actions, or that retained from prior actions), and the context in which the request is made.

access control decision information (ADI) The portion (possibly all) of the ACI made available to the ADF in making a particular access control decision.

access control enforcement function (AEF) A specialized function that is part of the access path between an initiator and a target on each access that enforces the decisions made by the ADF.

Access Control Information (ACI) Any information used for access control purposes, including contextual information.

access control list (ACL) An access control list is the usual means by which access to, and denial of, service is controlled. It is simply a list of the services available, each with a list of the hosts permitted to use the services. Most network security systems operate by allowing selective use of services.

access control mechanisms Hardware, software, or firmware features and operating and management procedures in various combinations designed to detect and prevent unauthorized access and to permit authorized access to a computer system.

access control policy The set of rules that define the conditions under which an access may take place.

access controls The management of permission for logging on to a computer or network.

access list A catalog of users, programs, or processes and the specifications of the access categories to which each is assigned.

access path The logical route that an end user takes to access computerized information. Typically, it includes a route through the operating system, telecommunications software, selected application software and the access control system.

access period A segment of time, generally expressed on a daily or weekly basis, during which access rights prevail.

access protocol A defined set of procedures that is adopted at an interface at a specified reference point between a user and a network to enable the user to employ the services or facilities of that network.

access provider (AP) Provides a user of some network with access from the user's terminal to that network. This definition applies specifically for the present document. In a particular case, the AP and network operator (NWO) may be a common commercial entity.

access rights Also called *permissions* or *privileges*, these are the right granted to users by the administrator or supervisor. These permissions can be read, write, execute, create, delete, etc.

access type The nature of access granted to a particular device, program, or file (e.g., read, write, execute, append, modify, delete, or create).

accident (1) Technical—any unplanned or unintended event, sequence, or combination of events that results in death, injury, or illness to personnel or damage to or loss of equipment or property (including data, intellectual property, etc.), or damage to the environment. (2) Legal—any unpleasant or unfortunate occurrence that causes injury, loss, suffering, or death; an event that takes place without one's foresight or expectation.

accountability A security principle stating that individuals must be able to be identified. With accountability, violations or attempted violations can be traced to individuals who can be held responsible for their actions.

accountability The ability to map a given activity or event back to the responsible party; the property that ensures that the actions of an entity may be traced to that entity.

accounting The process of apportioning charges between the home environment, serving network, and user.

accreditation A program whereby a laboratory demonstrates that something is operating under accepted standards to ensure quality assurance.

accreditation (1) A management or administrative process of accepting a specific site installation/implementation for operational use based upon evaluations and certifications. (2) A formal declaration by a designated approving authority (DAA) that the AIS is approved to operate in a particular security mode using a prescribed set of safeguards. Accreditation is the official management authorization for operation of an AIS and is based on the certification process as well as other management considerations. The accreditation statement affixes security responsibility with the DAA and shows that due care has been taken for security. (3) Formal declaration by a (DAA) that an information system is approved to operate in a particular security mode using a prescribed set of safeguards at an acceptable level of risk.

accreditation authority Synonymous with designated approving authority (DAA).

accreditation boundary All components of an information system to be accredited by designated approving authority and excluding separately accredited systems, to which the information system is connected.

accreditation letter The accreditation letter documents the decision of the authorizing official and the rationale for the accreditation decision and is documented in the final accreditation package, which consists of the accreditation letter and supporting documentation.

accreditation package A product of the certification effort and the main basis for the accreditation decision. Note: The accreditation package, at a minimum, will include a recommendation for the accreditation decision and a statement of residual risk in operating the system in its environment. Other information included may vary depending on the system and the DAA.

accredited Formally confirmed by an accreditation body as meeting a predetermined standard of impartiality and general technical, methodological, and procedural competence.

Accredited Standards Committee (ASC) An organization that has been accredited by ANSI for the development of American National Standards.

accrediting authority Synonymous with designated approving authority (DAA).

accumulator An area of storage in memory used to develop totals of units or items being computed.

accuracy A performance criterion that describes the degree of correctness with which a function is performed.

ACF User data protection access control functions.

ACG Ambulatory Care Group.

ACH See Automated Clearinghouse.

ACI Access control information.

ACK Acknowledgment.

Acknowledgment (ACK) A type of message sent to indicate that a block of data arrived at its destination without error. A negative acknowledgment is called a *NAK*.

ACL See access control list.

ACM Configuration management assurance class.

acquisition organization The government organization that is responsible for developing a system.

Acquisition, development, and installation controls The process of assuring that adequate controls are considered, evaluated, selected, designed, and built into the system during its early planning and development stages and that an on-going process is established to ensure continued operation at an acceptable level of risk during the installation, implementation, and operation stages.

ACR Abbreviation for acoustic conference room, an enclosure which provides acoustic but not electromagnetic emanations shielding; ACRs are no longer procured; TCRs are systematically replacing them.

acrostic A poem or series of lines in which certain letters, usually the first in each line, form a name, motto, or message when read in sequence.

action The operations and operands that form part of an attempted access.

action ADI Action decision information associated with the action.

active object An object that has its own process; the process must be ongoing while the active object exists.

active system A system connected directly to one or more other systems. Active systems are physically connected and have a logical relationship to other systems.

active threat The threat of a deliberate unauthorized change to the state of the system.

active wiretapping The attachment of an unauthorized device (e.g., a computer terminal) to a communications circuit to gain access to data by generating false messages or control signals or by altering the communications of legitimate users.

ActiveX Microsoft's Windows-specific non-Java technique for writing applets. ActiveX applets take considerably longer to download than the equivalent Java applets; however, they more fully exploit the features of Windows.

activity monitor Antiviral software that checks for signs of suspicious activity, such as attempts to rewrite program files, format disks, etc.

ad blocker Software placed on a user's personal computer that prevents advertisements from being displayed on the Web. Benefits of an ad blocker include the ability of Web pages to load faster and the prevention of user tracking by ad networks.

Ada A programming language that allows use of structured techniques for program design; concise but powerful language designed to fill government requirements for real-time applications.

adaptive array (AA) Continually monitors received signal for interference. The antenna automatically adjusts its directional characteristics to reduce the interference. Also called *adaptive antenna array.*

adaptive filter Prompts user to rate products or situations and also monitors your actions over time to find out what you like and dislike.

adaptivity The ability of intelligent agents to discover, learn, and take action independently.

add-on security The retrofitting of protection mechanisms, implemented by hardware, firmware, or software, on a computer system that has become operational.

address (1) A sequence of bits or characters that identifies the destination and sometimes the source of a transmission. (2) An identification (e.g., number, name, or label) for a location in which data is stored.

address mapping The process by which an alphabetic Internet address is converted into a numeric IP address, and vice versa.

address mask A bit mask used to identify which bits in an IP address correspond to the network address and subnet portions of the address. This mask is often referred to as the subnet mask because the network portion of the address can be determined by the class inherent in an IP address. The address mask has ones in positions corresponding to the network and subnet numbers and zeros in the host number positions.

address resolution A means for mapping network layer addresses onto media-specific addresses.

Address Resolution Protocol (ARP) The Internet protocol used to dynamically map Internet addresses to physical (hardware) addresses on the local area network. Limited to networks that support hardware broadcast.

adequate security Security commensurate with the risk and magnitude of the harm resulting from the loss, misuse, or unauthorized access to or modification of information. This includes assuring that systems and applications operate effectively and provide appropriate confidentiality, integrity, and availability, through the use of cost-effective management, acquisition, development, installation, operational, and technical controls.

ADG Ambulatory Diagnostic Group.

adjacent channel interference Interference of a signal caused by signal transmissions of another frequency too close in proximity.

ADM Guidance documents, administrator guidance.

administrative code sets Code sets that characterize a general business situation, rather than a medical condition or service. Under HIPAA, these are sometimes referred to as nonclinical or nonmedical code sets. Compare to medical code sets.

administrative controls The actions or controls dealing with operational effectiveness, efficiency and adherence to regulations and management policies.

administrative security The management constraints, operational procedures, accountability procedures, and supplemental controls established to provide an acceptable level of protection for sensitive data.

administrative security information Persistent information associated with entities; it is conceptually stored in the Security Management Information Base. An examples is security attributes associated with users and set up on user account installation, which is used to configure the user's identity and privileges within the system information configuring a secure interaction policy between one entity and another entity; this is used as the basis for the establishment of operational associations between those two entities.

administrative services only (ASO) An arrangement whereby a self-insured entity contracts with a third-party administrator (TPA) to administer a health plan.

administrative simplification (A/S) Title II, Subtitle F of HIPAA, which gives HHS the authority to mandate the use of standards for the electronic exchange of healthcare data; to specify what medical and administrative code sets should be used within those standards; to require the use of national identification systems for healthcare patients, providers, payers (or plans), and employers (or sponsors); and to specify the types of measures required to protect the security and privacy of personally identifiable healthcare information. This is also the name of Title II, Subtitle F, Part C of HIPAA.

ADO Delivery and operation assurance class.

ADSL Asymmetric digital subscriber line.

ADSP AppleTalk Data Stream Protocol.

ADV Development assurance class.

adversary Any individual, group, organization, or government that conducts activities, or has the intention and capability to conduct activities, detrimental to critical assets.

advisory sensitivity attributes User-supplied indicators of file sensitivity that alert other users to the sensitivity of a file so that they may handle it appropriate to its defined sensitivity. Advisory sensitivity attributes are not used by the AIS to enforce file access controls in an automated manner.

adware Software to generate ads that installs itself on your computer when you download some other (usually free) program from the Web.

AEF Access control enforcement function.

AES Advanced Encryption Standard, a new encryption standard, whose development and selection was sponsored by NIST, that will support key lengths of 128, 192, and 256 bits.

AFEHCT See the Association for Electronic Health Care Transactions.

affiliate programs Arrangements made between e-commerce sites that direct users from one site to the other and by which, if a sale is made as a result, the originating site receives a commission.

affordability Extent to which C4I features are cost effective on both a recurring and nonrecurring basis.

AFL Authentication failures.

AFP AppleTalk File Protocol.

AGD Guidance documents assurance class.

agent In the client/server model, the part of the system that performs information preparation and exchange on behalf of a client or server application.

aggregate information Information that may be collected by a Web site but is not “personally identifiable” to you. Aggregate information includes demographic data, domain names, Internet provider addresses, and Web site traffic. As long as none of these fields is linked to a user’s personal information, the data is considered aggregate.

aggregation A relation, such as CONSISTS OF or CONTAINS, between types that defines the composition of a type from other types.

aging The identification, by date, of unprocessed or retained items in a file. This is usually done by date of transaction, classifying items according to ranges of data.

AH Authentication header.

alarm collector function A function that collects the security alarm messages, translates them into security alarm records, and writes them to the security alarm log.

alarm examiner function A function that interfaces with a security alarm administrator.

ALARP “As low as reasonably practical”; a method of correlating the likelihood of a hazard and the severity of its consequences to determine risk exposure acceptability or the need for further risk reduction.

ALC Lifecycle support assurance class.

ALE Annual loss expectancy.

algorithm A computing procedure designed to perform a task such as encryption, compression, or hashing.

aliases Used to reroute browser requests from one URL to another.

alphabetic test The check on whether an element of data contains only alphabetic or blank characters.

alphanumeric A character set that includes numeric digits, alphabetic characters, and other special symbols.

alternate mark inversion (AMI) The line coding format in T-1 transmission systems whereby successive 1s (marks) are alternately inverted (sent with polarity opposite that of the preceding mark).

alternating current (AC) Typically, the 120-V electricity delivered by the local power utility to the three-pin power outlet in the wall. The polarity of the current alternates between positive and negative, 60 times per second.

AM Amplitude modulation.

ambulatory payment class (APC) A payment type for outpatient PPS claims.

amendment See amendments and corrections.

amendments and corrections In the final privacy rule, an amendment to a record would indicate that the data is in dispute while retaining the original information, whereas a correction to a record would alter or replace the original record.

American National Standards (ANS) Standards developed and approved by organizations accredited by ANSI.

American National Standards Institute (ANSI) The agency that recommends standards for computer hardware, software, and firmware design and use.

American Registry for Internet Numbers (ARIN) A nonprofit organization established for the purpose of administration and registration of Internet Protocol (IP) numbers to the geographical areas currently managed by Network Solutions (InterNIC). Those areas include, but are not limited to North America, South America, South Africa, and the Caribbean.

American Society for Testing and Materials (ASTM) A standards group that has published general guidelines for the development of standards, including those for healthcare identifiers. ASTM Committee E31 on Healthcare Informatics develops standards on information used within healthcare.

American Standard Code for Information Interchange (ASCII) A byte-oriented coding system based on an 8-bit code and used primarily to format information for transfer in a data communications environment.

AMI Alternate mark inversion (T1/E1).

AMIA See the American Medical Informatics Association.

ampere (amp) A unit of measurement for electric current. One volt of potential across a 1-ohm impedance causes a current flow of 1 ampere.

amplitude modulation (AM) The technique of varying the amplitude or wavelength of a carrier wave in direct proportion to the strength of the input signal while maintaining a constant frequency and phase.

AMT Protection of the TSF, underlying abstract machine test.

analog A voice transmission mode that is not digital in which information is transmitted in its original form by converting it to a continuously variable electrical signal.

analysis and design phase The phase of the systems development life cycle in which an existing system is studied in detail and its functional specifications are generated.

anamorphosis An image or the production of an image that appears distorted unless it is viewed from a special angle or with a special instrument.

annual loss expectancy (ALE) In risk assessment, the average monetary value of losses per year.

ANO Privacy, anonymity.

anonymity The state in which something is unknown or unacknowledged.

Anonymizer A service that prevents Web sites from seeing a user's Internet Protocol (IP) address. The service operates as an intermediary to protect the user's identity.

Anonymous File Transfer Protocol (FTP) A method for downloading public files using the File Transfer Protocol. Anonymous FTP is called *anonymous* because users do not provide credentials before accessing files from a particular server. In general, users enter the word anonymous when the host prompts for a username; anything can be entered for the password, such as the user's email address or simply the word guest. In many cases, an anonymous FTP site will not even prompt for a name and password.

anonymous Web browsing (AWB) Services hide your identity from the Web sites you visit.

ANS See American National Standards.

ANSI See American National Standards Institute.

antenna gain The measure in decibels of how much more power an antenna will radiate in a certain direction with respect to that which would be radiated by a reference antenna.

anti-air warfare (AAW) A primary warfare mission area dealing with air superiority.

anti-submarine warfare (ASW) A primary warfare mission area aimed against the subsurface threat.

anti-surface warfare (ASUW) A primary warfare mission area dealing with sea-going, surface platforms.

anti-virus software Applications that detect prevent and possibly remove all known viruses from files located in a microcomputer hard drive.

APC See ambulatory payment class.

APE Protection profile evaluation assurance class.

API Application programming interface. The interface between the application software and the application platform, across which all services are provided. The application programming interface is primarily in support of application portability, but system and application interoperability are also supported by a communication API.

applet A small Java program embedded in an HTML document.

application Computer software used to perform a distinct function. Also used to describe the function itself.

application architects IT professionals who can design creative technology-based business solutions.

application controls The transaction and data relating to each computer-based application system. Therefore, they are specific to each such application controls, which may be manual or programmed, are to endure the completeness and accuracy of the records and the validity of the entries made therein resulting from both manual and programmed processing. Examples of application controls include data input validation, agreement of batch controls and encryption of data transmitted.

application generation subsystem Contains facilities to help you develop transaction-intensive applications.

application layer The top-most layer in the OSI Reference Model providing such communication service is invoked through a software package. This layer provides the interface between end-users and networks. It allows use of e-mail and viewing Web pages, along with numerous other networking services.

application objects Applications and their components that are managed within an object-oriented system. Example operations on such objects are OPEN, INSTALL, MOVE, and REMOVE.

application program interface (API) A set of calling conventions defining how a service is invoked through a software package.

application programs Computer software designed for a specific job, such as word processing, accounting, spreadsheet, etc.

application proxy A type of firewall that controls external access by operating at the application layer. Application firewalls often readdress outgoing traffic so that it appears to have originated from the firewall rather than the internal host.

application service provider (ASP) Provides an outsourcing service for business software applications.

application software Software that enables you to solve specific problems or perform specific tasks.

APPN Advanced peer-to-peer networking.

approval to operate See certification and accreditation.

architecture The structure or ordering of components in a computational or other system. The classes and the interrelation of the classes define the architecture of a particular application. At another level, the architecture of a system is determined by the arrangement of the hardware and software components. The terms "logical architecture" and "physical architecture" are often used to emphasize this distinction.

ARCNET Developed by Datapoint Corporation in the 1970s; a LAN (local-area network) technology that competed strongly with Ethernet, but no longer does. Initially a computer connected via ARCNET could communicate at 2.5 Mbps, although this technology now supports a throughput of 20 Mbps (compared to current Ethernet at 100 Mbps and 1 Gbps).

arithmetic logic unit (ALU) A component of the computer's processing unit, in which arithmetic and matching operations are performed.

arithmetic operator In programming activities, a symbol representing an arithmetic calculation or process.

ARP Address Resolution Protocol. This is a protocol that resides in the IP/IP suite of protocols. Its purpose is to associate IP addresses at the network layer with MAC addresses at the data link layer.

ARPA Advanced Research Projects Agency.

array Consecutive storage areas in memory that are identified by the same name. The elements (or groups) within these storage areas are accessed through subscripts.

artificial intelligence (Al) A field of study involving techniques and methods under which computers can simulate such human intellectual activities as learning.

artificial neural network (ANN) Also called a *neural network*; an artificial intelligence system that is capable of finding and differentiating patterns.

AS Authentication server; part of Kerberos KDC.

ASBR Autonomous system boundary router.

ASC See Accredited Standards Committee.

ASCII American Standard Code for Information Interchange.

ASE Security target evaluation assurance class.

ASIC Application-specific integrated circuit.

ASIS American Society Industrial Security.

ASK Amplitude shift keying.

ASO See administrative services only.

ASP AppleTalk Session Protocol.

ASP/MSP A third-party provider that delivers and manages applications and computer services, including security services to multiple users via the Internet or virtual private network (VPN).

ASPIRE AFEHCT's Administrative Simplification Print Image Research Effort work group.

Assembler language A computer programming language in which alphanumeric symbols represent computer operations and memory addresses. Each assembler instruction translates into a single machine language instruction.

Assembler program A program language translator that converts assembler language into machine code.

assertion Explicit statement in a system security policy that security measures in one security domain constitute an adequate basis for security measures (or lack of them) in another.

assessment (1) An effort to gain insight into system capabilities and limitations. May be conducted in many ways including a paper analysis, laboratory type testing, or even through limited testing with operationally representative users and equipment in an operational environment. Not sufficiently rigorous in and of itself to allow a determination of effectiveness and suitability to be made for purposes of operational testing. (2) Surveys and inspections; an analysis of the vulnerabilities of an AIS. Information acquisition and review process designed to assist a customer to determine how best to use resources to protect information in systems.

asset Any person, facility, material, information, or activity which has a positive value to an owner.

Association Control Service Element (ACSE) Part of the application layer of the OSI Model. ASCE provides the means to exchange authentication information coming from the Specific Application Service Element (SASE) of the OSI Model.

Association for Electronic Health Care Transactions (AFEHCT) An organization that promotes the use of EDI in the healthcare industry.

association-security-state The collection of information that is relevant to the control of communications security for a particular application-association.

assumption of risk A plaintiff may not recover for an injury to which he assents; that is, that a person may not recover for an injury received when he voluntarily exposes himself to a known and appreciated danger. The requirements for the defense are that: (1) the plaintiff has knowledge of facts constituting a dangerous condition, (2) he knows that the condition is dangerous, (3) he appreciates the nature or extent of the danger, and (4) he voluntarily exposes himself to the danger. Secondary assumption of risk occurs when an individual voluntarily encounters known, appreciated risk without an intended manifestation by that individual that he consents to relieve another of his duty.

assurance (1) Grounds for confidence that the other four security goals (integrity, availability, confidentiality, and accountability) have been adequately met by a specific implementation. "Adequately met" includes the following: functionality that performs correctly, sufficient protection against unintentional errors (by users or software), and sufficient resistance to malicious penetration or by-pass. (2) A measure of confidence that the security features and architecture of an AIS accurately mediate and enforce the security policy. (3) A measure of confidence that the security features and architecture of an AIS accurately mediate and enforce the security policy. Note: Assurance refers to a basis for believing that the objective and approach of a security mechanism or service will be achieved. Assurance is generally based on factors such as analysis involving theory, testing, software engineering, validation, and verification. Life-cycle assurance requirements provide a framework for secure system design, implementation, and maintenance. The level of assurance that a development team, certifier, or accreditor has about a system reflects the confidence that they have that the system will be able to enforce its security policy correctly during use and in the face of attacks. Assurance may be provided through four means: (1) the way the system is designed and built, (2) analysis of the system description for conformance to requirement and for vulnerabilities, (3) testing the system itself to determine its operating characteristics, and (4) operational experience. Assurance is also provided through complete documentation of the design, analysis, and testing.

ASTM See the American Society for Testing and Materials.

asymmetric cryptosystem This is an information system utilizing an algorithm or series of algorithms which provide a cryptographic key pair consisting of a private key and a corresponding public key. The keys of the pair have the properties that (1) the public key can verify a digital signature that the private key creates, and (2) it is computationally infeasible to discover or derive the private key from the public key. The public key can therefore be disclosed without significantly risking disclosure of the private key. This can be used for confidentiality as well as for authentication.

asymmetric key (public key) A cipher technique whereby different cryptographic keys are used to encrypt and decrypt a message.

asynchronous A variable or random time interval between successive characters, blocks, operations, or events. Asynchronous data transmission provides variable intercharacter time but fixed interbit time within characters.

asynchronous transfer mode (ATM) A high-bandwidth, low-delay switching and multiplexing technology. It is a data-link layer protocol. This means that it is a protocol-independent transport mechanism. ATM allows very high-speed data transfer rates at up to 155 Mbps. Data is transmitted in the form of 53-byte units called *cells*. Each cell consists of a 5-byte header and a 48-byte payload. The term "asynchronous" in this context refers to the fact that cells from any one particular source need not be periodically spaced within the overall cell stream. That is, users are not assigned a set position in a recurring frame as is common in circuit switching. ATM can transport audio/-video/data over the same connection at the same time and provide QoS (quality of service) for this transport.

ATD Identification and authentication user attribute definition.

ATE Tests assurance class.

ATM See asynchronous transfer mode.

atomicity The assurance that an operation either changes the state of all participating objects consistent with the semantics of the operation or changes none at all.

atoms The smallest particle of an element that can exist alone or in combination.

ATP AppleTalk Transaction Protocol.

attenuation The decrease in power of a signal, light beam, or light wave, either absolutely or as a fraction of a reference value. The decrease usually occurs as a result of absorption, reflection, diffusion, scattering, deflection, or dispersion from an original level and usually not as a result of geometric spreading.

attribute A characteristic defined for a class. Attributes are used to maintain the state of the object of a class. Values can be connected to objects via the attributes of the class. Typically, the connected value is determined by an operation with a single parameter identifying the object. Attributes implement the properties of a type.

audio masking A condition where one sound interferes with the perception another sound.

audio output Voice synthesizers that create audible signals resembling a human voice out of computer-generated output.

audio response system The method of delivering output by using audible signals and transmitters that simulate a spoken language.

audit An independent review and examination of system records and activities that test for the adequacy of system controls, ensure compliance with established policy and operational procedures, and recommend any indicated changes in controls, policy, and procedures.

audit authority The manager responsible for defining those aspects of a security policy applicable to maintaining a security audit.

audit event detector function A function that detects the occurrence of security-relevant events. This function is normally an inherent part of the functionality implementing the event.

audit recorder function A function that records the security-relevant messages in a security audit trail.

audit review The independent review and examination of records and activities to assess the adequacy of system controls, to ensure compliance with established policies and operational procedures, and to recommend necessary changes in controls, policies or procedures.

audit risk The probable unfavorable monetary effect related to the occurrence of an undesirable event or condition.

audit trail A chronological record of system activities that is sufficient to enable the reconstruction, review, and examination of each event in a transaction from inception to output of final results.

audit trail analyzer function A function that checks a security audit trail in order to produce, if appropriate, security alarm messages.

audit trail archiver function A function that archives a part of the security audit trail.

audit trail collector function A function that collects individual audit trail records into a security audit trail.

audit trail examiner function A function that builds security reports out of one or more security audit trails.

audit trail provider function A function that provides security audit trails according to some criteria.

audit trail/log Application or system programs when activated automatically monitor system activity in terms of on-line users, accessed programs, periods of operation, file accesses, etc.

AUI Attachment unit interface.

AURP AppleTalk Update-Based Routing Protocol.

AUT CM automation.

Authenticate To verify the identity of a user, user device, or other entity, or the integrity of data stored, transmitted, or otherwise exposed to possible unauthorized modification in an automated information system, or establish the validity of a transmitted message.

authenticated identity An identity of a principal that has been assured through authentication.

authentication The act of identifying or verifying the eligibility of a station, originator, or individual to access specific categories of information. Typically, a measure designed to protect against fraudulent transmissions by establishing the validity of a transmission, message, station, or originator.

authentication certificate Authentication information in the form of a security certificate which may be used to assure the identity of an entity guaranteed by an authentication authority.

authentication exchange A sequence of one or more transfers of exchange authentication information (AI) for the purposes of performing an authentication.

authentication header An IPsec protocol that provides data origin authentication, packet integrity, and limited protection from replay attacks.

authentication information (AI) Information used to establish the validity of a claimed identity.

authentication initiator The entity which starts an authentication exchange.

authentication method Method for demonstrating knowledge of a secret. The quality of the authentication method, its strength is determined by the cryptographic basis of the key architecture for public-key infrastructure (APKI) draft distribution service on which it is based. A symmetric key based method, in which both entities share common authentication information, is considered to be a weaker method than an asymmetric key based method, in which not all the authentication information is shared by both entities.

authenticity (1) The ability to ensure that the information originates or is endorsed from the source which is attributed to that information. (2) The service that ensures that system events are initiated by and traceable to authorized entities. It is composed of authentication and nonrepudiation.

authorization The granting of right of access to a user, program, or process.

authorization policy A set of rules, part of an access control policy, by which access by security subjects to security objects is granted or denied. An authorization policy may be defined in terms of access control lists, capabilities or attributes assigned to security subjects, security objects or both.

authorize processing See accreditation.

authorized access list A list developed and maintained by the information systems security officer of personnel who are authorized unescorted access to the computer room.

authorizing official Official with the authority to formally assume responsibility for operating an information system at an acceptable level of risk to agency operations (including mission, functions, image, or reputation), agency assets, or individuals.

autofilter function Filters a list and allows you to hide all the rows in a list except those that match criteria you specify.

Automated Clearinghouse (ACH) See Health Care Clearinghouse.

automated information system (AIS) (1) An assembly of computer hardware, software, firmware, and related peripherals configured to collect, create, compute, disseminate, process, store, and control data or information; and (2) Information systems that manipulate, store, transmit, or receive information, and associated peripherals such as input/output and data storage and retrieval devices and media.

automated information system security program Synonymous with *information technology security program*.

automated security monitoring The use of automated procedures to ensure that the security controls implemented within a computer system or network are not circumvented or violated.

automatic call distribution (ACD) A specialized phone system originally designed simply to route incoming calls to all available personnel so that calls are evenly distributed. An ACD recognizes and answers an incoming call, looks in its database for instructions on what to do with that call, sends the call to a recording or voice response unit or to an available operator.

automatic speech recognition (ASR) A system that not only captures spoken words but also distinguishes word groupings to form sentences.

autonomy The ability of an intelligent agent to act without your telling it every step to take.

AVA Vulnerability assessment assurance class.

availability The property of being accessible and usable upon demand by an authorized entity.

availability formula This formula is used to calculate how reliable the equipment that is being installed will be for a particular application.

awareness Awareness programs set the stage for training by changing organizational attitudes toward realization of the importance of security and the adverse consequences of its failure. [NIST SP 800-18].

awareness, training, and education controls Awareness programs that set the stage for training by changing organizational attitudes to realize the importance of security and the adverse consequences of its failure; training that teaches people the skills that will enable them to perform their jobs more effectively; and education that is targeted for IT security professionals and focuses on developing the ability and vision to perform complex, multidisciplinary activities.

B2B marketplace An Internet-based service that brings together many buyers and sellers.

backbone The primary connectivity mechanism of a hierarchical distributed system. All systems that have connectivity to an intermediate system on the backbone are assured of connectivity to each other.

backbone network A network that interconnects various computer networks and mainframe computers in an enterprise. The backbone provides the structure through which computers communicate.

backdoor A function built into a program or system that allows unusually high or even full access to the system, either with or without an account in a normally restricted account environment. The backdoor sometimes remains in a fully developed system either by design or accident. (See also trap door.)

backoff The (usually random) retransmission delay enforced by contentious MAC protocols after a network node with data to transmit determines that the physical medium is already in use.

back-propagation neural network A neural network trained by someone.

backup and recovery The ability to recreate current master files using appropriate prior master records and transactions.

backup operation A method of operation used to complete essential tasks (as identified by risk analysis) subsequent to the disruption of the information processing facility and continuing to do so until the facility is sufficiently restored.

backup procedures Provisions make for the recovery of data files and program libraries and for the restart or replacement of computer equipment after the occurrence of a system failure or disaster.

backward chaining A process related to an expert system inference engine that starts with a hypothesis and attempts to confirm that the hypothesis is consistent with information in the knowledge base.

bandwidth Difference between the highest and lowest frequencies available for network signals. The term is also used to describe the rated throughput capacity of a given network medium or protocol.

banner ad A small ad on one Web site that advertises the products and services of another business.

bar code A series of solid bars of different widths used to encode data. Special optical character recognition (OCR) devices can read this data.

bar code reader Captures information that exists in the form of vertical bars whose width and distance from each other determine a number.

baseband A form of modulation in which data signals are pulsed directly on the transmission medium without frequency division and usually utilize a transceiver. In baseband the entire bandwidth of the transmission medium (cable) is utilized for a single channel. It uses a single carrier frequency and requires all stations attached to the network to participate in every transmission. See broadband.

baseline A set of critical observations or data used for a comparison or control. Note: Examples include a baseline security policy, a baseline set of security requirements, and a baseline system.

baseline architecture A complete list and description of equipment that can be found in operation today.

baseline security The minimum security controls required for safeguarding an IT system based on its identified needs for confidentiality, integrity, and availability protection.

BASIC See Beginner's All-Purpose Symbolic Instruction Code.

basic rate interface (BRI) Supports a total signaling rate of 144 kbps, which is divided into two B or bearer channels running at 64 kbps, and a D or data channel running at 16 kbps. The bearer channels carry the actual voice, video, or data information and the D channel is used for signaling.

Basic Service Set (BSS) Basic Service Set is a set of 802.11-compliant stations that operate as a fully connected wireless network.

basic text formatting tag HTML tags that allow you to specify formatting for text.

batch control A computer information processing technique in which numeric fields are totaled and records are tabulated to provide a comparison check for subsequent processing results.

baud Signal or state change during data transmission. Each state change can be equal to multiple bits, so the actual bit rate during data transmission may exceed the baud rate.

Bayesian belief network Graphical networks that represent probabilistic relationships among variables. The nodes represent uncertain variables and the arcs represent the causal/relevance relationships between the variables. The probability tables for each node provide the probabilities of each state of the variable for that node, conditional on each combination of values of the parent node.

BBA The Balanced Budget Act of 1997.

BBN Bayesian belief network.

BBRA The Balanced Budget Refinement Act of 1999.

BBS See bulletin board system.

BCBSA See Blue Cross and Blue Shield Association.

BCP The newest subseries of RFCs that are written to describe Best Current Practices in the Internet. Rather than specify the best ways to use the protocols and the best ways to configure options to ensure interoperability between various vendors' products, BCPs carry the endorsement of the IESG.

BDR Backup designated router.

beamwidth The width of the main lobe of an antenna pattern, usually defined as 3 db down from the peak of the lobe.

BECN Backward explicit congestion notification (frame relay).

Beginner's All-Purpose Symbolic Instruction Code (BASIC) A programming language designed in the 1960s to teach students how to program and to facilitate learning. The powerful language syntax was designed especially for time-sharing systems.

behavioral outcome What an individual who has completed the specific training module is expected to be able to accomplish in terms of IT security-related job performance.

behaviorally object-oriented The data model incorporates features to define arbitrarily complex object types together with a set of specific operators (abstract data types).

benchmark test A simulation evaluation conducted before purchasing or leasing equipment to determine how well hardware, software, and firmware perform.

benign environment A nonhostile environment that may be protected from external hostile elements by physical, personnel, and procedural security countermeasures.

benign system A system that is not related to any other system. Benign systems are closed communities without physical connection or logical relationship to any other system. Benign systems are operated exclusive of one another and do not share users, information, or end processing with other systems.

BER Bit error rate.

bespoke learning materials Materials that are designed and tailored to meet an organization's specific learning needs and outcomes. British Learning Association Glossary: http://www.baol.co.uk/glossary.htm

best-effort QoS The lowest of all QoS traffic classes. If the guaranteed QoS cannot be delivered, the bearer network delivers the QoS, which is called *best-effort QoS*.

best-effort service A service model that provides minimal performance guarantees, allowing an unspecified variance in the measured performance criteria.

between-the-lines entry Access obtained through the use of active wiretapping by an unauthorized user to a momentarily inactive terminal of a legitimate user assigned to a communications channel.

BGP Border gateway protocol.

BIA (1) Business impact analysis. (2) Burned-in address.

billing A function whereby CDRs generated by the charging function are transformed into bills requiring payment.

binary Where only two values or states are possible for a particular condition, such as "on" or "off" or "1" or "0." Binary is the way digital computers function because it represents data as on or off.

binary digit A state of function represented by the digit 0 or 1.

biometric system A pattern recognition system that establishes the authenticity of a specific physiological or behavioral characteristic possessed by a user.

biometrics A security technique that verifies an individual's identity by analyzing a unique physical attribute, such as a handprint.

BIOS The BIOS is built-in software that determines what a computer can do without accessing programs from a disk. On PCs, the BIOS contains all the code required to control the keyboard, display screen, disk drives, serial communications, and a number of miscellaneous functions.

bipolar 8-zero substitution (B8ZS) A technique used to accommodate the density requirement for digital T-carrier facilities in the public network, while allowing 64 kbps clear data per channel. Rather than inserting a 1 for every seven consecutive 0s, B8ZS inserts two violations of bipolar line encoding technique for digital transmission links.

B-ISDN Broadband ISDN.

bit A binary value represented by an electronic component that has a value of 0 or 1.

BIT Built-in test.

bit error rate (BER) The probability that a particular bit will have the wrong value.

bit map A specialized form of an index indicating the existence or nonexistence of a condition for a group of blocks or records. Although they are expensive to build and maintain, they provide very fast comparison and access facilities.

bit mask A pattern of binary values that is combined with some value using bitwise AND with the result that bits in the value in positions where the mask is zero are also set to zero.

bit rate This is the speed at which bits are transmitted on a circuit, usually expressed in bits per second.

bits per second (BPS) The speed at which bits are sent during data transmission.

bit-stream image Bit-streams backups (also referred to as *mirror-image backups*) involve all areas of a computer hard disk drive or another type of storage media. Such backups exactly replicate all sectors on a given storage device. Thus, all files and ambient data storage areas are copied.

black In the information processing context, black denotes data, text, equipment, processes, systems or installations associated with unencrypted information that requires no emanations security related protection. For example, electronic signals are "black" if bearing unclassified information. Antonym: red: Designation applied to information systems, and to associated areas, circuits, components, and equipment, in which national security information is not processed.

blackhat hackers Cyber vandals.

blind scheme An extraction process method that can recover the hidden message by means only of the encoded data.

block cipher A method of encrypting text to produce ciphertext in which a cryptographic key and algorithm are applied to a block of data as a group instead of one bit at a time.

block structure In programming, a segment of code that can be treated as an independent module.

blocking factor The number of records appearing between interblock gaps on magnetic storage media.

blog (1) A contraction of Weblog, a form of online writing characterized in format by a single column of chronological text, usually with a sidebar, and frequently updated. As of mid-2002, the vast majority of blogs are nonprofessional (with only a few experimental exceptions) and are run by a single writer. (2) To write an article on a blog. Samizdata.net: http://www.samizdata.net/blog/glossary.html

BLP Bypass label processing.

Blue Cross and Blue Shield Association (BCBSA) An association that represents the common interests of Blue Cross and Blue Shield health plans. The BCBSA serves as the administrator for the Health Care Code Maintenance Committee and also helps maintain the HCPCS Level II codes.

Bluetooth Technology that provides entirely wireless connections for all kinds of communication devices.

body One of four possible components of a message. Other components are the headings, attachment, and the envelope.

bootleg An unauthorized recording of a live or broadcast performance. They are duplicated and sold without the permission of the artist, composer or record company.

BOOTP Bootstrap Protocol.

bote-swaine cipher A steganographic cipher used by Francis Bacon to insert his name within the text of his writings.

bounds checking The testing of computer program results for access to storage outside of its authorized limits.

bounds register A hardware or firmware register that holds an address specifying a storage boundary.

Boyd cycle See OODA Loop and J. Boyd, *Patterns of Conflict*, December 1986. Unpublished study, 196 pages.

BP See business partner.

BPDU Bridge Protocol Data Unit.

bps Bits per second.

branch An alteration of the normal sequential execution of program statements.

brevity lists A coding system that reduces the time required to transmit information by representing long, stereotyped sentences with only a few characters.

BRI Basic rate interface (ISDN).

bridge A device that connects two or more physical networks and forwards packets between them. Bridges can usually be made to filter packets, that is, to forward only certain traffic.

broadband Characteristic of any network that multiplexes multiple, independent network carriers onto a single cable. Broadband technology allows several networks to coexist on one single cable; traffic from one network does not interfere with traffic from another because the conversations happen on different frequencies in the "ether," rather like the commercial radio system.

broadcast A packet delivery system where a copy of a given packet is given to all hosts attached to the network. Example: Ethernet.

broadcast storm A condition that can occur on broadcast type networks such as Ethernet. This can happen for a number of reasons, ranging from hardware malfunction to configuration error and bandwidth saturation.

brouter A concatenation of "bridge" and "router." Used to refer to devices that perform both bridging and routing.

browser Short for *Web browser*, a software application used to locate and display Web pages. The two most popular browsers are Netscape Navigator and Microsoft Internet Explorer. Both of these are graphical browsers, which means that they can display graphics as well as text. In addition, most modern browsers can present multimedia information, including sound and video, although they require plug-ins for some formats.

browser-safe colors A range of 216 colors that can be represented using 8 bits and are visible in all browsers.

browsing The searching of computer storage to locate or acquire information, without necessarily knowing whether it exists or in what format.

brute force The name given to a class of algorithms that repeatedly try all possible combinations until a solution is found.

brute-force attack A form of cryptoanalysis where the attacker uses all possible keys or passwords in an attempt to crack an encryption scheme or login system.

BSP Biometric service provider.

buffer A temporary storage area, usually in RAM. The purpose of most buffers is to act as a holding area, enabling the CPU to manipulate data before transferring it to a device. Because the processes of reading and writing data to a disk are relatively slow, many programs keep track of data changes in a buffer and then copy the buffer to a disk. For example, word processors employ a buffer to keep track of changes to files. Then when you *save* the file, the word processor updates the disk file with the contents of the buffer. This is much more efficient than accessing the file on the disk each time you make a change to the file. Note that because your changes are initially stored in a buffer, not on the disk, all of them will be lost if the computer fails during an editing session. For this reason, it is a good idea to save your file periodically. Most word processors automatically save files at regular intervals. Another common use of buffers is for printing documents. When you enter a PRINT command, the operating system copies your document to a print buffer (a free area in memory or on a disk) from which the printer can draw characters at its own pace. This frees the computer to perform other tasks while the printer is running in the background. Print buffering is called *spooling*. Most keyboard drivers also contain a buffer so that you can edit typing mistakes before sending your command to a program. Many operating systems, including DOS, also use a *disk buffer* to temporarily hold data that they have read from a disk. The disk buffer is really a cache.

bug A coded program statement containing a logical or syntactical error.

built-in test A design feature that provides information on the ability of the item to perform its intended functions. BIT is implemented in software or firmware and may use or control BIT equipment (BITE).

bulletin board bystem (BBS) A computer that allows you to log on and post messages to other subscribers to the service. To use a BBS, a modem and the telephone number of the BBS is required. A BBS application runs on a computer and allows people to connect to that computer for the purpose of exchanging e-mail, chatting, and file transfers. A BBS is not part of the Internet.

burn box A device used to destroy computer data. Usually a box with magnets or electrical current that will degauss disks and tapes.

burst The separation of multiple-copy printout forms into individual sheets.

bus An electrical connection that allows two or more wires or lines to be connected together. Typically, all circuit cards receive the same information that is put on the bus, but only the card the information is “addressed” to will use that data.

bus structure A network topology in which nodes are connected to a single cable with terminators at each end.

business associate Under HIPAA, a person who is not a member of a covered entity’s workforce (see *workforce*) and who performs any function or activity involving the use or disclosure of individually identifiable health information, such as temporary nursing services, or who provides services to a covered entity which involves the disclosure of individually identifiable health information, such as legal, accounting, consulting, data aggregation, management, accreditation, etc. A covered entity may be a business associate of another covered entity.

business continuity plan (BCP) A documented and tested plan for responding to an emergency.

business impact analysis An exercise that determines the impact of losing the support of any resource to an organization, establishes the escalation of that loss over time, identifies the minimum resources needed to recover and prioritizes the recovery of processes and supporting systems.

business intelligence Knowledge about customers, competitors, partners, and own internal operations. Business intelligence from information.

business model A model of a business organization or process.

business partner (BP) See business associate.

business process A standardized set of activities that accomplishes a specific task such as processing a customer's order.

business process reengineering (BPR) The reinventing of a process within a business.

business relationships

(1) The term agent is often used to describe a person or organization that assumes some of the responsibilities of another one. This term has been avoided in the final rules so that a more HIPAA-specific meaning could be used for business associate. The term business partner (BP) was originally used for business associate.

(2) A third-party administrator (TPA) is a business associate that performs claims administration and related business functions for a self-insured entity.

(3) Under HIPAA, a healthcare clearinghouse is a business associate that translates data to or from a standard format on behalf of a covered entity.

(4) The HIPAA Security NPRM used the term *Chain of Trust Agreement* to describe the type of contract that would be needed to extend the responsibility to protect healthcare data across a series of sub-contractual relationships.

(5) A business associate is an entity that performs certain business functions for you, and a trading partner is an external entity, such as a customer, with whom you do business. This relationship can be formalized via a trading partner agreement. It is quite possible to be a trading partner of an entity for some purposes, and a business associate of that entity for other purposes.

business requirement A detailed knowledge worker request that the system must meet to be successful.

business to business (B2B) Companies whose customers are primarily other businesses.

business to consumer (B2C) Companies whose customers are primarily individuals.

buyer agent or **shopping bot** An intelligent agent or application on a Web site that helps customers find the products and services they want.

byte The basic unit of storage for many computers; typically, one configuration consists of 8 bits used to represent data plus a parity bit for checking the accuracy of representation.

byte-digit portion Usually, the four rightmost bits in a byte.

C A third-generation computer language used for programming on microcomputers. Most microcomputer software products such as spreadsheets and DBMS programs are written in C.

C&A Certification and accreditation; a comprehensive evaluation of the technical and non-technical security features of a system to determine if it meets specified requirements and should receive approval to operate.

C2 A formal product rating awarded to a product by the National Computer Security Center (NCSC). A C2-rated system incorporates controls capable of enforcing access limitations on an individual basis, making users individually accountable for their actions through logon procedures, auditing of security relevant events, and resource isolation.

CA Certificate authority.

cable Transmission medium of copper wire or optical fiber wrapped in a protective cover.

cable modem A device that uses a TV cable to deliver an Internet connection.

cabulance A taxi cab that also functions as an ambulance.

cache Pronounced *cash*, a special high-speed storage mechanism. It can be either a reserved section of main memory or an independent highspeed storage device. Two types of caching are commonly used in personal computers: *memory caching* and *disk caching*. A memory cache, sometimes called a *cache store* or *RAM cache*, is a portion of memory made of high-speed static RAM (SRAM) instead of the slower and cheaper dynamic RAM (DRAM) used for main memory. Memory caching is effective because most programs access the same data or instructions over and over. Disk caching works under the same principle as memory caching, but instead of using high-speed SRAM, a disk cache uses conventional main memory. When data is found in the cache, it is called a *cache hit*, and the effectiveness of a cache is judged by its *hit rate*.

call Any connection (fixed or temporary) capable of transferring information between two or more users of a telecommunications system. In this context, a user may be a person or a machine. It is used for transmission of the content of communication. This term refers to circuit-switched calls only.

callback A procedure that identifies a terminal dialing into a computer system or network by disconnecting the calling terminal, verifying the authorized terminal against the automated control table, and then, if authorized, reestablishing the connection by having the computer system dial the telephone number of the calling terminal.

caller identification (CLID) One of several custom local-area signaling services (CLASS) provided by the local exchange carrier. The service that allows you to see the name and number of the person who is calling you.

call-identifying information (CII) Dialing or signaling information that identifies the origin, direction, destination or termination of each communication generated by means of any equipment, facility, service, or a telecommunications carrier.

CAP CM capabilities.

capability A token used as an identifier for a resource such that possession of the token confers access rights for the resource.

capacitor Capacitors provide a means of storing electric charge so that it can be released at a specific time or rate. A capacitor acts as a battery but does not use a chemical reaction.

capacity planning Determining the future IT infrastructure requirements for new equipment and additional network capacity.

Cardano's grille A method of concealing a message by which a piece of paper has several holes cut in it (the grille) and when it is placed over an innocent looking message the holes cover all but specific letters spelling out the message. It was named for its inventor, Girolamo Cardano.

carrier sense multiple access/collision detection (CSMA/CD) Also known as *carrier sense multiple access with collision avoidance* (CSMA/CA).

carrier sense, multiple access (CSMA) A multiple-station access scheme for avoiding contention in packet networks in which each station can sense the presence of carrier signals from other stations and thus avoid transmitting a packet that would result in a collision. See also collision detection.

cathode-ray tube (CRT) The display device for computer terminals, typically a television-like electronic vacuum tube.

cause (1) Technical: the action or condition by which a hazardous event (physical or cyber) is initiated; an initiating event. The cause may arise as the result of failure, accidental or intentional human error, design inadequacy, induced or natural environment, system configuration, or operational modes/states. (2) Legal: each separate antecedent of an event. Something that precedes and brings about an effect or result. A reason for an accident or condition.

CAVE (cave automatic virtual environment) A special 3-D virtual reality room that can display images of other people and objects located in other cave's all over the world.

CBC Cipher block chaining.

CBEFF Common biometric exchange file format; being defined by U.S. biometric consortium and ANSI X9F4 subcommittee.

CBO Congressional Budget Office or Cost Budget Office.

CBR Constant bit rate.

CC Common criteria; see ISO/IEC 15408.

CCA Vulnerability analysis, covert channel analysis.

CCF Common cause failure.

CCITT Consultative Committee for International Telegraph and Telephone.

CCITT See Telecommunications Standardization Sector of the International Telecommunications Union (TSSUITU).

CCO Cisco Connection Online.

CCP Compression Control Protocol.

CCS Common channel signaling.

CCTV Closed-circuit television.

CD CARRIER DETECT.

CDC See the Centers for Disease Control and Prevention.

CDDI Copper distributed data interface.

CDP Cisco Discovery Protocol.

CD-R (compact disc-recordable) An optical or laser disc that offers one-time writing capability with about 700 MB or greater of storage.

CD-ROM A compact disk, similar to an audio compact disk, which is used to store computer information (e.g., programs, data, or graphics).

CD-RW (compact disc-rewritable) A CD that offers unlimited writing and updating capabilities.

CDT See Current Dental Terminology.

CE See covered entity.

CEFACT See United Nations Center for Facilitation of Procedures and Practices for Administration, Commerce, and Transport (UN/CEFACT).

cell sites A transmitter-receiver location, operated by the wireless service provider, through which radio links are established between the wireless system and the wireless unit.

cellular service Also known as *cellular mobile telephone system*. A wireless telephone system using multiple transceiver sites linked to a central computer for coordination.

CEN European Center for Standardization, or Comité Européen de Normalisation.

central office of record Office of a federal department or agency that keeps (COR) records of accountable COMSEC material held by elements subject to its oversight.

central processing unit (CPU) The part of a computer that performs the logic, computation, and decision-making functions. It interprets and executes instructions as it receives them. PCs have one CPU, typically a single chip.

CEO Chief executive officer.

CEPS Common electronic purse specifications; a standard used with smartcards.

CER Crossover error rate.

CERN European Laboratory for Particle Physics. Birthplace of the World Wide Web.

CERT/CC Computer emergency response team coordination center, a service of CMU/SEI.

certificate A set of information which at least: identifies the certification authority issuing the certificate; unambiguously names or identifies its owner; contains the owner's public key; and is digitally signed by the certification authority issuing it.

certificate authority A trusted third party that associates a public key with proof of identity by producing a digitally signed certificate.

certification The acceptance of software by an authorized agent, usually after the software has been validated by the agent or its validity has been demonstrated to the agent.

certification agent The individual(s) responsible for making a technical judgment of the system's compliance with stated requirements, identifying and assessing the risks associated with operating the system, coordinating the certification activities, and consolidating the final certification and accreditation packages.

certification and accreditation plan A plan delineating objectives, responsibilities, schedule, technical monitoring, and other activities in support of the C&A process.

Certification and Repair Center (CRC) A U.S. Department of State (DoS) facility utilized by IM/SO/TO/OTSS departments for program activities.

certification authority (CA) Provides to users a digital certificate that links the public key with some assertion about the user, such as identity, credit payment card number etc. Certification authorities may offer other services such as time-stamping, key management services and certificate revocation services. It can also be defined as an independent trusted source which attests to some factual element of information for the purposes of certifying information in the electronic environment.

certification level A combination of techniques and procedures used during a certification and accreditation process to verify the correctness and effectiveness of security controls in an information technology system. Security certification levels represent increasing levels of intensity and rigor in the verification process and include such techniques as reviewing and examining documentation; interviewing personnel; conducting demonstrations and exercises; conducting functional, regression, and penetration testing; and analyzing system design documentation.

certification package Product of the certification effort documenting the detailed results of the certification activities. The certification package includes the security plan, developmental or operational certification test reports, risk assessment report, and certifier's statement.

certification path A chain of certificates between any given certificate and its trust anchor (CA). Each certificate in the chain must be verifiable in order to validate the certificate at the end of the path; this functionality is critical to the usable PKI.

certification practices statement A statement of the certification authorities practices with respect to a wide range of technical, business and legal issues that may be used as a basis for the certification authorities contract with the entity to whom the certificate was issued.

certification requirements review (CRR) The review conducted by the DAA, Certifier, program manager, and user representative to review and approve all information contained in the system security authorization agreement (SSAA). The CRR is conducted before the end of phase 1.

certification statement The certifier's statement provides an overview of the security status of the system and brings together all of the information necessary for the DAA to make an informed, risk-based decision. The statement documents that the security controls are correctly implemented and effective in their application. The report also documents the security controls not implemented and provides corrective actions.

certification test and evaluation (CT&E) Software and hardware security tests conducted during development of an IS.

certifier See certification authority.

certifier See certification agent.

CFO Chief financial officer.

CFR or C F R Code of Federal Regulations.

CGI Common gateway interface.

chain of custody (1) The identity of persons who handle evidence between the time of commission of the alleged offense and the ultimate disposition of the case. It is the responsibility of each transferee to ensure that the items are accounted for during the time that it is in their possession, that it is properly protected, and that there is a record of the names of the persons from whom they received it and to whom they delivered it, together with the time and date of such receipt and delivery. (2) The control over evidence. Lack of control over evidence can lead to it being discredited completely. Chain of custody depends upon being able to verify that evidence could not have been tampered with. This is accomplished by sealing off the evidence so that it cannot in any way be changed and providing a documentary record of custody to prove that the evidence was at all times under strict control and not subject to tampering.

chain of evidence The "sequencing" of the chain of evidence follows this order: Collection and identification; Analysis; Storage; Preservation; Presentation in court; Return to owner. Chain of evidence shows: who obtained the evidence; where and when the evidence was obtained; who secured the evidence; who had control or possession of the evidence.

chain of trust (COT) A term used in the HIPAA Security NPRM for a pattern of agreements that extend protection of healthcare data by requiring that each covered entity that shares healthcare data with another entity require that that entity provide protections comparable to those provided by the covered entity, and that that entity, in turn, require that any other entities with which it shares the data satisfy the same requirements.

Challenge Handshake Authentication Protocol A secure login procedure for dial-in access that avoids sending in a password in the clear by using cryptographic hashing.

CHAMPUS Civilian Health and Medical Program of the Uniformed Services.

channel Typically what you rent from the telephone company, voice-grade transmission facility with defined frequency response, gain, and bandwidth. A path of communication, either electrical or electromagnetic, between two or more points. Also a circuit, facility, line, or path.

channel service unit (CSU) or digital service unit (DSU) Devices used to interface between transmitting equipment and the external circuit in the wide area network that will carry the information.

CHAP (Challenge Handshake Authentication Protocol) Applies a three-way handshaking procedure. After the link is established, the server sends a "challenge" message to the originator. The originator responds with a value calculated using a one-way hash function. The server checks the response against its own calculation of the expected hash value. If the values match, the authentication is acknowledged; otherwise, the connection is usually terminated.

character A single numeric digit, special symbol, or letter.

charging data record (CDR) A formatted collection of information about a chargeable event (e.g., time of call set-up, duration of the call, amount of data transferred, etc.) for use in billing and accounting. For each party to be charged for parts of or all the charges of a chargeable event, a separate CDR shall be generated, i.e., more than one CDR may be generated for a single chargeable event, e.g., because of its long duration or because more than one charged party is to be charged.

chat room An area of a Web chat service that people can "enter" with their Web browsers where the conversations are devoted to a specific topic; equivalent to a channel in IRC.

check digit One digit, usually the last, of an identifying field is a mathematical function of all of the other digits in the field. This value can be calculated from the other digits in the field and compared with the check digit to verify validity of the whole field.

check digit A numeric digit that is used to verify the accuracy of a copied or transcribed number. The numeric digit is typically appended to the end of a number.

checksum A computed value that depends on the contents of a packet. This value is sent along with the packet when it is transmitted. The receiving system computes a new checksum based on receiving data and compares this value with the one sent with the packet. If the two values are the same, the receiver has a high degree of confidence that the data was received correctly.

chief information officer (CIO) The title for the highest-ranking MIS officer in the organization.

CHIM See the Center for Healthcare Information Management.

CHIME See the College of Healthcare Information Management Executives.

chip A wafer containing miniature electronic imprinted circuits and components.

CHIP Child Health Insurance Program.

choice The third step in the decision-making process where you decide on a plan to address the problem or opportunity.

chosen message attack A type of attack where the steganalyst generates a stego-medium from a message using some particular tool, looking for signatures that will enable the detection of other stego-media.

chosen stego attack A type of attack when both the stego-medium and the steganography tool or algorithm is available.

CIA With regard to information security: confidentiality, integrity, and availability.

CIDF Common Intrusion Detection Framework Model.

CIDR Classless interdomain routing.

CIO Chief information officer.

cipher disk An additive cipher device used for encrypting and decrypting messages. The disk consists of two concentric circular scales, usually of letters, and the alphabets can be repositioned with respect to one another at any of the 26 relationships.

cipher system A system in which cryptography is applied to plaintext elements of equal length.

cipher text A message that has been encrypted using a specific algorithm and key. (Contrast with *plain text.*)

ciphertext Information that has been encrypted, making it unreadable without knowledge of the key.

CIR Committed information rate.

circuit switching A communications paradigm in which a dedicated communication path is established between two hosts and on which all packets travel. The telephone system is an example of a circuit-switched network.

CISL Common Intrusion Specification Language.

CISM Certified Information Security Manager.

CISO Chief information security officer.

CISSP Certified Information Systems Security Professional.

CKM Cryptographic key management.

Claim Adjustment Reason Codes A national administrative code set that identifies the reasons for any differences, or adjustments, between the original provider charge for a claim or service and the payer's payment for it. This code set is used in the X12 835 Claim Payment & Remittance Advice and the X12 837 Claim transactions, and is maintained by the Health Care Code Maintenance Committee.

claim attachment Any of a variety of hardcopy forms or electronic records needed to process a claim in addition to the claim itself.

claim authentication information Information used by a claimant to generate exchange AI needed to 874 authenticate a principal.

Claim Medicare Remark Codes See Medicare Remittance Advice Remark Codes.

Claim Status Category Codes A national administrative code set that indicates the general category of the status of healthcare claims. This code set is used in the X12 277 Claim Status Notification transaction, and is maintained by the Health Care Code Maintenance Committee.

Claim Status Codes A national administrative code set that identifies the status of healthcare claims. This code set is used in the X12 277 Claim Status Notification transaction, and is maintained by the Health Care Code Maintenance Committee.

claimant An entity which is or represents a principal for the purposes of authentication. A claimant includes the functions necessary for engaging in authentication exchanges on behalf of a principal.

class An implementation of an abstract data type. A definition of the data structures, methods, and interface of software objects. A template for the instantiation (creation) of software objects.

classification The determination that certain information requires protection against unauthorized disclosure in the interest of national security, coupled with the designation of the level of classification as *top secret*, *secret*, or *confidential.*

classification authority The authority vested in an official of an agency to originally classify information or material which is determined by that official to require protection against unauthorized disclosure in the interest of national security.

classification guides Documents issued in an exercise of authority for original classification that include determinations with respect to the proper level and duration of classification of categories of classified information.

classified information Information that has been determined pursuant to Executive Order 12958 or any predecessor order, or by the Atomic Energy Act of 1954, as amended, to require protection against unauthorized disclosure and is marked to indicate its classified status.

classifier An individual who makes a classification determination and applies a security classification to information or material. A classifier may either be a classification authority or may assign a security classification based on a properly classified source or a classification guide.

clear mode Unencrypted plain text mode.

cleared U.S. citizen A citizen of the United States who has undergone a favorable background investigation resulting in the issuance of a security clearance by the Bureau of Diplomatic Security permitting access to classified information at a specified level.

clearinghouse See Health Care Clearinghouse.

cleartext Data that is not encrypted; plaintext.

CLIA Clinical Laboratory Improvement Amendments.

click trail A record of all the Web page addresses you have visited during a specific online session. Click trails tell not just what Web site you visited, but which pages inside that site.

clickstream A stored record of a Web surfing session containing information such as Web sites visited, how long the user was there, what ads were looked at, and the items purchased.

click-throughs A count of the number of people who visit one site and click on an ad, and are taken to the site of the advertiser.

client A workstation in a network that is set up to use the resources of a server.

client/server In networking, a network in which several PC-type systems (clients) are connected to one or more powerful, central computers (servers). In databases, refers to a model in which a client system runs a database application (front end) that accesses information in a database management system situated on a server (back end).

client/server architecture A local area network in which microcomputers, called *servers*, provide specialized service on behalf of the user's computers, which are called *clients*.

client/server model A common way to describe network services and the model user processes (programs) of those services. Examples include the name-serve/name-resolver paradigm of the DNS and file-server/file-client relationships such as NFS and diskless hosts.

Clinger-Cohen Act of 1996 Also known as the Information Technology Management Reform Act. A statute that substantially revised the way that information technology resources are managed and procured, including a requirement that each agency design and implement a process for maximizing the value and assessing and managing the risks of information technology investments.

Clinical Code Sets See Medical Code Sets.

CLNP Connectionless Network Protocol.

CLNS Connectionless network services.

cloning The term given to the operation of creating an exact duplicate of one medium on another like medium. This is also referred to as a *mirror image* or *physical sector copy*.

closed network/closed user group These are systems which generally represent those in which certificates are used within a bounded context such as within a payment system. A contract or series of contracts identify and define the rights and responsibilities of all parties to a particular transaction.

CLP Cell loss priority.

CM See ICD.

CMF Common mode failure.

CMI Coded mark inversion.

CO Central office.

coaxial cable A medium used for telecommunications. It is similar to the type of cable used for carrying television signals.

COB See coordination of benefits.

COBOL See Common Business-Oriented Language.

Code Division Multiple Access (CDMA) A technique permitting the use of a single frequency band by a number of users. Users are allocated a sequence that uniquely identifies them.

code generator A precompiler program that translates fourth-generation language-like code into the statements of a third-generation language code.

Code of Fair Information Practices The basis for privacy best practices, both online and offline. The practices originated in the Privacy Act of 1974, the legislation that protects personal information collected and maintained by the U.S. Government. In 1980, these principles were adopted by the Organization for Economic Cooperation and Development and incorporated in its Guidelines for the Protection of Personal Data and Transborder Data Flows. They were adopted later in the EU Data Protection Directive of 1995, with modifications. The Fair Information Practices include notice, choice, access, onward transfer, security, data integrity, and remedy.

code room The designated and restricted area in which cryptographic operations are conducted.

code set Under HIPAA, this is any set of codes used to encode data elements, such as tables of terms, medical concepts, medical diagnostic codes, or medical procedure codes. This includes both the codes and their descriptions. Also see Part II, 45 CFR 162.103.

code set maintaining organization Under HIPAA, this is an organization that creates and maintains the code sets adopted by the secretary for use in the transactions for which standards are adopted. Also see Part II, 45 CFR 162.103.

code system Any system of communication in which groups of symbols represent plaintext elements of varying length.

coder The individual who translates program design into executable computer code.

coding The activity of translating a set of computer processing specifications into a formal language for execution by a computer.

coefficient A number or symbol multiplied with a variable or an unknown quantity in an algebraic term.

cohesion The manner and degree to which the tasks performed by a single software module are related to another. Types of cohesion include coincidental, communication, functional, logical, procedural, sequential, and temporal.

cold site An IS backup facility that has the necessary electrical and physical components of a computer facility, but does not have the computer equipment in place. The site is ready to receive the necessary replacement computer equipment in the event the users have to move from their main computing location to the alternative computer facility.

collaboration Enabling collaboration which transforms shared awareness into actions which can achieve a competitive advantage.

collaboration system A system that is designed specifically to improve the performance of teams by supporting the sharing and flow of information.

collaborative filtering A method of placing you in an affinity group of people with the same characteristics.

collaborative planning, forecasting, and replenishment (CPFR) A concept that encourages and facilitates collaborative processes between members of a supply chain.

collaborative processing enterprise information portal Provides knowledge workers with access to workgroup information such as e-mails, reports, meeting minutes, and memos.

collateral information National security information classified in accordance with E.O. 12356, dated April 2, 1982.

College of Healthcare Information Management Executives (CHIME) A professional organization for healthcare chief information officers (CIOs).

collision (1) A condition that is present when two or more terminals are in contention during simultaneous network access attempts. (2) In cryptography, an instance when a hash function generates the same output for different inputs.

collision detection An avoidance method for communications channel contention that depends on two stations detecting the simultaneous start of each other's transmission, stopping, and waiting a random period of time before beginning again. See also carrier sense, multiple access.

collision resistance In cryptography, the idea that a hash function does not generate the same output for different inputs. Consider for example.

co-location A vendor that rents space and telecommunications equipment to other companies.

color palette A set of available colors a computer or an application can display. Also known as a *CLUT*: color look-up table.

COM (computer output microfilm) The production of computer output on photographic film.

command and control The exercise of authority and direction by a properly designated commander over assigned and attached forces in the accomplishment of the mission.

command and control warfare (C2W) The integrated use of operations security (OPSEC), military deception, psychological operations (PSYOP), electronic warfare (EW) and physical destruction, mutually supported by intelligence, to deny information to, influence, degrade or destroy adversary C2 capabilities, while protecting friendly C2 capabilities against such actions.

comment Public commentary on the merits or appropriateness of proposed or potential regulations provided in response to an NPRM, an NOI, or other federal regulatory notice.

commit A condition implemented by the programmer signaling to the DBMS that all update activity that the program conducts be executed against a database. Before the commit, all update activity can be rolled back or canceled without negative impact on the database contents.

commit protocol An algorithm to ensure that a transaction is successfully completed.

Common Business Oriented Language (COBOL) A high-level programming language for business computer applications.

common carrier An organization or company that provides data or other electronic communication services for a fee.

common-cause failure Failure of multiple independent system components occurring from a single cause that is common to all of them.

common control See HIPPA Part II, 45 CFR 164.504.

Common Criteria testing laboratory (CCTL) Within the context of the NIAP Common Criteria Evaluation and Validation Scheme, an IT security evaluation facility, accredited by the National Voluntary Laboratory Accreditation Program (NVLAP) and approved by the NIAP Oversight Body to conduct CC-based evaluations.

common-mode failure Failure of multiple independent system components that fail in the identical mode.

Common Object Request Broker Architecture (CORBA) CORBA is the Object Management Group's (OMG) answer to the need for interoperability among the rapidly proliferating number of hardware and software products available today. Simply stated, CORBA allows applications to communicate with one another no matter where they are located or who has designed them.

common operating environment The collection of standards, specifications, and guidelines, architecture definitions, software infrastructures, reusable components, application programming interfaces (APIs), methodology, runtime environment definitions, reference implementations, and methodology, that establishes an environment on which a system can be built. The COE is the vehicle that assures interoperability through a reference implementation that provides identical implementation of common functions. It is important to realize that the COE is both a standard and an actual product.

common ownership See Part II, 45 CFR 164.504.

common security control A security control that can be applied to one or more organization information systems and has the following properties: (1) the development, implementation, and assessment of the control can be assigned to a responsible official or organizational element (other than the information system owner); and (2) the results from the assessment of the control can be used to support the security certification and accreditation processes of an organization information system where that control has been applied.

communication Information transfer according to agreed conventions.

communication protocols A set of rules that govern the operation of hardware or software entities to achieve communication.

communications medium The path or physical channel in a network over which information travels.

communications protocol (protocol) A set of rules that every computer follows to transfer information.

communications satellite A microwave repeater in space.

communications security The protection that ensures the authenticity of telecommunications and that results from the application of measures taken to deny unauthorized persons access to valuable information that might be derived from the acquisition of telecommunications.

communications service provider A third party who furnishes the conduit for information.

communications software Helps you communicate with other people.

communications system A mix of telecommunications and automated information systems used to originate, control, process, encrypt, and transmit or receive information. Such a system generally consists of the following connected or connectable devices (1) automated information equipment (AIS) on which information is originated; (2) A central controller (i.e., CIHS, C-LAN) of, principally, access rights and information distribution; (3) a telecommunications processor (i.e., TERP, IMH) which prepares information for transmission; and (4) national-level devices which encrypt information (COMSEC/CRYPTO/CCI) prior to its transmission via Diplomatic Telecommunications Service (DTS) or commercial carrier.

companding The process where there is a greater number of samples provided at lower power conditions of the signal waveform rather than at the higher power portions of the same waveform.

compare A computer-applied function that examines two elements of data to determine their relationship to one another.

compartmentalization The isolation of the operating system, user programs, and data files from one another in main storage to protect them against unauthorized or concurrent access by other users or programs. Also, the division of sensitive data into small, isolated blocks to reduce risk to the data.

compartmented mode INFOSEC mode of operation wherein each user with direct or indirect access to a system, its peripherals, remote terminals, or remote hosts has all of the following: (1) valid security clearance for the most restricted information processed in the system; (2) formal access approval and signed nondisclosure agreements for that information which a user is to have access; and (3) valid need-to-know for information that a user is to have access.

competitive advantage Providing a product or service in a way that customers value more than what the competition is able to do.

competitive local exchange carriers (CLEC) A competitive access provider that also provides switched local services, such as local dial tone and Centrex. CLEC are authorized by state commissions to resell existing incumbent LEC services at wholesale rates and lease component facilities for use with their own facilities.

compiler A program that translates high-level computer language instructions into machine code.

complementor Provides services that complement the offerings of the enterprise and thereby extend its value-adding capabilities to its customers.

completeness The property that all necessary parts of an entity are included. Completeness of a product often means that the product has met all requirements.

compliance date Under HIPAA, this is the date by which a covered entity must comply with a standard, an implementation specification, or a modification. This is usually 24 months after the effective data of the associated final rule for most entities, but 36 months after the effective data for small health plans. For future changes in the standards, the compliance date would be at least 180 days after the effective data, but can be longer for small health plans and for complex changes. Also see Part II, 45 CFR 160.103.

component Basic unit designed to satisfy one or more functional requirements.

composite primary key The primary key fields from two intersecting relations.

composite threat list A Department of State threat list intended to cover all localities operating under the authority of a chief of mission and staffed by direct-hire U.S. personnel. This list is developed in coordination with the intelligence community and issued semiannually by the Bureau of Diplomatic Security.

compression A method of storing data in a format that requires less space than normal.

compromise Unauthorized disclosure or loss of sensitive information.

compromising emanations Electromagnetic emanations that convey data and that, if intercepted and analyzed, could compromise sensitive information being processed by a computer system.

COMPUSEC Computer security.

computer The hardware, software, and firmware components of a system that are capable of performing calculations, manipulations, or storage of data. It usually consists of arithmetic, logical, and control units, and may have input, output, and storage devices.

computer crime The act of using IT to commit an illegal act.

computer emergency response team (CERT) The CERT is chartered to work with the Internet community to facilitate its response to computer security events involving Internet hosts, to take proactive steps to raise the community's awareness of computer security issues, and to conduct research targeted at improving the security of existing systems. The U.S. CERT is based at Carnegie Mellon University in Pittsburgh; regional CERTs are like NICs, springing up in different parts of the world.

computer ethics The issues and standards that support the proper use of IT which are not criminal or threatening to another person or organization.

computer evidence Computer evidence is a copy of a document stored in a computer file that is identical to the original. The legal "best evidence" rules change when it comes to the processing of computer evidence. Another unique aspect of computer evidence is the potential for unauthorized copies to be made of important computer files without leaving behind a trace that the copy was made. This situation creates problems concerning the investigation of the theft of trade secrets (e.g., client lists, research materials, computer-aided design files, formulas, and proprietary software).

computer forensics The term *computer forensics* was coined in 1991 in the first training session held by the International Association of Computer Specialists (IACIS) in Portland, Oregon. Since then, computer forensics has become a popular topic in computer security circles and in the legal community. Like any other forensic science, computer forensics deals with the application of law to a science. In this case, the science involved is computer science and some refer to it as Forensic Computer Science. Computer forensics has also been described as the autopsy of a computer hard disk drive because specialized software tools and techniques are required to analyze the various levels at which computer data is stored after the fact. Computer forensics deals with the preservation, identification, extraction, and documentation of computer evidence. The field is relatively new to the private sector, but it has been the mainstay of technology-related investigations and intelligence gathering in law enforcement and military agencies since the mid-1980s. Like any other forensic science, computer forensics involves the use of sophisticated technology tools and procedures that must be followed to guarantee the accuracy of the preservation of evidence and the accuracy of results concerning computer evidence processing. Typically, computer forensic tools exist in the form of computer software.

Computer Fraud and Abuse Act PL 99-474 Computer Fraud and Abuse Act of 1986. Strengthens and expands the 1984 Federal Computer Crime Legislation. Law extended to computer crimes in private enterprise and anyone who willfully disseminates information for the purpose of committing a computer crime (i.e., distribute phone numbers to hackers from a BBS).

Computer Matching Act (P.L. 100-503) The Computer Matching and Privacy Act of 1988 ensures privacy, integrity, and verification of data disclosed for computer matching and establishes data integrity boards within federal agencies.

Computer Matching Act Public Law (PL) 100-53 Computer Matching and Privacy Act of 1988. Ensures privacy, integrity, and verification of data disclosed for computer matching; establishes Data Integrity Boards within federal agencies.

computer network Two or more computers connected so that they can communicate with each other and share information, software, peripheral devices, and processing power.

computer output microfilm (COM) The production of computer output on photographic film.

computer program A series of operations that perform a task when executed in logical sequence.

computer security The practice of protecting a computer system against internal failures, human error, attacks, and natural catastrophes that might cause improper disclosure, modification, destruction, or denial-of-service.

Computer Security Act PL 100-235 Computer Security Act of 1987 directs the National Bureau of Standards (now the National Institute of Standards and Technology [NIST]) to establish a computer security standards program for federal computer systems.

computer system An interacting assembly of elements, including at least computer hardware and usually software, data procedures, and people.

computer system security All of the technological safeguards and managerial procedures established and applied to computers and their networks (including related hardware, firmware, software, and data) to protect organizational assets and individual privacy.

computer virus Software that is written with malicious intent to cause annoyance or damage.

computer-aided design (CAD) A term used to describe the use of computer technology as applied to the design of problems and opportunities.

computer-aided instruction (CAI) The interactive use of a computer for instructional purposes. Software provides educational content to students and adjusts its presentation to the responses of the individual.

computer-aided manufacturing (CAM) The use of computer technology as applied to the manufacturing of computer technology as applied to the manufacturing of goods and services.

computer-aided software engineering (CASE) Tools that automate the design, development, operation, and maintenance of software.

Computer-Based Patient Record Institute (CPRI)–Healthcare Open Systems and Trials (HOST) An industry organization that promotes the use of healthcare information systems, including electronic healthcare records.

computing environment The total environment in which an automated information system, network, or component operates. The environment includes physical, administrative, and personnel procedures as well as communication and networking relationships with other information systems.

COMSEC Communications security.

COMSEC account Administrative entity, identified by an account number, used to maintain accountability, custody, and control of COMSEC material.

COMSEC custodian Person designated by proper authority to be responsible for the receipt, transfer, accounting, safeguarding, and destruction of COMSEC material assigned to a COMSEC account.

COMSEC facility Space used for generating, storing, repairing, or using COMSEC material.

COMSEC manager Person who manages the COMSEC resources of an organization.

COMSEC material Item designed to secure or authenticate telecommunications. COMSEC material includes, but is not limited to key, equipment, devices, documents, firmware, or software that embodies or describes cryptographic logic and other items that perform COMSEC function.

COMSEC material control system (CMCS) Logistics and accounting system through which COMSEC material marked “CRYPTO” is distributed, controlled, and safeguarded. Included are the COMSEC central offices of record, crypto-logistic depots, and COMSEC accounts.

COMSEC officer The properly appointed individual responsible to ensure that COMSEC regulations and procedures are understood and adhered to, that the COMSEC facility is operated securely, that personnel are trained in proper COMSEC practices, and who advises on communications security matters. Only Department of State personnel will be appointed.

concealment systems A method of keeping sensitive information confidential by embedding it in irrelevant data.

concentrator A computer that consolidates the signals from any slower speed transmission lines into a single faster line or performs the reverse function.

concurrent processing The capability of a computer to share memory with several programs and simultaneously execute the instructions provided by each.

condensation The process of reducing the volume of data managed without reducing the logical consistency of data. It is essentially different than compaction in that condensation is done at the record level whereas compaction is done at the system level.

condition test A comparison of two data items in a program to determine whether one value is equal to, less than, or greater than the second value.

conditional branch The alteration of the normal sequence of program execution following the text of the contents of a memory area.

conditional formatting Highlights the information in a cell that meets some specified criteria.

conductor A material that allows the easy transfer of electrons from one atom to another.

Conference on Data Systems Languages (CODASYL) A Department of Defense-sponsored group that studies the requirements and design specifications for a common business programming language.

confidence Confidence in electronic interactions can be significantly increased by solutions that address the basic requirements of integrity, confidentiality, authentication, authorization and access management or access control.

confidentiality A concept that applies to data that must be held in confidence and describes that status or degree of protection that must be provided for such data about individuals as well as organizations.

confidentiality loss The compromise of sensitive, restricted, or classified data or software.

configuration control The process of controlling modifications to the system's hardware, firmware, software, and documentation that provides sufficient assurance that the system is protected against the introduction of improper modifications prior to, during, and after system implementation. Compare *configuration management.*

configuration management The use of procedures appropriate for controlling changes to a system's hardware, software, or firmware structure to ensure that such changes will not lead to a weakness or fault in the system.

cnfiguration manager The individual or organization responsible for configuration control or configuration management.

confinement (1) Confining an untrusted program so that it can do everything it needs to do to meet the user's expectation, but nothing else. (2) Restricting an untrusted program from accessing system resources and executing system processes. Common confinement techniques include DTE, least privilege, and wrappers.

connected mode The state of user equipment switched on and an RRC connection established.

connection A communication channel between two or more endpoints (e.g., terminal, server, etc.).

connectionless The model of interconnection in which communication takes place without first establishing a connection. Sometimes (imprecisely) called *datagram.* Examples: Internet IP and OSI CLNP, UDP, ordinary postcards.

connection-oriented The model of interconnection in which communication proceeds through three well-defined phases: connection establishment, data transfer, and connection release. Examples: X.25, Internet IP and OSI TP4, ordinary telephone calls.

connectivity The uninterrupted availability of information paths for the effective performance of C2 functions.

connectivity software Enables a computer to "dial up" or connect to another computer.

consent Explicit permission, given to a Web site by a visitor, to handle her personal information in specified ways. Web sites that ask users to provide personally identifiable information should be required to obtain "informed consent," which implies that the company fully discloses its information practices prior to obtaining personal data or permission to use it.

consistency Logical coherency among all integrated parts; also, adherence to a given set of instructions or rules.

console operator Someone who works at a computer console to monitor operations and initiate instructions for efficient use of computer resources.

constant A value in a computer program that does not change during program execution.

construct An object; especially a concept that is constructed or synthesized from simple elements.

consumer electronics Any electronic/electrical devices, either AC- or battery-powered, which are not part of the facility infrastructure. Some examples are radios, televisions, electronic recording or playback equipment, PA systems, paging devices, and dictaphones (see also *electronic equipment*).

consumers Traditionally, the ultimate user or consumer of goods, ideas, and services. However, the term also is used to imply the buyer or decision maker as well as the ultimate consumer. A mother buying cereal for consumption by a small child is often called the *consumer*, although she may not be the ultimate user.

content See completeness.

content of communication (CC) Information exchanged between two or more users of a telecommunications service, excluding intercept related information (IRI). This includes information which may, as part of some telecommunications service, be stored by one user for subsequent retrieval by another.

content of communication link A communication channel for HI3 information between a mediation function and an LEMF.

contention Occurs during multiple access to a network in which the network capacity is allocated on a "first come, first served" basis.

contextual information Information derived from the context in which an access is made (for example, time of day).

contingency plans Plans for emergency response, backup operations, and post-disaster recovery maintained by a computer information processing facility as a part of its security program.

continuity The uninterrupted availability of information paths for the effective performance of organizational function.

continuous-mode operation Systems that are operational continuously, 24 h a day, 7 days a week.

contrary See Part II, 45 CFR 160.202.

control Any protective action, device, procedure, technique, or other measure that reduces exposures.

control break A point during program processing at which some special processing event takes place. A change in the value of a control field within a data record is characteristic of a control break.

control field A field of data within a record used to identify and classify a record.

control logic The specific order in which processing functions are carried out by a computer.

control signals Computer-generated signals for the automatic control of machines and processes.

control statement A command in a computer program that establishes the logical sequence of processing operations.

control structure A program that contains a logical construct of sequences, repetitions, and selections.

control totals Accumulations of numeric data fields that are used to check the accuracy of the input, processing, or output data.

control unit A component of the CPU that evaluates and carries out program processing and execution.

control zone The space surrounding equipment that is used to process sensitive information and that is under sufficient physical and technical control to preclude an unauthorized entry or compromise.

controllability The ability to control the situation following a failure. (Note that controllability has a different meaning when used in the context of testability analysis.).

controllable isolation Controlled sharing in which the scope or domain of authorization can be reduced to an arbitrarily small set or sphere of activity.

controlled access area Controlled access areas are specifically designated areas within a building where classified information may be handled, stored, discussed, or processed.

controlled cryptographic item (CCI) Secure telecommunications or information handling equipment, or associated cryptographic components, which are unclassified but governed by a special set of control requirements.

controlled security mode A system is operating in the controlled security mode when at least some users with access to the system have neither a security clearance nor a need-to-know for all classified material contained in the system. However, the separation and control of users and classified material on the basis, respectively, of security clearance and security classification are not essentially under operating system control as in the multilevel security mode.

controlled sharing The condition that exists when access control is applied to all users and components of a resource-sharing computer system.

controlled shipment The transport of material from the point at which the destination of the material is first identified for a site, through installation and use, under the continuous 24-hour control of secret-cleared U.S. citizens or by DS-approved technical means.

conversational program A program that permits interaction between a computer and a user.

conversion The process of replacing a computer system with a new one.

conversion rate The percentage of customers who visit a Web site and actually buy something.

cookie A cookie is a piece of text that a Web server can store on a user's hard disk. Cookies allow a Web site to store information on a user's machine and later retrieve it. The pieces of information are stored as name-value pairs.

cooperative processing The ability to distribute resources (i.e., programs, files, and databases) across the network.

coordination of benefits (COB) A process for determining the respective responsibilities of two or more health plans that have some financial responsibility for a medical claim. Also called *cross-over*.

COP Cryptographic operation.

copy An accurate reproduction of information contained on an original physical item, independent of the original physical item.

copyright The author or artist's right to control the copying of his or her work.

CORBA Common Object Request Broker Architecture, introduced in 1991 by the OMG, defined the Interface Definition Language (IDL) and the application programming interfaces (APIs) that enable client/server object interaction within a specific implementation of an object request broker (ORB).

CORBA security The Object Management Group standard that describes how to secure CORBA environments.

CORF Comprehensive outpatient rehabilitation facility.

corporate security policy The set of laws, rules and practices that regulate how assets including sensitive information are managed, protected and distributed within a user organization.

corrective Action The practice and procedure for reporting, tracking, and resolving identified problems, in both the software product and the development process. Their resolution provides a final solution to the identified problem.

corrective maintenance The identification and removal of code defects.

correctness The extent to which software is free from design and coding defects (i.e., fault free). Also, the extent to which software meets its specified requirements and user objectives.

corruption Departure from an original, correct data file or correctly functioning system to an improper state.

cost/benefit analysis Determination of the economic feasibility of developing a system on the basis of a comparison of the projected costs of a proposed system and the expected benefits from its operation.

cost-risk analysis The assessment of the cost of potential risk of loss or compromise of data in a computer system without data protection versus the cost of providing data protection.

COT See chain of trust.

COTS Commercial off-the-shelf software.

counterfeit software Software that is manufactured to look like the real thing and sold as such.

counterfeits Duplicates that are copied and packaged to resemble the original as closely as possible. The original producer's trademarks and logos are reproduced in order to mislead the consumer into believing that they are buying an original product.

countermeasure The deployment of a set of security services to protect against a security threat.

coupling The manner and degree of interdependence between software modules. Types include common environment coupling, content coupling, control coupling, data coupling, hybrid coupling, and pathological coupling.

courseware Computer programs used to deliver educational materials within computer-assisted instruction systems.

COV Tests, coverage.

cover escrow An extraction process method that needs both the original piece of information and the encoded one in order to extract the embedded data.

cover medium The medium in which we want to hide data; it can be an innocent looking piece of information for steganography, or an important medium that must be protected for copyright or integrity reasons.

covered entity The specific types of organizations to which HIPAA applies, including providers, health plans (payers), and clearinghouses (who process nonstandard claims from providers and distribute them to the payers in their required formats—a process that will not be necessary if providers adopt the HIPAA transactions standards).

covered function Functions that make an entity a health plan, a healthcare provider, or a healthcare clearinghouse. Also see Part II, 45 CFR 164.501.

covert channel A channel of communication within a computer system, or network, which is not designed or intended to transfer information.

covert storage channel A covert channel that involves the direct or indirect writing of a storage location by one process and the direct or indirect reading of the storage location by another process. Covert storage channels typically involve a finite resource that is shared by two subjects at different security levels.

covert timing channel A covert channel in which one process signals information to another by modulating its own use of system resources in such a way that this manipulation affects the real response time observed by the second process.

CPE Customer premise equipment.

CPRI Computer-based Patient Record Institute, an organization formed in 1992 to promote adoption of healthcare information systems. Has created a security toolkit with sample policies and procedures.

CPRI–HOST See the Computer-Based Patient Record Institute–Healthcare Open Systems and Trials.

CPT See current procedural terminology.

CPU The central processing unit; the brains of the computer.

cracker The correct name for an individual who hacks into a networked computer system with malicious intentions. The term hacker is used interchangeably (although incorrectly) because of media hype of the word hacker. A cracker explores and detects weak points in the security of a computer networked system and then exploits these weaknesses using specialized tools and techniques.

crash-proof software Utility software that helps save information if the system crashes and the user is forced to turn it off and then back on.

CRC Cyclical redundancy check.

credentials Data that is transferred to establish the claimed identity of an entity.

critical path A tool used in project management techniques and is the duration based on the sum of the individual tasks and their dependencies. The critical path is the shortest period in which a project can be accomplished.

critical software A defined set of software components that have been evaluated and whose continuous operation has been determined essential for safe, reliable, and secure operation of the system. Critical software is composed of three elements: (1) safety-critical and safety-related software, (2) reliability-critical software, and (3) security-critical software.

critical success factor (CSF) A factor simply critical to the organization's success.

criticality The severity of the loss of either data or system functionality. Involves judicious evaluation of system components and data when a property or phenomenon undergoes unwanted change.

criticality analysis An analysis or assessment of a business function or security vulnerability based on its criticality to the organization's business objectives. A variety of criticality may be used to illustrate the criticality.

CRL Certificate revocation list.

cross certification Practice of mutual recognition of another certification authority is certificates to an agreed level of confidence. Usually evidenced in contract.

crossover The process within a genetic algorithm where portions of the good outcome are combined in the hope of creating an even better outcome.

crossover error rate (CER) A comparison metric for different biometric devices and technologies; the error rate at which FAR equals FRR. The lower the CER, the more accurate and reliable the biometric device.

crosstalk An unwanted transfer of energy from one communications channel to another.

cross-walk See data mapping.

CRT A monitor that looks like a television set.

CRUD (create, read, update, delete) The four primary procedures or ways a system can manipulate information.

cryptanalysis The study of techniques for attempting to defeat cryptographic techniques and, more generally, information security services.

cryptanalyst Someone who engages in cryptanalysis.

CRYPTO Marking or designator identifying COMSEC keying material used to secure or authenticate telecommunications carrying classified or sensitive U.S. government or U.S. government-derived information.

crypto ignition key (CIK) The device or electronic key used to unlock the secure mode of crypto equipment.

cryptographic access The prerequisite to, and authorization for, access to crypto information, but does not constitute authorization for use of crypto equipment and keying material issued by the Department.

cryptographic algorithm A method of performing a cryptographic transformation (see *cryptography*) on a data unit. Cryptographic algorithms may be based on symmetric key methods (the same key is used for both encipher and decipher transformations) or on asymmetric keys (different keys are used for encipher and decipher transformations).

cryptographic checkvalue Information that is derived by performing a cryptographic transformation on a data unit.

cryptographic key A parameter used with a cryptographic algorithm to transform, validate, authenticate, encrypt or decrypt data.

cryptographic material All COMSEC material bearing the marking "CRYPTO" or otherwise designated as incorporating cryptographic information.

cryptographic system The documents, devices, equipment, and associated techniques that are used as a unit to provide a single means of encryption.

cryptography The study of mathematical techniques related to aspects of information security such as confidentiality, data integrity, entity authentication, and data origin authentication. Cryptography is not the only means of providing information security services, but rather one set of techniques. The word itself comes from the Greek word *kryptos*, which means "hidden" or "covered." Cryptography is a way to hide writing but yet retain a way to uncover it again.

cryptology The science that deals with hidden, disguised, or encrypted communications. It embraces communications security and communications intelligence.

cryptolope An IBM product which means "cryptographic envelope." Cryptolope objects are used for secure, protected delivery of digital content by using encryption and digital signatures.

cryptosystem A general term referring to a set of cryptographic primitives used to provide information security services.

CSI Computer Security Institute.

CSMA/CD Carrier sense multiple access/collision detect.

CSNP Complete sequence number PDU.

CSPDN Circuit-switched public data network.

CSU/DSU Channel service unit/digital service unit.

CTS Clear to send.

CUD Caller user data (X.25).

culture The collective personality of a nation, society, or organization, encompassing language, traditions, currency, religion, history, music, and acceptable behavior, among other things.

current A measure of how much electricity passes a point on a wire in a given time frame. Current is measured in amperes or amps.

Current Dental Terminology (CDT) A medical code set, maintained and copyrighted by the ADA, that has been selected for use in the HIPAA transactions.

Current Procedural Terminology (CPT) A medical code set, maintained and copyrighted by the AMA, that has been selected for use under HIPAA for non-institutional and non-dental professional transactions.

custodian An individual who has possession of or is otherwise charged with the responsibility for safeguarding and accounting for classified information.

custom auto filter function Allows one to hide all the rows in a list except those that match criteria specified.

customer relationship management (CRM) CRM entails all aspects of service and sales interactions a company has with its customer. CRM often involves personalizing online experiences, help-desk software, and e-mail organizers.

customer-integrated system An extension of a TPS that places technology in the hands of an organization's customers and allows them to process their own transactions.

customers The actual or prospective purchaser of products or services.

cybercops A criminal investigator of online fraud or harassment.

cybercrime A criminal offense that involves the use of a computer network.

cyberspace Refers to the connections and locations (even virtual) created using computer networks. The term "Internet" has become synonymous with this word.

cyberterrorist One who seeks to cause harm to people or destroy critical systems or information.

cycle One complete sequence of an event or activity. Often refers to electrical phenomena. One electrical cycle is a complete sine wave.

cyclical redundancy check (CRC) A process used to check the integrity of a block of data. It provides an integrity check of the data before it is sent out into the wide area network. Its value depends on the hexadecimal value of the number of 1s in the data block. The transmitting device calculates the value and appends it to the data block; the receiving end makes a similar calculation and compares its results to the added character. If there is a difference, the recipient requests retransmission.

DOD Department of Defense.

D2 A rating provided by the NCSC for PC security subsystems that corresponds to the features of the C2 level. A computer security subsystem is any hardware, firmware and software which are added to a computer system to enhance the security of the overall system.

DA Destination address.

DAC Discretionary access controls.

DAC Dual attached concentrator.

damage Loss, injury, or deterioration caused by the negligence, design, or accident of one person to another, in respect of the latter's person or property; the harm, detriment, or loss sustained by reason of an injury.

DARPA Defense Advanced Research Projects Agency.

DAS Dual attachment station (FDDI, CDDI).

DASS Distributed authentication security service.

data Raw facts and figures that are meaningless by themselves. Data can be expressed in characters, digits, and symbols, which can represent people, things, and events.

data administration The function in an organization that plans for, oversees the development of, and monitors the information resource.

data administration subsystem Helps manage the overall database environment by providing facilities for backup and recovery, security management, query optimization, concurrency control, and change management.

data aggregation See Part II, 45 CFR 164.501.

data classification Data classification is the assigning a level of sensitivity to data as they are being created, amended, enhanced, stored, or transmitted. The classification of the data should then determine the extent to which the data need to be controlled/secured and is also indicative of its value in terms of its importance to the organization.

data communications The transmission of data between more than one site through the use of public and private communications channels or lines.

data condition A description of the circumstances in which certain data is required. See also Part II, 45 CFR 162.103.

data contamination A deliberate or accidental process or act that compromises the integrity of the original data.

data content Under HIPAA, this is all the data elements and code sets inherent in a transaction, and not related to the format of the transaction. See also Part II, 45 CFR 162.103.

data content committee (DCC) See designated data content committee.

data council A coordinating body within HHS that has high-level responsibility for overseeing the implementation of the A/S provisions of HIPAA.

data definition language (DDL) A set of instructions or commands used to define data for the data dictionary. A data definition language (DDL) is used to describe the structure of a database.

data dictionary A document or listing defining all items or processes represented in a data flow diagram or used in a system.

data diddling Changing data with malicious intent before or during input to the system.

data element The smallest unit of data accessible to a database management system or a field of data within a file processing system.

Data Encryption Standard (DES) A private key cryptosystem published by the National Institutes of Standards and Technology (NIST). DES is a symmetric block cipher with a block length of 64 bits and an effective key length of 56 bits. DES has been used commonly for data encryption in the forms of software and hardware implementation.

data flow analysis A graphic analysis technique to trace the behavior of program variables as they are initialized, modified, or referenced during program execution.

data flow diagram A descriptive modeling tool providing a graphic and logical description of a system.

data grids Grids that provide shared data storage. Based on a catalog where logical file names are associated to physical file names.

data integrity The state that exists when automated information or data is the same as that in the source documents and has not been exposed to accidental or malicious modification, alteration, or destruction.

Data Interchange Standards Association (DISA) A body that provides administrative services to X12 and several other standards-related groups.

data item A discrete representation having the properties that define the data element to which it belongs. See also data element.

data link A serial communications path between nodes or devices without any intermediate switching nodes. Also, the physical two-way connection between such devices.

data link layer (DLL) A layer with the responsibility of transmitting data reliably across a physical link (cabling, for example) using a networking technology such as Ethernet. The DLL encapsulates data into frames (or cells) before it transmits it. It also enables multiple computer systems to share a single physical medium when used in conjunction with a media access control methodology such as CSMA/CD.

Data Manipulation Language (DML) A data manipulation language (DML) provides the necessary commands for all database operations, including storing, retrieving, updating, and deleting database records.

data mapping The process of matching one set of data elements or individual code values to their closest equivalents in another set of them. This is sometimes called a *cross-walk*.

data mart Subset of a data warehouse in which only a focused portion of the data warehouse is stored.

data mining A methodology used by organizations to better understand their customers, products, markets, or any other phase of the business.

data model A conceptual model of the information needed to support a business function or process.

data networking switches Equipment that performs the functions of establishing and releasing connections on a data network.

data normalization In data processing, a process applied to all data in a set that produces a specific statistical property. It is also the process of eliminating duplicate keys within a database. Useful as organizations use databases to evaluate various security data.

data objects Objects or information of potential probative value that are associated with physical items. Data objects may occur in different formats without altering the original information.

data origin authentication The corroboration that the entity responsible for the creation of a set of data is the one claimed.

data owner See information owner.

data profiling The use of information about your lifestyle and habits to provide a descriptive profile of your life. At its simplest, data profiling is used by marketing companies to identify you as a possible customer. At its most complex data profiling can be used by security services to identify potential suspects for unlawful activity, or to highlight parts of a person's life where other forms of surveillance may reveal something about their activities. In those states where the European Directive on Data Protection is in force, you have rights of access to any data held about you for the purposes of data processing or profiling.

data protection engineering The methodology and tools used to design and implement data protection mechanisms.

data record An identifiable set of data values treated as a unit, an occurrence of a schema in a database, or collection of atomic data items describing a specific object, event, or tuple (e.g., row of a table).

data representation The manner in which data is characterized in a computer system and its peripheral devices.

data safety Ensuring that (1) the intended data has been correctly accessed, (2) the data has not been manipulated or corrupted intentionally or accidentally, and (3) the data is legitimate.

data security The protection of data from accidental or malicious modification, destruction, or disclosure.

data segment A collection of data elements accessible to a database management system; a record in a file processing system.

data set A named collection of logically related data items, arranged in a prescribed manner and described by control information to which the programming system has access.

data warehouse A collection of integrated subject-oriented databases designed to support the decision support function, where each unit of data is relevant to some moment in time. The data warehouse contains atomic data and summarized data.

database An integrated aggregation of data usually organized to reflect logical or functional relationships among data elements.

database administrator (DBA) (1) A person who is in charge of defining and managing the contents of a database. (2) The individual in an organization who is responsible for the daily monitoring and maintenance of the databases. The database administrator's function is more closely associated with physical database design than the data administrator's function is.

database management system (DBMS) The software that directs and controls data resources.

database-based workflow system Stores the document in a central location and automatically asks the knowledge workers to access the document when it is their turn to edit the document.

data-dependent protection The protection of data at a level that is commensurate with the sensitivity of the entire file.

datagram Logical grouping of information sent as a network layer unit over a transmission medium without prior establishment of a virtual circuit. IP datagrams are the primary information units in the Internet. The terms "cell," "frame," "message," "packet," and "segment" are also used to describe logical information groupings at various layers of the OSI Reference Model and in various technology circles.

data-link control layer Layer 2 in the SNA architectural model. Responsible for the transmission of data over a particular physical link. Corresponds roughly to the data-link layer of the OSI model.

data-link layer Layer 2 of the OSI reference model. Provides reliable transit of data across a physical link. The data-link layer is concerned with physical addressing, network topology, line discipline, error notification, ordered delivery of frames, and flow control. The IEEE divided this layer into two sublayers: the MAC sublayer and the LLC sublayer. Sometimes simply called the *link layer.* Roughly corresponds to the data-link control layer of the SNA model.

data-mining agent An intelligent agent or application that operates in a data warehouse discovering information.

data-mining tool Software tool used to query information in a data warehouse.

data-related concepts (1) Clinical or medical code sets identify medical conditions and the procedures, services, equipment, and supplies used to deal with them. Nonclinical, nonmedical, or administrative code sets identify or characterize entities and events in a manner that facilitates an administrative process. HIPAA defines a data element as the smallest unit of named information. In X12 language, that would be a simple data element. But X12 also has composite data elements, which aren't really data elements, but are groups of closely related data elements that can repeat as a group. X12 also has segments, which are also groups of related data elements that tend to occur together, such as street address, city, and state. These segments can sometimes repeat, or one or more segments may be part of a loop that can repeat. For example, you might have a claim loop that occurs once for each claim, and a claim service loop that occurs once for each service included in a claim. An X12 transaction is a collection of such loops, segments, etc., that supports a specific business process, whereas an X12 transmission is a communication session during which one or more X12 transactions is transmitted. (2) Data elements and groups may also be combined into records that make up conventional files, or into the tables or segments used by DBMS. A designated code set is a code set that has been specified within the body of a rule. These are usually medical code sets. Many other code sets are incorporated into the rules by reference to a separate document, such as an implementation guide, that identifies one or more such code sets. These are usually administrative code sets. (3) Electronic data is data that is recorded or transmitted electronically, whereas non-electronic data would be everything else. Special cases would be data transmitted by fax and audio systems, which is, in principle, transmitted electronically, but which lacks the underlying structure usually needed to support automated interpretation of its contents. (4) Encoded data is data represented by some identification or classification scheme, such as a provider identifier or a procedure code. Nonencoded data would be more nearly freeform, such as a name, a street address, or a description. Theoretically, of course, all data, including grunts and smiles, is encoded. (5) For HIPAA purposes, internal data, or internal code sets, are data elements that are fully specified within the HIPAA implementation guides. For X12 transactions, changes to the associated code values and descriptions must be approved via the normal standards development process, and can only be used in the revised version of the standards affected. X12 transactions also use many coding and identification schemes that are maintained by external organizations. For these external code sets, the associated values and descriptions can change at any time and still be usable in any version of the X12 transactions that uses the associated code set. (6) Individually identifiable data is data that can be readily associated with a specific individual. Examples would be a name, a personal identifier, or a full street address. If life were simple, everything else would be non-identifiable data. But even if you remove the obviously identifiable data from a record, other data elements present can also be used to re-identify it. For example, a birth date and a ZIP code might be sufficient to re-identify half the records in a file. The re-identifiability of data can be limited by omitting, aggregating, or altering such data to the extent that the risk of it being re-identified is acceptable. (7) A specific form of data representation, such as an X12 transaction, will generally include some structural data that is needed to identify and interpret the transaction itself, as well as the business data content that the transaction is designed to transmit. Under HIPAA, when an alternate form of data collection such as a browser is used, such structural or format-related data elements can be ignored as long as the appropriate business data content is used. (8) Structured data is data the meaning of which can be inferred to at least some extent based on its absolute or relative location in a separately defined data structure. This structure could be the blocks on a form, the fields in a record, the relative positions of data elements in an X12 segment, etc. Unstructured data, such as a memo or an image, would lack such clues.

DAU User data protection data authentication.

DBMS Database management system.

DCC See data content committee.

DCE Data circuit-terminating equipment.

D-codes A subset of the HCPCS Level II medical code set with a high-order value of "D" that has been used to identify certain dental procedures. The final HIPAA transactions and code sets rule states that these D-codes will be dropped from the HCPCS, and that CDT codes will be used to identify all dental procedures.

DD See data dictionary.

DDE See direct data entry.

DDoS attacks Distributed denial of service attacks. These are denial-of-service assault from multiple sources.

DDP Datagram Delivery Protocol (AppleTalk).

DDR (1) Dial-on-demand routing. Dual data rate RAM.

dead drop A method of secret information exchange where the two parties never meet.

deadlock A condition that occurs when two users invoke conflicting locks in trying to gain access to a specific record or records.

deadlock A situation in which computer processing is suspended because two or more devices or processes are each awaiting resources assigned to the other.

debugging The process of correcting static and logical errors detected during coding. With the primary goal of obtaining an executable piece of code, debugging shares certain techniques and strategies with testing but differs in its usual ad hoc application and scope.

DeCC See Dental Content Committee.

decentralized computing An environment in which an organization splits computing power and locates it in functional business areas as well as on the desktops of knowledge workers.

deceptive trade practices Misleading or misrepresenting products or services to consumers and customers. In the United States these practices are regulated by the Federal Trade Commission at the federal level and typically by the Attorney General's Office of Consumer Protection at the state level. Microsoft: http://www.microsoft.com/security/glossary/

decipher The ability to convert, by use of the appropriate key, enciphered text into its equivalent plaintext.

decipherment The reversal of a corresponding reversible encipherment.

decision processing enterprise information portal Provides knowledge workers with corporate information for making key business decisions.

decision superiority Better decisions arrived at and implemented faster than an opponent can react, or in a noncombat situation, at a tempo that allows the force to shape the situation or react to changes and accomplish its mission.

decision support system (DSS) A computer information system that helps executives and managers formulate policies and plans. This support system enables the users to access information and assess the likely consequences of their decisions through scenario projections.

declassification The determination that particular classified information no longer requires protection against unauthorized disclosure in the interest of national security. Such determination shall be by specific action or automatically after the lapse of a requisite period of time or the occurrence of a specified event. If such determination is by specific action, the material shall be so marked with the new designation.

declassification event An event which would eliminate the need for continued classification.

decoding Changing a digital signal into analog form or another type of digital signal. The opposite of encoding.

decontrol The authorized removal of an assigned administrative control designation.

decrypt Synonymous with decipher.

decrypt/decipher/decode Decryption is the opposite of encryption. It is the transformation of encrypted information back into a legible form. Essentially, decryption is about removing disguise and reclaiming the meaning of information.

decryption The conversion through mechanisms or procedures of encrypted data into its original form.

decryption key A piece of information, in a digitized form, used to recover the plaintext from the corresponding ciphertext by decryption.

dedicated lines Private circuits between two or more stations, switches, or subscribers.

dedicated mode The operation of a computer system such that the central computer facility, connected peripheral devices, communications facilities, and all remote terminals are used and controlled exclusively by the users or groups of users for the processing of particular types and categories of information.

dedicated security mode A system is operating in the dedicated security mode when the system and all of its local and remote peripherals are exclusively used and controlled by specific users or groups of users who have a security clearance and need-to-know for the processing of a particular category and type of classified material.

dedicated server A microcomputer used exclusively to perform a specific service, such as to process the network operating system.

deduction A method of logical reasoning which results in necessarily true statements. As an example, if it is known that every man is mortal and that George is a man, then it can be deduced that George is mortal. Deduction is equivalent to the logical rule of modus ponens.

defect Deficiency; imperfection; insufficiency; the absence of something necessary for completeness or perfection; a deficiency in something essential to the proper use for the purpose for which a thing is to be used; a manufacturing flaw, a design defect, or inadequate warning.

defense in depth Provision of several overlapping subsequent limiting barriers with respect to one safety or security threshold, so that the threshold can only be surpassed if all barriers have failed.

defense information infrastructure (DII) The complete set of DoD information transfer and processing resources, including information and data storage, manipulation, retrieval, and display. More specifically, the DII is the shared or interconnected system of computers, communications, data, applications, security, people, training, and other support structure, serving the DoD's local and worldwide information needs. It connects DoD mission support, command and control, and intelligence computers and users through voice, data, imagery, video, and multimedia services; and it provides information processing and value-added services to subscribers over the DISN and interconnected Service and Agency networks. Data, information, and user applications software unique to a specific user are not considered part of the DII.

Defense Information Systems Network (DISN) A subelement of the Defense Information Infrastructure (DII), the DISN is the DoD's consolidated worldwide enterprise level telecommunications infrastructure that provides the end-to-end information transfer network for supporting military operations. It is transparent to its users, facilitates the management of information resources, and is responsive to national security and defense needs under all conditions in the most efficient manner.

defense-in-depth The practice of layering defenses to provide added protection. Security is increased by raising the cost to mount the attack. This system places multiple barriers between an attacker and an organization's business critical information resources. This strategy also provides natural areas for the implementation of intrusion-detection technologies.

defensive programming Designing software that detects anomalous control flow, data flow, or data values during execution and reacts in a predetermined and acceptable manner. The intent is to develop software that correctly accommodates design or operational shortcomings; for example, verifying a parameter or command through two diverse sources before acting upon it.68.

degauss To erase or demagnetize magnetic recording media (usually tapes) by applying a variable, alternating current (AC) field.

degraded-mode operation Maintaining the availability of the more critical system functions, despite failures, by dropping the less critical functions. Also referred to as graceful degradation.

degree (of a relation) The number of attributes or columns of a relation.

DEL Delivery and operation, delivery.

delegated accrediting authority (DAA) Official with the authority to formally assume responsibility for operating a system at an acceptable level of risk. This term is synonymous with designated accrediting authority and designated approval authority.

delegation The notation that an object can issue a request to another object in response to a request. The first object therefore delegates the responsibility to the second object. Delegation can be used as an alternative to inheritance.

Delphi A forecasting method where several knowledgeable individuals make forecasts and a forecast is derived by a trained analyst from a weighted average.

demand aggregation Combines purchase requests from multiple buyers into a single large order, which justifies a discount from the business.

demand-mode operation Systems that are used periodically on-demand; for example, a computer-controlled braking system in a car.

demodulation The reconstruction of an original signal from the modulated signal received at a destination device.

denial of service (DOS) The unauthorized prevention of authorized access to resources or the delaying of time-critical operations.

denial-of-service (DoS) attack The attacker floods a Web site with many electronic message requests for service that it slows down or crashes the network or computer targeted.

Dental Content Committee (DeCC) An organization hosted by the American Dental Association that maintains the data content specifications for dental billing. The Dental Content Committee has a formal consultative role under HIPAA for all transactions affecting dental healthcare services.

dependability That property of a computer system such that reliance can be justifiably placed on the service it delivers. The service delivered by a system is its behavior as it is perceived by its user(s); a user is another system or human that interacts with the former.

depth (1) Penetration layer achieved during or the degree of intensity of an IO attack. (2) The most profound or intense part or stage. The severest or worst part. The degree of richness or intensity.

derivative classification A determination that information is in substance the same as information currently classified, coupled with the designation of the level of classification.

DES Data Encryption Standard.

descriptive attributes The intrinsic characteristics of an object.

descriptor The text defining a code in a code set. See also Part II, 45 CFR 162.103.

design The aspect of the specification process that involves the prior consideration of the implementation. Design is the process that extends and modifies an analysis specification. It accommodates certain qualities including extensibility, reusability, testability, and maintainability. Design also includes the specification of implementation requirements such as user interface and data persistence.

design and implementation A phase of the systems development life cycle in which a set of functional specifications produced during systems analysis is transformed into an operational system for hardware, software, and firmware.

design review The quality assurance process in which all aspects of a system are reviewed publicly.

designated accrediting authority (DAA) Official with the authority to formally assume responsibility for operating a system at an acceptable level of risk. This term is synonymous with designated approval authority and delegated accrediting authority.

designated approving authority (DAA) The official who has the authority to decide on accepting the security safeguards prescribed for an AIS or that official who may be responsible for issuing an accreditation statement that records the decision to accept those safeguards.

designated code set A medical code set or an administrative code set that HHS has designated for use in one or more of the HIPAA standards.

designated data content committee or **designated DCC** An organization that HHS has designated for oversight of the business data content of one or more of the HIPAA-mandated transaction standards.

designated record set See Part II, 45 CFR 164.501.

designated standard A standard that HHS has designated for use under the authority provided by HIPAA.

designated standard maintenance organization (DSMO) See Part II, 45 CFR 162.103.

desktop computer The most popular choice for personal computing needs.

desktop publishing The use of computer technology equipped with special hardware, firmware, and software features to produce documents that look equivalent to those printed by a professional print company.

destruction Irretrievable loss of data file, or damage to hardware or software.

detect To discover threat activity within information systems, such as initial intrusions, during the threat activity or post-activity. Providing prompt awareness and standardized reporting of attacks and other anomalous external or internal system and network activity.

developer The organization that develops the IS.

DHCP Dynamic Host Configuration Protocol.

DHHS See HHS.

dial-up Access to switched network, usually through a dial or push-button telephone.

DIAP Defense-wide IA program (U.S. DoD).

DICOM See Digital Imaging and Communications in Medicine.

dielectric A nonconducting or insulating substance that resists passage of electric current, allowing electrostatic induction to act across it, as in the insulating medium between the plates of a condenser.

diffraction Signal loss as a result of variations in the terrain the signal crosses.

Digimark A company that creates digital watermarking technology used to authenticate, validate and communicate information within digital and analog media.

digit A single numeral representing an arithmetic value.

digital A mode of transmission where information is coded in binary form for transmission on the network.

digital audio tape (DAT) A magnetic tape technology. DAT uses 4-mm cassettes capable of backing up anywhere between 26 and 126 bytes of information.

digital cash An electronic representation of cash. Also called *e-cash*.

digital certificates A certificate identifying a public key to its subscriber, corresponding to a private key held by that subscriber. It is a unique code that typically is used to allow the authenticity and integrity of communication can be verified.

digital code signing The process of digitally signing computer code so that its integrity remains intact and it cannot be tampered with.

digital divide The fact that different peoples, cultures, and areas of the world or within a nation do not have the same access to information and telecommunications technologies.

digital economy Marked by the electronic movement of all types of information, not limited to numbers, words, graphs, and photos but also including physiological information such as voice recognition and synthesization, biometrics (a person's retina scan and breath, for example), and 3-D holograms.

digital fingerprint A characteristic of a data item, such as a cryptographic checkvalue or the result of performing a one-way hash function on the data, that is sufficiently peculiar to the data item that it is computationally infeasible to find another data item that possesses the same characteristics.

Digital Imaging and Communications in Medicine (DICOM) A standard for communicating images, such as radiographs, in a digitized form. This standard could become part of the HIPAA claim attachments standards.

digital modem A piece of equipment that joins a digital phone line to a piece of communication equipment, which may be a phone or a PC. Such equipment allows testing, condition, timing, interfacing, etc. But it does not do what a modem does: namely convert digital signals from machines into analog signals which can be carried on analog phone lines. The term digital modem, thus, is somewhat of a misnomer.

digital PABX An automatic switching system. No operator is needed to complete the call. In the original PBX system operators were sometimes needed to complete the calls. Also called *private automatic branch exchange.*

digital rights management (DRM) Focuses on security and encryption to prevent unauthorized copying limit distribution to only those who pay. This is considered first-generation DRM. Second-generation DRM covers: description, identification, trading, protection, monitoring and tracking of all forms of rights usages over both tangible and intangible assets including management of rights holders' relationships. It is important to note that DRM manages all rights, not just those involving digital content. Additionally, it is important to note that DRM is the "digital management of rights" and not the "management of digital rights." That is, DRM manages *all* rights, not only the rights applicable to permissions over digital content.

digital signature The act of electronically affixing an encrypted message digest to a computer file or message in which the originator is then authenticated to the recipient.

Digital Signature Standard (DSS) The National Security Administration's standard for verifying an electronic message.

digital subscriber line (DSL) A technology that dramatically increases the digital capacity of ordinary telephone lines (the local loops) into the home or office. DSL speeds are tied to the distance between the customer and the telephone company's central office.

digitize Converting an analog or continuous signal into a series of 1s and 0s, i.e., into a digital format.

DII Defense information infrastructure.

DIMM Dual inline memory module.

Diode Devices that conduct electricity in one direction only. They are sometimes referred to as *PN* (positive-negative) devices because they are made of a single semiconductive crystal with a positive terminal and a negative terminal.

direct access The method of reading and writing specific records without having to process all preceding records in a file.

direct access storage device (DASD) A data storage unit on which data can be accessed directly without having to progress through a serial file such as a magnetic tape file. A disk unit is a direct access storage device.

direct current (DC) A flow of electricity always in the same direction.

direct data entry (DDE) Under HIPAA, this is the direct entry of data that is immediately transmitted into a health plan's computer. See also Part II, 45 CFR 162.103.

direct organization A method of file organization under which records are located on the basis of their keys and associated addresses on the storage media.

direct treatment relationship See Part II, 45 CFR 164.501.

direction of arrival (DoA) The electromagnetic waves arrive at the directional antenna and are received more readily from one direction than from another. The antenna needs to be aligned with the direction of arrival.

directory A table specifying the relationships between items of data. Sometimes a table (index) giving the addresses of data.

directory engine search Organizes listings of Web sites into hierarchical lists.

directory service A service provided on a computer network that allows one to look up addresses (and perhaps other information such as public key certificates) based upon user-names.

DISA See the Data Interchange Standards Association.

disaster notification fees The fee a recovery site vendor usually charges when the customer notifies them that a disaster has occurred and the recovery site is required. The fee is implemented to discourage false disaster notifications.

disaster recovery cost curve Charts (1) the cost to the organization due to the unavailability of information and technology, and (2) the cost to the organization of recovering from a disaster over time.

disaster recovery plan A detailed process for recovering information or an IT system in the event of a catastrophic disaster such as a fire or flood.

disc mirroring This is the practice of duplicating data in separate volumes on two hard disks to make storage more fault-tolerant. Mirroring provides data protection in the case of disk failure, because data is constantly updated to both disks.

disclosure The release, transfer, provision of access to, or divulging in any other manner of information outside the entity holding the information. (See use, in contrast.).

disclosure history Under HIPAA, this is a list of any entities that have received personally identifiable healthcare information for uses unrelated to treatment and payment.

discrepancy reports A listing of items that have violated some detective control and require further investigation.

discrete cosine transform (DCT) Used in JPEG compression, the discrete cosine transform helps separate the image into parts of differing importance based on the image's visual quality; this allows for large compression ratios. The DCT function transforms data from a spatial domain to a frequency domain.

discretionary access control (DAC) A means of restricting access to objects based on the identity of subjects and groups to which they belong. The controls are discretionary in the sense that a subject with certain access permission is capable of passing that permission on to another subject.

disintermediation The use of the Internet as a delivery vehicle whereby intermediate players in a distribution channel can be bypassed.

disk address The positioned location of a data record on magnetic disk storage.

disk duplexing This refers to the use of two controllers to drive a disk subsystem. Should one of the controllers fail, the other is still available for disk I/O. Software applications can take advantage of both controllers to simultaneously read and write to different drives.

disk mirroring Disk mirroring protects data against hardware failure. In its simplest form, a two-disk subsystem would be attached to a host controller. One disk serves as the mirror image of the other. When data is written to it, it is also written to the other disk. Both disks will contain exactly the same information. If one fails, the other can supply the user data without problem.

disk operating system (DOS) Software that controls the execution of programs and may provide system services as resource allocation.

disk optimization software Utility software that organizes information on the hard disk in the most efficient way.

diskette A flexible disk storage medium most often used with microcomputers; also called a *floppy disk*.

distinguishing identifier Data that unambiguously distinguishes an entity in the authentication process. Such an identifier shall be unambiguous at least within a security domain.

distortion An undesired change in an image or signal. A change in the shape of an image resulting from imperfections in an optical system, such as a lens.

distributed application A set of information processing resources distributed over one or more open systems which provides a well-defined set of functionality to (human) users, to assist a given (office) task.

Distributed Component Object Model (DCOM) A protocol that enables software components to communicate directly over a network. Developed by Microsoft and previously called *Network OLE*, DCOM is designed for use across multiple network transports including Internet Protocols such as HTTP.

distributed computing The distribution of processes among computing components that are within the same computer or different computers on a shared network.

distributed computing environment (DCE) An architecture of standard programming interfaces, conventions, and server functionalities (e.g., naming, distributed file system, remote procedure call) for distributing applications transparently across networks of heterogeneous computers. Promoted and controlled by the Open Software Foundation (OSP), a consortium led by Hewlett-Packard, Digital Equipment Corp, and IBM.

distributed database A database management system with the ability to effectively manage data that is distributed across multiple computers on a network.

distributed denial-of-service (DDoS) attack Multiple computers flooding a Web site with so many requests for service that it slows down or crashes.

distributed environment A set of related data processing systems in which each system has its own capacity to operate autonomously but has some applications that are executed at multiple sites. Some of the systems may be connected with teleprocessing links into a network with each system serving as a node.

distributed system A multiworkstation, or terminal system where more than one workstation shares common system resources. The workstations are connected to the control unit/data storage element through communication lines.

dithering Creating the illusion of new colors and shades by varying the pattern of dots in an image. Dithering is also the process of converting an image with a certain bit depth to one with a lower bit depth.

DITSCAP Department of Defense Information Technology Security Certification and Accreditation Process.

diversity Using multiple different means to perform a required function or solve the same problem. Diversity can be implemented in software and hardware.

DIX Digital-Intel-Xerox.

DLC Data link control.

DLCI Data link connection identifier (frame relay).

DME Durable medical equipment.

DMEPOS Durable medical equipment, prosthetics, orthotics, and supplies.

DMERC See Medicare durable medical equipment regional carrier.

DMZ Commonly, it is the network segment between the Internet and a private network. It allows access to services from the Internet and the internal private network, while denying access from the Internet directly to the private network.

DNA SCP Digital Network Architecture Session Control Protocol (DECnet).

DNIC Data Network Identification Code (X.25).

DNS (domain name system, service, or **server)** A hierarchical database that is distributed across the Internet and allows names to be resolved to IP addresses and vice versa to locate services such as Web sites and e-mail. An Internet service that translates domain names into IP addresses.).

document Any recorded information regardless of its physical form or characteristics, including, without limitation, written or printed material; data processing cards and tapes; maps; charts; paintings; drawings; engravings; sketches; working notes and papers; reproductions of such things by any means or process; and sound, voice, or electronic recordings in any form.

documentation The written narrative of the development, workings, and operation of a program or system.

DoD Information Technology Security Certification and Accreditation Process (DITSCAP) The standard DoD process for identifying information security requirements, providing security solutions, and managing IS security activities.

DoD Trusted Computer System Evaluation Criteria (TCSEC) Document containing basic requirements and evaluation classes for assessing degrees of effectiveness of hardware and software security controls built into an IS. This document, DoD 5200.28 STD, is frequently referred to as the *Orange Book*.

domain The set of objects that a subject (user or process) has the ability to access.

domain and type enforcement A confinement technique in which an attribute called a *domain* is associated with each subject and another attribute called a *type* is associated with each object. A matrix specifies whether a particular mode of access to objects of a type is granted or denied to subjects in a domain.

domain dimension The dimension dealing with the structural aspects of the system involving broad, static patterns of internal behavior.

domain name The name used to identify an Internet host.

domain name server See DNS.

domain name system (DNS) The distributed name and address mechanism used in the Internet.

domain of interpretation (DOI) The DOI defines payload formats, the situation, exchange types, and naming conventions for certain information such as security policies, or cryptographic algorithms. It is also used to interpret the ISAKMP payloads.

DoS (1) Short for *denial-of-service attack*, a type of attack on a network that is designed to bring the network to its knees by flooding it with useless traffic. For all known DoS attacks, there are software fixes that system administrators can install to limit the damage caused by the attacks. (2) In general, any malicious action that denies availability of a system to users.

downgrading The determination that particular classified information requires a lesser degree of protection or no protection against unauthorized disclosure than currently provided. Such determination shall be by specific action or automatically after lapse of the requisite period of time or the occurrence of a specified event. If such determination is by specific action, the material shall be so marked with the new designation.

downlink frequencies Frequencies used in the transmission link reaching from a satellite to the ground.

downtime A period of time in which the computer is not available for operation.

DPT Tests, depth.

DQDB Distributed queue dual bus (SMDS).

DR Designated router.

Draft Standard for Trial Use (DSTU) An archaic term for any X12 standard that has been approved since the most recent release of X12 American National Standards. The current equivalent term is "X12 standard."

DRAM Dynamic random access memory.

DRG Diagnosis Related Group.

DRP Disaster recovery plan.

DS-0 Digital signal, level 0. A DS-0 is a voice-grade channel of 64 kbps.

DS-1 Digital signal, level 1 (1.544 Mb).

DS-3 Digital signal, level 3 (45 Mb).

DSA Digital Signature Algorithm.

DSAP Destination service access point (LLC).

DSE Data switching equipment.

DSL Digital subscriber line.

DSMO See designated standard maintenance organization.

DSR Data set ready.

DSS Digital signature standard; see FIPS PUB 186.165.

DSS (1) Digital subscriber signaling system 1. (2) Digital Signature Standard.

DSS shell A set of programs that can be used for constructing a decision support system.

DSSA Distributed system security architecture; developed by Digital Equipment Corporation.

DSTU See Draft Standard for Trial Use.

DSU Data service unit.

DTE Domain and type enforcement.

DTE Data terminal equipment.

DTR Data terminal ready.

DUAL Diffused Update Algorithm (EIGRP).

dual control A procedure that uses to or more entities (usually persons) operating in concert to protect a system resources, such that no single entity acting alone can access that resource.

dual tone multifrequency (DTMF) A term describing push button or touch-tone dialing. When you push a button, it makes a tone that is actually a combination of two tones, one high frequency and one low frequency.

due care Managers and their organizations have a duty to provide for information security to ensure that the type of control, the cost of control, and the deployment of control are appropriate for the system being managed.

dumb terminal A device used to interact directly with the end user where all data is processed on a remote computer. A dumb terminal only gathers and displays data; it has no processing capability.

dump The contents of a file or memory that are output as listings. These listing can be formatted.

duplex Communications systems or equipment that can simultaneously carry information in both directions between two points. Also used to describe redundant equipment configurations (e.g., duplexed processors).

DVS Lifecycle support, development security.

dynamic analysis Exercising the system being assessed through actual execution; includes exercising the system functionally (traditional testing) and logically through techniques such as failure assertion, structural testing, and statistical-based testing. Major system components have to have been built before dynamic analysis can be performed.

dynamic binding The responsibility for executing an action on an object resides within the object itself. The same message can elicit a different response depending upon the receiver.

dynamic dmension The dimension concerned with the nonstatic, process related properties of the system.

Dynamic Host Configuration Protocol (DHCP) DHCP is an industry standard protocol used to dynamically assign IP addresses to network devices.

dynamic processing The technique of swapping jobs in and out of computer memory. This technique can be controlled by the assignment priority and the number of time slices allocated to each job.

dynamically phased array (PA) Type of radio antenna used in certain satellite and wireless communications. This small flat antenna mounts on the side of a building or on a rooftop. It has an array of chip-based radio receivers, which lock in on the target transmission frequency on a dynamic basis. Also called a *pizza-box antenna*.

EAL Evaluation assurance level.

EAP Extensible Authentication Protocol.

early token release Technique used in Token Ring networks that allows a station to release a new token onto the ring immediately after transmitting, instead of waiting for the first frame to return. This feature can increase the total bandwidth on the ring. See also *Token Ring*.

Earth stations Ground terminals that use antennas and other related electronic equipment designed to transmit, receive, and process satellite communications.

ease Amount of time and skill level required to either penetrate or restore function. Measures the degree of difficulty.

eavesdropping The unauthorized interception of information-bearing emanations through methods other than wiretapping.

EBCDIC Extended Binary Encoded Decimal Interchange Code.

EBGP Exterior Border Gateway Protocol.

ebXML A set of technical specifications for business documents built around XML designed to permit enterprises of any size and in any geographical location to conduct business over the Internet.

EC See electronic commerce.

ECC Elliptic curve cryptography.

echo The display of characters on a terminal output device as they are entered into the system.

echo hiding Relies on limitations in the human auditory system by embedding data in a cover audio signal. Using changes in delay and relative amplitude; two types of echos are created which allows for the encoding of one's and zeros.

ecological dimension The dimension dealing with the interface properties of a system; inflow and outflow of forces in a system.

economy Scaleable system packages ease the application of economy. Space, weight, or time constraints limit the quantity or capability of systems that can be deployed. Information requirements must be satisfied by consolidating similar functional facilities, integrating commercial systems into tactical information works, or accessing to a different information system.

EDI Electronic data interchange (computer-to-computer transactions).

EDI translator A software tool for accepting an EDI transmission and converting the data into another format, or for converting a non-EDI data file into an EDI format for transmission.

EDIFACT See United Nations Rules for Electronic Data Interchange for Administration, Commerce, and Transport (UN/EDIFACT).

edit The process of inspecting a data field or element to verify the correctness of its content.

EDP auditor A professional whose responsibility is to certify the validity, reliability, and integrity of all aspects of the computer information system environment of an organization, a.k.a. IS auditor, CIS auditor, or IT auditor.

education IT security education focuses on developing the ability and vision to perform complex, multidisciplinary activities and the skills needed to further the IT security profession. Education activities include research and development to keep pace with changing technologies and threats.

EEPROM Electrically erasable programmable read-only memory.

effective date Under HIPAA, this is the date that a final rule is effective, which is usually 60 days after it is published in the *Federal Register*.

effectiveness Efficiency, potency, or capability of an act in producing a desired (or undesired) result. The power of the protection or the attack.

efficiency Capability, competency, or productivity. The efficiency of an act is a measure of the work required to achieve a desired result.

EFT See electronic funds transfer.

e-government The application of e-commerce technologies in government agencies.

EGP Exterior Gateway Protocol.

EHNAC See the Electronic Healthcare Network Accreditation Commission.

EIA Electronic Industries Association.

EIGRP Enhanced Interior Gateway Routing Protocol.

EIN Employer identification number.

electromagnetic emanations Signals transmitted as radiation through the air or conductors.

electromagnetic interference (EMI) Electromagnetic waves emitted by a device.

electron A light, subatomic particle that carries a negative charge.

electronic attack (EA) Use of EM or directed energy to attack personnel, facilities, or equipment to destroy/degrade combat capability.

electronic bill presentation and payment (EBPP) A system that sends people their bills over the Internet and gives them an easy way to pay.

electronic bulletin board An application program that lets users contribute messages via e-mail that can be routed or shared with users.

electronic business XML See ebXML

electronic catalog Designed to present products to customers via the Internet.

electronic code book (ECB) A basic encryption method that provides privacy but not authentication.

electronic commerce A broad concept that covers any trade or commercial transaction that is effected via electronic means; this would include such means as facsimile, telex, EDI, Internet, and the telephone. For the purpose of this book the term is limited to those commercial transactions involving computer to computer communications whether utilizing an open or closed network.

Electronic Communications Privacy Act of 1986 PL 99-508 (ECPA) Electronic Communications Privacy Act of 1986; extends the Privacy Act of 1974 to all forms of electronic communication, including email.

electronic data interchange (EDI) A process whereby such specially formatted documents as an invoice can be transmitted from one organization to another. A system allowing for inter-corporate commerce by the automated electronic exchange of structured business information.

electronic data vaulting Electronic vaulting protects information from loss by providing automatic and transparent backup of valuable data over high-speed phone lines to a secure facility.

electronic document file A magnetic storage area that contains electronic images of papers and other communications documents.

Electronic Frontier Foundation A foundation established to address social and legal issues arising from the impact on society of the increasingly pervasive use of computers as the means of communication and information distribution.

electronic funds transfer (EFT) The process of moving money between accounts via computer.

Electronic Healthcare Network Accreditation Commission (EHNAC) An organization that tests transactions for consistency with the HIPAA requirements, and that accredits healthcare clearinghouses.

electronic job market Consists of employers using the Internet to advertise for and screen potential employees.

electronic journal A computerized log file summarizing, in chronological sequence, the processing activities and events performed by a system. The log file is usually maintained on magnetic storage media.

electronic mail (e-mail) Formal or informal communications electronically transmitted or delivered.

electronic media claims (EMC) This term usually refers to a flat file format used to transmit or transport claims, such as the 192-byte UB-92 Institutional EMC format and the 320-byte Professional EMC NSF.

electronic office An office that relies on word processing, computer systems, and communications technologies to support its operations.

electronic portfolio Collection of Web documents used to support a stated purpose such as writing skills.

electronic protect (EP) Actions to protect personnel, facilities and equipment from enemy/friendly EW that degrade or destroy own-force combat capability.

electronic remittance advice (ERA) Any of several electronic formats for explaining the payments of healthcare claims.

electronic signature Any technique designed to provide the electronic equivalent of a handwritten signature to demonstrate the origin and integrity of specific data. Digital signatures are an example of electronic signatures.

electronic warfare (EW) Action involving the use of electromagnetic (EM) and directed energy to control the EM spectrum or to attack the enemy.

electronic warfare support (ES) That division of EW involving actions tasked by, or under direct control of, an operational commander to search for, intercept, identify, and locate sources of intentional and unintentional radiated electromagnetic energy for the purpose of immediate threat recognition. Thus, electronic warfare support provides information required for immediate decisions involving EW operations and other tactical actions such as threat avoidance, targeting and homing. ES data can be used to produce signals intelligence.

element management functions A set of functions for management of network elements on an individual basis. These are basically the same functions as those supported by the corresponding local terminals.

element manager Provides a package of end-user functions for management of a set of closely related types of network elements.

e-mail software (electronic mail software) Enables people to electronically communicate with other people by sending and receiving e-mail.

emanation security The protection that results from all measures designed to deny unauthorized persons access to valuable information that might be derived from interception and analysis of compromising emanations.

embedded message In steganography, it is the hidden message that is to be put into the cover medium.

embedding To cause to be an integral part of a surrounding whole. In steganography and watermarking, embedding refers to the process of inserting the hidden message into the cover medium.

EMC Electromagnetic conductance.

EMC See electronic media claims.

EMF Electromagnetic field.

EMI Electromagnetic interference.

emission security (EMSEC) The protection resulting from all measures taken to deny unauthorized persons information of value that might be derived from intercept and from an analysis of compromising emanations from systems.

EMP Electromagnetic pulse.

EMR Electronic medical record.

encapsulated security payload An IPsec protocol that provides confidentiality, data origin authentication, data integrity services, tunneling, and protection from replay attacks.

encapsulated subsystem A collection of procedures and data objects that is protected in a domain of its own so that the internal structure of a data object is accessible only to the procedures of the encapsulated subsystem and that those procedures may be called only at designated domain entry points. *Encapsulated subsystem*, *protected subsystem* and *protected mechanisms* of the TCB are terms that may be used interchangeably.

encapsulation The technique used by layered protocols in which a layer adds header information to the protocol data unit (PDI) from the layer above.

encipher The process of converting plaintext into unintelligible form by means of a cipher system.

encipherment The cryptographic transformation of data (see cryptography) to produce ciphertext.

enclave An environment that is under the control of a single authority and has a homogeneous security policy, including personnel and physical security. Local and remote elements that access resources within an enclave must satisfy the policy of the enclave. Enclaves can be specific to an organization or a mission and may also contain multiple networks. They may be logical, such as an operational area network (OAN) or be based on physical location and proximity.

encoding The process of converting data into code or analog voice into a digital signal.

encrypt To scramble information so that only someone knowing the appropriate secret can obtain the original information (through decryption).

encrypt/encipher/encode Encryption is the transformation of information into a form that is impossible to read unless you have a specific piece of information, which is usually referred to as the "key." The purpose is to keep information private from those who are not intended to have access to it. To encrypt is essentially about making information confusing and hiding the meaning of it.

encrypted text Data which is encoded into an unclassified form using a nationally accepted form of encoding.

encryption The use of algorithms to encode data in order to render a message or other file readable only for the intended recipient.

encryption algorithm A set of mathematically expressed rules for encoding information, thereby rendering it unintelligible to those who do not have the algorithm decoding key.

encryption key A special mathematical code that allows encryption hardware/software to encode and then decipher an encrypted message.

end entity An end entity can be considered as an end user, a device such as a router or a server, a process, or anything that can be identified in the subject name of a public key certificate. End entities can also be thought of as consumers of the PKI-related services.

end system An OSI system that contains application processes capable of communication through all seven layers of OSI protocols. Equivalent to Internet host.

endorsed cryptographic products list A list of products that provide electronic cryptographic coding (encrypting) and decoding (decrypting), and which have been endorsed for use for classified or sensitive unclassified U.S. government or government-derived information during its transmission.

endorsed TEMPEST products list A list of commercially developed and commercially produced TEMPEST telecommunications equipment that NSA has endorsed, under the auspices of the NSA Endorsed TEMPEST Products Program, for use by government entities and their contractors to process classified U.S. government information.

end-to-end encipherment Encipherment of data within or at the source end system, with the corresponding decipherment occurring only within or at the destination end system.

end-to-end encryption The encryption of information at the point of origin within the communications network and postponing of decryption to the final destination point.

enrollment The initial process of collecting biometric data from a user and then storing it in a template for later comparison.

enterprise application integration (EAI) The process of developing an IT infrastructure that enables employees to implement new or changing business processes.

enterprise application integration middleware (EAI middleware) Allows organizations to develop different levels of integration from the information level to the business process level.

enterprise information portal (EIP) Allows knowledge workers to access company information via a Web interface.

enterprise resource planning (ERP) The method of getting and keeping an overview of every part of the business, so that production and selling of goods and services will be coordinated to contribute to the company's goals.

enterprise root A certificate authority (CA) that grants itself a certificate and creates a subordinate CAs. The root CA gives the subordinate CAs their certificates, but the subordinate CAs can grant certificates to users.

enterprise software A suite of software that includes (1) a set of common business applications; (2) tools for modeling how the organization works; and (3) development tools for building applications unique to the organization.

entity Either a subject (an active element that operates on information or the system state) or an object (a passive element that contains or receives information).

entity barrier A product or service feature that customers have come to expect from companies.

entity class A concept—typically people, places, or things—about which information can be stored and then identified with a unique key called the *primary key*.

entity-relationship (ER) diagram A graphic method of representing entity classes and their relationships.

entrapment The deliberate planting of apparent flows in a system to invite penetrations.

ENV (1) Protection profile evaluation, security environment. (2) Security target evaluation, security environment.

environment (system) The aggregate of procedures, conditions, and objects that affects the development, operation, and maintenance of a system. Note: *environment* is often used with qualifiers such as computing environment, application environment, or threat environment, which limit the scope being considered.

EOB Explanation of benefits.

EOMB Explanation of Medicare benefits, explanation of Medicaid benefits, or explanation of member nenefits.

EOT End of transmission.

EPROM Erasable programmable read-only memory.

EPSDT Early and periodic screening, diagnosis, and treatment.

ERA See electronic remittance advice.

Erasable Programmable Read-Only Memory (EPEOM) A memory chip that can have its circuit logic erased and reprogrammed.

ERISA The Employee Retirement Income Security Act of 1974.

ERP Emergency response plan.

error (1) A discrepancy between actual values or conditions and those expected. (2) The difference between a computed, observed, or measured value or condition and the true, specified, or theoretically correct value or condition.

error of commission An error that results from making a mistake or doing something wrong.

error of omission An error that results from something that was not done.

error rate A measure of the quality of circuits or equipment. The ratio of erroneously transmitted information to the total sent (generally computed per million characters sent).

ESF Extended super framing (T1/E1).

ESP Encapsulated Security Payload protocol.

espionage The practice or employment of spies; the practice of watching the words and conduct of others, to make discoveries, as spies or secret emissaries; secret watching. This category of computer crime includes international spies and their contractors who steal secrets from defense, academic, and laboratory research facility computer systems. It includes criminals who steal information and intelligence from law enforcement computers, and industrial espionage agents who operate for competitive companies or for foreign governments who are willing to pay for the information. What has generally been known as *industrial espionage* is now being called *competitive intelligence*. A lot of information can be gained through "open source" collection and analysis without ever having to break into a competitor's computer. This information gathering is also competitive intelligence, although it is not as ethically questionable as other techniques.

ET Exchange termination.

e-tailor An Internet retail site.

ETC User data protection export to outside TSF control.

Ethernet A LAN technology that is in wide use today utilizing CSMA/CD (carrier sense multiple access/collision detection) to control access to the physical medium (usually a category-5 Ethernet cable). Normal throughput speeds for Ethernet are 10 Mbps, 100 Mbps, and 1 Gbps.

Ethernet card The most common type of network interface card.

ethical (whitehat) hacker A computer security professional who is hired by a company to break into its computer system.

ethics The principles and standards that guide people's behavior towards others.

ETSI European Telecommunication Standards Institute.

evaluated products list (EPL) A list of equipments, hardware, software, and firmware that have been evaluated against, and found to be technically compliant, at a particular level of trust, with the DoD TCSEC by the NCSC. The EPL is included in the National Security Agency Information Systems Security Products and Services Catalogue, which is available through the Government Printing Office.

evaluation The inspection and testing of specific hardware and software products against accepted Information Assurance/Information Security standards.

evaluation assurance level One of seven levels defined by the Common Criteria that represent the degree of confidence that specified functional security requirements have been met by a commercial product.

evaluation criteria See IT security evaluation criteria.

evaluation methodology See IT security evaluation methodology.

event A trigger for an activity.

evolution checking Testing to ensure the completeness and consistency of a software product at different levels of specification when that product is a refinement or elaboration of another.

evolutionary program strategies Generally characterized by design, development, and deployment of a preliminary capability that includes provisions for the evolutionary addition of future functionality and changes, as requirements are further defined.

exception report A manager report that highlights abnormal business conditions. Usually, such reports prompt management action or inquiry.

exchange authentication information Information exchanged between a claimant and a verifier during the process of authenticating a principal.

exchange type Exchange type defines the number of messages in an ISAKMP exchange and the ordering of the used payload types for each of these messages. Through this arrangement of messages and payloads security services are provided by the exchange type.

executive information system (EIS) A very interactive IT system that allows the user to first view highly summarized information and then choose how to see greater detail, which may be an alert to potential problems or opportunities.

expand To increase in extent, number, volume, or scope.

expandability Refers to how easy it is to add features or functions to a system.

expansion bus Moves information from the CPU and RAM to all other hardware devices such as a microphone or printer.

expansion card A circuit board that is inserted into an expansion slot.

expansion slot A long skinny pocket on the motherboard into which an expansion card can be inserted.

expert system The application of computer-based artificial intelligence in areas of specialized knowledge.

explanation module The part of an expert system where the "why" information, supplied by the domain expert, is stored to be accessed by knowledge workers who want to know why the expert systems asked a question or reached a conclusion.

exposure The potential loss to an area due to the occurrence of an adverse event.

Extended Binary-Coded Decimal Interchange Code (EBCDIC) A data representation and code system based on the use of an 8-bit byte.

Extended SuperFrame A new version of the SuperFrame that allows for more frames to be grouped together. In a T1 circuit, each of the 24 DS0 channels are sampled every 125 μs and 8 bits are taken from each. If you multiply the 8 bits by the 24 channels, you get 192-bits in a chain, and then add one bit for timing, you get 193 total bits in one frame. Twelve frames comprise the SuperFrame. For the Extended SuperFrame, we double the number of frames, making the total 24.

extensibility A property of software such that new kinds of object or functionality can be added to it with little or no effect to the existing system.

Extensible Authentication Protocol An IETF standard means of extending authentication protocols, such as CHAP and PAP, to include additional authentication data; for example, biometric data.349.

Extensible Markup Language (XML) Designed to enable the use of SGML on the World Wide Web, XML is a regular markup language that defines what you can do (or what you have done) in the way of describing information for a fixed class of documents (like HTML). XML goes beyond this and allows you to define your own customized markup language. It can do this because it is an application profile of SGML. XML is a metalanguage, a language for describing languages.

external certificate authority An agent that is trusted and authorized to issue certificates to approved vendors and contractors for the purpose of enabling secure interoperability with DoD entities. Operating requirements for ECAs must be approved by the DoD CIO, in coordination with the DoD Comptroller and the DoD General Counsel.

external information Describes the environment surrounding the organization.

extraction engine Smart software with a vocabulary of job-related skills that allows it to recognize and catalog terms in a scannable resume.

extranet An intranet that is restricted to an organization and certain outsiders, such as customers and suppliers.

facsimile (fax) A technology used to send document images over telecommunications lines.

fading Signal disruption caused by multipath signals and heavy rains.

fail operational The system must continue to provide some degree of service if it is not to be hazardous; it cannot simply shut down—for example, an aircraft flight control system. See degraded-mode operation.

fail safe The automatic termination and protection of programs or other processing operations when a hardware, software, or firmware failure is detected in a computer system.

fail safe/secure (1) A design wherein the component/system, should it fail, will fail to a safe/secure condition. (2) The system can be brought to a safe/secure condition or state by shutting it down; for example, the shutdown of a nuclear reactor by a monitoring and protection system.

fail soft The selective termination of nonessential processing affected by a hardware, software, or firmware failure in a computer system.

failure Failing to or inability of a system, entity, or component to perform its required function, according to specified performance criteria, due to one or more fault conditions. Three categories of failure are commonly recognized: (1) incipient failures are failures that are about to occur; (2) hard failures are failures that result in a complete shutdown of a system; and (3) soft failures are failures that result in a transition to degraded-mode operations or a fail operational status.

failure access Unauthorized and usually inadvertent access to data resulting from a hardware, software, or firmware failure in the computer system.

failure control The methodology used to detect and provide fail-safe or fail-soft recovery from hardware, software, or firmware failure in a computer system.

failure minimization Actions designed or programmed to reduce failure possibilities to the lowest rates possible.

Fair Credit Reporting Act (P.L. 91-508) A federal law that gives individuals the right of access to credit information pertaining to them and the right to challenge such information.

fair use doctrine Allows the use of copyrighted material in certain situations.

fallback procedures Predefined operations (manual or automatic) invoked when a fault or failure is detected in a system.

fall-through logic Predicting which way a program will branch when an option is presented. It is an optimized code based on a branch prediction.

false acceptance rate (FAR) The percentage of imposters incorrectly matched to a valid user's biometric. False rejection rate (FRR) is the percentage of incorrectly rejected valid users.

FAQ(s) Frequently asked questions.

fast Ethernet Any of a number of 100-Mbps Ethernet specifications. Fast Ethernet offers a speed increase ten times that of the 10Base-T Ethernet specification, while preserving such qualities as frame format, MAC mechanisms, and MTU. Such similarities allow the use of existing 10Base-T applications and network management tools on fast Ethernet networks. Based on an extension to the IEEE 802.3 specification. Compare with *Ethernet.*

FAU Security audit functional class.

fault (1) A defect that results in an incorrect step, process, data value, or mode/state. (2) A weakness of the system that allows circumventing protective controls.

fault tolerance Built-in capability of a system to provide continued correct execution in the presence of a limited number of hardware or software faults.

FBI Federal Bureau of Investigation.

FC Frame control (Token Ring).

FCC Federal Communications Commission.

FCO Communication functional class.

FCPA Foreign Corrupt Practices Act.

FCS Frame check sequence.

FCS Cryptographic support functional class.

FD Feasible distance (EIGRP).

FDA Food and Drug Administration.

FDD Floppy disk drive.

FDDI Fiber distributed data interface. This is a Token Ring technology that utilizes encoded light pulses transmitted via fiber optic cabling for communications between computer systems. It supports a data rate of 100 Mbps and is more likely to be used as a LAN backbone between servers. It has redundancy built in so that if a host on the network fails, there is an alternate path for the light signals to take to keep the network up.

FDM Frequency division multiplexing.

FDP User data protection functional class.

feasibility study An investigation of the legal, political, social, operational, technical, economic, and psychological effects of developing and implementing a system.

feature analysis The step of ASR in which the system captures the users' words as spoken into a microphone, eliminates any background noise, and converts the digital signals of speech into phonemes (syllables).

feature creep Occurs when developers add extra features that were not part of the initial requirements.

FECN Forward explicit congestion notification.

FedCIRC The U.S. Federal Government Computer Incident Response Center; managed by the General Services Administration (GSA).

Federal Computer Fraud Act The Counterfeit Access Device and Computer Fraud and Abuse Act of 1986 outlaws unauthorized access to the federal government's computers and financial databases as protected under the Right to Financial Privacy Act of 1978 and the Fair Credit Reporting Act of 1971. This act is an amendation of the 1984 Federal Computer Fraud Act.

Feistal network A Feistal network generates blocks of keystream from blocks of the message itself, through multiple rounds of groups of permutations and substitutions, each dependent on transformations of a key.

FEP Front-end processor.

FERPA Family Educational Rights and Privacy Act.

fetch protection A system-provided restriction to prevent a program from accessing data in another user's segment of storage.

FFIEC Federal Financial Institutions Examination Council.

FFS Fee-for-service.

FI See Medicare part A fiscal intermediary.

FIA Identification and authentication functional class.

Fiber Distributed Data Interface (FDDI) LAN standard, defined by ANSI X3T9.5, specifying a 100-Mbps token-passing network using fiberoptic cable, with transmission distances of up to 2 km. FDDI uses a dual-ring architecture to provide redundancy.

fiber-optic A strand of very pure, very clear glass that can carry more information longer distances.

FIC Federal Interest Computer.

fiche A sheet of photographic film containing multiple microimages; a form of computer output microfilm.

fidelity Accuracy, exact correspondence to truth or fact, the degree to which a system or information is distortion-free.

field A basic unit of data, usually part of a record that is located on an input, storage, or output microfilm.

field definition record (FDR) A record of field definition. A list of the attributes that define the type of information that can be entered into a data field.

FIFO First in, first out.

file A basic unit of data records organized on a storage medium for convenient location, access, and updating.

file creation The building of master or transaction files.

file format dependence A factor in determining the robustness of a piece of stegoed media. Coverting an image from on format to another will usually render the embedded message unrecoverable.

file inquiry The selection of records from files and immediate display of their contents on a terminal output device.

file maintenance The changing of master file by changing the contents of existing records, adding new records, or deleting old records.

file protection The aggregate of all processes and procedures established in a computer system and designed to inhibit unauthorized access, contamination, or elimination of a file.

file transfer The process of copying a file from one computer to another over a network.

File Transfer Protocol (FTP) The Internet protocol (and program) used to transfer files between hosts.

file updating The posting of transaction data to master files or maintenance of master files through record additions, changes, or deletions.

filter A process or device that screens incoming information for definite characteristics and allows a subset of that information to pass through.

financial cybermediaries Internet-based companies that make it easy for one person to pay another over the Internet.

financial EDI (FEDI) The use of EDI for payments.

finger A program (and a protocol) that displays information about a particular user, or all users, logged on a local system or on a remote system. It typically shows full-time name, last login time, idle time, terminal line, and terminal location (where applicable). It may also display plan and project files left by the user.

finger The traceroute or finger commands to run on the source machine (attacking machine) to gain more information about the attacker.

fingerprint A form of marking that embeds a unique serial number.

FIPS Federal Information Processing Standard.

firewall A device that forms a barrier between a secure and an open environment. Usually the open environment is considered hostile. The most notable open system is the Internet.

firmware Software or computer instructions that have been permanently encoded into the circuits of semiconductor chips.

FISMA Federal Information Security Management Act.

FISSEA The Federal Information Systems Security Educator's Association, an organization whose members come from federal agencies, industry, and academic institutions devoted to improving the IT security awareness and knowledge within the federal government and its related external workforce.

fixed wireless access (FWA) Replaces the last mile from the central office to the customer. This process usually consists of a pair of digital radio transmitters placed on rooftops, one at the central office and one at the users' site. These systems usually operate at the 38 Ghz portion of the spectrum. Also known as wireless fiber (because of the high speeds of throughput) and as fixed wireless local loop.

flame To express strong opinion or criticism of something, usually as a frank inflammatory statement in an electronic message.

flat file A collection of records containing no data aggregates, nested, or repeated data items, or groups of data items.

flat-panel display A thin, lightweight monitor that takes up much less space than a CRT.

flexibility Responsiveness to change, specifically as it relates to user information needs and operational environment.

flooded transmission A transmission in which data is sent over every link in the network.

floppy disk A flexible removable disk used for magnetic storage of data, programs, or information.

FLR Lifecycle support, flaw remediation.

FLS Protection of the TSF, failure secure.

FLT Resource utilization, fault tolerance.

FMBS Frame-Mode Bearer Service.

FMECA Failure mode effects criticality analysis; an IA analysis technique that systematically reviews all components and materials in a system or product to determine cause(s) of their failures, the downstream results of such failures, and the criticality of such failures as accident precursors.

FMECA can be performed on individual components (hardware, software, and communications equipment) and integrated at the system level. See IEC 60812 (1985).

FMT Security management functional class.

force A group of platforms and sites organized for a particular purpose.

Foreign Corrupt Practices Act The act covers an organization's system of internal accounting control and requires public companies to make and keep books, records, and accounts that, in reasonable detail, accurately and fairly reflect the transactions and disposition of company assets and to devise and maintain a system of sufficient internal accounting controls. This act was amended in 1988.

foreign government information (1) Information provided to the United States by a foreign government or international organization of governments in the expectation, express or implied, that the information is to be kept in confidence. (2) Information, requiring confidentiality, produced by the United States pursuant to a written joint arrangement with a foreign government or international organization of governments. A written joint arrangement may be evidenced by an exchange of letters, a memorandum of understanding, or other written record of the joint arrangement.

foreign key A primary key of one file (relation) that appears in another file (relation).

forensic examination After a security breach, the process of assessing, classifying and collecting digital evidence to assist in prosecution. Standard crime-scene standards are used.

forensic image copy An exact copy or snapshot of the contents of an electronic medium.

forgery A false, fake, or counterfeit datum, document, image, or act.

formal analysis The use of rigorous mathematical techniques to analyze a solution. The algorithms may be analyzed for numerical properties, efficiency, and correctness.

formal design The part of a software design written using a formal notation.

formal method (1) A software specification and production method, based on discrete mathematics, that comprises: a collection of mathematical notations addressing the specification, design, and development processes of software production, resulting in a well-founded logical inference system in which formal verification proofs and proofs of other properties can be formulated, and a methodological framework within which software can be developed from the specification in a formally verifiable manner. (2) The use of mathematical techniques in the specification, design, and analysis of computer hardware and software.

formal notation The mathematical notation of a formal method.

formal proof The discharge of a proof obligation by the construction of a complete mathematical proof.

formal review A type of review typically scheduled at the end of each activity or stage of development to review a component of a deliverable or, in some cases, a complete deliverable or the software product and its supporting documentation.

formal specification The part of the software specification written using a formal notation.

format The physical arrangement of data characters, fields, records, and files.

formerly restricted data Information removed from the restricted data category upon determination jointly by the Department of Energy and Department of Defense that such information relates primarily to the military utilization of atomic weapons and that such information can be adequately safeguarded as classified defense information subject to the restrictions on transmission to other countries and regional defense organizations that apply to restricted data.

Formula Translation (Fortran) A high-level programming language developed primarily to translate mathematical formulas into computer code.

formulary A technique for permitting the decision to grant or deny access to be determined dynamically at access time rather than at the time the access list is created.

Fortran See Formula Translation.

Forum of Incident Response and Security Teams (FIRST) A unit of the Internet Society that coordinates the activities of worldwide computer emergency response teams, regarding security-related incidents and information sharing on Internet security risks.

Fourier transform An image processing tool which is used to decompose an image into its constituent parts or to view a signal in either the time or frequency domain.

fourth-generation language (4GL) A computer language that is easy to learn and use and often associated with rapid applications development.

FPA Federal Privacy Act.

FPR Privacy functional class.

FPT Protection of the TSF functional class.

FRAD Frame relay access device.

fragile watermark A watermark that is designed to prove authenticity of an image or other media. A fragile watermark is destroyed, by design, when the cover is manipulated digitially. If the watermark is still intact then the cover has not been tampered with. Fragile watermark technology could be useful in authenticating evidence or ensuring the accuracy of medical records or other sensitive data.

fragment A piece of a packet. When a router is forwarding an IP packet to a network with a maximum transmission unit smaller than the packet size, it is forced to break up that packet into multiple fragments. These fragments will be reassembled by the IP layer at the destination host.

fragmentation The process in which an IP datagram is broken into smaller pieces to fit the requirements of a given physical network. The reverse process is termed "reassembly."

frame relay A switching interface that operates in packet mode. Generally regarded as the replacement for X.25.

framework Defines a set of application programming interface (API) classes for developing applications and for providing system services to those applications.

free electrons Electrons that are not attached to an atom or molecule. Also known as static electricity.

free space and atmospheric attenuation Defined by the loss the signal undergoes traveling through the atmosphere. Changes in air density and absorption by atmospheric particles are principle reasons for affecting the microwave signal in a free air space.

frequency The rate at which an electromagnetic waveform alternates, usually measured in Hertz.

frequency diversity A form of backup used to protect a radio signal. A second signal continually operates on a separate frequency and assumes the load when the regular channel fails.

frequency division multiple access (FDMA) FDMA is the allocation of specific channels within a defined radio frequency bandwidth to carry a specific user's information. FDMA is a mature, reliable method of RF communication, but requires more spectrum than competing technologies to deliver its payload.

frequency division multiplexing (FDM) An older technique in which the available transmission bandwidth of a circuit is divided by frequency into narrow bands, each used for a separate voice or data transmission channel, which many conversations can be carried on one circuit.

frequency domain A way of representing a signal where the horizontal deflection is the frequency variable and the vertical deflection is the signals amplitude at that frequency.

frequency masking A condition where two tones with relatively close frequencies are played at the same time and the louder tone masks the quieter tone.

frequency modulation (FM) A modulation technique in which the carrier frequency is shifted by an amount proportional to the value of the modulating signal. The amplitude of the carrier signal remains constant. The information signal causes the carrier signal to increase or decrease its frequency based on the waveform of the information signal.

front office space The primary interface to customers and sales channels.

front porch The access point to a secure network environment; also known as a firewall.

front-end computer A computer that offloads input and output activities from the central computer so it can operate primarily in a processing mode; sometimes called a *front-end processor.*

front-end processor (FEP) (1) A communications computer associated with a host computer can perform line control, message handling, code conversion, error control, and application functions. (2) A teleprocessing concentrator and router, as opposed to a back-end processor or a database machine.

FRU Resource utilization functional class.

FSIP Fast serial interface processor.

FSK Frequency shift keying.

FSP Development, functional specification.

FTA Fault tree analysis; an IA analysis technique by which possibilities of occurrence of specific adverse events are investigated. All factors, conditions, events, and relationships that could contribute to that event are analyzed. FTA can be performed on individual components (hardware, software, and communications equipment) and integrated at the system level. See IEC 61025 (1990).

FTP File Transfer Protocol.

FTP Trusted path/channels functional class.

FTP (File Transfer Protocol) server Maintains a collection of files that can be downloaded.

full operational capability (FOC) The time at which a new system has been installed at all planned locations and has been fully integrated into the operational structure.

full wave rectifier Diodes designed to be placed in an alternating current circuit and to convert alternating current into direct current.

Full-Duplex (FDX) An asynchronous communications protocol that allows the communications channel to transmit and receive signals simultaneously.

fully qualified domain name (FQDN) A complete Internet address, including the complete host and domain name.

FUN Tests, functional tests.

function In computer programming, a processing activity that performs a single identifiable task.

functional analysis Translating requirements into operational and systems functions and identifying the major elements of the system and their configurations and initial functional design requirements.

functional domain An identifiable DoD functional mission area. For purposes of the DoD policy memorandum, the functional domains are: command and control, space, logistics, transportation, health affairs, personnel, financial services, public works, research and development, and Intelligence, Surveillance, and Reconnaissance (ISR).

functional requirements Architectural atoms; the elementary building blocks of architectural concepts; made up of activities/functions, attributes associated with activities/processes and processes/methods sequencing activities.

functional safety The ability of a safety-related system to carry out the actions necessary to achieve or maintain a safe state for the equipment under control.

functional specification The main product of systems analysis, which presents a detailed logical description of the new system. It contains sets of input, processing, storage, and output requirements specifying what the new system can do.

functional testing The segment of security testing in which the advertised security mechanisms of the system are tested, under operational conditions, for correct operation.

functionality Degree of acceptable performance of an act.

GAO General Accounting Office, or Government Accountability Office.

garbage collection A language mechanism that automatically deallocates memory for objects that are not accessible or referenced.

gateway A product that enables two dissimilar networks to communicate or interface with each other. In the IP community, an older term referring to a routing device. Today, the term *router* is used to describe nodes that perform this function, and *gateway* refers to a special-purpose device that performs an application-layer conversion of information from one protocol stack to another. Compare with *router*.

GEN Security audit generation.

general support system An interconnected information resource under the same direct management control that shares common functionality. It normally includes hardware, software, information, data, applications, communications, facilities, and people and provides support for a variety of users and applications. Individual applications support different mission-related functions. Users may be from the same or different organizations.

general-purpose computer A computer that can be programmed to perform a wide variety of processing tests.

genetic algorithm An artificial intelligence system that mimics the evolutionary, survival-of-the-fittest process to generate increasingly better solutions to a problem.

Geographic Information System (GIS) A decision support system designed specifically to work with spatial information.

GIF Graphics Interchange Format.

Gigabyte (G byte) The equivalent of one billion bytes.

Gigahertz The number of billions of CPU cycles per second.

GIGO Garbage in, garbage out.

GII Global information infrastructure.

GLBA The Gramm-Leach-Bliley Act.

global digital divide The term used specifically to describe differences in IT access and capabilities between different countries or regions of the world.

global economy One in which customers, businesses, suppliers, distributors, and manufacturers operate without regard to physical and geographical boundaries.

global information grid The globally interconnected, end-to-end set of information capabilities, associated processes and personnel for collecting, processing, storing, disseminating and managing information on demand to warfighters, policy makers, and support personnel. The GiG includes all owned and leased communications and computing systems, services, software (including applications), data, security services and other associated services necessary to achieve Information Superiority.

global information grid architecture The architecture, composed of interrelated operational, systems and technical views, which defines the characteristics of and relationships among current and planned Global Information Grid assets in support to National Security missions.

global positioning system A collection of 24 Earth-orbiting satellites that continuously transmit radio signals to determine an object or target's current longitude, latitude, speed, and direction of movement.

global reach The ability to extend a company's reach to customers anywhere through an Internet connection and at a lower cost.

glove An input device that captures and records the shape, movement, and strength of the users' hands and fingers.

GNS Get Nearest Server (Novell).

GOSIP Government OSI profile (U.S.).

Governing security requisites Those security requirements that must be addressed in all systems. These requirements are set by policy, directive, or common practice; e.g., by executive order, Office of Management and Budget (OMB), Office of the Secretary of Defense, a military service, or DoD. Governing security requisites are typically high-level requirements. Although implementations will vary from case to case, these requisites are fundamental and must be addressed.

government OSI profile (GOSIP) A U.S. government procurement specification for OSI protocols.

government to business (G2B) The e-commerce activities performed between a government and its business partners for purposes such as purchasing materials or soliciting and accepting bids for work.

government to consumer (G2C) The e-commerce activities performed between a government and its citizens or consumers, including paying taxes and providing information and services.

government to government (G2G) The e-commerce activities limited to a single nation's government focusing on vertical integration (local, city, state, and federal) and horizontal integration (within the various branches and agencies).

GPKI Global public key infrastructure.

graceful degradation See degraded-mode operation.

grand design program strategies Characterized by acquisition, development, and deployment of the total functional capability in a single increment.

granularity The level of detail contained in a unit of data. The more there is, the lower the level of granularity; the less detail, the higher the level of granularity.

graphical user interface (GUI) An interface in which the user can manipulate icons, windows, pop-down menus, or other related constructs. A graphical user interface uses graphics such as a window, box, and menu to allow the user to communicate with the system. Allows users to move in and out of programs and manipulate their commands using a pointing device (usually a mouse). Synonymous with *user interface*.

graphics output Computer-generated output in the form of pictures, charts, and line drawings.

graphics software Helps the user create and edit photos and art.

graphics terminal An output device that displays pictures, charts, and line drawings, typically a high-resolution CRT.

GRE Generic routing encapsulation.

grid computing Harnesses computers together by way of the Internet or a virtual network to share CPU power, databases, and storage.

group document databases A powerful storage facility for organizing and managing all documents relayed to specific teams.

group health plan Under HIPAA, an employee welfare benefit plan that provides for medical care and that either has 50 or more participants or is administered by another business entity. See also Part II, 45 CFR 160.103.

groupware Software designed to function over a network to allow several people to work together on documents and files.

GSM Originally stood for Groupe Speciale Moble, but is now known as Global System for Mobile Communications. It is the standard for cellular phone service in Europe, Japan, and Australia, and will soon be the standard for 30–50 percent of the cellular networks in the Untied States.

guaranteed service A service model that provides highly reliable performance with little or no variance in the measured performance criteria.

guard A component that mediates the flow of information or control between different systems or networks.

GUI (graphical user interface) screen design The ability to model the information system screens for an entire system.

guidelines Documented suggestions for regular and consistent implementation of accepted practices. They usually have less enforcement powers.

GZL Get Zone List (AppleTalk).

hacker A person who attempts to break into computers that he or she is not authorized to use.

hacking A computer crime in which a person breaks into an information system simply for the challenge of doing so.

hacktivist A politically motivated hacker who uses the Internet to send a political message of some kind.

HAG High assurance guard.

Half-Duplex Capability for data transmission in only one direction at a time between a sending station and a receiving station.

Half-duplex A circuit designed for data transmission in both directions but not at the same time.

halon An abbreviation for halogenated hydrocarbon coined by the U.S. Army Corps of Engineers. Halon nomenclature follows the following rule: if a hydrocarbon compound contains the elements $C_aF_bCl_cBr_dI_e$, it is designated as Halon abcde (terminal zeros are dropped). Thus, Halon 1211 is chlorobromodifluoromethane, etc.

handoffs (or **switching**) A cellular call is switched from one cell tower to another as the user moves from one area to the next. The switch is usually unnoticed by the user.

handover interface A physical and logical interface across which the interception measures are requested from the NWO/AP/service provider, and the results of interception are delivered from a NWO/AP/service provider (SvP) to an LEMF.

handprint character recognition (HCR) One of several pattern recognition technologies used by digital imaging systems to interpret handprinted characters.

handshake Sequence of messages exchanged between two or more network devices to ensure transmission synchronization.

handshaking procedure Dialogue between a user and a computer, two computers, or two programs to identify a user and authenticate his or her identity. This is done through a sequence of questions and answers that are based on information either previously stored in the computer or supplied to the computer by the initiator of the dialogue.

Handspring A type of PDA that runs on the Palm Operating System (Palm OS).

hard disk A fixed or removable disk mass storage system permitting rapid direct access to data, programs, or information.

hard handoff Sometimes a cell phone user being switched from one site to the next will need to be disconnected and reconnected to make the switch possible. Also called a *break and make handoff*; it is usually unnoticed by the user.

hardware The physical components of a computer network.

hardware key logger A hardware device that captures keystrokes on their way from the keyboard to the motherboard.

hardware reliability The ability of an item to correctly perform a required function under certain conditions in a specified operational environment for a stated period of time.

hardware safety integrity The overall failure rate for continuous-mode operations and the probability to operate on demand for demand-mode operations relative to random hardware failures in a dangerous mode of failure.69.

hash Producing *hash values* for accessing data or for security. A hash value (or simply *hash*), also called a *message digest*, is a number generated from a string of text. The hash is substantially smaller than the text itself, and is generated by a formula in such a way that it is extremely unlikely that some other text will produce the same hash value. Hashing is also a common method of accessing data records. To create an index, called a *hash table*, for these records, you would apply a formula to each name to produce a unique numeric value.

hash function/hashing A hash function is a mathematical process based on an algorithm which creates a digital representation or compressed form of the message. It is often referred to as the message digest in the form of a hash value or hash result of a standard length which is usually much smaller than the message, but nevertheless substantially unique to it.

hash total A total of the values on one or more fields, used for the purpose of auditability and control.

hazard A source of potential harm or a situation with potential to harm. Note that the consequences of a hazard can be physical or cyber.

hazard likelihood The qualitative or quantitative likelihood that a potential hazard will occur. Most international standards define six levels of hazard likelihood (lowest to highest): incredible, improbable, remote, occasional, probable, and frequent.

hazard severity The severity of the worst-case consequences should a potential hazard occur. Most international standards define four levels of hazard severity (lowest to highest): insignificant, marginal, critical, and catastrophic.

HAZOP Hazard and operability study; a method of determining hazards in a proposed or existing system, their possible causes and consequences, and recommending solutions to minimize the likelihood of occurrence. Design and operational aspects of the system are analyzed by an interdisciplinary team.

HCFA See the Health Care Financing Administration. See also Part II, 45 CFR 160.103.

HCFA Common Procedural Coding System (HCPCS) A medical code set that identifies healthcare procedures, equipment, and supplies for claim submission purposes. It has been selected for use in the HIPAA transactions. HCPCS Level I contains numeric CPT codes that are maintained by the AMA. HCPCS Level II contains alphanumeric codes used to identify various items and services that are not included in the CPT medical code set. These are maintained by HCFA, the BCBSA, and the HIAA. HCPCS Level III contains alphanumeric codes that are assigned by Medicaid state agencies to identify additional items and services not included in levels I or II. These are usually called *local codes*, and must have *W*, *X*, *Y*, or *Z* in the first position. HCPCS procedure modifier codes can be used with all three levels, with the *WA–ZY* range used for locally assigned procedure modifiers.

HCFA-1450 HCFA's name for the institutional uniform claim form, or UB-92.

HCFA-1500 HCFA's name for the professional uniform claim form. Also known as the *UCF-1500.*

HCPCS See HCFA Common Procedural Coding System. See also Part II, 45 CFR 162.103.

HDLC (high-level data-link control) Bit-oriented synchronous datalink layer protocol developed by ISO. Derived from SDLC, HDLC specifies a data encapsulation method on synchronous serial links using frame characters and checksums.

HDSL High-data-rate digital subscriber line. One of four DSL technologies. HDSL delivers 1.544 Mbps of bandwidth each way over two copper twisted pairs. Because HDSL provides T1 speed, telephone companies have been using HDSL to provision local access to T1 services whenever possible. The operating range of HDSL is limited to 12,000 ft (3658.5 m), so signal repeaters are installed to extend the service. HDSL requires two twisted pairs, so it is deployed primarily for PBX network connections, digital loop carrier systems, interexchange POPs, Internet servers, and private data networks. Compare with *ADSL*, *SDSL*, and *VDSL*.

header The beginning of a message sent over the Internet; typically contains addressing information to route the message or packet to its destination.

heading tag HTML tag that puts certain information, such as the title, at the top of the page.

headset It combines input and output devices that (1) capture and record the movements of the user's head, and (2) contains a screen that covers the user's field of vision and displays various views of an environment based on the head's movements.

Health and Human Services (HHS) The federal government department that has overall responsibility for implementing HIPAA.

health care See Part II, 45 CFR 160.103.

Health Care Clearinghouse Under HIPAA, this is an entity that processes or facilitates the processing of information received from another entity in a nonstandard format or containing nonstandard data content into standard data elements or a standard transaction, or that receives a standard transaction from another entity and processes or facilitates the processing of that information into nonstandard format or nonstandard data content for a receiving entity. See also Part II, 45 CFR 160.103.

Health Care Code Maintenance Committee An organization administered by the BCBSA that is responsible for maintaining certain coding schemes used in the X12 transactions and elsewhere. These include the Claim Adjustment Reason Codes, the Claim Status Category Codes, and the Claim Status Codes.

health care component See Part II, 45 CFR 164.504.

Health Care Financing Administration (HCFA) The HHS agency responsible for Medicare and parts of Medicaid. HCFA has historically maintained the UB-92 institutional EMC format specifications, the professional EMC NSF specifications, and specifications for various certifications and authorizations used by the Medicare and Medicaid programs. HCFA also maintains the HCPCS medical code set and the Medicare Remittance Advice Remark Codes administrative code set.

health care operations See Part II, 45 CFR 164.501.

health care provider See Part II, 45 CFR 160.103.

Health Care Provider Taxonomy Committee An organization administered by the NUCC that is responsible for maintaining the provider taxonomy coding scheme used in the X12 transactions. The detailed code maintenance is done in coordination with X12N/TG2/WG15.

Health Industry Business Communications Council (HIBCC) A council of health care industry associations that has developed a number of technical standards used within the healthcare industry.

Health Informatics Standards Board (HISB) An ANSI-accredited standards group that has developed an inventory of candidate standards for consideration as possible HIPAA standards.

health information See Part II, 45 CFR 160.103.

health information clearinghouses Any public or private entities that process or facilitate processing nonstandard health information into standard data elements. For example, third party administrators; pharmacy benefits managers; billing services; information management and technology vendors; and others. (HIPAA).

Health Insurance Association of America (HIAA) An industry association that represents the interests of commercial healthcare insurers. The HIAA participates in the maintenance of some code sets, including the HCPCS Level II codes.

health insurance issuer See Part II, 45 CFR 160.103.

Health Insurance Portability and Accountability Act of 1996 (HIPAA) A federal law that allows persons to qualify immediately for comparable health insurance coverage when they change their employment relationships. Title II, Subtitle F, of HIPAA gives HHS the authority to mandate the use of standards for the electronic exchange of healthcare data; to specify what medical and administrative code sets should be used within those standards; to require the use of national identification systems for healthcare patients, providers, payers (or plans), and employers (or sponsors); and to specify the types of measures required to protect the security and privacy of personally identifiable healthcare information. Also known as the Kennedy–Kassebaum Bill, the Kassebaum–Kennedy Bill, K2, or Public Law 104-191.

Health Level Seven (HL7) An ANSI-accredited group that defines standards for the cross-platform exchange of information within a healthcare organization. HL7 is responsible for specifying the Level Seven OSI standards for the health industry. The X12 275 transaction will probably incorporate the HL7 CRU message to transmit claim attachments as part of a future HIPAA claim attachments standard. The HL7 Attachment SIG is responsible for the HL7 portion of this standard.

health maintenance organization (HMO) See Part II, 45 CFR 160.103.

health oversight agency See Part II, 45 CFR 164.501.

health plan See Part II, 45 CFR 160.103.

health plan ID See National Payer ID.

health plans Individual or group plans (or programs) that provide health benefits directly, through insurance, or otherwise. For example, Medicaid; State Children's Health Insurance Program (SCHIP); state employee benefit programs; Temporary Assistance for Needy Families (TANF); and others. (HIPAA).

Healthcare Financial Management Association (HFMA) An organization for the improvement of the financial management of healthcare-related organizations. The HFMA sponsors some HIPAA educational seminars.

Healthcare Information Management Systems Society (HIMSS) A professional organization for healthcare information and management systems professionals.

healthcare providers Providers (or suppliers) of medical or other health services or any other person furnishing health care services or supplies, and who also conduct certain health-related administrative or financial transactions electronically. For example, local health departments; community and migrant health centers; rural health clinics; school-based health centers; homeless clinics and shelters; public hospitals; maternal and child health programs (Title V); family planning programs (Title X); HIV/AIDS programs; and others. (HIPAA).

HEDIC The Healthcare EDI Coalition.

HEDIS Health Employer Data and Information Set.

help desk Responds to knowledge workers' questions.

HERF High-energy radio frequency.

Hertz The basic measurement of bandwidth frequency in cycles per second. 1 Hz equals 1 cycle per second.

Hertz (Hz) One cycle per second.

heuristics The mode of analysis in which the next step is determined by the results of the current step of analysis. Used for decision support processing.

hexadecimal A number system with a base of 16.

HFMA See the Healthcare Financial Management Association.

HHA Home Health Agency.

HHIC The Hawaii Health Information Corporation.

HHS See Health and Human Services. See also Part II, 45 CFR 160.103.

HIAA See the Health Insurance Association of America.

HIBCC See the Health Industry Business Communications Council.

hidden partition A method of hiding information on a hard drive where the partition is considered unformatted by the host operating system and no drive letter is assigned.

HIDS Host-based intrusion detection system.

hierarchical database In a hierarchical database, data is organized like a family tree or organization chart with branches of parent records and child records.

high-capacity floppy disk Storage device that holds between 100MB and 250MB of information. Superdisks and Zip disks are examples.

High-Level Data-Link Control (HDLC) A protocol used at the data-link layer that provides point-to-point communications over a physical transmission medium by creating and recognizing frame boundaries.

high-level language The class of procedure-oriented language.

HIMSS See the Healthcare Information Management Systems Society.

HIPAA Act of 1996 The Administrative Simplification provisions of the Health Insurance Portability and Accountability Act of 1996 (HIPAA, Title II) require the Department of Health and Human Services to establish national standards for electronic healthcare transactions and national identifiers for providers, health insurers, and employers. It also addresses the security and privacy of health data. Adopting these standards will improve the efficiency and effectiveness of the nation's healthcare system by encouraging the widespread use of electronic data interchange in healthcare.

HIPAA Data Dictionary or HIPAA DD A data dictionary that defines and cross-references the contents of all X12 transactions included in the HIPAA mandate. It is maintained by X12N/TG3.

HISB See the Health Informatics Standards Board.

HL7 See Health Level Seven.

HLD Development, high-level design.

HMO See health maintenance organization.

holographic device A device that creates, captures, and displays images in true three-dimensional form.

home page The initial screen of information displayed to the user when initiating the client or browser software or when connecting to a remote computer. The home page resides at the top of the directory tree.

Home PNA (Home Phoneline Networking Alliance) Allows one to network home computer using telephone wiring.

Homeland Security Act of 2002 The Act restructures and strengthens the executive branch of the federal government to better meet the threat to the United States posed by terrorism. In establishing a new department of Homeland Security, the Act for the first time creates a Federal department whose primary mission will be to help prevent, protect against, and respond to acts of terrorism on the U.S. soil.

honey-pots A specifically configured server, designed to attract intruders so their actions do not affect production systems; also known as a decoy server.

hop A term used in routing. A hop is one data link. A path from source to destination in a network is a series of hops.

horizontal market software Application software that is general enough to be suitable for use in a variety of industries.

host A remote computer that provides a variety of services, typically to multiple users concurrently.

host address The IP address of the host computer.

host computer A computer that, in addition to providing a local service, acts as a central processor for a communications network.

hostname The name of the user computer on the network.

hot site A fully operational offsite data processing facility equipped with both hardware and system software to be used in the event of disaster.

hot standby Secondary equipment in place as a back up in case of primary equipment failure.

HPAG The HIPAA Policy Advisory Group, a BCBSA subgroup.

HPSA Health professional shortage area.

HSRP Hot Standby Routing Protocol.

HSSI High-speed serial interface.

HTML See HyperText Markup Language.

HTML document A file made from the HTML language.

HTML tag Specifies the formatting and presentation of information in an HTML document.

HTTP See HyperText Transport Protocol.

hub A device connected to several other devices. In ARCnet, a hub is used to connect several computers together. In a message-handling service, a hub is used for transfer of messages across the network. An Ethernet hub is basically a "collapsed network-in-a-box" with a number of ports for the connected devices.

humanware Computer programs that interface or communicate with users by means of voice-integrated technology, interpret user-specified command, and execute or translate commands into machine-executable code.

HVAC Heating ventilation air conditioning systems.

hybrid entity A covered entity whose covered functions are not its primary functions. See also Part II, 45 CFR 164.504.

hypermedia An extension to hypertext in which frames contain graphics, illustrations, images, audio, animation, text, and other forms of information or knowledge.

hypertext Text that is held in frames and authors develop or define the linkage between frames.

Hypertext Markup Language A language created by programmers at the CERN in Switzerland to create Web pages.

HyperText Transfer Protocol (HTTP) A communication protocol used to connect to serves on the World Wide Web. Its primary function is to establish a connection with a Web server and transmit HTML pages to the client browser. The protocol used to transport hypertext files across the Internet.

I&A Identification and authentication.

IA (1) Information assurance. (2) Intra-area (OSPF).

IA integrity The likelihood of a system, entity, or function achieving its required security, safety, and reliability features under all stated conditions within a stated measure of use.

IA integrity case A systematic means of gathering, organizing, analyzing, and reporting the data needed by internal, contractual, regulatory, or certification authorities to confirm that a system has met the specified IA goals and IA integrity level and is fit for use in the intended operational environment. An IA integrity case includes assumptions, claims, and evidence.

IA integrity level The level of IA integrity that must be achieved or demonstrated to maintain the IA risk exposure at or below its acceptable level.

IAB Internet Architecture Board. Board of internetwork researchers who discuss issues pertinent to Internet architecture. Responsible for appointing a variety of Internet-related groups such as the IANA, IESG, and IRSG. The IAB is appointed by the trustees of the ISOC.

IA-critical A term applied to any condition, event, operation, process, or item whose proper recognition, control, performance, or tolerance is essential to the safe, reliable, and secure operation and support of a system.

IAIABC See the International Association of Industrial Accident Boards and Commissions.

IAP Information Awareness Program.

IA-related A system or entity that performs or controls functions which are activated to prevent or minimize the effect of a failure of an IA-critical system or entity.

IBGP Interior Border Gateway Protocol.

ICD & **ICD-n-CM** & **ICD-n-PCS** International classification of diseases, with $n=9$ for revision 9 or $n=10$ for revision 10, with CM = clinical modification, and with PCS = procedure coding system.

ICF Intermediate care facility.

ICMP Internet Control Message Protocol. Network layer Internet protocol that reports errors and provides other information relevant to IP packet processing. Documented in RFC 792.

icon A pictorial symbol used to represent data, information, or a program on a GUI screen.

ICQ Pronounced "I seek you." This is a chat service available via the Internet that enables users to communicate online. This service (you load the application on your computer) allows chat via text, voice, bulletin boards, file transfers, and e-mail.

ICSA Internet Computer Security Association.

ICZ Intensive control zone.

IDA (infrared date association) port A port for wireless devices that works in essentially the same way as the remote control on TV.

identification (1) The process, generally employing unique machine-readable names, that enables recognition of users or resources as identical to those previously described to the computer system. (2) The assignment of a name by which an entity can be referenced. The entity may be high level (such as a user) or low level (such as a process or communication channel.

identification media A building or visitor pass.

identifier A set of one or more attributes that uniquely distinguishes each instance of an object.

identity Information that is unique within a security domain and which is recognized as denoting a particular entity within that domain.

identity-based security policy A security policy based on the identities or attributes of users, a group of users, or entities acting on behalf of the users and the resources or targets being accessed.

IDN Integrated delivery network.

IDS Intrusion detection system.

IEC 61025 International Electrotechnical Commission Publication 61025, Fault tree analysis (FTA).

IEEE Institute of Electrical and Electronics Engineers.

IETF Internet Engineering Task Force; a public consortium that develops standards for the Internet.

IFC User data protection information flow control policy.

IFF User data protection information flow control functions.

IG See implementation guide.

IGP Interior Gateway Protocol.

IGRP Interior Gateway Routing Protocol.

IGS Delivery and operation, installation, generation, and start-up.

IHC Internet Healthcare Coalition.

IIHI See individually identifiable health information.

IKE Internet Key Exchange protocol.

IMP Development, implementation representation.

impact The amount of loss or damage that can be expected, or may be expected from a successful attack of an asset.

impact printer A hard-copy device on which a print mechanism strikes against a ribbon to create imprints on paper. Some impact printers operate one character at a time; others strike an entire line at a time.

impersonation An attempt to gain access to a system by posing as an authorized user.

implant chip A technology-enabled microchip implanted into the human body.

implementation The specific activities within the systems development life cycle through which the software portion of the system is developed, coded, debugged, tested, and integrated with existing or new software.

implementation guide (IG) A document that explains the proper use of a standard for a specific business purpose. The X12N HIPAA IGs are the primary reference documents used by those implementing the associated transactions, and are incorporated into the HIPAA regulations by reference.

implementation phase Distributes the system to the knowledge workers who begin using the system in their everyday jobs.

implementation specification Under HIPAA, this is the specific instruction for implementing a standard. See Part II, 45 CFR 160.103. See also implementation guide.

importance A subjective assessment of the significance of a system's capability and the consequences of the loss of that capability.

in-band Made up of tones that pass within the voice frequency band and are carried along the same circuit as the talk path established by the signals. Also known as *in-band signaling*.

inadvertent disclosure Accidental exposure of information to a person not authorized access.

inadvertent loss The unplanned loss or compromise of data or system.

incident An unusual occurrence or breach in the security of a computer system. An event that has actual or potentially adverse effects on an information system. A computer security incident can result from a computer virus, other malicious code, intruder, terrorist, unauthorized insider act, malfunction, etc.

incomplete parameter checking A system fault that exists when all parameters have not been fully checked for correctness and consistency by the operating system, thus leaving the system vulnerable to penetration.

incremental program strategies Characterized by acquisition, development, and deployment of functionality through a number of clearly defined system "increments" that stand on their own.

IND Tests, independent testing.

Independent Basic Service Set Network (IBSS Network) Independent Basic Service Set Network is an IEEE 802.11-based wireless network that has no backbone infrastructure and consists of at least two wireless stations. This type of network is often referred to as an ad hoc network because it can be constructed quickly without much planning.

indexed sequential filing A file organization method in which records are maintained in logical sequence and indices (or tables) are used to reference their storage addresses. The method allows direct and serial access to records.

indirect material Material that is necessary for running a modern corporation but does not relate to the company's primary business activities. Commonly called *MRO materials*.

induction A process of logically arriving at a conclusion about a member of a class from examining a few other members of the same class. This method of reasoning may not always produce true statements. As an example, suppose it is known that George's car has four tires and that Fred's car has four tires. Inductive reasoning would allow the conclusion that all cars have four tires. Induction is closely related to learning.

inference engine A system of computer programs in an expert systems application that uses expert experience as a basis for conclusions.

infobots Software agents that perform specified tasks for a user or application.

information Intelligence or knowledge capable of being represented in forms suitable for communication, storage, or processing. Information may be represented, for example, by signs, symbols, pictures, or sounds.

information age A time when knowledge is power.

information assurance (1) An engineering discipline that provides a comprehensive and systematic approach to ensuring that individual automated systems and dynamic combinations of automated systems interact and provide their intended functionality, no more and no less, safely, reliably, and securely in the intended operational environments. (2) Information operations that protect and defend information and information systems by ensuring their availability, integrity, authentication, confidentiality, and nonrepudiation; including providing for restoration of information systems by incorporating protection, detection, and reaction capabilities (DoD Directive 5-3600.1).

Information Assurance Support Environment (IASE) The IASE is an on-line Web-based help environment for DoD INFOSEC and IA professionals.

Information Assurance Vulnerability Alert (IAVA) The comprehensive distribution process for notifying CINC's, Services and agencies (C/S/A) about vulnerability alerts and countermeasures information. The IAVA process requires C/S/A receipt acknowledgment and provides specific time parameters for implementing appropriate countermeasures depending on the criticality of the vulnerability.

information attributes The qualities, characteristics, and distinctive features of information.

information category The term used to bind information and tie it to an information security policy.

information decomposition Breaking down the information for ease of use and understandability.

information environment The aggregate of individuals, organizations, and systems that collect, process, or disseminate information, including the information itself.

information float The amount of time it takes to get information from its source into the hands of the decision makers.

information granularity The extent of detail within the information.

information hiding (1) A software development technique in which each module's interfaces reveal as little as possible about the module's inner workings and other modules are prevented from using information about the module that is not in the module's interface specification. (2) A software development technique that consists of isolating a system function, or set of data and operations on those data, within a module and providing precise specifications for the module.

information in identifiable form Information in an IT system or online collection that (1) directly identifies an individual (e.g., name, address, Social Security number, or other identifying number or code, telephone number, e-mail address, etc.) or (2) by which an agency intends to identify specific individuals in conjunction with other data elements, i.e., indirect identification. These data elements may include a combination of gender, race, birth date, geographic indicator, and other descriptors.

information interoperability The exchange and use of information in any electronic form.

information model A conceptual model of the information needed to support a business function or process.

information operations (IO) Actions taken to affect adversary information and information systems while defending one's own information and information systems.

information operations condition (INFOCON) The INFOCON is a comprehensive defense posture and response based on the status of information systems, military operations, and intelligence assessments of adversary capabilities and intent. The INFOCON system presents a structured, coordinated approach to defend against a computer network attack. INFOCON measures focus on computer network-based protective measures. Each level reflects a defensive posture based on the risk of impact to military operations through the intentional disruption of friendly information systems. INFOCON levels are: NORMAL (normal activity); ALPHA (increased risk of attack); BRAVO (specific risk of attack); CHARLIE (limited attack); and DELTA (general attack). Countermeasures at each level include preventive actions, actions taken during an attack, and damage control/mitigating actions.

information owner An official having statutory or operational authority for specified information and having responsibility for establishing controls for its generation, collection, processing, dissemination, and disposal.

information partnership Two or more companies that cooperate by integrating their IT systems, thereby providing customers with the best of what each has to offer.

information requirements Those items of information regarding the enemy and his environment which need to be collected and processed in order to meet the intelligence requirements of a commander.

information resource management A concept or practice in which information is recognized as a key asset to be appropriately managed as a vital resource.

information security Safeguarding information against unauthorized disclosure; or, the result of any system of administrative policies and procedures for identifying, controlling, and protecting from unauthorized disclosure, information the protection of which is authorized by Executive Order or statute.

information security governance The management structure, organization, responsibility and reporting processes surrounding a successful information security program.

information security program The overall process of preserving confidentiality, integrity and availability of information.

information security service A method to provide some specific aspect of security. For example, integrity of transmitted data is a security objective, and a method that would achieve that is considered an information security service.

information services The offering of a capability for generating, storing, transforming, retrieving, utilizing, or making available information via telecommunications, and includes electronic publishing but does not include the use of such capability for the management, control, or operation of a telecommunications system or the management of a telecommunications service.

information sharing The requirements for information sharing by an IT system with one or more other IT systems or applications, for information sharing to support multiple internal or external organizations, missions, or public programs.

information superiority The capability to collect, process, and disseminate an uninterrupted flow of information while exploiting or denying an adversary's ability to do the same. Forces attain information superiority through the acquisition of systems and families-of-systems that are secure, reliable, interoperable, and able to communicate across a universal information technology (IT) infrastructure, to include national security systems (NSS). This IT infrastructure includes the data, information, processes, organizational interactions, skills, and analytical expertise, as well as systems, networks, and information exchange capabilities.

information system A discrete set of information resources organized for the collection, processing, maintenance, use, sharing, dissemination, or disposition of information.

information system owner (or program manager). See system owner.

information system security A system characteristic and a set of mechanisms that span the system both logically and physically.

information system security officer Individual responsible to the OA ISSO, designated approving authority, or information system owner for ensuring that the appropriate operational security posture is maintained for an information system or a closely related group of systems.

information systems security (INFOSEC) The protection of information systems against unauthorized access to or modification of information, whether in storage, processing, or transit, and against the denial-of-service to authorized users or the provision of service to unauthorized users, including those measures necessary to detect, document, and counter such threats.

information systems security program Synonymous with IT security program.

information technology (IT) The hardware and software operated by a federal agency or by a contractor of a federal agency or other organization that processes information on behalf of the federal government to accomplish a federal function, regardless of the technology involved, whether computers, telecommunications, or others. It includes automatic data processing equipment as that term is defined in Section 111(a)(2) of the Federal Property and Administrative Services Act of 1949. For the purposes of this Circular, automatic data processing and telecommunications activities related to certain critical national security missions, as defined in 44 USC. 3502(2) and 10 USC. 2315, are excluded.

information technology disruptions due to natural or man-made disasters Failure to exercise due care and diligence in the implementation and operation of the information technology system.

information view Includes all of the information stored within a system.

information warfare (IW) Actions taken to achieve information superiority by affecting adversary information, information-based processes, information systems and computer-based networks while defending one's own information, information-based processes, information systems and computer-based networks.

information-literate knowledge workers Can define what information they need, know how to obtain that information, understand the information once they receive it, and act appropriately to help the organization achieve the greatest advantage.

INFOSEC (1) The combination of COMSEC and COMPUSEC—the protection of information against unauthorized disclosure, transfer, modification, or destruction, whether accidental or intentional. (2) Protection of information systems against unauthorized access to or modification of information, whether in storage, processing, or transit, and against denial of service to authorized users, including those measures necessary to detect, document, and counter such threats.

infrared A wireless communications medium that uses light waves to transmit signals or information.

infrastructure The framework of interdependent networks and systems comprising identifiable industries, institutions, and distribution capabilities that provide a continual flow of goods and services essential to the defense and economic security of the United States, the smooth functioning of government at all levels, or society as a whole.

infrastructure system A network of independent, mostly privately owned, automated systems and processes that function collaboratively and synergistically to produce and distribute a continuous flow of essential goods and services. The eight critical infrastructure systems defined by PDD-63 are: telecommunications, banking and finance, power generation and distribution, oil and gas distribution and storage, water processing and supply, transportation, emergency services, and government services.

infrastructure-centric A security management approach that considers information systems and their computing environment as a single entity.

Inheritance The language mechanism that allows the definition of a class to include the attributes and methods for another more general class. Inheritance is an implementation construct for the specialization relation. The general class is the superclass and the specific class is the subclass in the inheritance relation. Inheritance is a relation between classes that enables the reuse of code and the definition of generalized interface to one or more subclasses.

inhibit A design feature that provides a physical interruption between an energy source and a function actuator. Two inhibits are independent if no single failure can eliminate them both.

initial operational capability (IOC) The first time a new system is introduced into operation.

initialization vector A nonsecret binary vector used as the initializing input algorithm for the encryption of a plaintext block sequence to increase security by introducing additional cryptographic variance and to synchronize cryptographic equipment.

initiator An entity (for example, human user or computer based entity) that attempts to access other entities.

initiator access control decision information ADI associated with the initiator.

initiator access control information Access control information relating to the initiator.

injection Using this method, a secret message is put in a host file in such a way that when the file is actually read by a given program, the program ignores the data.

injury Any wrong or damage done to another, either his person, rights, reputation, or property; the invasion of any legally protected interest of another.

inkjet printer Makes images by forcing ink droplets through nozzles.

inmate See Part II, 45 CFR 164.501.

input controls Techniques and methods for verifying, validating, and editing data to ensure that only correct data enters a system.

input device A tool used to capture information and commands by the user.

inquiry processing The process of selecting a record from a file and immediately displaying its contents.

insourcing It means that IT specialists within the organization will develop the system.

inspection A manual analysis technique that examines the program requirements, design, or code in a formal and disciplined manner to discover errors.

instance A set of values representing a specific entity belonging to a particular entity type. A single value is also the instance of a data item.

instance An occurrence of an entity class that can be uniquely described.

instrumental input The capture of data and its placement directly into a computer by machines.

insulator A material that does not conduct electricity but is suitable for surrounding conductors to prevent the loss of current.

INT (1) Protection profile evaluation, PP introduction. (2) Security target evaluation, ST introduction. (3) development, TSF internals.

integrated circuit A miniature microchip incorporating circuitry and semi-conductor components. The circuit elements and components are created as a part of the same manufacturing process.

Integrated Data Dictionary (IDD) A database technology that facilitates functional communication among system components.

Integrated Services Digital Network (ISDN) An emerging technology that is beginning to be offered by the telephone carriers of the world. ISDN combines voice and digital network services in a single medium, making it possible to offer customers digital data services as well as voice connections through a single wire. The standards that define ISDN are specified by ITU–TSS.

integration Allows separate systems to communicate directly with each other by automatically exporting data files from one system and importing them into another.

integration testing The orderly progression of testing in which software, hardware, or both are combined and tested until all intermodule communication links have been integrated.

integrator The organization that integrates the IS components.

integrity (1) The accuracy, completeness and validity of information in accordance with business values and expectations. The property that data or information has not been modified or altered in an unauthorized manner. (2) A security service that allows verification that an unauthorized modification (including changes, insertions, deletions and duplications) has not occurred either maliciously or accidentally. See also data integrity.

integrity checking The testing of programs to verify the soundness of a software product at each phase of development.

integrity level (1) A range of values of an item necessary to maintain system risks within acceptable limits. For items that perform IA-related mitigating functions, the property is the reliability with which the item must perform the mitigating function. For IA-critical items whose failure can lead to threat instantiation, the property is the limit on the frequency of that failure. (2) A range of values of a property of an item necessary to maintain risk exposure at or below its acceptability threshold.

intellectual property Intangible creative work that is embodied in physical form.

intellectual property identification A method of asset protection which identifies or defines a copyright, patent, trade secret, etc., or validates ownership and ensures that intellectual property rights are protected.

intellectual property management and protection (IPMP) A refinement of digital rights management (DRM) that refers specifically to MPEG's.

intelligence The first step in the decision making process where a problem, need, or opportunity is found or recognized. Also called the *diagnostic phase of decision making*.

intelligence method The method which is used to provide support to an intelligence source or operation, and which, if disclosed, is vulnerable to counteraction that could nullify or significantly reduce its effectiveness in supporting the foreign intelligence or foreign counterintelligence activities of the United States, or which would, if disclosed, reasonably lead to the disclosure of an intelligence source or operation.

intelligence source A person, organization, or technical means which provides foreign intelligence or foreign counterintelligence and which, if its identity or capability is disclosed, is vulnerable to counteraction that could nullify or significantly reduce its effectiveness in providing foreign intelligence or foreign counterintelligence to the United States. An intelligence source also means a person or organization which provides foreign intelligence or foreign counterintelligence to the United States only on the condition that its identity remains undisclosed.

intelligent agent Software that assists the user in performing repetitive computer-related tasks.

intelligent cabling Research is ongoing in this area. The goal is to eliminate the large physical routers, hubs, switches, firewalls, etc., and move these functions (i.e., embed the intelligence) into the cabling itself. Currently this is an electrochemical/neuronic research process.

intelligent transportation systems A subset or specific application of the NII that provides real-time information and services to the transportation sector. Specific examples include: travel and transportation management systems, travel demand management systems, public transportation operation systems, electronic payment systems, commercial vehicle operation systems, emergency management systems, and advanced vehicle control and safety systems.

interactive A mode of processing that combines some aspects of online processing and some aspects of batch processing. In interactive processing, the user can directly interact with data over which he or she has exclusive control. In addition, the user can cause sequential activity to initiate background activity to be run against the data.

interactive chat Lets the user engage in real-time exchange of information with one or more individuals over the Internet.

interactive video A system in which video segments are integrated via a menu-based processing application.

interagency coordination Within the context of Department of Defense involvement, the coordination that occurs between elements of the Department of Defense and engaged U.S. government agencies, nongovernment organizations, private voluntary organizations, and regional and international organizations for the purpose of accomplishing an objective.

interblock gap (IBG) A blank space appearing between records or groups of records on magnetic storage media.

interception Action (based on the law) performed by an NWO/AP/SvP, of making available certain information and providing that information to an LEMF. Usually, this term is not used to describe the action of observing communications directly by an LEA.

interception interface Physical and logical locations within the NWO/AP/SvP telecommunications facilities where access to the CC and IRI is provided. The interception interface is not necessarily a single fixed point.

interception measure A technical measure that facilitates the interception of telecommunications traffic pursuant to the relevant national laws and regulations.

interception subject A person or persons, specified in a lawful authorization, whose telecommunications are to be intercepted.

intercept-related information Collection of information or data associated with telecommunications services involving the target identity, specifically communication-associated information or data (including unsuccessful communication attempts), service-associated information or data (e.g., service-profile management by subscriber), and location information.

interconnection security agreement An agreement established between the organizations that own and operate connected information technology systems to document the technical requirements of the interconnection. The ISA also supports a memorandum of understanding or agreement (MOU/A) between the organizations.

interdiction Impeding or denying someone the use of system resources.

interface A shared boundary between devices, equipment, or software components defined by common interconnection characteristics.

interface analysis The checking and verification process that ensures intermodule communications links are performed correctly.

interference Electromagnetic energy that is picked up with the signal you are receiving. This extra energy distorts the signal and interferes with its transmission.

interim accreditation Temporary authorization granted by a designated approving authority for an information technology system to process, store, and transmit information based on preliminary results of security certification of the system.

interim approval to operate (IATO) Temporary approval granted by a DAA for an IS to process information based on preliminary results of a security evaluation of the system.

interleaving The alternating execution of programs residing in the memory of a multiprogramming environment.

intermediary A specialist company that provides services better than its client companies.

internal accounting control The process of safeguarding the accounting functions and processes of a business. This process includes validating that the accounting system complies with the appropriate, generally accepted accounting principles and that audit trails exist for verification of all processes.

internal control The method of safeguarding business assets, including verifying the accuracy and reliability of accounting data, promoting operational efficiency, and encouraging adherence to prescribed organizational policies and procedures.

internal information Information that describes specific operational aspects of the organization.

internal network interface Network's internal interface between the internal intercepting function and a mediation function.

International Association of Industrial Accident Boards and Commissions (IAIABC) One of their standards is under consideration for use for the First Report of Injury standard under HIPAA.

International Classification of Diseases (ICD) A medical code set maintained by the World Health Organization (WHO). The primary purpose of this code set was to classify causes of death. A U.S. extension, maintained by the NCHS within the CDC, identifies morbidity factors, or diagnoses. The ICD-9-CM codes have been selected for use in the HIPAA transactions.

international government-to-government (IG2G) The e-commerce activities performed between two or more governments, including foreign aid.

international organization An organization of governments.

International Organization for Standardization (ISO) An organization that coordinates the development and adoption of numerous international standards. "ISO" is not an acronym, but the Greek word for "equal."

International Standards Organization See International Organization for Standardization (ISO).

international virtual private network (IVPN) Virtual private networks that depend on services offered by phone companies of various nationalities.

Internet A global computer network that links minor computer networks, allowing them to share information via standardized communication protocols. The Internet consists of large national backbone networks (such as MILNET, NSFNET, and CREN) and a myriad of regional and local campus networks all over the world. The Internet uses the Internet Protocol suite. To be on the Internet, you must have IP connectivity (i.e., be able to Telnet to—or ping—other systems). Networks with only email connectivity are not actually classified as being on the Internet. Although it is commonly stated that the Internet is not controlled or owned by a single entity, this is really misleading, giving many users the perception that no one is really in control (no one "owns") the Internet. In practical reality, the only way the Internet can function is to have the major telecom switches, routers, satellite, and fiber optic links in place at strategic locations. These devices at strategic locations are owned by a few major corporations. At any time, these corporation could choose to shut down these devices (which would shut down the Internet), alter these devices so only specific countries or regions could be on the Internet, or modify these devices to allow/disallow/monitor any communications occurring on the Internet.

Internet address A 32-bit address assigned to hosts using IP/IP.

Internet Architecture Board (IAB) Formally called the *Internet Activities Board*. The technical body that oversees the development of the Internet suite of protocols (commonly referred to as IP/IP). It has two task forces (the IRTF and the IETF), each charged with investigating a particular area.

Internet Assigned Numbers Authority (IANA) A largely government-funded overseer of IP allocations chartered by the FNC and the ISOC.

Internet backbone The major set of connections for computers on the Internet.

Internet Control Message Protocol (ICMP) The protocol used to handle errors and control messages at the IP layer. ICMP is actually part of the IP.

Internet Engineering Task Force (IETF) The Internet standards setting organization with affiliates internationally from network industry representatives. This includes all network industry developers and researchers concerned with evolution and planned growth on the Internet.

Internet layer The stack in the IP/IP protocols that addresses a packet and sends the packets to the network access layer.

Internet Message Access Protocol (IMAP) A method of accessing electronic mail or bulletin board messages that are kept on a (possibly shared) mail server. IMAP permits a "client" email program to access remote message stores as if they were local. For example, email stored on an IMAP server can be manipulated from a desktop computer at home, a workstation at the office, and a notebook computer while traveling, without the need to transfer messages of files back and forth between these computers. IMAP can be regarded as the next-generation POP.

Internet Protocol (IP, lPv4) The Internet Protocol (version 4), defined in RFC 791, is the network layer for the IP/IP suite. It is a connectionless, best-effort, packet-switching protocol.

Internet Protocol (Ping, IPv6) IPv6 is a new version of the Internet Protocol that is designed to be evolutionary.

Internet server computer Computer that provides information and services on the Internet.

Internet service provider (ISP) An organization that provides direct access to the Internet, such as the provider that links your college or university to the Net.

Internet telephony A combination of hardware and software that uses the Internet as the medium for transmission of telephone calls in place of traditional telephone networks.

Internetwork A group of networks connected by routers so that computers on different networks can communicate; the Internet.

Interoperability The ability to exchange requests between entities. Objects interoperate if the methods that apply to one object can request services of another object.

interorganizational system (IOS) Automates the flow of information between organizations to support the planning, design, development, production, and delivery of products and services.

intersection relation A relation the user creates to eliminate a many-to-many relationship. Also called a *composite relation*.

intracell handovers A cellular call is passed from one frequency to the next or carrier to the next within a single cell site.

intranet An internal organizational Internet that is guarded against outside access by a special security feature called a *firewall*.

intrusion detection The process of monitoring the events occurring in a computer system or network, detecting signs of security problems.

intrusion-detection software Looks for unauthorized users on the Internet.

investigation The phase of the systems development life cycle in which the problem or need is identified and a decision is made on whether to proceed with a full-scale study.

invisible GIFs (Tracker GIF, Clear GIF) Electronic images, usually not visible to site visitors, that allow a Web site to count those who have visited that page or to access certain cookies.

invisible ink A method of steganography that uses a special ink that is colorless and invisible until treated by a chemical, heat, or special light. It is sometimes referred to as *sympathetic ink*.

invisible watermark An overlaid image which is invisible to the naked eye, but which can be detected algorithmically. There are two different types of invisible watermarks: fragile and robust.

IO Information operations.

IOM Institute of Medicine. Prestigious group of physicians that study issues and advise Congress. The IOM developed a report on computer-based patient records that led to the creation of CPRI.

IOS Internetwork operating system.

IP Internet Protocol.

IP address A unique number assigned to each computer on the Internet, consisting of four numbers, each less than 256, and each separated by a period, such as 129.16.255.0.

IP datagram The fundamental unit of information passed across the Internet. Contains source and destination addresses, along with data and a number of fields that define such things as the length of the datagram, the header checksum, and flags to say whether the datagram can be (or has been) fragmented.

IP security protocol (IPSec) A protocol in development by the IETF to support secure data exchange. Once completed, IPSec is expected to be widely deployed to implement virtual private networks (VPNs). IPSec supports two encryption modes: transport and tunnel. Transport mode encrypts the data portion (payload) of each packet but leaves the header untouched. Tunnel mode is more secure since in encrypts both the header and the payload. On the receiving side, an IPSec-compliant device decrypts each packet.

IP spoofing IP (address) spoofing is a technique used to gain unauthorized access to computers or network devices, whereby the intruder sends messages with an IP source address to pretend that the message is coming from a trusted source.

IPA Independent Providers Association.

IPC Inter-process communication.

IPL Initial program load.

IPSec The security architecture for IP; developed by the IETF to support reliable and secure datagram exchange at the IP layer. The IPSec architecture specifies AH, ESP, Internet Key Exchange (IKE), and Internet Security Association Key Management Protocol (ISAKMP), among other things.

IPX Internet packet exchange.

IRB Integrated routing and bridging.

IRB Institutional review board.

IRC Internet relay chat. This is a service (you must load the application on your computer) that allows interactive conversation on the Internet. IRC also allows you to exchange files and have "private" conversations. Some major supporters of this service are IRCnet and DALnet.

IS Intermediate system.

IS security goal See security goal.

ISACA Information Systems Audit and Control Association.

ISAKMP Internet Security Association Key Management Protocol.

(ISC)^2 International Information Systems Security Certification Consortium.

ISDN (Integrated Services Digital Network) There are two forms of ISDN: PRI and BRI. BRI interface supports a total signaling rate of 144 kbps, which is divided up into two B or bearer channels, which run at 64 kbps, and a D or data channel, which runs at 16 kbps. The bearer channels carry the actual voice, video, or data information, and the D channel is used for signaling. PRI or primary rate interface provides the same throughput as a T-1 1.544 Mbps, has 23 B or bearer channels, which run at 64 kbps, and a D or data channel, which runs at 16 kbps.

ISDN BRI Integrated Services Digital Network—Basic Rate Interface.

ISDN PRI Integrated Services Digital Network—Primary Rate Interface.

ISIS Intermediate System Intermediate System (OSI standard routing protocol).

ISM (industrial, scientific, and manufacturing) frequencies A term describing several frequencies in the radio spectrum set aside for specific purposes.

ISO See the International Organization for Standardization.

ISO 17799 ISO 17799 gives general recommendations for information security management. It is intended to provide a common international basis for developing organizational security standards and effective security management practice and to provide confidence in inter-organizational dealings.

ISO 9000 A certification program that demonstrates an organization adheres to steps that ensure quality of goods and services. A quality series that comprises a set of five documents and was developed in 1987 by the International Standards Organization (ISO).

isolation The separation of users and processes in a computer system from one another, as well as from the protection controls of the operating system.

ISP See Internet service provider.

IS-related risk The probability that a particular threat agent will exploit, or trigger, a particular information system vulnerability and the resulting mission/business impact if this should occur. IS related-risks arise from legal liability or mission/business loss due to (1) Unauthorized (malicious, nonmalicious, or accidental) disclosure, modification, or destruction of information; (2) Non-malicious errors and omissions; (3) IS disruptions due to natural or man-made disasters; (4) Failure to exercise due care and diligence in the implementation and operation of the IS.

ISSA Information Systems Security Association.

ISSO Information system security officer.

IT infrastructure The hardware, software, and telecommunications equipment that when combined provides the underlying foundation to support the organization's goal.

IT security Technological discipline concerned with ensuring that IT systems perform as expected and do nothing more; that information is provided adequate protection for confidentiality; that system, data and software integrity is maintained; and that information and system resources are protected against unplanned disruptions of processing that could seriously impact mission accomplishment. Synonymous with *automated information system security, computer security* and *information systems security.*

IT security architecture A description of security principles and an overall approach for complying with the principles that drive the system design; i.e., guidelines on the placement and implementation of specific security services within various distributed computing environments.

IT security basics A core set of generic IT security terms and concepts for all federal employees as a baseline for further, role-based learning.

IT security body of knowledge topics and concepts A set of 12 high-level topics and concepts intended to incorporate the overall body of knowledge required for training in IT security.

IT security goals See security goals.

IT security literacy The first solid step of the IT security training level where the knowledge obtained through training can be directly related to the individual's role in his or her specific organization.

IT security program A program established, implemented, and maintained to assure that adequate IT security is provided for all organizational information collected, processed, transmitted, stored, or disseminated in its information technology systems. Synonymous with *automated information system security program, computer security program*, and *information systems security program.*

IT system A collection of computing or communications components and other resources that support one or more functional objectives of an organization. IT system resources include any IT component plus associated manual procedures and physical facilities that are used in the acquisition, storage, manipulation, display, or movement of data or to direct or monitor operating procedures. An IT system may consist of one or more computers and their related resources of any size. The resources that comprise a system do not have to be physically connected.

ITA Protection of the TSF, availability of exported TSF data.

ITC (1) User data protection, import from outside TSF control; (2) protection of the TSF, confidentiality of exported TSF data; (3) trusted path/channels, inter-TSF trusted channel.

iterative development life cycle A strategy for developing systems that allows for the controlled reworking of parts of a system to remove mistakes or to make improvements based on feedback.

ITL Information technology laboratory.

IT-related risk The net mission/business impact considering the probability that a particular threat source will exploit, or trigger, a particular information system vulnerability, and the resulting impact if this should occur. IT-related risks arise from legal liability or mission/business loss due to, but not limited to (1) Unauthorized (malicious, nonmalicious, or accidental) disclosure, modification, or destruction of information; (2) Nonmalicious errors and omissions; (3) IT disruptions due to normal or man-made disasters; (4) Failure to exercise due care and diligence in the implementation and operation of the IT.

ITS Intelligent transportation systems.

ITSEC Information technology security evaluation criteria.

ITT (1) User data protection, internal TOE transfer. (2) protection of the TSF, internal TOE TSF data transfer.

ITU International Telecommunications Union.

ITU-T ITU Telecommunication Standardization Sector.

IW Information warfare.

jargon code A code that uses words (esp. nouns) instead of figure or letter-groups as the equivalent of plain language units.

Java Object-oriented programming language developed at Sun Microsystems to solve a number of problems in modern programming practice. The Java language is used extensively on the World Wide Web, particularly for applets.

JCAHO See the Joint Commission on Accreditation of Healthcare Organizations.

J-codes A subset of the HCPCS Level II code set with a high-order value of "J" that has been used to identify certain drugs and other items. The final HIPAA transactions and code sets rule states that these J-codes will be dropped from the HCPCS, and that NDC codes will be used to identify the associated pharmaceuticals and supplies.

JHITA See the Joint Healthcare Information Technology Alliance.

jitter attack A method of testing or defeating the robustness of a watermark. This attack applies "jitter" to a cover by splitting the file into a large number of samples, the deletes or duplicates one of the samples and puts the pieces back together. At this point the location of the embedded bytes cannot be found. This technique is nearly imperceptible when used on audio and video files.

job A complete set of programs to be executed in sequence on a computer.

job accounting system A set of systems software that can track the services and resources used by computer system account holders.

job function The roles and responsibilities specific to an individual, not a job title.

job queue A set of programs held in temporary storage and awaiting execution.

join An operation that takes two relations as operand and produces a new relation by concealing the tuples and matching the corresponding columns when a stated condition holds between the two.

joint application development (JAD) Occurs when knowledge workers and IT specialists meet, sometimes for several days, to define or review the business requirements for the system.

Joint Commission on Accreditation of Healthcare Organizations (JCAHO) An organization that accredits healthcare organizations. In the future, the JCAHO may play a role in certifying these organizations' compliance with the HIPAA A/S requirements.

Joint Healthcare Information Technology Alliance (JHITA) A healthcare industry association that represents AHIMA, AMIA, CHIM, CHIME, and HIMSS on legislative and regulatory issues affecting the use of health information technology.

JPEG Joint Photographic Experts Group.

judgment The ability to make a decision or form an opinion by discerning and evaluating.

jukebox Hardware that houses, reads, and writes to many optical disks using a variety of mechanical methods for operation.

just in time (JIT) An approach that produces or delivers a product or service just at the time the customer wants it.

KDC Key distribution center.

Kerberos Developing standard for authenticating network users. Kerberos offers two key benefits: it functions in a multi-vendor network, and it does not transmit passwords over the network.

Kerckhoff's principle A cryptography principle that states if the method used to encipher data is known by an opponent then security must lie in the choice of the key—can be expanded on.

Kermit A (once) popular file transfer and terminal emulation program.

key (cryptovariable) In cryptography, a sequence of symbols that controls encryption and decryption. For some encryption mechanisms (symmetric), the same key is used for both encryption and decryption; for other mechanisms (asymmetric), the keys used for encryption and decryption are different.

key fingerprint The actual binary code of an encryption key, which is presented in hexadecimal notation.

key generation The origination of a key or set of distinct keys.

key length The number of binary digits, or bits, in an encryption algorithm's key. Key length is sometimes used to measure the relative strength of the encryption algorithm.

key logger (or **key trapper) software** A program that, when installed on a computer, records every keystroke and mouse click.

key management The generation, storage, distribution, deletion, archiving and application of keys in accordance with a security policy.

key space The total number of possible values of keys in a cryptographic algorithm or other security measure such as a password. For example, a 20 bit key would have a key space of 1,048,576. See *key length* and *key fingerprint*.

key, primary A unique attribute used to identify a class of records in a database.

Key2audio A product of Sony designed to control the copying of CDs by embedding code within the CD that prevents playback on a PC or Mac preventing track ripping or copying.

keyboard Today's most popular input technology.

key-to-disk device A keyboard unit that records data as patterns of magnetic spots onto magnetic disks.

kilobyte (K byte) The equivalent of 1,204 bytes.

KMI Key management infrastructure.

knowledge Information from multiple sources integrated with common, environmental, real-world experience.

knowledge acquisition The component of the expert system that the knowledge engineer uses to enter the rules.

knowledge base The part of an expert system that contains specific information and facts about the expert area. Rules that the expert system uses to make decisions are derived from this source.

knowledge engineer The person who formulates the domain expertise of an expert system.

knowledge levels Verbs that describe actions an individual should be capable of performing on the job after completion of the training associated with the cell. The verbs are identified for three training levels: beginning, intermediate, and advanced.

knowledge worker Works with and produces information as a product.

knowledge-based system An artificial intelligence system that applies reasoning capabilities to reach a conclusion. Also known as an expert system.

known-cover attack A type of attack where both the original, unaltered cover and the stego-object are available.

known-message attack A type of attack where the hidden message is known to exist by the attacker and the stego-object is analyzed for patterns which may be beneficial in future attacks. This is a very difficult attack, equal in difficulty to a stego-only attack.

known-stego attack An attack where the tool (algorithm) is known and the original cover object and stego-object are available.

L2F protocol Layer-2 Forwarding Protocol. Protocol that supports the creation of secure virtual private dial-up networks over the Internet.

label A set of symbols used to identify or describe an item, record, message, or file.

LAN Local-area network. High-speed, low-error data network covering a relatively small geographic area (up to a few thousand meters). LANs connect workstations, peripherals, terminals, and other devices in a single building or other geographically limited area. LAN standards specify cabling and signaling at the physical and data-link layers of the OSI model. Ethernet, FDDI, and Token Ring are widely used LAN technologies. *Compare with* MAN and WAN.

LAN Switch High-speed switch that forwards packets between data-link segments. Most LAN switches forward traffic based on MAC addresses. This variety of LAN switch is sometimes called a *frame switch*. LAN switches are often categorized according to the method they use to forward traffic: cut-through packet switching or store-and-forward packet switching. Multi-layer switches are an intelligent subset of LAN switches. Compare with *multilayer switch*. See also *cutthrough packet switching* and *store-and-forward packet switching*.

language processing The step of ASR in which the system attempts to analyze and make sense of the user's verbal instructions by comparing the word phonemes generated in step 2 with a language model database.

language translator Systems software that converts programs written in assembler or a higher-level language into machine code.

LAPB Link Access Procedure—Balanced.

LAPD Link Access Procedure on the D Channel.

LAPF Link Access Procedure for Frame-Mode Bearer Services.

laser Light amplification by stimulated emission of radiation. Analog transmission device in which a suitable active material is excited by an external stimulus to produce a narrow beam of coherent light that can be modulated into pulses to carry data. Networks based on laser technology are sometimes run over SONET.

laser printer An output unit that uses intensified light beams to form an image on an electrically charged drum and then transfers the image to paper.

last mile bottleneck problem Occurs when information is traveling on the Internet over a very fast line for a certain distance and then comes near the user where it must travel over a slower line.

LAT Local area transport.

latency In local networking, the time (measured in bits at the transmission rate) for a signal to propagate around or throughput the network. The time taken by a DASD device to position a storage location to reach the read arm over the physical storage medium. For general purposes, average latency time is used. Delay between the time a device requests access to a network and the time it is granted permission to transmit.

law enforcement agency (LEA) Organization authorized by a lawful authorization based on a national law to receive the results of telecommunications interceptions.

law enforcement monitoring facility (LEMF) Law enforcement facility designated as the transmission destination for the results of interception relating to a particular interception subject.

law enforcement official See Part II, 45 CFR 164.501.

lawful authorization Permission granted to an LEA under certain conditions to intercept specified telecommunications and requiring cooperation from an NWO/AP/SvP. Typically, this refers to a warrant or order issued by a lawfully authorized body.

lawful interception or intercept. See interception.

laws and regulations Federal, government-wide and organization-specific laws, regulations, policies, guidelines, standards, and procedures mandating requirements for the management and protection of information technology resources.

layer-3 switching The emerging layer-3 switching technology integrates routing with switching to yield very high routing throughput rates in the millions-of-packets-per-second range. The movement to layer-3 switching is designed to address the downsides of the current generation of layer-2 switches, which are functionally equivalent to bridges. These downsides for a large, flat network include being subject to broadcast storms, spanning tree loops, and address limitations that drove the injection of routers into bridged networks in the late 1980s. Currently, layer-3 switching is represented by a number of approaches in the industry.

layered defense A combination of security services, software and hardware, infrastructures, and processes which are implemented to achieve a required level of protection. These mechanisms are additive in nature with the minimum protection being provided by the network and infrastructure layers.

LCD Lifecycle support, lifecycle definition.

LCN Logical Channel Number (X.25).

LCP Link Control Protocol (X.25).

LDAP Lightweight Directory Access Protocol. Protocol that provides access for management and browser applications that provide read/write interactive access to the X.500 Directory.

LDN Local dial number (ISDN).

learning Knowledge gained by study (in classes or through individual research and investigation).

learning continuum A representation in which the common characteristic of learning is presented as a series of variations from awareness through training to education.

learning objective A link between the verbs from the "knowledge levels" section to the "behavioral outcomes" by providing examples of the activities an individual should be capable of doing after successful completion of training associated with the cell. Learning Objectives recognize that training must be provided at beginning, intermediate, and advanced levels.

leased line An unswitched telecommunications channel leased to an organization for its exclusive use.

least-cost routing (LCR) The automatic selection of the most economically available route for each outgoing trunk call. Also known as automatic route selection.

least privilege Confinement technique in which each process is given only the minimum privileges it needs to function; also referred to as sandboxing. (See also need-to-know.)

least-recently used (LRU) A replacement strategy in which new data must replace existing data in an area of storage; the least recently used items are replaced.

least significant bit steganography A substitution method of steganography where the right most bit in a binary notation is replaced with a bit from the embedded message. This method provides "security through obscurity," a technique which can be rendered useless if an attacker knows the technique is being used.

legacy information system An operational IS that existed prior to the implementation of the DITSCAP.

legacy system A previously built system using older technologies such as mainframe computers and programming languages such as COBOL.

letter bomb A Trojan horse that triggers when an e-mail message is read.

liability Condition of being or potentially subject to an obligation; condition of being responsible for a possible or actual loss, penalty, evil, expense, or burden. Condition that creates a duty to perform an act immediately or in the future, including almost every character of hazard or responsibility, absolute, contingent, or likely.

Lightweight Directory Access Protocol (LDAP) This protocol provides access for management and browser application that provide read/write interactive access to the X.500 Directory.

Likert scale An evaluation tool that is usually from one to five (one being very good; five being not good, or vice versa), designed to allow an evaluator to prioritize the results of the evaluation.

limit check An input control text that assesses the value of a data field to determine whether values fall within set limits.

line conditioning A service offered by common carriers to reduce delay, noise, and amplitude distortion to produce transmission of higher data speeds.

line printer An output unit that prints alphanumeric characters one line at a time.

line speed The transmission rate of signals over a circuit, usually expressed in bits per second.

line-of-sight (LOS) Defined by the Fresnel zone. Fresnel zone clearance is the minimum clearance over obstacles that the signal needs to be sent over. Reflection or path bending occurs if the clearance is not sufficient.

linguistic steganography The method of steganography where a secret is embedded in a harmless message. See also jargon code.

link encryption The application of online crypto-operations to a link of a communications system so that all information passing over the link is encrypted in its entirety.

linkage The purposeful combination of data or information from one information system with that from another system in the hope of deriving additional information.

Linux An open-source operating system that provides a rich operating environment for high-end workstations and network servers.

list A collection of information arranged in columns and rows in which each column displays one particular type of information.

list definition table A description of a list by column.

LLC Logical link control.

LLD Development, low-level design.

LMI Local management interface (frame relay).

load sharing A multiple-computer system that shares the load during peak hours. During non-peak periods or standard operation, one system can handle the entire load with the others acting as fallback units.

Local-Area Network (LAN) The physical connection of microcomputers with communication media (e.g., cable and fiber optics) that allows the sharing of information and peripherals among those microcomputers.

local code(s) A generic term for code values that are defined for a state or other political subdivision, or for a specific payer. This term is most commonly used to describe HCPCS level-III codes, but also applies to state-assigned Institutional Revenue Codes, Condition Codes, Occurrence Codes, Value Codes, etc.

local loop The physical connection from the subscriber's premises to the carrier's point of presence (POP). The local loop can be provided over any suitable transmission medium.

local multipoint distribution services (LMDS) A method of distributing TV signals to households in a local community. LMDS uses broadcast microwave signals to contact local dishes. The received signal is then distributed through the central CATV system.

location information Information relating to the geographical, physical, or logical location of an identity relating to an interception subject.

lock/key protection system A protection system that involves matching a key or a password with a specified access requirement.

logged-on but unattended A workstation is considered logged on but unattended when the user is (1) Logged on but is not physically present in the office; and (2) there is no one else present with an appropriate level of clearance safeguarding access to the workstation. Coverage must be equivalent to that which would be required to safeguard hard copy information if the same employee were away from his or her desk. Users of logged-on but unattended classified workstations are subject to the issuance of security violations.

logging The automatic recording of data for the purpose of accessing and updating it.

logic bomb A Trojan horse that will trigger when a specific logical event or action occurs.

logical error A programming error that causes the wrong processing to take place in a syntactically valid program.

logical file organization The sequencing of data records in a file according to their key.

logical link control (LLC) The portion of the link level protocol in the 802 standards that is in direct contact with higher-level layers.

logical observation identifiers, names, and codes (LOINC) A set of universal names and ID codes that identify laboratory and clinical observations. These codes, which are maintained by the Regenstrief Institute, are expected to be used in the HIPAA claim attachments standard.

logical operation A comparison of data values within the arithmetic logic unit. These comparisons show when one value is greater than, equal to, or less than a second value.

logical operator A symbol used in programming that initiates a comparison operation of two or more data values.

logical organization Data elements organized in a manner that meets human and organizational processing needs.

logically disconnect Although the physical connection between the control unit and a terminal remains intact, a system enforced disconnection prevents communication between the control unit and the terminal.

LOINC See logical observation identifiers, names, and codes.

loop A repeating structure or process.

loophole An error of omission or oversight in software, hardware, or firmware that permits circumventing the access control process.

lost pouch Any pouch-out-of-control which is not recovered.

LRA Local registration authority (for digital certificates).

LSA Link-state advertisement.

LSP Link state packet.

LT Local termination.

LTC Long-term care.

M + CO Medicare Plus Choice Organization.

MAC (1) Mandatory access controls. (2) Message authentication codes. (3) Media access control.

MAC (media access control) See media access control.

MAC address Standardized data-link layer address ingrained into a NIC that is required for every port or device that connects to a LAN. Other devices in the network use these addresses to locate specific ports in the network and to create and update routing tables and data structures. MAC addresses are 6 bytes long and are controlled by the IEEE. Also known as a hardware address, MAC-layer address, and physical address. Compare with *network address*.

Mac OS The operating system for today's Apple computers.

Machine Language Computer instructions or code representing computer operations and memory addresses in a numeric form that is executable by the computer without translation.

Machine language Computer instructions or code representing computer operations and memory addresses in a numeric form that is executable by the computer without translation.

macro virus A computer virus that spreads by binding itself to software such as Word or Excel.

Madison Project A code name for IBM's Electronic Music Management System (EMMS). EMMS is being designed to deliver piracy-proof music to consumers via the Internet.

Magicgate A memory media stick from Sony designed to allow users access to copyrighted music or data.

magnetic disk A storage device consisting of metallic platters coated with an oxide substance that allows data to be recorded as patterns of magnetic spots.

magnetic ink character recognition (MICR) An input method under which data is encoded in special ink containing iron particles. These particles can be magnetized and sensed by special machines and converted into computer input.

magnetic tape A storage medium consisting of a continuous strip of coated plastic film wound onto a reel and on which data can be recorded as defined patterns of magnetic spots.

mail gateway A machine that connects two or more e-mail systems (especially dissimilar mail systems on two different networks) and transfers messages between them. Sometimes the mapping and translation can be quite complex, and generally it requires a store-and-forward scheme whereby the message is received from one system completely before it is transmitted to the next system after suitable translations.

mail relay server An e-mail server that relays messages where neither the sender nor the receiver is a local user. A risk exists that an unauthorized user could hijack these open relays and use them to spoof their own identity.

mail server Provides e-mail services and accounts.

mailing list Discussion groups organized by area of interest.

mainframe computer A computer designed to meet the computing needs of hundreds of people in a large business environment.

maintain or maintenance See Part II, 45 CFR 162.103.

maintainability The general ease of a system to be maintained, at all levels of maintenance.

maintenance Tasks associated with the modification or enhancement of production software.

maintenance organization The government organization responsible for the maintenance of an IS. (Although the actual organization performing maintenance on a system may be a contractor, the maintenance organization is the government organization responsible for the maintenance.).

maintenance phase Monitors and supports the new system to ensure it continues to meet the business goals.

maintenance programmer An applications programmer responsible for making authorized changes to one or more computer programs and ensuring that the changes are tested, documented, and verified.

major application An application that requires special attention to security due to the risk and magnitude of the harm resulting from the loss, misuse, or unauthorized access to, or modification of, the information in the application. A breach in a major application might comprise many individual application programs and hardware, software, and telecommunications components. Major applications can be either major software applications or a combination of hardware/software where the only purpose of the system is to support a specific mission-related function.

MAN Metropolitan area network.

management controls Actions taken to manage the development, maintenance, and use of the system, including system-specific policies, procedures, and rules of behavior, individual roles and responsibilities, individual accountability, and personnel security decisions.

management information systems (MIS) Deals with the planning, development, management, and use of information technology tools to help people perform tasks related to information processing and management.

mandatory access control (MAC) MAC is a means of restricting access to data based on varying degrees of security requirements for information contained in the objects.

mandatory access controls A policy-based means of restricting access to objects based on the sensitivity (as represented by a label) of the information contained in the objects and the formal authorization (access control privileges) of subjects to access information of such sensitivity.

man-in-the-middle attack Scenarios in which a malicious user can intercept messages and insert other messages that compromise the otherwise secure exchange of information between two parties.349.

MAP Manufacturing Automation Protocol.

maritime strategy Naval objectives for sea control, maritime power projection, and control and protection of shipping. The Naval objectives in support of the national strategy.

marketing See Part II, 45 CFR 164.501.

marketing mix The set of marketing tools that a firm uses to pursue its marketing objectives in the target market.

masquerade A type of security threat that occurs when an entity successfully pretends to be a different entity.

mass customization When a business gives its customers the opportunity to tailor its product or service to the customer's specifications.

Massachusetts Health Data Consortium (MHDC) An organization that seeks to improve healthcare in New England through improved policy development, better technology planning and implementation, and more informed financial decision making.

master file An automated file that contains semi-permanent or permanent information and is maintained over a time period required by organizational policy.

master plan A long-range plan, derived from the notional architecture, for development and procurement of capabilities.

matrix display The alphanumeric representation of characters as patterns of tiny dots in specific positions on a display terminal.

matrix printer A hard-copy printing device that forms alphanumeric characters with small pins arranged in a matrix of rows and columns.

mature system A fully operational system that performs all the functions it was designed to accomplish.

MAU Media attachment unit.

maximum defined data set Under HIPAA, this is all of the required data elements for a particular standard based on a specific implementation specification. An entity creating a transaction is free to include whatever data any receiver might want or need. The recipient is free to ignore any portion of the data that is not needed to conduct their part of the associated business transaction, unless the inessential data is needed for coordination of benefits. Also see Part II, 45 CFR 162.103.

MCO Managed care organization.

M-commerce The term used to describe e-commerce conducted over a wireless device such as a cell phone or personal digital assistant.

MCS TOE access, limitation on multiple concurrent sessions.

MD5 hash value A mathematically generated string of 32 letters and digits that is unique for an individual storage medium at a specific point in time.

MDx Message Digest (e.g., MD5).

media The various physical forms (e.g., disk, tape, and diskette) on which data is recorded in machine-readable formats.

media access control (MAC) Lower of the two sub-layers of the data-link layer defined by the IEEE. The MAC sub-layer handles access to shared media, such as whether token passing or contention will be used. A local network control protocol that governs station access to a shared transmission medium. Examples are token passing and CSMA. See also *carrier sense, multiple access*.

mediation Action by an arbiter that decides whether or not a subject or process is permitted to perform a given operation on a specified object.

mediation function A mechanism that passes information between an NWO, an AP or an SvP, and a handover interface, and information between the internal network interface and the handover interface.

Medicaid fiscal agent (FA) The organization responsible for administering claims for a state Medicaid program.

Medicaid state agency The state agency responsible for overseeing the state's Medicaid program.

Medical code sets Codes that characterize a medical condition or treatment. These code sets are usually maintained by professional societies and public health organizations. Compare to administrative code sets.

Medical Records Institute (MRI) An organization that promotes the development and acceptance of electronic healthcare record systems.

Medicare contractor A Medicare part A fiscal intermediary, a Medicare Part B carrier, or a Medicare durable medical equipment regional carrier (DMERC).

Medicare durable medical equipment regional carrier (DMERC) A Medicare contractor responsible for administering Durable Medical Equipment (DME) benefits for a region.

Medicare part A fiscal intermediary (FI) A Medicare contractor that administers the Medicare Part A (institutional) benefits for a given region.

Medicare part B carrier A Medicare contractor that administers the Medicare part B (professional) benefits for a given region.

Medicare remittance advice remark codes A national administrative code set for providing either claim-level or service-level Medicare-related messages that cannot be expressed with a Claim Adjustment Reason Code. This code set is used in the X12 835 Claim Payment & Remittance Advice transaction, and is maintained by the HCFA.

megabyte (Mbyte, MB) The equivalent of 1,048,576 bytes.

megahertz (MHz) The number of millions of CPU cycles per second.

memorandum of understanding (MOU) A document that provides a general description of the responsibilities that are to be assumed by two or more parties in their pursuit of some goal(s). More specific information may be provided in an associated SOW.

memorandum of understanding/agreement A document established between two or more parties to define their respective responsibilities in accomplishing a particular goal or mission. In this guide, an MOU/A defines the responsibilities of two or more organizations in establishing, operating, and securing a system interconnection.

memory The area in a computer that serves as temporary storage for programs and data during program execution.

memory address The location of a byte or word of storage in computer memory.

memory bounds The limits in the range of storage addresses for a protected region in memory.

memory chips A small integrated circuit chip with a semiconductor matrix used as computer memory.

menu A section of the computer program—usually the top-level module—that controls the order of execution of other program modules. Also, online options displayed to a user, prompting the user for specific input.

message (1) The data input by the user in the online environment that is used to drive a transaction. The output of transaction. (2) In steganography, the data a sender wishes to remain confidential. This data can be text, still images, audio, video or anything that can be represented as a bitstream.

message address The information contained in the message header that indicates the destination of the message.

message authentication code (MAC) Message authentication code is a one-way hash computed from a message and some secret data. It is difficult to forge without knowing the secret data. Its purpose is to detect if the message has been altered.

message digest An example would be MD5. A message digest is a combination of alphanumeric characters generated by an algorithm that takes a digital object (such as a message you type) and pulls it through a mathematical process, giving a digital fingerprint of the message (enabling you to verify the integrity of a given message).

message handling system (MHS) The system of message user agents, message transfer agents, message stores, and access units that together provide OSI e-mail. MHS is specified in the ITU–TSS X.400 series of recommendations.

message stream The sequence of messages or parts of messages to be sent.

message transfer agent (MTA) An OSI application process used to store and forward messages in the X.400 message handling system. Equivalent to Internet mail agent.

messaging application An application based on a store and forward paradigm; it requires an appropriate security context to be bound with the message itself.

messaging service An interactive service that offers user-to-user communication between individual users via storage units with store-and-forward, and mailbox or message handling functions (e.g., information editing, processing, and conversion).

messaging-based workflow system Sends work assignments through an e-mail system.

metadata The description of such things as the structure, content, keys, and indexes of data.

metalanguage A language used to specify other languages.

metatag A part of a Web site text not displayed to users but accessible to browsers and search engines for finding and categorizing Web sites.

method A function, capability, algorithm, formula, or process that an object is capable of performing.

Metropolitan Area Network (MAN) A data network intended to serve an area approximating that of a large city. Such networks are being implemented by innovative techniques, such as running fiber cables through subway tunnels.

MGMA Medical Group Management Association.

MHDC See the Massachusetts Health Data Consortium.

MHDI See the Minnesota Health Data Institute.

MIB Management information base.

microcomputer A small microprocessor-based computer built to handle input, output, processing, and storage functions.

microdot A detailed form of microfilm that has been reduced to an extremely small size for ease of transport and purposes of security.

microfilm A film for recording alphanumeric and graphics output that has been greatly reduced in size.

micro-payment A technique to facilitate the exchange of small amounts of money for an Internet transaction.

microphone For capturing live sounds, such as human voice.

microprocessor A single small chip containing circuitry and components for arithmetic, logical, and control operations.

Microsoft Windows 2000 Millennium (Windows 2000Me) An operating system for a home computer featuring utilities for setting up a home network and performing video, photo, and music editing and cataloging.

Microsoft Windows 2000 Professional (Windows 2000 Pro) An operating system for people who have a personal computer connected to a network of other computers at work or at school.

Microsoft Windows XP Home Microsoft's latest upgrade to Windows 2000Me, with enhanced features for allowing multiple users to use the same computer.

Microsoft Windows XP Professional (Windows XP Pro) Microsoft's latest upgrade to Windows 2000 Pro.

microwave A type of radio transmission used to transmit information.

middleware The distributed software needed to support interactions between client and servers.

MIDI Musical instrument digital interface.

millions of instructions per second (MIPS) Used as a measure for assessing the speed of mainframe computers. Also, meaningless indicator of processor speed.

minicomputer Typically, a word-oriented computer whose memory size and processing speed falls between that of a microcomputer and a medium-sized computer.

minimum level of protection The reduction in the total risk that results from the impact of in-place safeguards. See also total risk, acceptable risk, and residual risk.

minimum scope of disclosure The principle that, to the extent practical, individually identifiable health information should only be disclosed to the extent needed to support the purpose of the disclosure.

minimum security baseline A set of minimum acceptable security controls, which are applicable to a range of information technology systems.

minimum security baseline assessment An evaluation of controls protecting an information system against a set of minimum acceptable security requirements.

Minnesota Health Data Institute (MHDI) A public-private partnership for improving the quality and efficiency of healthcare in Minnesota. MHDI includes the Minnesota Center for Healthcare Electronic Commerce (MCHEC), which supports the adoption of standards for electronic commerce and also supports the Minnesota EDI Healthcare Users Group (MEHUG).

minor application An application, other than a major application, that requires attention to security due to the risk and magnitude of harm resulting from the loss, misuse, or unauthorized access to or modification of the information in the application. Minor applications are typically included as part of a general support system.

MIPS See millions of instructions per second.

mirror-image backup Mirror image backups (also referred to as bitstream backups) involve the backup of all areas of a computer hard disk drive or another type of storage media (e.g., Zip disks, floppy disks, Jazz disks, etc.). Such mirror image backups exactly replicate all sectors on a given storage device. Thus, all files and ambient data storage areas are copied. Such backups are sometimes referred to as "evidence-grade" backups and they differ substantially from standard file backups and network server backups. The making of a mirror image backup is simple in theory, but the accuracy of the backup must meet evidence standards. Accuracy is essential and to guarantee accuracy, mirror image backup programs typically rely on mathematical CRC computations in the validation process. These mathematical validation processes compare the original source data with the restored data. When computer evidence is involved, accuracy is extremely important, and the making of a mirror image backup is typically described as the preservation of the "electronic crime scene."

mirrored site An alternate site that contains the same information as the original. Mirror sites are set up for backup and disaster recovery as well to balance the traffic load for numerous download requests. Such "download mirrors" are often placed in different locations throughout the Internet.

mishap risk An expression of the possibility and impact of an unplanned event or series of events resulting in death, injury, occupational illness, damage to or loss of equipment or property (physical or cyber), or damage to the environment in terms of potential severity of consequences and likelihood of occurrence. See also risk.

MISPC Minimum interoperability specification of PKI components; a standard that specifies a minimal set of features, transactions, and data formats for the various certification management components that make up a PKI.

mission A specific task with which a person, or group of individuals, or organization is entrusted to perform.

mission criticality The property that data, resources, and processes may have, which denotes that the importance of that item to the accomplishment of the mission is sufficient to be considered an enabling/disabling factor.

mission justification The description of the operational capabilities required to perform an assigned mission. This includes a description of a system's capabilities, functions, interfaces, information processed, operational organizations supported, and the intended operational environment.

mistake An erroneous human action (accidental or intentional) that produces a fault condition.

Mjuice An online music store that provides secure distribution of MP3s over the Internet. A secure player and a download system allow users to play songs an unlimited number of times, but only on a registered player.

MLP Multilink PPP.

MLS Multilevel secure.

MMP Multichassis multilink PPP.

MNWF Must not work function.

mobile base stations (MBS) Component of cellular network that provides data link relay functions for a set of radio channels serving a cell.

mobile site The use of a mobile/temporary facility to serve as a business resumption location. They usually can be delivered to any site and can house information technology and staff.

mobile switching center (MSC) The location of the digital access and crossconnect system (DACS) in a cellular telephone network.

mobile telephone switching office (MTSO) Controls the entire operation of a cellular system. It is a sophisticated computer that monitors all cellular calls, arranges handoffs and manages billing information.

mode of operation A classification for systems that execute in a similar fashion and share distinctive operational characteristics (e.g., production, DSS, online, and interactive).

model A representation of a problem or subject area that uses abstraction to express concepts.

model management Component of a DSS that consists of the DSS models and the DSS model management system.

modeling The activity of drawing a graphical representation of a design.

modem (modulator/demodulator) This is a piece of hardware used to connect computers (or certain other network devices) together via a serial cable (usually a telephone line). When data is sent from your computer, the modem takes the digital data and converts it to an analog signal (the modulator portion). When you receive data into your computer via modem, the modem takes the analog signal and converts it to a digital signal that your computer will understand (the demodulator portion).

modification A type of security threat that occurs when its content is modified in an unanticipated manner by a non-authorized entity.

modify or modification Under HIPAA, this is a change adopted by the secretary, through regulation, to a standard or an implementation specification. See also Part II, 45 CFR 160.103.

modular treated conference room (MTCR) A second-generation design of the treated conference room (TCR), offering more flexibility in configuration and ease of assembly than the original TCR, designed to provide acoustic and RF emanations protection.

modularity Modular packages consist of sets of equipment, people, and software tailorable for a wide range of missions.

MOF Security management, management of functions in TSF.

molecules The smallest particle of a substance that retains all the properties of the substance and is composed of one or more atoms.

monitoring and surveillance agents (or **predictive agents**) Intelligent agents that observe and report on equipment.

monitoring policy The rules outlining the way in which information is captured and interpreted.

MOP Maintenance Operation Protocol.

more stringent See Part II, 45 CFR 160.202.

mosaic attack A watermarking attack that is particularly useful for images that are distributed over the Internet. It relies on a Web browsers ability to assemble multiple images so they appear to be one image. A watermarked image can be broken into pieces but displayed as a single image by the browser. Any program trying to detect the watermark will look at each individual piece, and if they are small enough, will not be able to detect the watermark.

MOU See memorandum of understanding.

mouse A hardware device used for moving a display screen cursor.

MP Multilink Protocol.

MPEG Motion Picture Experts Group.

MPR Multiprotocol PC-based routing.

MR Medical review.

MRI See the Medical Records Institute.

MRRU Maximum received reconstructed unit (PPP).

MSA Security management, management of security attributes.

MSAU Multistation access units (Token Ring).

MSP Medicare secondary payer.

MSU Vulnerability assessment, misuse.

MTD Security management, management of TSF data.

M-trax An encrypted form of MP3 watermarking technology from MCY Music that protects the music industry and artists from copyright infringments.

MTU Maximum transmission unit.

multiaccess rights terminal A terminal that may be used by more than one class of users, for example, users with different access rights to data or files.

multichannel multipoint distribution services (MMDS) An FCC name for a service where multiple video channels are broadcast within a limited geographic area. Often called *wireless cable*.

multidimensional analysis (MDA) tools Slice and dice techniques that allow viewing multidimensional information from different perspectives.

multifunction printer Scans, copies, and faxes as well as prints.

multilevel mode INFOSEC mode of operation wherein all the following statements are satisfied concerning the users who have direct or indirect access to the system, its peripherals, remote terminals, or remote hosts: (1) Some users do not have a valid security clearance for all the information processed in the IS; (2) all users have the proper security clearance and appropriate formal access approval for that information to which they have access; and (3) all users have a valid need-to-know only for information for which they have access.

multilevel secure A class of systems containing information with different sensitivities that simultaneously permits access by users with different security clearances and needs-to-know, but prevents users from obtaining access to information for which they lack authorization.

multilevel security (MLS) Concept of processing information with different classifications and categories that simultaneously permits access by users with different security clearances, but prevents users from obtaining access to information for which they lack authorization.

multinational operations A collective term to describe military actions conducted by forces of two or more nations usually undertaken within the structure of a coalition or alliance.

multiple inheritance The language mechanism that allows the definition of a class to include the attributes and methods defined for more than one superclass.

multiplexing To transmit two or more signals over a single channel.

multiprocessing A computer operating method in which two or more processors are linked and execute multiple programs simultaneously.

multiprogramming A computer operating environment in which several programs can be placed in memory and executed concurrently.

Multipurpose Internet Mail Extension (MIME) The standard for multimedia mail contents in the Internet suite of protocols.

multitasking Allows the user to work with more than one piece of software at a time.

Municipal Area Network (MAN) A network that covers a metropolitan area.

MUSE project An initiative which contributes to the continuing development of intellectual property standards. The MUSE project focuses on the electronic delivery of media, embedded signaling systems, and encryption technology with the goal of creating a global standard.

must not work function Sequences of events or commands that are prohibited because they would result in a system hazard.

must work function Software that, if not performed or performed incorrectly, inadvertently, or out of sequence, could result in a hazard or allow a hazardous condition to exist. This includes (1) software that directly exercises command and control over potentially hazardous functions or hardware; (2) software that monitors critical hardware components; and (3) software that monitors the system for possible critical conditions or states.

mutation The process within a genetic algorithm of randomly trying combinations and evaluating the success or failure of the outcome.

mutually suspicious Pertaining to a state that exists between interactive processes (systems or programs), each of which contains sensitive data and is assumed to be designed to extract data from the other and to protect its own data.

MW Multichannel interface proccessor.

MWF Must work function.

NAHDO See the National Association of Health Data Organizations.

NAIC See the National Association of Insurance Commissioners.

NAK Negative acknowledgment. Response sent from a receiving device to a sending device indicating that the information received contained errors. Compare with *acknowledgment*.

NAK attack A penetration technique that capitalizes on an operating system's inability to properly handle asynchronous interrupts.

name resolution The process of mapping a name into the corresponding address.

naming attributes Names carried by each instance of an object, such as name, or identification number.

NASMD See the National Association of State Medicaid Directors.

NAT Network address translation. A means of hiding the IP addresses on an internal network from external view. NAT boxes allow net managers to use any IP addresses they choose on internal networks, thereby helping to ease the IP addressing crunch while hiding machines from attackers.

National Association of Health Data Organizations (NAHDO) A group that promotes the development and improvement of state and national health information systems.

National Association of Insurance Commissioners (NAIC) An association of the insurance commissioners of the states and territories.

National Association of State Medicaid Directors (NASMD) An association of state Medicaid directors. NASMD is affiliated with the American Public Health Human Services Association (APHSA).

National Center for Health Statistics (NCHS) A federal organization within the CDC that collects, analyzes, and distributes healthcare statistics. The NCHS maintains the ICD-n-CM codes.

National Committee for Quality Assurance (NCQA) An organization that accredits managed care plans, or Health Maintenance Organizations (HMOs). In the future, the NCQA may play a role in certifying these organizations' compliance with the HIPAA A/S requirements. The NCQA also maintains the Health Employer Data and Information Set (HEDIS).

National Committee on Vital and Health Statistics (NCVHS) A federal advisory body within HHS that advises the secretary regarding potential changes to the HIPAA standards.

National Computer Security Center (NCSC) Originally named the DoD Computer Security Center, the NCSC is responsible for encouraging the widespread availability of trusted computer systems throughout the federal government. With the signing of NSDD-145; the NCSC is responsible for encouraging the widespread availability of trusted computer systems throughout the federal government.

National Council for Prescription Drug Programs (NCPDP) An ANSI-accredited group that maintains a number of standard formats for use by the retail pharmacy industry, some of which are included in the HIPAA mandates. Also see NCPDP Standard.

National Drug Code (NDC) A medical code set that identifies prescription drugs and some over-the-counter products, and that has been selected for use in the HIPAA transactions.

National Employer ID A system for uniquely identifying all sponsors of healthcare benefits.

National Health Information Infrastructure (NHII) This is a healthcare-specific lane on the information superhighway, as described in the National Information Infrastructure (NII) initiative. Conceptually, this includes the HIPAA A/S initiatives.

National Information Assurance Partnership (NIAP) A joint industry/government initiative, lead by NIST and NSA, to establish commercial testing laboratories where industry product providers can have security products tested to verify their performance against vendor claims.

national information infrastructure The total interconnected national telecommunications network of a country, which is made up of the private lines of major carriers, numerous carriers and interconnection companies, and thousands of local exchanges that connect private telephone lines to the national network and the world.279.

National Patient ID A system for uniquely identifying all recipients of healthcare services. This is sometimes referred to as the National Individual Identifier (NII), or as the Healthcare ID.

National Payer ID A system for uniquely identifying all organizations that pay for healthcare services. Also known as Health Plan ID or Plan ID.

National Provider File (NPF) The database envisioned for use in maintaining a national provider registry.

National Provider ID (NPI) A system for uniquely identifying all providers of healthcare services, supplies, and equipment.

National Provider Registry The organization envisioned for assigning National Provider IDs.

National Provider System (NPS) The administrative system envisioned for supporting a national provider registry.

National Science Foundation (NSF) Sponsors of the NSFNET.

National Science Foundation Network (NSFNET) A collection of local, regional, and mid-level networks in the U.S. tied together by a high-speed backbone. NSFNET provides scientists access to a number of supercomputers across the country.

national security The national defense or foreign relations of the United States.

national security information Information that has been determined pursuant to Executive Order 12958 as amended by Executive Order 13292, or any predecessor order, or by the Atomic Energy Act of 1954, as amended, to require protection against unauthorized disclosure and is marked to indicate its classified status.

national security system Any information system (including any telecommunications system) used or operated by an organization or by a contractor of the organization, or by other organization on behalf of the organization: (1) the function, operation, or use of which involves intelligence activities; involves cryptologic activities related to national security; involves command and control of military forces; involves equipment that is an integral part of a weapon or weapons system; or is critical to the direct fulfillment of military or intelligence missions (excluding a system that is to be used for routine administrative and business applications, for example, payroll, finance, logistics, and personnel management applications); or (2) is protected at all times by procedures established for information that have been specifically authorized under criteria established by an executive order or an Act of Congress to be kept classified in the interest of national defense or foreign policy.

National Standard Format (NSF) Generically, this applies to any nationally standardized data format, but it is often used in a more limited way to designate the Professional EMC NSF, a 320-byte flat file record format used to submit professional claims.

national strategy Objectives of the nation for dealing in the arena of international politics, military confrontation, and national defense.

National Uniform Billing Committee (NUBC) An organization, chaired and hosted by the American Hospital Association, that maintains the UB-92 hardcopy institutional billing form and the data element specifications for both the hardcopy form and the 192-byte UB-92 flat file EMC format. The NUBC has a formal consultative role under HIPAA for all transactions affecting institutional healthcare services.

National Uniform Claim Committee (NUCC) An organization, chaired and hosted by the American Medical Association, that maintains the HCFA-1500 claim form and a set of data element specifications for professional claims submission via the HCFA-1500 claim form, the Professional EMC NSF, and the X12 837. The NUCC also maintains the Provider Taxonomy Codes and has a formal consultative role under HIPAA for all transactions affecting non-dental non-institutional professional healthcare services.

natural language A language that is used in communication with computers and that closely resembles English syntax.

NAUN Nearest active upstream neighbor.

NBMA Nonbroadcast multiaccess.

NBP Name Binding Protocol (AppleTalk).

NCHICA See the North Carolina Healthcare Information and Communications Alliance.

NCHS See the National Center for Health Statistics.

NCP NetWare Core Protocol.

NCP Network Control Protocol (PPP).

NCPDP See the National Council for Prescription Drug Programs.

NCPDP Batch Standard An NCPDP standard designed for use by low-volume dispensers of pharmaceuticals, such as nursing homes. Use of version 1.0 of this standard has been mandated under HIPAA.

NCPDP Telecommunication Standard An NCPDP standard designed for use by high-volume dispensers of pharmaceuticals, such as retail pharmacies. Use of version 5.1 of this standard has been mandated under HIPAA.

NCQA See the National Committee for Quality Assurance.

NCSC National Computer Security Center; part of the U.S. Department of Defense.

NCVHS See the National Committee on Vital and Health Statistics.

NDC See National Drug Code.

NDIS Network Driver Interface Specification.

need-to-know A method of isolating information resources based on a user's need to have access to that resource in order to perform their job but no more; for example, a personnel officer needs access to sensitive personnel records and a marketing manager needs access to sensitive marketing information but not vice versa. The terms "need-to-know" and "least privilege" express the same idea. Need-to-know is generally applied to people, while least privilege is generally applied to processes.

negative Acknowledgment (NAK) A response sent by the receiver to indicate that the previous block was unacceptable and the receiver is ready to accept a retransmission.

negligence Failure to use such care as a reasonably prudent and careful person would use under similar circumstances; the doing of some act which a person of ordinary prudence would not have done under similar circumstances or failure to do what a person of ordinary prudence would have done under similar circumstances; conduct that falls below the norm for the protection of others against unreasonable risk of harm. It is characterized by inadvertence, thoughtlessness, inattention, recklessness, etc.

NetBIOS Network basic I/O system.

network An integrated, communicating aggregation of computers and peripherals linked through communications facilities.

network access layer The layer of the IP/IP stack that sends the message out through the physical network onto the Internet.

network access points (NAPs) (1) Nodes providing entry to the high-speed Internet backbone system. (2) Another name for an Internet exchange point.

network address The network portion of an IP address. For a class A network, the network address is the first byte of the IP address. For a class B network, the network address is the first two bytes of the IP address. For a class C network, the network address is the first three bytes of the IP address. In the Internet, assigned network addresses are globally unique.

network administrator The person who maintains user accounts, password files, and system software on your campus network.

Network Basic Input Output System (NetBIOS) The standard interface to networks on IBM PC and compatible system.

network centric A holistic view of interconnected information systems and resources that encourages a broader approach to security management than a component-based approach.

network element A component of the network structure such as a local exchange, higher-order switch, or service-control processor.

Network File Systems (NFS) A distributed file system developed by Sun Microsystems which allows a set of computers to cooperatively access each other's files in a transparent manner.

network hub A device that connects multiple computers into a network.

Network Information Center (NIC) Originally, there was only one, located at SRI International and tasked to serve the ARPANET (and later DDN) community. Today, there are many NICs, operated by local, regional, and national networks all over the world. Such centers provided user assistance, document service, training, and much more.

network layer The OSI layer that is responsible for routing, switching, and subnetwork access across the entire OSI environment. Think of this layer as a post office that delivers letters based on the address written on an envelope.

network manager Provides a package of end-user functions with the responsibility for the management of a network, mainly as supported by the EMs, but it may also involve direct access to the network elements. All communication with the network is based on open and well-standardized interfaces supporting management of multivendor and multitechnology network elements.

network operator (NWO) Operator of a public telecommunications infrastructure that permits the conveyance of signals between defined network termination points by wire, microwave, optical means, or other electromagnetic means.

network propagation system analysis A way of determining the speed and method of stego-object (or virus) movement throughout a network.

network service provider (NSP) Owns and maintains routing computers at NAPs and even the lines that connect the NAPs to each other. For example, MCI and AT&T.

network sink A router that drops or misroutes packets, accidentally or on purpose. Intelligent network sinks can cooperate to conceal evidence of packet dropping.

networking A method of linking distributed data processing activities through communications facilities.

networks Includes communication capability that allows one user or system to connect to another user or system and can be part of a system or a separate system. Examples of networks include local area network or wide area networks, including public networks such as the Internet.

neural network A type of system developed by artificial intelligence researchers used for processing logic.

newsgroups Usually discussions, but not "interactively live." Newsgroups are like posting a message on a bulletin board and checking at various times to see if someone has responded to your posting.

newspaper code A hidden communication technique where small holes are poked just above the letters in a newspaper article that will spell out a secret message. A variant of this technique is to use invisible ink place of holes.

NFS Network file system.

NHII See National Health Information Infrastructure.

NIACAP National Information Assurance Certification and Accreditation Process.

NIAP Joint industry/government (U.S.) National IA Partnership.

NIAP Common Criteria evaluation and validation scheme The scheme developed by NIST and NSA as part of the National Information Assurance Partnership (NIAP) establishing an organizational and technical framework to evaluate the trustworthiness of IT products.

NIAP oversight body A governmental organization responsible for carrying out validation and for overseeing the day-to-day operation of the NIAP Common Criteria evaluation and validation scheme.

NIC Network interface card. This is the card that the network cable plugs into in the back of your computer system. The NIC connects your computer to the network. A host must have at least one NIC; however, it can have more than one. Every NIC is assigned a MAC address.

NIDS Network intrusion detection system.

NII National information infrastructure of a specific country.

NIPC U.S. National Infrastructure Protection Center.

NIST National Institute of Standards and Technology.

NLPID Network Level Protocol Identifier.

NLS Network Layer Security Protocol.

NLSP NetWare Link Service Protocol.

NNI Network-to-network interface (ATM, frame relay).

NOC In HIPAA, not otherwise classified or nursing outcomes classification.

node A point of connection into a network. In multipoint networks, is a unit that is polled. In LANs, it is a device on the ring. In packet switched networks, it is one of the many packet switches that form the network's backbone.

NOI See notice of intent.

noise Random electrical signals introduced by circuit components or natural disturbances that tend to degrade the performance of a communications channel.

nonclinical or nonmedical code sets See administrative code sets.

noncomputing security methods Noncomputing methods are security safeguards which do not use the hardware, software, and firmware of the IS. Traditional methods include physical security (controlling physical access to computing resources), personnel security, and procedural security.

nondevelopmental item (NDI) Any item that is available in the commercial marketplace; any previously developed item that is in use by a department or agency of the United States, a state or local government, or a foreign government with which the United States has a mutual defense cooperation agreement; any item described above that requires only minor modifications in order to meet the requirements of the procuring Agency; or any item that is currently being produced that does not meet the requirements of definitions above, solely because the item is not yet in use or is not yet available in the commercial marketplace.

nondiscretionary access control A nondiscretionary authorization scheme is one under which only the recognized security authority of the security domain may assign or modify the ACI for the authorization scheme such that the authorizations of principals under the scheme are modified.

noninterference The property that actions performed by user or process A of a system have no effect on what user or process B can observe; there is no information flow from A to B.

nonintrusive monitoring The use on nonintrusive probes or traces to assemble information and track traffic and identity vulnerabilities.

nonprocedural language A programming language with fixed logic, which allows the programmer to specify processing operations without concern for processing logic.

nonrecord material Extra and duplicate copies that are only of temporary value, including shorthand notes, used carbon paper, preliminary drafts, and other material of similar nature.

nonrecurring (ad hoc) decision One that is made infrequently and may have different criteria for determining the best solution each time.

nonrepudiation A security service by which evidence is maintained so that the sender and recipient of data cannot deny having participated in the communication. Referred to individually as *nonrepudiation of origin* and *nonrepudiation of receipt*.

nonstructured decision A decision for which there may be several right answers and there is no precise way to get a right answer.

nontransparent proxy mode accelerator In a nontransparent proxy mode accelerator, the source addresses of all the packets decrypted by the SSL accelerator have a source address of that SSL accelerator and the client source addresses do not get to the server at all. From the server perspective, the request has come from the SSL accelerator.

normalization A process of assuring that a relational database structure can be implemented as a series of two-dimensional relations.

North Carolina Healthcare Information and Communications Alliance (NCHICA) An organization that promotes the advancement and integration of information technology into the healthcare industry.

NOS Network operating system.

notebook computer A highly portable, battery powered microcomputer with a display screen, carried easily in a briefcase, and used away from a user's workplace.

notice A privacy principle that requires reasonable disclosure to a consumer of an entity's personally identifiable information (PII) collection and use practices. This disclosure information is typically conveyed in a privacy notice or privacy policy. Microsoft: http://www.microsoft.com/security/glossary/.

notice of intent (NOI) A document that describes a subject area for which the federal government is considering developing regulations. It may describe the presumably relevant considerations and invite comments from interested parties. These comments can then be used in developing an NPRM or a final regulation.

notice of proposed rulemaking (NPRM) A document that describes and explains regulations that the federal government proposes to adopt at some future date, and invites interested parties to submit comments related to them. These comments can then be used in developing a final regulation.

notional architecture An alternative architecture composed of current systems, as well as, new procurements proposed for some future date.

NPF See National Provider File.

NPI See National Provider ID.

NPRM Notice of proposed rulemaking—the publication, in the *Federal Register*, of proposed regulations for public comment.

NPRM See notice of proposed rulemaking.

NPS See national provider system.

NRC National Research Council—quasi-governmental body that conducted a study on the state of security in health care: *For the Record: Protecting Electronic Health Information* (Washington, DC: National Academy Press, 1997).

NRO Communication nonrepudiation of origin.

NRR Communication nonrepudiation of receipt.

NSF See National Standard Format.

NT-1 Network termination 1.

NTN Network terminal number (X.25).

NTP Network Time Protocol.

NTSC/PAL National Television System Committee: The first color TV broadcast system was implemented in the United States in 1953. This was based on the NTSC (National Television System Committee) standard. NTSC is used by many countries on the American continent as well as many Asian countries, including Japan. NTSC runs on 525 lines/frame. PAL (Phase Alternating Line) standard was introduced in the early 1960s and implemented in most countries except for France. The PAL standard utilizes a wider channel bandwidth than NTSC, which allows for better picture quality. PAL runs on 625 lines/frame.

NUBC See the national uniform billing committee.

NUBC EDI TAG The NUBC EDI Technical Advisory Group, which coordinates issues affecting both the NUBC and the X12 standards.

NUCC See the national uniform claim committee.

nucleus The core of the atom that is made up of neutrons and protons.

null A symbol that means nothing that is included within a message designed to confuse unintended recipients.

null option The option to take no action.

numeric test An input control method to verify that a field of data contains only numeric digits.

NVA Network vulnerability assessment.

NVE Network-visible entity.

NVRAM Nonvolatile random access memory.

Nyquist theorem Theorem that dictates that sampling should occur at a rate that is twice the highest frequency being sampled.

OBJ (1) Protection profile evaluation, security objectives. (2) Security target evaluation, security objectives.

object (1) An entity that can have many properties (either declarative, procedural, or both) associated with it. (2) An instance of a class.

object identity In the object-oriented paradigm, each object has a unique identifier independent of the values of other properties.

object program A program that has been translated from a higher-level source code into machine language.

object request broker (ORB) A software mechanism by which objects make and receive requests and responses.

object reuse Reassignment and re-use of a storage medium containing one or more objects after ensuring no residual data remains on the storage medium.

objective information Quantifiably describes something that is known.

object-oriented Any method, language, or system that supports object identity, classification, and encapsulation and specialization. C++, Smalltalk, Objective-C, and Eiffel are examples of object-oriented implementation languages.

object-oriented analysis (OOA) The specification of requirements in terms of objects with identity that encapsulate properties and operations, messaging, inheritance, polymorphism, and binding.

object-oriented approach Combines information and procedures into a single view.

object-oriented database Works with traditional database information and also complex data types such as diagrams, schematic drawings, videos, and sound and text documents.

Object-Oriented Database Management System (OODBMS) A database that stores, retrieves, and updates objects using transaction control, queries, locking, and versioning.

object-oriented design (OOD) The development activity that specifies the implementation of a system using the conceptual model defined during the analysis phase.

object-oriented language A language that supports objects, method resolution, specialization, encapsulation, polymorphism, and inheritance.

object-oriented programming language A programming language used to develop object-oriented systems. The language groups together data and instructions into manipulative objects.

oblivious scheme See blind scheme.

observe, orient, decide, act (OODA) See OODA loop.

OC Optical circuit.

OCR See the Office for Civil Rights.

ODI Open datalink interface.

office automation The application of computer and related technologies to office procedure.

Office for Civil Rights The HHS entity responsible for enforcing the HIPAA privacy rules.

Office of Management and Budget (OMB) A federal government agency that has a major role in reviewing proposed federal regulations.

official information That information or material which is owned by, produced for or by, or under the control of the U.S. government.

off-line authentication certificate A particular form of authentication information binding an entity to a cryptographic key, certified by a trusted authority, which may be used for authentication without directly interacting with the authority.

offsite storage A storage facility located away from the building, housing the primary information processing facility (IPF), and used for storage of computer media such as offline backup data storage files.

Ohm's law This law applies to any resistive circuit with one of the values unknown and will allow the discovery of the unknown value.

OIG Office of the Inspector General.

OLE Microsoft's Object Linking and Embedding technology designed to let applications share functionality through live data exchange and embedded data. Embedded objects are packaged statically within the source application, called the *client*; linked objects launch the "server" applications when instructed by the client application. Linking is the capability to call a program, embedding places data in a foreign program.

OMB See the Office of Management and Budget.

one-time pad A system that randomly generates a private key, and is used only once to encrypt a message that is then decrypted by the receiver using a matching one-time pad and key. One-time pads have the advantage that there is theoretically no way to "break the code" by analyzing a succession of messages.

online analytical processing (OLAP) The manipulation of information to support decision-making.

online authentication certificate A particular form of authentication information, certified by a trusted authority, which may be used for authentication following direct interaction with the authority.

online processing Often called *interactive processing*. An operation in which the user works at a terminal or other device that is directly attached or linked to the computer.

online service A proprietary, commercial network that provides a variety of information and other services to its subscribers. Commercial online services typically provide their own content, forums (e.g., chat rooms, bulletin boards), e-mail capability, and information available only to subscribers.

online system Applications that allow direct interaction of the user with the computer (CPU) via a CRT, thus enabling the user to receive back an immediate response to data entered (i.e., an airline reservation system). Only one root node can be used at the beginning of the hierarchical structure.

online training Runs over the Internet or off a CD-ROM.

online transaction processing (OLTP) The gathering of input information, processing that information, and updating.

onward transfer The transfer of personally identifiable information (PII) by the recipient of the original data to a second recipient. For example, the transfer of PII from an entity in Germany to an entity in the United States constitutes onward transfer of that data.

OODA loop The observe, orient, decide, act (OODA) cycle (or Boyd cycle) first introduced by Col. John Boyd, USAF. Refers to steps in the decision-making process.

open code A form of hidden communication which uses an unencrypted message. Jargon code is an example of open code.

open network computing (ONC) A distributed applications architecture promoted and controlled by a consortium led by Sun Microsystems.

open network/system A network or systems in which, at the extremes, unknown parties, possibly in a different state or national jurisdictions will exchange/trade data. To do this, will require an overarching framework which will engender trust and certainty. A user of online services might go through a single authentication process with a trusted third party, receive certification of their public key, and then be able to enter into electronic transactions/data exchanges with merchants, governments, banks etc, using the certificate so provided for multiple purposes.

open system A system whose architecture permits components developed by independent organizations or vendors to be combined.

open systems interconnection (OSI) An international standardization program to facilitate communications among computers from different manufactures.

OpenMG A copyright protection technology from Sony that allows recording and playback of digital music data on a personal computer and other supported devices but prevents unauthorized distribution.

operand The portion of a computer instruction that references the memory address of an item to be processed.

operating environment The total environment in which an information system operates. Includes the physical facility and controls, procedural and administrative controls, personnel controls (e.g., clearance level of the least cleared user).

operating system A software program that manages the basic operations of a computer system. It calculates how the computer main memory will be apportioned, how and in what order it will handle tasks assigned to it, how it will manage the flow of information into and out of the main processor, how it will get material to the printer for printing and to the screen for viewing, how it will receive information from the keyboard, etc.

operating system software System software that controls the application software and manages how the hardware devices work together.

operation code The portion of the computer instruction that identifies the specific processing operation to be performed.

operational controls The security controls (i.e., safeguards or countermeasures) for an information system that primarily are implemented and executed by people (as opposed to systems).

operational database A database that supports online transaction processing (OLTP).

operational error An error that results from the incorrect use of a product, component, or system.

operational management Manages and directs the day-to-day operations and implementations of the goals and strategies.

operational profile The set of operations that the software can execute along with the probability with which they will occur.

operational security (OPSEC) Process denying information to potential adversaries about capabilities and intentions by identifying, controlling, and protecting unclassified generic activities.

operational security information Transient information related to a single operation or set of operations within the context of an operational association, for example, a user session. Operational security information represents the current security context of the operations and may be passed as parameters to the operational primitives or retrieved from the operations environment as defaults.

operational status Either it is (1) operational system is currently in operation, (2) under development system is currently under design, development, or implementation, or (3) undergoing a major modification system is currently undergoing a major conversion or transition.

operationally object-oriented The data model includes generic operators to deal with complex objects in their entirety.

operations security The implementation of standardized operational security procedures that define the nature and frequency of the interaction between users, systems, and system resources, the purpose of which is to (1) maintain a system in a known secure state at all times, and (2) prevent accidental or intentional theft, destruction, alteration, or sabotage of system resources.

operator overloading See polymorphism.

OPSEC Operations security.

optical character recognition (OCR) An input method in which handwritten, typewritten, or printed text can be read by photosensitive devices for input to a computer.

optical disk A disk that is written to or read from by optical means.

optical fiber A form of transmission medium that uses light to encode signals and has the highest transmission rate of any medium.

optical mark recognition (OMR) Detects the presence of or absence of a mark in a predetermined place (popular for multiple choice exams).

optical modulation The process of varying some characteristics of light pulses over a fiber-optic cable in order to pass information from one point to another.

optical storage A medium requiring lasers to permanently alter the physical media to create a permanent record. The storage also requires lasers to read stored information from this medium.

opt-in An option that gives you complete control over the collection and dissemination of your personal information. A site that provides this option is stating that it will not gather or track information about you unless you knowingly provide such information and consent to the site.

opt-out An option that gives you the choice to prevent personally identifiable information from being used by a particular Web site or shared with third parties.

Orange Book Common name used to refer to the DoD Trusted Computing System Evaluation Criteria (TCSEC), DoD 5200.28-STD.

orange forces Forces of the United States operating in an exercise in emulation of the opposing force.

organizational security policy Set of laws, rules, and practices that regulates how an organization manages, protects, and distributes sensitive information.

organized health care arrangement See Part II, 45 CFR 164.501.

original classification An initial determination that information requires protection against unauthorized disclosure in the interest of national security, and a designation of the level of classification.

original classifier An authorized individual in the executive branch who initially determines that particular information requires a specific degree of protection against unauthorized disclosure in the interest of national security and applies the classification designation "top secret," "secret," or "confidential."

OSI Open Systems Interconnection; a seven-layer model from the ISO that defines and standardizes protocols for communicating between systems, networks and devices.

OSI 7-layer model The Open System Interconnection 7-layer model is an ISO standard for worldwide communications that defines a framework for implementing protocols in seven layers. Control is passed from one layer to the next, starting at the application layer in one station, and proceeding to the bottom layer, over the channel to the next station and back up the hierarchy.

OSI reference model The seven-layer architecture designed by OSI for open data communications network.

OSPF Open shortest path first.

OUI Organizationally unique identifier.

out-of-band A LAN term which refers to the capacity to deliver information via modem or other asynchronous connection. Out-of-band signaling refers to signaling that is separated from the channel carrying the information. Signal and control information does not interfere with the data transmission.

output controls Techniques and methods for verifying that the results of processing conform to expectations and are communicated only to authorized users.

output device A tool used to see, hear, or otherwise accept the results of information-processing requests.

outsourcing The delegation of specific work to a third party for a specified length of time, cost, and level of service.

overlapped processing The simultaneous execution of input, processing, and output functions by a computer system.

overlaps Areas in which too much capability exists. Unnecessary redundancy of coverage in a given area or function.

overreach interference Caused by a signal feeding past a repeater (or receive antenna) to the receiving antenna at the next station in the route.

Overseas Security Policy Board (OSPB) The Overseas Security Policy Board (OSPB) is an interagency group of security professionals from the foreign affairs and intelligence communities who meet regularly to formulate security policy for U.S. missions abroad. The OSPB is chaired by the director of the Diplomatic Security Service.

overwriting The obliteration of recorded data by recording different data on the same surface.

P2P Peer-to-peer infrastructure. Often referred to simply as *peer-to-peer*, or abbreviated *P2P*, a type of network in which each workstation has equivalent capabilities and responsibilities. This differs from client/server architectures, in which some computers are dedicated to serving the others. Peer-to-peer networks are generally simpler, but they usually do not offer the same performance under heavy loads.

P3P (Platform for Privacy Preferences Project) An open privacy specification developed and administered by the World Wide Web Consortium (W3C) that, when implemented, enables people to make informed decisions about how they want to share personal information with Web sites./.

PABX Private automatic branch exchange. Telephone switch for use inside a corporation. PABX is the preferred term in Europe, while PBX is used in the United States.

packet Logical grouping of information that includes a header containing control information and (usually) user data. Packets are most often used to refer to network layer units of data. The terms "datagram," "frame," "message," and "segment" are also used to describe logical information groupings at various layers of the OSI Reference Model and in various technology circles.

packet filtering Controlling access to a network analyzing the attributes of the incoming and outgoing packets and either letting them pass, or denying them based on a list of rules.

packet Internet grouper (PING) A program used to test reachability of destinations by sending them an ICMP echo request and waiting for a reply. The term is used as a verb: "Ping host X to see if it is up."

packet switch WAN device that routes packets along the most efficient path and allows a communications channel to be shared by multiple connections. Formerly called an *interface message processor* (*IMP*).

packet switching A switching procedure that breaks up messages into fixed-length units (called *packets*) at the message source. These units may travel along different routes before reaching their intended destination.

PAD Packet assembler/disassembler.

padding A technique used to fill a field, record, or block with default information (e.g., blanks or zeros).

PAG See Policy Advisory Group.

page A basic unit of storage in main memory.

page fault A program interruption that occurs when a page that is referred to is not in main memory and must be read from external storage.

paging A method of dividing a program into parts called *pages* and introducing a given page into memory as the processing on the page is required for program execution.

Palm A type of PDA that runs on the Palm Operating System (Palm OS).

Palm Operating System The operating system for Palm and Handspring PDAs.

PAP (1) Password Authentication Protocol. Authentication protocol that allows PPP peers to authenticate one another. The remote router attempting to connect to the local router is required to send an authentication request. Unlike CHAP, PAP passes the password and hostname or username in the clear (unencrypted). PAP does not itself prevent unauthorized access, but merely identifies the remote end. The router or access server then determines if that user is allowed access. PAP is supported only on PPP lines. Compare with *CHAP.* (2) Printer Access Protocol (AppleTalk).

PAP PAP (Password Authentication Protocol)—Parallel connector Has 25 pins that fit into the corresponding holes in the port. Most printers use parallel connectors.

parallel conversion The concurrent use of new system by its users.

parallel port The computer's printer port, which in a pinch, allows user access to notebooks and computers that cannot be opened.

parent A unit of data in a 1:*n* relationship with another unit of data called a *child*, where the parent can exist independently but the child cannot.

parity A bit or series of bits appended to a character or block of characters to ensure that the information received is the same as the information that was sent. Parity is used for error detection.

parity bit A bit attached to a byte that is used to check the accuracy of data storage.

partition A memory area assigned to a computer program during its execution.

partitioning Isolating IA-critical, IA-related, and non-IA-related functions and entities to prevent accidental or intentional interference, compromise, and corruption. Partitioning can be implemented in hardware or software. Software partitioning can be logical or physical. Partitioning is often referred to as separability in the security community.

Pascal A computer programming language designed especially for writing structured programs. This language is based on the use of a minimum set of logical control structures.

passive response A response option in intrusion detection in which the system simply reports and records the problem detected, relying on the user to take subsequent action.

passive system A system related indirectly to other systems. Passive systems may or may not have a physical connection to other systems, and their logical connection is controlled tightly.

passive wiretapping The monitoring or recording of data while it is being transmitted over a communications link.

password A word or string of characters that authenticates a user, a specific resource, or an access type.

password cracker A password cracker is an application program that is used to identify an unknown or forgotten password to a computer or network resources. It can also be used to help a person obtain unauthorized access to a resource.

password entropy Stated in bits, the measure of randomness in a password.

password sniffing Eavesdropping on a communications line to capture passwords that are being transmitted unencrypted.

Patchwork An encoding algorithm that takes random pairs of pixels and brightens the brighter pixel and dulls the duller pixel and encodes one bit of information in the contrast change. This algorithm creates a unique change, and that change indicates the absense or presence of a signature.

patent Exclusive right granted to an inventor to produce, sell, and distribute the invention for a specified number of years.

pattern classification The step of ASR in which the system matches the user's spoken phonemes to a phoneme sequence stored in an acoustic model database.

payer In healthcare, an entity that assumes the risk of paying for medical treatments. This can be an uninsured patient, a self-insured employer, a health plan, or an HMO.

PAYERID HCFA's term for their pre-HIPAA National Payer ID initiative.

payload The amount of information that can be stored in the cover media. Typically the greater the payload the greater the risk of detection.

payment See Part II, 45 CFR 164.501.

PBX Private branch exchange.

PCM Pulse code modulation—a digital scheme for transmitting analog data.

PCS See ICD.

PDA Personal digital assistant. A handheld computer that serves as an organizer for personal information.

PDN Public data network.

PDU Protocol data unit.

peer-entity authentication The corroboration that a peer entity in an association is the one claimed.

peer-to-peer network A network in which a small number of computers share hardware (such as a printer), software, and information.

PEM Privacy Enhanced Mail; an e-mail encryption protocol.

penetration A successful unauthorized access to a computer system.

penetration profile A delineation of the activities required to effect penetration.

penetration signature The description of a situation or set of conditions in which a penetration might occur.

penetration testing Security testing in which the evaluators attempt to circumvent the security features of a system based on their understanding of the system design and implementation. The evaluators may be assumed to use all system design and implementation documentation, which may include listings of system source code, manuals, and circuit diagrams. The evaluators work under no constraints other than those applied to ordinary users or implementers of untrusted portions of the component.

perceptual masking A condition where the perception of one element interferes with the perception another.

perfect forward secrecy Perfect forward secrecy means that even if a private key is known to an attacker, the attacker cannot decrypt previously sent messages.

performance The ability to track service and resource usage levels and to provide feedback on the responsiveness and reliability of the network.

performance-based A method for designing learning objectives based on behavioral outcomes, rather than on content that provides benchmarks for evaluating learning effectiveness.

period The time it takes a waveform to complete one complete cycle.

permission marketing When a person has given a merchant permission to send special offers.

persistent object An object that can survive the process that created it. A persistent object exists until it is explicitly deleted.

personal agent (or user agent) An intelligent agent that takes action on the user's behalf.

personal computer A commonly used term that refers to a microcomputer. Often called a *PC*.

personal digital assistant (PDA) A small hand-held computer that helps surf the Web and perform simple tasks such as note taking, calendaring, appointment scheduling, and maintaining an address book.

personal finance software Helps the user maintain a checkbook, prepare a budget, track investments, monitor credit card balances, and pay bills electronically.

personal information management (PIM) software Helps create and maintain (1) lists, (2) appointments and calendars, and (3) points of contact.

personal productivity software Helps the user perform personal tasks—writing a memo, creating a graph, and creating a slide presentation—that can usually be done even if the user does not own a computer.

personalization When a Web site can know enough about the user's likes and dislikes that it can fashion offers that are more likely to appeal to the user.

personally identifiable information Information that can be traced back to an individual user, e.g., your name, postal address, or e-mail address. Personal user preferences tracked by a Web site via a "cookie" (see definition above) is also considered personally identifiable when linked to other personally identifiable information provided by you online.

pest program Collective term for programs with deleterious and generally unanticipated side effects; for example, Trojan horses, logic bombs, letter bombs, viruses, and malicious worms.

PGP Pretty Good Privacy. Public key cryptography software based on the RSA cryptographic method.

phased conversion The system installation procedure that involves a step-by-step approach for the incremental installation of one portion of a new system at a time.

PHB Pharmacy benefits manager.

PHI See protected health information.

PHP In Common Criteria, protection of the TSF; TSF physical protection.

PHS Public health service.

physical layer The OSI layer that provides the means to activate and use physical connections for bit transmission. In plain terms, the physical layer provides the procedures for transferring a single bit across a physical medium, such as cables.

physical organization The packaging of data into fields, records, files, and other structures to make them accessible to a computer system.

physical security The measures used to provide physical protection of resources against deliberate and accidental threats.

PictureMarc A DigiMarc application that embeds an imperceptible digital watermark within an image allowing copyright communication, author recognition and electronic commerce. It is currently bundled with Adobe Photoshop.

PIDAS Perimeter intrusion detection assessment system.

piggyback entry Unauthorized access to a computer system that is gained through another user's legitimate connection.

ping Packet Internet groper.

piracy (or **simple piracy**) The unauthorized duplication of an original recording for commercial gain without the consent of the rightful owner; or the packaging of pirate copies that is different from the original. Pirate copies are often compilations, such as the "greatest hits" of a specific artist, or a genre collection, such as dance tracks.

pirated software The unauthorized use, duplication, distribution, or sale of copyrighted software.

pivot table Enables to group and summarize information.

pixel Short for *picture element*, a pixel is a single point in a graphic image. It is the smallest thing that can be drawn on a computer screen. All computer graphics are made up of a grid of pixels. When these pixels are painted onto the screen, they form an image.

PKI Public key infrastructure.

PL or P. L Public law, as in PL 104-191 (HIPAA).

plain old telephone system (POTS) What we consider to be the "normal" phone system used with modems. Does not include leased lines or digital lines.

plain text A message before it has been encrypted or after it has been decrypted using a specific algorithm and key; also referred to as clear text. (Contrast with *cipher text.*)

plan administration functions See Part II, 45 CFR 164.504.

Plan ID See National Payer ID.

plan of action and milestones A document that identifies tasks needing to be accomplished. It details resources required to accomplish the elements of the plan, any milestones in meeting the tasks, and scheduled completion dates for the milestones.

plan sponsor An entity that sponsors a health plan. This can be an employer, a union, or some other entity. See also Part II, 45 CFR 164.501.

planning phase Involves determining a solid plan for developing information system.

platform Foundation upon which processes and systems are built and which can include hardware, software, firmware, etc.

platform domain A security domain encompassing the operating system, the entities and operations it supports and its security policy.

plotter A graphics output device in which the computer drives a pen that draws on paper.

PLP Packet-level protocol (X.25).

PMD Physical medium dependent.

PNA adapter card An expansion card that is put into the user's computer to act as a doorway for information flowing in and out.

Pocket PC A type of PDA that runs on Pocket PC OS that used to be called *Windows CE.*

Pocket PC OS (or Windows CE) The operating system for the Pocket PC PDA.

pointer The address of a record (or other data grouping) contained in another record so that a program may access the former record when it has retrieved the latter record. The address can be absolute, relative, or symbolic, and hence the pointer is referred to as absolute, relative, or symbolic.

pointing stick Small rubber-like pointing device that causes the pointer to move on the screen as the user applies directional pressure. Popular on notebooks.

point-of-presence (POP) A site where there exists a collection of telecommunications equipment, usually digital leased lines and multi-protocol routers.

point-of-sale (POS) Applications in which purchase transactions are captured in machine-readable form at the point of purchase.

point-to-point A network configuration interconnecting only two points. The connection can be dedicated or switched.

point-to-point protocol (PPP) The successor to SLIP, PPP provides router-to-router and host-to-network connections over both synchronous and asynchronous circuits.

polarization The direction of the electric field, the same as the physical attitude of the antenna (e.g., a vertical antenna transmits a vertically polarized wave). They receive and transmit antennas need to possess the same polarization.

policy See security policy.

policy advisory goup (PAG) A generic name for many work groups at WEDI and elsewhere.

polling A procedure by which a computer controller unit asks terminals and other peripheral devices in a serial fashion if they have any messages to send.

polymorphism A request-handling mechanism that selects a method based on the type of target object. This allows the specification of one request that can result in invocation of different methods depending on the type of the target object. Most object-oriented languages support the selection of the appropriate method based on the class of the object (classical polymorphism). A few languages or systems support characteristics of the object, including values and user-defined defaults (generalized polymorphism).

polymorphism Having many forms.

POP (1) Point-of-presence. (2) Post Office Protocol.

pop-up ads An ad that appears in its own window when a user opens or closes a Web page.

pop-up blockers A type of privacy enhancing technology.

port (1) An outlet, usually on the exterior of a computer system, that enables peripheral devices to be connected and interfaced with the computer. (2) A numeric value used by the TCP/IP protocol suite that identifies services and applications. For example, HTTP Internet traffic uses port 80.

portability The ability to implement and execute software in one type of computing space and have it execute in a different computing space with little or no changes.

Portable Document Format (PDF) The standard electronic distribution file format for heavily formatted documents such as a presentation resume because it retains the original document formatting.

ports An interface point between the CPU and a peripheral device.

POS Place of service or point of service.

postpay billing Billing arrangement between the customer and operator/SvP in which the customer periodically receives a bill for service usage in the past period.

Postscript A language used to describe the printing of images and text and typically used with laser printing capability. Word processor or desktop publishing applications generate postscript code for higher quality laser products.

POTS Plain old telephone service.

power (P) The measure of the rate at which work can be accomplished.

PP Protection profile.

PPC Security target evaluation, PP claims.

PPO Preferred provider organization.

PPP Point-to-Point Protocol.

PPS Prospective payment system.

PRA The Paperwork Reduction Act.

precision engagement The ability of joint forces to locate, surveil, discern, and track objectives or targets; select, organize, and use the correct systems; generate desired effects; assess results; and reengage with decisive speed and overwhelming operational tempo as required, throughout the full range of military operations.

preferred products list (PPL) A list of commercially produced equipments that meet TEMPEST and other requirements prescribed by the National Security Agency. This list is included in the NSA Information Systems Security Products and Services Catalogue, issued quarterly and available through the Government Printing Office.

prepay billing Billing arrangement between the customer and operator/SvP in which the customer deposits an amount of money in advance, which is subsequently used to pay for service usage.

preprocessors Software tools that perform preliminary work on a draft computer program before it is completely tested on the computer.

presentation layer The layer of the ISO reference model responsible for formatting and converting data to meet the requirements of the particular system being utilized.

presentation resume A format-sensitive document created in a word processor to outline job qualifications in one to two printed pages.

presentation software Helps create and edit information that will appear in electronic slides.

Pretty Good Privacy (PGP) PGP provides confidentiality and authentication services for electronic mail and file storage applications. Developed by Phil Zimmerman and distributed for free on the Internet. Widely used by the Internet technical community.

PRG Procedure-Related Group.

PRI Primary rate interface (ISDN).

pricer or repricer A person, an organization, or a software package that reviews procedures, diagnoses, fee schedules, and other data and determines the eligible amount for a given healthcare service or supply. Additional criteria can then be applied to determine the actual allowance, or payment, amount.

primary key An attribute that contains values that uniquely identifies the record in which the key exists.

primary mission area Synonymous with primary warfare mission area (PWMA). A warfare mission area concerned with a specific, major phase or portion of naval warfare.

primary rate interface (PRI) Provides the same throughput as a T-1, 1.544 Mbps, has 23 B or bearer channels, which run at 64 kbps, and a D or data channel, which runs at 16 kbps.

primary service An independent category of service such as operating system services, communication services and data management services. Each primary service provides a discrete set of functionality. Each primary service inherently includes generic qualities such as usability, manageability and security. Security services are therefore not primary services but are invoked as part of the provision of primary services by the primary service provider.

principal An entity whose identity can be authenticated.

principle of least privilege A security procedure under which users are granted only the minimum access authorization they need to perform required tasks.

print suppress The elimination of the printing of characters to preserve their secrecy—for example, the characters of a password as they are keyed by a user at a terminal or station on the network.

privacy (1) The prevention of unauthorized access and manipulation of data. (2) The right of individuals to control or influence what information related to them may be collected and stored and by whom and to whom that information may be disclosed.

Privacy Act of 1974 The federal law that allows individuals to know what information about them is on file and how it is used by all government agencies and their contractors. The 1986 Electronic Communication Act is an extension of the Privacy Act.

Privacy-Enhanced Mail (PEM) Internet email standard that provides confidentiality, authentication, and message integrity using various encryption methods. Not widely deployed in the Internet.

privacy impact assessment (PIA) An analysis of how information is handled (1) to ensure handling conforms to applicable legal, regulatory, and policy requirements regarding privacy, (2) to determine the risks and effects of collecting, maintaining and disseminating information in identifiable form in an electronic information system, and (3) to examine and evaluate protections and alternative processes for handling information to mitigate potential privacy risks.

privacy invasive technologies (PITs) Describes the many technologies that intrude into privacy. Among the host of examples are data-trail generation through the denial of anonymity, data-trail intensification (e.g., identified phones, stored-value cards, and intelligent transportation systems), data warehousing and data mining, stored biometrics, and imposed biometrics.

privacy policy An organization's requirements for complying with privacy regulations and directives.

privacy policy in standardized machine-readable format A statement about site privacy practices written in a standard computer language (not English text) that can be read automatically by a Web browser.

privacy protection The establishment of appropriate administrative, technical, and physical safeguards to protect the security and confidentiality of data records against anticipated threats or hazards that could result in substantial harm, embarrassment, inconvenience, or unfairness to any individual about whom such information is maintained.

privacy seal An online seal awarded by one of multiple privacy certification vendors to Web sites that agree to post their privacy practices openly via privacy statements, as well as adhere to enforcement procedures that ensure that their privacy promises are met. When you click on the privacy seal, typically you are taken directly to the privacy statement of the certified Web site.

privacy statement A page or pages on a Web site that lay out its privacy policies, i.e., what personal information is collected by the site, how it will be used, whom it will be shared with, and whether you have the option to exercise control over how your information will be used.

private branch exchange (PBX) A small version of the phone company's central switching office. Also known as a private automatic branch exchange.

private key The private or secret key of a key pair, which must be kept confidential and is used to decrypt messages encrypted with the public key, or to digitally sign messages which can then be validated with the public key.

private network A network established and operated by a private organization for the benefit of members of the organization.

privilege A right granted to an individual, a program, or a process.

privileged instructions A set of instructions generally executable only when the computer system is operating in the executive state (e.g., while handling interrupts). These special instructions are typically designed to control such protection features as the storage protection features.

PRO Professional review organization or peer review organization.

problem Any deviation from predefined standards.

problem reporting The method of identifying, tracking, and assigning attributes to problems detected within the software product, deliverables, or within the development processes.

procedural language A computer programming language in which the programmer must determine the logical sequence of program execution as well as the processing required.

procedure Required "how-to" instructions that support some part of a policy or standard, which state "what to do."

procedure division A section of a COBOL program that contains statements that direct computer processing operations.

procedure view Contains all of the procedures within a system.

process A sequence of activities.

process description A narrative that describes in sequence the processing activities that take place in a computer system and the procedures for completing each activity.

processing controls Techniques and methods used to ensure that processing produces correct results.

processor The hardware unit containing the functions of memory and the central processing unit.

product certification center A facility that certifies the technical security integrity of communications equipment. The equipment is handled and used within secure channels.

professional courier (or diplomatic courier) A person specifically employed and provided with official documentation by the U.S. Department of State to transport properly prepared, ad-dressed, and documented diplomatic pouches between the Department and its Foreign Service posts and across other international boundaries.

profile filtering Requires that the user choose terms or enter keywords to provide a more personal picture of preferences.

profiling Analyzing a program to determine how much time is spent in different parts of the program during execution.

program analyzers Software tools that modify or monitor the operation of an application program to allow information about its operating characteristics to be collected automatically.

program development process The activities involved in developing computer programs, including problem analysis, program design, process design, program coding, debugging, and testing.

program maintenance The process of altering program code or instructions to meet new or changing requirements.

program manager The person ultimately responsible for the overall procurement, development, integration, modification, or operation and maintenance of the IS.

programmable read-only memory (PROM) Computer memory chips that can be programmed permanently to carry out a defined process.

programmer The individual who designs and develops computer programs.

programmer/analyst The individual who analyzes processing requirements and then designs and develops computer programs to direct processing.

programming language A language with special syntax and style conventions for coding computer programs.

Programming Language/1 (PL/1) A general-purpose, high-level language that combines business and scientific processing features. The language contains advanced features for experienced programmers yet can be easily learned by novice programmers.

programming specifications The complete description of input, processing, output, and storage requirements necessary to code a computer program.

project manager An individual who is an expert in project planning and management, defines and develops the project plan, and tracks the plan to ensure all key project milestones are completed on time.

project milestone Key date by which a certain group of activities needs to be performed.

project plan Defines the what, when, and who questions of system development including all activities to be performed, the individuals or resources who will perform the activities, and the time required to complete each activity.

project scope Clearly defines the high-level system requirements.

project scope document A written definition of the project scope and usually no longer than a paragraph.

project team A team designed to accomplish specific one-time goals, which is disbanded once the project is complete.

prolog A language widely used in the field of artificial intelligence.

PROM Programmable read-only memory.

proof of correctness The use of mathematical logic to infer that a relation between program variables assumed true at the program entry implies that another relation between program variables holds at program exit.

proof-of-concept prototype A prototype used to prove the technical feasibility of a proposed system.

protect To keep information systems away from intentional, unintentional, and natural threats: (1) preclude an adversary from gaining access to information for the purpose of destroying, corrupting, or manipulating such information; or (2) deny use of information systems to access, manipulate, and transmit mission-essential information.

protected distribution system (PDS) Wire line or fiber optic distribution system used to transmit unencrypted classified national security information through an area of lesser classification or control.

protected health information (PHI) See Part II, 45 CFR 164.501.

protection ring A hierarchy of access modes through which a computer system enforces the access rights granted to each user, program, and process, ensuring that each operates only within its authorized access mode.

protection schema An outline detailing the type of access users may have to a database or application system, given a user's need-to-know; e.g., read, write, modify, delete, create, execute, and append.

protective layers Mechanisms for insuring the integrity of systems or data. See defense in depth.

protocol A set of instructions required to initiate and maintain communication between sender and receiver devices.

protocol analyzer A data communications testing unit set that enables a network engineer to observe bit patterns and simulate network elements.

protocol data unit (PDU) This is OSI terminology for "packet." A PDU is a data object exchanged by protocol machines (entities) within a given layer. PDUs consist of both protocol control information (PCI) and user data.

proton A heavy subatomic particle that carries a positive charge.

prototype A usable system or subcomponent that is built inexpensively or quickly with the intention of modifying or replacing it.

provider taxonomy codes An administrative code set for identifying the provider type and area of specialization for all healthcare providers. A given provider can have several Provider Taxonomy Codes. This code set is used in the X12 278 Referral Certification and Authorization and the X12 837 Claim transactions, and is maintained by the NUCC.

proxy server Proxy server is a server that acts as an intermediary between a remote user and the servers that run the desired applications. Typical proxies accept a connection from a user, make a decision as to whether or not client IP address is permitted to use the proxy, perhaps perform additional authentication, and complete a connection to a remote destination on behalf of the user.

PRS Resource utilization, priority of service.

PSDN Packet-switched data network.

PSE Privacy, pseudonymity.

pseudocode Program processing specifications that can be prepared as structured English-like statements which can then be easily converted into source code.

pseudoflow An apparent loophole deliberately implanted in an operating system program as a trap for intruders.

pseudonymity A condition in which you have taken on an assumed identity.

PSK Phase shift keying.

PSN Packet-switched network.

PSNP Partial sequence number PDU.

PSPDN Packet-switched public data network.

PSTN Public switched telephone network.

psychographic filtering Anticipates the user's preferences based on the answers given to a questionnaire.

psychotherapy notes See Part II, 45 CFR 164.501.

PTT Post, telephone, and telegraph.

public health authority See Part II, 45 CFR 164.501.

public key In an asymmetric cryptography scheme, the key that may be widely published to enable the operation of the scheme. Typically, a public key can be used to encrypt, but not decrypt or to validate a signature, but not to sign.

public key cryptography An asymmetric cryptosystem where the encrypting and decrypting keys are different and it is computationally infeasible to calculate one form the other, given the encrypting algorithm. In public key cryptography, the encrypting key is made public, but the decrypting key is kept secret.

Public Key Cryptography Standards Public Key Cryptography Standards (PKCS) are specifications produced by RSA Laboratories in cooperation with secure systems developers worldwide for the purpose of accelerating the deployment of public-key cryptography.

public key cryptosystem An asymmetric cryptosystem that uses a public key and a corresponding private key.

public key encryption An encryption scheme where two pairs of algorithmic keys (one private and one public) are used to encrypt and decrypt messages, files, etc.

public key infrastructure Supporting infrastructure, including non-technical aspects, for the management of public keys.

public network A network on which the organization competes for time with others.

Public Switched Telephone Network (PSTN) Refers to the local, long distance, and international phone system which we use every day. In some countries, it is a single phone company. In countries with competition, PSTN refers to the entire interconnected collections of local, long distance, and international phone companies, of which there could be thousands.

pulse amplitude modulation (PAM) The first step in converting analog waveforms into digital signals for transmission.

pulse code modulation (PCM) The most common and most important method that a telephone system in North America can use to sample a voice signal and convert that sample into an equivalent digital code. PCM is a digital modulation method that encodes a pulse amplitude modulated signal into a PCM signal.

purging The orderly review of storage and removal of inactive or obsolete data files.

push technology An environment in which businesses and organizations come to the user with information, services, and product offerings based on the user profile.

PVC Permanent virtual circuit.

QA Quality assurance.

QAM Quadrature amplitude modulation.

QC Quality control.

QoS Quality of service.

qualitative Inductive analytical approaches that are oriented toward relative, non-measurable, and subjective values, such as expert judgment.

quality The totality of features and characteristics of a product or service that bear on its ability to meet stated or implied needs.

quality assurance An overview process that entails planning and systematic actions to ensure that a project is following good quality management practices.

quality control Process by which product quality is compared with standards.

quality of service (QoS) The service level defined by a service agreement between a network user and a network provider, which guarantees a certain level of bandwidth and data flow rates.

quantitative Deductive analytical approaches that are oriented toward the use of numbers or symbols to express a measurable quantity, such as MTTR.

quantitizing The systematic method of providing standard binary numbering to PAM samples for PCM conversion.

query and reporting tools Similar to QBE tools, SQL, and report generators in the typical database environment.

query language A language that enables a user to interact indirectly with a DBMS to retrieve and possibly modify data held under the DBMS.

query-by-example tools (QBE) Helps the user graphically design the answer to a question.

queue A waiting line in which a set of computer programs is in secondary storage awaiting processing.

radiation field The radio frequency field that is created around the antenna and has specific properties that affect the signal transmission.

RADIUS Remote Authentication Dial-In User Service—Database for authenticating modem and ISDN connections and for tracking connection time. Remote authentication dial-in user service. A protocol used to authenticate remote users and wireless connections.

RAID (redundant arrays of inexpensive disks) Instead of using one large disk to store data, you use many smaller disks (because they are cheaper). See disk mirroring and duplexing. An approach to using many low-cost drives as a group to improve performance, yet also provides a degree of redundancy that makes the chance of data loss remote.

rain attenuation or **raindrop absorption** The scattering of the microwave signal, which can cause signal loss in transmissions.

Rainbow Series A multivolume set of publications on information assurance, information security and related topics. Published by the National Computer Security Center (NCSC) at the National Security Agency (NSA) in Fort Meade, Maryland. Each volume is published under a different color cover, hence the term "Rainbow" series.

rainbow tables A set of tools and techniques used for cracking MS Windows passwords.

RAM A type of computer memory that can be accessed randomly; that is, any byte of memory can be accessed without touching the preceding bytes. RAM is the most common type of memory found in computers and other devices, such as printers. There are two basic types of RAM: dynamic RAM (DRAM) and static RAM (SRAM).

random access A method that allows records to be read from and written to disk media without regard to the order of their record key.

random failure Failures that result from physical degradation over time and variability introduced during the manufacturing process.

range The distance a signal travels before it degrades and needs to be repeated.

RARP (Reverse Address Resolution Protocol) Protocol in the TCP/IP stack that provides a method for finding IP addresses based on MAC addresses. Compare with *Address Resolution Protocol* (*ARP*).

raster image An image that is composed of small points of color data called *pixels*. Raster images allow the representation complex shapes and colors in a relatively small file format. Photographs are represented using raster images.

RBOCs Regional Bell operating companies.

RCP Remote Copy Protocol.

RCR Development, representation correspondence.

RCV Protection of the TSF, trusted recovery.

reaccreditation The official management decision to continue operating a previously accredited system.

reach An aggregate measure of the degree to which information is shared.

react To respond to threat activity within information systems, when detected, and mitigate the consequences by taking appropriate action to incidents that threaten information and information systems.

read-only memory (ROM) Computer memory chips with preprogrammed circuits for storing such software as word processors and spreadsheets.

reality The real world.

real-time processing Computer processing that generates output fast enough to support multiple activities being performed concurrently.

real-time reaction A response to a penetration attempt that can prevent actual penetration because the attempt is detected and diagnosed in time.

reassembly The process by which an IP datagram is "put back together" at the receiving hosts after having been fragmented in transit.

recertification A reassessment of the technical and non-technical security features and other safeguards of a system made in support of the reaccreditation process.

reciprocal agreement Emergency processing agreements between two or more organizations with similar equipment or applications. Typically, participants promise to provide processing time to each other when an emergency arises.

reciprocity An antenna characteristic that essentially states that the antenna is the same regardless of whether it is sending or receiving electromagnetic energy.

recognition Capability to detect attacks as they occur and to evaluate the extent of damage and compromise.

record block A group or collection of records appearing between interblock gaps on magnetic storage media. This group of records is handled as a single entity in computer processing.

record blocking A technique of writing several records to magnetic storage media in between interblock gaps or spaces.

record material All books, papers, maps, photographs, or other documentary materials, regardless of physical form or characteristics, made or received by the U.S. government in connection with the transaction of public business and preserved or appropriated by an agency or its legitimate successor as evidence of the organization, functions, policies, decisions, procedures, or other activities of any agency of the government, or because of the informational data contained therein.

Recording Industry Association of America (RIAA) A trade group that represents the U.S. recording industry. The RIAA works to create a business and legal environment that supports the record industry and seeks to protect intellectual property rights.

recovery The restoration of the information processing facility or other related assets following physical destruction or damage.

recovery point objective (RPO) A measurement of the point prior to an outage to which data are to be restored.

recovery procedures The action necessary to restore a system's computational capability and data files after system failure or penetration.

recovery time objective (RTO) The amount of time allowed for the recovery of a business function or resource after a disaster occurs.

rectifier A diode designed to be placed in an alternating current circuit, used for converting AC to DC.

recurring decision A decision that you have to make repeatedly and often periodically, whether weekly, monthly, quarterly, or yearly.

recursion The definition of something in terms of itself. For example, a bill of material is usually defined in terms of itself.

red Designation applied to information systems, and associated areas, circuits, components, and equipment in which national security information is being processed.

Red Book Common name used to refer to the Network Interpretation of the TCSEC (Orange Book). Originally referred to in some circles as the "White Book."

red forces Forces of countries considered unfriendly to the United States and her Allies.

red team A group of people duly authorized to conduct attacks against friendly information systems, under prescribed conditions, for the purpose of revealing the capabilities and limitations of the information assurance posture of a system under test. For purposes of operational testing, the Red team will operate in as operationally realistic an environment as feasible and will conduct its operations in accordance with the approved operational test plan.

red/black concept Separation of electrical and electronic circuits, components, equipment, and systems that handle national security information (RED), in electrical form, from those that handle nonnational security information (BLACK) in the same form.

red-black separation The requirement for physical spacing between "red" and "black" processing systems and their components, including signal and power lines.

Reduced Instruction Set Computing (RISC) A method of processing by which the set of instructions available to the computer is a subset of that found on conventional computers.

redundancy Controlling failure by providing several identical functional units, monitoring the behavior of each to detect faults, and initiating a transition to a safe/secure condition if a discrepancy is detected.

redundant control capability Use of active or passive replacement, for example, throughout the network components (i.e., network nodes, connectivity, and control stations) to enhance reliability, reduce threat of single-point-of-failure, enhance survivability, and provide excess capacity.

redundant site A recovery strategy involving the duplication of key information technology components, including data, or other key business processes, whereby fast recovery can take place. The redundant site usually is located away from the original.

reference configuration A combination of functional groups and reference points that shows possible network arrangements.

reference monitor (1) An access control concept that refers to an abstract machine that mediates all accesses to objects by subjects. (2) A system component that mediates usage of all objects by all subjects, enforcing the intended access controls.

referential attributes The facts that tie an instance of one object to an instance of another object.

referential integrity The assurance that an object handle identifies a single object. The facility of a DBMS that ensures the validity of predefined relationships.

referrer field The referrer header field (mistakenly spelled referer in the HTTP standard) is a unit of information that contains the URL of the site you are currently in. The referrer header field is sent automatically to any site you are about to visit when clicking a link. Referrer headers allow reading patterns to be studied and reverse links drawn. The address of the page might contain privacy information (such as your name or e-mail address), or might reveal personal interests that you would rather keep private.

reflections When the microwave signal traverses a body of water or fog bank and causes multipath conditions.

regenstrief institute A research foundation for improving healthcare by optimizing the capture, analysis, content, and delivery of healthcare information. Regenstrief maintains the LOINC coding system that is being considered for use as part of the HIPAA claim attachments standard.

regional diplomatic courier officer (RDCO) The RDCO oversees the operations of a regional diplomatic courier division.

regression testing The rerunning of test cases that a program has previously executed correctly to detect errors created during software correction or modification. Tests used to verify a previously tested system whenever it is modified.

relation Describes each two-dimensional table or file in the relation model (hence its name relational database model).

relational database In a relational database, data is organized in two-dimensional tables or relations.

relevance Related to the matter at hand; directly bearing upon the current matter.

reliability The probability that a system or service will perform in a satisfactory manner for a given period of time when used under specific operating conditions.

reliability critical A term applied to any condition, event, process, or item whose recognition, control, performance or tolerance is essential to reliable system operation or support.

relying third party The entity, such as a merchant, offering goods or services online that will receive a certificate as part of a process of completing transactions with the user.

remanence The residual magnetism that remains on magnetic storage media after degaussing.

remediation plan See plan of action and milestones.

remote access The ability to dial into a computer over a local telephone number using a number of digital access techniques.

Remote Authentication Dial-In User Service (RADIUS) A security and authentication mechanism for remote access.

remote diagnostic facility An off-premise diagnostic, maintenance, and programming facility authorized to perform functions on the Department computerized telephone system via an external network trunk connection.

Remote File System (RFS) A distributed file system, similar to NFS, developed by AT&T and distributed with their UNIX System V operating system. See Network File System.

remote procedure call (RPC) An easy and popular paradigm for implementing the client/server model of distributed computing. A request is sent to a remote system to execute a designated procedure, using arguments supplied, and the result returned to the caller.

repeater A device that propagates electrical signals from one cable to another without making routing decisions or providing packet filtering. In OSI terminology, a repeater is a physical layer intermediate system. See bridge and router.

replay A type of security threat that occurs when an exchange is captured and resent at a later time to confuse the original recipients.

replication The process of keeping a copy of data through either shadowing or caching.

report Printed or displayed output that communicates the content of files and other activities. The output is typically organized and easily read.

report program generator (RPG) A nonprocedural programming language used for many business applications.

report writing The process of accessing data from files and generating it as information in the form of output.

repudiation Denying that you did something, or sent some message.

REQ (1) Protection profile evaluation, IT security requirements. (2) Security target evaluation, IT security requirements.

request for comments (RFC) The document series, begun in 1969, that describes the Internet suite of protocols and related experiments. Not all (in fact, very few) RFCs describe Internet standards, but all Internet standards are written up as RFCs.

request for proposal (RFP) A formal document that describes in detail logical requirements for a proposed system and invites outsourcing organizations (vendors) to submit bids for its development.

required by law See Part II, 45 CFR 164.501.

requirement definition document Defines all of the business requirements, prioritizes them in order of business importance, and places them in a formal comprehensive document.

residual risks The risk associated with an event when the control is in place to reduce the effect or likelihood of that event being taken into account.

residue Data left in storage after processing operations and before degaussing or rewriting has occurred.

resistance (1) The opposition to the flow of electric charge and is generally the function of the number of free electrons available to conduct the electric current. (2) Capability of a system to repel attacks.

resistor A component made of a material that has a specified resistance or opposition to the flow of electrical current. A resistor is designed to oppose but not completely obstruct the passage of electrical current.

resolution of a printer The number of dots per inch (dpi) a printer produces, which is the same principle as the resolution in a monitor.

resolution of a screen The number of pixels a screen has. Pixels (picture elements) are the dots that make up an image on the screen.

resonant frequency The frequency where inductive reactance equals capacitive reactance. Helps to define the maximum current or maximum voltage in a circuit.

resource In a computer system, any function, device, or data collection that can be allocated to users or programs.

resource sharing In a computer system, the concurrent use of a resource by more than one user, job, or program.

restricted area A specifically designated and posted area in which classified information or material is located or in which sensitive functions are performed, access to which is controlled and to which only authorized personnel are admitted.

result of interception Information relating to a target service, including the CC and IRI, which is passed by an NWO/AP/SvP to an LEA. IRI shall be provided whether or not call activity is taking place.

REV Security management, revocation.

RF shielding The application of materials to surfaces of a building, room, or a room within a room, that makes the surface largely impervious to electromagnetic energy. As a technical security countermeasure, it is used to contain or dissipate emanations from information processing equipment, and to prevent interference by externally generated energy.

RFA The Regulatory Flexibility Act.

RFC Request for comments.

RFI Radio frequency interference.

RFID (radio frequency identification system) An automatic identification and data capture system comprising one or more readers and one or more tags in which data transfer is achieved by means of suitable modulated inductive or radiating electromagnetic carriers.

RGB (red, green, blue) Refers to a system for representing the colors to be used on a computer display.

richness Defined by three aspects of the information itself: bandwidth (the amount of information), the degree to which the information is customized, and interactivity (the extent of two way communication).

ring side The side of the cable pair that when measured will read −48 V DC.

RIP (Routing Information Protocol) User data protection residual information protection.

RISC Reduced Instruction Set Computer.

risk The probability that a particular security threat will exploit a particular vulnerability.

risk analysis An analysis that examines an organization's information resources, its existing controls, and its remaining organization and computer system vulnerabilities. It combines the loss potential for each resource or combination of resources with an estimated rate of occurrence to establish a potential level of damage in dollars or other assets.

risk assessment A process used to identify and evaluate risks and their potential effects.

risk avoidance The process for systematically avoiding risk. Security awareness can lead to a better education staff, which can lead to certain risks being avoided.

risk control Techniques that are employed to eliminate, reduce, or mitigate risk, such as inherent safe and secure (re)design techniques/features, alerts, warnings, operational procedures, instructions for use, training, and contingency plans.

risk dimension See threat perspective.

risk exposure The exposure to loss presented to an organization or individual by a risk; the product of the likelihood that the risk will occur and the magnitude of the consequences of its occurrence.48.

risk index The disparity between the minimum clearance or authorization of system users and the maximum sensitivity (e.g., classification and categories) of data processed by a system.

risk management The discipline of identifying and measuring security risks associated with an information system, and controlling and reducing those risks to an acceptable level. The goal of risk management is to invest organizational resources to mitigate security risks in a cost-effective manner, while enabling timely and effective mission accomplishment. Risk management is an important aspect of information assurance and defense-in-depth.

risk mitigation Although some risks cannot be avoided, they can be minimized or mitigated by putting controls into place to mitigate the risk once an incident occurs.

risk transfer The process of transferring risk. An example can include transferring the risk of a building fire to an insurance company.

RJE Remote job entry.

rlogin A service offered by Berkeley UNIX that allows users of one machine to log into other UNIX systems (for which they are authorized) and interact as if their terminals were connected directly. Similar to Telnet.

RLP Remote Location Protocol.

RMON Remote monitoring.

robot A mechanical device equipped with simulated human senses and the capability of taking action on its own.

robotics The use of automated equipment for production work and other mechanical tasks.

robust watermark A watermark that is very resistant to destruction under any image manipulation. This is useful in verifying ownership of an image suspected of misappropriation. Digital detection of the watermark would indicate the source of the image.

robustness The system's ability to operate despite service interruption, system errors and other anomalous events.

ROI Return on investment.

ROL User data protection rollback.

role A job type defined in terms of a set of responsibilities.

role-based When mapped to job function, assumes that a person will take on different roles, over time, within an organization and different responsibilities in relation to IT systems.

roles and responsibilities Functions performed by someone in a specific situation and obligations to tasks or duties for which that person is accountable.

rollback (1) Restoration of a system to its former condition after it has switched to a fallback mode of operation when the cause of the fallback has been removed. (2) The restoration of the database to an original position or condition often after major damage to the physical medium. (3) The restoration of the information processing facility or other related assets following physical destruction or damage.

ROM See read-only memory.

root cause Underlying cause(s), event(s), conditions, or actions that individually or in combination led to the accident/incident; primary precursor event(s) that have the potential for being corrected.

rootkits (1) User-level rootkits: Programs that "infect" program files that are executed by the user and run under the user account's privileges (for example, the Explorer.exe or Word.exe program) (2) Kernel-level rootkits: Programs that "infect" functions belonging to the operating system kernel (i.e., the core Windows operating system) and are used by hundreds of applications (including the Windows API). Kernel-mode rootkits will modify (i.e., hijack) internal operating system functions that return lists of files, processes, and open ports.

rotary (or pulse) dialing The circular telephone dial. As it returns to its normal position, it opens and closes the electrical loop sent by the central office. Rotary dial telephones momentarily break the DC circuit to represent the digits dialed.

router (1) A system responsible for making decisions about which of several paths network (or Internet) traffic will follow. To do this, it uses a routing protocol to gain information about the network, and algorithms to choose the best route based on several criteria known as "routing metrics." (2) A network node connected to two or more networks. It is used to send data from one network (such as 137.13.45.0) to a second network (such as 43.24.56.0). The networks could both use Ethernet, or one could be Ethernet and the other could be ATM (or some other networking technology). As long as both speak common protocols (such as the TCP/IP protocol suite), they can communicate.

RPC Remote procedure call.

RPL Protection of the TSF; replay detection.

RSA A public key cryptosystem developed by Rivest, Shamir, and Adleman. The RSA has two different keys, the public encryption key and the secret decryption key. The strength of the RSA depends on the difficulty of the prime number factorization. For applications with high-level security, the number of the decryption key bits should be greater than 512 bits. RSA is used for both encryption and digital signatures.

RSA Resource utilization, resource allocation.

RTFM Read the "fine" manual.

RTMP Routing Table Maintenance Protocol (AppleTalk).

RTP Real-Time Transport Protocol.

rule-based expert The type of expert system that expresses the problem-solving process as rules.

rule-based security policy A security policy based on global rules imposed for all subjects. These rules usually rely on a comparison of the sensitivity of the objects being accessed and the possession of corresponding attributes by the subjects requesting access.

rules Constraints.

rules of behavior The rules that have been established and implemented concerning use of, security in, and acceptable level of risk for the system. Rules will clearly delineate responsibilities and expected behavior of all individuals with access to the system. Rules should cover such matters as working at home, dial-in access, connection to the Internet, use of copyrighted works, unofficial use of federal government equipment, the assignment and limitation of system privileges, and individual accountability.

RVM Protection of the TSF, reference mediation.

RVS Relative value scale.

S/MIME Secure Multipurpose Internet Mail Extensions; an e-mail and file encryption protocol.

SA (1) Source address. (2) Security association.

SAA Security audit analysis.

SABM Set asynchronous balanced mode.

SABME Set asynchronous balanced mode extended.

SAE Security management, security attribute expiration.

safe harbor principles The set of rules to which U.S. businesses that want to trade with the European Union (EU) must adhere.

safeguards Protective measures prescribed to meet the security requirements (i.e., confidentiality, integrity, and availability) specified for an information system. Safeguards may include security features, management constraints, personnel security, and security of physical structures, areas, and devices. Synonymous with security controls and countermeasures.

safety integrity (1) The likelihood of a safety-related system, function, or component achieving its required safety features under all stated conditions within a stated measure of use. (2) The probability of a safety-related system satisfactorily performing the required safety functions under all stated conditions within a stated period of time.

safety integrity level An indicator of the required level of safety integrity; the level of safety integrity that must be achieved and demonstrated.

safety kernel An independent computer program that monitors the state of the system to determine when potentially unsafe system states may occur or when transitions to potentially unsafe system states may occur. A safety kernel is designed to prevent a system from entering an unsafe state and retaining or returning it to a known safe state.

safety-critical A term applied to any condition, event, operation, process, or item whose proper recognition, control, performance, or tolerance is essential to safe system operation and support (such as a safety-critical function, safety-critical path, or safety-critical component.

safety-critical software Software that performs or controls functions which, if executed erroneously or if they failed to execute properly, could directly inflict serious injury to people, property, or the environment or cause loss of life.288.

safety-related software Software that performs or controls functions that are activated to prevent or minimize the effect of a failure of a safety-critical system.

sales force automation (SFA) system Automatically tracks all of the steps in the sales process.

salt Salt is a string of random (or pseudo-random) bits concatenated with a key or password to reduce the probability of pre-computation attacks.

sanitization (1) Removing the classified content of an otherwise unclassified resource. (2) Removing any information that could identify the source from which the information came.

sanitize The degaussing or overwriting of information on magnetic or other storage media.

sanitizing The degaussing or overwriting of sensitive information in magnetic or other storage media.

SAP (1) Service access point. (2) Service Advertisement Protocol (Novell).

SAR Security audit review.

Sarbanes-Oxley Act of 2002 (SOX) The most dramatic change to federal securities laws since the 1930s, the act radically redesigns federal regulation of public company corporate governance and reporting obligations. It also significantly tightens accountability standards for directors and officers, auditors, securities analysts, and legal counsel.

SAS Single attached station.

satellite modem A modem that allows Internet access from a satellite dish.

SC Subcommittee.

scalability The likelihood that an artifact can be extended to provide additional functionality with little or no additional effort.

scalability Refers to how well a system can adapt to increased demands.

scannable resume (ASCII resume, plain-text resume) Designed to be evaluated by skills-extraction software and typically contains all resume content without any formatting.

sanner Captures images, photos, and artwork that already exist on paper.

scavenging The searching of residue for the purpose of unauthorized data acquisition.

scheduling program A systems program that schedules and monitors the processing of production jobs in the computer system.

SCHIP The State Children's Health Insurance Program.

SCL Security certification level (see certification level).

scope creep Occurs when the scope of the project increases.

SCP CM scope.

script bunny (or **script kiddie**) Someone who would like to be a hacker but does not have much technical expertise.

scripts Executable programs used to perform specified tasks for servers and clients.

SDH Synchronous digital hierarchy.

SDI User data protection, stored data integrity.

SDLC System development life cycle.

SDO Under HIPAA, standards development organization.

SDU Service data unit.

search engine A program written to allow users to search the Web for documents that match user-specified parameters.

secrecy A security principle that keeps information from being disclosed to anyone not authorized to access it.

secret key cryptography A cryptographic system where encryption and decryption are performed using the same key.

secretary Under HIPAA, this refers to the secretary of HHS or his designated representatives. See also Part II, 45 CFR 160.103.

Secure Digital Music Initiative (SDMI) Forum of more than 160 companies and organizations representing a broad spectrum of information technology and consumer electronics businesses, Internet service providers, security technology companies, and members of the worldwide recording industry working to develop voluntary, open standards for digital music. SDMI is helping to enable the widespread Internet distribution of music by adopting a framework that artists and recording and technology companies can use to develop new business models.

secure electronic transaction (SET) The SET specification has been developed to allow for secure credit card and offline debit card (check card) transactions over the World Wide Web.

secure interoperability The ability to have secure, successful transactions. Today's interoperability expands that previous focus to also include information assurance considerations, and include the requirement to formally assess whether that traditional, successful transaction is also secure (i.e., secure interoperability meaning a secure, successful transaction exists).

secure operating system An operating system that effectively controls hardware, software, and firmware functions to provide the level of protection appropriate to the value of the data resources managed by this operating system.

secure room Any room with floor-to-ceiling, slab-to-slab construction of some substantial material, i.e., concrete, brick, cinder block, plywood, or plaster board. Any window areas or penetrations of wall areas over 15.25 cm (six inches) must be covered with either grilling or substantial type material. Entrance doors must be constructed of solid wood, metal, etc., and be capable of holding a DS-approved three-way combination lock with interior extension.

Secure Socket Layer (SSL) A protocol developed by Netscape for transmitting private documents via the Internet. SSL works by using a public key to encrypt data that is transferred over the SSL connection.

secure voice Systems in which transmitted conversations are encrypted to make them unintelligible to anyone except the intended recipient. Within the context of Department security standards, secure voice systems must also have protective features included in the environment of the systems terminals.

security (1) Freedom from undesirable events, such as malicious and accidental misuse; how well a system resists penetrations by outsiders and misuse by insiders. (2) The protection of system resources from accidental or malicious access, use, modification, destruction, or disclosure. (3) The protection of resources from damage and the protection of data against accidental or intentional disclosure to unauthorized persons or unauthorized modifications or destruction. Security concerns transcend the boundaries of an automated system.

security accreditation See accreditation.

security anomaly An irregularity possibly indicative of a security breach, an attempt to breach security, or of noncompliance with security standards, policy, or procedures.

security association A security association is a set of parameters which defines all the security services and mechanisms used for protecting the communication. A security association is bound to a specific security protocol.

security audit An examination of data security procedures and measures to evaluate their adequacy and compliance with established policy.

security authorization See accreditation.

security category The characterization of information or an information system based on an assessment of the potential impact that a loss of confidentiality, integrity, or availability of such information or information system would have on organizational operations, organizational assets, or individuals.

security classification designations Refers to "top secret," "secret," and "confidential" designations on classified information or material.

security controls Techniques and methods to ensure that only authorized users can access the computer information system and its resources.

security domain A set of subjects, their information objects, and a common security policy.

security equipment Protective devices such as intrusion alarms, safes, locks, and destruction equipment which provide physical or technical surveillance protection as their primary purpose.

security evaluation An evaluation done to assess the degree of trust that can be placed in systems for the secure handling of sensitive information. One type, a product evaluation, is an evaluation performed on the hardware and software features and assurances of a computer product from a perspective that excludes the application environment. The other type, a system evaluation, is done for the purpose of assessing a system's security safeguards with respect to a specific operational mission and is a major step in the certification and accreditation process.

security filter A set of software or firmware routines and techniques employed in a computer system to prevent automatic forwarding of specified data over unprotected links or to unauthorized persons.

security goals The five security goals are integrity, availability, confidentiality, accountability, and assurance.

security incident Any act or circumstance that involves classified information that deviates from the requirements of governing security publications. For example, compromise, possible compromise, inadvertent disclosure, and deviation.

security inspection Examination of an IS to determine compliance with security policy, procedures, and practices.

security kernel The central part of a computer system (hardware, software, or firmware) that implements the fundamental security procedures for controlling access to system resources.

security label Piece of information that represents the sensitivity of a subject or object, such as its hierarchical classification together with any applicable nonhierarchical security categories (e.g., sensitive compartmented information, critical nuclear weapon design information).

security metrics A standard of measurement used to measure and monitor information security-related information security activity.

security objective Confidentiality, integrity, or availability of information.

security parameter index (SPI) SPI is an identifier for a security association within a specific security protocol. This means that a pair of security protocol and SPI may uniquely identify a security association, but this is implementation dependent.

security plan See system security plan.

security policy The set of laws, rules, and practices that regulate how sensitive or critical information is managed, protected, and distributed.

security policy model A formal presentation of the security policy enforced by the system. It must identify the set of rules and practices that regulate how a system manages, protects, and distributes sensitive information.

security process The series of activities that monitor, evaluate, test, certify, accredit, and maintain the system accreditation throughout the system life cycle.

security program A systems program that controls access to data in files and permits only authorized use of terminals and other related equipment. Control is usually exercised through various levels of safeguards assigned on the basis of the user's need-to-know.

security purpose The IS security purpose is to provide value by enabling an organization to meet all mission/business objectives while ensuring that system implementations demonstrate due care consideration of risks to the organization and its customers.

security requirements The types and levels of protection necessary for equipment, data, information, applications, and facilities to meet security policy.

security requirements baseline A description of minimum requirements necessary for a system to maintain an acceptable level of security.

security service A capability that supports one, or many, of the security goals. Examples of security services are key management, access control, and authentication.

security specification A detailed description of the safeguards required to protect a system.

security test and evaluation (ST&E) An examination and analysis of the security safeguards of a system as they have been applied in an operational environment to determine the security posture of the system.

security testing A process used to determine that the security features of a system are implemented as designed. This includes hands-on functional testing, penetration testing, and verification.

security-critical A term applied to any condition, event, process, or item whose recognition, control, performance, or tolerance is essential to secure system operation or support.

seepage The accidental flow, to unauthorized individuals, of data or information that is presumed to be protected by computer security safeguards.

segment Under HIPAA, this is a group of related data elements in a transaction. See also Part II, 45 CFR162.103.

SEL Security audit event selection.

selection A program control structure created in response to a condition test in which one of two or more processing paths can be taken.

self sourcing (or **knowledge worker/end-user development**) The development and support of IT systems by knowledge workers with little or no help from IT specialists.

self-insured Under HIPAA, an individual or organization that assumes the financial risk of paying for healthcare.

self-organizing neural network A network that finds patterns and relationships in vast amounts of data by itself.

selling prototype A prototype used to convince people of the worth of a proposed system.

semagram A semantic symbol. Semagrams are assoicated with a concept and do not use writing to hide a message.

semiconductor Material used in electronic components that possesses electrical conducting qualities of conductors and resistors.

sensitive data Data that is considered confidential or proprietary. The kind of data that, if disclosed to a competitor, might give away an advantage.

sensitive information Any information that requires protection and that should not be made generally available.

sensitive intelligence information Such intelligence information, the unauthorized disclosure of which would lead to counteraction (1) jeopardizing the continued productivity of intelligence sources or methods which provide intelligence vital to the national security; or (2) offsetting the value of intelligence vital to the national security.

sensitive unclassified information Any information, the loss, misuse, or unauthorized access to or modification of which could adversely affect the national interest or the conduct of federal programs, or the privacy to which individuals are entitled under 5 USC Section 552a (the Privacy Act), but that has not been specifically authorized under criteria established by an executive order or an act of Congress to be kept secret in the interest of national defense or foreign policy. Note: Systems that are not national security systems, but contain sensitive information, are to be protected in accordance with the requirements of the Computer Security Act of 1987 (Public Law 100-235).

sensitivity An information technology environment consists of the system, data, and applications, which must be examined individually and in total. All systems and applications require some level of protection for confidentiality, integrity, and availability. This level of protection is determined by an evaluation of the sensitivity and criticality of the information processed, the relationship of the system to the organization's mission, and the economic value of the system components.

sensitivity attributes User-supplied indicators of file sensitivity that the system uses to enforce an access control policy.

sensitivity label A hierarchical classification and a set of nonhierarchical components that are used by mandatory access controls to define a process's resource access rights.

SEP Protection of the TSF, domain separation.

sequential organization The physical arrangement of records in a sequence that corresponds with their logical key.

serial connector Usually has 9 holes but may have 25 that fit into the corresponding number of pins in the port. Serial connectors are often used for monitors and certain types of modems.

Serial Line Internet Protocol (SLIP) An Internet protocol used to run IP over serial lines such as telephone circuits or RS-232 cables interconnecting two systems. SLIP is now being replaced by Point-to-Point Protocol. See Point-to-Point Protocol.

Serial Line IP (SLIP) An IP used to run over serial lines such as telephone circuits or RS-232 cables interconnecting two systems. SLIP is now being replaced by Point-to-Point Protocol. See Point-to-Point Protocol.

serial organization The physical arrangement of records in a sequence.

serial processing The processing of records in the physical order in which they appear in a file or on an input device.

server A computer that provides a service to another computer, such as a mail server, a file server, or a news server.

server farm A location that stores a group of servers in a single place.

service A component of the portfolio of choices offered by SvPs to a user, a functionality offered to a user.

service control The ability of the user, home environment, or serving environment to determine what a particular service does, for a specific invocation of that service, within the limitations of that service.

service control points (SCP) The local versions of the national 800 number database. They contain the intelligence to screen the full ten digits of an 800 number and route calls to the appropriate long distance carrier.

service information Information used by the telecommunications infrastructure in the establishment and operation of a network-related service or services. The information may be established by an NWO/AP/SvP or a network user.

service level agreement (SLA) Defines the specific responsibilities of the service provider and sets the customer expectations.

service program An operating system program that provides a variety of common processing services to users (e.g., utility programs, librarian programs, and other software).

service provider (SvP) A natural or legal person providing one or more public telecommunications services whose provision consists wholly or partly in the transmission and routing of signals on a telecommunications network. SvPs do not necessarily have to run their own networks.

service switching points (SSP) A switching system, including its remotes, that identifies calls associated with intelligent network services and initiates dialog with the SCP.

service transfer points (STP) A signaling point with the function of transferring messages from one signaling link to another and considered exclusively from the viewpoint of the transferor.

session A completed connection to an Internet service, and the ensuing connect time.

session hijacking An intruder takes over a connection after the original source has been authenticated.

session key Session key is a randomly-generated key that is used one time, and then discarded. Session keys are symmetric (used for both encryption and decryption). They are sent with the message, protected by encryption with a public key from the intended recipient. A session key consists of a random number of approximately 40–2000 bits. Session keys can be derived from hash values.

session layer The layer of the ISO reference model coordinating communications between network nodes. It can be used to initialize, manage, and terminate communication sessions.

SET Secure Electronic Transactions protocol.

SF Super framing (T1/E1).

SHA Secure Hash algorithm.

shared information An organization's information is in one central location allowing anyone to access and use it as they need it.

shareware Software available on the Internet that may be downloaded to your machine for evaluation and for which you are generally expected to pay a fee to the originator of the software if you decide to keep it.

sharing Providing access to and facilitating the sharing of information which enhances reach and creates shared awareness.

shortfalls Functional areas in which additional capability or coverage is required.

SIGINT A broad range of operations that involve the interception and analysis of signals across the electromagnetic spectrum.

sign a message To use your private key to generate a digital signature as a means of proving you generated, or certify, some message.

signaling The exchange of information specifically concerned with the establishment and control of connections, and with management, in a telecommunications network.

Signaling System 7 (SS7) SS7 employs a dedicated 64-kb data circuit to carry packetized machine language messages about each call connected between and among machines of a network to achieve connection control.

signal-to-interference ratio (SIR) The ratio of the usable signal being transmitted to the noise or undesired signal.

signature (digital) A quantity (number) associated with a message which only someone with knowledge of your private key could have generated, but which can be verified through knowledge of your public key.

signature dynamics A form of electronic signatures which involves the biometric recording of the pen dynamics used in signing the document.

sign-off The knowledge workers' actual signatures indicating they approve all of the business requirements.

SIL Safety integrity level.

SIMM Single inline memory module.

Simple Mail Transfer Protocol (SMTP) The Internet e-mail protocol.

Simple Network Management Protocol (SNMP) Provides remote administration of network device; "simple" because the agent requires minimal software.

simplicity The simplest correct structure is the most desirable.

simulation The use of an executable model to represent the behavior of an object. During testing, the computational hardware, the external environment, and even the coding segments may be simulated.

simultaneous processing The execution of two or more computer program instructions at the same time in a multiprocessing environment.

single inheritance The language mechanism that allows the definition of a class to include the attributes and methods defined for, at most, one superclass.

single sideband carrier An amplitude modulation technique for encoding analog or digital data using either analog or digital transmission. Single sideband suppresses one sideband of the carrier frequency at the source. As such, less power is used, and less bandwidth is required.

SIP SMDS Interface Protocol.

site An immobile collection of systems at a specific location.

site accreditation An accreditation where all systems at a location are grouped into a single management entity. A DAA may determine that a site accreditation approach is optimal given the number of information technology systems, major applications, networks, or unique operational characteristics. Site accreditation begins with all systems and their interoperability and major applications at the site being certified and accredited. The site is then accredited as a single entity, and an accreditation baseline is established.

situation Situation is a set of all security-relevant information. The decision of an entity on which security services it requires is based on the situation.

skill words Nouns and adjectives used by organizations to describe job skills that should be woven into the text of applicants' resumes.

skin affect The concept that high-frequency energy travels only on the outside skin of a conductor and does not penetrate into it any great distance.

slack space The unused space in a group of disk sectors. Or the difference in empty bytes of the space that is allocated in clusters minus the actual size of the data files.

SLARP Serial Link Address Resolution Protocol.

slave computer A front-end processor that handles input and output functions for a host computer.

SLDC (1) Systems development life cycle. (2) Synchronous data link control.

SLIP Serial Line Interface Protocol.

small health plan Under HIPAA, this is a health plan with annual receipts of $5 million or less. See also Part II, 45 CFR 160.103.

smartcard A small computer the size of a credit card that is used to perform functions such as identification and authentication.

SMDS Switched multi-megabit data service.

SML Strength of mechanism; a rating used by the IA Technical Framework to rate the strength or robustness required for a security mechanism. Currently, three ratings are defined: SML1—low, SML2—medium, and SML3—high. The SML is derived as a function of the value of the information being protected and the perceived threat to it. Compare with SOF.

SMR Security management, security management roles.

SMTP Simple Mail Transfer Protocol.

SNA Survivable network analysis method; developed by the CERT/CC.

SNA Systems network architecture.

SNAP Subnetwork Access Protocol.

SNF Skilled nursing facility.

sniffing An attack capturing sensitive pieces of information, such as a password, passing through the network.

SNIP Strategic National Implementation Process—sponsored by WEDI.

SNMP Simple Network Management Protocol.

SNOMED Under HIPAA, Systematized Nomenclature of Medicine.

sociability The ability of intelligent agents to confer with each other.

social engineering An attack based on deceiving users or administrators at the target site. For example, a person who illegally enters computer systems by persuading an authorized person to reveal IDs, passwords and other confidential information.

socket A paring of an IP address and a port number. See port.

SOF Strength of function; a rating used by the Common Criteria (ISO/IEC 15408) to rate the strength or robustness required for a security mechanism. Currently, three ratings are defined: basic, medium, and high. The SOF is derived as a function of the value of the information being protected and the perceived threat to it. Compare with SML.

softlifting Illegal copying of licensed software for personal use.

software Computer programs, procedures, rules, and possibly documentation and data pertaining to the operation of the computer system.

software integrity level The integrity level of a software item.

software life cycle The period of time beginning when a software product is conceived and ending when the product is no longer available for use. The software life cycle is typically broken into phases (e.g., requirements, design, programming, testing, conversion, operations, and maintenance).

software maintenance All changes, corrections, and enhancements that occur after an application has been placed into production.

software piracy To illegally copy software.

software reliability A measure of confidence that the software produces accurate and consistent results that are repeatable, under low, normal, and peak loads, in the intended operational environment.

software reliability case A systematic means of gathering, organizing, analyzing, and reporting the data needed by internal, contractual, regulatory, and certification authorities to confirm that a system has met specified reliability requirements and is fit for use in the intended operational environment; includes assumptions, claims, evidence, and arguments. A software reliability case is a component in a system reliability case.

software safety Design features and operational procedures which ensure that a product performs predictably under normal and abnormal conditions, and the likelihood of an unplanned event occurring is minimized and its consequences controlled and contained; thereby preventing accidental injury or death, environmental or property damage, whether intentional or accidental.

software safety case A systematic means of gathering, organizing, analyzing, and reporting the data needed by internal, contractual, regulatory and certification authorities to confirm that a system has met specified safety requirements and is safe for use in the intended operational environment; includes assumptions, claims, evidence, and arguments. A software safety case is a component in a system safety case.

software suite Bundled software that comes from the same publisher and costs less than buying all the software pieces individually.

SONET Synchronous optical network.

SOP Standard operating procedure.

sort The arrangement of data in ascending or descending, alphabetic or numeric order.

SOS Identification and authentication specification of secrets.

source document The form that is used for the initial recording of data prior to system input.

source program The computer program that is coded in an assembler or higher-level programming language.

SOW See statement of work.

space diversity Protection of a radio signal by providing a separate antenna located a few feet below the regular antenna on the same tower to assume the load when the regular transmission path on the tower fades.

Space Division Multiple Access (SDMA) Intelligent antenna systems use this access method to increase the capacity of cellular radio networks by separating frequencies within a cell site and allowing the same frequencies to be reused.

spam (1) The act of posting the same information repeatedly on inappropriate places or too many places so as to overburden the network. (2) Unsolicited e-mail.

spam filters Programs that detect and reject spam by looking for certain keywords, phrases or Internet addresses.

spatial domain The image plane itself; the collection of pixels that composes an image.

special agent A special agent in the Diplomatic Security Service (DSS) is a sworn officer of the Department of State or the Foreign Service, whose position is designated as either a GS-1811 or FS-2501, and has been issued special agent credentials by the director of the Diplomatic Security Service to perform those specific law enforcement duties as defined in 22 USC 2712.

special investigators Special investigators are contracted by the Department of State. They perform various noncriminal investigative functions in DS headquarters, field, and resident offices. They are not members of the Diplomatic Security Service and are not authorized to conduct criminal investigations.

specification A description of a problem or subject that will be implemented in a computational or other system. The specification includes both a description of the subject and aspects of the implementation that affect its representation. Also, the process and analysis and design that results in a description of a problem or subject that can be implemented in a computation or other system.

spectrum The radio frequency that is available for personal, commercial, and military use.

SPF Shortest path first.

spherical zone of control A volume of space in which uncleared personnel must be escorted which extends a specific distance in all directions from TEMPEST equipment processing classified information or from a shielded enclosure.

SPI Security parameter index; part of IPSec.

SPID Service provider identifier (ISDN).

split knowledge A security technique in which two or more entities separately hold data items that individually convey no knowledge of the information that results from combining the items. A condition under which two or more entities separately have key components which individually convey no knowledge of the plaintext key that will be produced when the key components are combined in the cryptographic module.

SPM Development, security policy modeling.

sponsor See plan sponsor.

spoof To make a transmission appear to come from a user other than the user who performed the action.

spoofing (1) Faking the sending address of a transmission to gain illegal entry into a secure system. (2) The deliberate inducement of a user or resource to take incorrect action.

spooling A technique that maximizes processing speed through the temporary use of high-speed storage devices. Input files are transferred from slower, permanent storage and queued in the high-speed devices to await processing, or output files are queued in high-speed devices to await transfer to slower storage devices.

SPP Sequenced Packet Protocol (Vines).

spread spectrum image steganography A method of steganographic communication that uses digital imagery as the cover signal.

spread spectrum techniques The method of hiding a small or narrow-band signal (message) in a large or wide band cover.

spreadsheet software Computer software that divides a display screen into a large grid. This grid allows the user to enter labels and values that can be manipulated or analyzed.

spread-spectrum image steganography A method of steganographic communication that uses digital imagery as the cover signal.

spread-spectrum techniques The method of hiding a small or narrow-band signal (message) in a large or wideband cover.

SPX Sequenced Packet Exchange (Novell).

spyware Any software that covertly gathers user information through the user's Internet connection without his or her knowledge, usually for advertising purposes. Spyware applications are typically bundled as a hidden component of freeware or shareware programs that can be downloaded from the Internet; however, it should be noted that the majority of shareware and freeware applications do not come with spyware. Once installed, the spyware monitors user activity on the Internet and transmits that information in the background to someone else. Spyware can also gather information about e-mail addresses and even passwords and credit card numbers. Also known as *adware*.

SQL See Structured Query Language.

SRAM Static RAM.

SRB Source route bridging.

SRE (1) Protection profile evaluation, explicitly stated IT security requirements; (2) Security target evaluation, explicitly stated IT security requirements.

SRTB Source route transparent bridging.

SRTP Sequenced Routing Update Protocol (Vines).

SS7 Signaling System 7.

SSAP Source service access point (LLC).

SSH Secure shell.

SSL Secure Sockets Layer.

SSL3 Secure Socket Layer protocol; see also *TLS1*.

SSN Social Security number.

SSO Single sign-on or standard-setting organization.

SSO See standard-setting organization.

SSP In Common Criteria, protection of the TSF, state synchrony protocol.

ST Security target.

stacked-job processing A computer processing technique in which programs and data awaiting processing are placed into a queue and executed sequentially.

standalone root A certificate authority that signs its own certificates and does not rely of a directory service to authenticate users.

standard Mandatory statement of minimum requirements that support some part of a policy.

Standard Generalized Markup Language (SGML) An international standard for encoding textual information that specifies particular ways to annotate text documents separating the structure of the document from the information content. HTML is a generalized form of SGML.

standard transaction Under HIPAA, this is a transaction that complies with the applicable HIPAA standard. See also Part II, 45 CFR 162.103.

Standard Transaction Format Compliance System (STFCS) An EHNAC-sponsored WPC-hosted HIPAA compliance certification service.

standardization The commander's information requirements must not be comprised by the use of nonstandard equipment.

standards A set of rules or specifications that, when taken together, define a software or hardware device. A standard is also an acknowledged basis for comparing or measuring something. Standards are important because new technology will only take root once a group of specifications is agreed upon.

standards audit The check to ensure that applicable standards are properly used.

standard-setting organization (SSO) See Part II, 45 CFR 160.103.

state A static condition of an object or group of objects.

state space The total collection of possible states for a particular object or group of objects.

state transition A change of state for an object; something that can be signaled by an event.

state uniform billing committee (SUBC) Under HIPAA, a state-specific affiliate of the NUBC.

state variable A property or type that is part of an identified state of a given type.

statement of work (SOW) Under HIPAA, a document describing the specific tasks and methodologies that will be followed to satisfy the requirements of an associated contract or MOU.

statement testing A test method of satisfying the criterion that each statement in a program be executed at least once during the program testing.

static analysis The direct analysis of the form and structure of a product that does not require its execution. It can be applied to the requirements, design, or code.

static data Data that, once established, remains constant.

Statistical Time Division Multiplexing (STDM) This form of multiplexing uses all available time slots to send significant information and handles inbound data on a first-come, first-served basis.

steering committee A management committee assembled to sponsor and manages various projects such as information security program.

steganalysis The art of detecting and neutralizing steganographic messages.

steganalyst One who applies steganalysis with the intent of discovering hidden information.

steganographic file system A method of storing files in such a way that encrypts data and hides it such that it cannot be proven to be there.

steganography (1) The method of concealing the existence of a message or data within seemingly innocent covers. (2) A technology used to embed information in audio and graphical material. The audio and graphical materials appear unaltered until a steganography tool is used to revel the hidden message.

stegokey A key that allows extraction of the secret information out of the cover.

stego-medium The resulting combination of a cover medium and embedded message and a stego key.

stego-only attack An attack where only the stego-object is available for analysis.

STFCS See the Standard Transaction Format Compliance System.

STG Security audit event storage.

StirMark A method of testing the robustness of a watermark. StirMark is based on the premise that many watermarks can survive a simple manipulation to the file, but not a combination of manipulations. It simulates a process similar to what would happen if an image was printed and then scanned back into the computer by stretching, shearing, shifting and rotating an image by a tiny random amount.

STM Protection of the TSF, time stamps.

storage media Floppy diskettes, tapes, hard disk drives, or any devices that store automated information.

storage object An object that supports both read and write accesses.

stored-program concept The location of the instructions placed in the memory of a common controlled switching unit and to which it refers while processing a call.

strategic management Provides an organization with overall direction and guidance.

strategic national implementation process (SNIP) Under HIPAA, a WEDI program for helping the healthcare industry identify and resolve HIPAA implementation issues.

stream cipher An encryption method in which a cryptographic key and an algorithm are applied to each bit in a datastream, one bit at a time.

strength The power of the information assurance protection.

strength of mechanism (SML) A scale for measuring the relative strength of a security mechanism hierarchically ordered from SML 1 through SML 3.

strike warfare A primary warfare mission area dealing with preemptive or retaliatory offensive strikes against inland or coastal ground targets.

strong authentication Strong authentication refers to systems that require multiple factors for authentication and use advanced technology, such as dynamic passwords or digital certificates, to verify a user's identity.

structurally object-oriented The data model allows definitions of data structures to represent entities of any complexity (complex objects).

structured data See data-related concepts.

structured design A methodology for designing systems and programs through a top-down, hierarchical segmentation.

structured programming The process of writing computer programs using logical, hierarchical control structures to carry out processing.

Structured Query Language (SQL) The international standard language for defining and accessing a relational database.

SUBC See state uniform billing committee.

subject An active entity, generally in the form of a person, process, or device that causes information to flow among objects or changes the system state.

subjective information Attempts to describe something that is unknown.

subnet A portion of a network, which may be a physically independent network segment, that shares a network address with other portions of the network and is distinguished by a subnet number. A subnet is to a network what a network is to the Internet.

subnet address The subnet portion of an IP address. In a subnetted network, the host portion of an IP address is split into a subnet and a host portion using an address (subnet) mask.

subroutine A segment of code that can be called up by a program and executed at any time from any point.

subscriber An entity (associated with one or more users) that is engaged in a subscription with a telecommunications service provider (TSP). The subscriber is allowed to subscribe to and unsubscribe from services, to register a user or a list of users authorized to enjoy these services, and also to set the limits relative to the use that associated users make of these services.

subscriber loop The circuit that connects the telephone company's central office to the demarcation point on the customer's premises. The circuit is most likely a pair of wires.

subscript A value used in programming to reference an item of data stored in a table.

substitution The steganographic method of encoding information by replacing insignificant bits from the cover with the bits from the embedded message.

Substitution-Linear Transformation Network A practical architecture based on Shannon's concepts for the secure, practical ciphers with a network structure consisting of a sequence of rounds of small substitutions, easily implemented by table lookup and connected by bit position permutations or linear transpositions.

subsystem A major subdivision or component of an information system consisting of information, information technology, and personnel that performs one or more specific functions.

suite A named set of resources and interfaces; a collection of resources; not a physical space.

summary health information See Part II, 45 CFR 164.504.

superclass A class from which another class inherits attributes and methods.

supercomputer The fastest, most powerful, and expensive type of computer.

SuperFrame A synchronization-framing format for a T1. In a T1 circuit, each of the 24 DS0 channels are sampled every 125 μs and 8 bits are taken from each. If you multiply the 8 bits by the 24 channels, you get 192-bits in a chain, and then add one bit for timing, you get 193 total bits in one frame. Twelve frames comprise the SuperFrame. A newer version of this T1 formatting is called *Extended Super Frame* (ESF).

supply chain The paths reaching out to all of a company's suppliers of parts and services.

supply-chain management (SCM) system Tracks inventory and information among business processes and across companies.

support mission area Synonymous with *support warfare mission area*. Areas of naval warfare that provide support functions that cut across the boundaries of all (or most) other warfare mission areas.

supraliminal channel A feature of an image which is impossible to remove without gross modifications, i.e., a visible watermark.

survivability The capability of a system to fulfill its mission, in a timely manner, in the presence of attacks, failures, or accidents. A survivability assessment covers the full threat control chronology.

SVC Switched virtual circuit.

swapping A method of computer processing in which programs not actively being processed are held on special storage devices and alternated in and out of memory with other programs according to priority.

SWG Under HIPAA, subworkgroup.

switch A mechanical, electrical, or electronic device that opens or closes circuits, completes or breaks an electrical path, or selects paths or circuits. A switch looks at incoming data to determine the destination address. Based on that address, a transmission path is set up through the switching matrix between the incoming and outgoing physical communications ports and links.

switch control point (SCP) also known as **service control point (SCP)** Provides computer services, such as database information, that defines the possible services and their logic.

switched beam Also called *switched lobe*. Smart antennas use power patterns that are more concentrated and directed than the regular antenna. The far end device receives a much more powerful signal from the antenna.

switched lobe (SL) Also called *switched beam*. Smart antennas use power patterns that are more concentrated and directed than the regular antenna. The far end device receives a much more powerful signal from the antenna.

switched virtual circuit (SVC) A virtual circuit connection established across a network on an as-needed basis and lasting only for the duration of the transfer.

switching costs Costs that can make customers reluctant to switch to another product or service.

symbolic evaluation The process of analyzing the path of program execution through the use of symbolic expressions.

symbolic execution The analytical technique of dissecting each program path.

symmetric key encryption In symmetric key encryption: two trading partners share one or more secrets, no one else can read their messages. A different key (or set of keys) is needed for each pair of trading partners. Same key used for encryption and decryption.

Synchronous A protocol of transmitting data over a network where the sending and receiving terminals are kept in synchronization with each other by a clock signal embedded in the data.

Synchronous Optical NETwork (SONET) SONET is an international standard for high-speed data communications over fiber-optic media. The transmission rates range from 51.84 Mbps to 2.5 Gbps.

syntax The statement formats and rules for the use of a programming language.

system A series of related procedures designed to perform a specific task.

system accreditation The official authorization granted to an information system to process sensitive information in its operational environment based on a comprehensive security evaluation of the system's hardware, firmware, and software security design, configuration and implementation and of the other system procedural, administrative, physical, TEMPEST, personnel, and communications security controls.

system analysis The process of studying information requirements and preparing a set of functional specifications that identify what a new or replacement system should accomplish.

system attributes The qualities, characteristics, and distinctive features of information systems.

system bus The electronic pathways that move information between basic components on the motherboard, including the pathway between the CPU and RAM.

system certification The technical evaluation of a system's security features that established the extent to which a particular information system's design and implementation meets a set of specified security requirements.

system design The development of a plan for implementing a set of functional requirements as an operational system.

system development life cycle The scope of activities associated with a system, encompassing the system's initiation, development and acquisition, implementation, operation and maintenance, and, ultimately, its disposal, which instigates another system initiation.

system entity A system subject (user or process) or object.

system environment The unique technical and operating characteristics of an IT system and its associated environment, including the hardware, software, firmware, communications capability, organization, and physical location.

system high A system is operating at system high security mode when the system and all of its local and remote peripherals are protected in accordance with the requirements for the highest classification category and types of material contained in the system. All users having access to the system have a security clearance, but not necessarily a need-to-know for all material contained in the system. In this mode, the design and operation of the system must provide for the control of concurrently available classified material in the system on the basis of need-to-know.

system high mode IS security mode of operation wherein each user, with direct or indirect access to the IS, its peripherals, remote terminals, or remote hosts, has all of the following: a. Valid security clearance for all information within an IS; b. Formal access approval and signed nondisclosure agreements for all the information stored and processed (including all compartments and special access programs); and c. Valid need-to-know for some of the information contained within the IS.

System integrity The attribute of an IS when it performs its intended function in an unimpaired manner, free from deliberate or inadvertent unauthorized manipulation of the system.

system integrity procedures Procedures established to ensure that hardware, software, firmware, and data in a computer system maintain their state of original integrity and are not tampered with by unauthorized personnel.

system interconnection The direct connection of two or more information technology systems for the purpose of sharing data and other information resources.

system log An audit trail of relevant system happenings (e.g., transaction entries, database changes).

system owner Official having responsibility for the overall procurement, development, integration, modification, or operation and maintenance of an information system.

system reliability The composite of hardware and software reliability for a specified operational environment. System reliability measurements combine qualitative and quantitative assessments.

system safety The application of engineering and management principles, criteria, and techniques to achieve acceptable mishap risk, within the constraints of operational effectiveness, time, and cost, throughout the life of a system.

system safety engineering An engineering discipline that employs specialized professional knowledge and skills in applying scientific and engineering principles, criteria, and techniques to identify and eliminate hazards, in order to reduce the associated mishap risk.

system security authorization agreement (SSAA) The SSAA is a formal agreement among the DAA(s), the certifier, user representative, and program manager. It is used throughout the entire DITSCAP to guide actions, document decisions, specify IA requirements, document certification tailoring and level-of-effort, identify potential solutions, and maintain operational systems security.

system security plan Formal document that provides an overview of the security requirements for the information system and describes the security controls in place or planned for meeting those requirements.

system survivability The ability to continue to make resources available, despite adverse circumstances including hardware malfunctions, accidental software errors, accidental and malicious intentional user activities, and environmental hazards such as EMC/EMI/RFI.

system test The process of testing an integrated hardware/software system to verify that the system meets its specified requirements.

systematic failure Failures that result from an error of omission, error of commission, or operational error during a life-cycle activity.

systematic safety integrity A qualitative measure or estimate of the failure rate due to systematic failures in a dangerous mode of failure.

systems analysis The process of studying information requirements and preparing a set of functional specifications that identify what a new or replacement system should accomplish.

systems architecture The fundamental and unifying system structure defined in terms of system elements, interfaces, processes, constraints, and behaviors.

systems design The development of a plan for implementing a set of functional requirements as an operational system.

systems development life cycle (SDLC) (1) The classical operational development methodology that typically includes the phases of requirements gathering, analysis, design, programming, testing, integration, and implementation. (2) The systematic systems building process consisting of specific phases; for example, preliminary investigation, requirements determination, systems analysis, systems design, systems development, and systems implementation.

systems engineering An integrated composite of people, products, and processes that provides a capability or satisfies a stated need or objective.

Systems Network Architecture (SNA) IBM's proprietary network architecture.

systems security There are three parts to systems security: (1) Computer security (COMPUSEC) is composed of measures and controls that protect an AIS against denial-of-service, unauthorized disclosure, modification, or destruction of AIS and data (information). (2) Communications security (COMSEC) is measures and controls taken to deny unauthorized persons information derived from telecommunications of the U.S. government. Government communications regularly travel by computer networks, telephone systems, and radio calls. (3) Information systems security (INFOSEC) is controls and measures taken to protect telecommunications systems, automated information systems, and the information they process, transmit, and store.

systems software The programs and other processing routines that control and activate the computer hardware facilitating its use.

system-specific security control A security control for an information system that has not been designated as a common security control.

T-1 Trunk level 1. A digital transmission link with a total signaling speed of 1.544 Mbps.

TA Terminal adapter.

TA/NT1TCB Terminal Adapter/Network Termination 1 (ISDN) Trusted Computing Base.

TAB TOE access, TOE access banners.

table An area of computer memory containing multiple storage locations that can be referenced by the same name.

table driven An indexed file in which tables containing record keys (i.e., disk addresses) are used to retrieve records.

TACACS (terminal access controller access control system) Authentication protocol, developed by the DDN community that provides remote access authentication and related services, such as event logging. User passwords are administered in a central database rather than in individual routers, providing an easily scalable network security solution.

TACACS+ Terminal Access Controller Access Control System Plus is an authentication protocol, often used by remote-access servers or single (reduced) sign-on implementations. TACACS and TACACS+are proprietary protocols from CISCO®.

tactical management Develops the goals and strategies outlined by strategic management.

TAG Under HIPAA, technical advisory group.

TAH TOE access, TOE access history.

tampering An intentionally caused event that results in modification of a system, its intended behavior, or data.

tandem switch A tandem switch connects one trunk to another. An intermediate switch or connection between an originating telephone call location and the final destination of the call. The tandem point passes the call along.

tape management system Systems software that assesses the given information on jobs to be run and produces information for operators and librarians regarding which data resources (e.g., tapes and disks) are needed for job execution.

target identification Identity that relates to a specific lawful authorization as such. This may be a serial number or a combination of characters and numbers. It is not related to the denoted interception subject or subjects.

target identity The identity associated with a target service used by the interception subject.

target of evaluation (TOE) Under Common Criteria, an IT product or system that is subject to an evaluation.

target service Telecommunications service associated with an interception subject and usually specified in a lawful authorization for interception. There may be more than one target service associated with a single interception subject.

task management system It allocates the processor unit resources according to priority scheme or other assignment methods.

TAT Lifecycle support, tools and techniques.

TCB Trusted computing base.

TCP Transport Control Protocol.

TCP sequence prediction Fools applications using IP addresses for authentication (like the UNIX rlogin and rsh commands) into thinking that forged packets actually come from trusted machines.

TCP/IP Transmission Control Protocol/Internet Protocol is a set of communications protocols that encompasses media access, packet transport, session communications, file transfer, electronic mail, terminal emulation, remote file access and network management. TCP/IP provides the basis for the Internet. The structure of TCP/IP is as follows:

Process layer clients: FTP, Telnet, SMTP, NFS, DNS:

Transport layer service providers: TCP (FTP, Telnet, SMTP), UDP (NFS, DNS): Network layer: IP (TCP, UDP): Access layer: Ethernet (IP), Token Ring (IP).

TCSEC Trusted Computer Systems Evaluation Criteria.

TDC In Common Criteria, protection of the TSF: inter-TSF TSF data consistency.

TDM Time division multiplexing.

TE Terminal equipment.

TE1 and TE2 Terminal endpoints.

technical architecture Defines the hardware, software, and telecommunications equipment required to run the system.

technical certification A formal assurance by the Undersecretary for Management to Congress that standards are met which apply to an examination, installation, test or other process involved in providing security for equipment, systems, or facilities. Certifications may include exceptions and are issued by the office or person performing the work in which the standards apply.

technical controls The security controls (i.e., safeguards or countermeasures) for an information system that are primarily implemented and executed by the information system through mechanisms contained in the hardware, software, or firmware components of the system.

technical penetration An unauthorized RF, acoustic, or emanations intercept of information. This intercept may occur along a transmission path which is (1) known to the source, (2) fortuitous and unknown to the source, or (3) clandestinely established.

technical steganography The method of steganography where a tool, device or method is used to conceal a message. Example: invisible inks and microdots.

technical surveillance The act of establishing a technical penetration and intercepting information without authorization.

technological attack An attack that can be perpetrated by circumventing or nullifying hardware, software, and firmware access control mechanisms rather than by subverting system personnel or other users.

technology-literate knowledge worker A person who knows how and when to apply technology.

telecommunications Any transmission, emission, or reception of signs, signals, writing, images, sounds, or other information by wire, radio, visual, satellite, or electromagnetic systems.

telecommunications carrier An entity engaged in the transmission or switching of wire or electronic communications as a common carrier for hire.

telecommunications device A tool used to send information to and receive it from another person or location.

telecommunications service The offering of telecommunications for a fee directly to the public or to such classes of users as to be effectively available directly to the public, regardless of the facilities used.

telecommunications service provider (TSP) Umbrella term for APs, SPs, SvPs, and NWOs.

Telecommunications Standardization Sector of the International Telecommunications Union (ITU–TSS) A unit of the International Telecommunications Union (ITU) of the United Nations. An organization with representatives from the post office, telegraph, and telecommunications agencies (PTTs) of the world. ITU–TSS produces technical standards, known as recommendations, for all internationally controlled aspects of analog and digital communications.

telecommuting The use of communications technologies (such as the Internet) to work in a place other than a central location.

teleprocessing Information processing and transmission performed by an integrated system of telecommunications, computers, and person-to-machine interface equipment.

teleprocessing security The protection that results from all measures designed to prevent deliberate, inadvertent, or unauthorized disclosure or acquisition of information stored in or transmitted by a teleprocessing system.

Telnet The virtual terminal protocol in the Internet suite of protocols. Allows users of one host to log into a remote host and interact as normal terminal users of that host.

TEMPEST The study and control of spurious electronic signals emitted from electronic equipment. TEMPEST is a classification of technology designed to minimize the electromagnetic emanations generated by computing devices. TEMPEST technology makes it difficult, if not impossible, to compromise confidentiality by capturing emanated information.

TEMPEST certification Nationally approved hardware that protects against the transmission of compromising emanations, i.e., unintentional signals from information processing equipment which can disclose information being processed by the system.

TEMPEST equipment (or **TEMPEST-approved equipment**) Equipment that has been designed or modified to suppress compromising signals. Such equipment is approved at the national level for U.S. classified applications after undergoing specific tests. National TEMPEST approval does not, of itself, mean a device can be used within the foreign affairs community. Separate DS approval is required.

TEMPEST hazard A security anomaly that holds the potential for loss of classified information through compromising emanations.

TEMPEST test A field or laboratory examination of the electronic signal characteristics of equipment or systems for the presence of compromising emanations.

TEMPEST-approved personal computer (TPC) A personal computer that is currently listed on the preferred products list (PPL) or evaluated products list (EPL).

temporal masking A form of masking that occurs when a weak signal is played immediately after a strong signal.

temporary advantage An advantage that, sooner or later, the competition duplicates or leap frogs with a better system.

tenant agency A U.S. government department or agency operating overseas as part of the U.S. foreign affairs community under the authority of a chief of mission. Excluded are military elements not under direct authority of the chief of mission.

terabyte (TB) Roughly 1 trillion bytes.

terminal identification The means used to establish the unique identification of a terminal by a computer system or network.

test condition A detailed step the system must perform along with the expected result of the step.

test data Data that simulates actual data to form and content and is used to evaluate a system or program before it is put into operation.

test data generators Computer software tools that help generate files of data that can be used to test the execution and logic of application programs.

testing The examination of the behavior of a program through its execution on sample data sets.

texture block coding A method of watermarking that hides data within the continuous random texture patterns of an image. The technique is implemented by copying a region from a random texture pattern found in a picture to an area that has similar texture, resulting in a pair of identically textured regions in the picture.

TFTP Trivial File Transfer Protocol.

TG Under HIPAA, task group.

the prisoner's problem A model for steganographic communication.

thin client A workstation with a small amount of processing power and costing less than a full-powered workstation.

third-party ad servers Companies that display banner advertisements on Web sites that you visit. These companies are often not the ones that own the Web site.

third-party administrator (TPA) Under HIPAA, an entity that processes healthcare claims and performs related business functions for a health plan.

threat The potential danger that a vulnerability may be exploited intentionally, triggered accidentally, or otherwise exercised.

threat agent A means or method used to exploit a vulnerability in a system, operation, or facility.

threat analysis A project to identify the threats that exist over key information and information technology. The threat analysis usually also defines the level of the threat and likelihood of that threat to materialize.

threat assessment Process of formally evaluating the degree of threat to an information system and describing the nature of the threat.

threat control measure (1) A proactive design or operational procedure, action, or device used to reduce the risk caused by a threat. (2) A proactive design technique, device, or method designed to eliminate or mitigate hazards, and unsafe and unsecure conditions, modes and states.

threat monitoring The analysis assessment and review of audit trails and other data collected to search out system events that may constitute violations or precipitate incidents involving data privacy.

threat perspective The perspective from which vulnerability/threat analyses are conducted (system owner, administrator, certifier, customer, etc.); also referred to as risk dimension.

threat source Either (1) intent and method targeted at the intentional exploitation of a vulnerability or (2) the situation and method that may accidentally trigger a vulnerability.

three generic strategies Cost leadership, differentiation, and a focused strategy.

three-dimensional (3D) technology Presentations of information that give the user the illusion that the object viewed is actually in the room with the user.

three-way handshake The process whereby two protocol entities synchronize during connection establishment.

thrill-seeker hacker A hacker who breaks into computer systems for fun.

throughput The process of measuring the amount of work a computer system can handle within a specified timeframe.

TIFF Tagged Image File Format.

time bomb A Trojan horse that will trigger when a particular time or date is reached.

Time Division Multiple Access (TDMA) One of several technologies used to separate multiple conversation transmissions over a finite frequency allocation of through-the-air bandwidth. TDMA is used to allocate a discrete amount of frequency bandwidth to each user in order to permit many simultaneous conversations. However, each caller is assigned a specific time slot for transmission.

time division multiplexing (TDM) A technique for transmitting a number of separate data, voice, and video signals simultaneously over one communications medium by interleaving a piece of each signal one after another.

time domain Method of representing a signal where the vertical deflection is the signals amplitude, and the horizontal deflection is the time variable.

time stamping An electronic equivalent of mail franking.

time-dependent password A password that is valid only at a certain time of day or during a specified timeframe.

timeliness The ability to ensure the delivery of required information within a defined time frame. Availability of required information in time to make decisions and permit execution within an adversary's decision and execution cycle.

timely In-time, reasonable access to data or system capabilities.

timestamping The practice of tagging each record with some moment in time, usually when the record was created or when the record was passed from one environment to another.

tip side Side of the line when measured with a voltmeter to an earth ground that should read zero voltage.

TLS1 Transport Layer Security protocol.

TNI Trusted network interpretation of TCSEC; see NCSC-TG-011.145,146.

TOCTTU Time of check to time of use; the time interval between when a user is authenticated and when they access specific system resources.

TOE Under Common Criteria, target of evaluation.

TOE security functions (TSF) Under Common Criteria, all parts of the TOE that have to be relied upon for enforcement of the TSP.

TOE security policy (TSP) Under Common Criteria, the rules defining the required security behavior of a TOE.

token passing A network access method that uses a distinctive character sequence as a symbol (token), which is passed from node to node, indicating when to begin transmission. Any node can remove the token, begin transmission, and replace the token when it is finished.

Token Ring A type of area network in which the devices are arranged in a virtual ring in which the devices use a particular type of message called a *token* to communicate with one another.

top-level domain Three-letter extension of a Web site address that identifies its type.

total risk The potential for the occurrence of an adverse event if no mitigating action is taken (i.e., the potential for any applicable threat to exploit a system vulnerability). See also acceptable risk, residual risk, and minimum level of protection.

touch screen Special screen the user touches to perform a particular function.

touchpad Popular on notebook computers, a stationary mouse that is touched with the finger.

TPA See third-party administrator or trading partner agreement.

traceroute (1) A program available on many systems that traces the path a packet takes to a destination. It is mostly used to debug routing problems between hosts. There is also a traceroute protocol defined in RFC 1393. (2) The traceroute or finger commands to run on the source machine (attacking machine) to gain more information about the attacker.

trackball An upside-down, stationary mouse in which the ball is moved instead of the device. Used mainly for notebooks.

trademark A registered word, letter, or device granting the owner exclusive rights to sell or distribute the goods to which it is applied.

trading partner agreement A contractual arrangement that specifies the legal terms and conditions under which parties operate when conducting transactions by the use of EDI. It may cover such things as: validity and formation of contract; admissibility in evidence of EDI messages; processing and acknowledgment of receipt of EDI messages; security; confidentiality and protection of personal data; recording and storage of EDI messages; operational requirements for EDI—message standards, codes, transaction and operations logs; technical specifications and requirements; liability, including use of intermediaries and third party service providers; dispute resolution; and, applicable law.

traditional technology approach Has two primary views of any system—information and procedures—and it keeps these two views separate and distinct at all times.

traffic analysis A type of security threat that occurs when an outside entity is able to monitor and analyze traffic patterns on a network.

traffic flow confidentiality A confidentiality service to protect against traffic analysis.

traffic flow security The protection that results from those features in some cryptography equipment that conceal the presence of valid messages on a communications circuit, usually by causing the circuit to appear busy at all times or by encrypting the source and destination addresses of valid messages.

traffic security A collection of techniques for concealing information about a message to include existence, sender, receivers and duration. Methods of traffic security include call-sign changes, dummy messages and radio silence.

training Teaching people the knowledge and skills that will enable them to perform their jobs more effectively.

training assessment An evaluation of the training efforts.

training effectiveness A measurement of what a given student has learned from a specific course or training event, i.e., learning effectiveness; a pattern of student outcomes following a specific course or training event; teaching effectiveness; and the value of the specific class or training event, compared to other options in the context of an agency's overall IT security training program; program effectiveness.

training effectiveness evaluation Information collected to assist employees and their supervisors in assessing individual students' subsequent on-the-job performance, to provide trend data to assist trainers in improving both learning and teaching, and to be used in return-on investment statistics to enable responsible officials to allocate limited resources in a thoughtful, strategic manner among the spectrum of IT security awareness, security literacy, training, and education options for optimal results among the workforce as a whole.

training matrix A table that relates role categories relative to IT systems.

transaction A transaction is an activity or request to a computer. Purchase orders, changes, additions, and deletions are examples of transactions that are recorded in a business information environment.

Transaction Change Request System A system established under HIPAA for accepting and tracking change requests for any of the HIPAA mandated transactions standards via a single Web site. See http://www.hipaa-dsmo.org

transaction file A collection of records containing data generated from the current business activity.

transaction path One of many possible combinations of a series of discrete activities that cause an event to take place. All discrete activities in a transaction path are logically possible. Qualitative or quantitative probability measures can be assigned to a transaction path and its individual activities.

Transactional Processing System (TPS) The processing of transactions as they occur rather than in batches.

transceiver The physical device that connects a host interface to a local area network, such as Ethernet. Ethernet transceivers contain electronics that apply signals to the cable and sense collisions.

transform domain techniques Various methods of signal and image processing (fast Fourier transform, discrete cosine transform, etc.) used mainly for the purposes of compression.

transformation analysis The process of detecting areas of image and sound files that is unlikely to be affected by common transformations and hide information in those places. The goal is to produce a more robust watermark.

translator See EDI translator.

Transmission Control Protocol (TCP) The major transport protocol in the Internet suite of protocols providing reliable, connection-oriented, full-duplex streams.

transnational firm A firm that produces and sells products and services all over the world.

transport layer The layer of the ISO reference model responsible for managing the delivery of data over a communications network.

Transport Layer Security protocol The public version of SSL3, being specified by the IETF.

Transport Mode An IPSec protocol used with ESP or Alt in which the ESP or Alt header is inserted between the IP header and the upper-layer protocol of an IP packet.252.

trap door A hidden software or hardware mechanism that permits system protection mechanisms to be circumvented. It is activated in some non-apparent manner; for example, a special "random" key sequence at a terminal.

treated conference room (TCR) A shielded enclosure that provides acoustic and electromagnetic attenuation protection.

Trojan horse A computer program that is apparently or actually useful and contains a trapdoor or unexpected code.

Trojan horse software Software the user does not want that is hidden inside software the user wants.

Trojan horse virus Hides inside other software. Usually an attachment or download.

TRP Trusted path/channels, trusted path.

true search engine Uses software agent technologies to search the Internet for key words and then places them into indices.

trust Reliance on the ability of a system or process to meet its specifications.

Trusted Computer Security Evaluation Criteria (TCSEC) A security development standard for system manufacturers and a basis for comparing and evaluating different computer systems. Also known as the *Orange Book*.

trusted computer system A system that employs sufficient hardware and software integrity measures to allow its use for simultaneously processing a range of sensitive or classified information.

trusted computing base The totality of protection mechanisms within a computer system, including hardware, software, and communications equipment, the combination of which is responsible for enforcing a security policy. A TCB consists of one or more components that together enforce a unified security policy over a product or system. The ability of a trusted computing base to correctly enforce a security policy depends solely on the mechanisms within the TCB and on the correct input by system administrative personnel of parameters (such as a user's clearance) related to the security policy.

trusted guard A computer system that is trusted to enforce a particular guard policy, such as ensuring the flow of only unclassified data from a classified system or ensuring no reverse flow of pest programs from an untrusted system to a trusted system.

trusted third party An entity trusted by other entities with respect to security related services and activities, such as a certification authority.

TSE In Common Criteria, TOE access, TOE session establishment.

TSF See TOE security functions.

TSP In Common Criteria, TOE security policy (TSP): the rules defining the required security behavior of a TOE.

TSS In Common Criteria, security target evaluation, TOE summary specification.

TST In Common Criteria, protection of the TSF, TSF self test.

TTL Time-to-live.

Tunnel Mode An IPsec protocol used with ESP in which the header and contents of an IP packet are encrypted and encapsulated prior to transmission, and a new IP header is added.

tunneling The use of authentication and encryption to set up virtual private networks (VPNs).

turnkey system A complete, ready-to-operate system that is purchased from a vendor as opposed to a system developed in-house.

twisted pair A type of network physical medium made of copper wires twisted around each other. Example: ordinary telephone cable.

twisted-pair wire A communication medium that consists of pairs of wires that are twisted together and bound into cable.

two-factor authentication The use of two independent mechanisms for authentication; for example, requiring a smart cart and a password.

type accreditation In some situations, a major application or general support system is intended for installation at multiple locations. The application or system usually consists of a common set of hardware, software, and firmware. Type accreditations are a form of interim accreditation and are used to certify and accredit multiple instances of a major application or general support system for operation at approved locations with the same type of computing environment.

UART Universal asynchronous receiver/transmitter.

UAU User authentication.

UB In HIPAA, Uniform Bill, as in UB-82 or UB-92.

UB-82 In HIPAA, a uniform institutional claim form developed by the NUBC that was in general use from 1983 to 1993.

UB-92 In HIPAA, a uniform institutional claim form developed by the NUBC that has been in general use since 1993.

UCF In HIPAA, Uniform Claim Form, as in UCF-1500.

UCTF See the Uniform Claim Task Force.

UDP User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

UHIN See the Utah Health Information Network.

UID User identification.

UN/CEFACT See the United Nations Center for Facilitation of Procedures and Practices for Administration, Commerce, and Transport.

UN/EDIFACT See the United Nations Rules for Electronic Data Interchange for Administration, Commerce, and Transport.

unallocated space The set of clusters that has been marked as available to store information but has not yet received a file, or still contains some or all of a file marked as deleted.

unauthorized (malicious or accidental) disclosure, modification, or destruction of information Unintentional errors and omissions.

unauthorized disclosure Exposure of information to individuals not authorized to receive it.

understanding Real-world knowledge in context.

UNI User network interface.

uniform claim task force (UCTF) In HIPAA, an organization that developed the initial HCFA-1500 Professional Claim Form. The maintenance responsibilities were later assumed by the NUCC.

Uniform Resource Locator (URL) The primary means of navigating the Web; consists of the means of access, the Web site, the path, and the document name of a Web resource, such as http://www.auerbach-publications.com

uninstaller software Utility software that can be used to remove software that the user no longer wants from the hard disk.

unit security officer A U.S. citizen employee who is a nonprofessional security officer designated with a specific or homogeneous working unit to assist the office of security in carrying out functions prescribed in these regulations.

unit testing The testing of a module for typographic, syntactic, and logical errors and for correct implementation of its design and satisfaction of its requirements.

United Nations Center for Facilitation of Procedures and Practices for Administration, Commerce, and Transport (UN/CEFACT) An international organization dedicated to the elimination or simplification of procedural barriers to international commerce.

United Nations Rules for Electronic Data Interchange for Administration, Commerce, and Transport (UN/EDIFACT) An international EDI format. Interactive X12 transactions use the EDIFACT message syntax.

universal product code (UPC) An array of varied width lines that can be read by special machines (e.g., OCR devices) and converted into alphanumeric data. This method is used to mark merchandise for direct input of sales transactions.

UNIX An operating system initially developed by Bell Labs. Used primarily on engineering workstations and computers, and networked systems. UNIX is difficult for nontechnical people to use but is becoming increasingly popular in the business environment in supporting GUI applications.

UNL Privacy, unlinkability.

UNO Privacy, unobservability.

unshielded twisted pair (UTP) A generic term for “telephone” wire used to carry data such as 10Base-T and 100Base-T. Various categories (qualities) of cable exist that are certified for different kinds of networking technologies.

UNSM United Nations Standard Messages.

unstructured data See data-related concepts.

update The file processing activity in which master records are altered to reflect the current business activity contained in transactional files.

upgrading The determination that particular unclassified or classified information requires a higher degree of protection against unauthorized disclosure than currently provided. Such determination shall be coupled with a marking of the material with the new designation.

UPIN Universal Provider Identification Number—to be replaced by National Provider Identifier under HIPAA.

uplink frequencies In satellites, the frequency used from the earth station up to the satellite. In data, the frequency used to send data from a station to a head end or mainframe.

UR In HIPAA, utilization review.

URAC The American Accreditation HealthCare Commission.

URL (Uniform Resource Locator) An address for a specific Web page or document within a Web site.

USB Identification and authentication user-subject binding.

USB (universal serial bus) It is becoming the most popular means of connecting devices to a computer. Most standard desktops today have at least two USB ports, and most standard notebooks have at least one.

USC or USC United States Code.

use With respect to individually identifiable health information, the sharing, employment, application, utilization, examination, or analysis of such information within an entity that maintains such information. (See disclosure, in contrast.).

USENET A facility of the Internet, also called *the news*, that allows users to read and post messages to thousands of discussion groups on various topics.

Usenet A worldwide collection/system of newsgroups that allows users to post messages to an online bulletin board.

user (1) The party, or his designee, responsible for the security of designated information. The user works closely with an ISSE. Also referred to as the customer. (2) Person or process accessing an AIS either by direct connections (i.e., via terminals), or indirect connections (i.e., prepare input data or receive output that is not reviewed for content or classification by a responsible individual).

user acceptance testing (UAT) Determines if the system satisfies the business requirements and enables the knowledge workers to perform their jobs correctly.

user agent An intelligent agent that takes action on the user's behalf.

User Datagram Protocol (UDP) A transport protocol in the Internet suite of protocols. UDP, like TCP, uses IP for delivery; however, unlike TCP, UDP provides for exchange of datagrams without acknowledgments or guaranteed delivery.

user documentation Highlights how to use the system.

user information The individual, or organization, who has been authorized access to the information asset by the owner.

user interface management The component of the expert system that is used to run a consultation.

user representative An individual that represents the operational interests of the user community and serves as the liaison for that community throughout the system development life cycle of the information system.

user/subscriber An individual procuring goods or services online who obtains a certificate from a certification authority. Since both consumers and merchants may have digital certificates which are used to conclude a transaction, they may both be subscribers in certain circumstances. This person may also be referred to as the signer of a digital signature or the sender of data message signed with a digital signature.

user's identification A character string which validates authorized user access.

USR Guidance documents, user guidance.

Utah Health Information Network (UHIN) Under HIPAA, a public-private coalition for reducing healthcare administrative costs through the standardization and electronic exchange of healthcare data.

utility software Software that provides additional functionality to the operating system.

UTP Unshielded twisted pair.

valid Logically correct (with respect to original data, software, or system).

validation The determination of the correctness, with respect to the user needs and requirements, of the final program or software produced from a development project.

validation phase The users, acquisition authority, and DAA agree on the correct implementation of the security requirements and approach for the completed IS.

validation, verification, and testing Used as an entity to define a procedure of review, analysis, and testing throughout the software life cycle to discover errors; the process of validation, verification, and testing determines that functions operate as specified and ensures the production of quality software.

value chain A tool that views the organization as a chain or series of processes, each of which adds value to the product or service for the customer.

value network All the resources behind the click on a Web page that the customer does not see, but that together create the customer relationship-service, order fulfillment, shipping, financing, information brokering, and access to other products.

value-added network (VAN) A communications network using existing common carrier networks and providing such additional features as message switching and protocol handling.

VBR Variable bit rate.

VC Virtual circuit.

VCI Virtual channel identifier (X.25).

VCN Virtual circuit number (X.25).

vector Also known as *attack vector* routes or methods used to get into computer systems, usually for nefarious purposes. They take advantage of known weak spots to gain entry. Many attack vectors take advantage of the human element in the system because that is often the weakest link.

vector image A digital image that is created through a sequence of commands or mathematical statements that places lines and shapes in a given two or three-dimensional space.

verification (1) The authentication process by which the biometric system matches a captured biometric against the person's stored template. (2) The demonstration of consistency, completeness, and correctness of the software at and between each stage of the development life cycle.

verification phase The process of determining compliance of the evolving IS specification, design, or code with the security requirements and approach agreed on by the users, acquisition authority, and DAA.

verify To determine accurately that (a) the digital signature was created by the private key corresponding to the public key and (b) the message has not been altered since its digital signature was created.

verify a signature Perform a cryptographic calculation using a message, a signature for the message, and a public key, to determine whether the signature was generated by someone knowing the corresponding private key.

versatility Versatility is the ability to adapt readily to unforeseen requirements. The subordinate elements of versatility are flexibility, interoperability, and autonomy.

vertical market software Application software that is unique to a particular industry.

video disk An optical disk that can store images.

videotext Generic text that refers to a computer information system that uses television, telecommunication, and computer technologies to access and manipulate large, graphics-oriented databases.

virtual circuit A network service that provides connection-oriented service, regardless of the underlying network structure.

virtual marketing Encourages users of a product or service supplied by a B2C (buyer to customer) company to ask friends to join.

virtual memory A method of extending computer memory using secondary storage devices to store program pages that are not being executed at the time.

virtual private network (VPN) A secure private network that uses the public telecommunications infrastructure to transmit data. In contrast to a much more expensive system of owned or leased lines that can only be used by one company, VPNs are used by enterprises for both extranets and wide are intranets. Using encryption and authentication, a VPN encrypts all data that passes between two Internet points, maintaining privacy and security.

virtual reality A three-dimensional computer simulation in which the user actively and physically participates.

virtual workplace A technology-enabled workplace—no walls, no boundaries, work anytime, anyplace. Linked to other people and information the user needs.

virus A type of malicious software that can destroy the computer's hard drive, files, and programs in memory, and that replicates itself to other disks.

virus signature files A file of virus patterns that are compared with existing files to determine if they are infected with a virus. The vendor of the antivirus software updates the signatures frequently and makes the available to customers via the Web.

visible noise The degradation of a cover as a result of embedding information. Visible noise will indicate the existence of hidden information.

visible watermark A visible and translucent image that is overlaid on a primary image. Visible watermarks allow the primary image to be viewed, but still marks it clearly as property of the owner. A digitally watermarked document, image, or video clip can be thought of as digitally "stamped."

VLA Vulnerability assessment, vulnerability analysis.

VLAN Virtual local-area network.

VLSM Variable-length subnet mask.

voice mail An e-mail system that allows a regular voice message to be digitally stored at the receiving location and converted back to voice form when it is accessed.

voice processing A system that recognizes spoken words as well as touch tones from telephones. Basically, a "voice" computer in that it (theoretically) can do anything a computer can do, and can recognize voice commands.

voice synthesizer An input and output device that can either interpret and convert human speech into digital signals for computer processing or convert digital signals into audible signals that resemble human speech.

volt The unit of measurement of electromotive force. It is expressed as the potential difference in available energy between two points. One volt is the force required to produce a current of one ampere through a resistance or impedance of 1 ohm.

voltage The pressure under which a flow of electrons moves through a device.

VPN Virtual private network—a private network that is configured within a public network.

VTAM Virtual terminal access method.

vulnerability A weakness in a system that can be exploited to violate the system's intended behavior relative to safety, security, reliability, availability, integrity, etc.

vulnerability analysis The systematic examination of systems in order to determine the adequacy of security measures, identify security deficiencies, and provide data from which to predict the effectiveness of proposed security measures.

vulnerability assessment Systematic examination of an IS or product to determine the adequacy of security measures identify security deficiencies, provide data from which to predict the effectiveness of proposed security measures, and confirm the adequacy of such measures after implementation.

WAIS Wide area information server.

walker An input device that captures and records the movement of the feet as the user walks or turns in different directions.

walk-through A manual analysis technique in which the module author or developer describes the module's structure and logic to colleagues.

WAN (wide-area network) Data communications network that serves users across a broad geographic area and often uses transmission devices provided by common carriers. Frame Relay, SMDS, and X.25 are examples of WANs. Compare with LAN and MAN.

warez Pronounced *wayrz* or *wayrss*. Commercial software that has been pirated and made available to the public via an electronic bulletin board system (BBS) or the Internet. Typically, the pirate has figured out a way to deactivate the copy protection or registration scheme used by the software. Note that the use and distribution of warez software is illegal. In contrast, shareware and freeware may be freely copied and distributed.

warm site A warm site is similar to a hot site; however, it is not fully equipped with all necessary hardware needed for recovery.

Washington Publishing Company (WPC) Under HIPAA, the company that publishes the X12N HIPAA Implementation guides and the X12N HIPAA Data Dictionary, developed the X12 Data Dictionary, and hosts the EHNAC STFCS testing program.

waterfall life cycle A software development process that structures the analysis, design, programming, and testing. Each step is completed before the next step begins.

watermarking A form of marking that embeds copyright information about the artist or owner.

watt The unit of electricity consumption and representing the product of amperage and voltage.

waveforms The characteristic shape of a signal usually shown as a plot of amplitude over a period of time.

waveguide A conducting or dielectric structure able to support and propagate one or more modes. More specifically, a hollow, finely engineered metallic tube used to transmit microwave radio signals from the microwave antenna to the radio and vice versa.

wavelength The length of a wave measured from any point on one wave to the corresponding point on the next wave.

WDM Wavelength-division multiplexing.

wearable computer A fully equipped computer that is worn just like a piece of clothing or attached to a piece of clothing similar to the way the cell phone is carried on the belt.

Web authoring software Helps design and develop Web sites and pages that are published on the Web.

Web beacon Web beacons are images that are placed in HTML documents (Web pages, HTML e-mail) to facilitate user activity tracking. Web beacons are usually used in conjunction with cookies and are often used to track visitors across multiple Internet domains. Web beacon images are usually, but not always, small and "invisible."

Web browser software Enables the user to surf the Web.

Web bugs Small image in an HTML page with all dimensions set to 1 pixel. Because of its insignificant size, it is not visible but used to pass certain information anonymously to third-party sites. Mainly used by advertisers. Can also be referred to as a Web beacon or invisible GIF.

Web crawler A software program that searches the Web for specified purposes such as to find a list of all URLs within a particular site.

Web defacement Also referred to as *defacement* or *Web site defacement*, a form of malicious hacking in which a Web site is "vandalized." Often the malicious hacker will replace the site's normal content with a specific political or social message or will erase the content from the site entirely, relying on known security vulnerabilities for access to the site's content.

Web farm Either a Web site that has multiple servers or an ISP that provides Web site outsourcing services using multiple servers.

Web hosting The business of providing the equipment and services required to host and maintain files for one or more Web sites and to provide fast Internet connections to those sites. Most hosting is "shared," which means that Web sites of multiple companies are on the same server in order to share costs.

Web log Most Web servers produce "log files," time stamped lists of every request that the server receives. For each request, the log file contains anonymous information such as date and time, the IP address of the browser making the request, the document or action that is being requested, the location of the document from which the request was made, and the type of browser that was being used. Log files are usually used to assure quality of service. They also can be used in a limited way to analyze visitor activity.

Web page A specific portion of a Web site that deals with a certain topic.

Web portal A site that provides a wide range of services including search engines, free e-mail, chat rooms, discussion boards, and links to hundreds of different sites.

Web server Using the client-server model and the World Wide Web's HyperText Transfer Protocol (HTTP), Web server is a software program that serves Web page files to users.

Web services Software applications that talk to other software applications over the Internet using XML as a key enabling technology.

Web site A specific location on the Web where the user can visit, gather information, and order products.

Web site address unique name that identifies a specific site on the Web.

Web space A storage area where the user's Web site can be kept.

WEDI Workgroup on Electronic Data Interchange.

WFQ Weighted fair queuing.

WG Under HIPAA, work group.

whitehat (or **ethical) hacker** A computer security professional who is hired by a company to break into its computer system.

WHO See the World Health Organization.

whois An Internet resource that permits users to initiate queries to a database containing information on users, hosts, networks, and domains.

wide-area networks (WAN) A communications network that covers a broad geographic area.

WiFi (wireless fidelity) A way of transmitting information in a wave form that is reasonably fast and is often used for notebooks. Also known as IEEE 802.11b.

wired communications Media that transmit information over a closed connected path.

wireless communications Media that transmit information through the air.

wireless Internet service provider (wireless ISP) A company that provides the same services as a standard Internet service provider except that the user does not need a wired connection for access.

wireless local area network (WLAN) A local area network using wireless communication protocol.

wireless local loop (WLL) A means of provisioning a local loop facility without wires. Employing low power, omnidirectional radio systems, they allow carriers to provision loops up to T-1 capacity to each subscriber.

wireless network access point A device that allows computers to access a network using radio waves.

wiring closet Specially designed room used for wiring a data or voice network. Wiring closets serve as a central junction point for the wiring and wiring equipment that is used for interconnecting devices.

wisdom Understanding of what is true, right or lasting.

word In computer memory, a contiguous set of bits used as a basic unit of storage. Words are usually 8,16, 32, or 64 bits long.

word processing The use of computers or other technology for storage, editing, correction, revision, and production of textual files in the form of letters, reports, and documents.

work factor The effort and time required to break a protective measure.

workflow Defines all of the steps or business rules, from beginning to end, required for a sprocess to run correctly.

workforce Under HIPAA, employees, volunteers, trainees, and other persons whose conduct, in the performance of work for a covered entity, is under the direct control of such entity, whether or not they are paid by the covered entity (See business associate, in contrast).

workgroup A group of people who can work together to achieve a common set of goals, linked together via technological tools and hardware.

Workgroup for Electronic Data Interchange (WEDI) A healthcare industry group that lobbied for HIPAA A/S, and that has a formal consultative role under the HIPAA legislation. WEDI also sponsors SNIP.

World Health Organization (WHO) An organization that maintains the International Classification of Diseases (ICD) medical code set.

World Wide Web or **Web** A multimedia-based collection of information, services, and Web sites supported by the Internet.

worm With respect to security, a special type of virus that does not attach itself to programs, but rather spreads via other methods such as e-mail.

worm attack A harmful exploitation of a worm that can act beyond normally expected behavior, perhaps exploiting security vulnerabilities or causing denials of service.

WPC See the Washington Publishing Company.

wrapper See cover medium.

WWW World Wide Web; also shortened to Web. Although WWW is used by many as being synonymous to the Internet, the WWW is actually one of numerous services on the Internet. This service allows e-mail, images, sound, and newsgroups.

X.25 WAN protocol.

X.400 A ITU–TSS international standard for reformatting and sending Internet work via e-mail.

X.500 The CITT and ISO standard for electronic directory services.

X.509 A standard which is part of the X.500 specifications which defines the format of a public key certificate.

X/recommendations The ITU–TSS documents that describe data communication network standards. Well-known ones include: X.25 Packet Switching Standard, X.400 Message Handling System, and X.500 Directory Services.

X12 An ANSI-accredited group that defines EDI standards for many American industries, including healthcare insurance. Most of the electronic transaction standards mandated or proposed under HIPAA are X12 standards.

X12 Standard The term currently used for any X12 standard that has been approved since the most recent release of X12 American National Standards. Because a full set of X12 American National Standards is only released about once every five years, it is the X12 standards that are most likely to be in active use. These standards were previously called *Draft Standards for Trial Use*.

X12/PRB In HIPAA, The X12 Procedures Review Board.

XDSL A group term used to refer to ADSL (asymmetrical digital subscriber line), HDSL (high data rate digital subscriber line), and SDSL (symmetrical digital subscriber line). All are digital technologies using the existing copper infrastructure provided by the telephone companies. XDSL is a high-speed alternative to ISDN.

XML (eXtensible Markup Language) A coding language for the Web that lets computers interpret the meaning of information in Web documents.

XNS Xerox Network Systems.

X-open A group of computer manufacturers who promote the development of portable applications based on UNIX. They publish a document called the *X-Open Portability Guide*.

XOR The XOR (exclusive-OR) gate acts in the same way as the logical "either/or." The output is "true" if either, but not both, of the inputs are "true." The output is "false" if both inputs are "false" or if both inputs are "true." Another way of looking at this circuit is to observe that the output is 1 if the inputs are different, but 0 if the inputs are the same.

XOT X.25 over TCP.

YCbCr A setting used in the representation of digital images. Y is the luminance component; Cb,Cr are the chrominance components.

zero code suppression (ZCS) The insertion of a "1" bit to prevent the transmission of eight or more consecutive "0" bits.

ZIP Zone Information Protocol (AppleTalk).

Zip drive A high capacity, removeable diskette drive that typically uses 100-MB Zip disks or cartridges.

ZIT Zone Information Table (AppleTalk).

Index

Information Security

Information Security Management Handbook

Sixth Edition

Harold F. Tipton, CISSP · Micki Krause, CISSP

Never before have there been so many laws designed to keep corporations honest. New laws and regulations force companies to develop stronger ethics policies and the shareholders themselves are holding publicly traded companies accountable for their practices. Consumers are also concerned over the privacy of their personal information and current and emerging legislation is reflecting this trend. Under these conditions, it can be difficult to know where to turn for reliable, applicable advice.

The sixth edition of the ***Information Security Management Handbook*** addresses up-to-date issues in this increasingly important area. It balances contemporary articles with relevant articles from past editions to bring you a well grounded view of the subject. The contributions cover questions important to those tasked with securing information assets including the appropriate deployment of valuable resources as well as dealing with legal compliance, investigations, and ethics. Promoting the view that the management ethics and values of an organization leads directly to its information security program and the technical, physical, and administrative controls to be implemented, the book explores topics such as risk assessments; metrics; security governance, architecture, and design; emerging threats; standards; and business continuity and disaster recovery. The text also discusses physical security including access control and cryptography, and a plethora of technology issues such as application controls, network security, virus controls, and hacking.

US federal and state legislators continue to make certain that information security is a board-level conversation and the ***Information Security Management Handbook, Sixth Edition*** continues to provide a clear understanding of the rules and regulations and an effective method for their implementation.
